AI as a Driving Force for Sustainability, Resilience, Regeneration and Inclusiveness in the Context of Smart Cities

Maximilian Broglio
Mercatorum University, Rome, Italy

Abstract

AI has become a factor capable of disruptively shaping human existence, from society to corporate world, from economy to urban systems; however its focus on efficiency without regard for socio-ecological impacts, is now being strongly questioned; it is therefore essential to adopt a path of "humanization" of AI so as to allow it to evolve and align with the vision of the *Great Transition Network* (Raskin, 2021), which proposes a systemic transformation capable of not neglecting concepts such as social justice, socio-environmental sustainability, and human prosperity. AI must be considered a tool to achieve results in terms of sustainable development, which must always be the compass to follow in decision-making; this is where the concept of knowledge management evolves from the "mechanical" management of information to the concept of *intelligent knowledge* in which, through AI, systems are also capable of reasoning, automating complex processes, bridging the gap between raw data and human understanding, while minimizing any biases deriving from AI.

The aim of the paper is analysing, through a qualitative research approach (reviewing the most recent literature), the impact of AI as lever for sustainability, resilience, regeneration, and inclusiveness in the context of smart cities, starting from the assumption that cities must evolve, abandoning the application (without concern for impact) of efficiency and intensification, embracing instead the idea of creating ecosystems oriented towards socio-environmental sustainability, cooperation and participation.

After the specification of the objectives of a more "humanized" AI along with the areas of intervention where AI can effectively operate and the risks associated with its shortsighted implementation, case studies of cities that have successfully implemented these innovative technological strategies are presented (selected according to relevance, transformative potential, and replicability with no restraints in terms of geographical boundaries).

Findings support the view that a sustainable implementation of AI can lead to sustainability, resilience, regeneration, and inclusiveness in the context of smart cities, promoting social and environmental equity (lower energy consumption, optimized resource management, better climate resilience, social inclusion). Examples in this sense can be Masdar City (UAE), where traffic congestion is reduced through AI systems capable of calibrating routes based on real-time weather and traffic information, Fukuoka (Japan) that, through the exploitation of AI-based sensors in its streetlights system, is saving up to 25% on electricity, Los Angeles (USA) that has applied predictive analytics to prevent homelessness by proactively identifying individuals at heightened risk of losing their home.

Keywords: AI; smart cities; sustainability; resilience; inclusiveness.

Paper type: Academic Research Paper

1 Introduction

Artificial intelligence is a multidisciplinary field of computer science characterized by a set of technologies that allow a machine to emulate human capabilities through algorithms that learn from available information and/or information collected directly by the machine to improve its performance over time; there are several types, including *Machine Learning*, which is characterized by algorithms capable of automatically learning from existing data and making predictions, *Deep Learning*, which uses deep artificial neural networks to learn complex representations from data (e.g. images and video), *Generative Artificial Intelligence*, in which algorithms, trained on large amounts of data, can generate new outputs similar to the original data and *Agentic AI* designed to pursue specific goals autonomously with capabilities to make decisions and take actions based on feedbacks and increasingly used in computer engineering, in robotics or in decision-support systems (Casper et al., 2025); noteworthy, dealing with smart cities, is the concept of *Edge AI*: it combines AI with edge computing, enabling machine learning algorithms and data analysis to be run directly on local devices such as cameras and sensors enabling real-time decisions, saving bandwidth and improving privacy (data remains on the device).

AI requires to be somehow "humanized" in order not to be exploited in a shortsighted race for efficiency devoid of any socio-ecological implications. In this context, *intelligent knowledge* was born, an evolution of the

traditional concept of knowledge management, leveraging the potential of AI, going beyond simple information retrieval to enable intelligent decisions and automate complex processes, bridging the gap between raw data and human understanding. Starting from the fact that knowledge management is linked to the mechanical management of information, while intelligence is linked to the ability to analyse it, *intelligent knowledge* represents a fusion, creating solutions capable of reasoning and deduction, reducing potential AI biases.

Analysing the impact of AI in urban context, a paradigm shift must be implemented with sustainability as guiding principle: AI must not be seen as a mere efficiency tool, but as a key tool for addressing all ESG aspects that holistically define the concept of sustainability. Cities are transitioning from "smart cities" to "cognitive cities", not because the underlying technology is different, but because the governance paradigm must evolve from a "technology-first" to a "human-first" approach.

The purpose of the paper is analysing the impact of AI as lever for sustainability, resilience, regeneration, and inclusiveness in the context of smart cities; these ones are cities capable of leveraging digital technologies such as IoT, AI, and Big Data to evolve their services and ecosystems, for example in the areas of urban planning, transportation, energy management, and waste management. Their goal is improving the overall quality of life of their inhabitants, socio-environmental sustainability, and operational efficiency, actively engaging citizens and businesses for sustainable development.

Urban contexts must evolve as fertile grounds for experimentation, abandoning the application (without regard to impacts) of efficiency and intensification, embracing instead the idea of creating ecosystems oriented towards socio-ecological sustainability, regeneration, resilience, and inclusiveness, where AI can also promote responsibility, cooperation, participation, sufficiency, and sharing, thus paving the way for more inclusive innovation (Zhang et al., 2025).

This paper analyses areas of intervention where AI can operate to achieve the sustainability goals promoted by the *Great Transition Network* and discusses case studies of smart cities that have successfully adopted and implemented these innovative technological strategies in a sustainable manner.

The ultimate goal of the paper is to act as a driving force for cities that are still hesitant and to demonstrate how a conscious and calibrated use of these digital technologies can truly contribute to the creation of sustainable, resilient, regenerative, and inclusive smart cities. The aim is triggering a process of "constructive emulation" in which cities, leveraging existing experiences and emerging opportunities, can provide a decisive boost to the evolutionary path toward more sustainable and contemporary cities.

2 Methodology

This study employs a qualitative research approach grounded in the Multilevel Perspective (Geels, 2002) with the aim of achieving tangible findings regarding the contribution of a calibrated and conscientious use of AI to the sustainable development of smart cities.

The research was conducted in two phases: the first involved a comprehensive review of the most recent technical literature to analyse the specific characteristics of a sustainable AI-approach in urban settings, defining objectives, areas of intervention, and potential negative impacts in order to provide an in-depth and up-to-date overview; the second involved a case studies review of cities that have successfully implemented innovative digital solutions, in order not only to provide a detailed overview, but also to act as a sounding board for other cities that have yet to take this step (case studies were selected based on their relevance, specificity, transformative potential, and replicability in the context of smart cities with no restraints of specific geographical boundaries; the only constraint is that they were recent and successful in order to represent a benchmark).

In terms of research framework, this work is connected to two research streams: AI, which is monopolizing interest in a wide variety of research fields, and sustainability, a really hot topic, as confirmed by the number of specific academic publications; the study stands out in a context of hybridization, considering concepts that synergistically intertwine between the two aforementioned streams. This research, like all sustainability research, is also part of the ESG framework. The specific topic of smart cities is gaining increasing attention in the research world as it relates to a topic that is proving to be particularly crucial for the sustainable and inclusive evolution of global urban systems, which must necessarily curb the negative spiral associated with the global context in which they exist (anthropogenic climate-altering emissions, indiscriminate use of non-renewable resources, biogeochemical pollution, social injustices, demographic increase, etc.).

3 Findings

3.1 Goals, areas of intervention, and risks of AI in the context of smart cities

Findings highlight how the careful use of AI in smart cities can effectively address several crucial issues, such as sustainability, resilience, regeneration, and inclusiveness without neglecting that an inappropriate use can lead instead to significant risks.

Leveraging these innovative digital technologies, capable of exploiting real-time data from sensors and IoT, and integrating predictive simulations for low-impact planning, can promote the optimization of urban resources and services, predict needs, and support informed and timely decisions reducing socio-environmental impacts, shaping cities that increasingly transform into intelligent, resilient, and adaptive ecosystems.

Four areas of intervention are identified where AI can operate in the smart cities' context: sustainability, resilience, regeneration, and inclusiveness.

In the area of sustainability, AI can have a significant impact in the environmental sphere: AI can lead to the optimization of resources and energy consumption (e.g. in the context of the smart grid[1]) and to a more efficient management of vehicular traffic reducing the impact in terms of emissions, it can help make water and waste management services more efficient, reducing waste and encouraging a transition to circular models and can support urban agriculture; within sustainability area, interventions can be categorized into four application sectors: energy management, mobility, waste/water management, and urban planning. In terms of energy management, AI can intervene through intelligent regulation of smart grids and buildings, to reduce consumption through adaptive air conditioning and lighting systems and allowing the integration of renewable energy sources (e.g. the Hudson Yards in New York); in terms of mobility, AI enables smarter traffic management through the use of predictive algorithms capable of managing traffic flows: in Masdar City (UAE), traffic congestion is reduced through AI systems capable of calibrating routes based on real-time weather and traffic information while "RoadSafeAI", a predictive model developed by the Polytechnic University of Milan and Unipoltec, exploits convolutional neural networks to analyse road images and telematics data, identifying high-risk areas for accidents with an accuracy of over 95%. For the environmental sector, AI can manage the monitoring of waste collection and recycling cycles through predictive models, optimizing routes, reducing transportation-related emissions, and promoting effective resource management. Similarly, through the use of predictive models and intelligent monitoring, it can ensure a reduction in water waste and a general systemic improvement in the integrated water service. For the urban planning sector, AI can support eco-design based on climate data and demographic assessments to guide adaptive projects; AI (in planning) can help identify pollutants and consequently plan green spaces to improve air quality and biodiversity (e.g. AI-enabled BIM can simulate the impacts of materials/buildings), anticipate sustainable expansions with tools such as those from IBM and SEforALL[2], and promote the circular economy by tracking resources.

In the area of resilience, AI works primarily in an anticipatory manner through predictive algorithms that, by processing large volumes of real time data from IoT sensors and integrating technologies such as digital twins, allow for the prevention of various types of emergencies: environmental emergencies such as earthquakes[3], heat waves[4], landslides and floods[5], system emergencies as blackouts or emergencies related to the digital resilience (the ability to anticipate, resist, respond and recover quickly from interruptions, cyberattacks, IT failures, ensuring operational continuity and protecting data, services, processes and technologies keeping critical functions active before, during and after an incident); in addition to forecasting, there is also monitoring: the use of AI-based automatic alert systems capable of monitoring traffic, fires, or floods and providing timely notifications to citizens and authorities significantly increases urban resilience. The impact of AI on urban resilience during emergency management must be also considered: AI optimizes evacuation routes and resources allocation, improving safety and response capacity, also leading to an accurate post-event damage assessment to prioritize interventions. It is fundamental to strengthen data-informed governance by enabling policymakers to anticipate problems, model scenarios and design adaptive responses to increase the overall resilience.

Another area of intervention is urban regeneration: in this case, generative AI models can directly influence the design of new spaces, promoting accessibility and sustainability in design choices (for example, supporting

---

[1] which in turn, by facilitating the integration of renewable sources and the management of distributed production, allows for the reduction of climate-altering emissions.

[2] SEforALL (Sustainable Energy for All) is an international organization working in partnership with the United Nations, government leaders, the private sector, financial institutions, and civil society to promote faster and more concrete action to achieve Sustainable Development Goal 7.

[3] Smart buildings with AI sensors can assess real time safety in case of earthquake.

[4] Vulnerability maps can identify at-risk areas and vulnerable patients.

[5] For example, Lisbon is leveraging AI-driven digital-twin modelling to simulate flood scenarios and plan adaptive infrastructure responses.

energy communities); through the analysis of large volumes of socio-environmental data and the use of simulations of intervention scenarios to predict impacts on different targets, the most suitable areas (degraded and problematic areas deserving of higher priority) can be selected and the most sustainable solutions can be implemented.

The final area of intervention examined concerns inclusiveness (linked to the "S" of ESG); AI works primarily on three aspects: digital accessibility, social inclusion, and inclusive design. In terms of digital accessibility, AI offers solutions for people with disabilities, such as voice recognition systems, AI-enhanced screen readers, automatic subtitles, and interface customization; it also enables access to services such as transportation or healthcare for non-native speakers through multilingual chatbots and virtual assistants. In terms of social inclusion, by monitoring inequalities through predictive analytics, enables interventions on digital literacy to prevent exclusion and supports inclusive work adapting tasks to the specific disability. AI also promotes inclusion and social sharing of benefits through integration of ethics and privacy to ensure fairness. For inclusive design, generative AI works on simulating accessible spaces, seeking to meet needs of people with disabilities, while also leveraging citizen participation (e.g. digital twins allow for exploiting citizen feedbacks on future projects to increase transparency[6] and engagement).

Social inclusion is one of the most insidious aspects dealing with the link between smart cities and AI: there is the risk, in administrators' strategic choices, of prioritizing issues like urban efficiency and economic growth, thus risking exacerbating social inequalities. These considerations are supported by a recent study (Ntanda and Carolissen, 2025), which highlights a complex relationship between smart cities development and social inequalities, characterized by the risk of amplifying existing disparities if not managed inclusively and requiring robust community involvement and adaptation of innovations to the local context.

AI is characterised by possible unsustainable aspects that must be taken into account analysing its relationship with smart cities: for Vinuesa et al. (2020), AI has the potential to have negative impacts on sustainability[7]; three types of risks can be considered: ecological risks (AI footprint)[8], socio-economic and ethical risks[9], risks related to data/algorithms[10]; in relation to this, the concept of the "green AI paradox" can be considered, i.e. the risk that the AI's environmental costs outweigh the benefits of AI-implemented green solutions: this aspect must certainly be addressed dealing with the aforementioned risks[11]. Furthermore, it is impossible to ignore the Jevons Paradox[12], which posits that technological improvements capable of increasing the efficiency can lead to an increase in the total consumption of a resource.

Moreover, the success of smart cities is amplified by the combination 'open data-AI' in which open data can provide a large amount of data for AI systems to function effectively[13].

3.2 Case studies

It is compelling to analyse case studies of AI application to support sustainable and inclusive smart cities in order to evaluate types of intervention, application rates and scalability with the ultimate goal of inspiring constructive emulation by which cities can embark on a path toward sustainability and inclusiveness.

In terms of characteristics, adoption rates and types of AI use, interesting results can be deduced from the study "AI-powered cities of the future" (2025)[14] based on the AI plans, investments, and practices of 250 cities in 78 countries; first of all what can be deduced is that 56% of surveyed cities actively use AI with a projected adoption rate up to 83%[15] in the next-three-years period. In addition, the study shows that in terms of smart

---

[6] An example in which there is the exploitation of real-time data to support transparent decision-making and collaborative urban planning, offering a practical example of how technology can enable sustainable and inclusive urban development is the city of Rotterdam (The Netherlands).

[7] according to authors 59 of the 169 sustainable development goals could be negatively impacted.

[8] For example, in terms of energy consumption (training AI models, especially large ones like deep learning models, requires a significant amount of energy), water consumption (some data centres use water cooling systems, which can consume significant amounts of fresh water), e-waste management (the rapid obsolescence of hardware technologies used for AI contributes to the growing amount of e-waste). All these factors can be summarized in the concept of digital pollution.

[9] For example, in terms of potential job losses (AI-powered automation can replace human jobs, especially in some sectors), technology dependence (the increased use of AI in various areas of daily life can lead to an overdependence on technology), security (AI can be used for malicious purposes), unequal access to technology (risk that AI will become the privilege of a few, accentuating inequalities).

[10] For example, in terms of "black box" responsibility, erosion of digital trust, systemic digital bias (AI algorithms can reflect and amplify biases present in the data they are trained on thus leading to discriminatory decisions).

[11] It should also be emphasized that achieving this goal also requires governance and international cooperation frameworks, financing and incentive policies for green AI, international collaboration, open-source platforms, and training programs.

[12] Named after the British economist and logician William Stanley Jevons who lived during the nineteenth century. Linked to the concept that greater efficiency reduces costs and stimulates greater demand, expanding overall use.

[13] an example is the Irish city of Dublin which demonstrated how open data help smart cities using digital twin technology for data-driven decision-making.

[14] Deloitte, ServiceNow, NVIDIA, ThoughtLab (2025) AI-powered cities of the future.

[15] this data is interesting due to the fact that, internationally, comparable data on levels of AI adoption across cities remain rare. In terms of adoption rate, it is compelling to underline that is in progress a faster than ever AI adoption, particularly in city administration and mobility, and in cities like Seoul (Korea) that have pioneered the integration of AI into urban infrastructure (The Smart City Index 2024, "AI Transforming Cities: Insights from Professor Jung-hoon Lee on the Smart Cities Index 2024". Based on the analysis of over 5000 smart city services, infrastructure and initiatives across 50 cities).

cities development, large metropolitan areas steal the spotlight[16] (in Europe cities considered pioneers in the most advanced implementation of AI are among the others Amsterdam, Barcelona, Berlin, Dublin, Helsinki, Madrid, Paris, Vienna while, outside of Europe, are New York, Boston, Chicago, Los Angeles, Toronto, Montreal, Sao Paulo, Istanbul, Beijing, Hong Kong, Melbourne, Seoul, Sydney and Tokyo) certainly related to greater economic possibilities, opportunities for research and development, possibility to build a modern IT foundation, greater ease in developing AI skills, talent, processes, possibility to combine AI with other technologies and greater propensity for innovation and change. It is interesting to underline that in this case ten areas of AI intervention in urban context are considered: traffic management, public safety, energy management, customer safety, predictive management, waste management, data analysis, urban planning, cybersecurity, fraud detection.

It is now compelling to review some examples[17] of AI applications at the service of sustainability, resilience, regeneration and inclusiveness so that they can serve as benchmarks for urban contexts that want to approach the world of AI to begin to accelerate their path toward sustainable development.

Fukuoka (Japan) through the exploitation of AI-based sensors in its streetlights system is saving up to 25% on electricity, Seattle (USA) is experimenting with an intelligent AI-based parking management system able to cut down on parking durations thus enhancing air quality, Shijiazhuang (China) is using AI in waste management in order to increase efficiency and recycling, Madrid (Spain), in the context of the EU-funded project "AMIGOS", uses AI-driven smart cameras and sensors to monitor city spaces in Las Rozas, providing real-time data helping city planners make informed decisions (a similar initiative, "ELABORATOR", is being implemented in the French district of Issy-les-Moulineaux, and is characterized by the usage of AI to automatically manage intersections, creating more space for cyclists and alerting drivers to their presence based on traffic conditions). Singapore, in its Changi Airport, uses AI to screen and sort baggage, as well as to power behaviour recognition technology for immigration clearance enhancing border security, Jaipur (India) implements AI to effectively manage water harvesting and environmental impact assessment reports in industrial areas to mitigate pollution, Dubai (UAE) is using AI to improve daily life with customer service chatbots (some upgraded to use generative AI, including those for the Roads and Transport Authority, and the Dubai Health Authority), and for mobility with an AI-powered traffic management system, San Francisco (USA) is exploring the use of Agentic AI, enabling machines to take decisions and actions without direct human intervention, through the usage of self-driving taxis, Raleigh (USA) uses a full digital twin of the city, paired with an AI-powered microclimate modelling system, for more intelligent and resilient urban development and also uses AI to forecast flooding in stormwater systems, based on factors such as age and condition of infrastructure, soil materials, and previous failures. Tokyo (Japan) is using a comprehensive disaster preparedness system consisting of a network of AI sensors combined with predictive modelling, simulation tools, and community-based disaster management initiatives, Yizhuang-Beijing (China) is using AI in the healthcare sector developing a cloud-based infrastructure that connects medical institutions across Beijing (including intelligent triage, pre-diagnosis consultations, and appointment scheduling), Sao Paulo (Brazil) has developed an AI predictive maintenance tool that can anticipate faults in its metro and has developed a mobility-as-a-service app to facilitate the transportation through the city for residents, Venice (Italy), to address overtourism, has implemented an AI-enabled smart control room, which gathers real-time data from existing digital infrastructure assets, including intelligent sensors and video cameras, to optimize network functionality. Melbourne (Australia) employs AI and uses sensors to monitor illegal waste dumping behaviours and to track trees in the city and make plans for future planting, Barcelona (Spain) exploits an AI-powered ventilation control platform called "RESPIRA" to address challenges of particulate matter pollution, thermal stress, and ventilation inefficiencies, Los Angeles (USA) has applied predictive analytics to prevent homelessness by proactively identifying individuals at heightened risk of losing their home, Eslöv (Sweden) uses an AI-assisted planning and design platform called "Hektar" characterized by generative design and data-driven analysis to support early-stage urban planning and zoning optimisation, Praga (Czech Republic) to improve the accessibility of urban services uses AI chatbot, Montevideo (Uruguay) has employed AI and predictive analytics to identify neighbourhoods most vulnerable to flooding, poverty, and service deprivation (to better prioritise social and infrastructural investments). Maastricht (The Netherlands) exploits soil moisture sensors linked to AI-based analytics to enable tree managers to respond to real-time alerts during heatwaves, Sydney (Australia) uses Google's Environmental Insights Explorer (EIE) "Tree Canopy", which applies machine learning to aerial imagery, to visualise canopy gaps at neighbourhood scale and plan where trees are most needed for heat-vulnerable areas, Bogotá (Colombia) uses AI-based chatbot "Candelaria" to strengthen perceptions of safety, improve

[16] however, small cities such as Drancy in France, prove that size is no barrier to innovation even if obviously the starting conditions are not the same.

[17] Found, among the others, in Deloitte, ServiceNow, NVIDIA, ThoughtLab (2025) AI-powered cities of the future and in OECD (2025) Artificial Intelligence for advancing smart cities, 5th OECD Roundtable on smart cities and Inclusive Growth.

tourist information and increase visitor engagement, Jammerbugt (Denmark) uses an AI-based early warning system for flooding integrating satellite imagery, weather forecasts and hydrological models to predict floods up to 48 hours in advance, Seoul (South Korea) has applied computer vision to the city's extensive CCTV network (more than 110.000 cameras) and launched an AI-enabled CCTV initiative to strengthen prevention, improve response times and build public trust in safety services by recognising behaviours such as wandering, aggression, crowd density.

4 Conclusions

Considerations thus far support the view that a correct and sustainable use of AI can lead to sustainability, resilience, regeneration, and inclusiveness in the context of smart cities. AI can promote social and environmental equity, leading to the creation of more liveable cities with lower energy consumption, optimized resource management, reduced waste, greater climate resilience, social inclusion.

It should be emphasized that the paradigm must evolve from a "technology-first" approach focused more on efficiency and intensification to a "human-first" approach that places human well-being at the centre, accounting for all ESG aspects holistically and in which technology is a tool at the service of social inclusion, environmental sustainability and economic development (where attention is paid not to reinforce digital divides and not to fall in excessive monitoring and privacy violations). It must also be noted that the progressive implementation of AI in smart cities must inevitably follow an incremental approach to allow cities to gradually reach maturity without simultaneously losing public trust: this can mean starting with strategically selected operational pilot projects that offer immediate value and then gradually expanding its use.

Another key concept is that of "constructive emulation": successful sustainable AI implementation can undoubtedly serve as a boost for other urban systems that have not yet integrated AI systems into their strategies, thus triggering emulation that can lead to a globally broadened impact in terms of sustainability, resilience, and inclusiveness.

Systemic scaling of AI is most feasible when national regulation and experimentation instruments are coordinated under a unified architecture: a top-down commitment is required, where laws are harmonized, coherent and effective and are capable of increasing citizens' trust (without clipping the wings of the innovative potential of AI); laws and plans as EU's AI Act (2024)[18], China's Algorithmic Recommendation Regulation (2022)[19] or the open AI registers[20] aimed to be responsible and transparent about the use of algorithms and AI, are fundamental to send a strong signal of transparency and trust.

In terms of limits, this paper does not take into account barriers that hinder AI use (implementation and maintenance costs, required skills, resistance to change)[21] and regulatory frameworks (to fully understand the frameworks within which AI-based strategies can flourish without incurring the risks associated with its unsustainable and erroneous use).

In terms of smart cities future developments, according to Zain (2025) one option is the *predictive city* where AI continuously analyses data from sensors and digital twins to anticipate needs and optimise services while another option (*participatory intelligent city*) may be characterized by an AI designed to increase collective intelligence where data and algorithms are open and co-created with citizens.

Research must seek to increasingly explore the connection between AI and sustainability in the context of smart cities through the analysis of innovative solutions, with the hope that the number of cities that can become benchmarks can further expand, as this would indicate that the process of constructive emulation is fully underway.

5 Ethics declaration

Ethical clearance was not required for the research.

6 AI declaration

Artificial Intelligence and Sustainability Management as Innovation Strategies for Sustainable Competitiveness: Evidence from Innovative SMEs

Giovanna Ferraro[1], Ivana Quinto[2], Giuseppe Scandurra[2], Antonio Thomas[2]
[1] University of Rome Tor Vergata, Rome, Italy
[2] Parthenope University of Naples, Naples, Italy

Abstract

In recent years, environmental, social, and governance (ESG) practices have progressively become a central component of corporate strategies and investment decisions. Although ESG is often associated with corporate social responsibility (CSR), the two concepts differ in important ways. CSR typically refers to voluntary initiatives oriented toward responsible business conduct, whereas ESG is based on standardized and measurable indicators that enable stakeholders to assess companies' sustainability performance in a more systematic and comparable manner. The growing relevance respect to ESG practices is driven by increasing societal awareness of sustainability challenges, stronger stakeholder expectations, and the evolution of regulatory frameworks aimed at promoting sustainable development However, the mechanisms that support ESG implementation among small and medium-sized enterprises (SMEs), as well as the potential competitive benefits associated with these practices, remain only partially explored. This study investigates the role of artificial intelligence (AI) and sustainability management (SM) as key drivers of ESG adoption and competitive perspectives in innovative SMEs. The empirical analysis is conducted using Partial Least Squares Structural Equation Modelling (PLS-SEM) on a sample of 163 Italian innovative SMEs located in Lazio Region. Data were collected through a structured online questionnaire administered to company representatives involved in strategic and innovation-related decision-making processes. The results show that both AI and SM significantly contribute to the adoption of ESG practices across environmental, social, and governance dimensions. However, only AI exerts a direct positive effect on competitive perspectives, while SM influences competitiveness indirectly through ESG practices. Furthermore, the ESG dimensions do not equally affect competitive outcomes. The environmental and governance dimensions positively influence competitive perspectives, whereas the social dimension does not exhibit a statistically significant effect. These results provide new insights into the mechanisms through which technological and managerial factors support sustainability-oriented strategies and competitiveness in SMEs, highlighting the importance of integrating digital capabilities and structured sustainability practices.

Keywords: Artificial intelligence; Sustainability management; ESG practices; SMEs competitiveness
Paper type: Academic Research Paper

1 Introduction

The adoption of ESG practices is increasingly relevant for companies of all sizes. Despite the increasing diffusion of ESG frameworks, their adoption among SMEs remains, in many cases, limited. SMEs frequently face structural constraints, including limited financial resources, lack of specialized managerial competencies, and difficulties in accessing tools for sustainability measurement and reporting (Rubino et al., 2024). These barriers contribute to a fragmented implementation of ESG practices and make it difficult to clearly identify the drivers that support their adoption. The existing literature has proposed several theoretical perspectives to explain companies' engagement in sustainability and ESG practices, including stakeholder theory, institutional theory, and legitimacy theory. These approaches mainly emphasize the role of external pressures, regulatory requirements, and the need for firms to align with stakeholder expectations. However, the internal mechanisms through which SMEs translate these pressures into concrete sustainability practices are still not fully understood. Recent studies suggest that both technological and managerial factors can play a crucial role in supporting ESG adoption. On the one hand, artificial intelligence (AI) enables companies to analyze large volumes of data, improve decision-making processes, and enhance the monitoring of environmental and social performance (Cheng et al., 2024; Tutore et al., 2024). On the other hand, sustainability management (SM) provides the organizational structures, routines, and policies necessary to embed sustainability principles into business strategies and operational activities (Lei and Yu, 2023). Although the role of digital technologies and sustainability-oriented managerial practices has received increasing attention, empirical evidence on how these factors jointly contribute to ESG adoption and influence companies' competitive perspectives remains limited. This gap is particularly relevant in the context of SMEs, which represent a fundamental component of economic systems and innovation ecosystems but often struggle to translate sustainability initiatives into tangible competitive outcomes. This study investigates the role of AI and SM as key drivers of ESG adoption and

competitive perspectives among innovative SMEs. The research focuses on understanding whether and how these factors support the implementation of ESG practices and whether ESG adoption contributes to strengthening companies' competitive positioning.

The study addresses the following research questions:

- *RQ1: How do AI and SM jointly influence the adoption of ESG practices in SMEs?*
- *RQ2: To what extent does the adoption of ESG practices contribute to enhancing SMEs' competitive perspectives?*

To answer these questions, the study develops a conceptual model and empirically tests it using Partial Least Squares Structural Equation Modelling (PLS-SEM) on a sample of 163 innovative Italian SMEs. These firms are characterized by strong technological orientation, high levels of human capital, and systematic investments in research and development, making them a particularly relevant context for analyzing the interplay between technological capabilities, sustainability practices, and competitiveness.

The paper is structured as follows. Section 2 presents the theoretical background and research hypotheses. Section 3 describes the methodology and data collection process. Section 4 reports the empirical results, Sections 5 and 6 discuss the findings and present the conclusions.

2 Theoretical Background

2.1 ESG Practices and SMEs

ESG practices have emerged as one of the most widely used frameworks for evaluating corporate sustainability performance. Through ESG indicators, stakeholders are able to assess companies' environmental impact, social responsibility, and governance quality using standardized and comparable criteria. Over time, ESG metrics have increasingly influenced corporate strategies, investment decisions, and stakeholder expectations (Sánchez-Torné et al., 2020; Jiang et al., 2024). Although ESG frameworks were initially developed for large corporations, growing attention has been directed toward their adoption among SMEs. SMEs represent a key component of national economies and innovation systems, yet their approach to sustainability often differs from that of larger firms. Due to their limited financial resources, less formalized organizational structures, and restricted access to specialized expertise, SMEs frequently encounter significant challenges in implementing ESG practices (Rubino et al., 2024). Despite these constraints, existing studies suggest that ESG adoption may generate several benefits for SMEs, including enhanced corporate reputation, improved stakeholder relationships, better access to financial resources, and increased resilience to market changes (Rodríguez-Gutiérrez et al., 2021; Garrido-Ruso et al., 2024; Murè et al., 2024). However, empirical evidence on the mechanisms that facilitate ESG adoption in SMEs remains fragmented. This highlights the need to identify the key drivers that can support SMEs in integrating sustainability principles into their strategic and operational activities.

2.2 Artificial Intelligence as a Driver of ESG Adoption

AI represents one of the most significant technological developments affecting modern organizations. By enabling companies to analyze large volumes of data, identify patterns, and automate decision-making processes, AI can improve operational efficiency, innovation capacity, and strategic responsiveness (Ancillai et al., 2023; Cheng et al., 2024). AI can support companies in monitoring environmental performance, optimizing resource utilization, and improving transparency in governance processes. Digital technologies also facilitate the collection and analysis of sustainability-related data, allowing companies to better assess their environmental and social impact and to respond more effectively to stakeholder expectations (Trueba-Castañeda et al., 2024; Tutore et al., 2024). AI can contribute to enhancing companies' ability to innovate and adapt their business models to sustainability challenges. By supporting predictive analytics and data-driven decision-making, AI enables companies to anticipate market trends and identify new opportunities related to sustainable products and processes. Despite these potential benefits, the adoption of AI may involve significant initial investments and implementation challenges, particularly for SMEs. Nevertheless, its role in improving decision-making processes and supporting sustainability-oriented strategies suggests that AI can be a key driver of ESG adoption and competitiveness.

2.3 Sustainability Management

SM refers to the integration of environmental and social considerations into corporate strategies, managerial practices, and organizational processes. It involves the development of policies, routines, and governance mechanisms aimed at aligning business activities with sustainability objectives and stakeholder expectations (Abad-Segura et al., 2020; Adewumi et al., 2024). SM encompasses a wide range of practices, including the implementation of environmental certifications, the adoption of sustainability reporting systems, the redesign of production processes to reduce environmental impact, and the development of training programs related to sustainability issues. Through these practices, companies can embed sustainability principles into their operational and strategic activities. Existing literature suggests that SM plays a crucial role in facilitating ESG adoption. Companies that develop structured sustainability-oriented processes are more likely to effectively implement ESG practices and align their strategies with broader societal and environmental goals (Lei and Yu, 2023). However, the relationship between SM and companies' competitive outcomes remains debated. While some studies highlight its positive impact on performance, others emphasize the potential organizational costs and challenges associated with sustainability implementation, particularly in resource-constrained contexts such as SMEs.

2.4 Competitive perspective in SMEs

In this study, competitive perspectives refer to a firm's perceived ability to maintain and strengthen its competitive position through innovation, adaptability, and long-term value creation. Rather than focusing exclusively on short-term financial performance, this concept captures broader dimensions of competitiveness, including market development, organizational resilience, and the capacity to innovate. Previous studies suggest that sustainability-oriented practices can contribute to improving firms' competitive positioning by enhancing reputation, strengthening stakeholder trust, and supporting innovation processes (Garrido-Ruso et al., 2024). However, the relationship between ESG practices and competitiveness is not always straightforward, especially in the context of SMEs. Resource limitations and structural constraints may influence the extent to which sustainability initiatives translate into tangible competitive advantages. Understanding how ESG practices affect SMEs' competitive perspectives therefore represents a relevant research challenge.

2.5 Research model and Hypotheses

Building on the existing literature, this study conceptualizes AI and SM as key drivers that support the adoption of ESG practices and influence companies' competitive perspectives.

AI can enhance companies' ability to process information, improve decision-making, and support sustainability-related initiatives. AI is expected to facilitate the implementation of ESG practices across their environmental, social, and governance dimensions. In addition, by improving operational efficiency and innovation capacity, AI may also directly contribute to companies' competitive perspectives. SM represents another important driver of ESG adoption. By embedding sustainability principles into organizational routines and managerial processes, companies are more likely to effectively implement ESG practices. However, its direct impact on competitive perspectives remains uncertain, as competitive benefits may emerge primarily through the effective implementation of sustainability practices. Finally, ESG practices themselves may influence companies' competitive perspectives. The environmental dimension may improve resource efficiency and reduce environmental risks, the social dimension may strengthen stakeholder relationships and employee engagement, and the governance dimension may enhance transparency and decision-making processes.

Based on these considerations, the following hypotheses are proposed:

- *H1.1 AI positively influences the environmental dimension of ESG.*
- *H1.2 AI positively influences the social dimension of ESG.*
- *H1.3 AI positively influences the governance dimension of ESG.*
- *H1.4 AI positively influences companies' competitive perspectives.*
- *H2.1 SM positively influences the environmental dimension of ESG.*
- *H2.2 SM positively influences the social dimension of ESG.*
- *H2.3 SM positively influences the governance dimension of ESG.*
- *H2.4 SM positively influences companies' competitive perspectives.*
- *H3.1 The environmental dimension of ESG positively influences companies' competitive perspectives.*
- *H3.2 The social dimension of ESG positively influences companies' competitive perspectives.*
- *H3.3 The governance dimension of ESG positively influences companies' competitive perspectives.*

We propose a conceptual model that integrates AI and SM as key drivers of ESG practices, and examine their effects on companies' competitive perspectives. The model captures both the influence of technological and managerial factors on ESG adoption and the role of ESG dimensions in shaping competitive outcomes.

Figure 1 shows the research model and the hypothesized relationships among the constructs. The model is tested empirically to assess the validity of the proposed relationships.

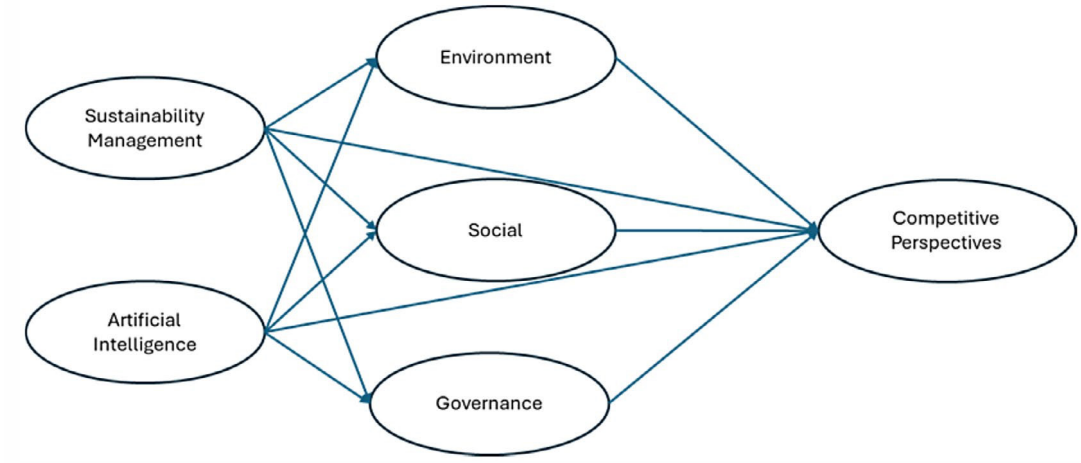

Figure 1: Conceptual model and hypothesized relationships.

3 Methodology

3.1 Sample and Data Collection

The empirical analysis is based on a sample of innovative SMEs operating in Italy. The firms were selected from the official national register of Innovative SMEs, established to support technologically advanced and research-oriented companies. These firms are characterized by systematic investments in research and development, the presence of intellectual property, and a high level of human capital, which are typical features of innovative SMEs. Such features make them a suitable context for analyzing the relationship between technological capabilities, sustainability practices, and competitive perspectives. To ensure greater consistency and reduce heterogeneity, the analysis focuses on SMEs located in the Lazio region. This region is considered representative of the national economic context in terms of industrial structure and development level. At the time of data collection, the regional register included 394 innovative SMEs. After excluding companies with incomplete contact information, the final population consisted of 355 companies. From this population, a random sample of 200 firms was selected. Data were collected through a structured online questionnaire administered to company representatives involved in strategic and innovation-related decision-making processes. The questionnaire consisted of closed-ended questions measured on a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). The questionnaire was validated through expert evaluation involving both academics and SME managers. A pilot test was also conducted to ensure clarity and relevance of the items. The final dataset includes 163 valid responses, corresponding to a response rate of approximately 81%.

3.2 Measurement of Variables

The constructs included in the research model were operationalized using multiple indicators derived from established measures in the literature on ESG practices, digital innovation, and sustainability management (Abad-Segura et al., 2020; Cheng et al., 2024; Lei and Yu, 2023).

Each latent construct was measured through a set of manifest variables capturing different dimensions of firms' technological, managerial, and sustainability-related practices. AI was measured through indicators related to the adoption of digital technologies and structured innovation management practices, reflecting the companies' capability to support data-driven decision-making (Ancillai et al., 2023; Cheng et al., 2024). SM was operationalized through indicators capturing the presence of sustainability-oriented strategies, policies, and managerial practices within the organization (Adewumi et al., 2024).

The ESG construct was modelled as a multidimensional concept composed of three distinct dimensions: environmental, social, and governance practices, as commonly adopted in the literature (Jiang et al., 2024). The

environmental dimension includes actions related to emissions reduction, energy efficiency, resource management, renewable energy use, and circular economy initiatives (Trueba-Castañeda et al., 2024). The social dimension captures practices related to diversity and equality, employee training, workplace safety, inclusion, and employee involvement. The governance dimension includes practices related to sustainability communication, stakeholder engagement, certifications, and sustainable innovation (Cardinali and De Giovanni, 2022). Competitive perspectives refer to the companies' perceived ability to strengthen their competitive position through sustainable strategic orientation, market development, and organizational resilience (Garrido-Ruso et al., 2024; Murè et al., 2024). All items were measured using a five-point Likert scale.

3.3 Data Analysis

The research model was tested using Partial Least Squares Structural Equation Modelling (PLS-SEM), implemented through SmartPLS software. PLS-SEM was selected for several reasons. First, it is particularly suitable for analyzing complex models involving multiple latent constructs and relationships among variables. Second, this approach is appropriate for exploratory research contexts and does not require strict assumptions of multivariate normality. Third, PLS-SEM is well suited for studies with relatively small sample sizes (Hair et al., 2019). The analysis followed a two-step procedure commonly adopted in structural equation modelling (Hair et al., 2019). In the first step, the measurement model was assessed to evaluate the reliability and validity of the constructs through indicators such as Cronbach's alpha, composite reliability, and average variance extracted (AVE). In the second step, the structural model was analyzed to test the hypothesized relationships among the constructs. The explanatory power of the model was evaluated using the coefficient of determination (R^2), while the significance of the relationships was assessed through a bootstrapping procedure with 6000 resamples.

4 Results

4.1 Measurement Model Assessment

The evaluation of the empirical model followed the standard two-step approach adopted in PLS-SEM. The results indicate that all constructs meet the recommended thresholds, with values generally exceeding 0.7, thus confirming satisfactory reliability. SM shows a relatively low Cronbach's alpha (0.353), even if it still fails within the range deemed acceptable by some scholars (Bonett and Wright, 2015). However, composite reliability exceeds the recommended threshold, and the construct demonstrates acceptable convergent validity, suggesting that the measurement remains adequate for exploratory analysis (Hair et al., 2019). Indicator reliability was assessed by analyzing factor loadings. Most of the indicators show loadings above the acceptable threshold, indicating that they adequately represent their respective latent constructs. A limited number of indicators exhibit slightly lower values, which remain acceptable in exploratory research contexts. Convergent validity was evaluated through the Average Variance Extracted (AVE). The AVE values for all constructs exceed the recommended threshold of 0.50, confirming that the constructs explain a sufficient proportion of variance in their indicators. Overall, the results of the measurement model assessment support the adequacy of the constructs and allow the analysis to proceed to the evaluation of the structural model. Table 1 reports the results of the measurement model assessment. All constructs show satisfactory levels of internal consistency reliability, with Cronbach's alpha and composite reliability values exceeding the recommended threshold of 0.7. In addition, the AVE values are above 0.50 for all constructs, confirming convergent validity.

Table 1. The results of the measurement model assessment.

Construct	Cronbach's Alpha	Composite Reliability	AVE
Artificial Intelligence (AI)	0.729	0.881	0.787
Sustainability Management (SM)	0.353	0.756	0.607
Environmental Practices (E)	0.798	0.860	0.559
Social Practices (S)	0.874	0.904	0.612
Governance Practices (G)	0.801	0.863	0.561
Competitive Perspectives (CP)	0.742	0.852	0.657

4.2 Structural Model Assessment

After confirming the reliability and validity of the measurement model, the structural model was analyzed to test the hypothesized relationships among the constructs. The explanatory power of the model was assessed

using the coefficient of determination (R^2) for the endogenous variables. The results indicate a satisfactory level of explained variance, particularly for competitive perspectives, which shows a relatively high R^2 value. The significance of the relationships was evaluated through a bootstrapping procedure with 6000 examples. The findings show that AI has a positive and statistically significant effect on all three ESG dimensions supporting hypotheses H1.1, H1.2, and H1.3. AI also exhibits a significant direct effect on competitive perspectives, supporting hypothesis H1.4. SM shows positive and significant effects on the ESG dimensions, confirming hypotheses H2.1, H2.2, and H2.3. However, the direct relationship between SM and competitive perspectives is not statistically significant, leading to the rejection of hypothesis H2.4. Regarding the effects of ESG dimensions on competitive perspectives, the results reveal heterogeneous outcomes. The environmental and governance dimensions exert a positive and significant influence, supporting hypotheses H3.1 and H3.3. However, the environmental dimension shows a marginally significant effect on competitive perspectives. In contrast, the social dimension does not show a statistically significant effect, and therefore hypothesis H3.2 is not supported. Table 2 presents the estimated path coefficients, standard errors and p-value and a summary of the hypothesis testing results, indicating the direction and significance of each relationship included in the model.

Table 2. Relationships, estimated Path coefficients, standard deviation, p-value and summary of the hypothesis testing results.

Hypothesis	Relationship	Path coefficients	Standard deviation	T statistics	P-values	Confirmed/ Not confirmed
H1.1	AI → Environmental ESG	0.403	0.064	6.275	0.000	YES
H1.2	AI → Social ESG	0.320	0.074	4.327	0.000	YES
H1.3	AI → Governance ESG	0.487	0.060	8.137	0.000	YES
H1.4	AI → Competitive Perspectives	0.592	0.053	11.216	0.000	YES
H2.1	SM → Environmental ESG	0.365	0.072	5.080	0.000	YES
H2.2	SM → Social ESG	0.518	0.066	7.810	0.000	YES
H2.3	SM → Governance ESG	0.353	0.066	5.345	0.000	YES
H2.4	SM → Competitive Perspectives	-0.005	0.072	0.076	0.940	NO
H3.1	Environmental ESG → Competitive Perspectives	0.110	0.064	1.716	0.086	YES
H3.2	Social ESG → Competitive Perspectives	-0.079	0.086	0.925	0.355	NO
H3.3	Governance ESG → Competitive Perspectives	0.239	0.089	2.680	0.007	YES

5 Discussion

The aim of this study was to examine the role of AI and SM in fostering ESG practices and enhancing competitive perspectives among innovative SMEs. The results highlight that AI positively influences all three ESG dimensions confirming its relevance as a key enabler of sustainability-oriented decision-making. By supporting data processing, predictive analytics, and automation, AI allows companies to improve the monitoring of environmental performance, enhance transparency in governance processes, and support socially responsible practices. In addition, AI shows a direct positive effect on competitive perspectives. This finding suggests that AI contributes more broadly to companies' ability to innovate, adapt, and strengthen their competitive positioning. In the context of SMEs, AI can represent a critical lever for enhancing both sustainability and competitiveness. The results also confirm that SM contributes to the adoption of ESG practices across all three dimensions. Companies that integrate sustainability principles into their managerial processes and organizational routines are more likely to implement ESG practices effectively. This finding reinforces the importance of structured sustainability-oriented approaches in translating sustainability objectives into concrete actions. However, the analysis shows that SM does not exert a direct effect on competitive perspectives. This suggests that the mere presence of sustainability-oriented managerial frameworks is not sufficient to generate competitive advantages. Instead, competitive benefits seem to emerge when sustainability principles are effectively translated into ESG practices. In this sense, ESG adoption appears to play a mediating role in the relationship between SM and competitiveness. The findings reveal that the impact of ESG dimensions on competitive perspectives is not uniform. The environmental and governance dimensions show a positive and significant effect, whereas the social dimension does not exhibit a statistically significant influence. One possible explanation may be related to the characteristics of the analyzed sample, composed of innovative SMEs with relatively high levels of human capital and collaborative organizational practices. In such contexts, social initiatives may already be embedded in companies' routines and therefore may not represent a distinctive source of competitive advantage. Overall,

the results suggest that the relationship between sustainability and competitiveness in SMEs is shaped by the interaction between technological capabilities and managerial practices. AI enhances firms' ability to process information and support decision-making, while SM provides the organizational framework necessary to implement sustainability strategies. ESG practices represent the point where these elements converge, translating strategic intentions into concrete outcomes that can influence competitive positioning. The study highlights that ESG implementation should be considered as a strategic process that can support companies' long-term development.

6 Conclusions

In relation to the research questions, the findings provide clear answers to both inquiries. With regard to RQ1, the results show that AI and SM jointly support the adoption of ESG practices in SMEs, although through different mechanisms. While AI directly enhances companies' ability to implement ESG initiatives, SM contributes by embedding sustainability principles into organizational processes. Concerning RQ2, the results indicate that ESG adoption contributes to enhancing companies' competitive perspectives, although the effect varies across dimensions. In particular, environmental and governance practices emerge as significant drivers of competitiveness, whereas the social dimension does not show a direct impact in the analyzed context. The findings offer several implications for managers and policymakers. First, the results emphasize the strategic importance of AI in supporting sustainability-oriented innovation. Companies should consider AI not only as a technological investment but as a key enabler of data-driven decision-making and sustainability performance improvement. Second, managers should develop structured SM practices that integrate ESG principles into organizational processes, governance mechanisms, and strategic planning. However, the results suggest that such practices must be effectively translated into concrete ESG initiatives in order to generate tangible competitive benefits. Third, policymakers should promote initiatives aimed at facilitating SMEs' adoption of both digital technologies and sustainability practices. Financial incentives, training programs, and knowledge-sharing platforms may help SMEs overcome resource constraints and accelerate the implementation of ESG strategies. Regarding the limitations, the analysis focuses on innovative SMEs located in a specific geographical context. Future studies could extend the analysis to companies operating in different regions to compare sustainability adoption patterns across diverse contexts. The study does not explicitly include control variables such as firm size, industry characteristics, ownership structure, or degree of internationalization. Incorporating these factors in future research could provide a more comprehensive understanding of the determinants of ESG adoption and competitiveness. Future research could also explore additional drivers of ESG adoption, such as organizational culture, and external collaboration networks, to better understand how SMEs can effectively integrate sustainability into their business models.

7 Ethics declaration

The authors confirm that the research was conducted in accordance with ethical standards. Participation in the survey was voluntary and anonymous.

8 AI declaration

The authors used AI-assisted technologies to enhance the stylistic quality of the text via grammar correction, and language refinement. After using AI tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

AI-Enabled Knowledge Ecosystems: Conditions for Learning and Deskilling Across Economic Sectors

Maria Cristina Manocchio[1], Francesca Di Virgilio[1], Gianluigi Mangia[2], Antonia Puccio[1]

[1] Department of Economics, University of Molise, Campobasso, Italy

[2] Department of Economics, Management, Institutions, University of Naples Federico II, Naples, Italy

Abstract

In modern organizations, the integration of artificial intelligence is revolutionizing how knowledge is created, shared, and utilized, while also altering the dynamics of organizational learning, skill enhancement, and governance frameworks. Generative AI is pivotal in making explicit knowledge more accessible and in optimizing both automation and decision-making processes. Nevertheless, it introduces challenges, such as the risk of diminishing tacit knowledge and an increasing reliance on algorithm-driven insights. Thus, AI is gradually becoming both a technological foundation and an active player in organizational knowledge environments. The effectiveness of AI in enhancing knowledge creation and innovation, or conversely, in causing skill mismatches and deskilling, is largely influenced by organizational learning capabilities, culture, and governance mechanisms. Although there is increasing academic interest, there remains a lack of empirical evidence on the influence of AI on organizational knowledge ecosystems beyond individual companies. This study addresses this gap by examining how various AI adoption configurations affect organizational knowledge ecosystems and learning dynamics at the sectoral level. The research employs secondary data from the 2025 Survey on Information and Communication Technologies in Enterprises by ISTAT, concentrating on Italian companies with at least 10 employees. Data at the firm level is aggregated by economic sector, allowing for a meso-level analysis of AI adoption patterns. From a capability-based viewpoint, the study distinguishes between AI technologies that are cognitively oriented, aiding in knowledge creation, and those that are automation-oriented, primarily focused on task substitution. A sector-level cluster analysis is conducted to pinpoint distinct AI adoption patterns and their integration within organizations. This research aims to reveal various organizational knowledge ecosystems, each defined by a unique balance between AI applications focused on learning and those centered on automation. By employing a configurational and sector-specific approach, the study enhances the knowledge management literature by clarifying the circumstances under which AI adoption promotes organizational learning and the development of sustainable capabilities, rather than leading to a reduction in skills.

Keywords: Artificial Intelligence, Knowledge Ecosystems, Organizational Learning, Deskilling, Knowledge Management.

Paper type: Academic Research Paper

1 Introduction

Across contemporary organizations, the adoption of artificial intelligence (AI) is reshaping how knowledge is created, shared, and applied, while simultaneously reconfiguring learning dynamics, skills, and governance structures (Alavi, Leidner and Mousavi, 2024; Leoni et al., 2024). Recent investigations indicate that AI, particularly generative AI (GenAI), fundamentally transforms knowledge management processes by enabling rapid access to explicit knowledge and supporting cognitive tasks such as analysis, forecasting, and decision-making (Lin and Wu, 2025; Dey et al., 2024; Leoni et al., 2024; Mikalef et al., 2023). Concurrently, these advancements elicit concerns regarding the potential erosion of tacit, experience-based knowledge and an excessive dependence on algorithmic outputs (Storey, 2025; Alavi, Leidner and Mousavi, 2024). AI adoption can generate both opportunities and tensions: it can enhance knowledge creation, learning, and innovation performance through human–AI collaboration, yet automation-oriented applications may induce deskilling, skill mismatches, and the need for reskilling (Arnaout et al., 2025; Cheng et al., 2025; Rostamzadeh et al., 2025; Cramarenco, Burcă-Voicu and Dabija, 2023). Organizational learning capabilities moderate these effects by converting individual gains into team-level advantages and dynamic capabilities (Han et al., 2025; Jamil et al., 2025; Yan, Husted and Fath, 2025). Proper governance, leadership, and skill development are critical for AI to support valuable learning activities and sustain competitive advantage (Schwaeke et al., 2025; Storey, 2025; Dey et al., 2024).

Despite these advancements, empirical evidence regarding the influence of AI adoption on organizational knowledge ecosystems beyond the firm level remains scarce (Dahlke et al., 2024; Leoni et al., 2024). Existing research has predominantly concentrated on firm-level adoption or performance outcomes, neglecting the

sectoral patterns through which AI diffusion impacts learning dynamics and knowledge management practices. This study expands upon this gap by examining the impact of varying AI adoption configurations on the learning dynamics and organizational knowledge ecosystems at the sectoral level. The research specifically addresses the following question:

- *RQ1: Under what conditions does AI adoption support organizational learning rather than deskilling within organizational knowledge ecosystems?*

This research utilizes the knowledge-based perspective of the firm alongside organizational learning theory to examine how diverse AI adoption strategies shape distinct organizational knowledge ecosystems. By investigating the sectoral trends of AI adoption within the Italian industrial landscape, the research aims to shed light on the interaction between AI technologies, organizational practices, and data capabilities, and how these elements collectively influence knowledge creation and learning outcomes at the meso level.

2 Literature Review

2.1 AI Adoption and Organizational Knowledge Ecosystems

The deployment of AI is progressively incorporated into the comprehensive knowledge structures of enterprises, affecting how companies create, share, and apply expertise (Schwaeke et al., 2025). AI transcends being a mere technological enhancement; it reconfigures organizational knowledge ecosystems, defined as the interplay among digital infrastructures, human capabilities, governance mechanisms, and inter-organizational networks (Cheng et al., 2025; Zhang, Zuo and Yang, 2025). The incorporation of AI within the Technology–Organization–Environment (TOE) framework is influenced by technological attributes such as relative advantage and compatibility, as well as organizational factors including readiness, leadership, skills, and learning orientation (Brennecke et al., 2025; Cimino et al., 2025). Dynamic capabilities, such as adaptability, absorptive capacity, and knowledge integration, are often linked to increased AI adoption intensity and more sophisticated implementation strategies. Conversely, challenges such as financial constraints, intellectual property issues, low trust levels, regulatory ambiguities, and resistance to change impede adoption and may restrict AI to narrower, efficiency-driven applications (Badghish and Soomro, 2024; Booyse and Scheepers, 2024). Existing literature indicates that AI facilitates various organizational pathways. In particular contexts, AI augments knowledge management systems, converting them into adaptive frameworks that support real-time analytics, collaborative learning, and innovation (Abdelrahman et al., 2025). Conversely, in different contexts, AI is utilized mostly for process automation and task replacement, exhibiting limited integration into comprehensive learning frameworks (Bankins et al., 2024). The distinct pathways of AI adoption underscore that the generation of knowledge-intensive outcomes is not inherently guaranteed but is contingent upon the surrounding ecosystem, which includes skills, culture, and governance. Furthermore, knowledge ecosystems are dependent on social capital and inter-organizational networks, which facilitate the flow of tacit knowledge and enhance collective resilience (Kucharska and Erickson, 2023). Leadership, culture, and skills development impact the extent to which AI enhances collaborative knowledge dynamics or perpetuates fragmented, efficiency-oriented structures (Dey et al., 2024).

2.2 Dynamics of Organizational Learning and Deskilling: Conditions and Mechanisms

Organizational learning (OL) is defined as the evolving process by which an organization's knowledge, actions, and collective beliefs develop through experience and become ingrained in its routines, systems, and culture (Nawaz et al., 2025; Ademi, Sætre and Klungseth, 2024). This process involves the development, preservation, distribution, and application of knowledge across individual, team, and organizational levels. It can occur through gradual modifications (single-loop learning) or through more substantial shifts that challenge fundamental beliefs and strategies (double-loop learning) (Ademi, Sætre and Klungseth, 2024). Conversely, deskilling involves the reduction or inadequate use of human abilities due to technology assuming cognitive responsibilities. In AI-enhanced workplaces, deskilling may happen when automation replaces human decision-making, leading to a decline in critical thinking, experiential learning, and cognitive engagement, particularly among employees with less experience (Choudhury and Chaudhry, 2024). The integration of AI in digital transformation brings both the promise of enhanced learning and the threat of skill erosion. From an organizational learning standpoint, AI systems are increasingly becoming partners in the creation, retention, and distribution of knowledge, thereby supporting continuous cycles of knowledge acquisition and organizational memory at micro, meso, and macro levels (Gibson et al., 2023; Jarrahi et al., 2022). When embedded within learning infrastructures, AI strengthens dynamic capabilities by enabling organizations to identify, leverage, and

adapt resources in response to shifting environments (Han et al., 2025). The outcomes largely depend on whether AI substitutes or augments human cognition. Substitution may generate reduced expertise and passive monitoring, whereas augmentation-based human–AI collaboration sustains reflection and competence development (Bauer et al., 2025; Mosqueira-Rey et al., 2022). Consequently, OL acts as a mediating mechanism through which AI adoption supports sustainable performance, provided organizations invest in human capital, AI literacy, and active engagement with AI outputs, thereby preventing deskilling and fostering adaptive capabilities (Rostamzadeh et al., 2025; Alavi, Leidner and Mousavi, 2024).

2.3 Role of Organizational Culture, Skills and Governance in Sustainable AI Integration

The influence of organizational culture, skills, and governance is pivotal in determining whether AI integration boosts learning and capabilities or results in reliance and diminished skills. Examining AI from a governance standpoint involves perceiving it as a framework of rules, practices, and processes that must align with an organization's strategies, objectives, and values to be both effective and legitimate (Birkstedt et al., 2023). A culture that prioritizes learning, fostering an environment of experimentation, knowledge exchange, and psychological safety, is essential for enhancing human–AI collaboration and reducing resistance to AI integration. Trust and ethical awareness play a crucial role in determining employees' readiness to rely on algorithmic outputs while maintaining their critical judgment (Schwaeke et al., 2025; Bankins et al., 2024). The extent to which workers embrace AI tools is significantly influenced by their skills and human capital, particularly in areas such as reskilling, upskilling, data literacy, and AI literacy. Research indicates that AI provides the most value when algorithmic skills are widely distributed among domain experts, allowing them to interpret, challenge, and incorporate model outputs into decision-making processes (Tambe, 2025; Li, 2022). Failing to continuously invest in skill development can lead to greater skill mismatches and jeopardize well-being, as it increases dependence on complex systems (Cramarenco, Burcă-Voicu, and Dabija, 2023). The third pillar of integration is governance and leadership. By employing AI governance frameworks, oversight units, and establishing clear accountability, strategic alignment, change management, and ethical oversight transform theoretical AI principles into practical, enforceable actions and consistent routines (Nair et al., 2024; Birkstedt et al., 2023; Kelley, 2022).

3 Research Methodology

This study examines the implementation and sectoral trends of AI in Italian companies with a minimum of 10 employees, emphasizing the coexistence of various AI applications and organizational digital competencies across sectors. Considering the diverse use of AI in business operations, a quantitative exploratory methodology is employed to delineate sectoral trends and discern unique knowledge ecosystems, rather than to evaluate causal hypotheses. Three composite indexes were developed to encapsulate the intricacies of AI deployment. Cognitive AI includes technologies that enhance knowledge, decision-making, and innovation; Automation AI refers to applications intended for task replacement and workflow automation; and Embeddedness denotes organizational digital competencies, encompassing the use of ERP, CRM, and BI systems, data analytics, and overall digitalization levels. These indices provide descriptive statistics and cluster analysis, facilitating a systematic evaluation of sectoral differences in AI utilization and digital competencies.

3.1 Data Collection

This study is based on data from ISTAT (2025), drawn from the ICT–Enterprises tables. It looks at 26,246 Italian companies with at least 10 employees, analyzing them at the sector level, which is the main focus of the study.

3.2 Descriptive Statistics

Three theoretically based indexes were developed to offer a comprehensive perspective of AI adoption and digital capabilities across sectors: Cognitive AI, Automation AI, and Embeddedness. Cognitive AI includes AI technologies that enhance knowledge, decision-making, and innovation, such as text mining, natural language processing, machine learning, workflow automation, and research and development activities. Automation AI reflects applications aimed at task substitution and process automation, such as image and video generation, object recognition, and autonomous robotics. Embeddedness represents organizational digital capabilities, combining ERP/CRM/BI usage, data analytics activities, and overall sectoral digitalization.

Table 1 provides the complete identification of the variables employed in the formulation of each index, along with their corresponding source tables and descriptions. This thorough mapping guarantees openness in

index formulation and facilitates the repetition of the analysis. All variables are represented as sectoral percentages of enterprises implementing each technology. To ensure comparability across dimensions, variables were standardized using min-max scaling prior to aggregation. Each index was calculated as the unweighted arithmetic mean of its normalized constituents. Robustness assessments employing different weighting methodologies produced consistent outcomes.

Table 1: Variables used to construct AI and digital capabilities indice

Index	Source Table	Description
Cognitive AI	9A	Extract knowledge and information from text documents (text mining)
	9A	Convert spoken language into machine-readable format (speech recognition)
	9A	Generate written or spoken language or programming code (natural language generation)
	9A	Analyze data through machine learning, deep learning, and neural networks
	9A	Automate workflows or support decision-making (RPA / decision support)
	9B	Research & Development (R&D) or innovation activities
Automation AI	9A	Generate images, video, or audio content
	9A	Identify objects or people based on images (image recognition)
	9A	Enable autonomous movement of machines based on environment observation (robots, drones, vehicles)
Embeddedness	6	Use of ERP software
	6	Use of CRM software
	6	Use of Business Intelligence software
	7	Data analytics via internal employees or other organizations
	7	Data analytics via external organizations
	3	Very low/ Low/ High/ Very high level of digitalization

Summary statistics of the three indices at the sectoral level are reported in **Table 2,** showing that Cognitive AI exhibits considerable variation (median = 34.53%, max = 57.41%), suggesting strong use of knowledge-enhancing AI in certain sectors. Automation AI exhibits reduced values (median = 21.48%), suggesting that task substitution is less common, whereas Embeddedness demonstrates moderate levels (median = 28.75%), indicating a broad degree of organizational digital capabilities.

Table 2: Summary statistics of AI and digital capability indices

Index	Min	1st Qu.	Median	Mean	3rd Qu.	Max
Cognitive AI	25.32	30.22	34.53	36.12	41.65	57.41
Automation AI	11.78	17.78	21.48	22.70	26.37	40.32
Embeddedness	19.69	25.87	28.57	29.17	32.12	37.66

Figure 1 shows the distribution of the three indices by implementing boxplots, highlighting disparities among macro-sector groups and the presence of outliers.

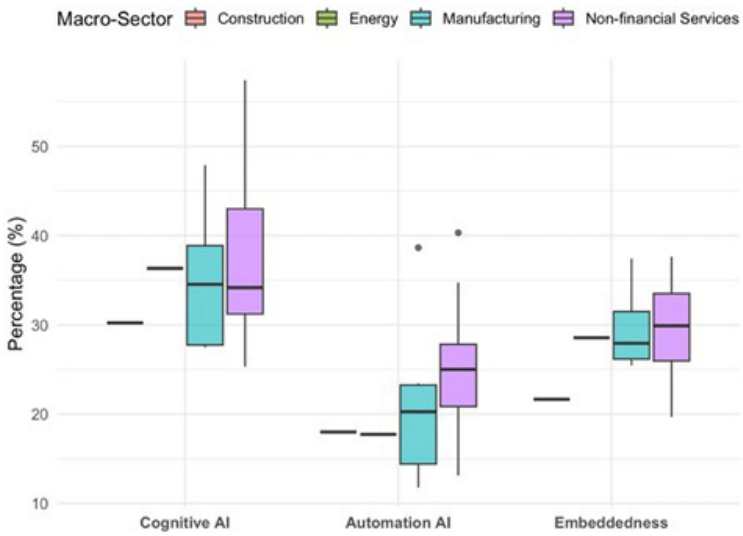

Figure 1: Distribution of AI and Digitalization Indices Across Sectors

Cognitive AI exhibits highest variability, with numerous sectors attaining levels over 55%, signifying robust utilization of AI for knowledge generation, decision-making assistance, and creativity. The prevalence of Automation AI is rather low, with median values about between 21% and 22%, indicating that the substitution of human tasks is not extensively adopted across many sectors. Embeddedness, which consolidates digitalization levels, ERP/CRM/BI utilization, and data analytics endeavors, exhibits a more concentrated distribution (median ~28.8%), suggesting that the majority of sectors possess a moderate level of organizational digital capabilities. The macro-sector color coding offers a prompt visual indication of which industries are at the forefront of AI adoption and which are underdeveloped, highlighting sectoral diversity and validating further cluster analysis to discern unique knowledge ecosystems.

3.3 Cluster Analysis

A cluster analysis was performed to identify patterns and classify sectors into distinct knowledge ecosystems. This analysis was based on the three indices of Cognitive AI, Automation AI, and Embeddedness, which are a widely used exploratory technique for grouping observations according to similarity across multiple dimensions (Hair et al., 2010). The cluster analysis revealed the fundamental patterns of AI deployment across several Italian sectors. The optimal number of clusters was determined using hierarchical clustering and silhouette analysis, resulting in a three-cluster solution that provided the clearest separation between sectoral knowledge ecosystems. Table 3 defines the sectoral distribution throughout the three clusters, specifying the composition of each cluster for macro-sector representation.

Table 3: Distribution of sectors across clusters by macro-sector

Cluster	Manufacturing	Energy	Construction	Non-Financial Services	Total
1	5	0	1	1	**7**
2	3	1	0	12	**16**
3	1	0	0	1	**2**

Cluster 1 is dominated by manufacturing sectors, with some representation from construction and non-financial services. Cluster 2 primarily comprises non-financial services, with a few manufacturing sectors included. Cluster 3 is small, including only one manufacturing and one service sector, highlighting the heterogeneous composition of sectoral knowledge ecosystems. Although Cluster 3 includes a limited number of sectors, silhouette scores confirmed the stability and internal coherence of the three-cluster solution.

A deeper examination of cluster profiles, reported in Table 4, shows differences in the mean, standard deviation, and median values of Cognitive AI, Automation AI, and Embeddedness across clusters.

Table 4: Cluster profiles: means, SD, and medians for Cognitive AI, Automation AI, and Embeddedness

Cluster	Mean Cognitive AI	SD Cognitive AI	Median Cognitive AI	Mean Automation AI	SD Automation AI	Mean Embeddedness	SD Embeddedness
1	47.60	5.95	46.80	26.50	6.05	33.50	3.70
2	31.80	4.37	31.80	19.20	5.34	28.30	3.68
3	30.40	6.95	30.40	37.50	3.95	20.90	1.69

Cognitive AI reaches its highest values in Cluster 1 (mean = 47.6%), indicating sectors where AI is predominantly leveraged for knowledge-intensive activities and innovation-oriented processes. Clusters 2 and 3 exhibit notably diminished values, suggesting limited cognitive applications. Automation AI exhibits a distinct pattern: Cluster 3 exhibits the highest mean (37.5%), indicating areas where AI deployment is predominantly focused on task automation. Clusters 1 and 2 have more moderate values, with Cluster 2 displaying the lowest intensity of automation-focused applications. Embeddedness displays a comparable gradient, with Cluster 1 demonstrating the highest level of digital integration (mean = 33.5%), Cluster 2 positioned at an intermediate level, and Cluster 3 indicating relatively lesser organizational digital capabilities.

On this basis, the clusters can be conceptually characterized as follows. Cluster 1, identified as "Cognitive Learning Ecosystems," is characterized by a high degree of cognitive intensity alongside significant digital integration. This cluster represents sectors where AI is extensively incorporated into processes of knowledge creation, decision support, and innovation. Cluster 2, identified as "Automation-Oriented Ecosystems," occupies an intermediate position, indicative of a more gradual and efficiency-focused adoption strategy that balances cognitive and automation-oriented applications. Cluster 3, referred to as "Emerging AI Ecosystems," is smaller and structurally distinct, marked by strong automation intensity but limited cognitive applications and weaker

digital integration. This suggests a concentrated focus on task substitution rather than comprehensive knowledge development.

Figures 2 and 3 further illustrate these patterns. Figure 2 shows the average values of the three indices for each cluster, emphasizing the disparities in AI adoption approaches.

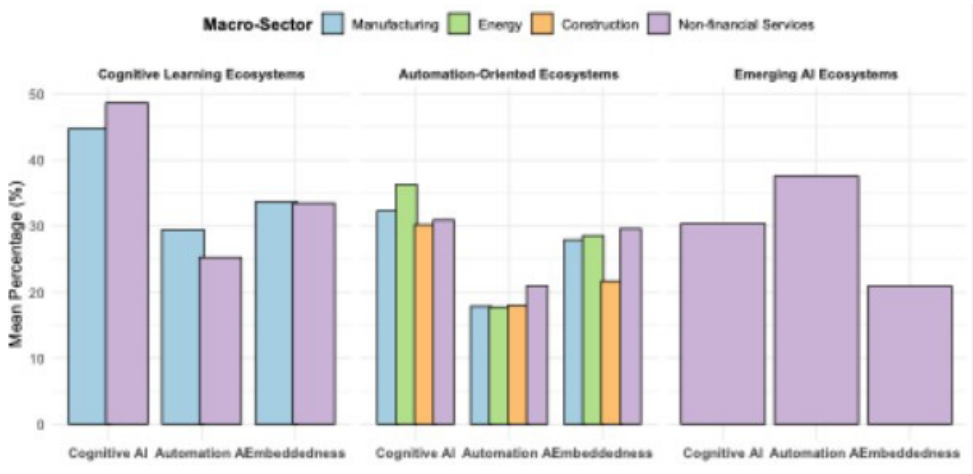

Figure 2: Mean values of Cognitive AI, Automation AI, and Embeddedness for each cluster with breakdown by macro-sector

The figure clearly differentiates the clusters and complements the numerical profiles reported in Table 3, reinforcing the sectoral heterogeneity and the existence of distinct knowledge ecosystems.

Figure 3 maps sectors along the Cognitive AI and Automation AI dimensions, revealing a clear spatial differentiation among clusters and their macro-sectoral composition.

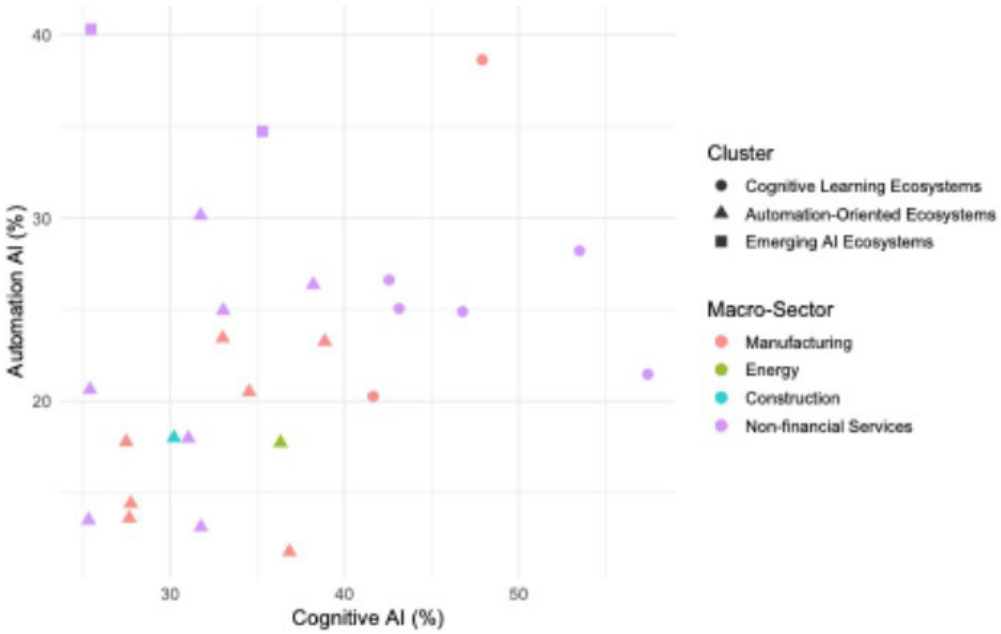

Figure 3: Sectoral Distribution of AI Adoption by Cluster and Macro-Sector

The scatterplot offers a clear spatial differentiation among clusters, so validating the internal coherence of the clustering solution. Cognitive Learning Ecosystems occupy the upper-left quadrant of the figure, distinguished by high levels of Cognitive AI and moderate levels of Automation AI, primarily linked to the Manufacturing and Non-financial Services sectors. Automation-Oriented Ecosystems hold a pivotal role, demonstrating intermediate values across all dimensions and a more diverse macro-sectoral composition. In contrast, Emerging AI Ecosystems are situated in the upper-right quadrant, characterized by high levels of Automation AI and little Cognitive AI, signifying a predominant emphasis on task automation over knowledge-

intensive applications. The figure illustrates the correlation between various AI adoption strategies and certain sectoral configurations, affirming the perspective of clusters as heterogeneous knowledge ecosystems.

3.1.1 Cluster Validation

A one-way analysis of variance (ANOVA) was performed for each of the three indices—Cognitive AI, Automation AI, and Embeddedness—to ascertain whether the identified clusters represent statistically distinct configurations. Table 5 illustrates statistically significant differences across clusters for all measured indices (Cognitive AI: $F = 25.70$, $p < 0.001$; Automation AI: $F = 12.18$, $p < 0.001$; Embeddedness: $F = 10.77$, $p < 0.001$). These results substantiate that the clusters are indicative of meaningful variations in AI adoption levels and organizational digital capabilities, rather than being arbitrary groupings.

Table 5: One-way ANOVA Results by Cluster

Index	F-statistic	p-value
Cognitive AI	25.70	< 0.001
Automation AI	12.18	< 0.001
Embeddedness	10.77	< 0.001

To investigate more thoroughly whether cluster pairs contributed to these differences, post-hoc multiple comparison tests utilizing Tukey's HSD were used (Tukey, 1949). The results are presented in Table 6, which demonstrates that there are substantial pairwise differences in Cognitive AI between Cluster 1 ("Cognitive Learning Ecosystems") and both Clusters 2 and 3. Automation AI also exhibits significant differences across all clusters, with Cluster 3 ("Emerging AI Ecosystems") exhibiting the highest values. Additionally, there are substantial disparities in embeddedness among all cluster pairings, which underscores a distinct division in the digital capabilities of organizations.

Table 6: Tukey HSD Post-Hoc Comparisons by Cluster

Index	Comparison	Mean difference	p-value
Cognitive AI	Cluster 2 – Cluster 1	−15.74	< 0.001
Cognitive AI	Cluster 3 – Cluster 1	−17.19	< 0.001
Cognitive AI	Cluster 3 – Cluster 2	−1.45	n.s.
Automation AI	Cluster 2 – Cluster 1	−7.25	0.021
Automation AI	Cluster 3 – Cluster 1	11.08	0.050
Automation AI	Cluster 3 – Cluster 2	18.33	< 0.001
Embeddedness	Cluster 2 – Cluster 1	−5.22	0.011
Embeddedness	Cluster 3 – Cluster 1	−12.64	< 0.001
Embeddedness	Cluster 3 – Cluster 2	−7.41	0.031

The aggregate evidence from ANOVA and post-hoc tests confirms the legitimacy of the cluster solution, indicating that the three clusters represent distinct sectoral knowledge ecosystems distinguished by varied adoption of Cognitive and Automation AI and various levels of Embeddedness.

4 Discussion

The examination of cluster characteristics and sectoral distributions highlights diverse configurations of AI adoption within Italian organizations, underscoring the importance of identifying distinct knowledge ecosystems. The clusters exhibit a non-random distribution, revealing unique macro-sectoral patterns that underscore the variations in AI adoption strategies and digital competencies. The Cognitive Learning Ecosystems cluster is primarily associated with knowledge-intensive manufacturing activities and advanced non-financial services. In these sectors, AI is embedded in processes of knowledge creation, decision support, and innovation. Increased levels of Cognitive AI, along with strong digital integration, signify organizational environments that promote learning, improve the collaboration between human talents and AI technologies, and support the advancement of technology capabilities. The Automation-Oriented Ecosystems cluster displays a broader and more heterogeneous sectoral composition, including traditional manufacturing, construction, and several non-financial services. The integration of AI within these sectors is both progressive and equitable, reflecting a systematic incorporation of AI into established production and organizational practices. This trend suggests a practical utilization of AI, largely focused on improving efficiency and partially replacing tasks, rather than completely revolutionizing knowledge-intensive processes. The Emerging AI Ecosystems cluster is relatively small and concentrated within a limited number of sectors. It is characterized by a high degree of Automation

AI, yet exhibits comparatively low levels of Cognitive AI and Embeddedness. These sectors primarily focus on task automation with limited integration into broader digital and organizational infrastructures. Although this strategy may result in short-term productivity gains, it presents fewer opportunities for learning and skill enhancement, thereby raising potential concerns regarding deskilling dynamics.

These findings emphasize the variability of AI adoption across business sectors and highlight the necessity of considering both technological and organizational skills when assessing the potential for knowledge creation and skill development. The identification of distinct industry knowledge ecosystems offers an analytical framework for comprehending diverse AI trajectories and their effects on skills and organizational learning. These findings suggest that AI adoption does not follow a uniform technological trajectory but is embedded within sector-specific organizational and knowledge structures that shape its developmental path.

5 Conclusion

The rapid diffusion of AI is increasingly reshaping how organizations generate, integrate, and exploit knowledge across economic sectors (Alavi, Leidner and Mousavi, 2024; Leoni et al., 2024; Storey, 2025). Within this evolving landscape, understanding how different configurations of AI adoption influence organizational learning and knowledge dynamics has become a central issue in management and knowledge management research. Drawing on sectoral data from Italian enterprises, this study identified three distinct configurations of AI adoption—Cognitive Learning Ecosystems, Automation-Oriented Ecosystems, and Emerging AI Ecosystems—based on the interaction between Cognitive AI, Automation AI, and organizational digital embeddedness. The empirical results highlight that AI adoption does not follow a uniform trajectory across sectors. Rather, different technological and organizational configurations shape alternative knowledge ecosystems, influencing whether AI supports knowledge creation and organizational learning or primarily drives efficiency-oriented automation. These findings reinforce prior research emphasizing that the outcomes of AI adoption depend not only on technological capabilities but also on organizational structures, skills, and governance mechanisms (Birkstedt et al., 2023; Bankins et al., 2024). Overall, the analysis suggests that sectors characterized by stronger digital infrastructures and cognitively oriented AI applications are more likely to foster learning-oriented ecosystems, while automation-focused configurations may generate productivity gains but potentially limit opportunities for knowledge development. Future research could extend this analysis by examining firm-level adoption patterns and exploring cross-country comparisons, in order to better understand how institutional contexts, organizational capabilities, and governance practices shape the long-term relationship between AI adoption, organizational learning, and knowledge ecosystems.

When Knowledge Hiding Enhances Self-Assessment in Multiple Sclerosis

Juan-Gabriel Cegarra-Navarro[1], Aurora Martínez-Martínez[1], Scott Erickson[2], Jorge Cegarra-Sánchez[3]

Abstract

Small variations in how information is framed or selectively presented can significantly shape how individuals interpret and internalize knowledge. Prior research has largely associated knowledge hiding with negative outcomes, partly due to its operationalization as perceived lack of help or misaligned information. In contrast, this study adopts a knowledge regulation perspective, focusing on how selective non-disclosure may shape cognitive processes. Therefore, we adopt a complementary perspective by examining evasive knowledge hiding as a form of knowledge regulation, where information is filtered and sequenced to reduce cognitive overload and prevent the formation of misconceptions.

This study examines how evasive knowledge hiding influences self-assessment among patients with Multiple Sclerosis, a context in which misconceptions and narrow mental models can significantly affect disease management. We argue that learning myopia, understood as the persistence of distorted or incomplete mental models, plays a central role in shaping how patients evaluate their own capabilities and progress. Drawing on survey data from 75 Multiple Sclerosis patients and analysed using Partial Least Squares Structural Equation Modeling (PLS-SEM), the results reveal that evasive knowledge hiding does not directly affect self-assessment. Instead, its impact is fully mediated by learning myopia. Greater evasive knowledge hiding is associated with lower levels of learning myopia, which in turn leads to higher levels of self-assessment. These findings suggest that selective non-disclosure, when enacted as a form of knowledge regulation, may help patients avoid misleading or overly complex information that could distort their understanding.

By challenging the dominant "dark side" view of knowledge hiding, this study highlights its contingent and potentially adaptive role in specific contexts. The findings contribute to knowledge management research by reframing evasive knowledge hiding as a mechanism of knowledge regulation and to healthcare research by showing how managing information flows can support more accurate self-evaluations among patients. Overall, the study uncovers a paradoxical pathway through which knowledge hiding can enhance learning outcomes by reducing cognitive distortions.

Keywords: Evasive knowledge hiding; learning myopia; self-assessment; systems thinking; healthcare knowledge management.

1 Introduction

Self-assessment is a central construct for understanding patient evolution because it marks the point at which knowledge and beliefs are transformed into action (Zheng et al., 2024). For individuals living with Multiple Sclerosis (MS), accurate self-assessment is not merely a psychological disposition but a practical capacity that guides everyday decisions, supports treatment adherence, and shapes interactions with healthcare providers (Tacchino et al., 2018). In contrast to broader constructs such as self-esteem, self-assessment focuses on situational judgments of one's abilities, confidence in managing challenges, and perceptions of progress in coping with the condition (Zell & Johansson, 2024).

From the perspective of individual learning, self-assessment can be hidden by learning myopia when misconceptions and narrow mental models distort how individuals interpret their own progress and capabilities (Dunning et al., 2004). Patients with MS who believe, for example, that the illness is inevitably fatal or that it only affects specific groups, are likely to undervalue their ability to manage the condition effectively (Cegarra-Sánchez et al., 2025). In this way, learning myopia clouds self-assessment, leading to either an exaggerated sense of limitation or an inaccurate sense of progress (Cegarra-Sánchez et al., 2025).

By reducing cognitive blind spots and encouraging broader, system-oriented thinking, healthcare providers can help patients form more balanced self-assessments, which are essential for informed decision-making and adaptive coping (Meissner et al., 2017; Pina e Cunha & Chia, 2007). The key question is how practitioners can achieve this in everyday encounters. From our perspective, evasive knowledge hiding offers one possible mechanism (Xia & Li, 2023). By filtering and sequencing information, providers prevent the reinforcement of

misconceptions and avoid overwhelming patients with details that may foster distorted interpretations (Hernaus et al., 2019). Seen through a systems thinking lens, such selective withholding is not a form of deception but a knowledge regulation strategy that maintains cognitive clarity. In this way, practitioners can support patients in moving beyond learning myopia, enabling more realistic and empowering self-assessments.

Despite the growing research on knowledge hiding, most studies describe it as a detrimental behavior with negative consequences for collaboration and learning (Černe et al., 2014; Connelly et al., 2012; Zhang & Min, 2021). Less attention has been paid to its potential adaptive functions (Cegarra-Navarro et al., 2021), particularly in healthcare settings where patients are vulnerable to misconceptions (Zhao & Xia, 2018). Building on this gap, our study explores the paradoxical role of evasive knowledge hiding in supporting patient learning. Specifically, we address the following research questions:

- *RQ1: How does evasive knowledge hiding influence cognitive myopia among patients with Multiple Sclerosis?*
- *RQ2: What is the relationship between cognitive myopia and self-assessment in this context?*
- *RQ3: Does cognitive myopia mediate the relationship between evasive knowledge hiding and self-assessment?*

The remainder of the paper is organized as follows. Section 2 develops the conceptual framework and hypotheses, drawing on the literatures on knowledge hiding, learning myopia, and systems thinking. Section 3 describes the methodology, including the sample, measures, and analytical procedures. Section 4 presents the results of the PLS-SEM analysis. Section 5 discusses the findings, highlighting their theoretical and practical implications. Finally, Section 6 concludes with limitations and directions for future research. In doing so, this study reframes knowledge hiding as a knowledge regulation strategy and demonstrates its paradoxical role in enhancing patient self-assessment.

2 Conceptual Framework

From a knowledge management perspective, self-assessment is not only a psychological trait but a knowledge outcome that reflects whether information has been effectively absorbed, contextualized, and applied (Xu et al., 2010). Nonaka and Takeuchi (1995) highlight that knowledge becomes valuable when it is internalized and externalized in practice, in this vein, self-assessment captures both dimensions by showing how patients internalize information and communicate their evaluation of capabilities. Similarly, Argyris and Schön (1996) emphasize reflection as a cornerstone of learning, where individuals reassess assumptions to adapt their actions. Davenport et al. (1998) similarly argue that knowledge emerges when information is enriched by reflection and experience, which positions self-assessment as a practical indicator of knowledge quality and effectiveness.

What these ideas underscore is that accurate self-assessment reflects the successful transformation of knowledge into actionable understanding, while distorted self-assessment reveals breakdowns in knowledge flows. In this sense, self-assessment provides a valuable lens for knowledge management research, as it not only signals whether knowledge is available but also whether it has been meaningfully applied in practice (Xu et al., 2010). This perspective becomes especially relevant in the case of MS, where learning myopia often shapes patient experience. Learning myopia refers to persistent misconceptions and narrow mental models, such as the belief that “MS affects only women” or that “MS is inherently fatal” (Cegarra-Sánchez et al., 2025).

Systems thinking views healthcare interactions as knowledge ecosystems. Within such systems, too much, too little, or poorly timed information can either destabilize or stabilise learning (Adam & De Savigny, 2012; Cresswell et al., 2021). From this perspective, learning myopia and systems thinking can be viewed as two sides of the same coin, whereas systems thinking emphasizes interconnections, feedback, and long-term implications (Thelen et al., 2023), learning myopia represents fragmented and short-sighted processing of information (Cegarra-Sánchez et al., 2025).

In healthcare contexts, the absence of systems thinking may trap patients in cognitive myopia, reinforcing misconceptions and limiting their self-assessment (Gao & Yin, 2025). Conversely, when providers adopt a systems thinking perspective, they are able to filter, organize, and sequence information in ways that reduce misperceptions and promote more adaptive learning (Adam & De Savigny, 2012). It should be noted here that organizational research has shown that hiding behaviors influence what becomes salient and shared in groups, with climates, leadership signals, and communication patterns directing attention and shaping belief formation (Ul Haq et al., 2024; C. Xu & Yao, 2025; Yang et al., 2024).

From a systems thinking perspective, evasive knowledge hiding (EKH) should not be understood simply as withholding knowledge. Although it shares similarities with information filtering and communication tailoring, EKH is distinct in that it involves intentional non-disclosure under conditions of asymmetric knowledge, where

clinicians control access to information that patients may expect or request. It also reflects a temporary and situational process, in which information is not necessarily denied but selectively delayed or redirected. These features position EKH within the broader knowledge hiding literature rather than as a purely neutral or patient-centered communication practice.

At the same time, EKH can be seen as a form of information filtering that regulates knowledge flows, helping patients process information without becoming overwhelmed or misled by distorted messages. While much of the literature associates knowledge hiding with negative antecedents such as the dark triad (Joshi et al., 2025), abusive contexts and organizational politics (Wang et al., 2024), or identity threats (Kumar et al., 2025; Lu & Zhou, 2025), and links it to harmful outcomes for collaboration and performance (Zhang & Min, 2024), more recent research highlights its contingent nature. In particular, supportive climates, leadership signals, and relational contexts can buffer or redirect its effects, revealing that knowledge hiding may not always be detrimental (Chacon-Henao & Arias-Perez, 2025; Fu et al., 2024; Islam et al., 2024; Semerci et al., 2025; C. Xu & Yao, 2025; Yang et al., 2024).

It follows from the above that the strength of the effect of evasive knowledge hiding on self-assessment may vary across contexts (Islam et al., 2024; C. Xu & Yao, 2025). Supportive communication climates, relational cues such as identity leadership or gratitude, and patient characteristics such as age or health literacy can amplify the benefits of selective withholding by sustaining trust and reducing susceptibility to misconceptions (Chacon-Henao & Arias-Perez, 2025; C. Xu & Yao, 2025). In contrast, when hiding arises as a self-protective response to stress, or in environments marked by moral disengagement and politics, evasive knowledge hiding may lose its adaptive function and reinforce rather than reduce misconceptions (Kumar et al., 2025; Wang et al., 2024). Importantly, this interpretation assumes that EKH is enacted with patient-centered intent and within a context of trust. When these conditions are absent, selective withholding may be perceived as neglect or paternalism, potentially undermining its beneficial effects.

Translating these ideas into clinical encounters, practitioners usually aim to serve the best interests of patients while managing cognitive overload, uncertainty, and time pressures. In such settings, selectively withholding details that are confusing or of little relevance can shield patients from misinformation, misattribution, or unnecessary rumination, particularly when their understanding of the illness is fragile. In this sense, evasive knowledge hiding can act as protective filtering rather than opportunistic concealment. By limiting exposure to misleading lay beliefs and preventing simplistic but inaccurate explanations from taking hold, clinicians reduce the likelihood that patients interpret their condition through misconceptions. This process lowers cognitive myopia. Research in knowledge management supports this logic, showing that environments which minimize noise and conflict improve clarity and strengthen self-regulatory capacity, whereas toxic climates erode it (Lu & Zhou, 2025; Mohamed et al., 2024; Wang et al., 2025). For patients with Multiple Sclerosis, fewer misconceptions lead to clearer mental models and more accurate self-evaluations of capability and progress. Therefore, we propose:

H1. *Evasive knowledge hiding is negatively related to learning myopia*.

Learning myopia narrows the cognitive space through which individuals evaluate themselves. When misconceptions persist, patients judge their progress and abilities through distorted frames, which can lead either to excessive pessimism or to an inaccurate sense of improvement. In this way, learning myopia undermines the capacity for realistic self-assessment. Evidence from organizational research shows that hidden or distorted knowledge often reduces performance because it erodes trust, generates conflict, and restricts opportunities for learning (Islam et al., 2024; Zhang & Min, 2024). In healthcare, this mechanism is primarily cognitive. Patients who remain trapped in narrow or mistaken beliefs about their illness lack the clarity needed to assess their situation effectively. By contrast, when learning myopia is reduced, patients are more likely to develop coherent mental models and provide accurate evaluations of their ability to cope. Therefore, we propose the second hypothesis:

H2. *Learning myopia is negatively related to self-assessment*.

This study conceptualises evasive knowledge hiding (EKH) as the selective non-disclosure or deflection of information that a provider judges as unnecessary, untimely, or potentially confusing in a specific interaction. Unlike rationalised hiding or playing dumb, EKH is not primarily hostile or competitive. It represents a situational choice to limit detail, postpone explanations, or steer away from topics considered irrelevant at that moment. This nuance differentiates EKH from the broader family of deceptive or self-protective hiding described in organisational settings, where intentions often relate to impression management, politics, or resource protection (Bashir et al., 2024; Wang et al., 2024; Wiggins, 2024; Xu et al., 2024).

As discussed previously, the effect of EKH on self-assessment is likely to depend on the context. Importantly, when knowledge is selectively withheld in a constructive way, it should not exert a direct influence on self-assessment. Instead, the main mechanism operates through cognition. By filtering and sequencing information,

clinicians help patients avoid misconceptions that would otherwise distort their judgments (Jones, 2024). This process reduces learning myopia, and as a result, patients develop clearer mental models and are better able to evaluate their own capabilities and progress. Thus, the mediation pathway explains why the direct link between EKH and self-assessment may be weak, while the indirect effect through learning myopia is expected to be positive.

H3. *Evasive knowledge hiding has a positive indirect effect on self-assessment through learning myopia*.

3 Method

3.1 Data collection

The study was carried out at the individual level, focusing on people living with Multiple Sclerosis (MS). Participants were between 22 and 67 years old, with 32 men and 51 women included in the sample. The wide age span was intentional, since age can shape how patients perceive and respond to their condition. Data were collected in October and November 2024 through a structured survey distributed by Multiple Sclerosis Associations, resulting in 75 valid responses. The questionnaire also captured demographic characteristics such as participants' region and province of residence.

To ensure sample adequacy, a power analysis was performed with G*Power (Cunningham & McCrum-Gardner, 2007). Following Cohen's (1998) recommendations, where f^2 values of 0.02, 0.15, and 0.35 represent small, medium, and large effects, the minimum requirement for a medium effect size with a one-tailed test was 74 respondents. The final sample of 75 thus satisfied this criterion.

Potential non-response bias was examined by comparing Self-Assessment scores from early and late respondents using an independent samples t-test. The results showed no significant differences ($p = 0.807$). Common method bias (CMB) was assessed following Podsakoff et al. (2012). Harman's single-factor test indicated that the first factor accounted for 40.38% of the variance, below the 50% threshold (Podsakoff et al., 2012). In addition, a confirmatory factor analysis (CFA) demonstrated that a one-factor model did not fit the data well (Satorra–Bentler $\chi^2(36) = 122.265$, $\chi^2/df = 3.39$) compared with the measurement model ($\chi^2(24) = 31.420$, $\chi^2/df = 1.30$). Taken together, these analyses confirmed that CMB was not a major concern (Armstrong & Overton, 1977).

3.2 Measures

In this study, Evasive Knowledge Hiding (EKH) was modeled as a reflective construct using three items adapted from (Connelly et al., 2019). These items capture patients' perceptions of whether medical staff avoided sharing information or support when it was requested. EKH emphasizes situations in which help was delayed, information was withheld, or guidance proved unhelpful. Importantly, this form of knowledge hiding may involve concealing information that is perceived as irrelevant by the provider, rather than intentionally withholding essential knowledge.

Cognitive Myopia (CM) was measured using three items adapted from (Cegarra-Sánchez et al., 2025). This construct represents the persistence of misconceptions or oversimplified beliefs about Multiple Sclerosis. The selected items capture distorted perceptions of the illness, for example, viewing it as exclusive to women, inherently fatal, or the result of unhealthy lifestyle choices. Together, they reflect a narrowed and biased understanding of the disease, consistent with the idea of cognitive blind spots.

Finally, Self-Assessment (SA) was measured with three reflective indicators based on (Fung et al., 2020). These items focus on individuals' ability to evaluate their own capabilities and progress. Respondents were asked to assess whether they feel as capable as others in managing their condition, whether they are confident in their ability to cope with challenges, and whether they maintain a positive outlook on their daily progress. These items align with prior research on self-concept and self-efficacy, while emphasizing the role of reflective self-evaluation in the context of chronic illness.

3.3 Assessment of the measures

Given the reflective nature of the constructs, all variables were modeled as Type A composites, where the direction of causality flows from the latent factor to its indicators Cepeda-Carrion et al., (2019). Following the guidelines of Henseler et al. (2016), we assessed item reliability, composite reliability, and convergent validity. All indicators loaded strongly on their constructs, with values ranging from 0.600 to 0.906. One item (CM1) fell slightly below the 0.70 threshold, loading at 0.600. We decided to retain it because it reflects an important aspect of Cognitive Myopia, is consistent with prior definitions of the construct, and its removal did not improve

reliability or validity. This decision aligns with established guidelines, which allow the inclusion of items with loadings between 0.50 and 0.70 when supported by theory and when the overall measurement quality remains strong (Hair et al., 2019; Henseler et al., 2016). Reliability and validity were confirmed across all constructs. Composite reliability values were above 0.80, and AVE scores exceeded 0.50 (EKH: AVE = 0.663, ρA = 0.855; CM: AVE = 0.616, ρA = 0.824; SA: AVE = 0.695, ρA = 0.872). Variance inflation factors ranged from 1.226 to 2.310, far below the cutoff of 5, ruling out multicollinearity concerns. Overall, the results confirm that the three constructs (i.e. Evasive Knowledge Hiding, Cognitive Myopia, and Self-Assessment), were measured with good reliability and validity.

Discriminant validity was assessed using the Fornell–Larcker criterion and the Heterotrait–Monotrait ratio (HTMT). In doing so, the square roots of the AVE values, shown on the diagonal, were higher than the correlations among the constructs, which satisfies the Fornell–Larcker criterion. In addition, all HTMT values were below the conservative threshold of 1.0 (Henseler et al., 2014), with the highest observed value being 0.818. These findings confirm that the constructs Evasive Knowledge Hiding (EKH), Cognitive Myopia (CM), and Self-Assessment (SA) are empirically distinct, supporting discriminant validity.

4 Results

Table 1 presents the structural model results. The results indicate a case of full mediation, as the direct effect of Evasive Knowledge Hiding (EKH) on Self-Assessment (SA) is not significant (β = -0.304, p = 0.135), while the indirect effect through Cognitive Myopia (CM) is significant (β = 0.210, p = 0.019). This suggests that EKH influences SA exclusively through its effect on CM, confirming the presence of total mediation (Hair et al., 2022; Zhao et al., 2010). These results support H1 and H2 and confirm the indirect effect proposed in H3.

Table 1: Effects on endogenous variables

Direct effects	Point estimate	Confidence Intervals 2.5%	97.5%	p-values	R^2	f^2
H_1: EKH→CM	-0.355	-0.646	-0.247	0.001	0.126	0.144
H_2: CM→SA	-0.707	-0.766	-0.234	0.000	0.429	0.585
H_3: EKH→SA	-0.304	-0.122	0.371	0.135	0.429	0.039
Indirect effects						
EKH→CM→SA	0.251	0.085	0.390	0.009	0.429	0.039

Global goodness of fit, Confirmatory composite analysis and bootstrap-based 95% and 99% quantiles

Goodness of Fit Measure	Estimated Model	Hi95	Hi99	Saturated Model	Hi95	Hi99
SRMR	0.083	0.112	0.132	0.083	0.112	0.132

Notes: Evasive Knowledge Hiding→(EKH); Cognitive Myopia →(CM); *Self-Assessment*→(SA).

5 Discussion

This study set out to examine the paradoxical role of evasive knowledge hiding in shaping patient learning and adaptation in the context of Multiple Sclerosis. The results confirm that evasive knowledge hiding reduces learning myopia (H1), learning myopia negatively affects self-assessment (H2), and that the effect of evasive knowledge hiding on self-assessment is transmitted indirectly through learning myopia (H3). The direct path from evasive knowledge hiding to self-assessment was non-significant, confirming that its influence is primarily cognitive and operates through the reduction of misconceptions.

Our findings contribute to a growing body of literature that challenges the traditional view of knowledge hiding as exclusively harmful. Most studies describe knowledge hiding as a dysfunctional behavior linked to distrust, conflict, and reduced performance (Černe et al., 2014; Connelly & Zweig, 2015; Zhang & Min, 2021). Recent work, however, has begun to explore its paradoxical aspects, noting that under certain conditions, selective withholding can protect knowledge quality and preserve group functioning (Chacon-Henao & Arias-Perez, 2025; Restrepo-Gil et al., 2024). The current study extends this line of inquiry by showing that in healthcare encounters, evasive knowledge hiding can operate as a form of protective filtering. By reducing patients' exposure to misconceptions, clinicians create conditions that limit cognitive distortions and support more accurate self-assessments.

The findings also align with prior research on learning myopia, which describes the persistence of narrow or mistaken cognitive frames that restrict adaptive learning (Cegarra-Sánchez et al., 2025). Consistent with

organizational studies showing that hidden or distorted knowledge reduces performance by undermining clarity (Islam et al., 2024; Zhang & Min, 2024), our results show that learning myopia has a detrimental impact on patients' ability to evaluate their own progress and capabilities. Importantly, our study bridges this construct with self-assessment, a psychological but also knowledge-based outcome that reflects the transformation of information into action (Nonaka & Takeuchi, 1995; Y. Xu et al., 2010).

Regarding H3, the mediation result is consistent with a systems thinking perspective. Systems thinking emphasizes the regulation of knowledge flows to maintain coherence and avoid overload (Adam & De Savigny, 2012). From this lens, evasive knowledge hiding is not a form of deception but a filtering mechanism that stabilizes patient cognition by reducing noise and limiting misperceptions.

6 Conclusion

This study makes three main contributions. First, it reframes evasive knowledge hiding as a knowledge regulation mechanism, extending the dominant "dark side" view. Second, it introduces learning myopia as a cognitive mechanism linking knowledge processes to self-assessment. Third, it integrates systems thinking into knowledge hiding research by showing how regulating information flows shapes cognitive outcomes.

Methodologically, the study applies PLS-SEM with endogeneity checks to a novel dataset of MS patients, extending the application of KM research methods into clinical settings. Conceptually, it demonstrates the value of focusing on indirect effects and mediation pathways, providing a more nuanced understanding of how knowledge processes translate into patient outcomes.

Practically, the findings suggest that healthcare providers can improve patient adaptation not by sharing every piece of information, but by carefully regulating knowledge flows. Selective withholding of low-value or confusing details can prevent misconceptions and enable patients to build clearer self-assessments, which are critical for adherence and long-term coping. This perspective has implications for medical training, communication strategies, and the design of patient education programs.

The study has limitations that open avenues for further research. First, the sample size, while adequate for PLS-SEM, was relatively small and limited to one national context. Future studies should test the model across larger and more diverse populations to enhance generalizability. Second, the cross-sectional design prevents causal inference; longitudinal or experimental studies could validate the mediation pathway over time. Third, while we focused on evasive knowledge hiding, future work could explore how other forms of knowledge hiding (rationalized, playing dumb) operate in clinical settings, and whether they have different or even harmful effects on patient learning. Finally, future research should examine moderators such as communication climate, leadership cues, or patient characteristics (e.g., age, health literacy) that may strengthen or weaken the positive role of evasive knowledge hiding.

7 Ethics Declaration

This study was conducted using anonymized survey data collected through Multiple Sclerosis Associations publicly available. No sensitive personal data were recorded, and participation was voluntary. According to applicable regulations, formal ethical approval was not required.

8 AI Declaration

AI tools were used to support language refinement and clarity of expression. No AI tools were used in the data analysis, interpretation of results, or development of the theoretical framework. The authors take full responsibility for the content of the paper.

Beyond Single Tasks: How Students Interact with AI in Design Processes

Matteo Meacci, Antonella Martini, Gabriele Goretti, Caterina Dastoli
University of Pisa, Pisa, Italy

Abstract

The advent of Generative Artificial Intelligence (GenAI) has led to a rapid expansion of AI use in educational contexts. This new technology is profoundly transforming students' learning experiences. However, a limitation of current research is its predominant focus on how AI influences student performance, concentrating on quantitative indicators such as test scores. In contrast, research on how AI tools are perceived and used by students remains limited, and it is still unclear how collaboration with AI supports students' knowledge-building processes. This study addresses this gap by exploring how students interact with AI and how they feel during these interactions in design processes. A mixed-methods study was conducted to investigate this question, involving 16 students enrolled in a bachelor's degree program in Industrial Design Engineering. The students were divided into groups and participated in a two-day workshop, during which they worked on product development following the Double Diamond process and supported by KOBI, an AI tool specialized in the field of arts and design. During the workshop, conversations between the students and the AI tool were recorded, along with data collected through questionnaires administered before and during the workshop activities. The data were analyzed through descriptive statistics and qualitative content analysis. The results show that students interact with AI in different ways depending on the cognitive nature of the task. Two main modes of interaction were identified: exploratory and executive. These modes differ in both the form of interaction and the type of request addressed to AI. The findings also show that these different modes of AI use influence students' perceptions of the tool's usefulness and lead to different emotional experiences. Overall, the study contributes to the literature on generative AI in education by deepening understanding of how students interact with AI systems. Furthermore, it proposes an interpretive model, inspired by the concept of absorptive capacity, that links the identified modes of AI use to students' knowledge-building processes.

Paper type: Academic Research Paper

1 Introduction

The application of artificial intelligence in education (AIEd) has been the subject of research for about thirty years (Zawacki-Richter et al., 2019). However, it is with the advent of Generative Artificial Intelligence (GenAI), which officially began with the release of ChatGPT in November 2022, that we have seen a rapid spread of AI use in educational contexts (Lodge, 2023; Batista et al., 2024; Yusuf et al., 2024). This new technology has emerged as an innovative force capable of transforming education, promising to personalize learning experiences by adapting courses to individual progress, increase student engagement, automate administrative tasks, reduce workloads, and enhance teacher skills (Kasneci et al., 2023; Al-Zahrani & Alasmari, 2024; Batista et al., 2024; Sahar & Munawaroh, 2025).

Despite these opportunities, the introduction of AI in educational contexts also raises numerous ethical and social challenges and concerns, including issues related to data privacy and algorithmic bias (Zawacki-Richter et al., 2019; Al-Zahrani & Alasmari, 2024; Batista et al., 2024; Sahar & Munawaroh, 2025). Academic integrity is also a challenge that is fueled by fears that students' cognitive and logical skills could be reduced by excessive use of generative AI tools (Yusuf et al., 2024).

One limitation of research on AIEd is that, in most cases, it has focused almost exclusively on the effectiveness of AI tools in improving individual students' academic performance on specific individual tasks. In particular, attention has been focused primarily on quantitative indicators such as improved test scores (Holmes & Tuomi, 2022; Muzumdar & Cheemalapati, 2025; Pulungan & Nora, 2025).

However, limiting the analysis to performance outcomes risks overlooking a more profound transformation. Generative AI does not simply act as a tool that improves task efficiency but participates in the dynamics of knowledge construction (Chen et al., 2023; Cress & Kimmerle, 2023). AI systems can support how knowledge is created, shared, and applied within learning environments (Tsoi & Strønen, 2024; Hagos et al., 2025). Rather than simply supporting individual outcomes, AI can reshape how students construct meaning, explore alternatives, and externalize ideas (Ahmed, 2025; Muzumdar & Cheemalapati, 2025; Pulungan & Nora, 2025).

This requires moving beyond outcome-based assessments toward a process-oriented understanding of student-AI interaction. In this regard, research on how AI tools are perceived and used by students remains limited, particularly on what students feel, how they reflect, and how they attribute meaning to what the AI tool does (Muzumdar & Cheemalapati, 2025; Pulungan & Nora, 2025). These emotional and reflective components of the experience play a crucial role in learning. We still know little about how collaboration with AI tools helps students build knowledge. The significance of this gap lies in the need to know how students interact with AI tools to ensure their effective integration into educational contexts (Strzelecki, 2024; Muzumdar & Cheemalapati, 2025).

This study addresses the above gap by exploring the following research question: How do students interact with AI tools, what do they ask, and how do they feel when interacting with AI in design processes?

Design processes refer to a structured sequence of interdependent activities, distinct from specific individual tasks. Particularly, design activities have long been recognized as inherently iterative, reflective, and meaning-making processes in which tools actively shape thinking and collaboration (Schön, 1983). This makes design a particularly relevant domain for examining how students perceive, engage with, and construct knowledge alongside generative AI, beyond measurable performance outcomes.

The study contributes to the literature on generative AI in education by deepening understanding of how students interact with AI and how they experience that interaction. Specifically, it shows that AI use is not uniform but changes depending on the cognitive demands of the task, triggering different modes of use that influence the student's experience. Furthermore, this study links the identified modes of AI use to the knowledge-building process and proposes an interpretive model based on the concept of absorptive capacity introduced by Cohen and Levinthal (1990).

The remainder of the paper is structured as follows. Section 2 describes the method adopted to explore the research question. Section 3 presents the results of the study. Section 4 discusses and interprets the findings, illustrates the proposed model, and outlines the main limitations of the study. Finally, Section 5 presents the conclusions.

2 Method

2.1 Study design and participants

To investigate the research question, an exploratory mixed-methods study was conducted involving 16 second-year students from the bachelor's degree course in Industrial Design Engineering. The students were divided into six groups and participated in a two-day workshop. During the workshop, they worked on product development starting from specific areas of reference (e.g., wood, marble, glass, etc.), following the Double Diamond process introduced by the Design Council in 2005 and supported by KOBI, an artificial intelligence tool specialized in the field of arts and design (Ripa di Meana et al., 2024).

2.2 Workshop setting

2.2.1 Double Diamond process

The workshop was structured according to the Double Diamond model (Design Council, 2005), a consolidated framework that splits the design process into divergent and convergent phases. The model consists of four phases:

- Discover, a divergent phase to identify the problem;
- Define, a convergent phase to frame the design challenge;
- Develop, a divergent phase to generate ideas;
- Deliver, a convergent phase to select and formalize the solution.

On the first day, the students completed the first two phases, while on the second day they completed the next two.

The Double Diamond was chosen for two main reasons. First, the structured alternation between moments of divergence and convergence allowed us to observe the students' interaction with the artificial intelligence tool in relation to cognitively different tasks. Second, participants were already familiar with this model, as it had previously been introduced in a university course and applied in a project carried out as part of the same course.

2.2.2 AI tool: KOBI

During the workshop, students were supported by KOBI, a digital knowledge ecosystem for research and education in the field of arts and design, developed by Ripa di Meana et al. (2024). Each group had access to one shared KOBI interface, which was collectively used during the design activities. KOBI uses Large Language Models (LLMs) to offer a nuanced understanding of the concepts required, drawing on a database of art and design literature.

The choice of KOBI over more mainstream tools (e.g., ChatGPT) was motivated by several characteristics. First, its specialization in the fields of arts and design. Secondly, in addition to a chat-based conversational interface, KOBI offers a three-dimensional representation of semantic space, allowing users to visualize the relationships between concepts related to the topic under discussion. This feature facilitates navigation between conceptual connections. Lastly, the system provides searchable references to support the information generated, allowing students to dive deeper into specific topics that emerge during interaction.

2.3 Data collection

During the workshop, conversations between students and the AI tool were recorded, for a total of 188 interactions, where each interaction corresponds to a prompt–response pair. Each group had a designated member responsible for systematically documenting the prompts entered and the corresponding responses generated by KOBI, organizing them according to the different phases of the Double Diamond. In addition, three questionnaires were administered to the participants. The first questionnaire was distributed before the beginning of the workshop to investigate students' familiarity with artificial intelligence tools and their perceptions of this technology. Two additional questionnaires were administered at the end of each workshop day. These questionnaires explored how students used AI during the activities, how they felt while interacting with it, and how useful they perceived the AI tool to be across the different phases of the Double Diamond. The first two aspects were investigated through open-ended questions, while perceived usefulness was measured on a 5-point rating scale.

2.4 Data analysis

2.4.1 Student-AI interaction analysis

The analysis of student–AI interactions was divided into three parts: a preliminary descriptive analysis, an analysis to identify students' intentions, and an analysis to highlight the themes of the requests. The term "themes" refers to what students asked the AI, while the term "intentions" refers to how those requests were formulated.

The analysis of students' intentions was conducted using a rule-based deductive content analysis, divided into two levels of coding applied to students' textual prompts.

The first level of coding concerns the form of interaction with the tool. A prompt is classified as a question if it contains a question mark or interrogative markers such as the 5Ws or How. If the prompt does not fall into this category but contains conversational request formulas, such as can you or could you, it is classified as a request, representing explicit requests that are not formulated in an imperative form. All remaining prompts are classified as commands, requests mainly formulated in an imperative form, in which the student asks the system to perform an action directly (e.g., generate, create, write).

The second level of coding concerns the type of request made to the tool. Specifically, requests were classified into two main categories: informational requests and generative requests. The classification was based on the identification of specific verbs and keywords. A prompt is classified as a generative request if it contains verbs that imply the production of structured content (e.g., write, generate, create) or project output objects (e.g., brief, scenario, personas). Conversely, a prompt is classified as an informational request if it contains words or expressions related to the search for information, such as information, examples, case studies. In cases where a prompt does not have sufficient indicators to be assigned to a specific category, it is classified as an unspecified request.

Subsequently, an analysis of the topics of the requests was conducted to identify the main thematic areas emerging in the interactions between students and AI. This analysis was carried out using inductive content analysis, to allow categories to emerge directly from the data, without imposing any prior thematic schemes.

The prompts were transformed into embeddings using a pre-trained language model for encoding textual meaning. The vectors obtained were then normalized to eliminate the effect of lexical redundancy and

expressive intensity. This operation made it possible to evaluate the similarity between prompts in terms of semantic affinity, making the Euclidean distance equivalent to the cosine similarity between vectors.

The categories were identified using an unsupervised density-based clustering algorithm (HDBSCAN), which identifies groups of semantically similar prompts only when there is sufficient density, avoiding the forced assignment of all prompts to a cluster. Because the algorithm does not assign semantic labels to the identified clusters, the interpretation and naming of the resulting categories was done manually by analyzing representative examples for each cluster. Prompts that were not automatically assigned to clusters or that were characterized by semantic ambiguity were subsequently examined and assigned to existing categories or, where necessary, used to define new categories.

In an initial implementation, the algorithm tended to group prompts mainly based on the starting contexts of the different groups (e.g., glass, wood, marble), rather than on the type of request. To remove this effect, semantic masking was introduced to neutralize the domain terms related to materials that influenced clustering. This made it possible to bring out themes related to the types of requests made to the AI, regardless of the specific project context.

The analyses were performed using Python scripts and then manually checked to verify the consistency of the results and refine the classification where necessary.

2.4.2 Questionnaire analysis

Data collected through questionnaires were analyzed using basic descriptive statistics and adopting the same approach used for analyzing interaction themes. Categories were identified from the open-ended responses regarding how students felt when using and interacting with AI during the different phases of the Double Diamond. Starting from these categories, a manual sentiment assessment was conducted by assigning +1 to positive connotations, -1 to negative ones, and 0 to neutral or unclassifiable categories. The values thus assigned were then aggregated for each phase, obtaining an overall sentiment score.

The results of the questionnaires were triangulated with those derived from the analysis of student-AI interactions to compare the usage patterns observed with the perception of usefulness and the experience reported by students during the design process.

3 Results

3.1 Two modes of student–AI interaction across the design process

The results show that the use of AI is not uniform across the design process, but changes in relation to the type of cognitive task that characterizes the phases. Different modes of interaction emerge, influencing the perception of usefulness and generating different emotional experiences. Two prevalent modes of interaction with AI have been identified: an exploratory mode and an executive mode. The transition from one mode to another is reflected both in the form of interaction and in the type of requests.

The results of the analysis of the intentions of student–AI conversations are shown in Figure 1 and Figure 2, which show the percentage distribution by phase of the types of requests and forms of interaction, respectively.

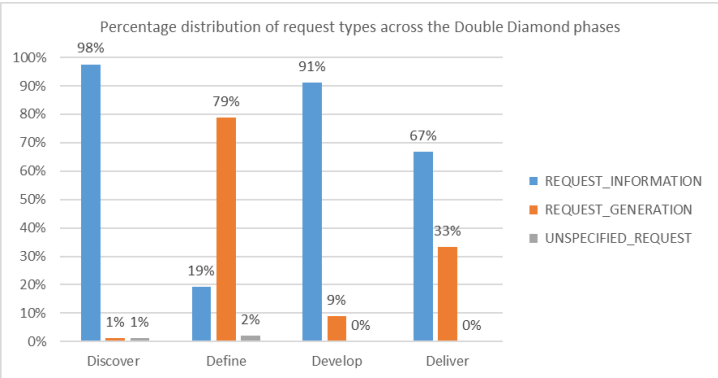

Figure 1: Percentage distribution of request types across the Double Diamond phases

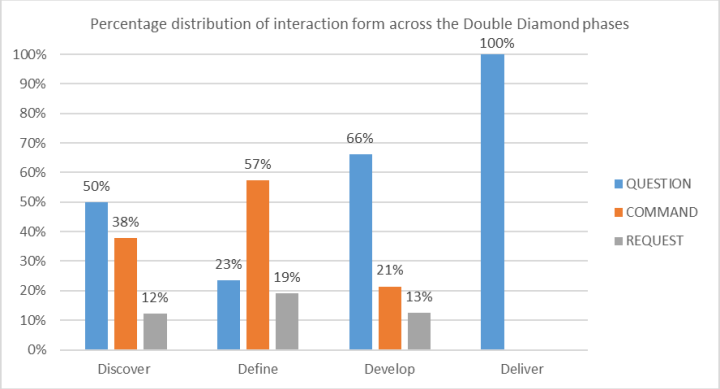

Figure 2: Percentage distribution of interaction form across the Double Diamond phases

The figures show the distribution of prompts in the different phases of the Double Diamond according to the two levels of coding. Figure 1 shows the second-level coding, which distinguishes between informational and generative requests, while Figure 2 shows the first-level coding, relating to the form of interaction with the tool.

As the two figures show, in the divergent phases, Discover and Develop, requests made to AI are almost exclusively informational, representing over 90% of requests in both phases. Furthermore, at least half of the interactions in these two phases are formulated as questions. This suggests that AI is used in an exploratory mode oriented toward information seeking.

In the convergent Define phase, generative requests prevail, accounting for 79% of the total, while over 50% of interactions take an imperative form. This indicates the use of AI in executive mode, where the tool is employed more directly to produce design outputs.

As for the Deliver phase, the results are not examined, since only 3 interactions out of 188 were recorded during this stage, a number too limited for interpretation.

3.2 Cross-check between request themes and interaction intentions

The results of the intention analysis were cross-referenced with those of the thematic analysis of student-AI interactions to verify whether requests classified as informational or generative were consistent with the actual content of the prompts. As Table 1 shows, informational requests are mainly associated with topics such as case studies or product examples. Generative requests, on the other hand, mainly concern the creation of personas and brief writing.

Table 1: Cross-check between thematic categories and request types in student–AI interactions

Theme	Informational	Generative
Case study	36	0
Product example	29	4
Technical support	31	1
Manufacturing techniques	29	0
Personas	3	20
Brief	0	10
Guidelines	3	5
Not classifiable	7	3

This cross-check supports consistency between the analysis of intentions and that of themes. Interactions that, based on the type of request and form of interaction, suggested the use of AI in exploratory mode are effectively oriented toward information searching, while those that suggested an executive mode are more often aimed at producing design outputs.

The Not classifiable category includes those prompts that could not be assigned to any of the thematic categories that emerged, because they were semantically difficult to interpret or not numerous enough to constitute a new category. For reasons of readability, the table shows only the main themes, excluding two less frequent categories, Moodboard and System-product scenario. The two unspecified requests have also not been included in the table and, if considered, would fall into the Not classifiable category.

3.3 Perceived usefulness and emotional experience of AI use

The results of the student–AI intention analysis were triangulated with questionnaire data to understand how different modes of AI use influenced students' experience, both in terms of perceived usefulness and emotional responses.

As Table 2 shows, the phases in which AI was used primarily in an exploratory mode, Discover and Develop, are those in which the tool was perceived as most useful. Perceived usefulness, however, decreases in the Define phase, where AI was used in executive mode. The sentiment score also follows a similar trend: it is positive in the divergent phases, neutral and negative in the convergent phases. Overall, these results suggest that the exploratory mode is associated with greater perceived usefulness and a more positive emotional experience.

Table 2: Perceived usefulness of AI and sentiment score across the Double Diamond phases

Phases	Mean perceived usefulness	Sentiment score
Discover	2.81	1
Define	2.44	0
Develop	2.86	4
Deliver	1.50	-1

Figure 3 shows the distribution, for each phase of the Double Diamond, of the emotional responses that emerged from the students' open-ended answers regarding their experience using AI.

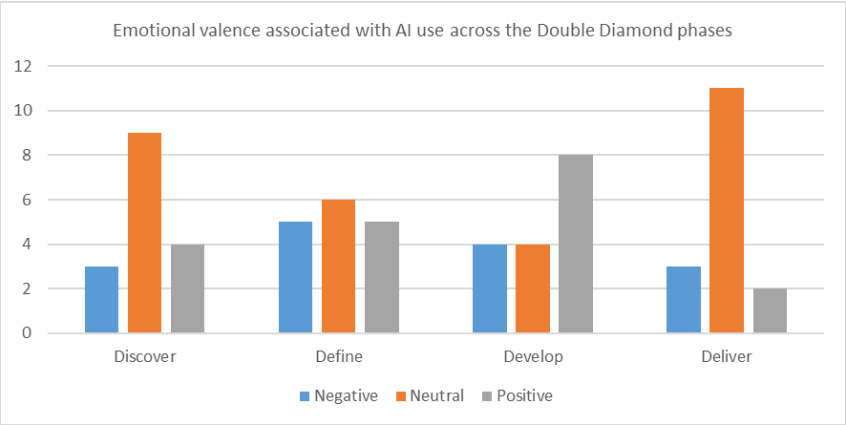

Figure 3: Distribution of emotional valence associated with AI use across the Double Diamond phases

The figure shows how positive, negative, and neutral responses are distributed across the various phases of the process. Responses classified as positive are primarily associated with the perception of having felt supported by the AI during the activity. Responses classified as negative, on the other hand, are primarily linked to experiences of limitation or discouragement when using the tool. Finally, neutral responses include ambivalent situations, such as feeling supported but limited, or supported but discouraged.

More specifically, feelings of discouragement are mostly linked to difficulties in interacting with the tool, particularly when trying to get the AI to understand the desired objective. The perception of limitations, on the other hand, is mainly attributed to outputs that are considered inadequate or fail to meet students' expectations.

4 Discussion

This study interprets interactions between students and AI as a bidirectional relationship, in which humans and AI collaborate in the construction and transformation of knowledge. This interpretation aligns with the perspective that generative AI not only acts as a tool to improve task efficiency but also participates in the dynamics of knowledge construction (Chen et al., 2023; Cress & Kimmerle, 2023). From this perspective, the identification of two prevalent modes of AI use, exploratory and executive, suggests that the tool can support different knowledge processes.

During the divergent phases, AI is used in an exploratory mode, where students employ it to search for information; this appears to be associated with knowledge acquisition processes. In the convergent phases, AI appears to be used in an executive mode, with requests focused on generating design outputs. This second mode appears closer to a phase of knowledge application, in which students use both prior knowledge and

knowledge acquired in the exploratory mode to produce, evaluate, and refine the outputs generated by AI. This interpretation is consistent with the literature highlighting how AI can support knowledge-building processes in education, through practices oriented toward both the creation and application of knowledge (Chen et al., 2023; Tsoi & Strønen, 2024).

Figure 4 presents an interpretive model that links the identified modes of AI use to the dynamics of knowledge construction. The two modes identified are interpreted not as strictly separate uses, but as prevailing configurations of student–AI interaction within a dynamic process, in which AI can assume different functions depending on the cognitive demands of the phase.

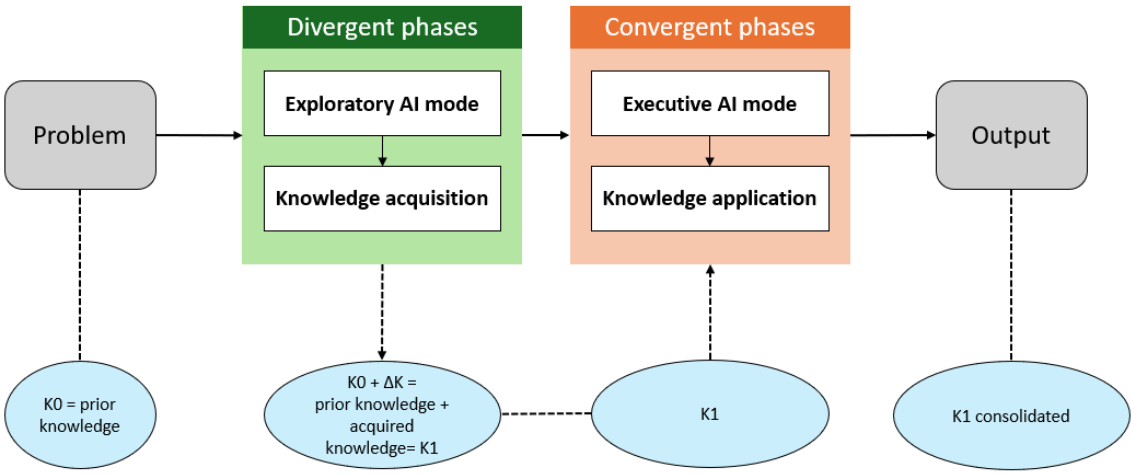

Figure 4: Interpretive model of student–AI interaction and knowledge building across the design process

Students begin with a challenge or problem with prior knowledge. During the divergent phases, they use AI in an exploratory mode to search for information, acquiring new knowledge that is combined with what they already know. In the convergent phases, AI is used in an executive mode to produce design outputs, which are evaluated and adapted based on the integration of prior knowledge and newly acquired knowledge, until the final result is achieved.

The model draws inspiration from the concept of absorptive capacity introduced by Cohen and Levinthal (1990), according to which learning depends on the ability to recognize the value of new knowledge, assimilate it, and apply it based on an existing knowledge base. Although this concept was formulated at the organizational level, it already assigned a central role to individuals. Subsequent developments on the topic then clarified this perspective at the individual level, leading to the concept of individual absorptive capacity. Sjödin et al. (2018) developed a model describing how individuals engage in the processes of absorbing new external knowledge. In this study, this perspective is reinterpreted and related to the ways in which students interact with generative AI systems within the design process.

This interpretation, however, should be treated with caution with regard to the convergent phases. In fact, even though the executive mode emerges quite clearly in the Define phase, it is not possible to extend this interpretation with the same certainty to the Deliver phase, because the number of interactions observed in the last phase was too limited to determine which mode of AI use actually prevails.

Furthermore, several limitations of the study should be considered. First, the small sample size of students limits the generalizability of the results. Second, the use of a single tool, KOBI, and its specific operational characteristics may have influenced both how the AI was used and the students' reported experience. Finally, the specific context of design and the adoption of the Double Diamond method may have encouraged modes of interaction with the AI that would not emerge in other disciplinary domains or in less design-oriented activities.

5 Conclusion

This study shows that the use of AI is not uniform but varies depending on the cognitive nature of the task. In particular, divergent activities are associated with an exploratory use of AI, in which students formulate prompts in interrogative form and the requests are oriented toward information-seeking. Convergent activities, on the other hand, are associated with an executive use of AI, in which prompts are primarily in the imperative form and requests are focused on generating design outputs. The results also show that the different modes of

AI use influence students' experience. Specifically, the exploratory mode was perceived as more useful and was associated with a positive sentiment, linked to a feeling of support during the activity.

This work contributes to a better understanding of how students interact with AI and how they experience that interaction. Furthermore, it proposes an interpretive model, inspired by the concept of absorptive capacity, that links the identified modes of AI use to the process of knowledge construction. The findings may provide useful guidance for the design of AI tools in education, which should be developed according to user-centered principles and taking into account the social, emotional, and cognitive aspects of the learning experience (Tlili et al., 2023; Muzumdar & Cheemalapati, 2025). At the same time, these findings are relevant because they provide insights for integrating AI more consciously and effectively into educational contexts, supporting students' learning processes (Lodge, 2023; Strzelecki, 2024; Muzumdar & Cheemalapati, 2025).

Future research could further examine how AI is used within the Double Diamond process, taking into account the limitations of this study. In addition, it would be useful to extend the research beyond the field of design, exploring other disciplinary contexts characterized by complex processes, in order to understand whether additional modes of interaction with AI might emerge. This understanding is fundamental to designing educational environments in which such tools do not just support task execution but contribute to learning processes.

6 Ethics declaration

Formal ethical clearance was not required for this study. The research was conducted in the context of an educational workshop, and the data were collected and analyzed in anonymized form. Participation in the questionnaires and in the use of interaction data for research purposes was voluntary.

7 AI declaration

The authors declare that ChatGPT was used to improve the readability and clarity of the text. All content has been reviewed and revised by the authors. The authors take full responsibility for the accuracy and originality of the work.

Building Trust in Hybrid Teams: The Role of AI-Assisted Storytelling

Suncana Tuksar, Vanja Bevanda
Juraj Dobrila University of Pula, Faculty of Economics and Tourism "Dr. Mijo Mirkovic", Pula, Croatia

Abstract

The aim of this study is to develop a theoretically integrated conceptual framework for trust formation in AI- hybrid teams. Drawing from Media Synchronicity Theory (MST), Computer-Supported Cooperative Work (CSCW), hybrid intelligence and knowledge management literature, the study reconceptualizes trust as a communicative co-construct, which emerges from socio-technical interactions. Hybrid teams increasingly rely on the AI for collaboration, yet little is known about how *AI-mediated narratives* shape trust and the knowledge co-creation. This gap is addressed by examining how AI-assisted storytelling communicates and supports sensemaking in shaping both relational and knowledge-based outcomes. The objectives are: (1) to conceptualize AI-assisted storytelling as a shared collaborative artifact that supports knowledge co-creation; (2) to examine the mechanisms through which trust develops, focusing on narrative construction, perceived social proximity and AI transparency; (3) to specify the role of digital literacy in trust formation when engaging with AI-mediated narratives; (4) to integrate MST and CSCW perspectives into a unified framework of those communication processes; (5) to propose a testable conceptual model (H1–H5) that advances theoretical understanding of trust in hybrid teams. Methodologically, the study integrates the computational bibliometric analysis and structured theoretical synthesis in a two-phase conceptual review. Phase 1 combines AI-assisted literature mapping with the semantic clustering to identify relevant thematic clusters and gaps. Phase 2 uses a theory-driven deductive synthesis to identify mechanisms and create the conceptual model and associated hypotheses. The findings indicate that hybrid team collaboration is most effective when AI-mediated structures are integrated with human-driven storytelling. AI contributes scalability and structural consistency, whereas human actors provide contextual nuance and foster relational trust. The results further suggest that AI-assisted storytelling enhances engagement, comprehension, relational cohesion, and trust. Finally, the study proposes a testable conceptual model (H1–H5) that offers theoretical guidance and practical implications for future research to further examine and extend these mechanisms.

Keywords: Hybrid teams; AI-assisted storytelling; Trust formation; Digital literacy; Knowledge management; Human-AI collaboration.

Paper type: an Academic Research Paper

1 Introduction

In hybrid work environments, where teams rely on AI for collaboration, trust is actively developed through digitally mediated interactions rather than stemming from physical proximity. Perceived social proximity, digital literacy and transparent AI systems are essential for the engagement, collaborative knowledge construction and coordination. In this context, trust serves as a critical foundation for effective knowledge sharing, while AI-assisted storytelling serves as a critical mechanism for sensemaking, structuring communication and reinforcing relational cohesion. Nevertheless, little is known about how AI-mediated narratives develop, as well as about the socio-technical interplay between AI and human capabilities. While research on AI-mediated collaboration mainly focuses on communication efficiency, performance and technology adoption, trust as a dynamic, co-constructed phenomenon has received limited attention. Similarly, although storytelling and AI tools are individually recognized for their value, few studies integrate them to examine how AI-assisted narratives influence relational and knowledge outcomes. These gaps call for a socio-technical framework that systematically links narrative practices, trust formation, AI transparency and digital literacy in hybrid teams. This study develops a theoretically integrated framework to explain how AI-assisted storytelling shapes trust formation in hybrid teams. It advances understanding of AI-augmented collaboration by conceptualizing storytelling as a shared collaborative artifact and examining how trust emerges through narrative construction, perceived social proximity and AI transparency. It further considers the moderating role of digital literacy, integrates insights from Media Synchronicity Theory and CSCW and proposes a testable conceptual model to guide both research and practice. The methodology adopts a theory-driven structured literature review comprising two complementary phases. In Phase 1, AI-assisted exploratory mapping with semantic clustering is used to chart the literature on hybrid teams, trust, storytelling and AI-mediated collaboration. This process identified dominant thematic clusters and ensured a systematically selected corpus by combining automated clustering with manual theoretical validation. In Phase 2, a deductive, theory-informed synthesis was conducted to extract core mechanisms, operationalize constructs and develop a set of hypotheses. The integration of AI-

assisted bibliometric mapping and structured conceptual analysis reduced selection bias and ensured transparent theory development. As a result, the study proposes a testable conceptual model (H1–H5) to explain trust formation and collaborative knowledge co-creation in hybrid teams, offering a theoretically grounded and practically applicable framework for advancing AI-augmented hybrid collaboration.

2 Literature Review and Theoretical Foundations

2.1 Hybrid teams, communication, and trust

Hybrid teams, which combine co-located and remote members, introduce structural and communicative complexities that shape trust formation (Bennett et al., 2023). Because hybrid work is highly context-specific, sustaining effective practices requires strategies that integrate organizational culture, technological infrastructure and employee experience (Wiatr and Skowron-Mielnik, 2024). Trust is particularly critical in such settings, where limited face-to-face interaction may constrain cooperation and coordination (Hacker et al., 2019). Further, prior research demonstrates that knowledge-sharing strengthens trust and collaboration among virtual team members, with collaboration mediating the relationship between trust and team effectiveness (Alsharo et al., 2017). Perceived social proximity reduces spatial and psychological distance, thereby reinforcing relational cohesion and supporting effective knowledge exchange in hybrid teams (Bennett et al., 2023).

2.2 AI-assisted collaboration and hybrid intelligence

The AI integration fosters hybrid intelligence by combining human and machine capabilities to enhance decision-making and knowledge co-creation (Dellermann et al., 2019). Transparency and explainability are critical for trust in human-AI collaboration, as uninterpretable systems can undermine confidence. In hybrid teams, adaptive interaction and trust-supportive AI design are necessary to balance predictability with autonomy (Klein et al., 2021). Trust, reinforced by organizational support, strengthens engagement and performance in hybrid contexts (Wahyutomo et al., 2024). Overall, effective AI-assisted collaboration reflects a socio-technical integration of system capabilities and relational dynamics that shape team outcomes.

2.3 Storytelling as knowledge co-construction

Storytelling enhances understanding, alignment, and behavioural change within teams (Trabucchi et al., 2022), while also enabling coordinated action and strengthening interpersonal connections – an especially critical function in hybrid contexts. Prior research shows that stories facilitate mutual understanding and trust by providing a shared frame of reference (Brown et al., 2019). Extending this perspective, AI-assisted storytelling supports the structuring, and integration of narratives (Javadi et al., 2024), as well as bridging temporal, spatial, and cognitive gaps in collaborative settings (Klein et al., 2021).

2.4 The moderating role of digital literacy

Digital literacy plays a critical moderating role in engagement with AI and collaborative technologies, strengthening trust and relational cohesion. Empirical evidence indicates that technical competence strongly predicts collaborative technology use ($\beta = .816$, $p < .001$) and perceived social proximity ($\beta = .311$, $p < .001$) (Bennett et al., 2023). Core competencies include information processing, communication, and critical thinking (European Commission, 2013, 2022). Recent research further suggests that digital literacy enables effective human–AI co-creation by enhancing interpretability, engagement, and trust within socio-technical interactions (Javadi, 2024; Tony et al., 2024; Chen et al., 2024; Kholina and Frolova, 2024).

2.5 Trust as a communicatively constructed phenomenon

Trust is constructed through ongoing interaction rather than existing a priori (Hao et al., 2022; Hacker et al., 2019). Prior research establishes a strong positive relationship between trust and knowledge sharing (Staples & Webster, 2008). In AI-mediated hybrid contexts, trust develops through shared narrative construction (Trabucchi et al., 2022), perceived social proximity (Bennett et al., 2023), AI transparency (Vodiskar and Ruiner, 2025), and digital literacy (Bennett et al., 2023; European Commission, 2022; Kholina and Frolova, 2024).

2.6 Theoretical integration

Although some foundational studies fall outside the scope of the current review, they provide essential theoretical grounding for the present framework. MST links communication effectiveness to task-media alignment by distinguishing between conveyance and convergence processes. AI-assisted storytelling supports both processes by structuring information and facilitating shared understanding. Complementing this perspective, CSCW emphasizes the role of technological mediation in enabling collaboration (Klein et al., 2021), with AI-generated narratives bridging spatial and temporal gaps (Trabucchi et al., 2022). The integration of human and AI capabilities thus gives rise to HI, in which co-created knowledge artifacts enhance decision-making, creativity, and team problem-solving (Dellermann et al., 2019).

2.7 Research gap

Despite growing research on hybrid collaboration and AI, trust as a communicatively constructed phenomenon in AI-mediated storytelling remains underexplored (Alsharo et al., 2017; Hincapie and Costa, 2024). Much of the existing literature emphasizes efficiency and technology adoption, often overlooking relational and interpretive processes that underpin effective collaboration. This gap emphasizes the importance of understanding trust in the development of a framework that links storytelling, digital literacy and socio-technical dynamics "to support hybrid intelligence and collaborative knowledge creation" (Trabucchi et al., 2022).

3 Methodology: Theory-Driven Structured Literature Review

3.1. Research design

As shown in Table 1, the study employed a hybrid-structured conceptual review to ensure thematic relevance and contemporary applicability, comprising two complementary phases. Phase 1 used AI-assisted literature mapping with semantic clustering to identify key research clusters in hybrid teams, trust, and storytelling. Phase 2 applied a theory-driven conceptual review to analyse retained literature and develop hypotheses. Together, this approach integrates AI-assisted bibliometrics with deductive synthesis to support the conceptual model.

Table 1: Literature distinction model for screening criteria

Phase	Purpose / Role	Relevant Paper Section
Phase 1: AI-assisted literature mapping	Exploratory and cartographic; Identifies thematic clusters; Charts the systematic and unbiased coverage of literature	Methodological; Demonstrates literature selection and corpus mapping
Phase 2: Theory-driven structured conceptual review	Deductive and synthesis-oriented; Extracts mechanisms; Develops hypotheses; Builds the conceptual model	Theoretical Background; Provides conceptual and theoretical foundations for the conceptual model.

3.2 Phase 1: AI-assisted literature mapping and thematic clustering

Phase 1 examined the conceptual background of hybrid teams, trust, storytelling and AI-mediated collaboration to identify gaps and inform the theory-driven synthesis of Phase 2. An initial set of 128 publications was retrieved and semantic clustering was performed using SciSpace Agent to detect conceptual linkages across the corpus. After removing duplicates (n = 21) and non-relevant publications (n = 33), 74 studies were retained. Inclusion required explicit attention to trust development in hybrid teams, mechanisms linking communication quality to performance, or storytelling in relational and leadership contexts. Clustering was conducted in two stages. Automated semantic grouping first organized publications into preliminary clusters, which were then manually refined for theoretical coherence. This process identified four dominant thematic clusters. The first, trust-building mechanisms in hybrid teams, emphasizes trust as multidimensional and dynamic. It develops through stages – formation, facilitation, establishment, acceleration, and reinforcement – rather than as a static construct. Early-stage cognitive trust is particularly important in partially distributed teams as the evidence shows that interactions between trust types and team efficiency evolve over time, with virtuality reshaping, but not weakening, trust dynamics. The second cluster, communication quality and performance translation, links micro-level interactions to macro-level outcomes. High-quality communication, shared mental models and collaborative practices mediate the relationship between trust and project success. The third cluster, storytelling as a relational and leadership mechanism, positions narratives as socio-cultural tools for identity construction, belonging and leader credibility, which indirectly builds trust. Across clusters, key interconnections emerged:

communication quality mediates the influence of storytelling and trust on performance and virtuality shapes the salience of trust dimensions. Phase 1 generated a visual literature network and a clustered reference dataset documenting thematic clusters and conceptual relationships. These outputs enhance transparency, reduce selection bias, and guided the Phase 2 deductive synthesis on AI-assisted storytelling, transparency, digital literacy, and hybrid intelligence.

Figure 1 illustrates the Phase 1 research design, depicting the systematic search, filtering, semantic clustering, and manual validation that produced four thematic clusters: trust dynamics, communication and performance mechanisms, storytelling in relational leadership, and socio-technical mediation.

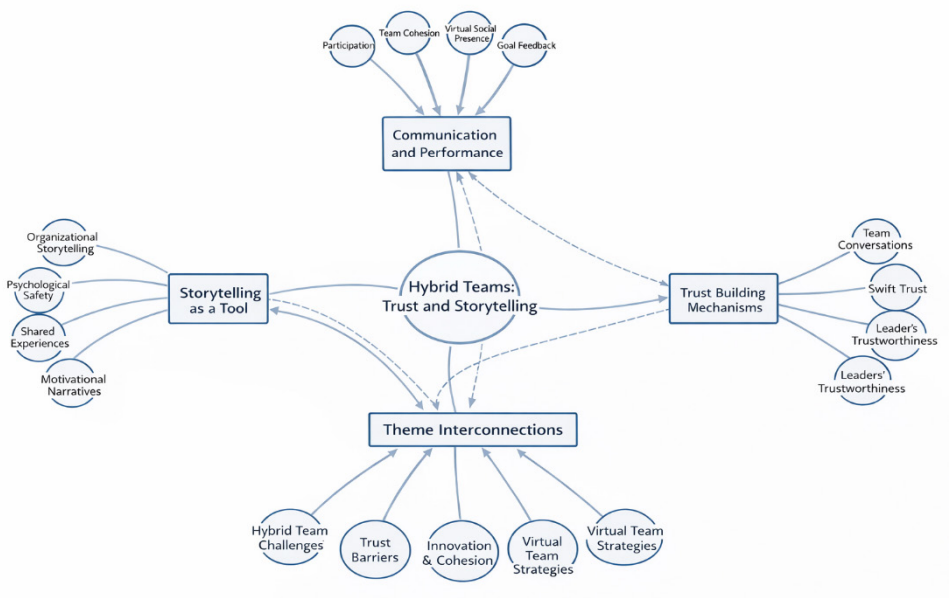

Figure 1: AI-assisted literature mapping

3.3 Phase 2: conceptual synthesis and model development

Phase 2 applies a theory-driven structured review to synthesize studies on AI-assisted storytelling, digital literacy and trust formation in hybrid teams. The review integrates MST, CSCW, HI and KM research. Foundational studies pre-2018 provide theoretical grounding, while empirical analysis focuses on 2018–2025, reflecting the acceleration of hybrid work post-COVID-19, adoption of applied AI and emergence of generative AI and human–AI collaboration systems. Phase 2 identifies mechanisms linking AI-assisted storytelling to trust, operationalizes constructs, formulates hypotheses (H1–H5), and ensures theoretical alignment across retained literature. Structured searches were conducted in Google Scholar, Scopus, and Web of Science (Core Collection) for their indexing quality and interdisciplinary coverage. A Boolean query combined thematic clusters to ensure relevance: ("hybrid teams" or "hybrid work" or "virtual teams") and ("AI-assisted collaboration" or "artificial intelligence" or "human–AI interaction") and ("storytelling" or "narrative") and ("trust" or "social proximity") and ("digital literacy" or "digital competence"). Searches were limited to titles, abstracts, and keywords, and included only peer-reviewed journal articles published over the last decade, with a particular focus on 2018–2025). Selected studies covered a range of collaborative, socio-technical, communicative and relational perspectives, ensuring methodological and contextual diversity.

Table 2 summarizes the Phase 2 literature by research approach, context and core mechanisms, illustrating methodological plurality and diversity and supporting mechanism extraction for the conceptual model.

Table 2: Literature base (Phase 2)

Research Approach	Context / Domain	Core Conceptual Mechanisms Identified
Quantitative surveys	Virtual and hybrid teams	Trust, knowledge sharing, social proximity
Experimental studies	Human-AI collaboration; AI storytelling; learning	AI transparency, shared narrative construction, engagement
Qualitative case studies	Organizational change; hybrid work design	Narrative alignment, relational cohesion, hybrid collaboration
Conceptual reviews	Human-AI teaming; virtual collaboration	Hybrid intelligence, socio-technical interaction, trust dynamics

Digital competence frameworks	Work; education; society	Digital literacy as enabling competence
Conceptual-experimental AI research	AI-mediated co-creation	Narrative curation, interpretive skills, collaborative knowledge creation

3.4 Analytical procedure

Phase 2 applied a theory-driven review with optimized Boolean searches to extract mechanisms and formulate hypotheses. The corpus comprised diverse methodologies, including conceptual analyses, surveys, case studies, experiments and structured reviews. This ensured comprehensive theoretical and empirical insights to support thematic synthesis, coding and model development. Cross-study comparison revealed underexplored intersections among communication, knowledge management and human-AI collaboration, indicating that trust is rarely examined as a dynamic, AI-mediated socio-technical process. To address this, a three-step integrative procedure was applied: thematic synthesis, conceptual coding, and theory mapping. The focus was on communication processes, digital literacy as a moderator and trust as a co-constructed dimension. This procedure directly guided the formulation of the hypotheses (H1-H5) and supported the development of the integrated conceptual model.

Figure 2 shows the systematic progression from exploratory mapping to focused synthesis. Phase 1 employed AI-assisted bibliometric mapping to explore the broader literature landscape and identify four thematic clusters.

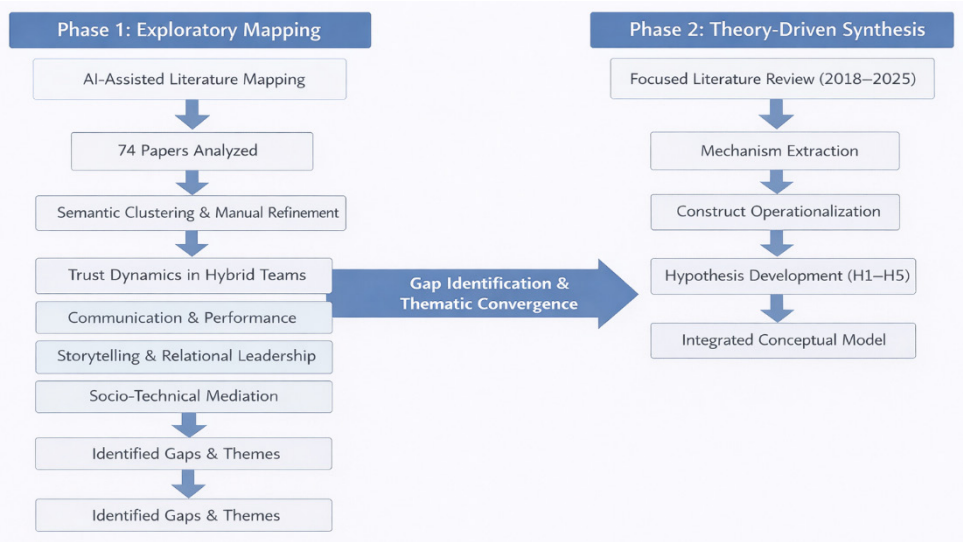

Figure 2: The two-phase research design for conceptual model development

4 Results: Hypotheses and the Conceptual Model

Following the structured literature synthesis, the results are formalized as theoretically grounded hypotheses and an integrated conceptual model.

4.1 Hypotheses

- ***H1:*** *AI-assisted storytelling functions as a shared collaborative artifact that facilitates collective sensemaking and positively influences trust in hybrid teams.*
- ***H2:*** *Perceived social proximity among hybrid team members is positively associated with trust in AI-mediated collaborative storytelling contexts.*
- ***H3:*** *The transparency and explainability of AI-assisted storytelling processes positively influence trust in hybrid team collaboration.*
- ***H4:*** *Digital literacy moderates the relationship between AI-assisted storytelling and trust, such that higher levels of digital literacy strengthen this relationship.*
- ***H5:*** *Hybrid team configurations characterized by higher degrees of digital mediation strengthen the positive effect of AI-assisted storytelling on trust formation compared to less digitally mediated contexts.*

4.2 Conceptual model

Based on the insights of the researchers in this study, the model frames trust as a co-constructed outcome of socio-technical interactions rather than a static antecedent or consequence. AI-assisted storytelling serves as a shared collaborative artifact that structures communication and supports collective sensemaking. Trust emerges through three mechanisms: shared narrative construction, which enables knowledge co-creation, perceived social proximity, which reduces spatial and psychological distance, and AI transparency and explainability, which reinforcing confidence in human-AI interaction. Digital literacy is theorized as a moderating capability, which assists in the engagement with AI-assisted storytelling and sustaining trust development. Hybrid team configuration further conditions these relationships, with greater digital mediation amplifying the impact of AI-assisted storytelling on trust. Overall, such framework integrates communication processes, technological affordances and human competencies into a coherent socio-technical structure, formalized in five analytically grounded and empirically testable hypotheses (H1–H5).

Figure 3 presents the conceptual model of trust formation in AI-augmented hybrid teams.

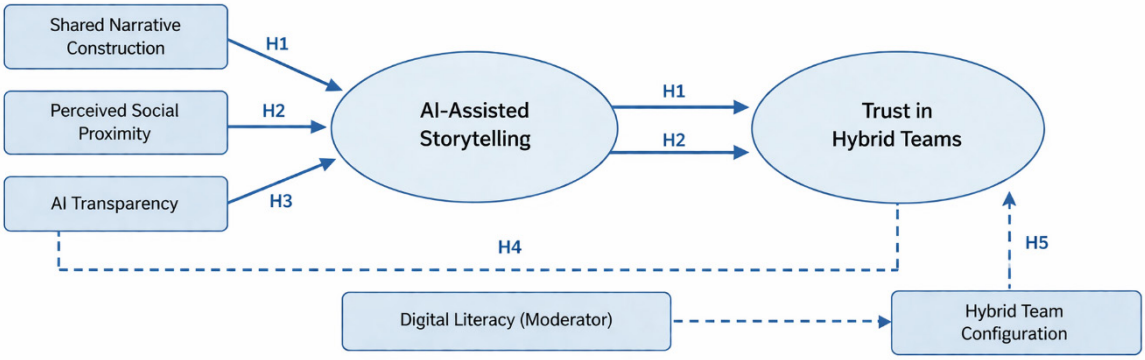

Figure 3: Conceptual model of trust formation in AI-augmented hybrid teams.

4.3 Conceptual mechanisms and hypotheses mapping

Table 3 summarizes how the literature review supports the mechanisms of the proposed model. Trust in hybrid teams emerges dynamically through socio-technical interactions, with human contributions, social proximity and AI transparency, while digital literacy enables the knowledge co-creation. The structure of a hybrid team further shapes these effects, as digitally mediated arrangements amplify the influence of AI-assisted storytelling. Together, these insights provide the empirical and conceptual foundation for hypotheses H1–H5.

Table 3: Hypotheses mapping

Hypothesis	Concept – Mechanism	Key Findings – Contributions
H1	Shared narrative construction	AI-assisted storytelling enables collective sensemaking and knowledge co-creation; Human input adds contextual nuance and adaptive reasoning
H2	Social proximity	Perceived closeness fosters engagement, relational cohesion and trust in hybrid teams
H3	AI transparency and explainability	Transparent AI outputs enhance predictability and confidence, supporting effective human-AI collaboration
H4	Digital literacy	Higher digital competence strengthens engagement with AI narratives, improves interpretation and sustains trust and relational cohesion
H5	Hybrid team configuration	Flexible, distributed team arrangements amplify AI-assisted storytelling effects, supporting trust, collaboration and knowledge sharing

4.4 Literature retention by conceptual constructs

The retained literature provides strong empirical and conceptual support for the following model constructs: shared narrative construction, social proximity, AI transparency, AI-assisted storytelling, digital literacy, and hybrid team configuration. Together, these constructs shape trust, engagement, and knowledge co-creation in AI-augmented hybrid teams and support the five proposed hypotheses (H1–H5).

4.5 Critical synthesis and gap analysis

Table 4 summarizes key mechanisms supporting AI-assisted hybrid collaboration and highlights their main contributions and critical gaps. Most studies examine mechanisms in isolation, leaving AI-assisted storytelling, digital literacy and team-trust interactions underexplored. However, this study addresses these gaps with a unified socio-technical framework for trust formation in AI-augmented hybrid teams.

Table 4: Synthesis and gap analysis

Mechanism	Strengths	Gaps / Limitations
Shared narrative construction	Supports knowledge co-creation, alignment and trust	Few studies on AI-assisted storytelling in hybrid teams
Perceived social proximity	Reduces distance; Fosters relational cohesion	Limited research on AI-mediated influence on social proximity
AI transparency and explainability	Enhances trust and effective human-AI collaboration	Lack of empirical quantification of transparency effects in hybrid teams
AI-assisted storytelling	Demonstrated as co-creative tool; Supports learning	Scarce longitudinal or large-scale studies; Novelty underexplored
Digital literacy	Strengthens engagement, interpretation and trust	Mostly self-reported; Limited intervention-based evidence
Trust in hybrid teams	Central to collaboration and knowledge sharing	Limited focus on trust in AI-mediated narrative practices
Hybrid team configuration	Shapes relational and communicative dynamics	Few studies link team structure with AI-assisted collaboration and trust

5 Discussion, Implications and Future Research

Based on the critical synthesis, AI-assisted storytelling is positioned as a central socio-technical mechanism driving trust in hybrid teams. Table 5 summarizes the key findings, theoretical contributions, and practical implications.

Table 5: Key findings, implications and mechanisms

Hypothesis – Aspect	Key Findings	Implications
H1: AI-assisted narratives	Facilitates co-construction of meaning, alignment and relational cohesion	Supports shared sensemaking, knowledge co-creation and team cohesion
H2: Perceived social proximity	AI-mediated narratives reduce spatial and psychological distance; Foster engagement	Enhances trust, relational cohesion and psychological safety in hybrid collaboration
H3: AI transparency and explainability	Transparent AI outputs increase predictability and trust	Highlights need for user-centered and more explainable AI systems
H4: Digital literacy	Higher digital competence improves engagement with AI outputs, narrative integration and trust	Justifies investment in digital skills to enable effective human-AI collaboration
H5: Hybrid team configurations	AI-assisted co-creation allows distributed teams to achieve outcomes comparable to co-located teams	Encourages strategic hybrid team design and AI-supported workflows
Overall socio-technical mechanism	Trust emerges dynamically from narratives, proximity, transparency and digital literacy (moderator)	Demonstrates the integrated socio-technical nature of AI-assisted hybrid collaboration

5.1 Key findings

AI-assisted narratives act as shared collaborative artifacts, facilitating alignment, mutual understanding and knowledge co-creation in hybrid teams. Social proximity and transparent AI outputs strengthen relational cohesion and trust, while digital literacy enables effective interpretation and integration of AI-generated narratives. Hybrid team configurations show that distributed teams can achieve outcomes comparable to co-located teams when AI-assisted storytelling is applied. Together, these mechanisms demonstrate that trust in hybrid teams is a dynamic, co-constructed socio-technical phenomenon.

5.2 Theoretical contributions

This study reconceptualizes trust in hybrid teams as a communicatively co-constructed phenomenon and positions AI-assisted storytelling as a knowledge artifact that fosters alignment and relational cohesion. It highlights digital literacy as a key moderating capability connecting human competencies to AI-mediated collaboration. It further demonstrates the integrated socio-technical nature of trust formation, where narrative artifacts, relational practices and technological affordances together generate knowledge and engagement outcomes.

5.3 Practical implications

The findings suggest that AI systems should prioritize transparency, explainability and user-cantered interaction. AI-mediated narratives can strengthen social proximity, engagement and relational cohesion in distributed teams, while digital literacy programs enhance interpretation of AI outputs and support collaborative knowledge co-creation. Structuring hybrid teams to leverage AI-assisted storytelling can thus improve both relational and knowledge-based performance.

5.4 Future research directions

Future research should empirically test the proposed model using surveys, experiments and field studies, including organizational, cultural and industry-specific moderators of trust formation. Longitudinal studies could illuminate the evolving dynamics of trust in AI-mediated hybrid teams, while further investigation into AI functionalities and storytelling interventions could optimize engagement, knowledge co-creation and socio-technical collaboration.

6 Conclusion

This study advances understanding of trust formation in AI-augmented hybrid teams by positioning AI-assisted storytelling as a central socio-technical mechanism that shapes collective sensemaking and co-created knowledge. Trust is reconceptualized as a dynamic, communicatively co-constructed outcome, which emerges from the interplay of narrative practices, relational interactions and technological affordances. Hereby, AI functions as an active collaborative partner, providing structure, interpretability and alignment, while human contributions deliver contextual nuance and relational trust. Digital literacy serves as a moderator which enforces the engagement with AI, as well as influences the integration of narratives and the development of trust. The conceptual framework highlights AI-assisted storytelling as a key facilitator of knowledge co-creation and identifies digital literacy as a critical competence in hybrid collaboration. Practically, it guides organizations in designing AI narrative practices and structuring hybrid teams to enhance relational cohesion and collaborative outcomes. Although conceptual and literature-based, the study lays a foundation for empirical research, including longitudinal, cross-cultural and tool-specific investigations, offering a socio-technical lens to understand and enhance trust in AI-augmented hybrid teams.

7 AI Declaration

ChatGPT Pro (OpenAI) was used to support the generation of Figures 1-3, which were subsequently reviewed and edited by the authors. The AI-generated material was used as a drafting aid for visualization and not as an autonomous source of scientific content. SciSpace Agent (TL;DR) was used to cluster and summarise an initial set of 128 publications during the literature review process. AI tools were employed solely as assistive instruments for visualization support and literature organization. No AI tool was used to generate final scientific claims, results or conclusions presented in the manuscript. All content has been reviewed, validated and approved by the authors.

8 Ethics Declaration

This research did not involve human participants, personal data, or animal subjects; therefore, no ethical approval from an institutional review board was required. All work complies with general ethical standards for scholarly research and publication.

ChatGPT Acceptance among Higher Education Students: A Simplified Model

László Berényi
Institute of Management Science, University of Miskolc, Miskolc, Hungary

Abstract

Understanding and predicting the use of generative AI chatbots is an urgent task due to the rapid spread and rapid changes in technology. SEM models are popular in the field because they can account for the complex effects of multiple influencing factors. A serious problem is the data requirement of the analysis. Long surveys and large sample sizes are difficult to make feasible for the numerous targeted questions that arise in connection with the acceptance of generative AI use. The education system is significantly transformed by the emergence of AI. Strengthening its role in learning support and addressing academic misconduct requires actions grounded in readily accessible, up-to-date information. New framework models may support effective strategy building. The study aims to present a pilot framework model derived from existing models (Berényi et al., 2025) to measure the intention to use AI tailored to higher education students. The reflective measurement constructs are defined for PLS-SEM analysis. The limited number of items in the model enables rapid data collection by reducing the risk that respondents will lose interest while completing the survey. The pilot study for model validation used a sample of 281 students at the University of Miskolc (Hungary) and focused on ChatGPT use. SmartPLS4 was used for analysis. The pilot run confirmed acceptable reliability, with AVE between 0.626 and 0.814, HTMT <= 0.860, and VIF <= 1.974. Model fit is good (SRMR = 0.070). The model explained 55.9% of the total variance in intention to use and 47.2% of the total variance in usefulness. Path coefficients are significant, except for the impact of price-value. The results suggest that information quality impacts usefulness through usability; the direct impact is remarkably lower. The total impact of usability on intention to use is high (path coefficient is 0.629), partly through usefulness. Among the respondents, the impact of pricing on the intention to use was not significant, which may be due to free academic access to the chatbots or to the hoped-for profit exceeding the price. The results contribute to the body of knowledge on the acceptance of AI technologies among higher education students, but they can easily be extended to other purposes if it is assumed that intention to use depends on the quality of the information. The limited survey length increases the likelihood of completion, and the policymakers can work with more reliable information.

Keywords: technology acceptance, information quality, chatbot, PLS-SEM, higher education

Paper type: Academic Research Paper

1 Introduction

The introduction of generative artificial intelligence (genAI) chatbots led to remarkable changes in academic life and beyond. Although artificial intelligence has been incorporated much earlier into various services, planning assignments, and task-automation solutions, its popularity has increased with the spread of large language model (LLM)- based chatbots. The way of asking questions and receiving responses has become "human-like," making communication with the software easy. Since students realized that genAI can support writing homework, analyzing data, and solving many tasks with less effort than before, new challenges have emerged. Academic integrity recently includes AI-based cheating, or in a broader sense, the ethical use of genAI. Policymaking usually follows technological development. Effective policymaking requires understanding the complex motivations and habits of students. Second-generation multivariate statistical analysis offers reasonable opportunities in the field. Framework models such as the Technology Acceptance Model (TAM) (Davis, 1989; Venkatesh and Bala, 2008), the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003; Venkatesh et al., 2012), or the Delone and McLean Information Systems Success Model (DM) (Delone and McLean, 1992; 2003) can be adopted to explore the factors influencing genAI use. However, the data collection survey is usually very long and detailed to ensure the consideration of several factors, and large samples are collected to ensure statistical validity. At the same time, the rapid development of technology makes results quickly outdated. Repeated surveys may lead to response bias, and students may lose interest in completing long questionnaires. The study aims to propose and validate a simplified framework suitable for repeated measurements in a rapidly evolving context. The model allows exploring the main influencing factors and comparing results over time, and across genAI versions. Using this model, the research goal is to measure the factors influencing ChatGPT use among higher education students. The results are based on a pilot study conducted with 281 business students at the University of Miskolc (Hungary).

The rest of the paper is organized into five main sections. Literature review highlights the appreciation of genAI in higher education. The materials and methods section presents the process of framework model development and the characteristics of the pilot sample. The results section gives an overview of the PLS-SEM modeling, followed by the discussion of the results. The conclusions include the main implications and limitations of the study.

2 GenAI in Higher Education

The spread of genAI chatbots meets the requirements imposed on universities to improve productivity. Publication pressure on teachers and researchers, as well as the need to complete students' mid-term tasks, may motivate people to use chatbot services to save time and effort. Hussein et al. (2025) emphasized that education is among the most frequently discussed themes in the context of genAI use. Considering that higher education prepares the next generation of engineers, medical doctors, economists, and philosophers, the spread of AI technology has a multiplicative impact on the economy and society.

The Student Generative AI Survey 2025 reported that 92% of UK undergraduate students used genAI, and the ratio has increased from 66% in 2024 (Freeman, 2025). The main reason for genAI covered saving time by summarizing content or generating ideas, as well as explaining information. Additionally, improving the quality of work through corrections was marked in the study.

Based on international comparisons, Annamalai et al. (2025) found a positive impact of genAI use on learning, including positive experiences with learning and the development of critical thinking. By offering styles explored by large language models, academic writing can be improved beyond grammar corrections (Ayoubi et al., 2024).

Although the opportunities are promising, cautious use must be considered due to mixed lessons (Farrokhnia et al., 2024; Zhou et al., 2024; Zábrátzky, 2025). The urge of institutional policies (Yang, 2024) is driven by the risks of falling academic work quality, writing skills, and critical thinking due to extensive reliance on genAI chatbots (Medina et al., 2024). At the same time, Jahani et al. (2024) emphasized the positive impact of genAI use on students' motivation, and Mohamed et al. (2025) highlighted its support for writing skills through grammatical and lexical corrections. Moreover, ethical issues must be considered when integrating genAI into education (Kumar et al., 2024). Kovari (2025) has proposed comprehensive strategic guidelines for reducing genAI risk. Since large language model-based chatbots can be considered emerging technologies, we cannot yet see their true impact despite numerous studies and opinions; more time and experience are needed. However, this does not mean that efforts to understand are pointless. Diverse opinions may be traced to local characteristics, but the wide variety of measurement models prevents a comprehensive comparison of results.

In the Hungarian context, Berényi and Csiszárik-Kocsir (2025) found generational differences in the use of genAI. Older generations are characterized as cautious users focused on professional tasks, while younger generations are confident users who have integrated genAI into their everyday activities. According to the scope, research, information synthesis, and translation are the main fields of use, similar to international surveys.

3 Materials and Methods

3.1 Framework model and hypothesis development

The research framework model (Figure 1) established intention to use ChatGPT as an exogenous construct, and information quality, usability, and usefulness as endogenous ones. Additionally, the impact of price-value was included. The model was designed for PLS-SEM analysis, following the instructions of Hair et al. (2022).

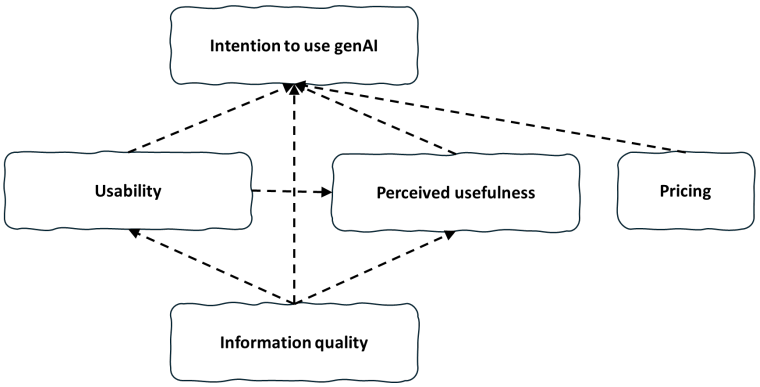

Figure 1: This is how a figure should appear

The latent variable constructs were defined as follows:

Information quality (IQ): the construct was adopted from the DM model and refers to the usefulness, accuracy, reliability, and comprehensibility of the information produced by an information system, as well as the extent to which it supports user decisions. (Delone and McLean, 2003).

Usability (US): is developed by the author, considering facilitating conditions in UTAUT2 (Venkatesh et al., 2012) and perceived ease of use in TAM (Venkatesh and Bala, 2008), referring to the perceived usability and enjoyment of the genAI chatbot.

Usefulness (PU): refers to the belief that using the genAI will contribute to performing tasks more efficiently.

Price-value (PV): is adapted from the UTAUT2 model (Venkatesh et al., 2012) and refers to the perceived return on investment (fees) of using genAI.

Intention to use (IU): is a general construct in similar models. The construct in the model refers to the intention of the respondents to use genAI for educational purposes and beyond in the future.

The research question was formulated as follows: How do information quality, usability, and perceived usefulness influence the intention to use ChatGPT? A methodological question is whether the provided framework model is applicable in the field.

There were six hypotheses formulated following the paths in the model:

- *H1: Information quality provided by ChatGPT affects its perceived usability.*
- *H2: Information quality provided by ChatGPT affects its perceived usefulness.*
- *H3: Perceived usability of ChatGPT affects perceived usefulness.*
- *H4: Information quality provided by ChatGPT affects the students' future intentions to use it.*
- *H5: Perceived usability of ChatGPT affects the students' future intentions to use it.*
- *H6: Perceived usefulness of ChatGPT affects the students' future intentions to use it.*
- *H7: Price-value of ChatGPT affects the students' future intentions to use it.*

The survey items selected from the previous analysis (Berényi et al., 2025) and their coding for the analysis section are summarized in Table 1.

Table 1**:** Survey items and coding

Construct	Item Code	Survey item
Information Quality	IQ1	ChatGPT offers reliable information
	IQ2	The information from ChatGPT is useful and easy to understand
	IQ3	Information from ChatGPT is in a form that is readily usable
Usability	UA1	I know how to find solutions for my problems about using ChatGPT features
	UA2	Using ChatGPT makes me satisfied in general
	UA3	I use ChatGPT for various solving tasks
	UA4	I spend a lot of time with ChatGPT
Usefulness	PU1	I think ChatGPT is useful for my studies
	PU2	ChatGPT can help improve the quality of my work
Price-value	PV1	ChatGPT is available at a reasonable price
	PV2	Pricing options of ChatGPT are flexible
Intention to use	IU1	I intend to continue using ChatGPT for my studies in the future
	IU2	I predict I will use ChatGPT beyond my studies

3.2 Data collection and sample

Data collection was conducted through a multipurpose online survey designed to assess ChatGPT use among higher education students in the fall semester of the 2024/2025 academic year. The questions were prepared in Google Forms using a 7-point scale. The study processes the responses of students at the University of Miskolc (Miskolc, Hungary). A total of 281 responses were available for analysis after filtering for academic misconduct, partially completed surveys, responses with very low standard deviation, and suspicious respondents. The representativeness of the sample was not checked. The sample consists of 73 female and 208 male students. 66.9% are aged 18-25 years, 18.5% are aged 26-35 years, and 14.6% are aged 36 years or older.

3.3 Method selection

Based on the guidance of Hair et al (2022), the PLS-SEM method was selected for the analysis. As the study aimed to develop a methodological pilot for a simplified theoretical approach to technology acceptance; the

sample size, the model structure, and the distribution of responses suggest using a PLS-SEM model. SmartPLS 4 software (Ringle et al., 2024) was used for the calculations. The bootstrapping procedure was performed with the bias-corrected and accelerated (BCa) method with 5000 subsamples. The significance level in the study was 0.05.

Based on the inverse-square-root method proposed by Kock and Hadaya (2018), the sample size is acceptable. The method suggests a minimum sample size n_{min} > (2.486(/p)2, where p stands for the minimum path coefficient in the PLS path model expected to be statistically significant. The study's sample size allows p = 0.148 as a minimum, which is lower than the value of 0.264 obtained during the run.

4 Results

4.1 Model validation

The descriptive statistics for model elements, their outer loadings, and the Variance Inflation Factor (VIF) values are summarized in Table 2. The outer loadings exceed the threshold of 0.708, except for IQ1, which equals 0.699. Since the value is close to acceptable and dropping the item would negatively impact model fit, it was retained in the model. The maximum VIF of 1.974 is less than 3, so there are no multicollinearity issues.

Table 2**:** Descriptive statistics of survey items, outer loadings, and VIF (based on SmartPLS output)

	Mean	Standard deviation	Excess kurtosis	Skewness	Outer loadings	VIF
IQ1	4.075	1.273	-0.185	-0.224	0.699	1.259
IQ2	5.235	1.345	-0.037	-0.620	0.858	1.628
IQ3	4.996	1.536	-0.443	-0.521	0.831	1.530
IU1	5.537	1.537	0.311	-0.984	0.912	1.717
IU2	5.609	1.527	0.605	-1.124	0.903	1.717
PV1	4.281	1.356	-0.127	-0.134	0.925	1.487
PV2	4.039	1.430	-0.255	-0.062	0.840	1.487
UA1	4.352	1.743	-0.824	-0.239	0.858	1.974
UA2	4.758	1.509	-0.385	-0.496	0.732	1.467
UA3	5.053	1.739	-0.629	-0.629	0.829	1.729
UA4	3.021	1.741	-0.668	0.573	0.739	1.506
PU1	5.413	1.488	0.036	-0.843	0.918	1.654
PU2	4.836	1.662	-0.636	-0.486	0.886	1.654

The reliability of the constructs is good (Table 3). Cronbach's alpha values are between 0.716 and 0.801, composite reliability indicators are higher than 0.7, and the average variance extracted (AVE) exceeds 0.5 in each case.

Table 3**:** Reliability analysis (based on SmartPLS output)

	Cronbach's alpha	Composite reliability (rho_a)	Composite reliability (rho_c)	AVE
Information quality	0.716	0.737	0.840	0.639
Intention to use	0.785	0.786	0.903	0.823
Price value	0.728	0.793	0.877	0.781
Usability	0.801	0.820	0.870	0.626
Usefulness	0.772	0.785	0.897	0.814

The model's discriminant validity was confirmed using the Fornell-Larcker criteria (Table 4) and the Heterotrait-Monotrait Ratio (HTMT) analysis (Table 5). The root squares of AVE indicators per construct are higher than the correlations with other constructs. According to HTMT, all values are below the threshold value of 0.85.

Table 4**:** Fornell-Larcker criteria (based on SmartPLS output)

	Information quality	Intention to use	Price value	Usability	Usefulness
Information quality	0.799				
Intention to use	0.398	0.907			
Price value	0.176	0.205	0.884		
Usability	0.458	0.685	0.228	0.791	
Usefulness	0.504	0.670	0.182	0.646	0.902

Table 5: Heterotrait-monotrait ratio (HTMT) analysis (based on SmartPLS output)

Relation	Heterotrait-monotrait ratio (HTMT)
Intention to use <-> Information quality	0.522
Price value <-> Information quality	0.239
Price value <-> Intention to use	0.265
Usability <-> Information quality	0.609
Usability <-> Intention to use	0.843
Usability <-> Price value	0.296
Usefulness <-> Information quality	0.672
Usefulness <-> Intention to use	0.849
Usefulness <-> Price value	0.240
Usefulness <-> Usability	0.810

The Standardized Root Mean Square Residual (SRMR) indicators suggest acceptable model fit ($SRMR_{saturated}$ = 0.700, $SRMR_{estimated}$ = 0.800). Other indicators suggest caution: NFI = 0.684, d_ULS = 0.448, d_G = 0.279, and Chi-square = 486.965 for the saturated model.

4.2 Model results

The path coefficients with bootstrapping are presented in Figure 2. Information quality (IQ) has a significant impact on Usability (UA) (ß = 0.458) and Usefulness (PU) (ß = 0.264), while its direct effect on the intention to use (IU) is negligible. Both UA (ß = 0.425) and PU (ß = 0.388) have significant effects on IU. The effect of price-value (PV) in IU (ß = 0.038) was not confirmed by the study.

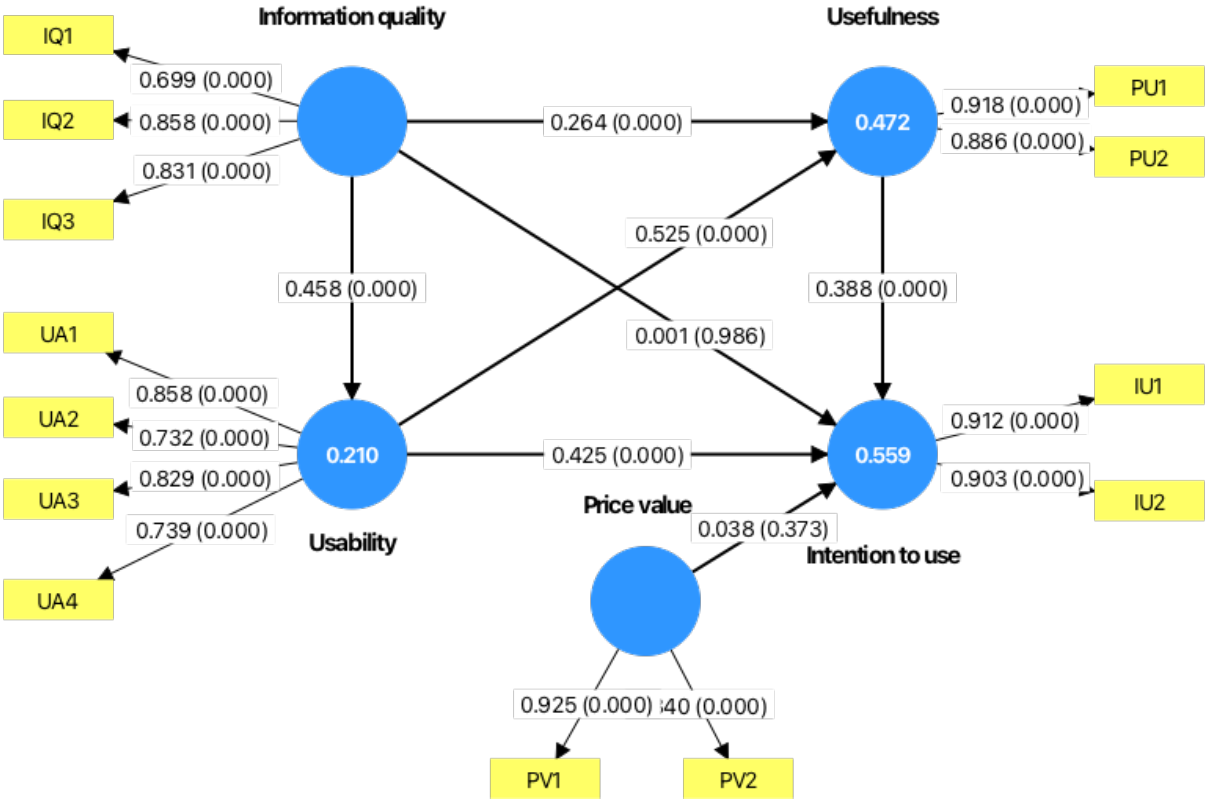

Figure 2: Path analysis results with significance levels (SmartPLS output)

The model explained 55.9% of the variance of the intention to use ChatGPT. IQ affects IU through UA and PU. The path coefficient between IQ and UA is higher than between IQ and PU, but the variance explained is the opposite. The path coefficient between UA and IU is higher than that between PU and IU (Table 6).

Table 6: Total effects and indirect effects (based on SmartPLS output)

	Total effect	p values	Total indirect effects	p values
IQ -> IU	0.391	0.000	0.390	0.000
IQ -> UA	0.458	0.000		
IQ -> PU	0.504	0.000	0.240	0.000
PV -> IU	0.038	0.373		
UA -> IU	0.629	0.000		
UA -> PU	0.525	0.000	0.204	0.000
PU -> IU	0.388	0.000		

Table 7: Path coefficients and effect size for hypothesis testing (based on SmartPLS output)

Hypothesis	Path	ß	T statistics (|O/STDEV|)	P values	f^2	Decision
H4	IQ -> IU	0.001	0.017	0.986	0.000	Rejected
H1	IQ -> UA	0.458	9.768	0.000	0.265	Supported
H2	IQ -> PU	0.264	5.127	0.000	0.104	Supported
H7	PV -> IU	0.038	0.892	0.373	0.003	Rejected
H5	UA -> IU	0.425	8.229	0.000	0.225	Supported
H3	UA -> PU	0.525	11.127	0.000	0.412	Supported
H6	PU -> IU	0.388	6.936	0.000	0.180	Supported

The hypotheses were related to the paths defined in the model (Table 7). The study confirmed significant effects of IQ, UA, and PU on the other factors, but no significant effect was found directly between IQ and IU. In addition, the effect of PV was not proven.

5 Discussion

From a methodological perspective, the model validation and the results confirmed the usability of the simplified model for assessing the intention to use genAI chatbots, namely ChatGPT, in this study. Although model fit indices could be improved, the results are acceptable for a pilot model. The related survey with 13 items may not be exhausting for respondents, and a greater willingness to answer the questions can be expected.

The research question about the impacts of the proposed influencing factors was mostly confirmed. The results show that information quality has a strong influence on the intention to use only through indirect paths. The direct path coefficient is negligible, but perceived usefulness and usability uncover a valuable impact chain. The significant paths explored suggest that the combination of usability and usefulness can explain intention to use remarkably, and the coefficient between them confirms that the perception of usefulness largely depends on the system's usability. The results are in line with former results. Information quality has a strong effect on intermediate constructs (Berényi et al., 2025; Chu 2023; Chen et al., 2024).

The intention to use ChatGPT is high among the respondents, both for study purposes and beyond, and it is not directly dependent on the information quality provided by the system. The intention is based on the perceived usability and usefulness of the users. Information quality and usability explain an acceptable ratio of variance explained (R^2 = 47.2%), and the total model explains 55.9% of the variance in the outcome construct.

According to former studies (Hasanein and Sobaih, 2023; Romero-Rodríguez et al., 2023; Grassini et al., 2024; Gulati et al., 2024; Strzelecki, 2024), behavioral intention significantly predicts genAI use among students, but actual use was not involved in the simplified framework model due to the difficulties of measuring fair values with a self-managed voluntary survey.

The usability construct is a mixed construct within the proposed framework, incorporating facilitating conditions, effort expectancy, and enjoyment. The role is to measure the influencing factors of satisfaction more concisely than the UTAUT2 model.

Regarding effort expectancy, some studies confirmed a positive relationship (Hasanein and Sobaih, 2023), whereas others report non-significant effects, highlighting the context-dependent nature of this construct in genAI adoption. The lack of effect was confirmed by Habibi et al. (2023) and Salifu et al. (2024). The usability construct in this pilot study is a significant contributor.

A notable characteristic of the framework model is that usability incorporates satisfaction. Although it might be worth treating satisfaction as an outcome variable, the opposite approach is intentional since it allows the analysis of its effect in a model where loops and bidirectional relations are not feasible (Hair et al., 2022).

The growing supply of genAI chatbots at various pricing options suggested testing the effect of price-value. The results show that intention to use is not affected by pricing. Price-value was found to be a driver of intention

to use by Romero-Rodríguez et al. (2023), while most studies did not find significant effects in the higher education context. This construct can be omitted if the target audience remains higher education, especially given recent service provider offerings, e.g., Copilot or Gemini access to the academic community.

6 Conclusion

The intention to use genAI chatbots is remarkably high among students at the University of Miskolc, driven primarily by perceived usability and usefulness. At the same time, the direct impact of information quality and price-value is negligible. The results confirmed that promoting cautious use of GenAI is a critical issue. Since genAI may occasionally provide confusing information, rapid, seemingly comprehensive responses can be harmful. The insignificant path between information quality and intention to use is a warning sign, especially since information quality has a stronger effect on usability than on usefulness. That implies that students base their decisions on convenience rather than quality, which poses an educational policy risk. Therefore, university-level policymaking should focus less on restrictions and more on developing the skills to use and raising awareness of computer-generated information. Since the simplified framework model allows quick data collection and is not sensitive to the chatbot used by students, repeated surveys support evidence-based refinement of policies over time.

Despite the contributions and the careful research design, the study has several limitations. Data collection for the pilot study was limited to a single university; further research can test validity using a broader sample. The sample size was acceptable for model testing, but it was not representative. Additionally, existing models were used in the survey design, and simplifications were made on a trial basis. Actual use is not included in the model, which is essential in some situations, given local data and opportunities.

7 Ethics Declaration

The study was conducted in accordance with the Declaration of Helsinki, and approved by the Scientific Committee of the University of Miskolc (TNI/1836/2025, 23. 09. 2025).

8 AI Declaration

No AI tool was used in the development and writing of this paper.

Advancing Foresight and Futures Literacy by Generative Artificial Intelligence

Tamás Kristóf
Institute of Entrepreneurship and Innovation, Corvinus University of Budapest, Hungary

Abstract

In the era of accelerating technological change and systemic uncertainty, foresight has become a critical capability for organizations seeking to anticipate and navigate complex futures. At the same time, advances in generative artificial intelligence (GenAI) are rapidly transforming how foresight is conducted, enabling new forms of future exploration, data synthesis, scenario generation, and forward-looking analysis. Despite this growing relevance, the role of GenAI in foresight remains conceptually underdeveloped, with existing research predominantly framing artificial intelligence (AI) as a tool for augmenting human cognition. This paper addresses this gap by conceptualizing the role of GenAI in reshaping foresight practices and contributes to the development of futures literacy – the capacity to understand, imagine, and use the future in decision-making. Drawing on insights from futures studies, knowledge management, and socio-technical systems theory, this paper develops a conceptual framework that positions GenAI as a knowledge infrastructure mediating foresight processes. The paper's main contribution is the identification of a dual-path transformation in AI-supported foresight. The first, the augmentation paradigm, conceptualizes GenAI as a cognitive collaborator that enhances human sensemaking, supports participatory foresight processes, and fosters futures literacy as a learning-oriented capability. The second, the autonomous foresight paradigm, reflects an emerging trajectory in which GenAI systems increasingly perform foresight tasks with limited human intervention, prioritizing efficiency, scalability, and accessibility. The paper highlights a fundamental tension between these two paradigms. While automation expands access to foresight and reduces costs, it may also weaken the reflexive and participatory processes that underpin futures literacy. This raises critical questions regarding the relationship between foresight production and anticipatory learning, as well as the role of human agency in AI-mediated knowledge creation. The paper contributes to the literature by advancing a novel conceptualization of AI-supported foresight as a socio-technical transformation characterized by competing epistemic logics. It further outlines implications for organizational practice, emphasizing the need for hybrid foresight models that integrate AI-driven capabilities with human-centered sensemaking, and identifies key directions for future research on governance, ethics, and human–AI co-creation in foresight.

Keywords: Futures Studies, Foresight, Futures Literacy, Generative AI

Paper type: Academic Research Paper

1 Introduction

In the era characterized by accelerating technological change, systemic uncertainty, and increasingly complex global challenges, organizations face growing pressure to anticipate and navigate uncertain futures. Foresight has therefore emerged as a critical capability for strategic decision-making, enabling organizations to explore alternative futures, identify emerging risks and opportunities, and support long-term resilience. Within this context, futures literacy – the capacity to understand, imagine, and utilize the future – has gained prominence as a key competence for sustainable organizations (Miller, 2018).

Traditionally, foresight practices have relied on expert judgment, stakeholder engagement, qualitative sensemaking, and participatory approaches, such as horizon scanning, trend analysis, technological assessment, Delphi, futures wheel, causal layered analysis, scenario planning, visioning, backcasting, roadmapping, simulations, or gamification. However, recent advances in GenAI are rapidly transforming these practices. Large language models (LLM) and multimodal generative systems are now capable of synthesizing vast amounts of information, generating narrative-rich scenarios, and supporting interactive exploration of uncertainty (Finkenstadt et al., 2024). As a result, GenAI is increasingly positioned as a powerful enabler of foresight, with the potential to enhance anticipatory intelligence and democratize access to futures thinking (Zoccarato et al., 2025).

Despite this growing interest, the role of GenAI in foresight remains conceptually underdeveloped. Existing literature predominantly frames AI as a tool for augmenting human cognition (Mollick, 2024). This aligns with a learning-oriented perspective of foresight, wherein the principal objective is not precision but the augmentation of organizational competence to navigate uncertainty (Poli, 2019). While this perspective captures important developments, it overlooks a more fundamental transformation: the possibility that GenAI may not only support foresight but increasingly perform it autonomously. Emerging applications suggest that generative systems can

execute substantial parts of foresight activities – including horizon scanning, scenario generation, and evaluation – raising important questions about the future role of human agency in anticipatory processes. This shift suggests that GenAI does not merely enhance foresight practices but may fundamentally transform the epistemic logic through which futures are constructed and legitimized.

This paper addresses this gap by proposing a dual-path conceptualization of GenAI-supported foresight, distinguishing between an *augmentation paradigm* and an *autonomous paradigm*. In the augmentation paradigm, GenAI functions as a cognitive collaborator, enhancing human sensemaking and supporting the development of futures literacy. In contrast, the autonomous paradigm reflects an emerging trajectory in which GenAI systems act as semi-autonomous foresight agents, prioritizing efficiency and scalability but potentially altering the epistemic and learning foundations of foresight practice. Emerging market solutions (i.e. https://preempt.life) offering low-cost, AI-generated foresight outputs further indicate a shift toward increasingly automated foresight services.

Building on insights from futures studies, knowledge management, and socio-technical systems theory, this paper develops a conceptual framework that positions GenAI as a knowledge infrastructure mediating these two pathways. It advances a novel theoretical perspective by conceptualizing AI-supported foresight as a dual-path transformation characterized by a tension between augmentation and autonomy. Furthermore, it integrates futures literacy into this framework, highlighting how different modes of human–AI interaction can influence anticipatory learning.

The remainder of the paper is structured as follows. Section 2 reviews the relevant literature on foresight, futures literacy, and GenAI. Section 3 presents the conceptual framework. Section 4 discusses the implications of the dual-path model for theory and practice. Section 5 concludes with key insights and directions for future research.

2 Literature Review

2.1 From prediction to futures literacy

Foresight research has increasingly moved beyond predictive approaches toward a knowledge-based and learning-oriented understanding of the future. Rather than predicting singular outcomes, foresight is conceptualized as a process of sensemaking, anticipation, and knowledge creation under uncertainty. In this context, futures literacy refers to the capability to explore multiple plausible futures, recognize underlying assumptions, and use anticipatory thinking to inform present action (Miller, 2018).

This epistemological shift reflects a broader transition in futures studies toward plurality, reflexivity, and constructivism. Foresight methods and practices are increasingly understood as cognitive and social processes shaping collective organizational intelligence, rather than merely analytical tools. AI-supported foresight further reinforces this perspective by enabling new forms of anticipatory knowledge production (Chodakowska et al., 2026).

2.2 AI as a knowledge infrastructure for foresight

The integration of AI into foresight represents a significant evolution in anticipatory practices. Earlier applications of AI focused primarily on data-driven analysis, including trend identification, clustering, synthesization, and technological assessment. While these approaches enhanced analytical capabilities, they remained largely complementary to expert-driven foresight processes.

The emergence of GenAI introduces a qualitative shift. Unlike traditional analytical tools, GenAI systems – especially LLM – are capable of generating narratives, simulating future scenarios, and engaging in dialogical interactions. This positions GenAI as an active participant in knowledge creation and sensemaking, rather than a passive analytical instrument (Trujillo-Cabezas, 2025; Zoccarato et al., 2025).

Prior empirical research demonstrates that GenAI can significantly enhance foresight practices by enabling rapid scenario generation, synthesis of diverse knowledge domains, and the articulation of complex systemic dynamics (Ferrer i Picó et al., 2025). These developments suggest that GenAI is evolving into a knowledge infrastructure for foresight, fundamentally transforming how futures are explored and constructed.

2.3 Human–AI collaboration in foresight

A central theme in recent literature is the emergence of human–AI collaboration as the prevalent driving force in AI-supported foresight. Rather than replacing human expertise, GenAI is increasingly conceptualized as augmenting cognitive processes and supporting strategic imagination (Hao et al., 2024).

Zoccarato et al. (2025) identify three modes of interaction with GenAI – delegation, confirmation, and cognitive support – each influencing the diversity and critical depth of foresight outcomes. Similarly, Picavet et al. (2025) show that while AI enhances efficiency and scenario richness, effective foresight requires human validation, iterative design, and stakeholder engagement.

Conceptual frameworks further emphasize the importance of collaborative intelligence. Wang (2025) proposes a multi-agent AI architecture that supports foresight processes while maintaining human agency and ethical oversight. In educational contexts, the integration of GenAI with foresight methodologies enhances intellectual agility, creativity, and future-oriented thinking, particularly through iterative and dialogical engagement (Patel & Lim, 2025).

These findings collectively suggest that the value of GenAI lies not in automation but in augmenting human cognition and expanding the space of possible futures.

2.4 Methodological innovation in AI-supported foresight

GenAI is driving substantial methodological innovation in futures studies. Its capacity to generate, iterate, and visualize scenarios enables new hybrid approaches that integrate traditional foresight methods with computational capabilities (Spaniol & Rowland, 2023). For example, hybrid frameworks combining design futures and GenAI enable the creation of archetypal scenarios and participatory tools that enhance engagement and creativity (Bevolo & Draeger, 2025). Similarly, GenAI has been applied to evaluate foresight projects, offering new possibilities for retrospective learning and validation (McIntosh, 2026).

In qualitative research, GenAI functions as an anticipatory infrastructure, supporting the generation of narratives, images, and speculative artifacts that stimulate imagination and facilitate participatory foresight processes (Pink et al., 2025; Gomez-Hernandez, 2026). These developments highlight a shift toward more interactive, experiential, and democratized foresight approaches.

2.5 Critical perspectives: Risks, bias, and reflexivity

Despite its transformative potential, the integration of GenAI into foresight raises important epistemic and ethical concerns. One key issue is the tendency of generative systems to reproduce dominant narratives and biases embedded in their training data, potentially limiting the diversity of imagined futures (Bechthold, 2026). Hence, GenAI might steer futures studies back toward prediction, as opposed to modern human-centered foresight, since it fundamentally analyzes accessible information.

Moreover, the increasing reliance on GenAI in anticipatory governance introduces risks related to opacity, loss of accountability, and technocratic decision-making, particularly when AI-generated outputs are treated as authoritative (Cugurullo & Xu, 2025). These concerns are compounded by the potential erosion of reflexivity if AI-generated futures are accepted uncritically (Floridi, 2023).

Scholars also emphasize the importance of preserving human creativity and embodied sensemaking, warning that over-reliance on AI-generated knowledge may lead to epistemic stagnation and reduced novelty (Peschl, 2024).

2.6 Research gaps

The literature reveals several important gaps. First, there is limited integration between futures theory and GenAI, with most studies focusing on specific applications rather than broader capability development. Second, a multi-level perspective linking individual, organizational, and ecosystem dynamics remains underdeveloped. Third, there is a lack of governance frameworks for responsible AI-supported foresight. Fourth, more research is needed on human–AI co-creation processes and their impact on the quality and diversity of generated futures.

3 Conceptual Framework

The proposed conceptual framework positions GenAI as a knowledge infrastructure that reconfigures the epistemic foundations of foresight, rather than merely a technological tool. Building on insights from futures studies, knowledge management, and socio-technical systems theory, the framework conceptualizes foresight as a multi-layered process of knowledge creation, interpretation, and anticipatory learning.

At the input level, foresight processes draw upon diverse forms of knowledge and contextual information, including weak signals, emerging trends, expert knowledge, stakeholder perspectives, and organizational strategic intent (Chodakowska et al., 2026; Zoccarato et al., 2025). These inputs represent both structured and unstructured knowledge sources that must be synthesized and interpreted under conditions of uncertainty. In

this context, GenAI introduces new capabilities for handling complexity by rapidly integrating heterogeneous data, identifying patterns, and generating coherent representations of possible futures.

At the technological layer, GenAI systems provide a set of core capabilities that fundamentally reshape foresight practices. These include narrative generation, scenario simulation, pattern synthesis, and dialogical interaction (Ferrer i Picó et al., 2025; Trujillo-Cabezas, 2025). Unlike traditional analytical tools, GenAI is capable of producing context-sensitive, narrative-rich outputs and engaging in iterative exchanges with users. As such, it operates not merely as an analytical instrument but as an active participant in sensemaking processes, enabling the co-construction of futures.

A central contribution of the framework is the conceptualization of human–AI interaction as a continuum rather than a fixed mode. In the dominant configuration identified in literature, GenAI functions as a cognitive collaborator within a human-centered foresight process. In this *augmentation paradigm*, interaction modes include delegation of sub-tasks, iterative co-creation, and critical interrogation of AI-generated outputs (Zoccarato et al., 2025; Wang, 2025). Here, foresight remains a fundamentally human-driven activity, with AI augmenting cognitive capacities by expanding the space of possible futures, challenging assumptions, and supporting exploratory thinking.

Within this augmentation pathway, GenAI enhances key foresight processes (Bevolo & Draeger, 2025; Patel & Lim, 2025). By lowering the cost and increasing the speed of scenario generation, GenAI contributes to the democratization of foresight practices, making them more accessible beyond expert communities. Importantly, this pathway supports the development of futures literacy by fostering reflexivity, critical thinking, and the ability to engage with multiple plausible futures (UNESCO, 2023). In this sense, the primary outcome of AI-supported foresight is the enhancement of organizational and individual capacities to navigate uncertainty.

However, the framework introduces a second, more exploratory and disruptive pathway, referred as the *autonomous paradigm*. In this configuration, GenAI systems move beyond augmentation toward performing substantial parts of the foresight process with limited human intervention. Evidence of this trajectory can be found in studies identifying “full delegation” modes of AI use (Zoccarato et al., 2025), multi-agent foresight architectures capable of integrating data and generating scenarios (Wang, 2025), and early applications of AI in anticipatory governance (Cugurullo & Xu, 2025). In the autonomous pathway, GenAI systems may execute end-to-end foresight activities, including horizon scanning, scenario generation, evaluation, and the preparation of comprehensive foresight studies, effectively acting as semi-autonomous foresight agents. This shift increases efficiency and scalability, enabling rapid and cost-effective foresight production. Emerging market developments, including automated foresight platforms, suggest that such configurations are becoming increasingly feasible in practice.

Nevertheless, the autonomous paradigm entails fundamentally different implications for knowledge creation and futures literacy. While it may enhance efficiency and accessibility, it risks reducing the learning-oriented and reflexive dimensions of foresight, which are central to futures literacy. If foresight outputs are generated and consumed without active human engagement, the process may shift from participatory sensemaking to passive reception. Furthermore, autonomous foresight systems may reinforce dominant narratives embedded in existing data and knowledge, limiting the diversity of imagined futures (Bechthold, 2026), and create an illusion of objectivity that obscures underlying assumptions and value judgments (Floridi, 2023).

To account for these tensions, this framework incorporates a set of moderating factors that influence both pathways. These include data biases, ethical governance, transparency, and the preservation of human agency and reflexivity (Floridi, 2023; Cugurullo & Xu, 2025). These moderators shape not only the quality and diversity of foresight outputs, but also the extent to which AI-supported foresight contributes to meaningful futures literacy.

Taken together, the framework conceptualizes GenAI as enabling a dual-path transformation of foresight. On the one hand, it supports human–AI co-creation, enhancing anticipatory intelligence and futures literacy through interactive and reflexive processes. On the other hand, it opens the possibility of increasingly autonomous foresight systems that prioritize efficiency and scalability but may alter the epistemic and learning foundations of foresight practice.

The theoretical contribution of this framework lies in articulating this tension between augmentation and autonomy as a defining characteristic of AI-enabled foresight. By positioning GenAI as an enabling epistemic infrastructure operating across multiple interaction modes, the framework integrates foresight theory, knowledge management, and AI studies into a unified perspective. Moreover, it highlights the importance of human–AI co-creation as a critical mechanism for preserving the transformative potential of foresight in the age of GenAI, while recognizing the emerging trajectory toward automation as a key area for future research.

Figure 1 illustrates how GenAI operates as a mediating knowledge infrastructure, transforming inputs into foresight processes through human–AI interaction, ultimately enhancing futures literacy, while being shaped by ethical and epistemic moderators.

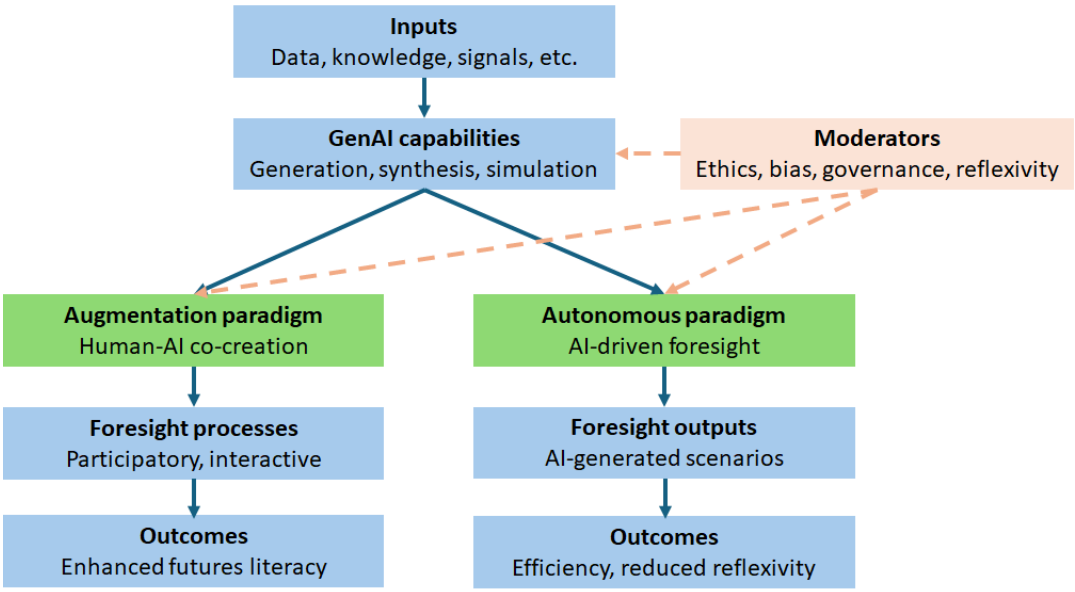

Figure 1. A dual-path conceptual framework of GenAI in foresight
Source: own work

Beyond the distinction between augmentation and autonomy, the proposed framework suggests a deeper shift in the epistemic foundations of futures studies. In the augmentation paradigm, foresight operates as a participatory epistemic process, in which knowledge about the future is co-constructed through interaction, interpretation, and reflexive learning. In contrast, the autonomous paradigm reflects a transition toward a more computational epistemic mode, in which futures are generated through algorithmic synthesis and probabilistic reasoning, with reduced human involvement in meaning-making. This distinction demonstrates that the transformation introduced by GenAI is not merely methodological, but fundamentally epistemological, redefining how futures are known, constructed, and legitimized. Understanding this shift is critical for assessing the long-term implications of AI-supported foresight for organizational learning and strategic decision-making.

Building on this epistemic shift, the framework further implies an anticipatory agency shift, whereby the locus of foresight increasingly moves from human actors toward AI systems. In the augmentation paradigm, agency remains distributed and human-centered, with AI supporting interpretation and exploration. In contrast, the autonomous paradigm reflects a relocation of anticipatory agency toward algorithmic systems, where futures are generated with reduced human intervention. This shift has important implications for accountability, responsibility, and the legitimacy of foresight outputs, particularly in organizational and policy contexts.

4 Discussion

This study sets out to examine how GenAI transforms foresight practices and contributes to the development of futures literacy. Building on the literature and the proposed conceptual framework, the findings suggest that GenAI does not simply enhance existing foresight approaches but introduces a fundamental reconfiguration of the epistemic and organizational foundations of anticipation. This epistemic shift is closely linked to a parallel transformation in anticipatory agency.

4.1. From augmentation to autonomy: A paradigmatic tension

A central insight emerging from this study is the identification of a dual-path transformation in AI-supported foresight.

In the augmentation paradigm, GenAI acts as a cognitive partner that enhances anticipatory intelligence by expanding the space of possible futures, supporting sensemaking, and enabling iterative exploration. This aligns with established views of foresight as a learning-oriented and participatory process (Miller, 2018; UNESCO, 2023), where the primary value lies in developing futures literacy rather than producing accurate predictions.

Here, the interaction between humans and AI fosters reflexivity, critical thinking, and the ability to question underlying assumptions.

In contrast, the autonomous foresight paradigm represents a more disruptive development. As generative systems become capable of performing end-to-end foresight tasks, the role of human actors may shift from active sensemakers to supervisors or consumers of AI-generated outputs. This transition reflects broader trends in AI-enabled knowledge work, where efficiency and scalability increasingly drive adoption.

This duality introduces a fundamental paradigmatic tension. While automation enhances efficiency and accessibility, it may simultaneously undermine the epistemic depth and learning potential that define foresight as a practice. The findings therefore suggest that the future of foresight will not be characterized by a linear progression toward automation, but by the coexistence and interaction of these two paradigms.

4.2. Implications for futures literacy

The distinction between augmentation and autonomy has significant implications for the concept of futures literacy. In the augmentation pathway, futures literacy is actively developed through engagement with uncertainty, exploration of alternative futures, and critical reflection on assumptions. GenAI, in this context, functions as a catalyst for anticipatory learning, enabling individuals and organizations to deepen their understanding of complexity.

However, in the autonomous pathway, the relationship between foresight and learning becomes more ambiguous. If foresight outputs are generated with minimal human involvement, the process may shift from participatory sensemaking to passive consumption. This raises the possibility of a decoupling between foresight production and futures literacy development, where organizations benefit from AI-generated insights without necessarily enhancing their internal anticipatory capabilities.

This distinction highlights a critical question for both research and practice: *Can futures literacy be meaningfully developed without active participation in foresight processes?*

The framework proposed in this paper suggests that while GenAI can increase access to foresight outputs, the transformative potential of futures literacy depends on maintaining human engagement in the process.

4.3. Reconfiguring organizational foresight practices

From an organizational perspective, the integration of GenAI into foresight practices implies a shift from resource-intensive, expert-driven processes toward more distributed, efficient, and technology-mediated approaches. This transformation lowers barriers to entry and enables a wider range of actors to engage with futures thinking.

At the same time, the emergence of autonomous foresight systems raises important questions about the role of expertise, participation, and governance. Traditional foresight practices emphasize stakeholder involvement, collective intelligence, and deliberation. In contrast, AI-driven foresight may centralize knowledge production within technological systems, potentially reducing transparency and inclusiveness.

Organizations therefore face a strategic choice between leveraging GenAI to enhance participatory foresight processes and adopting automated solutions that prioritize efficiency and cost reduction.

Rather than viewing these options as mutually exclusive, the findings suggest that organizations should develop hybrid foresight models, in which AI-driven outputs are integrated into human-centered processes of interpretation and deliberation. Such models can combine the scalability of automation with the reflexivity and contextual sensitivity of human judgment. This tension can be understood as a foresight automation paradox, whereby increasing efficiency through AI may simultaneously reduce the learning-oriented value of foresight.

This suggests that foresight capabilities may increasingly become a strategic differentiator, not only in analytical capacity but in the ability to integrate human and artificial intelligence in anticipatory processes.

4.4. Ethical and epistemic considerations

The increasing role of GenAI in foresight also introduces significant ethical and epistemic challenges. As highlighted in the literature, generative systems are prone to reproducing biases and dominant narratives embedded in their historically available data (Bechthold, 2026), which may constrain the diversity of imagined futures. In autonomous configurations, these biases may become less visible, as the underlying processes of knowledge generation remain opaque.

Moreover, the perceived authority of AI-generated outputs may create an illusion of objectivity, leading decision-makers to over-rely on automated foresight. This risk is particularly pronounced in policy and

governance contexts, where AI systems may influence anticipatory decision-making without adequate transparency or accountability (Cugurullo & Xu, 2025).

These considerations reinforce the importance of embedding ethical governance, transparency, and critical AI literacy within foresight practices. Rather than treating these factors as external constraints, they should be understood as integral components of AI-supported foresight systems, shaping both processes and outcomes.

4.5. Toward a research agenda

The conceptual framework developed in this paper opens several avenues for future research. First, empirical studies are needed to examine how different modes of human–AI interaction influence the quality, diversity, and impact of foresight outcomes. Comparative research between augmentation and autonomous approaches could provide valuable insights into their respective strengths and limitations.

Second, further work is required to explore the relationship between AI-supported foresight and futures literacy. This includes investigating how different levels of human engagement affect learning outcomes at individual and organizational levels.

Third, the development of governance frameworks for responsible AI-supported foresight represents a research priority. Such frameworks should address issues of bias, transparency, accountability, and inclusiveness, ensuring that AI contributes to sustainable and equitable futures.

Fourth, future research should examine the emergence of AI-native foresight practices, including fully automated or multi-agent systems, and their implications for the role of human agency in anticipatory processes.

4.6. Concluding reflection

Overall, this study suggests that GenAI does not simply improve foresight, but it fundamentally redefines its nature. The key challenge is not whether AI can perform foresight tasks, but how its integration reshapes the relationship between knowledge, anticipation, and human agency.

The framework highlights that the future of foresight will likely be shaped by an ongoing tension between augmentation and autonomy. Navigating this tension will be critical for ensuring that the increasing efficiency of AI-supported foresight does not come at the expense of its most valuable outcome: the development of futures literacy as a capability for understanding and shaping complex, uncertain futures.

This tension is particularly relevant in the context of sustainable organizations, where long-term decision-making requires not only efficient foresight outputs but also deep reflexive understanding of complex socio-ecological systems.

5 Conclusions

This paper examined the transformative role of GenAI in foresight practices and its implications for the development of futures literacy. It conceptualized GenAI as a knowledge infrastructure that reshapes how futures are constructed, interpreted, and utilized. In the long term, the evolution of AI-supported foresight may redefine not only how organizations anticipate the future, but who – or what – participates in its construction.

The primary contribution of the paper lies in the development of a conceptual framework, which distinguishes between two emerging paradigms of AI-supported foresight. The augmentation paradigm positions GenAI as a cognitive collaborator that enhances human sensemaking, supports participatory foresight processes, and fosters futures literacy as a learning-oriented capability. The autonomous paradigm reflects an emerging trajectory in which GenAI systems increasingly perform foresight tasks with limited human intervention, prioritizing efficiency and accessibility.

By articulating the tension between augmentation and autonomy, the paper contributes to the literature by reframing AI-supported foresight not as a linear technological progression, but as a socio-technical transformation characterized by competing epistemic logics. While autonomous foresight offers significant advantages in terms of cost reduction and scalability, it also raises concerns regarding reflexivity, diversity of future imaginaries, and the potential decoupling of foresight from futures literacy development. This highlights that the future of foresight will depend not only on technological capabilities, but on how organizations choose to configure the relationship between human and AI.

From a practical perspective, the findings suggest that organizations currently should avoid viewing GenAI as a substitute for human foresight capabilities. Instead, the most promising approach lies in developing hybrid foresight models that combine the efficiency of AI-driven processes with the interpretive and reflective capacities of human actors. Such models can ensure that foresight remains not only a tool for strategic anticipation but also a mechanism for organizational learning and capability building.

However, this study is not without limitations. As a theoretical paper, it cannot provide empirical validation of the proposed framework. Future research is therefore needed to examine how different configurations of human–AI interaction influence foresight outcomes and futures literacy in practice. Comparative studies between augmentation and autonomous approaches, as well as investigations into governance mechanisms for responsible AI-supported foresight, represent promising avenues for further inquiry.

In conclusion, GenAI has the potential to fundamentally redefine foresight. However, the key challenge is not whether AI can perform foresight tasks, but how its integration shapes the relationship between knowledge, anticipation, and human agency. Ensuring that the increasing efficiency of AI-supported foresight does not come at the expense of its most valuable outcome – the development of futures literacy – remains a central challenge for organizations navigating an increasingly complex and uncertain world. Ultimately, the future of foresight will depend not only on what AI can do, but on how organizations choose to engage with it.

Beyond Solutionism: A Pre-Implementation Diagnostic Framework for Strategic Knowledge Management Alignment

Maayan Nakash
Department of Management, Bar-Ilan University, Ramat Gan, Israel

Abstract

Despite the recognized strategic value of knowledge, many Knowledge Management (KM) initiatives fail due to "solutionism" – the premature deployment of advanced technologies without clarifying business objectives, structural knowledge requirements, or cultural readiness. To address this persistent gap, this paper introduces a pre-implementation diagnostic framework designed to guide Chief Knowledge Officers (CKOs) before designing and deploying Knowledge Management Systems (KMSs). Grounded in the Knowledge-Based View (KBV) and Socio-Technical Systems (STS) theory, the conceptual framework is empirically enriched by participant observation within a large, knowledge-intensive financial institution. The framework is anchored in the central premise that knowledge must be purposefully managed to advance specific organizational goals, thereby positioning a KMS as an enabling socio-technical infrastructure rather than an isolated technological artifact. To operationalize this perspective, the framework prescribes two integrated dimensions: (1) strategic goal setting to align KM initiatives with organizational intent, and (2) a tripartite needs assessment evaluating dynamic knowledge flows, technological specifications, and leadership and cultural commitment. Each dimension is translated into targeted diagnostic questions that convert abstract strategic intent into actionable design requirements and governance practices. By utilizing this diagnostic "compass," organizations can shift from deterministic tool selection to rigorous contextual analysis, identifying structural gaps and mitigating knowledge risks. This ensures that KMS investments generate sustained value and are deeply embedded within the organizational fabric.

Keywords: Knowledge Management Strategy, Pre-Implementation Diagnosis, Strategic Alignment, Knowledge Flow, Knowledge Risk, Socio-Technical Systems

Paper type: Academic Research Paper

1 Introduction

The contemporary volatile and complex business environment compels organizations to leverage knowledge effectively, elevating knowledge management (KM) to a strategic imperative rather than a discretionary function (Bolisani and Bratianu, 2018; Bratianu et al., 2023; do Céu Morais Cláudio and Santos, 2022). KM encompasses systematic processes for creating, structuring, sharing, and applying both explicit assets and tacit know-how to support operational effectiveness and innovation (Alavi and Leidner, 2001). To orchestrate these knowledge flows, organizations deploy knowledge management systems (KMSs) – integrated configurations of digital platforms, governance mechanisms, and work practices. Effective KMSs extend beyond mere storage; they are designed to embed knowledge into everyday workflows and translate dispersed expertise into coordinated organizational action (Thomas, 2024).

Despite sustained scholarly attention and the acknowledgment of knowledge as a critical strategic resource (Bergh et al., 2025), many KM initiatives fail to generate meaningful impact, often resulting in underutilized, symbolic, or abandoned systems (Akhavan et al., 2005; Dalkir, 2013; Haug, 2026; Koivisto and Taipalus, 2025). While prior research has extensively examined KM success factors (Conley and Zheng, 2009; Du Plessis, 2007; Jennex and Olfman, 2009) and developed retrospective maturity models (Escrivão and Silva, 2019; Henz and Oliveira, 2024), comparatively little attention has been devoted to the critical pre-implementation phase. This gap frequently manifests in organizational practice as "solutionism" – the premature deployment of advanced technologies without a clear understanding of the underlying organizational needs. Such a technology-first logic misframes KM as a purely technical challenge (Nakash and Bouhnik, 2022), creating misalignment and yielding repositories that are rich in content but poor in sustained value creation (Davenport and Prusak, 1998).

To address this gap, this study develops a structured pre-implementation diagnostic framework aimed at guiding KM decision-making. The conceptual development of this framework is empirically enriched by prolonged participant observation and ethnographic engagement within a large, knowledge-intensive organization. Designed to counter solutionism and mitigate the risk of implementation failure, the proposed framework equips Chief Knowledge Officers (CKOs) with a diagnostic compass prior to resource allocation. It is structured around two complementary dimensions: 1) strategic goal setting, which anchors KM design in business strategy, and 2) needs assessment, which translates these goals into operational requirements across

knowledge flows, technological readiness, and leadership commitment. Ultimately, this pre-implementation diagnosis ensures that KM investments result in fit-for-purpose systems that are deeply embedded in organizational workflows and sustainable over time.

2 Research Foundations: Theoretical and Field-Based Insights

2.1 Theoretical Background

The proposed diagnostic framework is grounded in complementary streams of organizational research that elucidate why KM initiatives frequently underperform when introduced without systematic prior diagnosis.

2.1.1 The Knowledge-Based View and Strategic Alignment

The Knowledge-Based View (KBV) positions knowledge as the firm's most critical strategic resource, asserting that sustained competitive advantage stems from the organization's capability to integrate, recombine, and apply knowledge in pursuit of its goals (Curado and Bontis, 2006; Eisenhardt and Santos, 2002; Grant, 1996). Within this paradigm, knowledge acquires economic value exclusively when it is embedded within organizational routines, decision-making processes, and coordinated actions. Consequently, knowledge assets that remain disconnected from core activities become inert, regardless of their scope or quality (Davenport and Prusak, 1998; Nakash and Bolisani, 2025; Nonaka and Takeuchi, 1995).

Strategic Alignment Theory complements this by establishing that organizational investments yield performance returns only when coherently linked to strategic intent (Henderson and Venkatraman, 1999). In the KM domain, misalignment occurs when systems are implemented without a clear articulation of how they resolve priority challenges. Under such conditions, KM initiatives may function efficiently at a technical level yet remain strategically irrelevant (do Céu Morais Cláudio and Santos, 2022). This theoretical linkage underscores that the efficacy of a KMS is fundamentally contingent upon its alignment with broader organizational strategies rather than its technological completeness.

2.1.2 The Socio-Technical Nature of Knowledge Management

KM is inherently socio-technical, emerging from the continuous interaction between digital infrastructures and social systems (Assegaff and Hussin, 2012; Dalkir, 2013; Šajeva, 2010). Socio-Technical Systems Theory (STS) emphasizes that organizational effectiveness relies on the joint optimization of technical components (e.g., platforms, tools, formal protocols) and social components (e.g., professional roles, organizational norms, leadership practices, motivational structures) (Cherns, 1976, 1987). From this perspective, a KMS is not a neutral repository; it is an organizational arrangement that both shapes and is shaped by everyday work practices (Nakash and Bouhnik, 2022).

The STS lens explains why technology-centric KM initiatives frequently fail. Systems designed without regard for existing workflows, professional identities, or internal power dynamics often encounter resistance, superficial adoption, or the creation of parallel "shadow" workarounds. These outcomes are manifestations of socio-technical misalignment. Effective KM therefore requires congruence between system affordances and organizational realities, positioning social conditions – such as trust and psychological safety – as constitutive elements of the KMS rather than secondary considerations (Figueiredo et al., 2025; Liebowitz and Beckman, 2020; Min et al., 2022; Thomas, 2024).

2.1.3 Knowledge Flow Dynamics

A further foundation lies in the processual view of knowledge as a dynamic and situated organizational asset (Bratianu, 2023; Bratianu and Bejinaru, 2026). Knowledge generates value through movement – across individuals, departments, and tasks – via interconnected processes of creation, codification, sharing, and application (Durst and Zieba, 2019; Liebowitz and Beckman, 2020; Nonaka and Takeuchi, 1995). Therefore, KM effectiveness is measured by the continuity and reliability of these knowledge flows, not merely by the capacity of storage repositories (Davenport and Prusak, 1998; Jennex and Olfman, 2009).

These flows are frequently disrupted by structural silos, fragmented digital ecosystems, and misaligned incentives (Nakash, 2025). Such challenges are compounded by the fundamental distinction between tacit and explicit knowledge. Tacit knowledge, which is deeply embedded in human experience and judgment, resists rigid codification and relies heavily on interpersonal interaction and trust. Conversely, explicit knowledge benefits from systematic documentation and standardization (Collins, 2019; Nonaka, 1994). Recognizing these fundamental differences is essential to avoid structural mismatches that frequently undermine KM implementations despite heavy technological investments.

2.2 Participant Observation and Contextual Methodology

Complementing its theoretical foundations, the development of the diagnostic framework was informed by prolonged participant observation within a complex, knowledge-intensive organizational setting. This ethnographic engagement spanned 18 months at a major financial institution with approximately 8,000 employees, providing a rich context for observation across diverse divisions, including retail banking, operations, risk management, compliance, and strategy. To ensure methodological rigor and uphold established ethical standards within the scientific community (Lipson, 1994), the research was conducted while strictly maintaining participant anonymity and data confidentiality.

The researcher adopted an embedded observer role, facilitating access to both formal KM initiatives and informal daily work routines through a multifaceted qualitative data collection strategy. This involved sustained field presence and reflective journaling, complemented by ongoing informal and semi-structured conversations with a broad cross-section of the workforce – ranging from CKOs and KM tool implementers to frontline knowledge leaders.

The primary focus of this observation was not to evaluate specific software tools, but rather to examine the pre-implementation ecosystem: specifically, how KM initiatives were conceptualized, justified, translated into system requirements, and ultimately experienced within the organization. The observational data were analyzed using an inductive thematic approach (Clarke and Braun, 2017) to uncover recurring systemic tensions. Ultimately, these field-observed misalignments directly informed the identification of the "diagnostic blind spots" that constitute the structural basis of the proposed pre-implementation framework.

3 Conceptual Anchor

Building upon the theoretical and empirical foundations discussed previously, the proposed diagnostic approach is anchored in a singular conceptual premise: KM must function as a strategic conduit rather than an isolated administrative end. When conceptualized merely as a functional imperative or confined within a technological silo, KM initiatives risk becoming symbolic exercises detached from actual organizational value creation.

Consequently, effective KM necessitates deliberate calibration with specific organizational objectives. Core knowledge processes – spanning acquisition, documentation, sharing, and application – must be explicitly designed to drive tangible outcomes, such as accelerating onboarding efficiency, minimizing operational errors, or enhancing competitive differentiation. Within this paradigm, knowledge derives its value strictly from its capacity to inform action and elevate performance, rather than from its mere codification or storage.

Accordingly, KMSs are conceptualized not as self-contained technological artifacts, but as socio-technical infrastructures that enable knowledge work. Their architecture, scope, and governance must dynamically mirror both strategic intent and operational realities. This pragmatic orientation serves as the interpretive lens for the proposed framework, dictating the translation of abstract strategic aspirations into concrete, actionable system requirements through targeted diagnostic inquiry.

4 The Diagnostic Framework

To operationalize the conceptual anchor, the proposed diagnostic framework is structured around two sequential dimensions:

- The “Why” – Strategic Goal Setting (Section 4.1)
- The “What” and “How” – Needs Assessment (Section 4.2)

This deliberate sequencing ensures that KM initiatives are firmly rooted in strategic intent prior to the translation of broad objectives into specific operational and technical requirements.

4.1 Strategic Goal Setting

Purpose: The initial diagnostic phase is designed to mitigate the risk of "solutionism" – the premature deployment of technology in search of a problem. Its primary objective is to guarantee that KM interventions address critical organizational imperatives rather than degrading into symbolic, isolated IT projects.

Table 1: Guiding Questions for Strategic Goal Setting

Dimension	Guiding Diagnostic Questions
Strategic Necessity	• Is the KM initiative explicitly linked to the organization's overarching strategy? • Why is a KMS required at this specific point in time?
Process Alignment	• Which core business processes will the KMS support? • How will these processes be transformed or enhanced?
Success Metrics	• What Key Performance Indicators (KPIs) will define success? • How will KM's contribution to organizational performance be measured?
Operational Feasibility	• Have employees' daily workflows been analyzed to inform design? • Which goals are prioritized, and what trade-offs (scope, speed, investment) are acceptable?

Rationale: These guiding questions function as a strategic threshold, mandating clarity before any technological resource allocation occurs. KM initiatives frequently originate from vague aspirations, such as "enhancing collaboration", which lack actionable specificity and baseline metrics. If organizational leadership cannot articulate a compelling urgency for the KM investment (e.g., mitigating tacit knowledge loss due to expert retirement, or accelerating time-to-market in R&D), the initiative is highly vulnerable to becoming a superficial undertaking.

Furthermore, this phase forces an explicit alignment with macro-organizational goals; for instance, an enterprise strategy focused on global expansion requires a KMS architecture deliberately optimized for cross-border knowledge sharing. By interrogating how core processes will demonstrably change, the framework compels KM leaders to precisely define the organizational "to-be" state. Ultimately, shifting the discourse from technological implementation to measurable value creation ensures the system is evaluated on its capacity to enable action rather than its mere operational existence.

4.2 Needs Assessment

Once the strategic imperative (the "Why") is firmly established, the diagnostic framework advances to the operational level. The needs assessment phase translates overarching strategic goals into actionable system specifications across three interdependent domains:

- Knowledge Flow Processes (Section 4.2.1)
- Technological Implementation Specification (Section 4.2.2)
- Leadership and Cultural Commitment (Section 4.2.3)

Together, these dimensions provide a holistic evaluation of what specific knowledge is required, how it should circulate throughout the organization, which technical architectures can best enable this movement, and whether the enterprise possesses the cultural and leadership capacity to sustain it.

4.2.1 Knowledge Flow Processes

Purpose: Mapping knowledge flows is essential for understanding the lifecycle of knowledge within the organization – specifically how it is acquired, documented, shared, and applied. Effective KMS design is fundamentally contingent upon identifying structural gaps, characterizing knowledge consumers, pinpointing critical points of application, and diagnosing systemic barriers to knowledge dissemination.

Table 2: Guiding Questions for Knowledge Flow Processes

Dimension	Guiding Diagnostic Questions
General Ecosystem	• Who consumes the knowledge? • Are consumers centralized or dispersed? • What are the main work interfaces?
Knowledge Acquisition	• What are the primary sources? • How reliable are they? • Who originates the knowledge? • What proportion is tacit vs. explicit?
Knowledge Documentation	• Where are the main documentation nodes? • How much knowledge must be captured and in what format? • Who validates and approves content? • Is there a plan for content currency?

Dimension	Guiding Diagnostic Questions
Knowledge Sharing	• How accessible and retrievable is the knowledge? • Is sharing institutionalized or ad hoc? • What are the current channels? • What barriers exist (technical, procedural, cultural)? • Can professional communities be leveraged?
Knowledge Application	• When and how is knowledge needed (real-time vs. on-demand)? • Preferred consumption mode: Push (automated alerts) or Pull (active search)? • Is the knowledge temporary or permanent?

Rationale: Addressing these specific diagnostic questions ensures that KM initiatives accurately reflect the socio-technical realities of the workforce rather than being dictated solely by software capabilities. For example, precise user segmentation is critical; an R&D department and a sales division inherently require different levels of knowledge granularity, rendering a “one-size-fits-all” system architecture highly detrimental. Furthermore, if the diagnosis reveals that the organization's most critical asset is tacit knowledge, a static document repository will inevitably fail. In such scenarios, the architectural solution must purposefully emphasize "connecting people to experts" rather than merely "collecting documents."

Additionally, rigorously assessing knowledge quality and ownership protocols prevents the KMS from degrading into an obsolete repository – a significant knowledge risk that erodes user trust. This analysis also exposes whether current knowledge-sharing behaviors rely on ad hoc individual efforts or systemic planning, thereby enabling targeted managerial interventions to dismantle structural silos and alleviate time constraints. Retention strategies must also be explicitly tailored based on whether the knowledge is tribal (deeply embedded in the minds of specific experts) or ephemeral. Finally, aligning consumption modes with actual workflows is vital for sustained adoption: a frontline support agent, for instance, requires a robust "Pull" mechanism (rapid search during live client interactions), whereas a compliance officer necessitates a reliable "Push" mechanism (automated alerts regarding regulatory shifts).

4.2.2 Technological Implementation Specification

Purpose: Technological readiness is a critical determinant of KM success. This dimension evaluates whether the organization’s existing digital infrastructure can robustly support the defined knowledge goals or if it requires significant augmentation. The overarching objective is to ensure seamless integration into daily workflows, thereby avoiding the creation of fragmented technological silos that undermine system adoption.

Table 3: Guiding Questions for Technological Implementation Specification

Dimension	Guiding Diagnostic Questions
Existing Infrastructure	• Which systems are currently in place (CRM, ERP, SharePoint, Slack)? • Do they enable or conflict with KM processes?
Integration & Interoperability	• Do systems integrate smoothly or operate as isolated silos? • Can knowledge flow automatically between the proposed KMS and core business applications?
Search & Retrieval	• Is there a robust, multi-channel search engine indexing federated repositories? • How effective is retrieval in terms of speed and relevance?
Functional Gaps	• Which knowledge processes are unsupported by current technology?
User Accessibility (UX)	• How easily can employees access systems (Single Sign-On, mobile, remote)? • Is the interface intuitive enough to minimize friction?
Security & Governance	• What security constraints and compartmentalization policies exist? • How do these balance protection with accessibility?

Rationale: Addressing these questions directly mitigates the risk of deploying technological tools that are fundamentally incompatible with the existing digital ecosystem. If a KMS introduces procedural friction, employees will inevitably bypass it. Rigorous integration checks avert the creation of isolated "knowledge islands" where critical knowledge is trapped and rendered unsearchable. Search and retrieval capabilities are equally paramount; without highly intuitive, federated search experiences, user trust in the system erodes rapidly.

Furthermore, security governance must strike an optimal equilibrium – avoiding both excessive compartmentalization, which stifles cross-functional knowledge flow, and unchecked accessibility, which exposes the organization to severe knowledge risks (such as unauthorized exposure or misuse). Ultimately, this

diagnostic specification converts abstract operational needs into concrete technical requirements, ensuring the technology functions as a seamless enabler rather than an administrative barrier.

4.2.3 Leadership and Cultural Commitment

Purpose: This dimension assesses the organization's socio-cultural infrastructure – namely, leadership and organizational culture – which profoundly influences KM outcomes. It is designed to distinguish genuine strategic intent from merely symbolic gestures, evaluating whether existing governance structures, motivational frameworks, and organizational mindsets can sustain a robust knowledge culture.

Table 4: Guiding Questions for Leadership and Cultural Commitment

Dimension	Guiding Diagnostic Questions
Leadership Support	• Is there visible backing from C-level executives? • Are leaders modeling desired behaviors?
Cultural Readiness	• Does the organization foster psychological safety for learning from mistakes? • Is knowledge hoarding rewarded or discouraged?
Incentives & Motivation	• What mechanisms reward knowledge sharing and KMS adoption? • Are incentives intrinsic (recognition) or extrinsic (bonuses), and do they align with team goals?
Sustainability & Vision	• Is KM viewed as a continuous process or a one-time project? • Are resources allocated for long-term maintenance?

Rationale: While technology provides the structural capacity for knowledge exchange, organizational culture dictates the behavioural willingness to engage in it. Visible and sustained leadership sponsorship is pivotal; absent this support, KM is quickly relegated to a discretionary function, rendering it highly vulnerable during budget constraints.

Furthermore, incentive structures must systematically address the individual motivational calculus: if performance metrics disproportionately reward isolated individual achievement, employees lack a rational imperative to share knowledge. By exposing whether the initiative is merely symbolic, this framework forces a critical reality check prior to implementation: are genuine behavioural shifts feasible, or is the organization simply deploying software? These insights are crucial for developing tailored change management strategies to dismantle entrenched cultural barriers.

5 Discussion

This study bridges a critical gap in contemporary KM literature and practice by shifting the analytical focus from post-implementation maturity to pre-implementation diagnosis. While traditional KM maturity models provide valuable descriptive benchmarks for evaluating existing organizational capabilities, they are inherently retrospective (Escrivão and Silva, 2019; Henz and Oliveira, 2024). By proposing a structured diagnostic compass, this research moves beyond the pervasive trap of "solutionism," offering a prescriptive, methodological bridge that connects abstract organizational theories with the localized, operational realities of system deployment prior to implementation.

A primary theoretical contribution of this framework is the reconceptualization of organizational "readiness." Moving away from technologically deterministic models that equate readiness solely with IT infrastructure (Alavi and Leidner, 2001; Thomas, 2024), this approach strictly applies STS theory to the pre-implementation phase. Specifically, the proposed diagnostic dimensions systematically address the four interacting variables central to STS configurations: technology, people, tasks, and structure (Bostrom and Heinen, 1977). The technological specification targets the technology; the assessment of cultural commitment evaluates the people; mapping knowledge flows addresses the tasks; and strategic goal setting aligns with the organizational structure. This mapping highlights that technological maturity alone is entirely insufficient for success; rather, the technological architecture must be jointly optimized with these strategic, cultural, and processual dimensions. By exposing how a lack of psychological safety or a culture that implicitly rewards knowledge hoarding can derail even the most advanced platforms, the framework demonstrates that socio-technical congruence is a fundamental prerequisite for adoption, not merely a secondary enabler.

Furthermore, the framework effectively operationalizes the KBV (Grant, 1996) by translating its abstract principles into an actionable diagnostic protocol. Instead of treating knowledge as a static commodity to be warehoused, the needs assessment focuses on mapping dynamic knowledge flows and rigorously differentiating between tacit and explicit requirements. By interrogating actual work-as-done – rather than idealized, formal

procedures – the framework uncovers critical socio-technical friction points, such as tacit knowledge bottlenecks or structural mismatches in knowledge consumption modes (e.g., Push vs. Pull). This empirical grounding ensures that knowledge assets are deliberately mobilized to enhance performance and inform action, thereby fulfilling the core tenet of the KBV.

From a managerial and implementation standpoint, the diagnostic process functions as a vital mechanism for early intervention and risk mitigation. It equips CKOs with a structured mandate to identify structural silos, evaluate the authenticity of leadership commitment, and calibrate technical specifications before irrecoverable resources are expended. Consequently, this diagnostic phase actively shifts the perception of KMSs from peripheral IT projects to core strategic infrastructures intricately linked to organizational performance outcomes.

Finally, acknowledging the volatility of the contemporary business environment (Bolisani and Bratianu, 2018; Botha et al., 2014; Bratianu et al., 2023), the framework is expressly designed for iterative application. As strategic priorities pivot and digital ecosystems inevitably evolve, the diagnostic tool acts as a continuous compass, providing a current operational bearing while supporting necessary recalibrations. This longitudinal adaptability ensures that KM initiatives remain deeply embedded within the organizational fabric—functioning as resilient, evolving infrastructures rather than finite, standalone projects.

6 Conclusion

Successful KMS implementation fundamentally transcends mere technological readiness; it necessitates deliberate alignment with strategic objectives, optimized knowledge flows, and unwavering cultural commitment. The proposed pre-implementation diagnostic framework provides a structured methodology to achieve this essential socio-technical congruence. By integrating strategic goal setting with a comprehensive, tripartite needs assessment, the framework shifts the organizational focus from deterministic tool selection to context-driven analysis. Rather than prescribing universal solutions, it compels organizations to engage in critical diagnostic inquiry, thereby mitigating the risk of "solutionism" and maximizing long-term value realization. Future research should seek to empirically validate this framework across diverse sectors, specifically exploring the longitudinal and structural relationships between these pre-implementation diagnostic indicators and measurable organizational performance outcomes.

Emotional Knowledge and Manipulative Design in AI-Powered Fashion Recommendation Systems

Hairong Zhai, Farag Edghiem
Faculty of Arts and Humanities, Manchester Metropolitan University, Manchester, United Kingdom

Abstract

AI-powered recommendation systems have evolved to offer more than just convenience, increasingly shaping consumer identity and purchasing behaviour in the online fashion retail sector. In the context of fashion e-commerce, recommendation systems assist users in navigating information overload by predicting their preferences and suggesting items that align with their tastes. Technical advances, such as deep learning and multimodal integration, significantly improved the performance of fashion recommendation systems. These systems can now incorporate product images, textual descriptions, reviews, as well as videos to capture style, fit, and context more precisely. Nevertheless, these technical advances that could enhance accuracy also empower greater influence over how consumers perceive themselves, others, and what is considered desirable.

Extant research has predominantly focused on technical search engine optimisation and algorithmic performance, leaving the ethical, psychological, and emotional dimensions of fashion recommendation comparatively neglected, particularly significant given fashion's intimate links to self-image, body perception, and social validation. Online interfaces routinely employ dark patterns such as scarcity cues, obstruction, and interface interference to exploit cognitive biases and bounded rationality. Users frequently feel manipulated even when aware of it, expressing frustration and resignation toward persuasive design. Manipulation and autonomy have been identified as central ethical challenges in AI-based systems, alongside concerns about the algorithmic exploitation of vulnerabilities such as insecurity and compulsive tendencies. These debates have, however, largely overlooked the fashion-specific context and the tacit, emotional, and relational knowledge that such systems produce, reshape, and exploit.

This paper contributes towards addressing the paucity of research on emotional fashion recommendation by examining the implementation of manipulative design strategies, that is integrated into AI-powered fashion recommendation systems, and how users experience them. This study conceptualises fashion recommendation systems as socio-technical, arguing that they manage not only data, but also tacit, emotional and relational knowledge. Six semi-structured interviews were conducted with Generation Z fashion consumers in the United Kingdom with data analysed thematically to explore emotional and subjective responses to algorithmic persuasion, urgency cues, social validation signals, and curated recommendation feeds. The study findings make the following contributions: it extends dark pattern and algorithmic persuasion research into the under-explored domain of fashion; it foregrounds the emotional dimensions of manipulation, showing how aesthetic and social cues shape identity-related behaviour beyond cognitive bias; and it offers practical ethical insights for designers, retailers, and policymakers developing more transparent, responsible, and human-centred recommendation systems.

Keywords: AI-powered Recommendation Systems, AI-driven Fashion Retail, Manipulative Design and Dark Patterns, Digital Ethics, Tacit and Emotional Knowledge

Paper type: Academic Research Paper

1 Introduction

It has been frequently debated that when consumers mention a product in conversations, their social media feeds ‘ For You Page’ flood with related advertising content. More persistently when searching for fashion items algorithmic suggestions carry on across platforms. These increasingly recognised digital experiences are powered by AI-driven recommendation systems, technologies designed to track user behaviour and deliver personalised suggestions. Recommendation systems use complex algorithms to process extensive amounts of user data, helping individuals navigate overwhelming product landscapes and discover items aligned with their tastes and interests (Masciari et al., 2024).

In the fashion domain, recommendation systems play a particularly persuasive role. They not only suggest products based on an individual’s browsing and purchasing history, but also factor in social signals, aesthetic preferences, and real-time trend analysis. Social-network-based fashion recommendation models consider factors such as a user’s social circle, fashion product attributes, and stylistic suggestions that make consumer feel personally and socially validated (Chakraborty et al., 2021). The economic benefits for fashion retailers are clear, as these algorithms enhance customer engagement, increase sales, and provide a competitive edge.

However, over-reliance on recommendation systems raises growing concerns. Previous studies show that nearly all users are aware of personalised recommendations and acknowledge difficulty resisting their influence,

even when they are aware of manipulative design patterns (Bongard-Blanchy et al., 2021; Mathur et al., 2019). While there is limited academic work clearly linking manipulation and fashion recommendation systems, this study aims to critically examine the manipulative design strategies employed by AI-powered fashion recommendation systems to influence consumer behaviour, and to explore the ethical implications of fashion recommendation systems for consumer autonomy.

2 Theoretical Background

2.1. The Evolution and Application of AI-Based Recommendation Systems

Recommendation systems have become an essential component of modern e-commerce, offering a solution to the "information overload" problem faced by consumers (Geetha & Renuka, 2019). A recommendation system is to predict a user's preference for a set of items, such as movies, music, or fashion items. Early recommendation methods relied on collaborative filtering and content-based filtering, but recent advancements in AI, particularly the application of deep learning models, have significantly enhanced their accuracy and scalability. Geetha and Renuka (2019) note that deep learning, a sub-domain of machine learning, is utilised in RSs to enhance the feature of predicted outputs. Similarly, Chakraborty et al. (2021) highlight the use of deep matrix factorisation models and neural autoregressive approaches in collaborative filtering for fashion, which helps provide a more personalised and effective shopping experience. The social-network-based fashion recommendation system also leverages information about a user's social circles and fashion trends, further personalising recommendations and influencing purchasing decisions (Chakraborty et al., 2021).

Traditional recommender system approaches, such as collaborative and content-based filtering, have significant limitations when applied to fashion. These stem primarily from the irregularity of individual purchase histories and the inadequate representation of visual attributes, as the aesthetic complexity of fashion items is rarely captured by category names and metadata (Liao et al., 2022). Consequently, more recent research has shifted towards multimodal recommendation models that integrate richer sources of information. These models incorporate product images to convey colour, silhouette, and pattern; textual descriptions and customer reviews to communicate perceived fit and quality; and video-based content to capture movement and real-world garment presentation (Deldjoo et al., 2023).

Another challenge is predicting fit, which is a key driver of consumer dissatisfaction and product returns in online fashion retail. AI-enhanced systems now address this issue by using biometric data, purchase feedback and machine learning techniques to improve size and fit recommendations (Deldjoo et al., 2023). Therefore, these developments represent a significant shift towards models that are visually and contextually aware, rather than purely data-driven. However, as recommendation systems become increasingly adaptive and AI-driven, they also gain the capacity to influence consumer decisions in subtle and often unrecognised ways.

2.2. Manipulative Design and "Dark Patterns"

Manipulation refers to the intentional attempt to influence someone’s decisions or behaviour in a way that undermines their rational thought or ability to make their own decisions. (Buss, 1987) In psychology field, manipulation is a mind control, specifically abuse of power, which is domination. (Van Dijk, 2006) It’s different from persuasion, which allows space for informed consent. Manipulation often targets cognitive biases, emotional vulnerabilities, or informational asymmetries to steer choices in a concealed or coercive manner. According to Susser, Roessler and Nissenbaum (2019), manipulation in digital environments occurs when systems 'covertly influence users by targeting their subconscious vulnerabilities', often through opaque algorithms and behavioural data mining. In the context of digital commerce, this can include encouraging consumers to make purchases by using urgency cues, biased defaults or aesthetic triggers that override reflective decision-making. Although such strategies may boost engagement and conversions, they raise significant ethical issues regarding user self-determination and fairness (Mathur et al., 2019).

Manipulative design through the lens of "dark patterns”, which is in user experiences, a persuasive design that intentionally coerce and deceive users into actions against their best interests, such as nagging, obstruction and interface interference (Gary et al., 2018). Dark patterns are believed to be effective because they manipulate cognitive biases and human bounded rationality (Bösch et al., 2016; Waldman, 2020). AI-powered recommendation systems push fast fashion by continuously feeding users’ decisions tailored to preferences and emerging trends. This personalisation can lead to compulsive buying, creating endless loops of new suggestions that fuel overconsumption and environmental harm.

2.3 Manipulative Design in Fashion Recommendation Systems

AI-powered recommendation systems in the fashion industry not only predict consumer preferences, but also increasingly shape them. Through interface design and algorithmic personalisation, these systems are blurring the boundary between assistance and manipulation (Susser et al., 2019). In the context of fashion, an industry deeply linked to self-expression and identity, such influence takes on an emotional dimension, enhancing desires, insecurities, and social aspirations (Entwistle, 2015; Belk, 2013).

Urgency cues, such as “only 2 left in stock” or “sale ends in 3 hours” are among the most common dark patterns in online fashion platforms. These features increase consumers ’fear of missing out (FOMO) and loss aversion, psychological biases that trigger impulsive purchasing (Gray et al., 2018; Mathur et al., 2019). In algorithmic systems, urgency cues are often personalised, generated in real time based on user engagement data, thereby enhancing their persuasive power. While initially intended to drive efficiency in decision-making, these cues manipulate affective states like anxiety and excitement, resulting in reduced reflective thought before purchase.

Another dominant manipulative feature is social validation. Recommender systems frequently display messages such as '10 people bought this in the last hour' or 'popular among people like you'. These design patterns simulate social proof, targeting users' desire for acceptance and belonging to encourage conformity (Cialdini, 2009). On fashion platforms in particular, this social mirroring is powerfully effective because fashion choices are deeply social and identity-affirming (McCracken, 1986). Even when generated by algorithms, the perceived approval of others can alter individual taste and reinforce collective trends, aligning consumer behaviour more closely with commercial objectives than personal expression.

Aesthetic persuasion is more sophisticated yet equally powerful. AI-driven recommendation feeds are visually tailored to stimulate aesthetic desire through lighting, body imagery and visual repetition (Nasser, 2023). Platforms such as Instagram and Pinterest employ algorithmic aesthetics to create an illusion of harmony and belonging by matching colour tones, models, and visual style (Li et al., 2025). This aesthetic uniformity influences emotional engagement and perceived self-congruence, prompting users to equate algorithmic beauty with their own aspirations. Under these circumstances, the recommender system serves not only as a sales tool, but also as a cultural script that guides users in what to desire and how to construct their identity.

Research on this topic has so far focused on the efficiency of algorithms and data ethics, with few studies exploring the emotional impact of algorithmic manipulation on consumers. In the context of fashion, this emotional entanglement is compounded because the consumption of clothing interacts with body image, self-esteem, and the formation of identity (Dittmar, 2008). When users are exposed to aesthetically persuasive and socially validated recommendations, they may internalise these cues as aspirational signals, thereby reinforcing algorithmically mediated standards of beauty and taste. Therefore, algorithmic manipulation in fashion is an affective and ethical issue as well as a commercial one, as it changes how consumers feel, desire, and define themselves in digital retail spaces.

2.4 Ethical Considerations and Algorithmic Exploitation of Vulnerabilities

The ethical implications of AI-based recommendation systems extend beyond just user privacy and data security. The literature identifies more insidious forms of harm, particularly the potential for algorithms to exploit human vulnerabilities. Strümke et al. (2023) introduce the critical concept of machine learning models that imitate human characteristics which are considered vulnerabilities, such as young age, depression, or a tendency towards gambling addiction. This approach raises ethical alarms around emotional manipulation and mental health impact. The authors caution that decisions made by algorithms based on these 'vulnerable state representations' could be perceived as manipulative and exacerbate the situation of vulnerable individuals.

The fashion industry is a domain where exploitation is particularly concerning, given its emphasis on social trends, self-image, and impulse purchases. An AI system that identifies a user's insecurities or tendency to shop emotionally could, intentionally or not, make recommendations that reinforce these vulnerabilities. Previous scholars indicate that most participants were aware of manipulative design patterns but still felt they could not avoid or resist them in practice (Bongard-Blanchy et al., 2021), while some participants described ‘feeling manipulated even when they knew it’, expressing frustration and resignation toward online persuasive tactics. This tension, described by Elliott 2024, as a form of algorithmic anxiety, reflects a deeper uncertainty in which consumers begin to question whether their desires are genuinely their own or the product of algorithmic construction. As a result, participants expressed a desire for greater transparency from online platforms, seeking clearer communication about the intent behind personalised and persuasive design. Masciari et al. (2024)

emphasise the importance of designing fair and transparent systems to address these ethical implications, highlighting that responsible AI development is essential for achieving equitable and non-exploitative outcomes.

2.5 Research gaps and research question

Although AI-based recommendation systems have received extensive scholarly attention, most studies in the fashion domain remain technically driven, emphasising algorithmic design, prediction accuracy and system typology rather than user experience (Deldjoo et al., 2023; Shirkhani et al., 2023; Guan et al., 2025). This reveals a significant gap between the technological optimisation of recommendation systems and their psychological and ethical implications in fashion retail.

RS 1. How do AI-powered fashion recommendation systems manipulate consumer behaviour through design and algorithmic personalisation, and what are their perceptions and emotional responses?

Research on dark patterns has begun to address user experience more broadly. Bongard-Blanchy et al. (2021) called for further investigation into how users perceive manipulative design features, while Gray et al. (2021) found that users experience frustration, resignation and loss of control when confronted with manipulative interfaces. Liao et al. (2022) further explored how different algorithmic models affect user trust and credibility. However, none of these studies have examined these dynamics specifically in fashion, where visual, social and identity factors heighten emotional vulnerability.

RS 2. What ethical issues arise from the use of manipulative AI design in fashion recommender systems?

Masciari et al. (2024) identify manipulation and autonomy as major ethical challenges in AI-based recommender systems, yet acknowledge these dimensions remain largely conceptual rather than empirically tested. The fashion industry is closely tied to self-presentation, body image and social validation, that has notably been absent from this ethical discourse. This study addresses these gaps by empirically examining how manipulative design features in AI-powered fashion recommendation systems influence consumers' perceptions, emotional experiences, and sense of autonomy, contributing to a more ethically responsible approach to algorithmic innovation in digital fashion.

3 Methodology

This study adopts a qualitative research design using semi-structured interviews to gain in-depth insights into how consumers perceive and emotionally respond to manipulative features embedded in AI-powered fashion recommendation systems. Qualitative methods are particularly suited to capturing the subjective, emotional, and interpretive dimensions of consumer–technology interactions (Creswell, 2013; Denzin & Lincoln, 2018). Through open-ended dialogue, this approach enables a deeper understanding of how algorithmic persuasion and digital personalisation shape shopping behaviour and perceptions of autonomy in online fashion contexts.

A purposive sampling strategy was employed to recruit participants who represent active Gen Z fashion consumers in the United Kingdom. Generation Z, typically defined as individuals born between 1995 and 2010, are the most digitally immersed consumers, known for frequent online shopping and high engagement with social media and fashion trends. Six participants aged 20 to 30 were interviewed, all residing in the UK. This age group aligns with prior research identifying Gen Z as the dominant demographic shaping digital retail and algorithmic consumption.

Interviews were conducted in person between September and October 2025, which are essential when exploring affective responses to digital experiences. Each interview lasted approximately 20–30 minutes and followed a semi-structured format with open-ended questions concerning participants' experiences with personalised fashion recommendations, targeted advertising, and perceptions of manipulation or autonomy. All participants were informed of the study's purpose and provided consent prior to participation. Interviews were audio-recorded and transcribed verbatim for analysis. Data were analysed thematically following Braun and Clarke's (2006) six-phase framework. Initial codes were generated from the interview transcripts and then refined into broader themes that reflect consumer emotions, perceptions of AI-driven recommendation systems, and experiences of algorithmic persuasion.

4 Findings

The thematic analysis revealed the following four main findings: (1) AI-powered fashion recommendation systems are perceived as both helpful and manipulative; (2) the most salient manipulative mechanisms are urgency, repetition and social proof; (3) participants are aware of these tactics yet still experience emotional pressure; and (4) there are ethical concerns around autonomy, privacy and creativity. Overall, the findings

demonstrate that fashion recommendation systems not only assist with product discovery, but also mediate tacit, emotional and relational forms of knowledge. This shapes what consumers find desirable and how they interpret their own preferences.

4.1 Between convenience and coercion: recommendation as both helpful and manipulative

Participants rarely viewed recommendation systems as either entirely positive or entirely negative, describing them as simultaneously useful and manipulative. Many appreciated personalised suggestions that saved time and matched their taste or browsing behaviour. Participant 5 noted that recommendations were useful because they "speed up finding what you want." However, this usefulness was consistently qualified by discomfort. Participant 6 argued that recommendation systems ""puts you in a little box you never come out of... They're always going to go for what you're always on. But I'm not always on the same thing, my style changes all the time. I feel like the recommendation ruins it for me." It reflects that AI recommendation system effectively reduces individuality and encourages consumers to "dress like everyone else." Participant 4 reflected that repeated exposure can create a false sense of desire, making consumers think "it's my own idea" when a product has simply been pushed repeatedly. Participants did not reject personalisation itself, rather, they objected to assistance becoming coercive.

4.2 Manipulative mechanisms: repetition, scarcity and social validation

Three mechanisms emerged as especially prominent: repetition, urgency and social proof. Repetition was among the most frequently cited tactics, with participants reporting exposure to the same products across multiple platforms after a single search. Participant 5 recalled an advertisement appearing "over 20 times" even after clicking "not interested", while Participant 4 described cross-platform tracking from Google to Instagram as "weird" and subtly influential.

Scarcity and urgency cues, such as "discount ends in 24 hours" or "only two left in stock" were widely recognised as manipulative yet acknowledged as effective. Participants admitted that countdown timers could influence their behaviour, particularly when prices genuinely increased afterwards. As Participant 6 admitted, "Even though I know it's a marketing trick, I still sometimes fall for it." These responses highlight that scarcity cues are effective not because consumers fail to recognise them, but because they trigger emotional states that interfere with rational decision-making.

Social validation messages such as "545 people bought this" produced more mixed reactions. Participant 3 stated that if too many people had purchased the same item, she would be less inclined to want it, valuing individuality over conformity. Even this rejection confirms the role of relational knowledge in fashion consumption, with participants interpreting such prompts through the lens of social comparison, belonging and distinction.

4.3 Awareness without resistance: emotional responses to algorithmic persuasion

A key finding was that awareness of manipulation did not prevent participants from experiencing its emotional effects. Most understood how algorithms used browsing history and behavioural data to shape recommendations, yet this awareness coexisted with frustration, resignation and unease. Participant 3 described her phone as "stalking" her, while Participant 5 openly acknowledged purchasing products she did not need following repeated algorithmic exposure.

Participants were not simply misled by false information, but nudged emotionally through anxiety, urgency, and repetition. This indicates that algorithmic persuasion not only alters what consumers know, but also shapes how they feel about their own decision-making.

4.4 Autonomy, privacy and ethical concerns

Most participants claimed a sense of control over their purchases, yet often framed this autonomy as something requiring active defence through planning ahead, rejecting cookies, or comparing options across multiple sites. Even those who felt personally resistant expressed concern that less experienced shoppers might be more vulnerable. Privacy concerns were significant, with participants uncomfortable about the extent of data collection even when accepting it as unavoidable. Participant 3 felt platforms wanted "height, weight, blood... literally everything", while Participant 4 questioned why brands should use his data when he could simply search for products himself. Some were willing to tolerate data use if it improved relevance, indicating an uneasy trade-off between convenience and surveillance. These responses emphasise the fundamental ethical conflict

between personalisation and the right to informed consent. Users are rarely given meaningful control over how their data is collected, processed, or used to influence their behaviour.

Participants also expressed concern that recommendation systems were limiting their sense of self and creative freedom beyond individual purchases. Participant 3 argued that AI "strips the artist from the artwork", while Participant 6 suggested that excessive recommendations made it "hard to hear your own opinion", particularly significant in fashion, where consumption is closely tied to identity and self-expression. These concerns are particularly significant in the context of fashion, where consumption is closely tied to identity formation and self-expression. When recommendation systems encourage conformity and restrict exploration, they raise ethical questions about both individual autonomy and the cultural implications of algorithmically mediated style.

Despite their varying levels of technical awareness, participants in the study all expressed a desire for greater transparency regarding how recommendations are generated and how personal data is used. Participant 2 stated that 'too many recommendations annoy customers, transparency is better', while Participant 4 noted that some platforms are 'manipulative and it's unclear how they use your data', suggested that transparency should at least be offered as an option. Some people might find it scary or intrusive, especially older adults who aren't familiar with social media, more transparency could be more ethical. These perspectives reveal a clear consumer expectation for greater accountability from platforms, demonstrating that the current opacity of algorithmic systems represents an ethical deficit in the digital fashion industry.

Overall, the findings show that AI-powered fashion recommendation systems are perceived as providing both assistance and influence. Although participants valued personalisation that was relevant to them, they became critical when systems relied on repetition, scarcity and social validation to influence behaviour. Thus, awareness of manipulation did not only eliminate its emotional impact, and the accounts of participants reveal a variety of ethical concerns, ranging from the covert use of data and deceptive design to the erosion of creative autonomy.

5 Conclusion

This paper explores the intersection between AI-powered fashion recommendation systems and the emotionally manipulative design practices embedded within them. As these systems evolve and become more sophisticated by incorporating deep learning, multimodal data and affective profiling, they transform from passive tools of convenience into active shapers of consumer identity, self-perception and purchasing behaviour. The findings argue that algorithmic fashion curation is not neutral, instead, it draws on tacit emotional knowledge and exploits well-documented cognitive biases, employing dark patterns that undermine individual autonomy.

The fashion industry is particularly vulnerable to manipulation. Due to its close links with body image, social validation and self-expression, consumers are susceptible to personalisation systems based on insecurities rather than genuine preferences. The convergence of scarcity cues, social proof and identity-targeted recommendations in a single interface creates a situation where desire is manufactured, blurring the line between autonomous choice and algorithmic influence.

Therefore, policymakers must extend their oversight to include affective manipulation as a distinct category of harm, going beyond transparency requirements such as the disclosure of algorithmic decision-making process. Regulatory bodies should consider mandating 'dark pattern audits' for AI-powered retail platforms, paying particular attention to features that exploit emotional vulnerability or body-related insecurities. Those engaged in the realm of fashion AI, encompassing designers and developers, bear an ethical responsibility to distinguish between personalisation that assists the user and that which prioritises conversion metrics at the expense of the user's psychological well-being. It is crucial to adopt value-sensitive design principles.

Consumers should be aware that simply being aware of manipulative design is not enough to protect against its effects. However, digital literacy initiatives that help consumers recognise emotional targeting, artificial urgency, and algorithmic self-image construction can meaningfully shift the power balance. Educating users about how their emotional data is inferred and used is a necessary step towards more informed and autonomous consumption.

This paper highlights a gap in the literature to be addressed in future research: the psychological and emotional dimensions of AI-driven fashion recommendations are comparatively under-explored in relation to technical performance metrics. Future research could focus on longitudinal studies examining the effects of prolonged exposure to emotionally targeted fashion AI on body image, self-esteem, and purchasing autonomy, particularly among younger and more vulnerable demographic groups. Qualitative approaches based on the

consumers' lived experiences will help to capture the tacit, subjective dimensions of algorithmic influence, that quantitative methods struggle to reach.

6 Ethics Declaration

This research involved semi-structured interviews with human participants, followed by established research ethics standards. All participants were fully informed of the study's purpose, their right to withdraw at any time without consequence, and how their data would be used and stored. Written informed consent was secured from each participant before data collection commenced. The principles of anonymity, confidentiality, and data protection were strictly adhered to. No conflicts of interest are declared.

7 AI Declaration

No AI tools were used in the conceptualisation, research design, data preparation, data analysis, presentation of findings, and list of references. AI language tool ChatGPT by OpenAI was used selectively during the revision and editing stage of this paper to support grammar checking, sentence refinement, and proofreading. The authors carefully reviewed and verified AI-assisted output before inclusion in the final manuscript. All citations and references were checked by the authors. The authors acknowledge the limitations of AI tools, including the potential for bias, errors, and gaps in knowledge.

Project Tailoring as a Knowledge Legitimacy Process in Hybrid Intelligence Environments

Anikó Csepregi[1], Coşkun Akça[2]
[1]University of Pannonia, Veszprém, Hungary
[2]Kastamonu University, Kastamonu, Türkiye

Abstract

Organizational change is increasingly implemented through projects that operate as temporary organizational settings where actors interpret uncertainty, negotiate priorities, and enact change through coordinated action. While project tailoring is traditionally understood as a technical adaptation of project management methods, recent research suggests that tailoring decisions emerge through collective sensemaking processes embedded in organizational and technological contexts. However, existing literature has paid limited attention to how organizational culture and digital technologies jointly shape knowledge processes through which tailoring decisions are enacted.

This paper explains how organizational culture and hybrid intelligence jointly shape knowledge legitimacy processes through which decisions are enacted in project-based organizations. This conceptual paper develops an integrative framework explaining project tailoring as a knowledge enactment process emerging from collective sensemaking and knowledge legitimacy processes. More specifically, the paper conceptualizes project tailoring as a knowledge legitimacy process emerging from collective sensemaking in hybrid intelligence environments. The framework integrates literature on project-based organizing, sensemaking, organizational culture, and sociomateriality, and introduces hybrid intelligence as a socio-technical context that shapes the visibility, measurability, interpretation, and legitimacy of knowledge in project environments.

The paper argues that project tailoring decisions should be understood as outcomes of culturally and sociomaterially embedded knowledge processes rather than purely technical adjustments. Organizational culture is conceptualized as an interpretive and knowledge logic that shapes how actors evaluate and legitimize knowledge, while hybrid intelligence environments influence what knowledge becomes visible, measurable, and actionable in decision-making processes. Project tailoring is therefore interpreted as an enacted outcome of interacting cultural, interpretive, and technological processes.

The paper contributes to knowledge management and project studies by reframing project tailoring as a culturally embedded knowledge process, introducing knowledge legitimacy as a key mechanism linking collective sensemaking and project decision making, and by conceptualizing hybrid intelligence as a sociomaterial context influencing organizational knowledge processes and decision outcomes. The paper concludes by outlining implications for organizational change and knowledge-based decision making in hybrid intelligence environments.

Keywords: organizational culture; hybrid intelligence; knowledge legitimacy; collective sensemaking; project-based organizations

Paper type: Academic Research Paper

1 Introduction

Organizational change is frequently enacted through projects that function as temporary organizational settings in which new structures, practices, and meanings are negotiated under conditions of uncertainty (Packendorff, 1995; Cicmil et al., 2006; Sloot et al., 2024; Antonova, 2025). In such contexts, projects are not merely execution mechanisms but organizational arenas where actors interpret situations, negotiate priorities, and enact change through coordinated action (de Metz et al., 2024). Project tailoring therefore cannot be understood only as a technical adjustment to project characteristics, but also as a socially embedded process through which actors interpret situations, negotiate priorities, and justify decisions in uncertain environments (Söderlund, 2011; Lundin and Söderholm, 1995; Sydow and Windeler, 2020).

Within project-based organizing, project tailoring has traditionally been understood as a mechanism for adapting project management practices to contextual conditions such as project size, complexity, or uncertainty (Miterev et al., 2017; Araki and Martins, 2023). This contingency-based perspective conceptualizes tailoring as a rational adjustment process aimed at achieving fit between project characteristics and management approaches. However, this view under-theorizes the interpretive and social processes through which adjustments occur (Whittle et al., 2023). Project tailoring can therefore be understood not only as a technical adjustment but also as a socially embedded process of interpretation and negotiation, highlighting the need to examine how such decisions are socially constructed and justified in project environments (Söderlund, 2011; Lundin and Söderholm, 1995; Sydow and Windeler, 2020).

Research on sensemaking shows that decisions in uncertain organizational environments emerge through collective processes of interpretation through which actors construct shared meanings and justify action (Maitlis and Christianson, 2014; Whittle et al., 2023). These processes are shaped by organizational culture, which shapes how situations are interpreted and what forms of knowledge are considered legitimate for decision making (Schein, 2010; Pagnozzi et al., 2024). At the same time, digital technologies and artificial intelligence increasingly shape organizational decision making by influencing knowledge visibility, interpretation, and coordination, highlighting the sociomaterial nature of contemporary organizational environments (Orlikowski, 2007; Ledro et al., 2023; Sherson, 2024). Hybrid intelligence environments therefore not only support decision-making but also shape how knowledge is produced, evaluated, and applied in organizational contexts (Shrestha et al., 2019; Sherson, 2024).

Despite growing research on project tailoring, organizational culture, sensemaking, and hybrid intelligence, these streams have largely been examined separately. As a result, we know relatively little about how project tailoring decisions emerge as outcomes of collective sensemaking and knowledge legitimacy processes embedded in cultural and technological contexts. This fragmentation indicates the need for an integrative perspective that connects project studies, sensemaking theory, knowledge management, and sociomateriality in order to better understand project-level decision making in contemporary organizational environments (Sydow and Windeler, 2020; Sandberg and Tsoukas, 2015).

This paper addresses this gap by explaining how organizational culture and hybrid intelligence jointly shape knowledge legitimacy processes through which decisions are enacted in project-based organizations. By doing so, the paper shifts the focus from project tailoring as a technical adjustment to project tailoring as a knowledge-based and socially constructed organizational process and develops a process perspective on project decision making based on collective sensemaking and knowledge legitimacy (Maitlis and Christianson, 2014; Sandberg and Tsoukas, 2015; Andrews et al., 2024; Sydow and Windeler, 2020).

This paper positions project tailoring within process and knowledge-based perspectives on organizational decision making. Rather than conceptualizing tailoring as a contingency-based adaptation or methodological choice, the paper conceptualizes project tailoring as an outcome of knowledge legitimacy processes through which certain interpretations become accepted as valid bases for action. This shifts the focus from project methodologies to the social and sociomaterial processes through which decisions become justified and enacted in project environments. In this sense, the paper contributes to project studies by explaining project tailoring as a knowledge selection process, to sensemaking research by linking interpretation to decision outcomes through legitimacy, and to sociomaterial research by conceptualizing hybrid intelligence as a cultural actor shaping what knowledge becomes legitimate in organizational decision making.

The research question guiding this paper is:

How do organizational culture and hybrid intelligence configurations co-shape collective sensemaking and knowledge legitimacy processes through which project tailoring decisions are enacted during organizational change?

This paper makes three theoretical contributions. First, it contributes to project studies by reconceptualizing project tailoring as an outcome of knowledge legitimacy processes rather than a technical adaptation task. Second, it contributes to sensemaking and knowledge management literature by introducing knowledge legitimacy as a knowledge validation and selection mechanism linking collective sensemaking and project decisions. Third, it contributes to sociomaterial and hybrid intelligence research by explaining how digital technologies and AI systems shape knowledge visibility, interpretation, and legitimacy in project environments.

The remainder of the paper is structured as follows. The next section reviews the theoretical background, followed by the development of the conceptual framework. The paper then discusses theoretical contributions and implications, and concludes with limitations and directions for future research.

2 Theoretical Background

2.1 Projects and Organizational Change

In organizations, change is often implemented through projects that function as temporary settings in which actors interpret uncertainty, negotiate priorities, and make decisions (Lundin and Söderholm, 1995; Packendorff, 1995). Projects are therefore not merely execution units but organizational spaces where change is interpreted and enacted through collective processes (Sydow and Windeler, 2020; Sloot et al., 2024). Because project environments are characterized by uncertainty and evolving conditions, decisions cannot be fully predefined, and actors must continuously interpret situations and adapt their actions (Söderlund, 2011; Clegg et al., 2018).

In this context, project tailoring has traditionally been understood as a contingency-based alignment process aimed at achieving fit between project management methods and project characteristics (Miterev et al., 2017; Araki and Martins, 2023). However, recent research suggests that tailoring decisions are not purely technical adjustments but the result of interactions, interpretations, and negotiations between competing knowledge claims (de Metz et al., 2024; Brill et al., 2025). Project tailoring should therefore be understood as a socially embedded decision in which certain interpretations become accepted as legitimate bases for action in a given organizational context (Abimbola et al., 2024; Andrews et al., 2024).

2.2 Sensemaking and knowledge legitimacy

In uncertain and complex organizational environments, decisions emerge through collective sensemaking processes in which organizational actors jointly interpret situations and construct shared meanings that guide action (Maitlis and Christianson, 2014; Sandberg and Tsoukas, 2015). However, not all interpretations become the basis for decisions. Decision making is shaped by knowledge that organizational actors accept as legitimate, relevant, and credible (Deephouse et al., 2017; Andrews et al., 2024). Knowledge legitimacy is therefore the outcome of social processes in which different knowledge claims compete and some become accepted as valid bases for action while others remain marginal (Abimbola et al., 2024).

Organizational decisions can thus be understood as outcomes of two linked processes: collective sensemaking, which produces interpretations, and knowledge legitimacy, which selects which interpretations become accepted as the basis for decisions.

2.3 Organizational culture as interpretive and knowledge logic

Organizational culture can be understood as an interpretive system that shapes how organizational actors interpret situations and what knowledge they consider relevant and acceptable for decision making (Harris, 1994; Long and Fahey, 2000). In this sense, culture not only provides values and norms but also acts as a knowledge evaluation logic that determines what knowledge becomes legitimate for decision making (Adeinat and Abdulfatah, 2019).

This is particularly important in project environments, where temporary organizational forms rely heavily on interpretive processes and where different professional groups possess different forms of knowledge (Clegg et al., 2018; Wei and Miraglia, 2017). Organizational culture therefore shapes which knowledge sources are considered credible and relevant and what decision logic guides decision making (Pagnozzi et al., 2024; Pescatore et al., 2022). Organizational decision making can thus be understood as a culturally embedded process in which culture shapes both sensemaking and knowledge legitimacy.

2.4 Sociomateriality, Technology, Hybrid Intelligence

The sociomaterial perspective suggests that technology and organizational practices are intertwined in shaping organizational functioning and decision making (Orlikowski, 2007). Digital technologies and artificial intelligence increase the visibility and measurability of organizational processes, thereby influencing what information and forms of knowledge become the basis of decisions (Olan et al., 2022; Ledro et al., 2023). Technology therefore does not merely support decision making but shapes what becomes visible, measurable, and legitimate knowledge in organizations (Andrews et al., 2024; Brill et al., 2025).

With the emergence of artificial intelligence, decision making increasingly takes place in hybrid intelligence systems where human and artificial intelligence jointly contribute to decision processes (Jarrahi, 2018; Shrestha et al., 2019; Sherson, 2024). Decisions thus emerge in sociomaterial practices where human interpretation and algorithmic analysis jointly shape the knowledge that becomes the basis for decisions (Fabri et al., 2023; Orlikowski, 2007).

2.5 Integrative theoretical framework

This paper integrates project studies, sensemaking theory, knowledge management, and sociomateriality in order to explain how project tailoring decisions emerge in contemporary organizations. Project studies conceptualize projects as temporary organizational contexts in which decisions are enacted under conditions of uncertainty (Lundin and Söderholm, 1995; Sydow and Windeler, 2020). Sensemaking theory explains how actors interpret uncertain situations and construct shared meanings (Maitlis and Christianson, 2014; Sandberg and Tsoukas, 2015), while knowledge management research explains how certain knowledge becomes validated and accepted as a basis for decisions (Deephouse et al., 2017; Abimbola et al., 2024). Sociomateriality and hybrid

intelligence further explain how digital technologies and AI systems shape the visibility and measurability of knowledge in organizational decision-making (Orlikowski, 2007; Shrestha et al., 2019; Sherson, 2024).

By linking these perspectives, the paper develops a process framework in which collective sensemaking produces interpretations, knowledge legitimacy selects which interpretations become accepted as valid knowledge, and these legitimized knowledge claims form the basis of project tailoring decisions. Organizational culture shapes what knowledge is considered legitimate, while hybrid intelligence shapes what knowledge becomes visible and measurable. Project tailoring is therefore conceptualized as the outcome of a culturally and technologically embedded process of sensemaking and knowledge legitimacy.

3 Conceptual Framework

This paper develops a conceptual framework that explains project tailoring as a culturally embedded knowledge enactment process emerging from collective sensemaking and knowledge legitimacy processes in hybrid intelligence environments. By integrating project-based organizing, sensemaking, organizational culture, and sociomaterial perspectives, the framework explains how project tailoring decisions emerge through collective interpretation and knowledge legitimation rather than purely technical decision making.

This paper argues that project tailoring should be understood not as a purely technical adjustment process but as a knowledge enactment process shaped by organizational culture, collective sensemaking, knowledge legitimacy, and hybrid intelligence.

3.1 Organizational culture as interpretive and knowledge logic

The framework conceptualizes organizational culture as an interpretive infrastructure that shapes how actors understand situations, evaluate knowledge, and justify decisions (Schein, 2010; Maitlis and Christianson, 2014). In project environments characterized by ambiguity and time pressure, actors rely on shared assumptions and culturally embedded expectations when interpreting situations and making decisions.

Organizational culture can therefore be understood as a knowledge logic that shapes what is considered credible and relevant knowledge in project decision making (Pagnozzi et al., 2024; Pescatore et al., 2022). Different cultural contexts privilege different forms of knowledge, such as formal methodologies, expert judgment, data-driven insights, or experiential knowledge. Culture thus shapes which knowledge becomes legitimate and is used in project tailoring decisions.

3.2 Collective sensemaking in project environments

Project decision making is conceptualized as a collective sensemaking process through which actors construct shared meanings and coordinate action in uncertain situations (Maitlis and Christianson, 2014; Whittle et al., 2023). During organizational change, project actors interpret situations, define problems, and negotiate appropriate courses of action. Project tailoring decisions therefore emerge through interaction and interpretation rather than purely analytical decision making.

Sensemaking also explains why project decisions are socially constructed and path-dependent, as decisions depend on dominant interpretations developed through interaction and organizational context.

3.3 Knowledge legitimacy as a validation and selection mechanism

A central concept in the framework is knowledge legitimacy, defined as the process through which certain knowledge claims become accepted as valid and appropriate for decision making (Andrews et al., 2024; Abimbola et al., 2024). Knowledge legitimacy functions as a validation and selection mechanism that determines which knowledge becomes actionable in project environments.

Organizational culture shapes evaluation criteria by influencing what is considered credible and relevant knowledge, while collective sensemaking shapes how actors interpret situations and evaluate competing knowledge claims. Knowledge legitimacy therefore explains how interpretations are translated into concrete project decisions and practices.

3.4 Hybrid intelligence as a sociomaterial context

The framework incorporates a sociomaterial perspective by recognizing that digital technologies and artificial intelligence systems influence knowledge processes and decision making (Orlikowski, 2007; Jansson et al., 2020). Technologies shape what becomes visible, measurable, and analyzable in organizations, thereby influencing knowledge evaluation and legitimacy.

From a hybrid intelligence perspective, decision making increasingly emerges from the interaction between human actors and technological systems (Sherson, 2024). Technology therefore acts as a sociomaterial context that shapes knowledge visibility, interpretation, and coordination processes in project environments.

3.5 Project tailoring as knowledge enactment

Based on these mechanisms, project tailoring is conceptualized as the outcome of culturally embedded collective sensemaking and knowledge legitimacy processes in hybrid intelligence environments. Project tailoring is therefore understood as a knowledge enactment process through which actors translate interpretations and legitimized knowledge into project structures, practices, and governance mechanisms.

The framework proposes that project tailoring emerges from the interaction of four elements: organizational culture, collective sensemaking, knowledge legitimacy, and hybrid intelligence. Organizational culture shapes interpretive frameworks, collective sensemaking constructs shared meanings, knowledge legitimacy determines which knowledge is accepted for decision making, and hybrid intelligence shapes knowledge visibility and interpretation. Together, these elements explain how project tailoring decisions are enacted during organizational change.

3.6 Conceptual model

Figure 1 presents the conceptual model developed in this paper. The model explains project tailoring as an outcome of culturally embedded collective sensemaking and knowledge legitimacy processes in hybrid intelligence environments. Organizational culture shapes interpretation and knowledge evaluation (Schein, 2010), collective sensemaking constructs shared understanding (Maitlis and Christianson, 2014; Whittle et al., 2023), knowledge legitimacy determines which knowledge becomes actionable (Andrews et al., 2024), and hybrid intelligence shapes knowledge visibility and evaluation (Orlikowski, 2007; Sherson, 2024).

The model proposes that knowledge legitimacy functions as a knowledge validation and selection mechanism that determines which knowledge claims become accepted and translated into project-level decisions and practices. Project tailoring is therefore conceptualized as the enacted outcome of culturally embedded collective sensemaking and knowledge legitimacy processes shaped by hybrid intelligence.

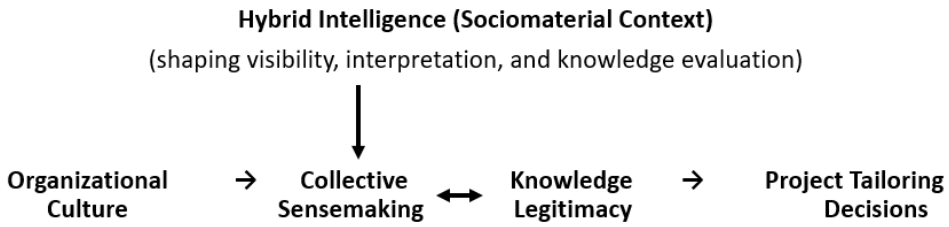

Figure 1: Conceptual model of project tailoring as a knowledge legitimacy process in hybrid intelligence environments.

The model does not conceptualize hybrid intelligence as a mediating variable but as a sociomaterial context that shapes knowledge visibility, interpretation, and evaluation throughout the decision process. Hybrid intelligence influences what becomes visible, measurable, and legitimate knowledge, thereby shaping both collective sensemaking and knowledge legitimacy processes through which project tailoring decisions are enacted.

The arrows in the model represent shaping relationships rather than linear causal effects. The model should therefore be interpreted as a process model that explains how project tailoring decisions emerge from interacting cultural, interpretive, and sociomaterial processes rather than as a variance-based causal model. Project tailoring is thus conceptualized as an emergent outcome of knowledge legitimacy processes embedded in organizational culture and hybrid intelligence environments.

4 Methodology

This paper is a theory-building conceptual study that develops a conceptual framework explaining how project tailoring decisions emerge in organizational change. Conceptual research focuses on developing new theoretical relationships and mechanisms rather than testing existing theories (Jaakkola, 2020; Whetten, 1989). The paper applies theory synthesis and conceptual integration by combining project studies, sensemaking theory, knowledge management, and sociomateriality to develop an integrative process model (MacInnis, 2011).

The aim is to explain the mechanisms through which project tailoring decisions emerge; therefore, the paper develops a process model linking collective sensemaking, knowledge legitimacy, and hybrid intelligence in project decision-making.

5 Discussion

This paper contributes to the literature by reframing project tailoring as a culturally embedded knowledge enactment process and by introducing knowledge legitimacy as a mechanism linking collective sensemaking and project-level decisions in hybrid intelligence environments. In doing so, it shifts the understanding of project tailoring from a contingency-based adjustment perspective toward a knowledge legitimacy perspective that explains how decisions emerge through socially and technologically embedded knowledge processes.

5.1 Project tailoring as knowledge enactment and knowledge legitimacy

This paper argues that project tailoring should be understood not primarily as a technical adjustment but as a knowledge enactment process emerging from collective interpretation and legitimation. While traditional literature conceptualizes tailoring as contingency-based adaptation (Miterev et al., 2017; Araki and Martins, 2023), this paper shows that tailoring decisions emerge through collective sensemaking processes in which actors interpret situations and justify action under uncertainty (Maitlis and Christianson, 2014; Whittle et al., 2023). By introducing knowledge legitimacy, the paper explains how certain interpretations become accepted as valid knowledge and translated into project practices, shifting the focus from analytical choice to culturally embedded knowledge validation and selection.

5.2 Hybrid intelligence as a sociomaterial context

The paper contributes to sociomateriality research by conceptualizing hybrid intelligence as a context that shapes knowledge visibility and evaluation. Technologies influence what becomes visible and measurable, thereby shaping which knowledge claims can become legitimate (Orlikowski, 2007; Jansson et al., 2020). From a hybrid intelligence perspective, decision-making emerges from the interaction between human and technological actors (Shrestha et al., 2019; Sherson, 2024). Technology thus actively participates in knowledge legitimacy processes by shaping what counts as credible knowledge and can be understood as a cultural actor co-shaping meaning and decision-making processes.

5.3 Theoretical contributions and managerial implications

The paper makes three main theoretical contributions. First, it reconceptualizes project tailoring as a knowledge enactment process rather than a methodological adjustment, extending project studies beyond contingency-based views (Miterev et al., 2017; Sydow and Windeler, 2020). Second, it introduces knowledge legitimacy as a mechanism linking collective sensemaking and project decision-making (Maitlis and Christianson, 2014; Andrews et al., 2024). Third, it conceptualizes hybrid intelligence as a sociomaterial context shaping knowledge visibility and legitimacy (Orlikowski, 2007; Shrestha et al., 2019).

From a managerial perspective, project tailoring should not be treated as a technical decision but as a knowledge legitimacy process in which competing knowledge claims are evaluated and made visible through collective sensemaking. Managers should move beyond selecting tools and actively govern how knowledge is validated and legitimized. This includes balancing multiple knowledge forms, ensuring transparency in decision criteria, and recognizing that organizational culture shapes what knowledge is accepted. In hybrid intelligence environments, managers must recognize that AI and digital tools shape knowledge visibility and thus influence decision outcomes, requiring the orchestration of interactions between human judgment and algorithmic reasoning.

5.4 Limitations and future research

The main limitation of this paper lies in its conceptual nature, as the proposed model has not been empirically tested. Future research could examine how collective sensemaking and knowledge legitimacy processes unfold in projects through qualitative, longitudinal, and process-oriented designs (Maitlis and Christianson, 2014; Orlikowski, 2007; Sherson, 2024). Multi-level studies could further explore how these dynamics evolve across individual, team, and organizational levels. Further research is also needed to investigate how hybrid intelligence reshapes knowledge legitimacy, particularly when algorithmic recommendations and human judgment diverge, and how organizational culture influences these processes in practice.

6 Conclusions

This paper set out to explain how organizational culture and hybrid intelligence jointly shape knowledge legitimacy processes through which decisions are enacted in project-based organizations. The paper showed that project tailoring decisions emerge from culturally and sociomaterially embedded processes of collective sensemaking and knowledge legitimation. Projects should therefore be understood as temporary organizational settings in which decisions emerge through collective interpretation and evaluation of knowledge rather than purely technical decision making (Packendorff, 1995; Sydow and Windeler, 2020; Maitlis and Christianson, 2014).

The paper developed a conceptual framework that explains project tailoring as a culturally embedded knowledge enactment process in which organizational culture shapes knowledge evaluation, collective sensemaking constructs interpretations, knowledge legitimacy determines which knowledge becomes accepted for decision making, and hybrid intelligence shapes knowledge visibility and measurability (Schein, 2010; Orlikowski, 2007; Andrews et al., 2024). Project tailoring is therefore conceptualized as an emergent outcome of interacting cultural, interpretive, and sociomaterial processes.

The main contribution of the paper is the conceptualization of project tailoring as a knowledge legitimacy process and the development of a process model that explains how project decisions emerge in hybrid intelligence environments. The paper contributes to project studies, knowledge management, and organizational research by explaining project decision making as a culturally and technologically embedded knowledge process.

Rethinking Help-Seeking in AI-Mediated Workplaces: A Socio-Technical and Resource-Based Perspective

Filomena Pagnozzi[1], Zhijie (Helen) Zhao[2]
[1]University of G. d'Annunzio, Chieti-Pescara, Italy
[2]Amsterdam Business School, University of Amsterdam, Amsterdam, The Netherlands

Abstract

Artificial intelligence (AI) systems are increasingly embedded in contemporary workplaces, offering employees new sources of assistance for obtaining information and receiving support during work tasks. This transformation is reshaping how help is accessed, as employees can now turn not only to colleagues and supervisors but also to AI-based tools such as chatbots and generative AI systems.

However, the help-seeking literature has traditionally conceptualized this behavior as inherently interpersonal, shaped by relational dynamics such as reputational concerns and power relations. While this perspective has generated important insights, it offers only a partial account of help-seeking in AI-mediated workplaces, where sources of assistance extend beyond human interactions.

In these contexts, help-seeking decisions are shaped by the interaction between socio-technical infrastructures, including availability, accessibility, characteristics of AI systems and individuals' evaluations of potential resource gains and losses related to help sources. Despite the relevance of this shift, existing research lacks a framework that conceptualizes help-seeking as a multi-level phenomenon emerging from the interaction of organizational and individual factors.

To address this gap, this paper integrates Socio-Technical Systems theory and Conservation of Resources theory to examine how organizational and individual antecedents jointly shape help-seeking behaviors. Drawing on this integrated perspective, we propose a conceptual framework that identifies organizational infrastructure conditions and individual intrapersonal and interpersonal factors of three help-seeking strategies: AI-based, human-based, and hybrid help-seeking.

By combining these perspectives, we reconceptualize help-seeking in AI-mediated workplaces as a multi-level resource-regulation process and provide a foundation for future research on help-seeking in AI-mediated workplaces.

Keywords: AI-mediated work; Help-seeking behavior; Socio-Technical Systems; Conservation of Resources

Paper type: Academic Research Paper

1 Introduction

In contemporary workplaces, the way employees seek and obtain help is quietly but changing. For a long time, when individuals encountered difficulties in their work tasks, they turned to humans (i.e. supervisors, colleagues) to access the knowledge and support needed to move forward. Within this traditional view, help-seeking has been understood as an interpersonal process—one that unfolds through social relationships and is shaped by concerns about reputation, power dynamics, and norms of reciprocity (Lee, 1997; Bamberger, 2009; Hargadon and Bechky, 2006; Pagnozzi et al., 2024). Asking for help was therefore not a neutral act: it often meant exposing one's limitations, navigating social expectations, and weighing the benefits of receiving support against the costs of appearing incompetent or dependent in front of others (Nadler et al., 2003; Lee, 1997).

This understanding is being challenged by the presence of Artificial Intelligence (AI) in organizational settings. Increasingly, employees can rely not only on other people but also on AI-based systems—such as chatbots and generative AI tools—to obtain assistance. These technologies provide support that is immediate, scalable, and often anonymous, making it possible to seek help without the social exposure typically associated with interpersonal interactions. In many cases, AI tools are already being used as everyday problem-solving companions or personal assistants, offering on-demand guidance that is independent of others' availability or willingness to help (Meyer von Wolff et al., 2020; Gkinko and Elbanna, 2023; Brynjolfsson et al., 2023; Noy and Zhang, 2023).

As a consequence, help-seeking can no longer be seen as purely a social act. It is becoming a hybrid behavior that takes shape at the intersection of human and technological interactions. This shift raises new and important questions: why do individuals choose to seek help from AI rather than from other people? How do they evaluate the costs and benefits associated with these different sources of support? And how do organizational contexts and technological infrastructures influence these choices?

Despite the relevance of these questions, existing research has yet to capture this transformation. Studies on help-seeking continue to emphasize interpersonal dynamics (Bamberger, 2009), often overlooking the role

of technological systems. At the same time, research on AI adoption tends to focus on usage and performance outcomes, paying less attention to the behavioral and motivational processes that underlie decisions to seek help (Davis, 1989; Venkatesh et al., 2003). More broadly, although socio-technical scholars have long argued for the need to jointly consider social and technological dimensions (Trist and Bamforth, 1951; Bostrom and Heinen, 1977; Pasmore et al., 2019), this integration remains largely absent in the study of help-seeking.

Against this backdrop, we propose that help-seeking in AI-mediated workplaces can be understood as a multi-level resource regulation process, shaped by the interplay between socio-technical conditions and individual resource evaluations. To do so, we develop an integrated framework that combines Socio-Technical Systems (STS) theory (Bednar and Welch, 2020; Pagnozzi and Antonelli, 2025) with Conservation of Resources (COR) theory (Hobfoll, 1989; 2001). This approach allows us to capture both the structural context in which help-seeking takes place and the underlying motivations that drive individuals' decisions. By bringing these perspectives together, the study contributes to a more nuanced understanding of help-seeking in contemporary organizations, where the boundaries between human and technological sources of support are becoming increasingly blurred.

2 Theoretical Background

2.1 Help-Seeking as an Interpersonal Behavior

Help-seeking is a fundamental process through which individuals address work-related challenges and acquire knowledge to perform tasks effectively. It is defined as requesting assistance from others to solve problems (Lee, 1997; Bamberger, 2009). In organizations, it is inherently relational, involving interactions between help-seekers and help-givers within social and organizational networks (Hargadon and Bechky, 2006; Mueller and Kamdar, 2011). Research has examined help-seeking mainly through social and psychological perspectives, showing that individuals consider not only task needs but also social implications. Asking for help may signal lack of competence or autonomy, threatening image, status, or power (Nadler et al., 2003; Lee, 1997). Thus, help-seeking reflects a trade-off between expected benefits and perceived interpersonal costs (Bamberger, 2009). Help-seeking is also linked to positive outcomes, including learning, problem-solving, and performance (Mueller and Kamdar, 2011), as well as stronger relationships, trust, and collaboration (Hargadon and Bechky, 2006). However, it remains a complex and potentially risky behavior shaped by individual and organizational factors. Despite these insights, prior research largely treats help-seeking as socially embedded, focusing on interpersonal dynamics. This view is partial in contemporary organizations. First, it assumes support is provided by individuals, overlooking technological systems. Yet digital infrastructures—including platforms, knowledge management systems, and AI-based tools—shape how employees access expertise (Leonardi and Barley, 2010; Faraj and Azad, 2012). Second, organizational conditions are underexplored. Leadership and culture can enable or constrain help-seeking: supportive leadership fosters psychological safety (Edmondson, 1999; Detert and Burris, 2007; Carmeli et al., 2010), while collaborative cultures promote knowledge sharing, unlike competitive environments (Schein, 2010; Van Dyne et al., 2003; Bamberger, 2009). Finally, motivational processes remain underexplored. Although individuals evaluate costs and benefits, it is unclear how these evaluations unfold when both human and technological support are available (Nadler et al., 2003; Bamberger, 2009). These limitations call for an integrated perspective on individual, organizational, and technological factors.

2.2 The Emergence of AI-Mediated Help

The growing diffusion of AI in organizations highlights the limitations of traditional views of help-seeking by introducing new forms of support. AI-based systems—such as chatbots, recommendation engines, and generative tools—are increasingly embedded in everyday work, offering alternative sources of assistance that differ from human interactions. Unlike traditional help providers, AI systems offer immediate, continuously available, and scalable support. This reduces constraints associated with interpersonal help-seeking, including availability, time coordination, and social risk. Studies show that generative AI tools enhance productivity and support complex problem-solving, improving access to assistance (Brynjolfsson et al., 2023; Noy and Zhang, 2023). Interacting with AI in less socially exposed contexts may also lower psychological barriers to asking for help (Gkinko and Elbanna, 2023). At the same time, AI-mediated help-seeking introduces new forms of uncertainty. Individuals must evaluate the reliability, usefulness, and quality of AI outputs, as well as their ability to interact effectively with these systems. Research on technology adoption highlights the role of trust, perceived usefulness, and ease of use in shaping behavior (Davis, 1989; Venkatesh et al., 2003; Glikson and

Woolley, 2020). Thus, turning to AI is not simply a substitute for human help but involves distinct cognitive and behavioral considerations. More broadly, the integration of AI reflects a transformation of work systems. Tools such as chatbots are reshaping help-seeking practices by requiring new skills, redefining roles, and influencing organizational structures and cultures.

3 Theoretical Foundation

3.1 Socio-Technical Systems (STS) Theory

STS theory provides a valuable lens for understanding help-seeking in organizations shaped by technological mediation. Originating from Trist and Bamforth (1951), STS posits that organizational outcomes emerge from the interaction between two interdependent subsystems: the social subsystem (individuals, relationships, structures) and the technical subsystem (tools, technologies, processes, tasks) (Bostrom and Heinen, 1977; Cherns, 1987; Mumford, 2006). Rather than treating these as separate, STS emphasizes their mutual interdependence: technological changes reshape social dynamics, while human needs and organizational arrangements influence how technologies are designed and used (Pasmore et al., 2019; Bednar and Welch, 2020; Leonardi, 2011). Applied to help-seeking, this perspective suggests that the behavior is not purely interpersonal but embedded in a broader socio-technical system. While prior research has focused on social dimensions such as trust and reciprocity, technological infrastructures also shape when, how, and from whom help is sought (Faraj and Azad, 2012; Leonardi and Barley, 2010; Pagnozzi and Antonelli, 2025). Digital platforms, knowledge management systems, and AI-based tools influence the visibility of expertise, access to support, and the timing and modality of help requests. AI systems, such as chatbots and generative tools, represent a key evolution of the technical subsystem. They provide new sources of assistance while reshaping interaction patterns, expectations, and organizational norms (Brynjolfsson and McAfee, 2014; Raisch and Krakowski, 2021). These tools offer immediate and scalable support but also require new skills and forms of coordination (Noy and Zhang, 2023; Pagnozzi et al., 2024).From an STS perspective, this transformation is socio-technical, affecting culture, work design, and how individuals engage with human and non-human sources of help (Orlikowski, 2007; Leonardi, 2011). Help-seeking in AI-mediated workplaces thus emerges from the interplay between social structures and technological affordances. However, while STS explains the contextual conditions of help-seeking, it does not fully account for individual motivations and decision-making processes.

3.2 Conservation of Resources (COR) Theory

COR theory provides a complementary lens to explain the individual-level motivations underlying help-seeking in AI-mediated workplaces. Developed by Hobfoll (1989), it posits that individuals seek to acquire, retain, and protect resources—broadly defined as anything valued for achieving goals. Central to the theory is the tension between resource acquisition and conservation: individuals evaluate whether investing resources such as time, effort, and social capital will generate sufficient gains to justify the cost (Hobfoll et al., 2018; Halbesleben et al., 2014). From this perspective, help-seeking is a resource investment strategy, where individuals expend resources to obtain greater returns (Lim et al., 2020). Engagement in help-seeking depends not only on need, but on the evaluation of expected gains relative to potential losses, shaped by individuals' current resource state and prior experiences (Hobfoll et al., 2018). In AI-mediated workplaces, this evaluation involves new trade-offs. The primacy of loss principle suggests that individuals are particularly sensitive to the costs of help-seeking, including effort, social exposure, and psychological risks such as appearing incompetent or incurring indebtedness (Halbesleben et al., 2014). AI-based assistance alters this cost structure by reducing social visibility, thereby lowering psychological barriers and enabling help-seeking that might otherwise be avoided (Bamberger, 2009; Lim et al., 2020). At the same time, the resource investment principle suggests that individuals with higher AI self-efficacy or prior positive experiences are more likely to engage in AI-based help-seeking, as they expect greater returns from their investment (Hobfoll et al., 2018; Lim et al., 2020).

4 Integrating STS and COR: Toward a Multi-Level Perspective

4.1 Limitations of Single-Theory Explanations

STS and COR theories each offer valuable but partial insights into help-seeking in AI-mediated workplaces. STS explains how social and technical subsystems shape the conditions under which help-seeking becomes possible or constrained (Trist and Bamforth, 1951; Pasmore et al., 2019; Bednar and Welch, 2020), but it does not fully account for individual decision-making. COR theory, by contrast, explains individual motivations and

differences in help-seeking based on resource dynamics (Hobfoll, 1989; Halbesleben et al., 2014), yet overlooks the technological and organizational context in which these evaluations occur. Taken separately, neither perspective fully explains help-seeking in AI-mediated workplaces.

4.2 Why an Integrated Perspective is Needed

Help-seeking in AI-mediated workplaces is inherently multi-level and cannot be explained by individual or contextual factors alone. Integrating STS and COR enables a more complete understanding of three key issues. First, why individuals choose AI or human help: this depends on the interaction between available socio-technical conditions and individual resource evaluations (Hobfoll et al., 2018; Pasmore et al., 2019). Second, why the same AI system produces different behaviors: STS highlights variation in organizational embedding, while COR explains differences in individual resource states. Third, how organizational contexts shape decisions, as socio-technical conditions define the environment within which individuals evaluate costs and benefits (Orlikowski, 2007; Leonardi, 2011). This integration provides a more comprehensive account of help-seeking in AI-mediated workplaces.

4.3 Help-Seeking as a Multi-level Resource Regulation Process

Building on this integration, we conceptualize help-seeking in AI-mediated workplaces as a multi-level resource regulation process arising from the interaction between socio-technical infrastructures and individual resource motives. Organizational infrastructures—including the design, availability, and embedding of AI tools—define what forms of assistance are accessible, at what cost, and under which norms. Within this environment, individuals evaluate whether seeking help from AI or human sources is likely to generate resource gains or losses, considering effort, social exposure, and potential image risks (Hobfoll et al., 2018; Halbesleben et al., 2014; Lim et al., 2020). Help-seeking thus emerges from the ongoing interplay between organizational conditions and individual acquisition–conservation orientations.

5 Conceptual Framework of Help-Seeking in AI-Mediated Workplaces

Building on the integrated STS-COR perspective, we propose that help-seeking in AI-mediated workplaces is shaped by a set of organizational and individual factors that influence how individuals evaluate the relative costs and benefits of seeking help from AI versus human sources. From this perspective, help-seeking can be conceptualized as a choice among alternative resource-seeking strategies, in which individuals select the source of assistance that maximizes expected resource gains while minimizing resource losses.

5.1 Help-Seeking Behaviors

We conceptualize help-seeking as a set of alternative resource-seeking strategies through which individuals address work-related challenges (Bamberger, 2009; Nadler et al., 2003). These strategies differ in their cost–benefit profiles and reflect different ways of navigating the socio-technical environment.

AI-based help-seeking occurs when individuals rely primarily on AI systems. This strategy involves lower social costs and higher accessibility but may entail uncertainty about output quality and limited contextual understanding in complex situations (Glikson and Woolley, 2020; Raisch and Krakowski, 2021).

Human-based help-seeking involves seeking assistance from colleagues or supervisors. It provides richer, context-sensitive support and relational benefits but entails higher social and psychological costs, such as impression management and indebtedness (Nadler et al., 2003; Bamberger, 2009).

Hybrid help-seeking combines AI and human sources, allowing individuals to balance their advantages and limitations. This aligns with perspectives on human–AI collaboration emphasizing their complementarity (Jarrahi, 2018).

In line with the STS-COR perspective, these strategies emerge from the interplay between organizational infrastructures and individual motivations. Individuals tend to select the option that maximizes expected gains while minimizing perceived costs.

5.2 Organizational Infrastructures

Organizational infrastructures define the socio-technical environment within which help-seeking decisions are made. These infrastructures shape the structural conditions of action by influencing the accessibility, perceived legitimacy, and expected value of different sources of assistance (Faraj and Azard, 2012; Leonardi, 2011).

First, AI accessibility refers to the availability and integration of AI tools in everyday work. High levels of accessibility reduce the effort and time required to seek help, thereby lowering the resource costs associated with AI-based help-seeking (Gkinko and Elbanna, 2023).

Second, technological affordances capture the capabilities of AI systems to provide accurate, timely, and task-relevant support (Leonardi, 2011; Orlikowski, 2007). Strong affordances increase the perceived usefulness of AI, enhancing the expected resource gains from engaging with these systems (Davis, 1989; Vankatesh et al., 2013; Pagnozzi et al., 2024).

Third, organizational norms shape the social acceptability of help-seeking. In collaborative environments, both human and AI-based help are supported, while in competitive contexts individuals may prefer AI as it reduces social exposure (Schein, 2010; Van Dyne et al., 2003; Bamberger, 2009).

Finally, AI legitimacy reflects the extent to which its use is considered appropriate and valued. When legitimized, the reputational and psychological costs decrease, making AI-based or hybrid help-seeking more attractive (Martin and Waldman, 2023; Scott, 2013).

5.3 Individual Motivations

While organizational infrastructures define the external conditions of action, individual factors shape how these are interpreted. In line with COR theory, individuals differ in their sensitivity to resource gains and losses and in their willingness to seek help from different sources (Hobfoll, 1989; Hobfoll et al., 2018). Importantly, these factors influence not only whether individuals seek help, but also which source they choose.

Intrapersonal factors shape preferences toward help-seeking. Individuals with a high learning goal orientation are more likely to prioritize resource acquisition and engage in help-seeking, including through AI (Lim et al., 2020). Openness to experience increases experimentation with new technologies, while trust in AI enhances expectations about its usefulness and reliability (McGrath et al., 2025; Wanberg and Kammeyer-Mueller, 2000).

Interpersonal factors influence sensitivity to social costs. High performance goal orientation increases concerns about appearing incompetent, making individuals less likely to seek help from others and more likely to rely on AI (VandeWalle, 1997). Similarly, avoidance of indebtedness and relational conflicts increase the perceived costs of asking others for help, leading individuals to prefer AI-based support (Chan, 2013).

In line with the STS-COR perspective, the three help-seeking strategies emerge from the interplay between organizational infrastructures and individual motivations. Organizational infrastructures define available sources, while individual factors shape their evaluation, leading to preferences for AI-based, human-based, or hybrid help-seeking. This framework is summarized in Figure 1.

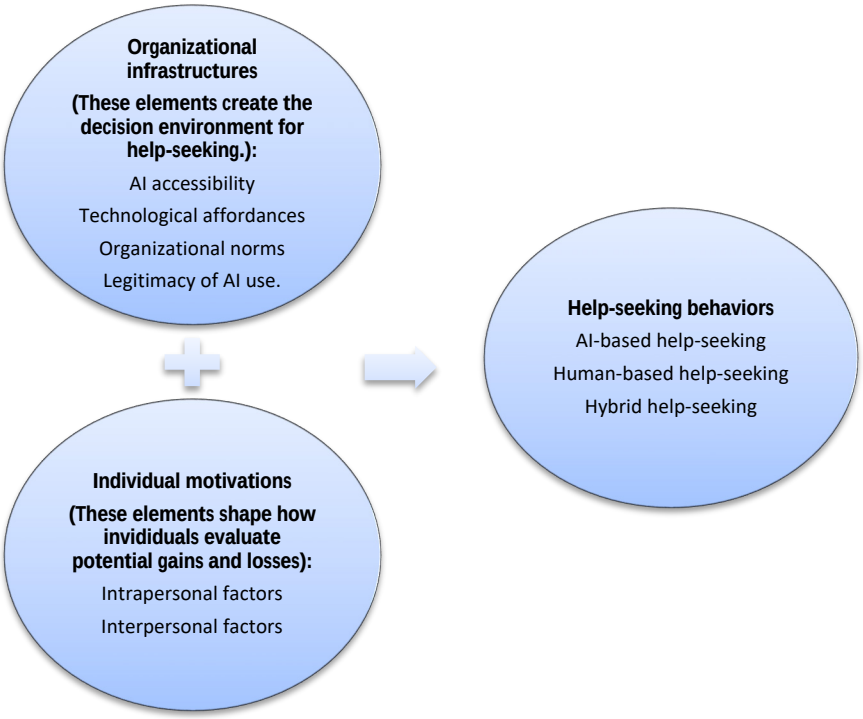

Figure 1 Conceptual Framework of Help-Seeking in AI-Mediated Workplaces

6 Discussion

6.1 Theoretical Implications

This paper offers theoretical contributions to the help-seeking literature. First, we extend the help-seeking literature by challenging its dominant view as an inherently interpersonal behavior (Bamberger, 2009), showing that, in AI-mediated workplaces, help-seeking is better understood as a socio-technical and multi-source decision process. While STS theory explains how socio-technical conditions shape the context of action (Trist and Bamforth, 1951; Pasmore et al., 2019), and COR theory explains how individuals evaluate resource gains and losses (Hobfoll, 1989; Hobfoll et al., 2018), we show that help-seeking emerges from their joint interaction. In doing so, we provide a more complete account of help-seeking that captures both structural conditions and individual motivations (Halbesleben et al., 2014; Lim et al., 2020).

While prior research has largely focused on whether individuals seek help (Nadler et al., 2003; Bamberger, 2009), our framework explains how employees choose between AI-based, human-based, and hybrid help-seeking when multiple sources are available (Chen et al., 2024; Lim et al., 2020). By organizing antecedents into organizational infrastructures and individual motivations, we identify the conditions under which different help-seeking strategies are more likely to emerge. This contributes to a more nuanced understanding of help-seeking in contemporary organizations where employees navigate between human and technological sources of support (Chen et al., 2024; Lim et al., 2020).

6.2 Practical Implications

This paper also offers practical implications for managing work in AI-integrated environments. Organizations should not rely on technological deployment alone, but actively design the socio-technical conditions surrounding AI tools. Factors such as accessibility, organizational norms, and the legitimacy of AI use shape how employees perceive and engage with different help sources (Leonardi, 2011; Faraj and Azad, 2012). Managers and HR practitioners should should pay attention to reduce the perceived costs and increase the expected benefits of using AI where appropriate.

At the same time, employees do not respond uniformly to the availability of AI tools. Individual factors such as goal orientation and trust in AI shape how employees evaluate and engage with AI as a help source. This heterogeneity implies that organizations should invest in targeted support, such as AI literacy programs and psychologically safe environments, to help employees develop the confidence needed to engage effectively with AI tools.

Finally, AI and human help should not be treated as substitutes. but as complementary resources. Encouraging norms that support both forms of help-seeking can enable hybrid strategies that leverage the strengths of human and AI collaboration (Jarrahi, 2018).

6.3 Future Directions and Conclusion

This paper is conceptual in nature and the framework we propose calls for empirical validation across multiple methodological approaches. Quantitative studies could test the relationships between individual antecedents and help-seeking source preferences through survey-based or experimental designs, examining for instance how organizational and individual factors predict AI-based, human-based, or hybrid help-seeking. Qualitative approaches, including interviews and ethnographic observation, would complement this by capturing how individuals navigate and make sense of help-seeking decisions in AI-mediated workplaces in practice, as well as how organizational infrastructures shape these processes over time.

Beyond methodology, our conceptual framework invites further refinement. Adopting a dynamic perspective could help explain how help-seeking patterns evolve as employees accumulate experience with AI tools, and whether early interaction experiences create trajectories of increasing AI reliance or continued preference for human support. Furthermore, future work could examine the outcomes of different help-seeking strategies, exploring whether AI-based, human-based, and hybrid help-seeking differ in their effects on individual performance and well-being, as well as on collective knowledge sharing and team collaboration.

In conclusion, the way employees seek and obtain help—once understood as an inherently interpersonal process—is now being fundamentally redefined. Help-seeking can no longer be understood as a purely social act, but a socio-technical and multi-level process, in which individual motivations and socio-technical conditions jointly determine how employees choose between different sources of support. By integrating STS and COR theories, we reconceptualize help-seeking as a resource regulation process in which individuals evaluate the costs and benefits of alternative help sources within a socio-technical environment. In doing so, we shift the

focus from whether individuals seek help to how they select among AI-based, human-based, and hybrid forms of assistance. This offers a foundation for future research on help-seeking in AI-mediated workplaces.

7 Ethics Declaration

This paper is a conceptual study and does not involve the collection or analysis of empirical data from human participants. Therefore, no ethical approval was required.

8 AI Declaration

Claude (Anthropic), an AI language model, was used for linguistic refinement of the manuscript. All AI-assisted content was critically reviewed by the authors. The use of AI was limited to language editing and did not extend to the development of ideas or the conceptual framework, which remain the authors' original work.

AI–Gamification Role Matrices in Knowledge Management: Evidence and Research Gaps

Behrooz Moradi[1], Ettore Bolisani[1], Enrico Scarso[1], Kathrin Kirchner[2], Furong Cai[1]

[1] Department of Management and Engineering, University of Padova, Vicenza, Italy

[2] Department of Engineering Technology, Technical University of Denmark, Ballerup, Denmark

Abstract

As knowledge work becomes more digital and distributed, organizations increasingly rely on two levers to sustain knowledge management (KM) performance: Artificial Intelligence (AI) to expand what KM systems can do and gamification to strengthen why people contribute and reuse knowledge. Yet prior research rarely specifies how AI and gamification are jointly organized across KM subfields, thereby limiting both theory building and design guidance. This study analyzes the AI–gamification–KM triad using a structured evidence synthesis that combines systematic searching, qualitative content analysis, and matrix-based modeling. Drawing on 44 peer-reviewed studies retrieved from four major scholarly databases with coverage through December 1, 2025, two independent coders classified each study by KM subfield, sector, outcome type, and AI and gamification role assignments. Descriptive statistics were produced in SPSS, and role matrices were constructed and visualized in R to generate a configurational evidence map linking role combinations to effect categories. The results show a clear division of labor: human involvement concentrates on learning and knowledge acquisition, while AI involvement concentrates on system-supported functions, most frequently knowledge representation, collection, and analysis. Evidence also clusters by context, with higher education dominating and outcomes primarily reported as systems and platforms. Across effect categories, the evidence base is dominated by a narrow configuration that combines engagement-oriented gamification with tailoring AI functions, while many other role combinations remain sparse or absent. These gaps are most pronounced in KM processes that require transfer, externalization, fusion, and refinement. The study contributes a framework that clarifies how AI and gamification co-configure KM outcomes and provides an evidence-based agenda for testing missing configurations across KM subfields and sectors.

Keywords: Knowledge Management, Artificial Intelligence, Gamification, Research gaps.

Paper type: Academic Research Paper.

1 Introduction

KM remains a central concern for organizations that rely on distributed digital work (Watson and Hewett, 2006; Beesley and Cooper, 2008). The rapid pace of technological change and the proliferation of information sources increase the effort needed to find, evaluate, and reuse knowledge (Tatsiopoulos and Katsanta, 2018; Fensel *et al.*, 2020; Moradi *et al.*, 2024). KM research, therefore, spans both human-centered processes and the functions of KM systems (KMSs) (Watson and Hewett, 2006; Fensel *et al.*, 2020; Moradi *et al.*, 2025).

Recent KM-related studies have examined the joint use of AI and gamification to support KM initiatives (Sánchez *et al.*, 2024; Umer *et al.*, 2024; Huang and Chuang, 2025). AI is typically studied as a set of AI-enabled functions embedded in KMSs that enable knowledge activities such as collection, validation, and dissemination of knowledge (Ipeirotis and Gabrilovich, 2014; Fensel *et al.*, 2020; Cai *et al.*, 2023). Gamification, the application of game design elements (Deterding *et al.*, 2011), is associated with improvements in knowledge acquisition and transfer (Tenorio *et al.*, 2018; Ahmed *et al.*, 2024; Youyou, Zihan and Mengfang, 2025). Therefore, studying them together matters because AI shapes KMS capability and gamification shapes user participation and engagement, and both can affect the same KM initiative.

This systematic literature review (SLR) synthesizes how AI and gamification are examined together in KM. It addresses (RQ1) how human-related and AI-related involvement is distributed across KM subfields, (RQ2) in which sectors this combination is applied and what outcome types are reported, and (RQ3) what kinds of effects are associated with different AI–gamification role configurations. The study develops a configurational evidence map that synthesizes prior work and reveals systematically underexplored AI–gamification role combinations across KM subfields.

2 Literature Review

KM research has traditionally emphasized human-driven knowledge processes through which individuals and organizations manage knowledge. Core human-related KM subfields discussed in foundational KM research include learning, knowledge acquisition, sharing, contribution, application, transfer, externalization, and creation (Nonaka, Toyama and Konno, 2000; Alavi and Leidner, 2001; Alavi and Tiwana, 2002; Watson and Hewett, 2006; Beesley and Cooper, 2008; Wang and Noe, 2010; Carleton, 2011). Within this stream, gamification is often examined as a design approach to strengthen engagement in KM activities, such as collaborative knowledge construction and refinement (Tenorio *et al.*, 2018; Ralli *et al.*, 2020; Moradi *et al.*, 2024).

In parallel, AI in KM research has emphasized system-level knowledge functions implemented within KMSs. Drawing on the Knowledge Graph lifecycle, prior work highlights functions such as knowledge collection, aggregation, validation, fusion, refinement, representation, storage, analysis, and dissemination (Fensel *et al.*, 2020). In this line of work, AI is examined as a component that can directly support KMS functions or indirectly enhance KMS performance by optimizing features that enable KM processes, including knowledge validation, refinement, and dissemination (Ipeirotis and Gabrilovich, 2014; Ralli *et al.*, 2020; Huang and Wen Chuang, 2024).

Prior reviews often examine AI, gamification, and KM separately, and they vary widely in the extent to which they cover this triad. Some reviews focus on a single AI artifact class, such as chatbots, with gamification treated as a minor facilitation, and KM coverage concentrated on knowledge acquisition in educational settings (Ma *et al.*, 2025). Related reviews treat gamification mainly as an instructional method and include only a minimal or peripheral AI role. At the same time, “knowledge” is operationalized primarily as skills or knowledge acquisition rather than as a structured set of KM subfields (Ahmed *et al.*, 2024). Other reviews integrate AI-driven personalization and gamification and include KM subfields such as learning. Still, their synthesis remains centered on learning outcomes, limiting coverage across a broader set of KM subfields (Sheejamol, Chacko and Kumar, 2025). One review maps gamification across multiple KM subfields. However, it does not include AI, so the combined evidence on AI, gamification, and KM remains incomplete and supports the need for an integrative synthesis (Moradi *et al.*, 2024).

To address these gaps, this study adopts an AI–gamification–KM lens that treats the triad as a unified configuration. This lens enables a structured synthesis of how prior studies combine these elements across KM subfields, sectors, and outcomes and forms the basis of the evidence map presented in the Results section.

3 Methodology

The study used a structured search across four databases: Scopus, Web of Science, IEEE Xplore, and the ACM Digital Library. Predefined keyword groups for gamification, KM, and AI were used to retrieve records containing terms from all three categories (Table 1). Searches covered all available years up to December 1, 2025, were limited to English-language records, and were executed on the same date.

Table 1. Search String and Keyword Categories Used in the SLR

Keywords
(“gamification” OR “game element” OR” game mechanics” OR” game dynamics” OR” Game components” OR “Gamify*"OR" gamified*"OR” Gameful”)
(“knowledge management” OR “knowledge creation” OR “knowledge acquisition” OR “knowledge storage” OR “knowledge sharing” OR “knowledge transfer” OR “knowledge application” OR “knowledge protection “OR “knowledge process“ OR “intellectual capital” OR” knowledge engineering” OR” knowledge representation” OR” knowledge mapping” OR” knowledge extraction” OR” knowledge discovery” OR” knowledge retention” OR” knowledge utilisation” OR” knowledge audit” OR “knowledge-based systems” OR” knowledge economy” OR” KM practices” OR” knowledge management practices”)
("artificial intelligence" OR "machine learning" OR "deep learning" OR "neural network" OR "natural language processing" OR "NLP" OR "expert system" OR "intelligent system*" OR "intelligent agent*" OR "automated reasoning" OR "decision support system*" OR "data mining" OR "text mining" OR "semantic system*" OR "ontolog*" OR "computational intelligence" OR "generative model*" OR "large language model*" OR "LLM*" OR "AI")

Screening was conducted in two stages: first title and abstract, then the full text. Studies were included if they were peer-reviewed journal articles or conference papers in English and contained at least one keyword from each category. Books, book chapters, theses, reports, non-peer-reviewed materials, and duplicates were excluded. Finally, 44 studies met the inclusion criteria. No backward or forward snowballing was conducted. The screening flow is presented in the PRISMA diagram (Figure 1).

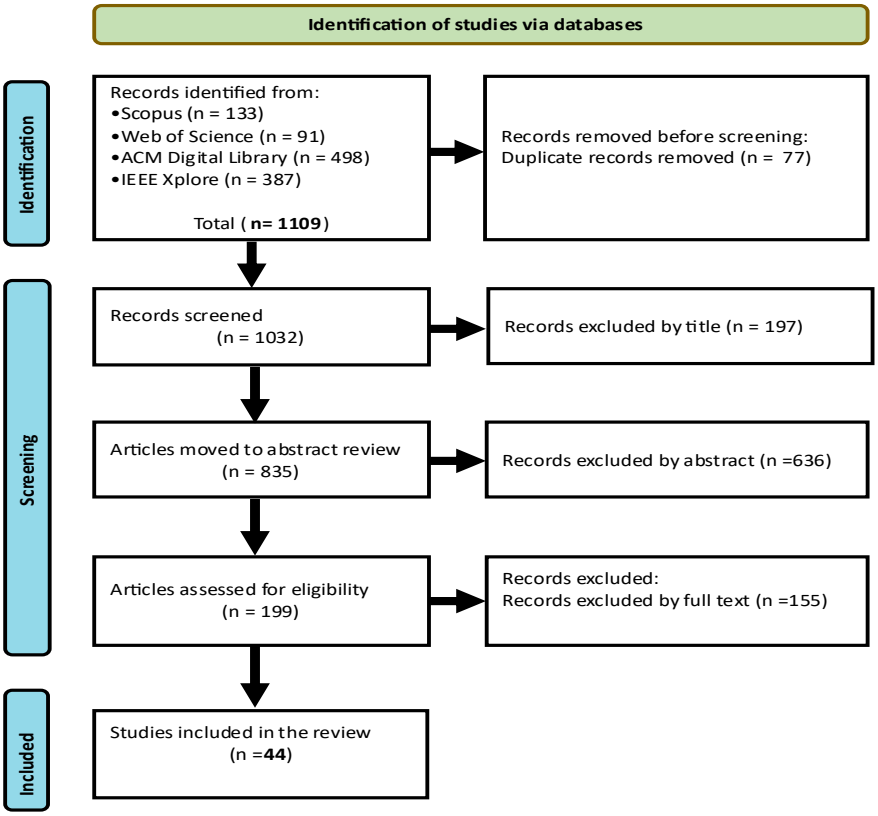

Figure 1. PRISMA Flow Diagram of Study Selection

For analysis, the included studies were examined using an SLR and qualitative content analysis through a triadic lens to assess how AI, gamification, and KM are addressed together across contexts. Study screening and coding were independently conducted by two researchers, with discrepancies resolved through consensus. Each study's KM subfield(s) and AI–gamification roles were coded, and data analysis was supported using SPSS for descriptive statistics and R for matrix construction and visualization.

Regarding the operationalization of the roles, an AI role was coded as the dominant functional contribution AI performs within the KMS. For example, AI that analyzes learner data and adapts task difficulty or generates personalized scenarios was coded as A2 (tailoring), whereas AI that optimizes system parameters through simulation was coded as A6 (system optimization). A gamification role was coded as the dominant behavioral or structural function through which game elements shape KM activities. For instance, using items to increase motivation and engagement were coded as G1, while age-appropriate items supporting knowledge acquisition were coded as G2. The detailed results are explained in the following section.

4. Result and discussion

4.1. Publication Trends and Overview of the Reviewed Study Corpus

Figure 2 shows that, although no time restrictions were applied, the earliest relevant record dates to 2013. From 2013 to 2023, output remained low, never exceeding 3 studies per year. Publication volume then increased sharply in 2024 and remained high in 2025, with 14 and 12 records, respectively. This surge reflects growing scholarly interest, likely driven by AI advancements and the need to enhance KM through motivational design. The trend confirms the triad's emergence as a cohesive research configuration and underscores the need for systematic synthesis to guide future integration and theorization.

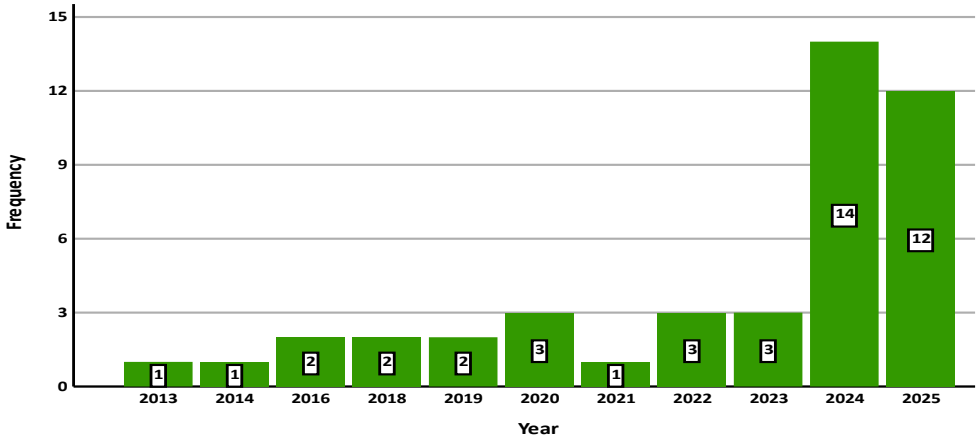

Figure 2. Annual AI–gamification–KM publications

Table 2 summarizes the coded study set and provides the data foundation for the analyses of the KM subfield, sectoral distribution, outcome types, and AI–gamification role configurations reported in Sections 4.2–4.4.

4.2. Human and AI Involvement Across KM Subfields (RQ1)

Figures 3 and 4 visualize the resulting distributions for RQ1 and RQ2. Figure 3 uses color coding to distinguish human-related (green) and AI-related (blue) subfields. Human involvement is concentrated in learning (40.0%) and knowledge acquisition (22.2%), with smaller shares in knowledge creation and knowledge sharing. At the lower end, knowledge externalization and knowledge transfer are least represented (2.2% each). Regarding AI involvement, knowledge representation is most frequent (28.6%), followed by knowledge collection and knowledge analysis, while knowledge fusion and knowledge refinement are least frequent (2.9% each). This distribution indicates that the literature most often places humans at the center of KM subfields that depend on learning and interpersonal exchange, where meaning and context are critical.

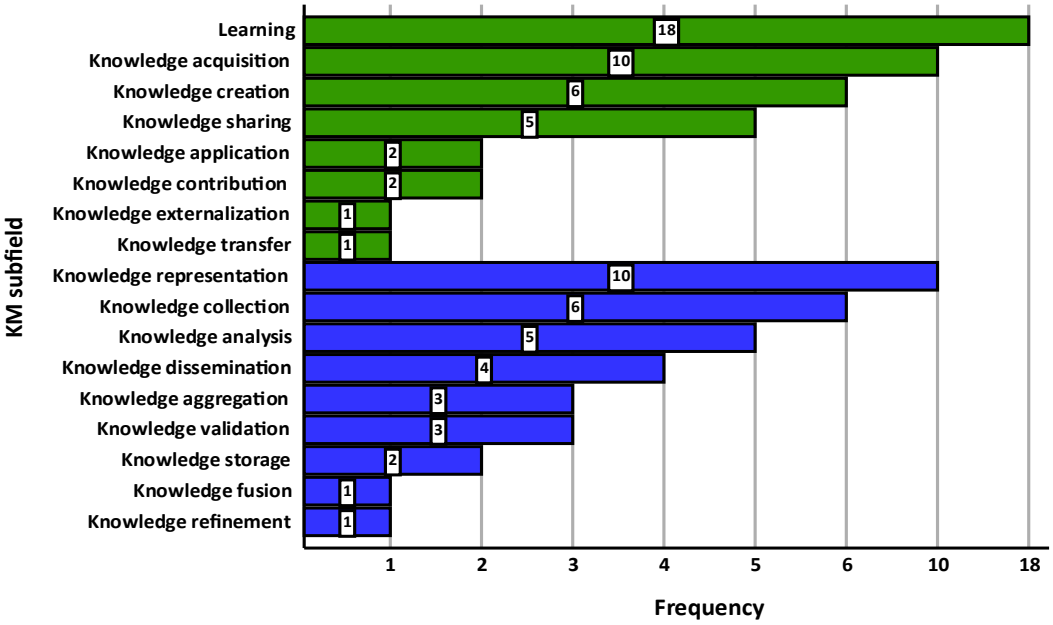

Figure 3. Human and AI involvement across KM subfields
Note: Studies may contribute to multiple subfields

AI involvement clusters in subfields that structure and process knowledge inside KMSs, especially representation, collection, and analysis. The pattern suggests that current studies more often treat AI as infrastructure that organizes and delivers knowledge rather than as a direct substitute for human knowledge work. Knowledge transfer, externalization, fusion, and refinement appear only rarely in the reviewed studies. As a result, the evidence is limited on how human and AI involvement is reported and characterized for these KM processes across sectors.

4.3. Sectoral Outcome Patterns in KM Studies (RQ2)

Figure 4 summarizes the reviewed studies by sector and outcome type, showing a pronounced concentration in three domains. Higher education (HE) accounts for 18 studies, followed by K–12 education (6) and computational knowledge systems (5). The remaining sectors, including societal contexts, professional training, and health, are evenly represented, each contributing 4 studies, while enterprise operations contribute 3

studies. Regarding outcomes, *systems* are the most frequently reported artifact, appearing in 11 studies, followed by *platforms* in 9 and *models* in 8. Other outcomes, such as prototypes and applications, occur less frequently, while frameworks, approaches, and analytical studies are comparatively limited.

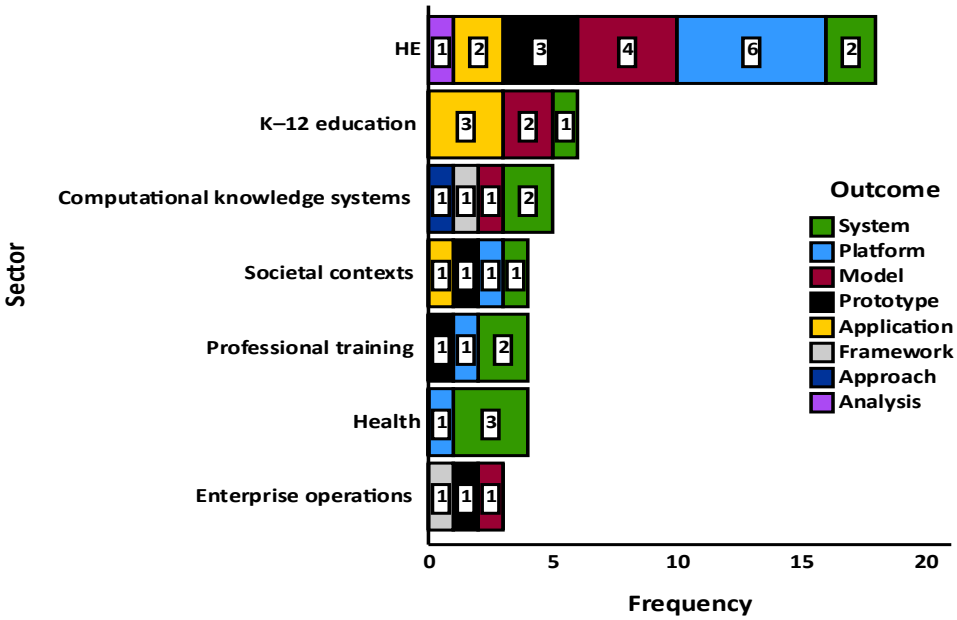

Figure 4. Sector and outcome distribution of studies

4.4. AI–Gamification Role Configurations and Associated Effects (RQ3)

Based on a cross-study synthesis, Figure 5 synthesizes the reviewed evidence by illustrating how AI roles (A1–A7) and gamification roles (G1–G7) are combined across studies addressing knowledge-related contexts to produce distinct effect categories (F1–F7). Across the seven matrices, a clear concentration emerges around G1 (82) and A2 (42), with their co-occurrence (G1–A2; 27) as the most frequent configuration. This dominance indicates that tailoring AI functions (recommendation, adaptation, and personalization) are predominantly used to steer engagement-oriented gamification, while most other AI–gamification role combinations remain sparsely examined. Building on this overall concentration, the following patterns differentiate how specific AI–gamification role configurations align with distinct effect categories.

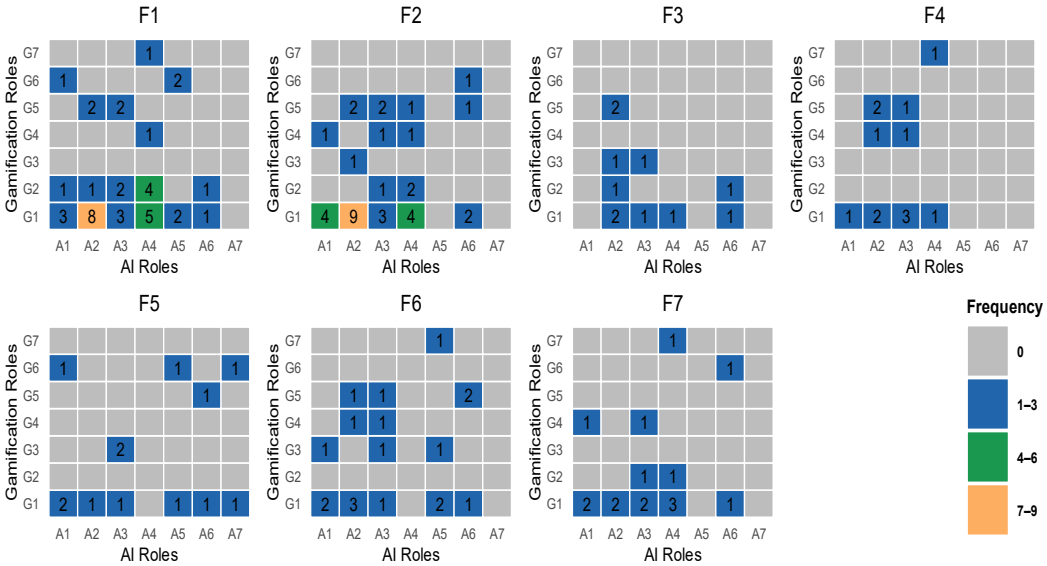
Engagement-centered, low-complexity configurations characterize F1 and F2, where effects are primarily supported by G1 combined with A2 and A4. At the same time, F3 reflects a weaker extension of this pattern with a modest presence of A6, indicating reliance on engagement and tailoring approaches with limited system-driven reinforcement.

Balanced dual-role configurations emerge in F4, where G1 is combined equally with A2 and A3, suggesting that task-related effects are supported through the joint contribution of tailored guidance and information provision rather than a single dominant AI role.

Distributed, multi-role configurations are evident in F5 and F6, where G1 co-occurs with multiple AI roles (A1, A3, A5, A6), indicating that creation- and system-level effects are associated with broader AI role combinations.

Interaction-focused configurations characterize F7, where G1 is combined with A4 and complemented by A3 and A1, highlighting the importance of interactive and informational support for satisfaction-related effects.

Overall, the findings show that AI–gamification effects in knowledge-related contexts depend on how specific roles are configured, rather than on AI or gamification alone. Unpopulated and sparsely populated matrix cells highlight evidence-based research gaps that point to unexplored AI–gamification role configurations.



Code	AI Roles	Description
A1	Detect / Analyze / Assess	Recognize patterns, classify inputs, and analytically assess data without prescribing actions.
A2	Recommend / Adaptation/ Personalization	Provide personalized recommendations or adapt content, difficulty, or pathways based on user data.
A3	Content Generating	Automatically generate content such as text, quizzes, explanations, or questions.
A4	Conversational Support	Deliver dialog-based interaction through chatbots or virtual tutors to support users.
A5	Knowledge Representation & Reasoning	Structure, represent, and reason over knowledge using ontologies, rules, or knowledge bases.
A6	Simulate / Optimize / Control	Simulate environments, manage agents, or optimize system parameters and control processes.
A7	Extract / Annotate / Validate	Extract metadata, propose annotations, or support human validation and curation tasks.

Code	Gamification Roles	Description
G1	Motivation & Engagement	Increase general motivation, engagement, persistence, and enjoyment.
G2	Knowledge acquisition and Learning	Support knowledge acquisition, learning outcomes, and skill development.
G3	Behavior Change	Encourage long-term behavior change (e.g., health, sustainability, compliance).
G4	Progression & Competition Structuring	Organize progression through levels, challenges, goals, and competitive structures.
G5	Effort & Quality Recognition	Recognize effort or contribution quality using points, badges, rewards, or achievements.
G6	Knowledge Contribution & Collaboration	Drive social participation, crowdsourcing, and collaborative knowledge contribution.
G7	Decision & Pathway Guidance	Guide user decisions and learning paths through nudging, branching, or adaptive choice structures.

Code	Findings	Description
F1	Knowledge Acquiring & Transfer	AI-enabled personalization and collaborative tools were associated with stronger knowledge acquisition and transfer.
F2	Participation Intensity & Use	Interactive system design and engagement mechanisms were linked to higher participation and sustained use.
F3	Sustained Behavior Adoption	Personalized training and persuasive gamification supported continued behavioral change and compliance.
F4	Decision & Task Performance	Prediction, recommendation, and personalization tools were associated with better decisions and task performance.
F5	Collaborative Knowledge Creation and Review	Collaboration, crowdsourcing, AI evaluation, and contribution validation enhanced knowledge creation and contribution quality.
F6	System Effectiveness & Efficiency	AI optimization, ontologies, recommendations, and automation contributed to greater system effectiveness and efficiency.
F7	User Satisfaction & Perceived KMS Value	Engaging, explainable, and user-friendly systems were linked to higher satisfaction and perceived KMS value.

Figure 5. AI–gamification role configurations and associated effects

5 Conclusion

This study examines how AI and gamification are jointly applied in KM using a configurational perspective. Through an SLR and qualitative content analysis, it synthesizes KM subfields, sectors, outcomes, and AI–gamification roles, supported by analysis in SPSS and matrix-based modeling in R.

The findings show that human involvement concentrates on learning- and acquisition-oriented KM subfields, while AI involvement is most prominent in system-supported KM functions such as representation, collection, and analysis, with studies predominantly situated in higher education and reporting system- and platform-level outcomes. Engagement-oriented gamification combined with tailoring AI functions emerges as the dominant configuration.

Theoretically, the study advances KM research by conceptualizing AI and gamification as configurable roles whose alignment explains variation in KM effects. This lens clarifies how human and system roles interact across KM subfields and shape distinct effect categories.

Methodologically, the study contributes a replicable, role-based configurational approach, operationalized through matrix-based evidence mapping, which enables systematic cross-study comparison of AI–gamification role combinations and their effects. This approach supports both synthesis and explicit identification of underexplored configurations.

This study offers practical implications for designing AI-enabled gamified KMS. The evidence indicates that personalization-oriented AI, such as adaptive feedback or content recommendations, commonly complements engagement-focused gamification when the goal is to increase user participation. For more complex KM objectives, such as structured task performance or knowledge creation, broader combinations of analytical, optimization, and guidance-oriented AI capabilities appear more suitable than engagement-centered designs alone. Thus, the matrices support informed managerial decisions when configuring AI and gamification for specific knowledge goals.

Finally, the presence of sparsely populated and empty matrix cells reveals evidence-based research gaps, pointing to AI–gamification role combinations that remain largely unexplored. Future research should empirically examine these missing configurations across KM subfields and sectors to assess their effects and boundary conditions. This study is limited by its reliance on peer-reviewed, English-language publications retrieved from selected academic databases, which may exclude relevant work published elsewhere or in other languages.

6 Acknowledgments

The study that led to these results received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement No. 101034319 and from the European Union's NextGenerationEU.

7 Ethics Declaration

This study relies on an SLR and content analysis of published studies and, therefore, did not require ethical approval.

8 AI Declaration

AI tools (ChatGPT 5.3 and Grammarly) were used solely to improve grammar and sentence structure.

Decision-Making Approaches and Entrepreneurs' Pivot Decisions? An RCT Experiment

Micol Di Vita, Andrea Panelli
Department of Management and Production Engineering, Politecnico di Torino, Turin, Italy

Abstract

Do decision-making approaches affect entrepreneurs' pivot decisions on the Business Model Canvas? To address our research question, we investigated how decision-making approaches, namely the scientific method (Camuffo et al., 2024) and the effectuation method (Sarasvathy, 2008), affect entrepreneurs' pivot decisions. In particular, we analysed how entrepreneurs tend to change blocks on the left or right of the Business Model Canvas BMC (Osterwalder, 2004), depending on the methods they are approaching. In order to achieve our goal, we based our research on entrepreneurial learning (Cohen et al., 2019; McDonald and Eisenhardt, 2020; Pillai et al. 2020), included in entrepreneurial theories (Ott and Hannah, 2024) and we applied it to the scientific method, according to the theory-and-evidence-based approach (Agarwal et al., 2024), and to Saras Sarasvathy's theory of effectuation (Sarasvathy, 2008), related to the evidence-based approach. By building on previous literature, little is known about which specifically BMC's blocks entrepreneurs adopting these approaches tend to change, in particular during entrepreneurial training programs. In this vein, we collected evidence via a randomized control trial (RCT) experiment with 308 Italian early-stage startups randomly assigned to "treatment" (scientific, effectuation) and "control" group (trial-and-error), involved in a pre-acceleration program. We observed early-stage startups throughout and post-training and we compared differences concerning which side of the BMC entrepreneurs changed and how many times they made pivots to modify the BMC. We find that entrepreneurs using a scientific method are more likely to make one pivot both on the left and on the right side of the BMC compared to the control group. On the other hand, entrepreneurs using an effectuation method tend to make at least one pivot only on the right side compared to the control group. Furthermore, considering the cumulate number of pivots, we found that entrepreneurs who learn a scientific method made more pivots on the left side of the BMC. On the other hand, entrepreneurs approaching the effectuation method made more pivots on the right side of the BMC. These findings demonstrate that the scientific method and effectuation method can shape pivot decisions differently.

Keywords: decision-making, scientific approach, pivot, randomized control trial, business model canvas

Paper type: Academic Research Paper

1 Introduction

At the origin of a startup, entrepreneurs usually build a business model to implement their entrepreneurial idea. This model includes nine blocks (value proposition, customer segments, customer relationships, channels, revenue streams, key activities, key resources, key partners and cost structure) necessary for the survival of the startup under extreme uncertainty. To address this uncertainty, previous research has proposed Business Model Canvas BMC (Osterwalder, 2004), as a tool to visualize the components necessary for entrepreneurial idea. Entrepreneurs typically represent the BMC with blocks on the left side that manage infrastructure (key partners, key activities, key structure, cost structure) and blocks on the right side related to value creation (value proposition, customer relationships, customer segments, channels, revenue streams). For instance, during early-stage phase entrepreneurs need to verify frequently their business model to address problems or strategic additions. In this vein entrepreneurs tend to make a pivot, which represents a strategic action to reallocate activities, resources and attention through an accumulated series of decisions by reorienting the startup's direction (Kirtley & O'Mahony, 2020). Moreover, pivots are knowledge-adaptation processes that can contribute to the sustainability of the business model development. Based on previous literature, startups create an iterate process to validate assumptions with high frequency of changes across multiple components of the BMC (Bellavitis et al., 2024). They aim to respond to market feedback and align their innovations with market needs. In particular, entrepreneurs tend to change the block of value proposition and customer segments because these are the levers for finding product–market; on the other hand, key blocks remain below-average developed (Slavik, 2019). This perspective is consistent with trial-and-error epitomized by Lean Startup methodologies (Ries, 2011) but it does not specify how many pivots might be needed nor how to halt the decision-making process (Sarasvathy, 2024). For this reason, recent research has proposed various interventions to help entrepreneurs' pivot decisions, typically provided in the form of entrepreneurial training (ET) programs (Alexandria et al., 2014; Bacigalupo et al., 2016; Morris et al., 2023). ET programs aim to enhance entrepreneurs' decision-making processes by helping them collect information to refine their BMC and better understand

whether to pivot. Furthermore, there is an existing research stream showing that entrepreneurs who learn specific decision-making methods through ET programs perform differently from those who do not (Camuffo et al., 2024). In this context, researchers indicate that entrepreneurs trained with the scientific method are more likely to make fewer strategic pivots, showing how they seem thrifty with resources and more strategic-oriented. In addition, another approach that focuses on resources' availability is Sarasvathy's effectuation method, according to which entrepreneurial process moves forward only through commitments that make the next step affordable loss (Sarasvathy, 2024). These outcomes occur because these entrepreneurs, by leveraging specific decision-making frameworks, collect different types of information and feedback that ultimately shape their pivot decisions. Nevertheless, we lack evidence on which specifically BMC's blocks entrepreneurs tend to change when they adopt the scientific method or the effectuation method during ET programs. This gap is particularly relevant for both scholars and practitioners, as different training programs can prompt entrepreneurs to change different BMC's blocks, choosing to focus on a specific side of the BMC. In that sense, this research aims to investigate how entrepreneurs tend to change blocks on the left or right of the BMC depending on the methods they are approaching. Given these premises, we address the following research question *"Do decision-making approaches affect entrepreneurs' pivot decisions on the Business Model Canvas?"*. We based our research on entrepreneurial learning (Cohen et al., 2019; McDonald and Eisenhardt, 2020; Pillai et al. 2020), included in entrepreneurial theories (Ott and Hannah, 2024) and we applied it to the scientific method, according to the theory-and-evidence-based approach (Agarwal et al., 2024), and to Saras Sarasvathy's theory of effectuation (Sarasvathy, 2008), related to the evidence-based approach. In order to achieve our goal, we leveraged data collected through a randomized control trial (RCT) embedded in a pre-acceleration program. We randomly assigned 308 Italian entrepreneurs to three different groups, each exposed to a distinct entrepreneurial training. One group received training in a scientific decision-making method (Camuffo et al., 2020), another group in effectuation (Sarasvathy, 2008), and the last group in a heuristic approach emphasizing trial and error. We observed early-stage startups throughout and post-training and we compared differences concerning which side of the BMC entrepreneurs changed and how many times they made pivots to modify the BMC. Our econometric analyses show that entrepreneurs who learn a scientific method seem to adjust the left side of the BMC related to infrastructure after the value creation side is validated. On the other hand, entrepreneurs adopting an effectuation method prefer to look for blocks on the right side of the BMC, in particular related to customers. As results, both scientific and effectuation methods impact on entrepreneurs' pivot decisions, showing which side of the BMC they prefer to change.

2 Theoretical Background and Hypothesis Development

Previous literature has focused on entrepreneurial learning (Cohen et al., 2019; McDonald and Eisenhardt, 2020; Pillai et al. 2020), included in entrepreneurial theories (Ott and Hannah, 2024), to develop mental models able to organize and capture a business opportunity. In this context, entrepreneurs learn how to develop theories that can be combined to "fragments" of experience and observation. In this way, entrepreneurs can extend beyond existing experiences and observations to create cohesive understanding about how to act (Ott and Hannah, 2024). This combination is achieved through experimentation that works and illustrates its intersections with other learning processes and commitment. Entrepreneurs combine action and cognition by using business-model templates to guide experiments. They recognize the role of Business Model Canvas as cognitive schema, providing broad guidance on developing early prototypes that advance learning and create value (McDonald and Eisenhardt, 2020). Such experiments are the key to success for those startups that have associated learning to economical experiments to make strategic pivots (Pillai et al. 2020). For this reason, entrepreneurial training programs (ET) for early-stage startups play a vital role in supporting entrepreneurs combining theory and experimentation. These programs seek to provide entrepreneurs with decision-making abilities, enabling them to shape a new business and understand whenever make pivotal decisions. More precisely entrepreneurs, who learn specific decision-making approach through ETs have a better understanding of the value of their idea, thus the number of pivots made (Camuffo et al., 2020). For instance, research on programs based on teaching a scientific method to decision-making has shown that entrepreneurs who learn this approach are more likely to make fewer changes to their value proposition and customer segments (Camuffo et al., 2024). On the other hand, entrepreneurs who learn effectuation method are explicitly open to changing their goals and they can assent to a wider variety of products and services sooner (Sarasvathy, 2024). Despite these premises, little is known about which specifically BMC's blocks entrepreneurs tend to change when they adopt the scientific method or the effectuation method. In particular, which side of the BMC entrepreneurs prefer to change during ET programs.

Building on these studies, we argue that different decision-making methods taught in ET can push entrepreneurs to pivot on different parts of their BMC. Due scientific entrepreneurs tend to make fewer pivots to the value creation side, we propose that they will be more inclined to explore the left side of the BMC related to infrastructure than other entrepreneurs; on the other hand, due entrepreneurs approaching the effectuation method prefer to satisfy customers interest, we expect that they will prefer to focus more on pivoting the right side of the BMC related to value creation compared to other entrepreneurs.

Accordingly, we propose the following hypothesis:

H: *Different decision-making methods push entrepreneurs to pivot on different parts of their BMC.*

3 Methodology and Data

3.1 Methodology

We collected evidence via a randomized control trial (RCT) in which 308 early-stage startups from Italy involved in a pre-acceleration program were randomly assigned to "treatment" (scientific, effectuation) and "control" group, similarly to previous studies (Camuffo et al., 2024). At the beginning of the experiment, we randomly assigned entrepreneurs to two treatment groups (being taught how to develop a business model using the scientific method; and being taught how to develop a business model using the effectuation method). We also assigned entrepreneurs to a third control group where they approached trial-and-error and they have to develop a business model using heuristics.

The pre-acceleration program was delivered online (due to Covid-19 lockdowns) and it provided training to early-stage startups for a short period of time (four months and a half). After the call for application, our initial samples include 308 early-stage startups. Using randomization, we divided the 308 startups between the two treatment groups and the control group. We checked that each treatment group (102 startups for the scientific method and 105 startups for the effectuation method) and the control group (101 startups) were balanced on several key covariates that might affect the absorption of the treatments and subsequent outcomes. Differences between the treatment groups and control are small in magnitude, and there are no significant differences between the three groups. The pre-acceleration program lasted from October 2020 to February 2021. The program was focused on market validation. The contents and length of each session was the same for each group, but with different logics in the decision-making approaches taught to each group. The first treatment group learnt to develop the BMC using the scientific method; entrepreneurs assigned to the second treatment group learnt to develop the BMC adopting the effectuation method. The control group learnt how to develop the BMC using the same tools of the two treatment groups, but without learning how to use these tools following the scientific method or the effectuation method. We avoided possible contaminations among the three groups following previous best practices used in field experiments regarding decision-making approaches (Camuffo et al. 2024). We observed startups throughout and post-training and we compared differences concerning which side of the BMC entrepreneurs changed and how many times they made pivots to modify the BMC. We considered a left pivot as a change made by blocks that manage infrastructure (key partners, key activities, key structure, cost structure), and a right pivot as a change made by blocks related to value creation (value proposition, customer relationships, customer segments, channels, revenue streams).

3.2 Data collection

We collected data following a two-step approach. The first stage of data collection was performed before the beginning of the pre-acceleration program, during the enrolment phase. Before enrolling in the pre-acceleration program, we asked entrepreneurs to fill out a survey regarding the characteristics of their entrepreneurial idea and about the demography characteristics and human capital of the founding team. This data collection was used to randomize the entrepreneurs between the three treatments and to create part of the independent variables. During the second stage of the data collection, we collected data for 10 points of observation using monthly interviews for ten and a half months. Each interview was led following a semi-structured approach to collect information about the entrepreneurs' decision-making, whether they pivoted or not in terms of changes to their BMC.

3.3 Dependent Variables and Independent Variables

3.3.1 Dependent Variables

As dependent variables, first we used two dependent binary variables to capture which side of the BMC entrepreneurs tend to change. We employed *Left pivot* taking the value 1 whenever an entrepreneur made at least one pivot changing at least one block of the left side of the BMC along the 10 points of observation, 0 otherwise. In a similar vein, we created the variable *Right pivot* taking the value 1 whenever an entrepreneur made at least one pivot changing one block of the right side of the BMC along the 10 points of observation, 0 otherwise.

Second, we investigated the total number of pivots made to the left and right side of the BMC along the 10 points of observation using respectively *Cumulate left pivot*, the cumulate number of pivots made on the left, and *Cumulate right pivot*, the cumulate number of pivots made on the right.

3.3.2 Independent Variables

As independent variable, we employed a categorical variable *Intervention* taking the value 1 whenever an entrepreneur was in the control group, 2 in the scientific group, 3 in the effectuation group.

Finally, we controlled for early termination of the entrepreneurial idea using the control variable *Termination*, taking the value 1 whenever an entrepreneur terminated the entrepreneurial idea, 0 otherwise.

Table 1 presents the descriptive statistics for both the independent and dependent variables.

Table 1**:** Descriptive statistics

Variable	Observations	Mean	Standard deviation	Min	Max	Description
Dependent						
Left pivot	3,388	0.03	0.17	0	1	Binary variable. 1 whenever an entrepreneur makes at least one pivot changing at least one block of the left side of the BMC along the 10 points of observation; 0 otherwise
Right pivot	3,388	0.12	0.33	0	1	Binary variable. 1 whenever an entrepreneur makes at least one pivot changing at least one block of the right side of the BMC along the 10 points of observation; 0 otherwise
Cumulate Left pivot	3,388	0.19	0.50	0	4	Cumulate number of pivots made on the left side of the BMC along the 10 points of observation.
Cumulate Right pivot	3,388	0.91	1.09	0	7	Cumulate number of pivots made on the right side of the BMC along the 10 points of observation.
Independent						
Intervention	308	2.01	0.82	1	3	Binary variable. 1 if an entrepreneur belongs to Control group, 2 to Scientific group, 3 to Effectuation group.
Termination	3,388	0.22	0.41	0	1	Binary variable. 1 whenever an entrepreneur terminates the idea; 0 otherwise.

3.4 Statistical approach

We tested our hypothesis using econometrics analysis, leveraging on data collected along the 10 points of observation. Given the nature of our dependent variables, we first adopted probit model for testing left pivot and right pivot, then negative binomial model for testing the cumulate amount of left pivot and right pivot of early-stage startups. We include a vector of control variables to capture potential differences in the instructors' teaching styles, and we cluster standard errors at both the instructor and intervention levels.

4 Results

Table 2 shows the results of entrepreneurs learning specific entrepreneurial decision-making methods who make pivot decisions on the BMC. Models (1) and (2) present the empirical analysis of Left pivot and Right pivot. Entrepreneurs adopting a scientific method are more likely to make one pivot both on the left and on the right side compared to the control group. On the other hand, entrepreneurs using an effectuation method tend to

make at least one pivot only on the right side compared to the control group. Furthermore, models (3) and (4) consider the cumulate number of pivots. We found that entrepreneurs who learn a scientific method make more pivots on the left side of the BMC along the 10 points of observation. On the other hand, entrepreneurs approaching the effectuation method make more pivots on the right side of the BMC along the 10 points of observation. Collectively, these results confirm our hypothesis showing that different decision-making methods seem to push entrepreneurs to pivot on different parts of their BMC. More precisely, entrepreneurs who learn a scientific method seem to follow a more holistic approach when evolving their entrepreneurial idea, adjusting both the infrastructure side and the value creation side of the BMC. In particular, scientific entrepreneurs tend to make at least one pivot to test their theory with potential customers and, once it is validated, they tend to make more pivots on the left side to focus on infrastructure. On the other hand, entrepreneurs adopting an effectuation method prefer to look for an additional customer segment or identify a different value their idea can offer in response to market conditions rather than modify the initial resources. As a result, both scientific and effectuation entrepreneurs tend to be very careful making strategical pivots showing which side of the BMC they prefer to change.

Table 2: Regressions with *Radical pivot* and *Incremental pivot* as dependent variables.

Variables	**(1)** **DV: Left Pivot** **Probit** **Cross Sections**	**(2)** **DV: Right Pivot** **Probit** **Cross Sections**	**(3)** **DV: Cumulative** **Left Pivot** **Negative Binomial Cross Sections**	**(4)** **DV: Cumulative** **Right Pivot** **Negative Binomial Cross Sections**

5 Conclusions

This work makes three contributions. First, it contributes to the literature on ET (Alexandria et al., 2014, McKenzie and Woodruff, 2014) and the role of methods applied to entrepreneurial decision-making (Camuffo et al., 2020, Sarasvathy, 2008). In particular, the scientific method and the effectuation method are relevant to create and validate processes. Second, we offer useful insights to literature on pivot decisions in early-stage startups. Pivots are typically associated with organizational flexibility. Thanks to decision-making methods, entrepreneurs learn to consider resources' availability choosing which BMC's blocks are necessary to change, without compromising on flexibility. This consideration has managerial implications that are relevant to practice for entrepreneurs' decisions, concerning resources allocation and long-term development of startups. Third, this study advances entrepreneurial learning process applied to entrepreneurs' pivot decisions involved in RCT experiments. In this way, our findings can support universities and accelerators programs involved in the creation and supply of ETs.

Artificial Intelligence Ambidexterity and Sustainable Business Models: A Configurational Case Study

Francesca Loia[1], Irene Fulco[2], Barbara Aquilani[2], Marcello Martinez[1]
[1] University of Campania Luigi Vanvitelli, Capua, Italy
[2] University of Tuscia, Viterbo, Italy

Abstract

This study explores how artificial intelligence (AI) enables organizational ambidexterity to support sustainability-oriented business models. Building on the knowledge-based view of the firm and organizational ambidexterity theory, it conceptualizes AI as a knowledge-enabling infrastructure that transforms how organizations generate, integrate, and apply knowledge. AI is framed as a dual capability that simultaneously supports knowledge exploitation - through optimization, automation, and efficiency - and knowledge exploration - through experimentation, simulation, and the generation of new insights.

Although prior research on AI and sustainability has expanded, it remains fragmented and often focused on linear applications of AI, overlooking its configurational nature. To address this gap, the study adopts a configurational perspective and investigates how different combinations of AI-enabled exploitation and exploration shape sustainability-oriented business models. A qualitative multiple-case study design is used, based on four multinational firms operating in different industries: Enel, Siemens, Unilever, and Nestlé. Data were collected from secondary sources, including sustainability reports, annual reports, and corporate strategy documents, and analyzed through within-case and cross-case comparison.

The findings identify four distinct archetypes of AI-enabled knowledge ambidexterity: (1) an ambidextrous sustainability transformer characterized by high levels of both exploitation and exploration; (2) an efficiency-oriented sustainability optimizer dominated by exploitation; (3) an innovation-oriented sustainability explorer driven mainly by exploration; and (4) a limited AI adoption configuration with weak integration of both processes. Each configuration corresponds to a different sustainability-oriented business model logic, ranging from system-level transformation to incremental efficiency gains and exploratory but less scalable innovation.

The results show that sustainability outcomes are not determined by AI adoption alone, but by how AI-enabled knowledge processes are configured and aligned with organizational structures and business model logic. The study highlights equifinality, demonstrating that different configurations can lead to sustainability through distinct pathways.

Theoretically, the paper contributes by reframing AI-enabled ambidexterity as a configurational knowledge capability and integrating ambidexterity theory with sustainable business model research. Practically, it suggests that managers should move beyond fragmented AI initiatives and instead design integrated systems that balance exploitation and exploration within coherent organizational and strategic architectures.

Keywords: Artificial intelligence; ambidexterity; business model; sustainable business model

Paper type: Academic Research Paper

1 Introduction

The increasing urgency of environmental, social, and governance (ESG) challenges is fundamentally reshaping how organizations create, manage, and leverage knowledge to support sustainable value creation. In this context, Artificial Intelligence (AI) is emerging as a critical knowledge-enabling technology, transforming how organizations generate, integrate, and exploit knowledge for sustainability-oriented strategies (George et al., 2021).

Despite growing scholarly attention, existing research on AI and sustainability remains fragmented. Prior studies tend to adopt linear perspectives, focusing either on efficiency-oriented applications (e.g., optimization, cost reduction) or on innovation-driven initiatives (Bai et al., 2020). Such approaches overlook the inherently ambidextrous nature of AI when understood as a knowledge-based organizational capability.

Drawing on the knowledge-based view of the firm (Grant, 1996) and organizational ambidexterity theory (March, 1991), this study argues that AI enables organizations to simultaneously engage in knowledge exploitation and exploration. While exploitation supports sustainability through efficiency, optimization, and reuse of existing knowledge, exploration enables experimentation, learning, and the generation of novel sustainability solutions. Importantly, these processes are not independent but interdependent and configurational in nature (Raisch et al., 2009).

This configurational perspective is particularly relevant in sustainability contexts, where organizations must address complex, systemic, and long-term challenges requiring both incremental improvements and

transformative innovation. However, there remains limited understanding of how different configurations of AI-enabled knowledge processes shape sustainability-oriented business models.

To address this gap, this study investigates the following research question:

How do different configurations of AI-enabled exploitation and exploration shape sustainability-oriented business models?

Adopting a configurational case study approach based on four multinational firms - Enel, Siemens, Unilever, and Nestlé - this study identifies archetypal patterns of AI-enabled knowledge ambidexterity and links them to distinct sustainable business model logics.

This study contributes to the literature in three ways. First, it conceptualizes AI ambidexterity as a knowledge-based and configurational capability rather than a linear technological investment. Second, it integrates ambidexterity theory with sustainable business model research by highlighting the role of business model alignment. Third, it demonstrates equifinality in AI-enabled sustainability, showing how different configurations of knowledge processes can lead to distinct sustainability pathways.

2 Theoretical Background

2.1 AI as a knowledge-enabling infrastructure

AI is increasingly conceptualized not merely as a technological tool, but as a knowledge-enabling infrastructure that fundamentally reshapes how organizations generate, process, and leverage knowledge (Ferraris et al., 2019). Unlike traditional information systems, AI systems are capable of autonomously identifying patterns, generating predictions, and supporting decision-making processes, thereby transforming raw data into actionable organizational knowledge (Barney, 2021; George et al., 2021).

From a knowledge-based perspective, the firm can be understood as an entity specialized in the integration and application of knowledge (Nonaka, 1994; Grant, 1996). Within this view, AI extends the firm's knowledge-processing capabilities by enhancing key processes such as knowledge codification, integration, and recombination (Alavi & Leidner, 2001; Davenport & Ronanki, 2018). In particular, AI enables the transformation of dispersed and unstructured data into structured knowledge, facilitating its reuse across organizational domains (Brynjolfsson & McElheran, 2016; Jarrahi, 2018).

This role becomes especially critical in sustainability contexts, where organizations must process complex, multidimensional information related to environmental impact, social responsibility, and governance practices. AI allows firms to handle such complexity by integrating heterogeneous data sources and generating insights that support sustainability-oriented decision-making (Vinuesa et al., 2020; Urbanovič & Holubčík, 2026).

However, the impact of AI on organizational knowledge processes is not unidimensional. While AI can enhance efficiency through optimization and automation, it also enables experimentation and the generation of novel knowledge through simulations, predictive modeling, and scenario analysis (Ransbotham et al., 2017; Raisch & Krakowski, 2021). This dual role suggests that AI should be understood as a technology that simultaneously supports both the exploitation and exploration of knowledge.

2.2 Organizational ambidexterity as knowledge process integration

The distinction between exploitation and exploration represents a foundational lens for understanding organizational learning and adaptation (March, 1991). Exploitation refers to activities aimed at refining and extending existing knowledge, emphasizing efficiency, reliability, and incremental improvement. Exploration, in contrast, involves experimentation, variation, and the pursuit of new knowledge, often associated with uncertainty and risk.

Traditional perspectives have framed exploitation and exploration as competing activities, requiring organizations to balance trade-offs between efficiency and innovation (Levinthal & March, 1993; He & Wong, 2004). However, more recent research has challenged this dichotomy, emphasizing the interdependence and configurational nature of these processes (Raisch et al., 2009; O'Reilly & Tushman, 2013; Zhao & Gao, 2024). Rather than being mutually exclusive, exploitation and exploration can be understood as complementary and mutually reinforcing components of organizational learning (Liu, 2024).

From a knowledge-based perspective, ambidexterity reflects the organization's ability to manage and recombine different types of knowledge processes (Andriopoulos & Lewis, 2009; Smith & Lewis, 2011). Exploitation supports the accumulation and refinement of existing knowledge, while exploration enables the generation of new knowledge and the discovery of novel opportunities. The effectiveness of ambidexterity thus

depends not only on the presence of both processes, but on how they are combined and embedded within organizational structures and routines.

AI technologies play a critical role in enabling this integration. AI-driven exploitation enhances knowledge efficiency through automation, predictive analytics, and optimization (McAfee & Brynjolfsson, 2017; Davenport et al., 2020). Conversely, AI-driven exploration facilitates knowledge creation by enabling simulation, experimentation, and the exploration of alternative scenarios (Cockburn et al., 2018; Haefner et al., 2021). Rather than operating as independent processes, exploitation and exploration are recursively intertwined, as efficiency-oriented learning processes enable the conditions under which novel variation and innovation can emerge.

2.3 Sustainable business models and knowledge alignment

Sustainable business models extend traditional business model frameworks by integrating economic, environmental, and social value creation (Boons & Lüdeke-Freund, 2013; Bocken et al., 2014; Lüdeke-Freund & Dembek, 2017). These models require organizations to rethink how value is created, delivered, and captured, incorporating sustainability considerations into core strategic and operational processes (Fulco, 2025).

Achieving sustainability outcomes involves more than adopting isolated technologies or practices. Instead, it requires the alignment of organizational capabilities, knowledge processes, and strategic objectives (Stubbs & Cocklin, 2008; Schaltegger et al., 2016). In particular, sustainability challenges often involve systemic complexity, long time horizons, and multiple stakeholders, requiring organizations to integrate diverse forms of knowledge and continuously adapt their strategies.

In this context, knowledge plays a central role in enabling sustainable business models (Adams et al., 2016; Raina, 2026). Organizations must be able to leverage existing knowledge to improve efficiency and reduce environmental impact, while also generating new knowledge to develop innovative solutions and business practices. This dual requirement highlights the importance of ambidextrous knowledge processes.

However, existing research has largely overlooked how these knowledge processes are configured within organizations and how they interact with business model structures. As a result, there remains limited understanding of how AI-enabled knowledge processes contribute to sustainability outcomes through their alignment with business model logic.

2.4 A Configurational view of AI-enabled knowledge ambidexterity

Building on the previous sections, this study proposes a configurational perspective on AI-enabled knowledge ambidexterity. Rather than treating exploitation and exploration as independent or additive dimensions, this perspective emphasizes their interdependence and the importance of their alignment within organizational contexts.

AI-enabled exploitation and exploration represent distinct but interconnected knowledge processes. Their interaction shapes the organization’s ability to generate, integrate, and apply knowledge for sustainability (Raisch & Birkinshaw, 2008; O’Reilly & Tushman, 2013). Importantly, different combinations of these processes may lead to different organizational outcomes, suggesting the presence of multiple pathways to sustainability.

This perspective aligns with configurational approaches, which emphasize that organizational outcomes result from specific combinations of interdependent elements rather than from individual factors considered in isolation (Ragin, 2009; Fiss, 2011). In this view, sustainability-oriented business models emerge from coherent configurations of AI-enabled knowledge processes embedded within the organization.

Accordingly, this study examines how different configurations of AI-enabled exploitation and exploration give rise to distinct sustainability-oriented business model archetypes.

3 Methodology

3.1 Research design

This study adopts a qualitative, configurational multiple-case study design to investigate how different combinations of AI-enabled knowledge processes shape sustainability-oriented business models. A configurational approach is particularly suitable for this research, as it enables the analysis of complex causal patterns characterized by interdependence, equifinality, and non-linearity (Ragin, 2009; Fiss, 2011). While configurational theory is often associated with set-theoretic methods such as fuzzy-set qualitative comparative analysis (fsQCA) (Ragin, 2009), this study adopts a qualitative configurational approach aimed at theory building and pattern identification rather than formal set-theoretic analysis.

Rather than focusing on the net effects of individual variables, the study examines how specific configurations of AI-enabled exploitation and exploration jointly produce distinct sustainability-oriented outcomes. This perspective is particularly relevant given the systemic and multi-dimensional nature of sustainability challenges, which require the alignment of technological capabilities, knowledge processes, and business model structures.

The multiple-case study design enhances analytical robustness by enabling systematic cross-case comparison and pattern identification (Yin, 2018; Eisenhardt & Graebner, 2007). In line with configurational theorizing, the objective is not statistical generalization, but the development of analytical generalizations in the form of empirically grounded configurational archetypes, synthesized in a comparative table.

3.2 Case selection

The empirical analysis is based on four multinational firms: Enel, Siemens, Unilever, and Nestlé. These cases were selected through purposeful theoretical sampling to ensure variation across industries while maintaining relevance to the research objective. The selection was guided by three criteria:
(1) the presence of significant or emerging AI adoption in organizational processes,
(2) a clearly articulated strategic commitment to sustainability objectives, and
(3) the availability of rich and reliable secondary data sources.

The selected firms operate in distinct sectors - energy, industrial manufacturing, consumer goods, and food and beverage - allowing for cross-industry comparison. This heterogeneity increases the likelihood of identifying diverse configurations of AI-enabled knowledge processes and strengthens the analytical generalizability of the findings (Eisenhardt, 1989).

3.3 Data collection

Data were collected from multiple secondary sources to ensure richness, depth, and triangulation. These sources include sustainability reports, integrated annual reports, corporate strategy documents, AI and digital transformation reports, investor presentations, and publicly available executive communications.

Secondary data are particularly appropriate for this study, as multinational firms systematically disclose both sustainability and digital transformation initiatives, providing detailed insights into organizational practices and strategic orientations.

Data collection focused specifically on identifying AI-enabled activities related to organizational knowledge processes, as well as their integration into sustainability strategies and business model configurations.

Triangulation across multiple sources enhances construct validity and reduces interpretive bias (Yin, 2018; Denzin, 1978, 2017). Furthermore, the analysis was conducted by two researchers, who independently examined the data and subsequently compared and discussed their interpretations, thereby strengthening the reliability and robustness of the findings.

3.4 Data analysis

The data analysis followed a structured, iterative, and comparative process consistent with configurational research logic.

First, AI-enabled activities were identified and coded inductively from the dataset, focusing on their role in organizational knowledge processes such as data processing, optimization, decision-making, experimentation, and learning.

Second, these activities were categorized as either AI-enabled exploitation or AI-enabled exploration, following established definitions in the ambidexterity literature (March, 1991).

Third, within-case analysis was conducted to assess the relative dominance and interaction of exploitation and exploration within each organization, as well as their embedding in sustainability-oriented business model structures. This step enabled the construction of detailed case profiles.

Fourth, a cross-case comparison was performed to identify similarities and differences across cases. Through iterative comparison and abstraction, cases were grouped into higher-order configurational archetypes.

Finally, these archetypes were synthesized in a comparative table (Table 1), which summarizes the identified configurations, their dominant knowledge processes, and associated sustainability-oriented business model logics.

Importantly, ambidexterity is conceptualized not as a continuous or additive construct, but as a configurational property emerging from the interaction and alignment of AI-enabled knowledge processes

within organizational contexts. This enables a more nuanced understanding of how sustainability outcomes are generated through interdependent mechanisms rather than isolated factors.

4 Findings

The analysis reveals four distinct configurations of AI-enabled knowledge ambidexterity, each corresponding to a specific sustainability-oriented business model logic. Table 1 presents these configurational archetypes, illustrating how AI-enabled exploitation and exploration interact to shape underlying knowledge processes and their alignment with sustainability-oriented business model logics.

Table1. Configurational archetypes of AI-enabled knowledge ambidexterity

Archetype	Firm	AI exploitation	AI exploration	Dominant knowledge processes	Business model logic	Sustainability outcome
Ambidextrous sustainability transformer	Enel	High	High	Knowledge integration, recombination, continuous learning	Transformative, system-level	Balanced efficiency and innovation; long-term sustainability transition
Efficiency-oriented sustainability optimizer	Siemens	High	Low	Knowledge codification, optimization, reuse	Efficiency-driven	Incremental sustainability improvements; operational excellence
Innovation-oriented sustainability explorer	Unilever	Low-Moderate	High	Knowledge creation, experimentation, learning	Innovation-driven	Exploratory sustainability initiatives; limited scalability
Limited AI adoption	Nestlé	Low	Low	Fragmented knowledge processes	Conventional/ transitional	Limited sustainability impact; low transformation

Source: Authors' elaboration

The first configuration, labelled Ambidextrous sustainability transformer and exemplified by Enel, is characterized by high levels of both exploitation and exploration. In this case, AI is deployed not only to optimize existing energy infrastructures through predictive maintenance, smart grid management, and real-time monitoring of distributed assets, but also to support exploratory capabilities such as digital twin infrastructures and advanced scenario simulations for the integration of renewable energy sources into the grid. This combination enables Enel to simultaneously pursue operational efficiency and systemic transformation, particularly in the context of energy transition and decarbonization strategies. The dual orientation supports the development of a transformative business model that balances short-term efficiency gains with long-term infrastructural innovation. The tight integration of exploitation and exploration fosters continuous feedback loops between operational data and strategic foresight, positioning sustainability as a core strategic driver embedded within the organization's socio-technical architecture.

A second configuration, the Efficiency-oriented sustainability optimizer, represented by Siemens, reflects a strong emphasis on AI-enabled exploitation combined with limited exploration. Siemens primarily leverages AI in industrial and engineering contexts to enhance operational efficiency, optimize manufacturing systems, and improve resource utilization across complex industrial environments. Applications such as predictive maintenance for industrial equipment, process automation, and energy efficiency optimization dominate the AI portfolio, while exploratory initiatives remain more selective and often confined to specific innovation units. As a result, sustainability outcomes are largely driven by incremental efficiency improvements and the systematic refinement of existing engineering and process knowledge. The corresponding business model is strongly anchored in industrial reliability, performance optimization, and scalable efficiency, with relatively limited engagement in experimental or radically innovative sustainability pathways.

In contrast, the Innovation-oriented sustainability explorer, exemplified by Unilever, displays a configuration in which exploration dominates over exploitation. Here, AI is primarily used to generate new knowledge related to sustainable sourcing strategies, product innovation, and evolving consumer behavior patterns. Machine learning and advanced analytics are applied to identify emerging sustainability trends, support portfolio redesign, and guide experimentation in areas such as circular economy initiatives and responsible consumption models. This orientation supports a business model centered on experimentation, rapid learning, and portfolio

diversification in sustainability-oriented offerings. However, the relatively lower level of exploitation limits the scalability of these initiatives, as many remain at pilot or project level, with partial integration into standardized operational routines and global supply chain processes.

Finally, the Limited AI adoption configuration, represented by Nestlé, is characterized by low levels of both exploitation and exploration. In this case, AI initiatives appear more fragmented and less systematically embedded within core organizational knowledge processes. While some applications of digital analytics and data-driven decision support exist - particularly in areas such as supply chain monitoring or demand forecasting - these initiatives do not yet constitute a fully integrated AI-enabled knowledge system. Consequently, sustainability efforts remain largely grounded in established managerial practices and incremental improvements rather than in AI-driven transformation. This configuration highlights that the absence of a coherent integration between AI-enabled knowledge processes and business model structures significantly constrains the potential for sustainability-oriented innovation and systemic impact.

5 Discussion

The findings offer a configurational explanation of how AI-enabled knowledge processes shape sustainability-oriented business models, moving beyond linear and technology-centric interpretations of AI impact. Rather than viewing artificial intelligence as an exogenous driver of sustainability performance, the analysis shows that sustainability emerges from the systemic alignment of AI-enabled knowledge processes within organizational architectures and business model logics.

A first theoretical contribution lies in the reconceptualization of AI-enabled ambidexterity as a configurational and relational knowledge capability. Consistent with knowledge-based and ambidexterity perspectives (March, 1991; Grant, 1996; O'Reilly & Tushman, 2013), the findings show that exploitation and exploration are not independent organizational choices, but mutually constitutive processes embedded in AI-mediated knowledge systems.

AI plays a dual role in this configuration: it simultaneously enhances the efficiency of knowledge exploitation (e.g., optimization, prediction, automation) and expands the scope of knowledge exploration (e.g., simulation, pattern discovery, scenario building). However, the study demonstrates that value does not stem from AI in isolation, but from how these two logics are configured, balanced, and institutionally embedded within organizational practices.

This shifts the theoretical focus from AI as a capability to AI as a meta-enabler of organizational knowledge configurations, where sustainability outcomes emerge from interaction effects rather than additive contributions.

A second contribution concerns the identification of equifinality in AI-enabled sustainability transformation. The results show that multiple distinct configurations can lead to sustainability-oriented outcomes, confirming configurational logic (Ragin, 2009; Fiss, 2011). However, this equifinality is not homogeneous.

Instead, different configurations produce qualitatively distinct sustainability pathways, ranging from efficiency-driven incrementalism to exploratory innovation and system-level transformation. This suggests that sustainability is not a single outcome, but a plural and path-dependent phenomenon shaped by underlying knowledge architectures.

Accordingly, the study extends prior research on sustainable business models (Boons & Lüdeke-Freund, 2013; Bocken et al., 2014) by showing that heterogeneity is a structural feature of how AI-enabled firms pursue sustainability.

A third key insight is the role of business model alignment as a critical mediating mechanism linking AI-enabled knowledge processes to sustainability outcomes. The findings suggest that AI-driven exploitation and exploration generate strategic value only when they are embedded within coherent configurations of value creation, delivery, and capture.

This extends the sustainable business model literature by shifting attention from "what firms do" to how firms structurally integrate AI-enabled knowledge processes into their business logic. In other words, AI does not automatically translate into sustainability benefits; rather, it requires architectural alignment between knowledge processes and business model design.

Without such alignment, AI remains fragmented, underutilized, or confined to localized efficiency gains, limiting its systemic sustainability impact.

Finally, the findings highlight a structural paradox of imbalance in AI-enabled ambidexterity. Configurations dominated by exploitation tend to generate efficiency gains but risk reinforcing incrementalism and path dependency. Conversely, configurations dominated by exploration foster innovation and learning but often suffer from weak operationalization and limited scalability.

This tension reflects broader ambidexterity paradoxes (Raisch & Birkinshaw, 2008; Smith & Lewis, 2011), but the study extends this logic by showing that AI intensifies both sides of the tension. AI amplifies exploitation through automation and optimization, while simultaneously lowering the cost of exploration through simulation and data-driven experimentation.

As a result, AI does not resolve the ambidexterity paradox - it reconfigures and potentially amplifies it, making organizational alignment even more critical for achieving sustainable outcomes.

6 Conclusions

This study advances the literature on artificial intelligence and sustainability by conceptualizing AI-enabled ambidexterity as a configurational knowledge capability. By integrating insights from the knowledge-based view, organizational ambidexterity theory, and sustainable business model research, it explains how organizations leverage AI not as a standalone technology, but as an enabler of complex knowledge configurations for sustainable value creation.

The findings demonstrate that the effectiveness of AI in sustainability contexts does not depend on technological adoption per se, but on how AI is embedded within organizational knowledge processes and aligned with business model structures. In this sense, sustainability emerges from the coherence between technological affordances, knowledge dynamics, and business model design, rather than from isolated digital initiatives. This shifts the analytical focus from AI as a tool to AI as a structural enabler of organizational configuration.

From a managerial perspective, the study suggests that organizations should move beyond fragmented AI implementations and instead deliberately orchestrate AI-enabled exploitation and exploration as interconnected processes. The results highlight the importance of embedding these processes within organizational routines, decision-making systems, and strategic architectures. In particular, managers should be aware that imbalances in ambidexterity may generate unintended consequences: overemphasis on exploitation can lead to incrementalism and rigidity, while excessive exploration may hinder scalability and operational integration.

Despite these contributions, the study has limitations that open avenues for future research. First, the analysis is based on a limited number of cases, which, while appropriate for configurational theory-building, constrains broader generalizability. Second, the reliance on secondary data may not fully capture micro-level organizational dynamics, informal practices, or internal decision-making processes underlying AI adoption and use. Future research could address these limitations by adopting longitudinal designs to capture the temporal dynamics of AI-enabled ambidexterity, as well as by incorporating primary data such as interviews and ethnographic observations.

Further research could also extend the configurational framework proposed in this study by testing it across a larger and more diverse set of organizations, industries, and institutional contexts. Importantly, the equifinality emerging from our findings - namely, the existence of multiple, functionally equivalent configurations leading to sustainability outcomes - calls for more systematic empirical validation. Future studies could employ methodologies such as fsQCA to rigorously test alternative configurational pathways and assess their relative consistency and coverage across contexts. In addition, comparative studies could explore how national or regulatory environments shape the emergence of different AI-enabled sustainability configurations. Finally, future work could investigate the micro-foundations of AI-enabled ambidexterity, particularly the role of managerial cognition, organizational culture, and data governance in shaping configurational outcomes.

Hybrid-Knowledge Management for Sustainable Competitiveness: AI-Human Synergy as Value Enabler

Andrea Gargiulo, Daniele Leone, Salvatore Scognamiglio, Petrella Raffaele Clemente
University of Naples "Parthenope", Naples, Italy

Abstract

This paper examines how firms can govern hybrid-knowledge management to transform sustainability information into customer-perceived competitive value. The study starts from a practical problem related to sustainability investments, which often fail to generate advantage. This occurs because customers receive fragmented or poorly translated signals. In response, the paper defines hybrid-knowledge management as the deliberate design and governance of customer-facing hybrid sustainability knowledge flows. These exchanges combine AI-generated cues with human-mediated interpretation provided by influencers, frontline employees, and brand communicators. The research asks how sustainable competitiveness can be strengthened through hybrid-knowledge mechanisms involving both humans and AI agents. A qualitative multi-case study design is adopted, involving four cases selected across the food and fashion industries. This setting was chosen because both sectors are highly exposed to sustainability-sensitive consumer choice and feature visible customer journeys in which knowledge is mediated through both digital and human channels. Data collection combined direct observation of customer-facing interfaces and campaign touchpoints with documentary secondary sources, enabling triangulation across firms, channels, and touchpoints. Data were analysed inductively through the Gioia methodology. The findings show that sustainable competitiveness is shaped by three interrelated levers. First, claim integrity, which rests on sustainability cues being auditable, standardised, and accompanied by human explanation. Second, choice guidance, which requires sustainability information to be translated into decision-ready comparisons at the point of choice. Third, relational sensemaking, which depends on customers' ability to resolve ambiguity through trusted human interaction and receive continuity after purchase. Across the cases, no instance of full alignment was observed. Two-lever configurations generated partial clarity, while one-lever configurations produced sustainability blur, scepticism, or weak conversion. The paper contributes by theorising hybrid-knowledge management as a strategic capability for orchestrating customer perceptions of sustainability, rather than as a purely internal knowledge process. It also offers actionable implications for managers, specifically to align verification, explainability, and human interpretation across touchpoints, and for policymakers seeking stronger traceability and comparability standards in both digital and human communication channels.

Keywords: Hybrid-knowledge management; artificial intelligence; sustainable competitiveness; customer perception

Paper type: Academic Research Paper

1 Introduction

Sustainable competitiveness increasingly depends on the way firms mobilise knowledge assets to shape market understanding, customer judgement, and organisational adaptation over time (Grant, 1996; Nonaka and Toyama, 2003). Recent advances in artificial intelligence have amplified this challenge by extending the scale, speed, and standardisation with which firms can create, store, retrieve, and apply knowledge in customer-facing settings (Jarrahi et al., 2023). At the same time, the business returns from responsible conduct remain contingent on customer awareness, because sustainability investments do not create value when customers neither notice nor understand them (Servaes and Tamayo, 2013; Du, Bhattacharya and Sen, 2010). This communication problem becomes more severe when stakeholders suspect exaggeration, symbolic signalling, or selective disclosure, since sustainability claims that lack credible support can trigger greenwashing inferences rather than competitive gains (Delmas and Burbano, 2011). From a strategic standpoint, sustainable offerings only become sources of advantage when firms connect responsible practices with clear value propositions that customers can interpret and use in choice situations (Kahupi et al., 2021; Hermundsdottir and Aspelund, 2022). In practice, sustainability-related knowledge now reaches customers through two intertwined mediation paths: human actors such as influencers and frontline employees, and AI-enabled interfaces such as recommender systems, labels, filters, and decision-support cues (Lou and Yuan, 2019; Cambra-Fierro, Melero-Polo and Vázquez-Carrasco, 2014). These AI-enabled cues may raise perceived objectivity and decision relevance, but they also reshape human judgement in ways that depend on trust, interpretability, and the context of decision support (Logg, Minson and Moore, 2019; Poszler and Lange, 2024). Despite growing work on knowledge management,

algorithmic advice, customer awareness, and sustainability strategy, research still says little about how firms should intentionally combine AI-mediated and human-mediated knowledge as a strategic capability for sustainable competitiveness. In this paper, hybrid-knowledge management is therefore defined as the deliberate design and governance of customer-facing sustainability knowledge flows that combine AI-generated cues with human-mediated interpretation across touchpoints in the customer journey. This definition addresses two limitations highlighted in current managerial debates. First, it specifies what is hybrid in operational terms. Second, it links the topic more directly to strategy by treating the orchestration of knowledge flows as a deliberate managerial capability rather than a background communication condition. The study accordingly investigates the following research question: How can sustainable competitiveness be increased through hybrid-knowledge mechanisms involving humans and AI agents?

2 Literature review

2.1 Hybrid-knowledge management and customer-facing knowledge flows

Knowledge-based theory explains competitive advantage in terms of how firms integrate and deploy knowledge assets more effectively than rivals (Grant, 1996). Knowledge creation theory further shows that value emerges when distributed experience is synthesised into actionable meaning rather than merely accumulated as information (Nonaka and Toyama, 2003). As contemporary work extends these insights to partnerships between AI systems and humans combining codification with interpretation, the concept of hybrid-knowledge management emerges (Lu, Nerode and Subrahmanian, 1996; Jarrahi et al., 2023). In market-facing contexts, frontline employees mediate knowledge by helping customers interpret offers, evaluate trade-offs, and make sense of brand claims in interaction (Cambra-Fierro, Melero-Polo and Vázquez-Carrasco, 2014). Influencer communication similarly depends on perceived message value and source credibility, which means that human-mediated sustainability claims are shaped by trust as much as by information content (Lou and Yuan, 2019). Follower cues and perceived popularity can strengthen influencer effectiveness, especially in image-driven categories such as fashion where social proof often substitutes for technical explanation (De Veirman, Cauberghe and Hudders, 2017).

2.2 AI-mediated knowledge and sustainability perception

AI-mediated knowledge operates through scalable recommendations, rankings, and decision-support outputs that can increase reliance on algorithmic judgement when users perceive advice as useful and objective (Logg, Minson and Moore, 2019). However, resistance emerges when users observe errors and conclude that algorithmic systems are less forgivable or less adaptive than human advisors (Dietvorst, Simmons and Massey, 2015). One design response is to demonstrate that algorithmic systems learn over time, because visible learning can offset the negative effects of familiarity on reliance (Berger et al., 2021). Acceptance also depends on system transparency, since explainability indirectly shapes trust and thereby affects whether intelligent systems are used in consequential tasks (Wanner et al., 2022). Research on intelligent decision-support systems similarly shows that ethical decision support requires intelligible rationales rather than opaque optimisation alone (Poszler and Lange, 2024).

2.3 Sustainability communication, competitiveness and the analytical framework

Corporate Social Responsibility (CSR) efforts create more value when customers are aware of them, because stakeholder response mediates the effect of responsible conduct on firm outcomes (Servaes and Tamayo, 2013). CSR communication research therefore emphasises that awareness must be paired with favourable attributions if firms are to capture reputational and behavioural returns from responsible action (Du, Bhattacharya and Sen, 2010). When communication outruns substantiation, greenwashing becomes more likely and can erode confidence in green products, green firms, and sustainability claims more broadly (Delmas and Burbano, 2011). Consumer scepticism toward sustainability claims is heightened by previous greenwashing incidents and can even make quieter communication strategies appear more credible than vocal campaigns (Farooq and Wicaksono, 2021). Consumers can distinguish between honest green and greenwashed products more effectively when they are prompted to evaluate greenwashing cues explicitly, which underlines the importance of claim design and interpretation (Fella and Bausa, 2024). At the strategic level, sustainability contributes to competitiveness when it is embedded in products, stakeholder value creation, and innovation outcomes rather than treated as a symbolic add-on (Kahupi et al., 2021; Hermundsdottir and Aspelund, 2022). In food markets especially, labels and origin information act as credence cues that guide consumer choice when direct

verification of production attributes is difficult (Thøgersen, Pedersen and Aschemann-Witzel, 2019). Taken together, this literature suggests that customer-facing sustainability knowledge is most likely to generate competitive value when firms align three levers: claim integrity, choice guidance, and relational sensemaking.

3 Methodology

The paper adopts a qualitative multi-case design because the objective is to explain an emerging phenomenon and develop analytically generalisable mechanisms rather than test a mature theory (Yin, 2018). Theoretical sampling guided case selection so that each case could illuminate similarities and contrasts relevant to the research question, which is consistent with theory-building logic in case research (Eisenhardt, 1989; Eisenhardt and Graebner, 2007). The two industries were selected for three reasons. First, both food and fashion are highly visible to consumers and strongly exposed to sustainability-sensitive choice. Second, both industries combine digital touchpoints with human mediation. Third, they differ in the immediacy with which customers can verify sustainability-related outcomes, allowing stronger theoretical contrast between cases. The four focal cases were chosen as bounded examples of customer-facing sustainability knowledge pathways. McDonald's and H&M were selected as cases in which human-mediated communication was especially visible through influencer or campaign storytelling. Carrefour, in partnership with Too Good To Go, was selected as a case in which digital intermediation translated sustainability into a purchase architecture. SHEIN was selected as a contrasting case in which AI-mediated recommendation could amplify sustainability cues at scale while leaving verification contested. The unit of analysis is the customer-facing sustainability knowledge pathway through which a firm's sustainability-related information reaches customers and influences perceived competitiveness. This unit of analysis shifts attention from the firm in general to the specific combination of actors, artefacts, interfaces, and interpretive processes that shape customer judgement. The study combined primary and secondary data. Primary data consisted of anonymous semi-structured interviews of customers from the selected case studies. Secondary data included company reports, webpages, campaign materials, sustainability documents and platform descriptions. Triangulation across these sources increased the robustness of within-case interpretations (Yin, 2018). The analysis followed the Gioia methodology to move inductively from empirical material to a structured explanatory framework (Gioia, Corley and Hamilton, 2013). First-order concepts were generated from observed claims, interfaces, cues, explanations, and customer-facing interactions. These concepts were then grouped into second-order themes that captured how sustainability meaning was verified, translated, or socially interpreted. Finally, three aggregate dimensions emerged: claim integrity, choice guidance, and relational sensemaking. To answer the reviewers' concern regarding transparency, alignment across the three levers was assessed through a simple comparative rule. A case was treated as aligned on a lever when the customer journey displayed a consistent mechanism for that lever across the dominant touchpoints. Cases were then classified as two-lever, one-lever, or absent alignment configurations according to the number of levers clearly supported by the observed pathway. Case quality was strengthened through protocol-driven case documentation, within-case narratives, cross-case comparison, and explicit reflection on how interpretations were derived from the empirical material, in line with recommendations for rigorous case research (Goffin et al., 2019).

4 Findings

4.1 Claim integrity

Claim integrity captures whether sustainability claims appear auditable, standardised, and bounded by intelligible explanation. This dimension emerged when the coding process distinguished between cues that merely attracted attention and cues that allowed the customer to verify what the claim meant. In the Carrefour case, claim integrity was comparatively strong because the sustainability proposition was embedded in a concrete commercial mechanism. The discounted surprise basket made the anti-food-waste claim tangible at the moment of purchase. The customer did not need to infer a distant environmental virtue from a broad narrative; the value proposition was directly connected to the rescue of unsold food and to an observable price discount. Digital mediation therefore translated the sustainability claim into a bounded and testable commercial offer. In McDonald's and H&M, claim integrity was more fragile. Human-mediated storytelling increased salience and trust by attaching sustainability meaning to familiar brand narratives and socially credible messengers. Yet the same strength also introduced ambiguity. The sustainability message depended heavily on how influencers or campaign materials framed the offering. In these cases, human mediation made the claim understandable, but it did not always make its limits equally visible. As a result, customers could recognise the intended

sustainable positioning without receiving the same degree of auditable substantiation found in the Carrefour pathway. SHEIN represented the weakest configuration on this dimension. Here, sustainability cues appeared to benefit from algorithmic amplification and repeated exposure, but not from a robust verification architecture. AI-mediated visibility could raise the prominence of eco-related labels during browsing, yet the browsing journey offered little support for customers who wished to establish what made the highlighted item more sustainable in operational terms. In this configuration, AI acted mainly as an amplifier of eco-signals rather than as a verifier of claim content. Across cases, claim integrity was highest when AI standardised and bounded the claim while human channels clarified trade-offs and limits. Where human mediation operated without auditable cues, or AI visibility operated without verification, sustainability meaning became more contestable and more exposed to scepticism.

4.2 Choice guidance

Choice guidance refers to the extent to which sustainability information is translated into decision-ready comparisons at the point of selection. This dimension emerged from the distinction between cases that made sustainability actionable in the buying moment and cases that treated sustainability mainly as a background narrative. Carrefour again provided the clearest evidence of strong choice guidance. The digital interface and offer structure linked sustainability with price, availability, and immediate purchase action. The customer did not simply learn that waste reduction was desirable; the pathway guided the customer toward a specific decision in which sustainability and value converged. This is an example of hybrid-knowledge management at its most practical: information was not only communicated but converted into a simple, comparable, and economically legible choice. SHEIN also displayed a powerful form of choice guidance, but of a different kind. Recommendation routines, visibility ranking, and repeated eco-cues could channel attention toward items carrying sustainability labels. However, this guidance was stronger on navigation than on informed comparison. The customer was guided to click, view, and possibly purchase, but the rationale remained thinner than in the Carrefour case. The result was behavioural direction without equivalent interpretive depth. In McDonald's and H&M, choice guidance was weaker because the sustainability message was not always anchored in the exact moment of selection. Human endorsement could stimulate trial, brand warmth, or perceived relevance before the choice, but unless menus, labels, or filters reinforced the message at the final decision point, the customer still had to bridge the gap between general sustainability meaning and concrete selection criteria. The cross-case pattern therefore suggests that sustainable competitiveness benefits when AI converts sustainability claims into decision-ready comparisons and when human mediation ensures that the comparison remains intelligible rather than merely persuasive. Where this translation is absent, sustainability remains a favourable association but not a strong basis for customer choice.

4.3 Relational sensemaking

Relational sensemaking captures the extent to which ambiguity can be resolved through trusted interaction and sustained after the initial purchase decision. This dimension emerged as distinct from the other two because some cases were effective in explanation and reassurance even when their point-of-choice design remained weak. McDonald's and H&M showed the clearest signs of relational sensemaking. Human-mediated communication made sustainability easier to connect with everyday meanings, lifestyle aspirations, and socially shared language. In these cases, people rather than systems played the central role in reducing ambiguity. Human actors could translate abstract sustainability cues into narratives that customers recognised as relevant to eating habits, fashion identity, or responsible consumption. This did not fully solve the problem of verification, but it reduced interpretive distance and strengthened authenticity. Carrefour showed a more partial version of relational sensemaking. The digital pathway offered continuity after purchase by allowing the customer to connect the bargain with a concrete anti-waste outcome, yet the pathway was less relational in the interpersonal sense. The customer received continuity and coherence, but not the same capacity for trust repair, reassurance, or conversational explanation that human channels can provide. SHEIN again represented the weakest configuration. When ambiguity arises in a highly algorithmic environment, the customer has fewer relational resources with which to interpret or challenge sustainability cues. Without trusted human mediation, the pathway depends disproportionately on interface signals. This can sustain exposure, but it does not readily repair doubt once doubt is activated. Considering the three levers together, none of the cases displayed complete alignment. Carrefour approximated a two-lever configuration, with strong claim integrity and choice guidance but only partial relational sensemaking. McDonald's and H&M approximated one-to-two-lever configurations centred on human interpretation rather than auditable verification. SHEIN represented a one-lever configuration in which guidance through visibility was not matched by integrity or relational support. These

patterns explain why sustainable competitiveness was strengthened only partially across the observed cases: when one or more levers were missing, sustainability value remained visible but unstable.

5 Conclusions

The study set out to explain how sustainable competitiveness can be strengthened through hybrid-knowledge mechanisms involving both humans and AI agents. The evidence indicates that the key issue is not the simple presence of AI or human mediation, but the alignment of three customer-facing levers: claim integrity, choice guidance, and relational sensemaking. Hybrid-knowledge management becomes strategically valuable when firms govern these levers together across the customer journey. The paper makes three theoretical contributions. First, it extends knowledge-based and knowledge-creation perspectives by shifting attention from internal knowledge stocks to customer-facing sustainability knowledge flows as a source of competitive value (Grant, 1996; Nonaka and Toyama, 2003). Second, it refines the literature on human–AI partnership in knowledge management by showing that hybrid-knowledge management is not only a technological complementarity but also a governance capability that coordinates verification, translation, and interpretation across touchpoints (Lu, Nerode and Subrahmanian, 1996; Jarrahi et al., 2023). Third, it bridges CSR awareness and communication research with work on algorithmic transparency and trust by explaining why sustainability communication creates competitive value only when awareness becomes credible, decision-relevant, and interpretable to customers (Servaes and Tamayo, 2013; Wanner et al., 2022). Managerially, the findings imply that firms should not rely on one mediation path alone. AI systems should be designed to surface auditable cues, standardise labels, and make sustainability comparisons explainable at the moment of choice. Human channels should then be equipped to translate these cues, explain trade-offs, and repair ambiguity when customer doubt emerges. Different configurations require different managerial priorities. Where firms already possess strong digital guidance but weak trust, they need more human interpretation. Where they possess strong storytelling but weak substantiation, they need stronger verification infrastructures. For policymakers, the results support stricter comparability and traceability requirements across both digital and human channels. If recommendation systems elevate sustainability cues, there is a growing case for transparency duties regarding the basis of that elevation, especially when customers cannot otherwise distinguish verified information from persuasive amplification. The study has limitations. It relies on four cases and on publicly observable customer-facing pathways rather than on direct measurement of customer behaviour. In addition, no case displayed full alignment across all three levers, which means that the proposed ideal-type remains analytically inferred rather than fully observed. Future research could test the framework quantitatively, examine boundary conditions across industries and customer segments, and connect alignment configurations to outcomes such as willingness to pay, retention, or backlash risk. Longitudinal research could also explore how repeated exposure to hybrid mediation changes trust over time.

6 Ethics Declaration

The study did not raise any specific ethical concerns, and formal ethical approval was not required.

7 AI Declaration

The authors declare that no AI tools were used in the preparation, analysis, interpretation, or writing of this manuscript. The authors take full responsibility for the content of the paper.

The Key Factors in RTO Spin-off Development: Reconfiguring Organizational Knowledge for Spin-off Ventures

Guan-Ting Chen, Sirirat Sae Lim
Institute of Management of Technology, National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Abstract

Research and Technology Organizations (RTOs) are under growing pressure to convert publicly funded knowledge assets into market-facing ventures, yet the mechanisms through which RTOs reconfigure knowledge across the parent-spin-off boundary remain insufficiently theorized. Drawing on the Knowledge-Based View, knowledge-creation theory, and intellectual-capital theory, this paper asks how RTOs combine intellectual property (IP), tangible assets, tacit know-how, human capital, and relational capital during spin-off development, and how Resource Coordination Capability enables such reconfiguration. The study uses a qualitative, theory-elaborating design based on semi-structured interviews with twenty-two respondents, including thirteen investors and nine policymakers with direct exposure to RTO spin-off cases. This external stakeholder sample was selected because investors and policymakers observe multiple reconfiguration attempts and evaluate whether ventures are investment-ready or policy-ready. A six-phase thematic analysis generated two linked theoretical artifacts. First, the Knowledge Asset Reconfiguration (KAR) Model shows that licensing, assignment, and joint development are normally combined across different subsets of the knowledge-asset portfolio rather than chosen as mutually exclusive alternatives. Second, the Progressive Separation Model explains spin-off emergence as a three-phase process of incubation, acceleration, and independent operation, with different capital forms moving at different speeds. Findings indicate that structural capital can be formalized relatively quickly, human capital migrates in clusters around formation, and relational capital remains the slowest and most consequential asset to rebuild. Across both models, Resource Coordination Capability acts as the meta-capability that allows RTOs to assemble, sequence, and reallocate heterogeneous resources across a changing boundary. The paper contributes to RTO spin-off research by replacing a single-transfer view with a boundary-reconfiguration view. This processual framing treats the venture not as an entity born at incorporation but as an evolving arrangement through which codified IP, people, routines, facilities, and relationships are progressively recombined. It is especially relevant for publicly funded technologies, where market uncertainty, policy accountability, and knowledge-leakage concerns must be balanced. The paper offers managers, investors, and policymakers practical diagnostics for judging reconfiguration readiness.

Paper type: Academic Research Paper

1 Introduction

Public research organizations across Europe, Asia, and North America are increasingly expected to do more than produce publications and patents. Research and Technology Organizations (RTOs), including institutions such as Fraunhofer, ITRI, CSIRO, and SINTEF, are asked to translate publicly funded research into commercially viable spin-off ventures that create employment, tax revenue, industrial upgrading, and sovereign technology capability. The policy objective is clear. The organizational mechanics are less clear.

Much of the technology-transfer literature treats spin-off formation as a discrete decision: license the technology, assign the intellectual property, or create a joint venture. Each modality is often compared on control, revenue capture, and transaction cost. Practitioners describe a more complicated process. A patent may be assigned at formation, while process know-how remains inside the RTO, a laboratory facility is shared, and future improvements are governed by joint-development clauses. Recent work on academic spin-offs has therefore begun to shift attention from one-off transfer events to organization-embedded emergence (Opizzi, Loi, and Lamine, 2025; Prokop, 2023).

The stakes of this distinction are practical as well as theoretical. Public sponsors want evidence that publicly funded knowledge is being mobilized rather than privatized too cheaply. Investors want evidence that a venture controls enough knowledge to execute, but also enough access to the parent organization to learn. RTO managers must protect the scientific platform while giving the venture room to build a distinct market identity. These goals cannot be reconciled through a single legal transaction.

This empirical pattern creates a theoretical gap. The Knowledge-Based View (KBV) treats knowledge as the strategically central resource of the firm and emphasizes the coordination mechanisms required to integrate specialized knowledge (Grant, 1996; Kogut and Zander, 1992). However, the RTO-spin-off interface is not a stable

firm. It is a boundary in motion, where some knowledge must move, some must remain accessible, and some must be jointly created after separation. Complementary perspectives on tacit-explicit knowledge conversion (Nonaka and Takeuchi, 1995) and intellectual capital (Bontis, 1998) help specify what moves, but they have rarely been integrated into a process account of RTO spin-off development.

The study asks two research questions. RQ1: Through what configurations of IP modalities and tangible or intangible assets do RTOs reconfigure organizational knowledge across the parent-spin-off boundary? RQ2: How does Resource Coordination Capability shape whether these configurations produce investable ventures? The paper contributes by developing the Knowledge Asset Reconfiguration (KAR) Model, by specifying a Progressive Separation Model of incubation, acceleration, and independent spin-off, and by using investor and policymaker perspectives to reveal diagnostic criteria that are often hidden in internal RTO accounts.

2 Theoretical Background

2.1 Knowledge-Based View and Boundary Reconfiguration

The KBV refines the resource-based view by treating knowledge as the firm's most important productive input. Grant (1996) argues that knowledge is largely held by individuals, that organizations exist to integrate specialized knowledge, and that integration depends on mechanisms such as rules, routines, sequencing, and group problem solving. Later reviews confirm that KBV remains influential in international business and capability research, particularly where knowledge must be recombined under uncertainty (Stoian, Tardios, and Samdanis, 2024; Tamirat and Amentie, 2023).

For RTO spin-offs, these premises have three implications. First, transferring a patent does not transfer all knowledge required to use the patent; tacit know-how remains embedded in scientists, engineers, laboratory routines, and accumulated troubleshooting experience. Second, integration mechanisms that worked inside the RTO may fail once founders, legal rights, equipment, and customer relationships are split across organizations. Third, a spin-off is not only a recipient of knowledge but also a new site of knowledge integration. Spin-off development is therefore a boundary-reconfiguration problem rather than a simple boundary-crossing event.

This boundary-reconfiguration view also clarifies why spin-off timing is difficult. If separation occurs too late, the venture may remain dependent on the parent and lose entrepreneurial momentum. If separation occurs too early, the venture may acquire formal rights without the routines required to use them. The challenge is not merely to transfer knowledge but to design a sequence in which knowledge can continue to be integrated while organizational autonomy increases.

2.2 Knowledge Creation and Intellectual Capital

Nonaka and Takeuchi's (1995) SECI model explains knowledge creation through socialization, externalization, combination, and internalization. In the RTO context, externalization is visible when tacit laboratory knowledge is codified into patents, specifications, and manuals. Combination occurs when the spin-off recombines transferred IP with external technologies. Socialization is less visible but critical, because founders and technical staff carry process knowledge through shared work. Internalization begins when the venture converts licensed or assigned knowledge into its own operational routines.

Bontis's (1998) taxonomy of intellectual capital further decomposes the asset base into human, structural, and relational capital. Human capital includes individual expertise and experience; structural capital includes patents, data, routines, software, and organizational procedures; relational capital includes customer, supplier, regulator, and partner relationships. Cosa, de Matos Pedro, and Urban (2024) show that this tripartite logic remains central to contemporary intellectual-capital measurement. In spin-off formation the three capital forms rarely move together. Structural capital may be codified and transferred quickly, human capital moves when people change roles, and relational capital must be rebuilt through repeated external interactions.

Combining SECI with intellectual-capital theory allows the analysis to avoid an IP-only account. A patent is structural capital and an outcome of externalization, but the ability to enact the patent may depend on human capital acquired through socialization. A first customer introduction is relational capital, but the venture must internalize the relationship by becoming credible in its own right. The same technology therefore contains different knowledge assets that move through different mechanisms.

2.3 IP Modalities and Resource Coordination Capability

RTOs commonly use three IP modalities. Licensing preserves parent ownership while granting the spin-off defined rights of use. Assignment transfers ownership, often in return for equity, payment, or a strategic public-

interest arrangement. Joint development defines how future inventions will be owned or used when the parent and spin-off continue to collaborate. Prior research often treats these modalities as substitutes (Clarysse et al., 2005; Grimaldi et al., 2011; Rothaermel, Agung, and Jiang, 2007). This paper instead treats them as instruments that can be combined across different assets and phases.

Resource Coordination Capability refers to the RTO's capacity to assemble, sequence, and reallocate human, financial, infrastructural, legal, and relational resources across organizational boundaries over time. It is not simply resource ownership or technical excellence. It is the capability to decide which asset moves under which modality, when people should migrate, how shared infrastructure should be governed, and how external relationships should be transferred or substituted. This construct connects KBV's integration logic with the operational reality of spin-off formation.

The capability is visible in mundane organizational practices. High-capability RTOs maintain clear decision rights between technology-transfer offices, legal units, laboratory directors, and executive sponsors. They can distinguish assets that should be transferred from assets that should remain accessible through collaboration. Low-capability RTOs tend to convert uncertainty into delay, or to force diverse assets into one contract because the organization lacks a process for managing a hybrid arrangement.

3 Conceptual Framework and Proposed Models

3.1 Knowledge Asset Reconfiguration Model

The KAR Model treats RTO spin-off development as a portfolio problem. The relevant question is not whether the RTO should license, assign, or jointly develop IP. The question is which subsets of the knowledge-asset portfolio should be governed by each modality at a specific moment. A core platform patent may be assigned, background technology may remain licensed, and next-generation improvements may be placed under joint development. Tangible assets, such as pilot equipment, can follow a different route from intangible assets, such as process know-how or regulatory credibility.

The model therefore shifts attention from choosing the best modality to maintaining fit between asset characteristics and governance arrangements. Assets that are mature, codified, and separable may be assigned. Assets that are valuable but still connected to the parent platform may be licensed. Assets that will evolve through continued collaboration require joint-development governance. A venture may need all three at once if it is to satisfy investor demands for control while preserving access to parent knowledge.

Three propositions follow. P1: RTO spin-offs using hybrid IP configurations will be perceived by investors as more reconfiguration-ready than those using a single modality. P2: Asset portfolios rich in tacit know-how benefit more from joint-development anchors, because these preserve socialization channels. P3: Resource Coordination Capability is a necessary condition for executing hybrid configurations without creating legal, operational, or relational fragmentation.

Table 1: KAR Model: IP Modalities and Reconfiguration Challenges

IP modality	Knowledge-asset role	Capital and SECI emphasis	Coordination challenge
Licensing	Preserves parent ownership while granting defined use rights.	Structural capital; combination of explicit knowledge.	Scope control, royalty monitoring, and continued access to background know-how.
Assignment	Transfers ownership of selected platform or application-specific IP.	Structural capital with human-capital support; externalization and internalization.	Avoiding tacit-knowledge loss and preserving founder-team continuity.
Joint development	Governs future inventions and ongoing parent-spin-off collaboration.	Structural and relational capital; socialization and externalization.	Allocating future IP, aligning incentives, and sustaining knowledge channels.

3.2 Progressive Separation Model

The Progressive Separation Model explains the temporal side of reconfiguration. In incubation, the prospective venture remains embedded in the RTO and learns through shared routines. In acceleration, selective decoupling begins: patents are formalized, some assets are assigned, human capital starts to migrate, and joint-development rules are negotiated. In the spin-off phase, the venture becomes legally and operationally independent but remains relationally coupled to the parent while it builds its own market standing.

Separation is progressive because legal independence, operational independence, and relational independence do not arrive at the same time. Incorporation may create a legal boundary before routines have stabilized. Assignment may transfer ownership before the venture has full operating confidence. Customer introductions may continue long after the venture has its own employees and accounts.

The model generates three further propositions. P4: Ventures that compress incubation are more likely to fail because they lack absorptive capacity. P5: Acceleration is the highest-risk phase because IP, governance, and human-capital reconfiguration occur concurrently. P6: In the independent spin-off phase, relational-capital substitution becomes the binding constraint on performance.

Table 2: Progressive Separation Model

Phase	Knowledge position	Dominant transition	Main coordination task
Incubation	Venture remains embedded in the RTO.	Tacit learning and absorptive-capacity building.	Shield the venture from premature market exposure.
Acceleration	Selective decoupling becomes visible.	IP formalization, partial assignment, founder migration, and joint-development governance.	Time legal, human, and governance changes without destabilizing either organization.
Spin-off	Venture is independent but relationally coupled.	Relational-capital substitution and autonomous routine building.	Replace parent-derived credibility with independent market standing.

4 Methodology

4.1 Research Design and Sample

The study adopts a qualitative, theory-elaborating design. Existing theory supplied the sensitizing concepts: KBV for knowledge integration, SECI for tacit-explicit conversion, intellectual capital for asset categories, and Resource Coordination Capability for cross-boundary orchestration. Empirical analysis then elaborated these concepts into the KAR and Progressive Separation Models.

The sample consisted of twenty-two respondents: thirteen investors and nine policymakers. Investors included venture capital partners, corporate venture investors, and government-affiliated investment-fund managers. Policymakers included officials from technology-policy ministries, agency leaders responsible for RTO oversight, and public program directors. All respondents had direct decision-making exposure to at least three RTO spin-off cases within the preceding five years. The sample intentionally privileges an external vantage point because investors and policymakers compare multiple reconfiguration attempts and must judge whether a spin-off is more than a technology demonstration.

This sampling strategy also reduces reliance on self-reported organizational success. RTO managers and founders may emphasize strategic intent, scientific promise, or entrepreneurial commitment. External stakeholders instead ask whether asset control, team migration, governance, and market relationships are credible enough to justify capital or policy support.

4.2 Data Collection and Analysis

Semi-structured interviews of sixty to ninety minutes were conducted between September 2025 and February 2026 in Mandarin Chinese or English. The protocol moved from general framing of RTO spin-offs to case-specific discussion of IP modality, tangible and intangible asset movement, phase-specific risks, and diagnostic cues for reconfiguration readiness. Interviews were recorded with consent, transcribed, anonymized, and analyzed using a six-phase thematic-analysis procedure (Braun and Clarke, 2006, 2019).

Coding combined deductive and inductive steps. Initial coding in NVivo 14 produced 147 first-order codes. Axial coding consolidated these into 24 second-order themes under six aggregate dimensions: IP modality configuration, tangible-asset reconfiguration, intangible-asset reconfiguration, phase-specific coordination challenges, Resource Coordination Capability indicators, and investor or policymaker diagnostic cues. A 25 percent sub-sample was double-coded by an independent coder, producing Cohen's kappa of 0.81. Trustworthiness was strengthened through member checking with six respondents, triangulation with public case documentation, and an audit trail of coding decisions.

The analysis treated respondent quotations as evidence of recurring evaluation logics rather than as isolated opinions. Themes were retained only when they appeared across respondent types or when a minority pattern

explained a theoretically important exception, such as policy regimes that restricted IP assignment but still produced spin-offs through joint-development vehicles.

5 Findings

5.1 Hybrid IP Configurations

The most consistent empirical pattern was the combined use of licensing, assignment, and joint development. Respondents rarely described successful spin-offs as clean transfers. Instead, they expected a structured bundle in which different assets moved under different instruments. One investor summarized the diagnostic logic: "A mature RTO gives you a portfolio: a core assignment, a platform license, and a joint-development clause for the next generation. That tells me somebody thought about it."

Investors treated single-modality deals as warning signs because they often concealed unaddressed tacit knowledge, data, or future improvement rights. Policymakers made a similar point in regulatory language. When rules restricted outright assignment of publicly funded IP, spin-off activity did not necessarily decline; it shifted toward licensing and joint-development vehicles. This supports the KAR Model's claim that policy constraints change the modality mix rather than eliminating reconfiguration, provided coordination capability is strong enough.

Two sub-patterns appeared repeatedly. First, respondents distinguished platform IP from application-specific IP. Platform IP was often licensed to preserve public or parent optionality, while application-specific improvements were more likely to be assigned to the venture. Second, joint-development clauses functioned as anchors for future knowledge creation. Even where pre-existing IP was assigned, respondents expected a mechanism for handling improvements, data, and derivative inventions generated after launch.

5.2 Tangible and Intangible Asset Reconfiguration

Respondents distinguished sharply between tangible assets and intangible assets. Tangible assets, such as equipment, prototype inventories, and pilot infrastructure, were described as administratively heavy but conceptually straightforward. Intangible assets, especially process know-how and relational capital, were described as the real bottleneck. As one investor put it, "The equipment transfer is a purchase order. The know-how transfer is a human-resources problem. The relational-capital transfer is a three-year project."

The three intellectual-capital forms moved at different speeds. Structural capital reconfigured fastest once legal instruments were ready. Human capital moved in clusters as founders and engineers shifted time allocation or employment. Relational capital moved slowest because customers, regulators, suppliers, and strategic partners had to learn to trust the spin-off without relying entirely on the RTO's reputation. Respondents repeatedly identified this relational substitution as the determinant of survival in the two-to-five-year period after formation.

This finding explains why formal asset lists often overstate readiness. A venture may show assigned patents, transferred equipment, and founder employment agreements while still lacking the routines and relationships that make the technology usable. Investors therefore examined evidence of operational learning: whether engineers had run the process outside the parent laboratory, whether customers had interacted directly with the venture, and whether regulatory bodies recognized the venture as a credible counterparty.

5.3 Phased Dynamics of Progressive Separation

Interview accounts supported the three-phase separation model. Incubation was often invisible to external stakeholders but crucial to absorptive capacity. Respondents argued that ventures pushed out too early may possess formal IP but lack the tacit routines needed to operate it. Acceleration was the phase where tensions became visible, because legal transfer, founder migration, infrastructure access, and governance of future IP had to be resolved at the same time.

Acceleration was also the phase in which misalignment became expensive. If the legal team optimized assignment terms without understanding technical dependency, the venture could lose access to necessary know-how. If the laboratory delayed founder release, the venture could miss investor milestones. If policymakers pushed for rapid commercialization without supporting governance of future IP, the spin-off could inherit unresolved conflicts.

In the spin-off phase, formal independence did not mean complete separation. Ventures continued to depend on parent-derived credibility, introductions, test facilities, and regulatory history. One investor noted that a venture may call itself independent while its customer list still reveals dependence on parent

introductions. Technical and financial indicators could appear healthy twelve to eighteen months after formation, while relational indicators lagged by several more years.

5.4 Resource Coordination Capability

Across both models, Resource Coordination Capability was the strongest discriminator between successful and unsuccessful reconfiguration. Respondents described it through observable cues: clear decision rights among the technology-transfer office, legal counsel, scientific leadership, and executive sponsors; routinized processes for resolving trade-offs; and a documented history of prior spin-offs or licensing arrangements. High-capability RTOs were able to adapt the mix of licensing, assignment, and joint development as new information emerged.

Low-capability RTOs tended to simplify prematurely. They used a single legal instrument because it was administratively convenient, delayed decisions about founder migration, or relied too heavily on the parent organization's reputation after launch. The resulting ventures could look complete on paper while remaining fragile in practice. Resource Coordination Capability therefore operates as a meta-capability: it does not replace scientific excellence, IP quality, or market demand, but it governs whether those elements can be assembled into an investable venture.

Respondents emphasized that the capability can be assessed early. Meetings in which legal, technical, and commercial actors could discuss trade-offs without escalation were interpreted as positive signals. Meetings in which each actor deferred to another unit were interpreted as evidence that the RTO had not developed routines for cross-boundary orchestration.

6 Discussion

The findings extend KBV by specifying a class of knowledge-integration problems in which the boundary of integration is itself under construction. Grant's (1996) mechanisms of rules, routines, sequencing, and group problem solving remain central, but they must operate across an emerging parent-spin-off boundary. Licensing preserves a coordination channel without moving ownership. Assignment moves codified structural capital but not the full tacit base. Joint development keeps a channel open for knowledge that will be created after separation.

The findings also refine SECI theory. Single assignment executes externalization and combination, but it does not ensure socialization. Joint-development arrangements can be interpreted as institutionalized socialization channels after formal separation. Incubation is socialization-heavy, acceleration is externalization- and combination-heavy, and the independent spin-off phase begins a new cycle of internalization as the venture converts transferred knowledge into its own routines.

Finally, the findings extend intellectual-capital theory by showing that human, structural, and relational capital do not reconfigure at the same speed. Structural capital moves through documents and contracts; human capital moves through career decisions and role redesign; relational capital moves through repeated external validation. Resource Coordination Capability is thus a form of structural capital that governs the movement of other capital forms.

Together, the two models reposition spin-off formation as a designed transition rather than a transaction. The KAR Model explains the content of the transition, while the Progressive Separation Model explains its timing. Their integration helps explain why ventures with strong technology may still fail: the formal knowledge asset may have moved, but the sequence of socialization, externalization, combination, internalization, and relational substitution may be incomplete.

7 Implications, Limitations, and Conclusion

7.1 Implications

For RTO managers, the KAR Model provides a practical diagnostic question: which assets should be licensed, assigned, shared, or jointly developed, and does the organization have the coordination capability to manage that mix? For policymakers, the Progressive Separation Model suggests that instruments should differ by phase. Incubation policies should protect learning; acceleration policies should support co-ownership governance and founder transition; spin-off policies should help ventures replace parent-derived relational capital with independent market standing.

For investors, Resource Coordination Capability offers due-diligence signals that complement technology and team assessment. Investors can examine whether the RTO's legal, technical, and executive actors make decisions

coherently, whether prior reconfigurations are documented, and whether the venture has a credible plan for relational-capital substitution.

The implication is not that every spin-off requires a complex contract. Rather, complexity should match the knowledge asset. Simple assignments may be appropriate for mature, separable assets. Hybrid configurations are needed when the venture depends on continuing access to parent routines, facilities, or external relationships.

7.2 Limitations and Future Research

The study has three limitations. First, the investor and policymaker sample illuminates cross-boundary evaluation but under-represents RTO managers and founders. Future research should test the models through multi-informant designs. Second, the qualitative design supports theory elaboration rather than statistical generalization. Quantitative research could test the propositions using survey or archival data. Third, the empirical base is concentrated in Asian-Pacific and European RTO ecosystems; comparative work should examine whether the models travel to U.S. federal laboratories and emerging-economy research institutes.

Future research could also examine ecosystem-level effects. If Resource Coordination Capability is unevenly distributed across RTOs, national spin-off output may depend not only on science quality or funding volume but also on the institutional routines that allow knowledge assets to be recombined across boundaries.

7.3 Conclusion

RTO spin-off development is not a single transfer decision. It is a boundary-reconfiguration process in which IP, equipment, tacit know-how, human capital, and relational capital move at different speeds under different instruments. The KAR Model explains the combinatorial content of this process, while the Progressive Separation Model explains its temporal phasing. Resource Coordination Capability determines whether the reconfiguration can produce ventures that are investable, governable, and capable of building independent market standing.

8 Ethics Declaration

The study was based on expert interviews with informed consent. Respondents were anonymized, and no personally identifying information is reported. The authors should insert any institutional ethics approval reference required by their university before final submission.

9 AI Declaration

Generative AI assistance (Gemini/ChatGPT) was used to support language condensation, editorial rewriting, and Word-format preparation. The authors reviewed the resulting manuscript and remain responsible for its content, arguments, citations, and declarations.

The Impact of Networking Skills on Quiet Quitting and Knowledge Hiding: Mediating Role of Job Crafting and Moderating Effect of Mindful Leadership

Wan-Jung Chung, Guo-Jia Bo, Hao-Chieh Lin
National Sun Yat-sen University, Kaohsiung City, Taiwan, R.O.C.

Abstract

As businesses recover from the impact of the COVID-19 pandemic, the post-pandemic workplace has undergone substantial transformation. Currently, many studies consider quiet quitting to be indicators of low work attitude, decreased work engagement, and reduced performance and retention willingness. By enabling employees to rediscover the value and meaning of their work through job reinvention, they can achieve work goals more energetically and efficiently (Lu & Chen, 2020). Connelly et al. (2012) argue that employees' knowledge-hiding behavior stems primarily from their distrust of the organization or their own interpersonal relationships within it (Černe et al., 2014; Connelly et al., 2012). When employees quietly leave, the organization may lose not only enthusiasm and additional investment, but also a weakening of knowledge flow, knowledge contributions, and collaborative wisdom.

From a knowledge management perspective, preventing quiet quitting is not only about work engagement, but also about the continuity of knowledge flow, knowledge sharing, and the operation of intelligent organizations. Cultivating trust can indeed help employees overcome self-interest and share knowledge, especially at the group level (Weng & Li, 2015). Although research on quiet quitting is increasing, existing literature mainly focuses on the results; comparatively, there is insufficient attention paid to how to prevent quiet quitting. To fill this gap, this study uses Conservation of Resources theory (COR) as its theoretical basis to explore how network capabilities as personal resources and job crafting as a proactive resource management behaviour affect quiet quitting. Furthermore, the discussion explores how a quiet quitting can affect knowledge hiding. Furthermore, this study also discusses the impact of mindfulness leadership on the process of transforming personal resources into proactive action.

To fill this gap, it examines networking ability as a personal resource and job crafting as a proactive form of resource management and investigates how these factors influence quiet quitting. It further explores how quiet quitting affects knowledge hiding. In addition, mindful leadership is conceptualized as a contextual resource that may shape the process through which personal resources are translated into proactive action.

Accordingly, this study investigates how networking ability influences quiet quitting through job crafting and how quiet quitting, in turn, affects knowledge hiding. Through this design, quiet quitting is positioned not merely as a problem of low engagement, but as a knowledge management risk with important organizational implications.

Keywords: Networking Ability, Job Crafting, Quiet Quitting, Mindful Leadership, Conservation of Resources (COR) Theory

Paper type: Academic Research Paper

1 Introduction

The post-pandemic workplace has undergone substantial transformation. Flexible work arrangements, accelerated digitalization, and the widespread use of AI systems have changed not only how work is performed, but also how employees relate to their organizations, roles, and colleagues. From a knowledge management perspective, preventing quiet quitting is not only about work engagement, but also about the continuity of knowledge flow, knowledge sharing, and the operation of intelligent organizations. Cultivating trust can indeed help employees overcome self-interest and share knowledge, especially at the group level (Weng & Li, 2015). Although research on quiet quitting is increasing, existing literature mainly focuses on the results; comparatively, there is insufficient attention paid to how to prevent quiet quitting. To fill this gap, this study uses Conservation of Resources theory (COR) as its theoretical basis to explore how network abilities as personal resources and job crafting as a proactive resource management behaviour affect quiet quitting. Furthermore, the discussion explores how a quiet quitting can affect knowledge hiding. Furthermore, this study also discusses the impact of mindfulness leadership on the process of transforming personal resources into proactive action.

To fill this gap, it examines networking ability as a personal resource and job crafting as a proactive form of resource management and investigates how these factors influence quiet quitting. It further explores how quiet quitting affects knowledge hiding. In addition, mindful leadership is conceptualized as a contextual resource that may shape the process through which personal resources are translated into proactive action.

Accordingly, this study investigates how networking ability influences quiet quitting through job crafting and how quiet quitting, in turn, affects knowledge hiding. Through this design, quiet quitting is positioned as a knowledge management risk with important organizational implications.

2 Literature Review and Hypothesis Development

2.1 Quiet quitting

That is often defined as "merely completing work tasks rather than investing in learning new skills or enhancing abilities.", The employee did not actually leave the company, but their work engagement and performance significantly decreased, and they were only fulfilling the basic responsibilities outlined in the job crafting（Scheyett, 2022）. Current research on quiet quitting largely focuses on work attitudes and performance consequences. Employees also realize that work is just work, work to earn a living, and once they leave their positions, the knowledge they have acquired becomes personal (Kao & Fu, 2023). However, employees' willingness and participation in knowledge sharing are still influenced by their intrinsic motivation (Meng-Chuan Tsai et al., 2018). Knowledge silencing initially exists only between two individuals but can erode trust mechanisms within an organization through continuous cycles, reducing organizational and individual creativity and performance, and ultimately potentially leading to the organization's overall collapse (Hung-Yu Chen & Hao-Chieh Lin., 2023).

Therefore, this study argues that quiet quitting may weaken the flow of tacit knowledge, impede collaborative problem-solving, and hinder the continuous updating of organizational knowledge, and should be understood as a knowledge management risk.

2.2 Networking ability and job crafting

According to the Conservation of Resources Theory (COR), individuals with abundant resources have a stronger motivation to "invest in resources," thereby initiating positive gain spirals to acquire more resources and mitigate potential losses (Hobfoll, 2011; Hobfoll et al., 2018). Within this framework, networking ability is considered a key personal trait resource, reflecting an individual's comprehensive effectiveness in building, maintaining, and utilizing interpersonal networks to obtain social support, critical information, and career influence. Employees with high networking ability excel at mobilizing external assistance, identifying environmental opportunities, and effectively transforming social capital into tangible professional knowledge.

Job crafting refers to the proactive structural adjustments employees make to task boundaries, interpersonal interactions, or cognitive frameworks to optimize personal-environment fit (P-E Fit) and the meaning of their work (Tims & Bakker, 2010; Wrzesniewski & Dutton, 2001). From a COR perspective, the information flow and interpersonal support brought by Networking Ability provide employees with the "psychological and social ammunition" needed for job crafting. When individuals have sufficient resources, they are more willing to invest resources (such as energy and social capital) to proactively rewrite their work scope, thereby achieving resource value-added. According to the Conservation of Resources Theory (COR), individuals with abundant resources have a stronger motivation to "invest in resources," thereby initiating positive gain spirals to acquire more resources and prevent potential losses (Hobfoll, 2011; Hobfoll et al., 2018). Based on this, this study proposes the following hypothesis:

H1: An individual's Networking Ability have a significant positive impact on their job crafting behaviour.

2.3 Job crafting and quiet quitting

When employees face persistently high work demands, role ambiguity, and resource scarcity, and their invested effort fails to yield commensurate resource returns, they face the threat of a "loss spiral" (Hobfoll, 2001; Hobfoll et al., 2018). To prevent further resource depletion, employees adopt defensive protective strategies, selectively reducing task engagement and emotional connection. In the contemporary context, quiet quitting can be seen as a psychological "withdrawal strategy" or resource-preserving behavior, aimed at maintaining remaining personal resources to avoid collapse (Klotz & Bolino, 2022).

In contrast, job crafting is a proactive resource-enhancing behaviour. Employees actively adjust their job design to improve their job fit by increasing structural or social resources, challenging requirements, or reducing hindering requirements (Tims et al., 2012; Bakker et al., 2012). From a COR perspective, job crafting can enhancing a sense of control and meaning in work, thereby suppressing the motivation for psychological withdrawal and negative engagement. Therefore, employees exhibiting higher levels of job crafting behaviour

have more abundant psychological resources and are less likely to need to protect themselves through quiet quitting. Based on this, this study proposes:

H2: There is a significant negative correlation between employees' level of job crafting and their tendency to leave quietly.

2.4 Quiet quitting and knowledge hiding

Knowledge hiding is defined as the intentional withholding or concealment of relevant information by an individual when others explicitly request it (Connelly et al., 2012). For organizations seeking innovation, fostering knowledge sharing among employees through institutional and psychological means is crucial for enhancing competitiveness (Jiang Dingyu & Lin Jiahua, 2019). According to Conservation of Resource Theory (COR), knowledge is considered a core personal resource with a competitive advantage, and sharing requires time, cognitive effort, and risk-taking. When employees perceive resource depletion or organizational reciprocity imbalances, they often employ hiding behavior as a defensive strategy to protect remaining resources and maintain career adaptability (Hobfoll et al., 2018; Xiao & Cooke, 2019).

When individuals perceive their resources as threatened or lost, they will mobilize existing resources to minimize the loss (Liu & Lin, 2022). Because the transformation and transmission of tacit knowledge highly depend on informal interactions and spontaneous input, this study argues that knowledge hiding is a psychological mechanism similar to quiet quitting.

In today's rapidly evolving knowledge economy, a large part of an organization's competitiveness comes from the knowledge possessed by its employees. For organizations that wish to innovate, how to promote knowledge sharing among employees through systems and mindset will be a key factor in enhancing their competitiveness (Jiang Dingyu & Lin Jiahua, 2019). When employees perceive resource depletion or organizational reciprocity imbalances, they often resort to covert behaviors as a defensive strategy to protect remaining resources and maintain personal career adaptability (Hobfoll et al., 2018; Xiao & Cooke, 2019).

If quiet quitting result in the loss of high-quality knowledge, it will directly weaken the organization's learning foundation and the digitization process of organizational wisdom (Cacciotti et al., 2020). Therefore, this study argues that quiet quitting are a key antecedent driving knowledge hiding and proposes the following hypothesis:

H3: Quiet quitting are positively correlated with knowledge hiding.

2.5 The mediating role of job crafting

According to the Conservation of Resources (COR) theory, owning resources is not the same as solving the problem. Individuals must increase the value of resources and resist the spiral of loss through "resource investment" (Hobfoll et al., 2018).

Employees with strong networking skills have greater "resource availability," which gives them a greater ability to reshape their work—for example, by obtaining feedback through interpersonal resources and by adjusting task boundaries through information advantages (Tims et al., 2012). In other words, network capabilities provide the "raw materials" for reshaping work, while work reshaping is the process of refining the raw materials into a "stress shield" (Halbesleben et al., 2014). This study argues that while networking provides employees with abundant resources such as information and social support, these external resources need to be actively internalized and transformed through job reengineering to be effective. Based on this, this study proposes:

H4: Job crafting mediates the relationship between networking ability and quiet quitting.

2.6 The moderating role of mindful leadership

Mindful leadership refers to the present-moment awareness, openness, and non-judgmental qualities that leaders demonstrate in their interactions with subordinates (Good et al., 2016). From the perspective of Conservation of Resource Theory (COR), mindful leadership not only represents external resources available to subordinates but also constitutes a stable "resource caravan passageway, " creating a psychologically safe and supportive environment (Hobfoll et al., 2018). If leaders lack mindfulness, even employees with networking resources may limit their initiative due to concerns about assessing risks or environmental pressures (Roche et al., 2014). Based on this, this study proposes:

H5: Mindful leadership has a positive moderating effect on the relationship between Networking Ability and Job crafting.

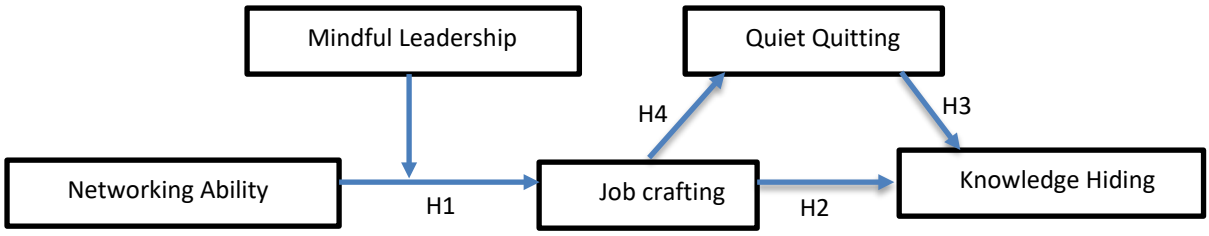

Figure 1 Research Framework

3 Research Methods

This study investigated full-time employees in Taiwan and collected data through a questionnaire survey, obtaining 321 valid samples. The mean age of the participants was 34.57 years (SD = 8.22), and the mean total years of work experience was 10.97 years (SD = 8.20). This study included gender, marital status, and education level as control variables.The mean values were 0.40, 0.37, and 1.24 (SD = 0.57).

Networking Ability was assessed using the Network Competence Scale from the Political Skill Inventory developed by Ferris et al. (2005). The Cronbach's α was 0.894. The Job crafting study used the Sora, Caballer and García (2018) scale, with 12 items, Cronbach's α = 0.893. Mindfulness leadership uses a modified set of items by Brown and Ryan (2003), consisting of 5 items, all on a Likert seven-point scale, where 1 represents "strongly disagree" and 7 represents "strongly agree", with Cronbach's α = 0.882. Quiet quitting was assessed using a scale modified from Galanis et al. (2023). Cronbach's α = 0.797. Knowledge hiding was assessed using the knowledge hiding scale developed by Connelly et al. (2012). The scale included three dimensions: feigning ignorance, avoidance hiding, and rationalization hiding. Cronbach's α = 0.957. All items were on a Likert seven-point scale, with 1 representing "strongly disagree" and 7 representing "strongly agree".

And used SPSS and Hayes' PROCESS for data analysis. PROCESS Model 7 was used to examine the relationships between networking skills, Job crafting, quiet quitting, and mindful leadership; PROCESS Model 4 was used to examine the relationships between Job crafting, quiet quitting, and knowledge hiding. All indirect effects were estimated using 5,000 bootstrap resampling.

4 Result

Descriptive statistics and correlation analysis showed that knowledge hiding was positively correlated with quiet quitting ($r = 0.260$, $p < 0.001$) and negatively correlated with job crafting ($r = -0.192$, $p < 0.001$). Networking ability was significantly positively correlated with job crafting ($r = 0.329$, $p < 0.01$) and significantly negatively correlated with quiet quitting ($r = -0.174$, $p < 0.01$). Job crafting was significantly negatively correlated with quiet quitting ($r = -0.457$, $p < 0.001$). Mindful leadership was significantly positively correlated with job crafting ($r = 0.172$, $p < 0.01$) and significantly negatively correlated with quiet quitting ($r = -0.198$, $p < 0.01$). Overall, the directions of the correlations were largely consistent with the theoretical expectations of this study.

Table 1 Correlation coefficients of variables

Variable	Mean	SD	1	2	3	4	5	6	7
1.Gender	--	--							
2. Marital Status	--	--	-0.016						
3. Education Level	--	--	0.085	-0.083					
4. Networking Ability	26.11	6.766	0.156**	0.097	0.074				
5. Job crafting	58.07	10.843	-0.052	0.143*	-0.005	0.329**			
6. Mindfulness leadership	24.16	6.687	-0.076	0.077	0.002	0.015	0.172**		
7. Quiet quitting	15.22	5.634	0.046	-0.115*	-0.078	-0.174**	-0.457**	-0.198**

Note：***p < .001, **p < .01, *p < .05。

This study used SPSS and Hayes' PROCESS macro for data analysis. PROCESS Model 7 was employed to examine the relationships among networking ability, job crafting, quiet quitting, and mindful leadership, whereas PROCESS Model 4 was used to test the relationships among job crafting, quiet quitting, and knowledge hiding. The results indicated that networking ability had a significant positive effect on job crafting ($B = 0.9493$, $SE = 0.2063$, $t = 4.6027$, $p < .001$), supporting H1. In addition, job crafting had a significant negative effect on quiet quitting ($B = -0.2269$, $SE = 0.0278$, $t = -8.1581$, $p < .001$), supporting H2. By contrast, the direct effect of

networking ability on quiet quitting was not significant (B = -0.0177, SE = 0.0449, t = -0.3950, p = .6931). Regarding the moderating effect, the interaction between networking ability and mindful leadership had a significant negative effect on job crafting (B = -0.0254, SE = 0.0114, t = -2.2396, p = .0258).

As shown in Table 2, networking ability had a significant positive effect on job crafting (B = 0.9493, SE = 0.2063, t = 4.6027, p < .001), supporting H1. Job crafting had a significant negative effect on quiet quitting (B = -0.2269, SE = 0.0278, t = -8.1581, p < .001), supporting H2. The direct effect of networking ability on quiet quitting was not significant (B = -0.0177, SE = 0.0449, t = -0.3950, p = .6931). In addition, the interaction between networking ability and mindful leadership had a significant negative effect on job crafting (B = -0.0254, SE = 0.0114, t = -2.2396, p = .0258), indicating that mindful leadership weakened rather than strengthened the positive relationship between networking ability and job crafting.

Table 2 Moderated Mediation Analysis Results (Model 7)

Path	coefficient (β)	SE	t	p value	95% CI
Networking Ability→Job crafting	0.9493	0.2063	4.6027	<0.001	[0.544, 1.355]
Networking Ability→Quiet quitting	-0.0177	0.0449	-0.395	0.693	[-0.106, 0.071]
Mindful leadership→Job crafting	0.4373	0.3154	1.3867	0. 1665	[-0.183, 1.058]
Networking Ability * Mindful leadership→ Job crafting	-0.0254	0.0114	-2.24	0.0258	[-0.048, -0.003]
Job crafting→Quiet quitting	-0.2269	0.0278	-8.158	<0.001	[-0.282, -0.172]

Note: Sex, marital status, and education were included as control variables. Unstandardized coefficients are reported.

Table 3. Mediation Analysis Results (PROCESS Model 4)

Path	coefficient (β)	SE	t	p value	95% CI
Job Crafting → Quiet Quitting	-0.2305	0.0262	-8.7900	< .001	[-0.282, -0.179]
Quiet Quitting → Knowledge Hiding	0.5515	0.1489	3.7036	.0003	[0.259, 0.845]
Job Crafting → Knowledge Hiding (direct effect)	-0.1182	0.0773	-1.5281	.1275	[-0.270, 0.034]
Job Crafting → Knowledge Hiding (total effect)	-0.2453	0.0707	-3.4702	.0006	[-0.384, -0.106]
Indirect effect via Quiet Quitting:	-0.1271	0.0480			[-0.226, -0.036]

Note. Sex, marital status, and education were included as control variables. Unstandardized coefficients are reported.

To further examine the relationship among job crafting, quiet quitting, and knowledge hiding, this study employed Hayes' PROCESS Model 4. The results showed that job crafting had a significant negative effect on quiet quitting (B = -0.2305, SE = 0.0262, t = -8.7900, p < .001), indicating that employees who engaged in higher levels of job crafting were less likely to exhibit quiet quitting tendencies. In turn, quiet quitting had a significant positive effect on knowledge hiding (B = 0.5515, SE = 0.1489, t = 3.7036, p = .0003), supporting H3.

The total effect of job crafting on knowledge hiding was significant (B = -0.2453, SE = 0.0707, t = -3.4702, p = .0006). However, after quiet quitting was included in the model, the direct effect of job crafting on knowledge hiding became non-significant (B = -0.1182, SE = 0.0773, t = -1.5281, p = .1275). Furthermore, the indirect effect of job crafting on knowledge hiding through quiet quitting was significant (Effect = -0.1271, BootSE = 0.0480, 95% BootCI = [-0.2265, -0.0368]). Because the bootstrap confidence interval did not include zero, the mediation effect was confirmed. These findings indicate that quiet quitting fully mediated the relationship between job crafting and knowledge hiding.

5 Discussion

The results of this study show that Networking Ability significantly promote Job crafting, which in turn significantly reduces quiet quitting. This aligns closely with Generation Z's work values; they value self-actualization, personal growth, fair compensation, and a positive organizational atmosphere. Furthermore, they believe that quiet quitting are unavoidable in this era (Chang & Chen, 2023). Networking ability significantly promote Job crafting, which in turn significantly reduces quiet turnover. This supports the COR theory's explanation of the proactive resource management process: employees with higher networking ability are more effective at obtaining support, information, and assistance, and translate these resources into proactive adjustments to work tasks, interactions, and cognition, thereby improving their resource status and reducing psychological detachment.

To enhance knowledge sharing within an organization, companies should emphasize coordination through interpersonal networks to create an environment conducive to knowledge sharing (Tung, 2004). When

employees leave quietly, the organization loses not only interpersonal communication but also the high-quality knowledge input supporting the operation of intelligent systems. This can result in aging knowledge bases, biased decision-making models, and decreased effectiveness of intelligent management tools. From this perspective, quiet departures in the AI era are not only a human resources issue but also a problem of intelligent knowledge governance.

This study found that mindful leadership has a significant negative moderating effect on the relationship between networking ability and Job crafting. Specifically, when the level of mindful leadership is lower, the promoting effect of networking ability on Job crafting is stronger. This result may suggest that, under less supportive contexts, employees with high networking ability are more likely to proactively adjust their work by relying on their own relationship resources; in contrast, under higher mindful leadership contexts, the support and security provided by supervisors may partially replace the necessity for employees to mobilize their personal network resources. When mindful leadership is low, the positive impact of networking skills on Job crafting is stronger; when mindful leadership is high, this effect is weaker. One possible explanation is that when situational support is low, employees with high networking skills need to rely more on their relationship resources to proactively adjust their work; conversely, when supervisors have provided high levels of support and psychological safety, the marginal utility of individual networking skills may decrease.

6 Conclusions

This study makes several theoretical contributions. First, compared to most studies that emphasize the consequences of quiet departure, this study further explores how organizations and employees can mitigate its occurrence through personal resources and proactive behaviors. It expands the application of COR theory, demonstrating that networking ability and job repositioning constitute a meaningful mechanism chain that helps employees prevent quiet departure. This shows that COR can explain not only defensive exits but also the proactive process of resource investment and gains. Second, this study incorporates knowledge hiding into the follow-up results of quiet quitting, expanding the explanatory power of quiet quitting research in the field of knowledge management. This indicates that quiet quitting are not only a low-input phenomenon, but also an important mechanism that weakens knowledge flow, knowledge contribution, and the transfer of tacit knowledge. Finally, this study links psychological withdrawal with the operation of intelligent organizations. The interruption of knowledge flow caused by employee psychological withdrawal in an organization may further affect the knowledge base and decision-making quality upon which intelligent systems rely, thus opening up new avenues for discussion on the application of COR theory in the context of intelligent management.

From a practical perspective, this study shows that organizations cannot rely solely on institutional controls or performance pressure to reduce quiet quitting and knowledge hiding; they should also emphasize employee access to resources and flexibility in job crafting. First, companies can enhance employees' networking and resource mobilization capabilities by encouraging cross-departmental interaction, building supportive networks, and promoting peer collaboration. Second, managers should provide more work autonomy and role adjustment opportunities, encouraging employees to reinvent their jobs to enhance their sense of control, purpose, and sustainable engagement.

Urthermore, organizations should view quiet quitting as a knowledge risk. The effectiveness of intelligent systems depends not only on the amount of data but also on the freshness, context, and willingness to continuously update the knowledge input. If employees are generally in a state of low engagement or knowledge silencing, even if the intelligent system appears to be operating continuously, the quality of its output, the accuracy of its predictions, and the credibility of its management recommendations may gradually decline.

This study, based on COR theory, the results show that networking capabilities significantly promote job reshaping, which in turn further reduces quiet departure; quiet departure significantly increases knowledge hiding and plays a fully mediating role between job reshaping and knowledge hiding. Mindful leadership has a marginally significant moderating effect on the relationship between networking capabilities and job reshaping.

The research results indicate that networking skills significantly promote job repositioning, which in turn significantly reduces the likelihood of employees leaving quietly. This confirms the resource conservation theory's explanation of proactive resource management. Overall, this study not only supplements the theoretical framework of the formation and subsequent impact of quiet quitting, but also reminds organizations to re-understand quiet quitting from the perspectives of resource management, knowledge flow, and intelligent management. By promoting job reshaping, strengthening interpersonal resource mobilization, and establishing intelligent knowledge governance mechanisms, organizations can reduce employee psychological withdrawal and mitigate its negative impact on knowledge management and intelligent management systems.

7 Ethics Declaration

This study collected data using anonymous questionnaires. Before completing the questionnaire, participants were informed of the research purpose, data usage, and confidentiality principles. This study did not collect any personally identifiable information; all data was used solely for academic research analysis, and the results were presented in a holistic statistical manner to protect participant privacy and research ethics.

8 AI Declaration

During the preparation of this manuscript, generative CHATGPT were used to assist with Chinese–English translation, and language polishing. These tools were not involved in data collection, statistical analysis, interpretation of results, or conclusion development. The research design, theoretical development, data analysis, interpretation of findings, and final approval of the manuscript were completed by the author, who assumes full responsibility for the content.

Knowledge Dissemination Strategies for Circular Economy: Evidence from Italian Local Governments

Miriana Ferrara[1], Nicola Capolupo[2]
[1] University of Salerno, Fisciano, Italy
[2] San Raffaele Roma University, Rome, Italy

Abstract

The circular economy (CE) has emerged as a central paradigm in the governance of urban sustainability, assigning local governments a crucial role in the transition towards regenerative models of production and consumption. However, the success of CE initiatives depends not only on the design of regulatory strategies and instruments, but also on the ability of public institutions to disseminate knowledge effectively to citizens and stakeholders. However, the literature has devoted greater attention to the design of CE policies rather than to the processes through which such policies are made accessible and socially embedded.

This study investigates the knowledge dissemination strategies adopted by three Italian regional capitals (Florence, Turin and Genoa) through their institutional channels. The analysis draws on the framework of Green et al. (2009), which articulates the dissemination process into five constituent dimensions: the source, the content, the medium, the user and the context. The research design is based on a multiple-case approach, involving the collection of qualitative secondary data, primarily institutional websites, project documentation and official reports, analysed through direct qualitative content analysis.

The findings reveal that, while sharing a formal commitment to the circular transition as signatories of the European Circular Cities Declaration, the three cities are developing structurally distinct dissemination strategies. Florence adopts a civic dissemination strategy towards citizens' behavioural compliance. Turin develops a business-oriented ecosystemic strategy, in which knowledge is co-produced within a permanent urban innovation platform. Genoa presents the most complex architecture, characterized by a dual-track system that explicitly differentiates the registers intended for citizens and economic actors.

The study contributes to the literature by extending the application of Green et al's framework to the domain of CE governance in local public administration, demonstrating how choices across the five dimensions do not operate independently but constitute coherent epistemic architectures that encode distinct governance philosophies.

Keywords: Circular Economy, Circular Cities, Public Administrations, knowledge dissemination

Paper type: Academic research paper

1 Introduction

Circular economy (CE) has emerged as one of the defining paradigms of contemporary sustainability governance, offering a systemic alternative to the linear "take-make-dispose" model that has underpinned industrial production for decades (MacArthur, 2013; Geissdoerfer et al., 2017). By designing out waste, maintaining materials and products in circulation at their highest utility, and regenerating natural systems, CE provides an integrated framework through which economic growth can be progressively decoupled from resource consumption and environmental degradation (Kirchherr et al., 2017). In this evolving policy landscape, cities and metropolitan areas have assumed a central governance role: urban territories concentrate both the resource flows that CE seeks to reconfigure (waste, mobility, construction, consumption) and the institutional density required to translate strategic commitments into operational practice (Fratini et al., 2019; Paiho et al., 2020).

Local governments are accordingly positioned as key actors in CE governance, tasked not only with designing regulatory instruments and investment strategies but also with managing the communicative and participatory dimensions of the transition. CE initiatives, particularly those addressing urban waste and sustainable consumption, cannot succeed without the active involvement of citizens as both behavioural actors and co-producers of sustainable practices (Moreau et al., 2017). This civic dimension of CE governance places knowledge dissemination - the capacity of public institutions to share actionable, meaningful knowledge with diverse stakeholder communities - at the heart of any effective urban CE strategy. Yet this dimension remains comparatively underexplored in the scholarly literature, which has devoted substantially greater attention to the design of CE strategies than to the communicative and epistemic processes through which these strategies are made accessible and socially embedded (Pozzetto & Leoni, 2025; Ducci, 2025).

The present study addresses this gap by investigating how three Italian regional capitals - Turin, Florence, and Genoa - disseminate CE knowledge to citizens and other stakeholders through their institutional websites and associated communication channels. To analyze knowledge dissemination strategies in a theoretically systematic way, this study draws on the knowledge communication framework developed by Green et al. (2009). The framework identifies five constitutive and interrelated elements of any dissemination process: the source, who produces the knowledge; the content, what knowledge is shared and how it is framed; the medium, through which channels knowledge is conveyed; the user, who is expected to receive and apply the knowledge; and the context, the institutional and community environment within which dissemination occurs. Applied to the institutional websites of local governments, this framework enables a structured comparative analysis that moves beyond descriptive accounts of CE communication towards an examination of the underlying strategic logics shaping how cities conceptualize their roles as knowledge disseminators.

The paper contributes to the literature in two principal ways. Theoretically, it extends the application of the framework to the domain of CE governance in local public administration, demonstrating its analytical purchase as a tool for mapping knowledge dissemination strategies across diverse institutional contexts. Empirically, it provides comparative evidence on how Italian municipalities with comparable CE commitments nonetheless develop markedly distinct approaches to civic knowledge sharing. The paper is organized as follows. Section 2 reviews the relevant literature and presents the theoretical framework. Section 3 describes the research methodology. Section 4 presents the within-case and cross-case analysis. Section 5 discusses findings and implications, and Section 6 offers brief concluding remarks.

2 Literature Review and Theoretical Background

2.1 The role of knowledge dissemination for circular economy

Research on sustainability transitions highlights that the successful implementation of CE strategies depends not only on policy design and material infrastructures, but also on how knowledge is actively disseminated and internalized by diverse actors within a territory (Bourdin & Jacquet, 2025; Kasmi et al., 2022). Circularity involves complex changes in behaviors, organizational routines, and market practices (Klein et al., 2022); thus, knowledge dissemination is a core governance function that shapes how stakeholders interpret, prioritize, and operationalize CE principles in practice (Mele et al., 2025).

Dissemination in this context is not a unidirectional information broadcast but a deliberate process of engagement, translation, and sense-making. It involves tailoring information to the specific knowledge levels, expectations, and motivational frames of different actor groups, including citizens, firms, and civic organisations (Avelino et al., 2016). Research on sustainability communication shows that generic informational campaigns rarely translate into behavioural change when they fail to align with individuals' pre-existing values, ideological orientations, and perceived behavioural control, which are particularly influential in circular economy practices such as recycling, reuse, and sharing (Shah & Yang, 2025, Lorincová & Osvaldovà, 2025).

In municipal governance, the capacity to disseminate circular-economy knowledge intersects with core administrative functions such as coordination, openness, and institutional trust, which in turn influence citizens' willingness to participate in sustainability actions. Moreover, interactive dissemination practices, those that go beyond one-way information provision and create dialogue spaces, can facilitate collective and reflective learning among stakeholders, helping to co-develop shared understandings, align expectations, and adapt policies responsively (Jacobi & De Souza, 2021). Such collaborative learning processes are increasingly recognized as vital in environmental governance, where everyday actions by households and local businesses shape the overall effectiveness of policy interventions

A further theme concerns the digitalization of knowledge dissemination. Digital platforms, open data initiatives, and social media are increasingly deployed by local governments not just to distribute information but to create spaces for dialogue, feedback, and collaborative problem-solving. These tools can reduce information asymmetries and enhance accessibility to CE knowledge (Hossain et al., 2016; Ranta et al., 2018), although their effectiveness depends on design choices that acknowledge digital inclusiveness and trust dynamics (Cerić & Ivić Jazvec, 2026). Hence, knowledge dissemination for CE should be analyzed as a governance mechanism that influences cognitive frames, social norms, and institutional relationships, rather than as a peripheral communication task. Assessing how municipalities craft, tailor, and mediate CE-related knowledge flows therefore becomes essential to understanding CE implementation processes in urban contexts.

2.2 A knowledge dissemination framework

To provide a structured analytical lens for examining CE knowledge dissemination in local government contexts, this study adopts the framework developed by Green et al. (2009). Originally conceived in the field of public health as a model for understanding the conditions under which research-based knowledge is diffused, utilized, and integrated into practice, the framework has since been taken up in management and organizational studies as a generalized interpretive schema for analyzing knowledge transformation processes (Serrat, 2017). Its relevance to the present study rests on its explicit conceptualization of dissemination as a multi-dimensional and relational process rather than a simple act of information transfer, and its consequent capacity to illuminate the strategic choices embedded in any act of institutional knowledge communication.

The framework identifies five constitutive elements of the dissemination process, each of which shapes the conditions under which knowledge is effectively produced, transmitted, received, and applied. To better describe and contextualize them, this study draws on the definitional elaborations provided by the National Center for the Dissemination of Disability Research (NCDDR, 1996), which operationalizes each dimension in terms of its practical functions within a dissemination process.

The first element is the source, which refers to the actor or institution originating the knowledge. The credibility, authority, and perceived expertise of the source significantly influence whether disseminated knowledge is perceived as trustworthy by its intended recipients; in public sector contexts, the institutional position of the source, whether a municipality acting alone, a public-private partnership, or a multi-stakeholder network, shapes the epistemic authority with which knowledge is invested.

The second element is the content, which encompasses the nature, scope, framing, and cognitive objectives of the knowledge being shared. Content may range from prescriptive and behavioral-directive to exploratory and project-based, inviting businesses and institutions to co-construct novel circular solutions. The third element is the medium, which refers to the channels and formats through which knowledge is conveyed. The choice of medium affects not only the reach of dissemination but also its depth, interactivity, and the degree to which it can accommodate diverse knowledge needs. Institutional websites, social media, physical spaces, and documentary artifacts each carry distinct affordances and limitations as knowledge dissemination tools (Pozzetto & Leoni, 2025).

The fourth element is the user, which refers to the intended or actual recipients of the disseminated knowledge, including their prior knowledge, motivations, and contextual capacity to absorb and act upon it. The conceptualization of the user reflects deeper assumptions about the role of citizens and other stakeholders in CE governance: whether they are positioned as passive recipients of prescriptive guidance, as active participants in co-creation processes, or as economic actors whose engagement is sought based on professional or entrepreneurial interest.

The fifth and final element is the context, which encompasses the institutional, social, and political environment within which dissemination occurs. Contextual factors such as governance structures, formal policy commitments, civic culture, and administrative capacity all condition the production, circulation, and reception of CE knowledge, and must be considered in any comparative analysis of dissemination strategies.

These five dimensions constitute an integrated analytical framework that is particularly well-suited for the examination of institutional communication channels as artifacts of CE public knowledge dissemination (Fig.1).

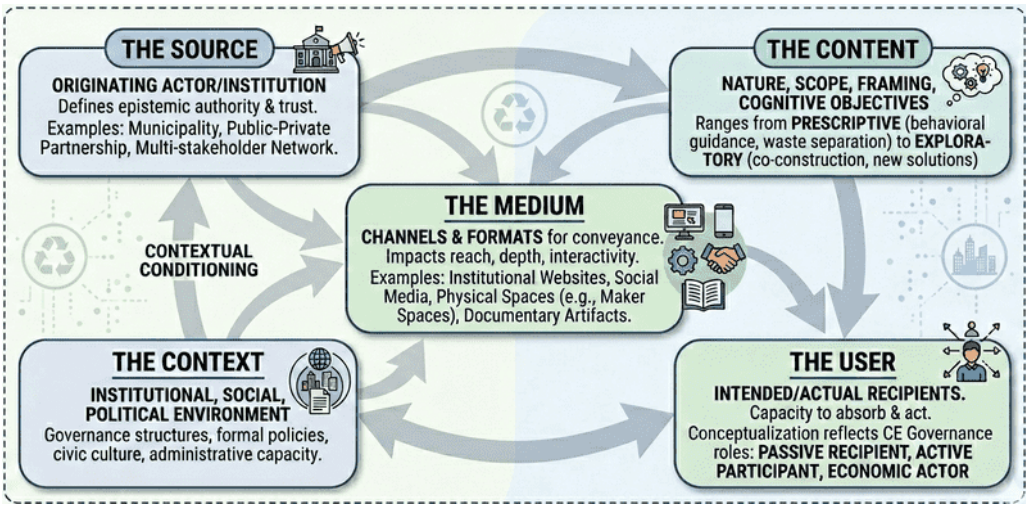

Figure 1: Circular city knowledge dissemination framework, authors 'elaboration through Nano Banana 2 AI software

3 Research Methodology

3.1 Research design and research context

Since the objective of the study is to understand knowledge dissemination strategies developed by diverse local governments to share their CE initiatives, the present study adopts a multiple case study approach (Yin, 2009). Indeed, this method is appropriate for collecting evidence about contemporary and complex real-life that requires deeper investigation by comparing and pointing out similarities and differences of the case studies (Yin, 2018). In this logic, the study first unfolds the knowledge dissemination elements according to the framework provided by Green et al. (2009), then conducts a cross-case analysis to uncover different strategic approaches and identify the main knowledge dissemination strategy developed by local governments.

The cases were selected according to a non-probability sampling (i.e., purposive) (Rapley, 2014), that matched the following parameters:

- being from the same country, to unify national legislation and socio-cultural backgrounds, then implementing the replication logic identifying similarities and difference;
- being from Italy, which ranks as a leading country among the largest EU economies for CE initiatives;
- being regional capital, to have comparable level of organizational complexity;
- being signatories to the European Circular Cities Declaration, since this shows the formal commitment that these cities have taken towards CE initiatives;
- being limited to three cases in line with the replication logic of multiple case study design, which recommends a manageable number of cases for in-depth cross-case comparison rather than breadth of coverage (Yin, 2018).

Three Italian local governments were selected for the analysis, i.e., Florence, Turin and Genoa.

Florence has institutionalized its efforts towards CE through the Florence Circular City Strategy 2021-2023, which has seen the development of two main projects named Florence Plastic Free and Florence Circular City.

Turin has seen its commitment to CE initiatives as part of a strategic approach to innovating the city. In this regard, the local government has promoted Turin City Lab, which is an urban digital platform, established to create a streamlined environment in which businesses, start-ups, research bodies and public sector organizations can test innovative solutions in real-world conditions.

Genoa has developed and implemented a participatory CE strategy as part of the C-City project. The strategy considers the short, medium and long-term perspective, and on the upstream objective of reducing raw material and produce usage in the city, aiming long-term towards a zero-waste city.

3.2 Data collection and data analysis

Secondary qualitative data were collected, as they were produced by institutional actors for other purposes than those of this research and are publicly accessible without intermediaries. No primary data collection was carried out, in line with the study's focus on the dissemination of produced knowledge, rather than on individual perceptions or behaviors. They were collected in January 2026 mainly through local governments official websites, since these are considered as primary public channels for the dissemination of knowledge, representing institutional artifacts through which administrations seek to make information on circular economy policies and initiatives understandable and usable (Pozzetto & Leoni, 2025; Ducci, 2025). Beyond the screening of official websites (torinocitylab.it/; firenzecittacircolare.it; c-citygenovacircolare.eu), other analyzed sources included: the most updated Circular Cities Declaration Report (which refers to 2024), websites devoted to individual CE initiatives, the documentation for each CE initiative (e.g., Florence Plastic Free Action Plan, Genoa 2050 Action Plan, Turin Urban Innovators Guide).

The data were analyzed using qualitative directed content analysis (Hsieh & Shannon, 2005). This approach was chosen because it allows existing theory or theoretical frameworks to guide the initial coding process, providing a well-defined set of analytical dimensions that are then applied to the empirical context. This approach is particularly appropriate for the present study, in which the framework provided by Green et al. (2009) defines the main categories that are then conceptualized in a novel context. Therefore, the coding scheme was structured around the five dimensions identified by Green et al. (2009): source, content, medium, user and context. The analysis was conducted in two sequential stages. Firstly, a within case analysis was carried out for each city separately, examining how each of the five dimensions is represented. Secondly, a cross-case analysis was conducted, identifying systematic similarities and differences, finally extrapolating the main knowledge dissemination strategy for each local government. To enhance the reliability of the coding process,

the two authors independently coded a subset of the data and subsequently compared and reconciled their interpretations through iterative discussion until consensus was reached on all categorizations.

4 Results

4.1 Within case analysis

4.1.1 Florence

As aforementioned, Florence CE initiatives are embedded in two main activities: Florence Circular City and Florence Plastic Free.

Regarding Florence Circular City, the knowledge source is represented by the Municipality of Florence and Alia Servizi Ambientali S.p.A., the private operator responsible for environmental services within the city. The partnership model positions knowledge production as a shared responsibility between these two actors. The content of knowledge, disseminated primarily through dedicated websites, mainly regards the description of the city's circular economy activities in the waste sector, the provision of detailed guidance on how to carry out separate waste collection, and the indication of the collection points distributed across the urban area. The medium, beyond the institutional website, extends beyond the website and includes social media channels (Instagram and Facebook), radio broadcasts, face-to-face community meetings (coordinated by the A-team) and a dedicated mobile app, reflecting a deliberate multi-platform strategy aimed at maximising the reach of citizens. The target user is primarily the individual citizen in their capacity as an urban resident and waste producer.

Florence Plastic Free is a second initiative launched in partnership with the waste collection service provider and the water service provider. Beyond these actors, the initiative further involves knowledgeable partners, such as trade associations in the tourism sector, operators of food and non-food markets, trade associations for commercial activities, and managers of public and private canteens, recognising the systemic role of economic actors in reducing plastic. The content is structured around four explicitly stated objectives: reducing the consumption of single-use plastic, promoting good practices through information and incentives, the proper management of plastic waste, and the cleaning of urban areas. The medium is related to a dedicated page on the municipal environmental services website (ambiente.comune.fi.it), which hosts the initiative's action plan. Other forms of knowledge dissemination regard the promotion of targeted awareness campaigns in schools and public offices, and the organisation of waste collection days in sensitive urban areas in collaboration with schools and local associations. The main users include primarily individual citizens.

The context is characterized by formal commitment to CE initiatives, through the Florence Circular City Strategy, however it lacks a unified strategic document.

4.1.2 Turin

The source of knowledge production is the Local Department for Ecological and Digital Transition, working in synergy with Torino City Lab, bringing together public administration, private enterprises and academic stakeholders in real-world experimentation. Therefore, the knowledge source emerges to be produced by not a single institutional actor but by a multi-stakeholder network that co-produces and co-disseminates knowledge in a systematic and formalised manner.

The content of knowledge regards focusing on the development of circular urban supply chains, local infrastructure for reuse and repair, and products and services based on circular design. The aim of the content is not to teach but to engage partners to co-produce CE initiatives with, then shaping a collaborative and project-based approach.

The medium used are the institutional website and social network pages which function primarily as vehicles for calls to action aimed at potential business partners. These channels are not designed to disseminate knowledge or best practices to the public; on the contrary, they assume a proactive audience capable of responding concretely to institutional push. Consequently, the target audience consists almost exclusively of players from the business world such as companies, start-ups and research bodies, while individual citizens are largely absent as recipients of communication on the circular economy.

The institutional context is characterized by the institutional effort of the local government to shape an innovative city, capable of integrating technological experimentation, social impact and ecological transition.

4.1.3 Genoa

In terms of the source, knowledge production is anchored to the Municipality of Genoa as the central institutional actor. The distinctive feature of the Genoese model, however, lies in the participatory and multi-

stakeholder nature of the knowledge production process: the city's CE strategy was developed through a process co-designed with citizens, the third sector, businesses and major economic operators, creating a source that is not merely institutional but ecosystemic and deliberately inclusive (ICLEI, 2024).

The content disseminated through Genoa's institutional channels is organised into seven thematic domains (i.e., energy, food, the sea, textiles, construction, mobility, materials and products) reflecting a specific effort in each sector. The content to convey practical and replicable knowledge includes best practices, neighbourhood-scale intervention models, and tools for monitoring and governing the circular transition.

In terms of its medium, Genoa is building a communication infrastructure that stands out for its combination of physical and digital spaces for knowledge exchange. The Circular Hub, located in the city centre, is an on-site and digital space of knowledge exchange among different stakeholders to co-create urban circular economy microprojects. The Circular Desk represents a second physical tool for knowledge diffusion, specifically dedicated to businesses: it functions as a technical facilitation desk that builds relationships between actors for CE initiatives and provides a preliminary assessment for open innovation activities linked to circular processes. The communication toolkit is complemented by the dedicated institutional website (c-citygenova.eu), editorial articles and structured events, including the Circular City Forum 2026, which Genoa will host as the host city.

The user dimension is explicitly dual and hierarchically differentiated. Citizens are engaged through the Circular Hub and its digital platform, which involves them not as passive recipients of prescriptive content but as active participants in the development of urban-scale circular micro-projects. Businesses, on the other hand, are directed towards the Circular Desk, which supports them on their path towards circularity and enables them to propose projects and share best practices.

The institutional context moves around the Genoa 2050 Action Plan, approved by municipal resolution, which provides the CE strategy with a stable and verifiable governance framework.

4.2 Cross-case analysis

The cross-case comparison reveals that, despite sharing a formal commitment to circular economy transition as signatories of the European Circular Cities Declaration, the three cities exhibit markedly distinct characteristics across all five dimensions framework. These differences track diverse knowledge dissemination strategies for each local government (Tab.1).

With regard to the nature of the source, all three cities involve the local municipality as the central institutional actor but differ significantly in the structure of knowledge production. Florence operates through a public-private partnership model, in which knowledge is co-produced with private service providers. Turin has established a networked institutional production in which the administration operates within a permanent platform that integrates businesses, start-ups and research bodies. Genoa developed a multi-stakeholder ecosystemic model for which the municipality plays a key role in co-producing knowledge with both business actors and citizens.

In terms of content, the clearest difference emerges between Florence on the one hand, and Genoa and Turin on the other. Florence produces prescriptive-behavioral knowledge, focused on individual daily actions. Turin develops content of a project-based and collaborative nature, in which knowledge is not transmitted but co-constructed with economic actors. Genoa adopts a strategic-programmatic approach, applying the CE across seven thematic domains within a deliberated action plan. This variation in the type of content signals profound differences in the very conception of dissemination: informing, planning or co-constructing.

Regarding the medium, Florence stands out for its greater diversification of channels, combining digital, physical and traditional tools in a multi-channel strategy aimed at maximum reach. Turin, by contrast, employs a minimal communication repertoire used mostly to convey entrepreneurial calls to action. Genoa builds a hybrid communication infrastructure, which combines a thematic platform dedicated to physical tools.

The user dimension represents the most marked divergence between the three cases and the one with the most direct implications for civic engagement. Florence directs its communication primarily with the individual citizen. Genoa explicitly adopts a dual model, establishing distinct communication channels for citizens and businesses. Turin effectively focuses on economic and institutional actors.

In terms of context, all three cities share the same formal starting point (i.e., adherence to the Circular Cities Declaration) but differ to the degree to which their commitment has been institutionalized. Florence maintains a general enabling framework, without a unified policy document to structure initiatives into a coherent strategy. Turin has built a permanent innovation infrastructure, that is Turin City Lab. Genoa has translated its formal commitment into a deliberate governance tool which provides EC initiatives with a stable and verifiable institutional foundation.

Florence adopts a diffusive civic dissemination strategy, in which source authority, behavioral content, multi-channel media, and a citizen-as-target user conception combine into a coherent logic of compliance-oriented civic mobilization. Turin has devised a business-oriented ecosystemic dissemination strategy, where a multi-stakeholder source, strategic-programmatic content, and a permanent institutional platform converge into a model in which knowledge is not transmitted but co-constructed. Genoa presents the most structurally complex strategy, characterized by a dual-track knowledge architecture that deliberately separates epistemic registers, directing action-oriented content to citizens while engaging businesses as strategic partners in CE governance. These three strategies do not constitute a hierarchy of effectiveness; rather, they reflect diverse yet coherent ways in which local governments translate a shared formal commitment to CE into structurally distinct knowledge governance arrangements.

Table 1: Results summary

Dimension	Florence	Turin	Genoa	
Source	Public-private partnership	Networked institutional production	Multi-stakeholder ecosystem	
Content	Prescriptive-behavioural	Project-based-collaborative	Strategic-programmatic	
Medium	Diffusive multi-channel	Action-oriented digital	Physical and Digital Platform	
User	Citizen	Businesses	Citizens and businesses	
Context	Formal commitment, no unified strategic document	Permanent innovation infrastructure (Torino City Lab)	Formal commitment + Action Plan (Genoa 2050)	

5 Discussion, Implications and Conclusions

The application of the Green et al. (2009) framework reveals that the five dimensions do not operate as independent conditions but as an integrated system in which choices along one dimension constrain and shape the others. What emerges is not simply variation in communication style, but three coherent epistemic architectures encoding distinct governance philosophies about who holds legitimate knowledge, for whom it is produced, and to what end.

Source and content are the dimensions most directly shaped by how cities conceptualize CE knowledge production. The shift from a public-private partnership source (Florence) to a multi-stakeholder ecosystemic model (Genoa) corresponds to a transition from institutional transfer to distributed co-production (Nonaka & Takeuchi, 1995). Correspondingly, the content variation, from prescriptive-behavioral to strategic-programmatic, maps onto a well-established typology in science communication between the "deficit model," which treats publics as lacking knowledge to be filled, and dialogic models that treat knowledge production as inherently participatory (Wynne, 1992; Felt et al., 2016).

Medium and users carry the most direct implications for civic engagement. The choice of channel presupposes and constructs an imagined audience: Florence serves a citizenry conceived as compliance targets; Turin serves professional co-innovators; Genoa differentiates explicitly between citizens and businesses. Mapping these onto Fung's (2006) typology, Florence approximates "managed participation," Turin resembles "stakeholder representation," and Genoa approaches "deliberative co-governance." The user dimension is the most politically significant of the five because it encodes the relationship between the local state and its publics, whether citizens are positioned as recipients or co-producers of knowledge (Bovaird, 2007).

Context conditions the coherence and durability of dissemination strategies over time. All three cities share the same formal commitment through the Circular Cities Declaration, yet this produces markedly different contextual architectures. Research on institutional capacity indicates that formal commitments generate sustained governance outcomes only when translated into binding programmatic instruments and dedicated organizational structures (Termeer et al., 2017). Genoa's Action Plan and Turin's permanent platform represent such translations; Florence's absence of a unified strategic document represents a contextual limitation that may limit the long-term scalability of its dissemination efforts.

This study makes two principal contributions to the emerging literature on knowledge governance for circular economy in urban contexts. Theoretically, it extends the application of the Green et al. (2009) knowledge dissemination framework beyond its original public health domain, demonstrating its analytical productivity as a lens for mapping the strategic logics embedded in institutional CE communication in local public administration. Empirically, it provides comparative evidence on how three Italian regional capitals (Florence, Turin, and Genoa) develop structurally distinct knowledge dissemination strategies despite sharing a common formal commitment to CE transition, yielding three coherent archetypes (diffusive civic, business-oriented ecosystemic, and dual-track knowledge architecture).

Several limitations must be acknowledged. The study relies exclusively on secondary, publicly available institutional sources, which by design reflect governance narratives rather than the actual reception, uptake, or practical effectiveness of disseminated knowledge. The purposive sample of three Italian cities, while analytically justified, limits the transferability of findings to other national governance contexts. These limitations outline a new research agenda. Future studies should integrate primary data collection, including citizen surveys, stakeholder interviews, and digital engagement analytics, to evaluate whether and how disseminated knowledge is received, interpreted, and translated into action. Comparative research extending beyond Italy and encompassing cities from different governance traditions and CE maturity levels, would enrich understanding of the structural and cultural determinants of dissemination strategy choice. Longitudinal designs would permit investigation of how strategies co-evolve with governance capacity and civic engagement over time. Finally, future research could productively examine the relationship between dissemination strategy type and measurable CE outcomes providing an empirical foundation for normative claims about the relative effectiveness of different knowledge governance approaches.

Sustainability and Project Management: Discovering Skills Relations to Support Knowledge-Intensive Organizations

Irene Spada, Antonella Martini, Gualtiero Fantoni
University of Pisa, Pisa, Italy

Abstract

The integration of sustainability in project management is becoming essential to navigate the transformation of industries and societies overcoming the technical-environmental trade-off in Knowledge Intensive Organizations. Although sustainability is a key driver for long-term orientation and competitive advantage, identifying and operationalizing sustainability-related capabilities in project contexts remains complex. One challenge lies in the identification of skills and practices to understand how sustainability related capabilities can be operationalized in project contexts. This contribution propose a data-driven approach for skills paths design to map relations among skills with a focus on project management and sustainability requirements. This study considers field-specific requirements with over 5,000 PM-related job vacancies and Project Management Body of Knowledge (PM-BOK®), and adopts the European Classification of Skills, Competences and Occupation (ESCO). The methodology develops the so-called *Prerequisite Discovery* approach, that integrates text mining, graph theory, and machine learning, leveraging BERT-based word embeddings and link prediction algorithms, to extract and model skill interdependencies. Results identify 165 PM skills, including five green PM skills, namely environmental engineering, lean manufacturing, energy efficiency, ecosystems, and detecting bottlenecks. By mapping more than 14,000 prerequisite relations and 456 cross-domain links the study reveals the current PM-sustainability interplay. Project management competences can act as enablers for green skills, and conversely, how green skills function as foundational prerequisites for sustainability-oriented project practices. While the current PM-sustainability interplay remains predominantly technical, emerging connections with digital, behavioural, decision-making, and creative competences suggest the potential for a more holistic integration. The findings therefore indicate that PM green skills can serve as strategic enablers in knowledge creation, sharing, and integration. A framework is proposed to operationalize sustainability by grafting the knowledge cycle onto the green engine of the identified PM green skills. These information can feed adaptive educational and training paths to transform sustainability from a specialized concept into a cross-cutting strategic capability.

Keywords: skill, job vacancies, textbook, labour market intelligence

Paper type: Academic Research Paper

1 Introduction

Technological advancements in last decades are impacting every aspect of our lives (Wang et al., 2020) and are strongly intertwined with the increasing commitment towards sustainability (Saunila et al., 2019). Industry 4.0 and digitalization relate sustainability in multiple ways: improving performance and resources consumption optimization, but also with waste production and resource demand (Beltrami et al., 2021). In such context, managerial practices are gaining the momentum, as sustainable project management can be paramount to overcome the technical-environmental trade-off (Silvius & Schipper, 2014; Orieno et al., 2024). Companies are asked to reconfigure managerial competences, integrating technological skills and an holistic, systemic, and ethical approach, but guidance on how such competences relate to one another and how they can be effectively developed is still limited (Gomes et al., 2025). Training providers are proposing updated learning activities, although these efforts sometimes lag behind due to the different pace of labour-market evolution and educational programme renewal (Mukul & Buyukozkan, 2023; Tasdemir & Gazo, 2020). Data-driven methods can offer a powerful lever to timely inform educational and training design, enabling effective and efficient responses to technological and societal transformations (Ahmad et al., 2023; Nabizadeh et al., 2020).

The challenge thus is not only to integrate sustainability-oriented competences into project management programmes, but to understand which competences should be incorporated and how they interrelate within learning and career pathways. The reciprocal enabling relations between project management skills and sustainability-related capabilities, particularly in knowledge intensive contexts, has become a central managerial imperative for understanding how sustainability can be operationalized in project contexts. These considerations frame our Research Question as follows: *Which project management competences enable the development of sustainability, and which sustainability-related skills can advance project management capabilities relevant to sustainable project delivery?*

To address this two-side question, the study adopts a data-driven approach to map relations among technical, managerial, and sustainability-related competences in the field of Project Management. The relations

enable the mutual reinforcement of project management and sustainability capabilities. We develop *Prerequisite Discovery*, an approach combining text mining, graph theory, and machine learning to identify and model prerequisite skills relations. The approach adopts labour market data (job vacancies) and domain knowledge (Project Management Body of Knowledge PMBOK® 7th Edition and Green Skills from European Classification of skills and occupations ESCO). *Prerequisites Discovery* is deployed on 3 tasks: (1) *Competence Identification* extracts competences from job vacancies with their frequency (Kobayashi et al., 2018); (2) *Prerequisite Relation Identification* delineates skills prerequisites from domain related books based on rules of mentioning in the books (Xiao et al., 2022; Lu et al., 2019); (3) *Prerequisite Relation Prediction* defines relations among demanded exploiting word embeddings in link prediction algorithm (Devlin et al., 2018; Kumar et al., 2020). This enables the construction of a map that highlights competence relations supporting sustainability-oriented project management.

This study aims to advance design for sustainable project management training opportunities by uncovering the structure of relations among technical, managerial, and sustainability-related skills using a data-driven approach. The paper explores how project management competences can act as enablers for green skills, and conversely, how green skills function as foundational prerequisites for sustainability-oriented project practices. The map of skills describe the development of sustainable project management capabilities, presenting the configuration of technical and managerial competences required for project management roles together with the sustainable related skills. The structured representation of skills relations provides a robust foundational knowledge base that could be leveraged in large-language-model architectures to generate informed inputs for adaptive and sustainability-oriented training programmes. The findings reveals how green skills are embedded within PM competence structures, showing both the prerequisites needed to develop green skills and the PM competences that green skills enable.

2 Background Literature

Sustainability-oriented project management is being addressed in literature in a triple-bottom line perspective: economic, social, and environmental (Martens & Carvalho, 2017). The convergence of green-related skill sets with managerial practices is leveraged for addressing the tension between technical performance and environmental responsibility, with key capabilities including technical expertise, behavioural dispositions, and value-driven orientations (Beducci et al., 2024; Consoli et al., 2016). An holistic, systemic, and ethically grounded approach is gradually permeating project management practices (Silvius & Schipper, 2014; Orieno et al., 2024; Gomes et al., 2025). A growing body of research is re-examining professional roles through a greener lens. Lupi et al. (2022) conceptualise an updated engineer archetype by quantifying technological competences and their contribution to Sustainable Development Goals achievement. The professional profile required for the green transition extends well beyond technical and job-specific expertise, including, business management skills, soft skills, environmental awareness, and willingness-to-engage (Nikolajenko-Skarbalė et al., 2021). Translating these professional requirements into educational pathways requires targeted actions (Suciu & Nsulea, 2019) and curricula update (Spada et al., 2022). Yet these efforts often struggle to keep pace with labour market demands (Mukul & Buyukozkan, 2023). Data-driven approaches can provide timely evidences, enabling agile and effective responses (Ahmad et al., 2023; Nabizadeh et al., 2020).

Relations among skills in education are expressed as prerequisites, i.e., the prior knowledge needed to understand a course, and learning outcomes, which specify what students are expected to achieve and to what level (Resnick et al., 1973; Biggs, 2012). Their links develop learning paths, sequences of learning objects or courses (Nabizadeh et al., 2020). Such paths support study-plan design (Auvinen et al., 2014), career planning (Zhang et al., 2019; Sodanil et al., 2019), and curriculum tailoring for specific job roles (Demchenko et al., 2021). To model these relations, scholars increasingly rely on data-driven and AI-based approaches (Ahmad et al., 2023), such as binary classification (Liang et al.,2018; Xiao et al. 2022), multidimensional scaling (Ang et al., 2014), graphs and network analysis (Wang et al., 2016; Auvinen et al., 2024). Sequential learning materials, as textbooks and MOOCs, are exploited (Lu et al., 2019; Wang et al., 2016). Learning content can be connected as career trajectories, providing insights for career paths and detecting skill gaps for specific jobs (Sodanil et al., 2019; Demchenko et al., 2021).

3 Data and Methods

The method is deployed on 3 tasks (Figure 1). It starts with in-demand skills Identification from job vacancies, then prerequisite relations are mapped by analysing domain related books, and finally these information are used to predicted prerequisite links. The final map focus on the intersection of sustainability and project management.

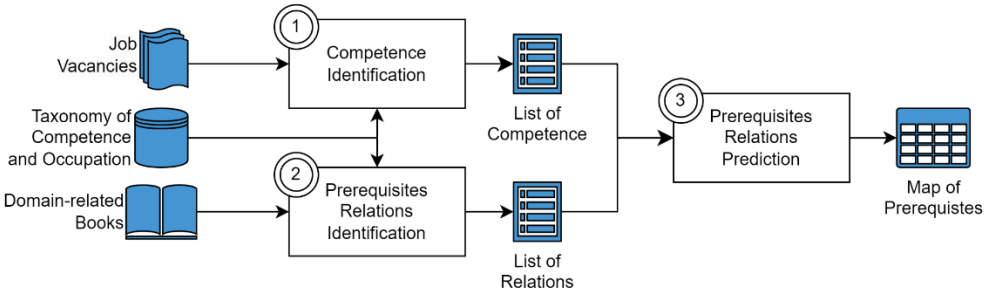

Figure 1 - Flowchart of the proposed method.

The reference framework for labour market terminology is the European Classification of Skills Competences and Occupations (ESCO). It is a multilingual classification of skills, jobs and qualifications, adopted in studies on labour market and education (Chiarello et al., 2021; Spada et al., 2022). It is based on the International Standard Classification of Occupations (ISCO-08) and continuously updated. Each skill provides a description, a tag for the type (e.g., skill/knowledge), and is related to one or more professional profiles. The same applies for job profiles. The English version v1.1 was used, including 13.890 skills and knowledge and 3.008 job profiles. ESCO includes also a green label for 571 items referring "knowledge, abilities, values and attitudes needed to live in, develop and support a society which reduces the impact of human activity on the environment" (Cedefop, 2012).

Job vacancies are the data for labour market demand, as widely used to analyse the competences and professionalism required and examine trends (Kobayashi et al., 2018).

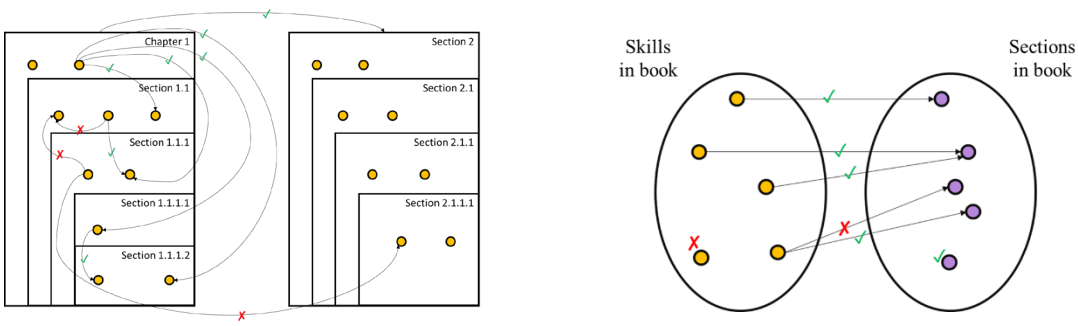
Books are used to describe domain requirements and relations among the learning concepts considering their table of content (Lu et al., 2019; Wang et al., 2016). We used the 7th edition of the PM-BOK® ("*A guide to the project management body of knowledge (PM-BOK® guide) and the standard for project management*" published by Project Management Institute in 2021) as it is widely credited by professional and institutional PM communities (Timinger et al., 2021).

3.1 Competence identification

Competences from ESCO are searched in job vacancies using a string-matching algorithm for exact matches. Then, the occurrence analysis in job vacancies, i.e., counting the number of ads mentioning a given competence, was used to identify the most relevant competences for project management (Kobayashi et al., 2018).

3.2 Prerequisites Relations Identification

The domain-related competencies are searched in books using string-matching algorithms with ESCO, as for the job vacancies. The structure of the book is processed following its table of contents. Each of the identified competences is assigned to only one section considering the order of mention in the book. This hypothesis is based on literature on hierarchical task relations (Nabizadeh et al., 2020; Resnick et al., 1973). From this hypothesis we derive the assumptions about competence-section belonging and ranking, presented in Figure 2. For the *assumption of belonging*, each competence can be mentioned in more than one section, but one and only one section elaborates on it; each section can mention one, several, or no one competences. For the *assumption of ranking*, the relation can exist only inside a single chapter in subsequent sections or in different chapters considered as a whole.



(a) *(b)*

Figure 2 - Association and positioning rules in assumptions of belonging (a) and ranking (b). Green marks (✓) are for the acceptable cases, red marks (✗) otherwise.

3.3 Prerequisites Relations Prediction

We combine the obtained information in the machine learning process in Figure 3. Competencies identified in book are used to train a neural network in predicting prerequisite links. Competences identified in ads but not in book have been processed with the trained model to identify new links. The predictive features include: the ESCO tag for skill and knowledge concepts (ESCO Skill-Type, https://esco.ec.europa.eu/en/escopedia/skills-pillar), the ESCO metric for degree of competence reusability, i.e., transversal, cross sectoral, sector specific, and occupation specific (ESCO Reuse Level, http://esco.ec.europa.eu/en/escopedia/skill-reusability-level), and the vectorized representation of competence labels obtained using BERT model (Devlin et al., 2018). We used the full ESCO classification to map the overall landscape and its relationships, while the ESCO Green Collection was used to examine the results on how sustainability relates with project management.

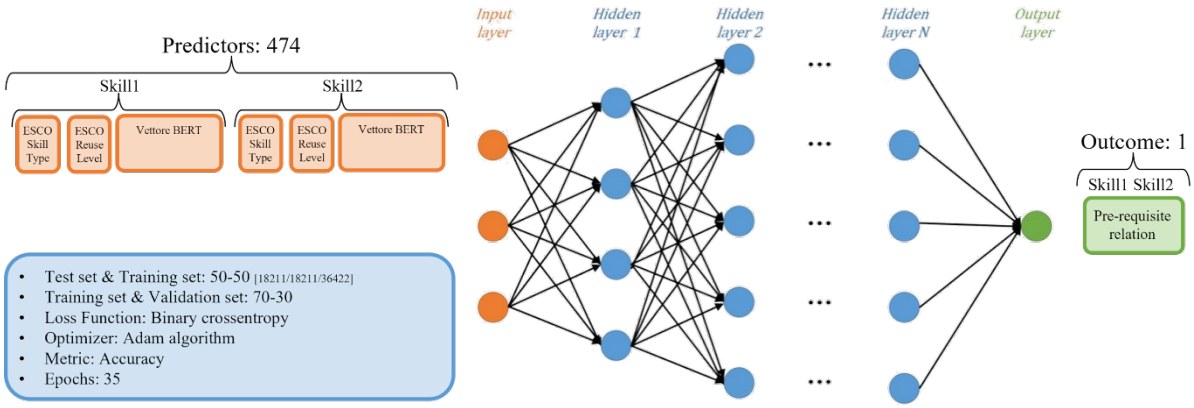


Figure 3 - Machine model used to predict the links among the competences.

4 Results and Discussion

We analysed 5,885 LinkedIn job vacancies, published between August 2021 and February 2022. We identify: 165 relevant PM competences, five of which tagged as *green skill* in ESCO Green Collection; 5,535 prerequisite relationships among 116 competences within PM-BOK®; 8,488 new prerequisite relations with a probability threshold above 70%[1]. These relations were enriched with metadata from ESCO, including skill types, reuse levels, and relevance based on job market demand. The ESCO Green Collection allows us to identify 103 relations where green skills serve as prerequisites of PM skills and 353 relations where PM skills enable green capabilities.

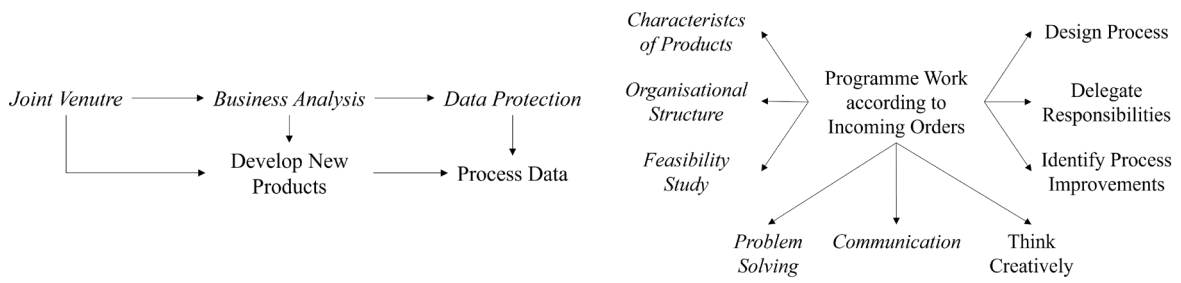
4.1 Overview from job vacancies and PM-BOK®

Figures 4 show the charts of the top 30 most requested competences resulted from job ads. The two rankings provide an overview on the core project management knowledge and skills, fundamental for effective project execution, team coordination, and project planning. Analytical and decision-making abilities characterise this professional field. But also digital and technical expertise emerges, more and more important in the contemporary digital business environment, as well as transversal abilities related to creativity and adaptability. Overall, these lists illustrate the multifaceted nature of project management and collectively shape the complexity of the project management role.

Figure 5 presents two examples of relations from the PM-BOK® field. The skills path in presents how theoretical foundations (e.g., *business analysis*, *data protection*) support new product development and data processing; while the example in Figure 7b shows how practical planning abilities can support effective workflow design, stakeholder alignment, and adaptive problem-solving.

[1] *The machine learning algorithm demonstrated strong performance metrics (Precision 0.931, Recall 0.904, F1 score 0.918, Accuracy 0.916), predicting 22,900 potential skill links, resulting in almost 8,500 relations based on the set threshold. We used: feedforward artificial neural network (ANN) via keras package in R, TensorFlow backend, Adam optimizer and binary cross-entropy loss function. Model performance was evaluated using typical metrics (Puccetti et al., 2023). Training and test sets were in 50% split proportion.*

Figure 4 - Top 20 ESCO knowledge and skills extracted from job vacancies in the PM field.



(a) *(b)*

Figure 5 - Skills path of 'Joint venture' (a) and 'Programming work according to incoming orders' (b) in PM-BOK®. Skills are in plain text, knowledge in italic.

4.2 Map of sustainability-oriented project management

The full *Map of Prerequisites* for the PM field is available in interactive version (*link_will_be_available*). Here the intersection between PM and sustainability are reported.

Among the 165 ESCO competences identified in the PM field, only five are tagged as green. This suggests that the integration between PM and sustainability is still in the rough: there is a gap between the ambitions and the reality of the labour market. Those five competences are strongly connected, as depicted in Figure 6: environmental engineering is the theoretical base enabling two direction, i.e., energy efficiency and lean manufacturing. Thus, sustainability is intended in its engineering lens of process optimization to improve environmental impact and waste reduction. An attention to a more systemic approach can be suggested by ecosystems, however, this is still a too weak signal to be confirmed. So green skills are few, fragmented and technical, and sustainability is seen as an efficiency goal.

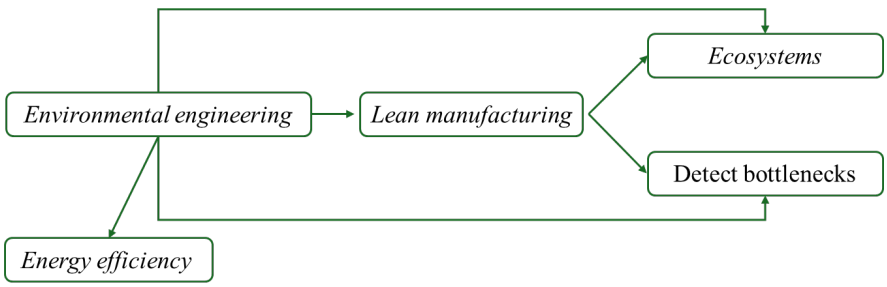


Figure 6 - Skills relations among green PM skills. Skills are in plain text, knowledge in italic.

These green PM skills can be enabled by PM skills or be prerequisites. In the first case, we can measure how expensive is acquiring green skill, so their cognitive dependence. In the second case, we can measure how much green PM skills contribute to PM transformation. Table 1 shows these values. Green PM skills require many prerequisites, possibly because they are considered advanced and specialized. These values confirm sustainability is not yet a transformative driver of PM, because only 2 skills are prerequisites of other PM skills, and one of these (lean manufacturing) is more lean than green. In this overview, environmental engineering appear as the only "cognitive hub", connecting a substantial group of skills.

Table 1 – Number of PM skills required as prerequisites for green skills and enabled by green skills.

	Green PM Skills				
	Environmental engineering	**Lean manufacturing**	**Detect bottlenecks**	**Ecosystems**	**Energy efficiency**
N. of PM prerequisite	45	59	92	92	75
N. of PM skill enabled	77	20	0	0	0

Figures 7 and 8 represent skills as nodes and their relations as flows, coloured to distinguish PM skills and green PM skills. The structure is organised into different vertical stages with prerequisites and enabled skills from left to right. Figure 7 presents the most in demand PM skills, Figure 8 reports PM-related soft skills; both map their links to the five green PM skills

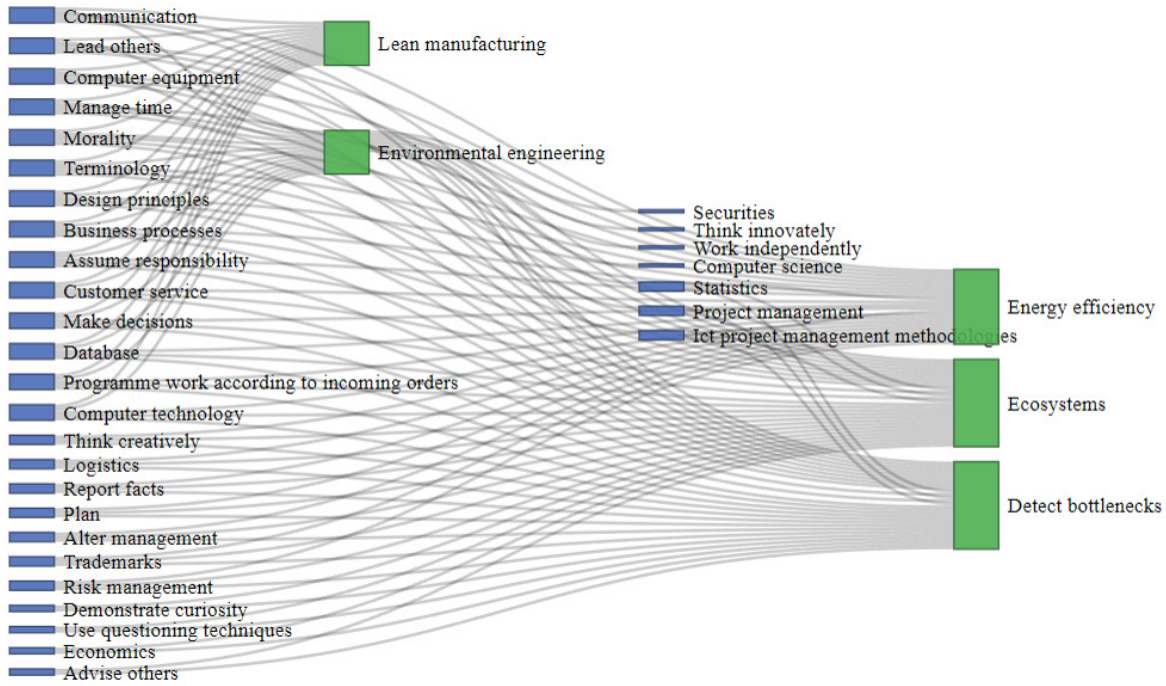

Figure 7 - Diagram of relations among PM skills, in blue, and green PM skills, in green.

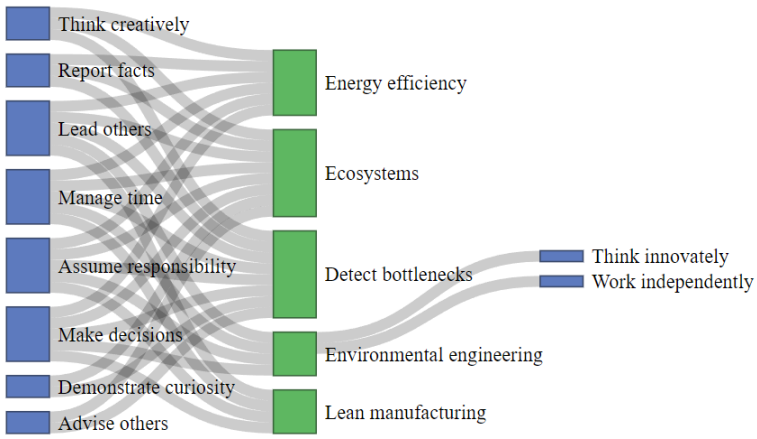

Figure 8 - Diagram of relations among soft skills related to PM, in blue, and green PM skills, in green.

In Figure 7, PM green skills emerge as convergence nodes and are highly dependent on traditional PM skills: the flow from left to centre is denser than the flow from centre to right. A technical, engineering, efficiency-oriented sustainability emerges, given the presence of skills such as *design principles*, *business process*, *programme work according to incoming orders*, *logistics*. There are digital skills (*computer technologies*, *database*, *computer science*), decision-making and behavioural abilities (*lead others*, *assume responsibility*, *advise others*), as well as *think innovatively* and *creatively*; suggesting data-driven reasoning can support green practices, particularly for optimisation and system integration. Sustainability-related approach is highly dependent on technical expertise but also on interpersonal competence and adaptive mindset, combining in a hybrid profile engineering, digital literacy, decision-making abilities, and creative thinking.

Figure 8 deepen the analysis only on soft skills. In this diagram sustainability is enabled by behavioural and cognitive abilities, emphasizing the role of transversal skills act as enablers for a greener approach, supporting project managers to engage with sustainability challenges and not just comply with standard and optimization.

4.3 Interplay between PM and sustainability skills in KIOs

Knowledge is the primary resource and the main source of competitive advantage for Knowledge Intensive Organizations (KIOs) (Makani and Marche, 2010). KIOs have flexible organizational structure, with unique and not predefined processes, and highly specialize human capital, with high discretionary power; usually coordination and exchanges among experts does not follow pre-established mechanisms (Makani and Marche, 2010). These elements often make traditional PM paradigms ineffective, especially with standardized work plans (Nieto-Rodriguez A., 2021). Sustainability introduces additional peculiarities that can radically transform the way these organizations operate (Bertello et al 2022). The simultaneous integration of multidimensional objectives on long term brings out the need to define programmatic objectives and plans. So PM capabilities became paramount: project managers should facilitate knowledge creation, integration and sharing, ensuring the required flexibility while operationalizing sustainable capabilities in knowledge-driven environments (Lundin et al., 2015).

The present study depicts how sustainability-related skills are remains predominantly technical and efficiency-oriented within the broader architecture of PM skills. The support of transversal and digital competences appear still not embedded as a strategic capability. For KIOs, where sustainable project delivery requires not only technical proficiency but also systems thinking, these results further emphasize the need of reconfiguring PM skills for integrating sustainability not as a specialized add-on but as a cross-cutting capability. Such integration can shape knowledge practices to strengthen the whole project lifecycle for sustainable knowledge transformation cycle.

Knowledge creation promoting sustainable oriented experimentation and practices (e.g., Medina and Medina, 2015; Sjödin, 2019). *Environmental engineering* and *energy efficiency* enable continuous exploration of technical and regulatory solutions, feeding experimental learning cycles. *Lean manufacturing* and *detect bottlenecks* promote rapid experimentation, iterative problem-solving, and continuous improvement, all of which are central to knowledge creation processes. Those abilities also push cross-functional teams to identify inefficiencies and co-design innovative solutions, and integrate operational, analytical, and digital approaches, facilitating alignment between efficiency, quality, and sustainability goals.

Knowledge sharing leveraging cross-functional collaboration and communities of practice (e.g., Yeh, 2008; Barbosa and Carvalho, 2025). *Lean manufacturing* favors the dissemination of good practices and lessons learned across projects, functions and departments. *Ecosystems* introduces a systems perspective that encourages interdependencies.

Knowledge integration adopting frameworks that connect processes and competences (e.g., Atkočiūnienė et al., 2022; Oyeyipo et al., 2026). *Environmental engineering* and *ecosystems* involve technical experts, environmental stakeholders and project managers, creating spaces for structured exchange, and help to connect PM skills with sustainability and impact assessment logics.

From these considerations, we derive the visual framework in Figure 9, where green PM skills are positioned as enablers of organizational change, supporting knowledge creation, sharing, and integration in KIOs. When green PM skills are considered as strategic enablers, rather than mere add-ons, they provide the necessary structure through which sustainability-related capabilities can be operationalized within project contexts as a green engine. This process of operationalization ensures that the knowledge cycle in KIOs can be effectively grafted onto the organization's practices. The green PM skills can thus be drivers for continuous experimentation (creation), cross-functional dissemination of best practices (sharing), and alignment of diverse technical expertise (integration), leveraging sustainability as a cross-cutting capability in project lifecycle.

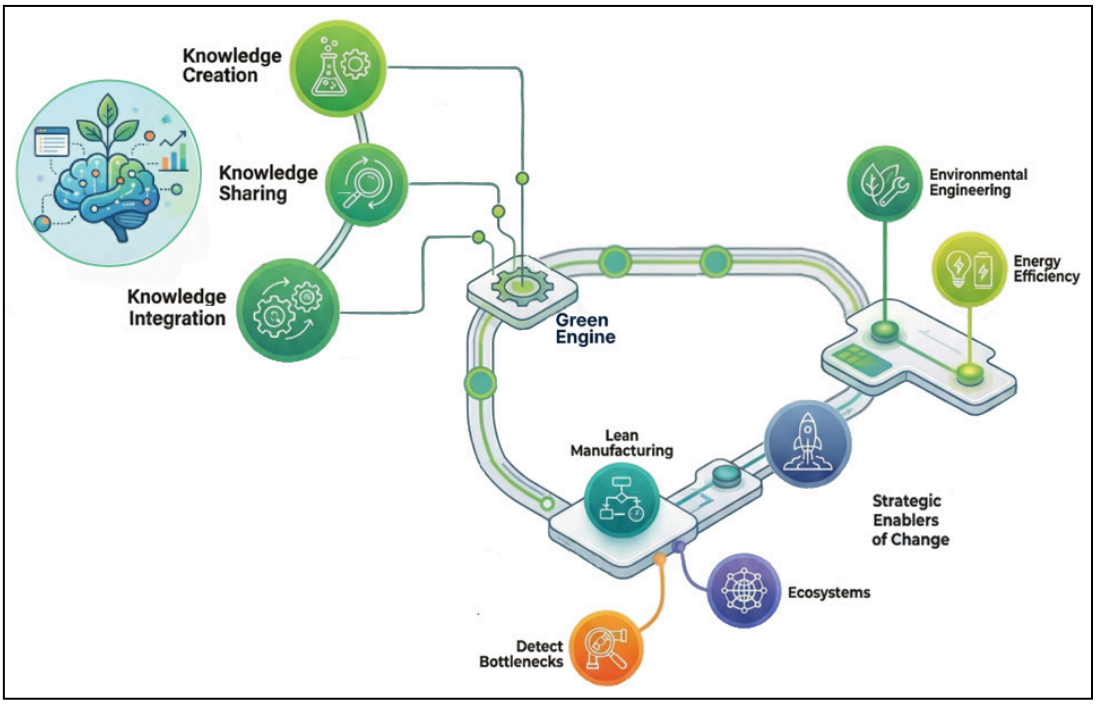

Figure 9 - Framework of PM green skills as enablers for sustainable knowledge transformation cycle.

6 Conclusions

The study extracts in-demand skills from over 5,000 PM-related job vacancies, maps prerequisite relations from PM-BOK®, and predicts additional links, identifying 165 PM skills including five green skills, over 14,000 prerequisite relations, and 456 cross-domain links showing how PM and sustainability relate. Results emphasize a technical and lean-centric approach in PM-sustainability interplay. The relations with digital skills, decision-making and behavioural abilities, as well as creativity and soft skills suggest that a more holistic approach can be reached.

The proposed approach includes market-driven data, prioritizing the logical sequence of skills development rather and job profile/roles needs. This ensures that learners and professionals can develop expertise through a structured progression. These results offer actionable guidance for designing training programmes that support the evolution of skills for sustainable project management in knowledge-intensive organizations, fostering knowledge integration, cross-functional collaboration, and sustainability-oriented decision-making. We leverage on the established techniques in the field of educational design (graph-based machine learning) for identifying skills relations. This enable potential for application across various educational contexts, including universities, schools, and training providers for upskilling and reskilling initiatives, support programmes update and lifelong

learning. Educational institutions and training providers can improve their responsiveness to labour market trends, enhancing employability and relevance.

We must acknowledge that when skills are anchored within a specific domain (like PM in the analysed case) the skills requirements may be constrained by the field knowledge and practices. Indeed, the amount of green skills detected is strongly dependent on the set of data adopted (job vacancies and PM-BOK®). This raises awareness on the importance of keeping as much as open the design process, allowing the integration of skills set from various disciplines.

The work can be improved, paving the way for future studies. Concerning the data, here just one textbook is used, but the several domain-specific books can feed the process, contributing to a more fine-grained result and probably positively affecting the performance. It is possible to use different techniques for identifying skills. Such may include other Named Entity Recognition approaches and also the novel Generative AI techniques. Then, further tests can be executed on which parameters of the prediction algorithm contribute at most for higher performance of the model. Future studies can explore how PM green skills can be integrated in organizational culture and knowledge-sharing practices. Sustainability norms and PM practices can vary across industries and countries, so comparative researches can identify sector-specific patterns, maturity levels and gaps, cultural and institutional factors influencing skills integration, offering more targeted insights for training and policy. Empirical studies could assess further effects of integrating sustainability and PM on company performance, stakeholder engagement, innovation, strengthening sustainability strategies.

7 Acknowledgements

Authors would like to thank Beam Me Up (a spin-off of the University of Pisa), for the possibility to test and implement the proposed method in real use cases.

8 Ethics Declaration

The study did not involve people or animals, thus ethical clearance was not required.

9 AI Declaration

The authors declare that NotebookLM was used for generating icons and visual elements included in the framework visualization (Figure 9). All components were subsequently assembled, reviewed, and refined by the authors. The authors take full responsibility for the accuracy and originality of the work.

Mentoring as a Sociodigital Ecosystem: Knowledge Sharing, Digital Communities and Student Support in an Engineering Department

Demetrio Alessandro Trunfio[1], Ferdinando Potenza[1], Anna Mezzapesa[1], Carl Harvey Miguel[2], Giovanna Rotella[1]
[1] LUM University, Casamassima, Italy
[2] University of Bari, Bari, Italy

Abstract

Universities increasingly face the challenge of supporting diverse engineering students through critical transitions, while leveraging mentoring and digital infrastructures as strategic levers for knowledge management and student success. Building on mentoring and communities-of-practice literatures, this paper conceptualises mentoring in an engineering department as a sociodigital ecosystem that integrates formal, informal and peer-based practices with digital communities and AI-enabled tools. Empirically, the study focuses on the *"continuous mentoring"* initiative developed at the Engineering Department of a medium-sized private university in Southern Italy, where a department-wide digital community, cohort and event-based groups, course-specific chats and project teams have progressively evolved into a multi-layered knowledge infrastructure.

The research adopts a qualitative single-case design, drawing on internal project reports, departmental documents, social media analytics, extended abstracts and digital traces from student communities. These materials were coded inductively and organised into an ecosystem representation capturing layers, roles and knowledge flows, then interpreted through the lens of mentoring ecosystems and socio-digital knowledge infrastructures. The findings show how a persistent core community, surrounded by cohort-specific and project-based groups, supports first-year students by lowering the threshold for asking questions, sharing tacit tips and accessing timely guidance from faculty mentors, peer tutors and community administrators. The same ecosystem also amplifies participation in extracurricular and research-oriented initiatives, such as the *European Researchers Night* and the *Ingenium* entrepreneurship team, enabling students to mobilise situated know-how on how to prepare, present and learn from comparison with peers from other institutions.

Theoretically, the paper extends mentoring research by framing mentoring not as a single programme, but as an ecosystem of interconnected practices embedded in socio-digital infrastructures, where human relations, community practices and AI-enabled assistants jointly sustain knowledge creation and sharing. Practically, it identifies three design principles for universities seeking to build mentoring-based knowledge infrastructures: anchoring mentoring in a persistent core community; cultivating flexible satellite communities around cohorts, courses and projects; and augmenting, rather than replacing, human mentoring with AI tools for routine queries. The contribution speaks to scholars and practitioners interested in mentoring, knowledge management and the design of learning ecosystems in engineering and beyond.

Keywords: Knowledge management, mentoring, sociodigital skills, Communities of Practice, third mission

Paper type: Practical Paper

1 Introduction

Research on mentoring highlights multiple models – informal, peer, reverse and formal – as complementary mechanisms for supporting knowledge transfer, development and retention in organisations (Karkoulian et al., 2008; Short, 2014; Yusof et al., 2012). However, most empirical studies focus on workplace settings and pay less attention to how mentoring can be orchestrated as a continuous ecosystem for engineering students, where the risk of early drop-out and disengagement remains significant (Bryant, 2006; Fowler et al., 2019). This paper addresses this gap by analysing a "*continuous mentoring*" initiative at LUM's Engineering Department, examining how structured and peer-based mentoring practices, supported by digital and AI-enabled tools, contribute to knowledge sharing, student success and community building.

In this context, the Engineering Department at LUM University has developed a mentoring continuum that combines institutional mentoring, peer mentoring and informal community practices to support students from their first contact with the programme to the more advanced stages of their academic journey. The initiative specifically targets critical transition phases – such as the first year, changes of study path and entry into representative or project roles – by offering structured guidance, proximity support from senior students and digitally mediated access to knowledge resources. This mentoring ecosystem is embedded in a broader strategy of student engagement and retention, positioning mentoring not as a one-off intervention, but as a permanent knowledge infrastructure that connects people, practices and digital tools across cohorts.

The contribution of this paper is twofold: first, it conceptualises the LUM Engineering initiative as a "mentoring ecosystem" that integrates formal, informal and peer-based mentoring with socio-digital infrastructures for knowledge sharing; second, it offers an empirically grounded account of how such an ecosystem can be designed and managed to reduce fragmentation, support transitions and enhance student success. Accordingly, the study is guided by the following research questions: (1) how do different forms of mentoring formal, informal, peer contribute to knowledge creation and sharing in an engineering education context? (2) in what ways do digital and AI-enabled tools augment or transform mentoring practices within this ecosystem? and (3) what design principles emerge for universities seeking to build mentoring-based knowledge infrastructures that are scalable and sustainable over time?

2 Theoretical Background

Mentoring has long been recognised as a relational mechanism that supports both individual development and organisational knowledge processes, especially where tacit, experience-based knowledge plays a central role (Karkoulian et al., 2008; Yusof et al., 2012). Prior studies distinguish between formal mentoring, structured and institutionally designed, and informal mentoring, which emerges spontaneously from everyday work relationships; evidence suggests that informal mentoring may have particularly strong effects on knowledge sharing in contexts where trust and social proximity are critical (Karkoulian et al., 2008; Bjørnson and Dingsøyr, 2005). More recent work extends this view by emphasising peer mentoring among colleagues at similar hierarchical levels, showing that such arrangements can significantly predict organisational knowledge creation and sharing in knowledge- intensive settings such as software firms (Bryant, 2006).

Beyond informal and peer arrangements, the literature also highlights the role of structured mentoring programmes and reverse mentoring in shaping knowledge flows and innovation. Formal mentoring programmes, typically coordinated by HR and targeted at specific groups such as newcomers or high-potentials, have been associated with improved workplace networks, organisational outcomes and talent development, although their effectiveness depends heavily on the quality of the mentor–mentee relationship and programme governance (Srivastava, 2015; Fowler et al., 2019). At the same time, reverse mentoring initiatives, in which younger or more digitally skilled employees mentor senior colleagues, show how intergenerational exchange can accelerate the diffusion of digital capabilities, challenge traditional hierarchies and foster bidirectional learning in public and corporate settings (Short, 2014; Fowler et al., 2019). These contributions suggest that mentoring should be understood less as a single practice and more as a portfolio of interconnected mechanisms that, if designed as an ecosystem, can support knowledge sharing, innovation and inclusion across roles, cohorts and generations.

In parallel with mentoring research, work on communities of practice has shown how sustained, informal interaction around shared problems can generate powerful knowledge networks that complement formal structures (Wenger, 1998). In the LUM Engineering case, for instance, the growth of a large WhatsApp community around courses, exams and student initiatives has effectively turned everyday exchanges into a living CoP, where questions, solutions and tacit tips circulate continuously across cohorts. Digital group spaces, when combined with mentoring roles and light governance, can thus act as socio-technical infrastructures that make mentoring more scalable and visible, while preserving the relational richness of peer support.

Building on the mentoring and community-of-practice literatures, this paper adopts the notion of a "mentoring ecosystem" to capture the interdependence between multiple mentoring forms, community practices and socio-digital tools. Rather than treating mentoring programmes, peer support and digital communities as separate interventions, the ecosystem lens emphasises how they jointly constitute a knowledge infrastructure that spans roles (students, staff, administrators), temporal horizons (onboarding, progression, transition to work) and technological layers (messaging platforms, institutional systems, AI-enabled assistants). This perspective reson- ates with broader work on entrepreneurial and innovation ecosystems, but relocates the focus from firm–region dynamics to the micro-level of a university engineering department, where mentoring is mobilised as a strategic lever for talent development, retention and spin-off creation (Autio et al., 2018; Etzkowitz and Leydesdorff, 2000; Trunfio, 2024).

3 Case Context: The Engineering Department and its Mentoring Initiative

The empirical setting of this study is the Engineering Department of LUM University, an Italian private institution that has invested in positioning engineering education as a laboratory for innovation and student-centric learning. The department offers a management engineering programme with relatively small cohorts, which creates both opportunities for close interaction and challenges related to visibility, attraction and the risk of early drop-out in the first academic year. Over the last three years, the department has progressively developed a "*continuous mentoring*" initiative that integrates formal mentoring structures, peer-based support and digitally mediated communication channels, with the dual objective of improving onboarding and leveraging student com- munities as strategic assets.

3.1 Data collection

The study adopts a qualitative single-case design, combining multiple sources of evidence to reconstruct the mentoring ecosystem and its evolution over time. Data collection drew on: (1) internal documents and project reports on mentoring and student engagement, including the departmental mentoring project, design thinking outputs and social media analytics; (2) teaching and project materials produced in courses directly linked to the mentoring initiative; and (3) digital traces from the main communication and community channels used by engineering students, such as messaging groups and online platforms. These materials were complemented by informal conversations with key actors (programme coordinators, student mentors, community administrators), documented in analytic memos rather than formal interviews, according to the exploratory focus of the paper.

In addition to these documentary sources, we extracted basic activity metrics from the main digital communities used by engineering students, including the number of members per group, the share of active participants and the monthly volume of messages over a multi-year period. These metrics were not used for statistical modelling, but rather to calibrate the qualitative reconstruction of the mentoring ecosystem's layers and to distinguish between core, cohort-specific and project-based communities in terms of size and intensity of use. Finally, a preliminary semantic scan of message content was conducted using an external keyword analysis tool, with the aim of identifying recurrent terms and themes at community level. This semantic layer is not the focus of the present paper, but serves as a first step towards more systematic analyses of how concerns, emotions and topics evolve across the mentoring ecosystem over time. Figure 1 summarises the analytical flow adopted in this study. The paper combines documentary evidence, descriptive community metrics and a preliminary semantic scan of message content to reconstruct the mentoring ecosystem as a layered socio-digital infrastructure. This is not a full computational analysis, but a lightweight interpretive pipeline designed to contextualise the case, identify recurrent patterns and support the qualitative discussion of the ecosystem's functioning.

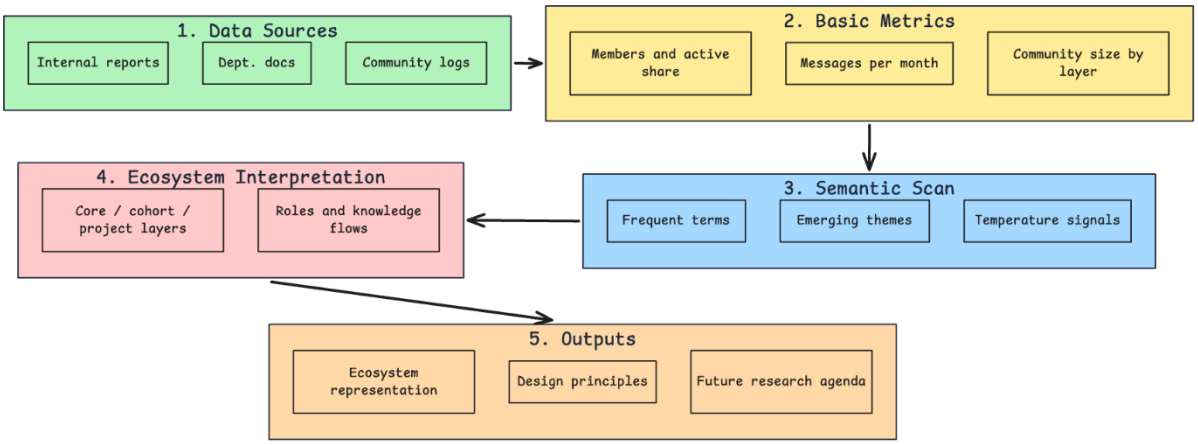

Figure 1: Analytical flow used to reconstruct the mentoring ecosystem through documentary sources, basic community metrics and preliminary semantic scanning.

3.2 Case context: LUM Engineering Department

The case is situated in the Department of Engineering of a medium-sized private university in Southern Italy, which offers undergraduate and graduate programmes in management and computer engineering. In recent years, the department has experienced a steady increase in enrolments and a progressive diversification of the student body, with a growing share of first-generation students and commuters. These dynamics have intensified typical challenges of engineering education, including high perceived difficulty of core courses, risk of early disengagement in the first year and the need to coordinate multiple actors involved in teaching, tutoring and student services.

To address these issues, the department launched a *continuous mentoring* initiative in 2023, designed as a multi-layered support system accompanying students from their first contact with the degree programme to graduation. The initiative combines formal elements – such as designated faculty mentors, structured tutoring activities and recognition of mentoring engagement within the study plan – with informal, student-led practices that emerged organically over time. A distinctive feature of the case is the deliberate use of digital communities and communication channels as the backbone of the mentoring system, turning scattered chats and groups into a more coherent sociodigital ecosystem.

At the core of this ecosystem lies a department-wide community that brings together students from different cohorts, peer tutors and faculty members in a persistent digital space. Around this core, additional communities have developed over time, including cohort-specific groups for first-year students, event-based communities such as those created for the annual European Researchers Night (ERN) initiative, and project teams such as the Ingenium team participating in entrepreneurship competitions. Course-specific chats, often initiated by students, represent a further layer focused on the day-to-day management of individual modules. Taken together, these communities form a dense network of interactions in which informational, emotional and knowledge-sharing exchanges coexist.

This configuration makes the department a particularly suitable case for examining mentoring as a sociodigital ecosystem. The coexistence of a stable core community, recurring event-based groups and temporary course or project teams offers a natural laboratory to compare different patterns of participation, content and value creation. It also allows the study to respond directly to the reviewers' request for a richer description of the context and of the specific characteristics that make the case relevant for the conference themes.

4 Layers and Actors of the Mentoring Ecosystem

The *continuous mentoring* initiative at the Engineering Department can be understood as a multi-layered ecosystem composed of partly overlapping communities, roles, and tools. At the centre lies a core department-wide community, hosted on a persistent messaging channel, where students from different cohorts, peer tutors, and faculty members interact around general announcements, cross-cutting questions, and community life. This core space functions as a shared "backbone" that provides visibility, quick access to help, and an always-on entry point into the mentoring ecosystem.

Surrounding this core, a second layer is formed by cohort-specific and event-based communities, including dedicated groups for first-year students, communities created for initiatives such as the annual ERN, and temporary teams such as the Ingenium group participating in entrepreneurship competitions.

Table 2: Overview of the mentoring ecosystem communities (March 2026)

Layer / function	Example communities	Typical size	Main role in the ecosystem
Core backbone	Main departmental noticeboard	177 members	Cross-cohort coordination, announcements, low-threshold entry point
Cohort groups	1st year bachelor engineering(L9); 2nd and 3rd year bachelor cohorts; 1st and 2nd year master's in management engineering	20 – 45 members	Navigation of the programme,first-year support, peer Q&A
Course communities	Quality management; Digital law & cybersecurity; Advanced robotics; Innovation & IP; Business eth- ics; Digital marketing; Risk management; Digital twin; Cloud data management	9 –18 members	Day-to-day management of modules, sharing of notes, tips and explanations among peers
Project and event groups	*ERN* 2025; Ingenium operations and events; Internship circle; Graduation sessions	4 –27 members	Preparation for events, project coordination, external visibility
Operational /technical	Erasmus engineering; iMensa technical core	3 –8 members	Logistical and technical support for mobility and lab-related activities

These communities focus on transition moments and collective projects, where mentoring takes the form of guidance on how to navigate the programme, coordinate activities, and translate opportunities into concrete experiences. A third layer is made up of course-specific chats and project groups, often initiated and moderated by stu- dents, which support the day-to-day management of individual modules, assignments and exams. Here, peer mentoring is particularly visible, as students share explanations, resources and tacit tips about how to approach specific topics, teachers or assessment formats. Across these layers, different actors play complementary roles – faculty mentors, peer tutors, community administrators and, increasingly, AI-enabled assistants that answer frequently asked questions – collectively sustaining the flow of informational, emotional and knowledge-rich exchanges within the ecosystem.

4.1 Knowledge flows in first-year support and extracurricular participation

Within the ecosystem, first-year students represent a critical target group, as they face the transition from secondary school to university, often with limited prior exposure to engineering programmes and with commuting or first-generation backgrounds. Knowledge flows towards this group through multiple, partially overlapping channels: core community announcements and FAQs, cohort-specific groups that address practical and emotional concerns, and course-specific chats where senior students and peer tutors share explanations, study strategies and tacit tips about how to approach demanding modules and assessment formats. Faculty mentors intervene mainly at key checkpoints (orientation events, feedback meetings, formal tutoring), while peer mentors and community administrators ensure day-to-day responsiveness, lowering the threshold for asking questions and normalising the sharing of difficulties and solutions.

A second set of knowledge flows concerns participation in extracurricular and research-oriented initiatives, where the mentoring ecosystem acts as an amplifier of opportunities and capabilities. For events such as the annual ERN in Bari, the core and cohort communities are used to identify interested students, form teams and circulate information on deadlines, logistics and expected contributions, while experienced participants mentor newcomers on how to design engaging demos, communicate research topics and position LUM Engineering alongside other universities. Similarly, the Team Ingenium initiative – an informal research and entrepreneurship-oriented group that, for the first time, was invited to present with a dedicated stand – illustrates how mentoring relations, community channels and faculty support can converge to transform a loosely connected group of students into a visible actor in regional innovation events, with spillover effects on skills, confidence and external recognition. In both cases, the ecosystem enables students to access not only information about opportunities, but also situated know-how on "how to be there": how to prepare, how to present themselves and how to learn from comparison with peers from other institutions.

The Ingenium initiative further illustrates how the mentoring ecosystem can translate into recognisable external outcomes. One of them, in December 2025, during the "Women in Big Data" hackathon hosted by the Innovation Department of the University of Salento, the team – combining female and male students from LUM

Engineering with a computer science student from another local university – received a Collaboration Award for its cross-institutional and gender-diverse composition and way of working.

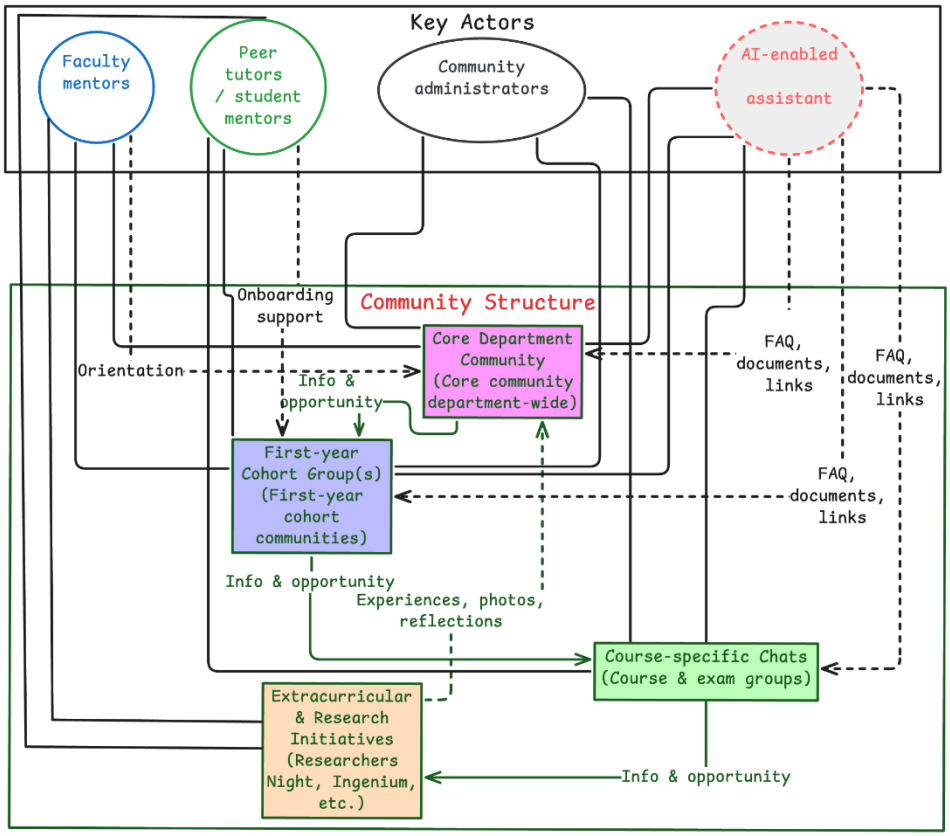

Figure 2: Knowledge flows in the "continuous mentoring" ecosystem (first-year support and extracurricular participation)

4.2 Key outcomes of the continuous mentoring ecosystem at LUM Engineering Department

The basic analytics of the digital communities provide additional insight into how the mentoring ecosystem operates in practice. Across several cohorts, first-year groups maintain participation rates that often exceed 70 – 80 % of enrolled students over multiple semesters, with cumulative message volumes in the thousands. This sustained activity suggests that the communities are not merely activated around onboarding events, but continue to function as day-to-day infrastructures for sharing information, study strategies and tacit tips about demanding courses and assessment formats. Figure 3 shows the growth of the core departmental noticeboard community over time, with the number of members increasing and then stabilising as new cohorts are added, confirming its role as a persistent backbone that consolidates communication across generations of students.

The temporal distribution of messages further reveals clear peaks in activity around key transition points, such as the start of the academic year, exam sessions and major initiatives like the annual ERN or entrepreneurship-oriented events.Project-based communities, such as those created for the Ingenium team and time-management workshops, show smaller membership but very high levels of active participation, reflecting their function as intensive learn- ing spaces where mentoring takes the form of close guidance and collaborative problem-solving. Figure 4 illustrates the evolution of total and active members in a first-year cohort community. Over multiple semesters, active participants consistently represent a large share of enrolled students, suggesting that the group functions as a sustained "safety net" rather than a short-lived onboarding channel.

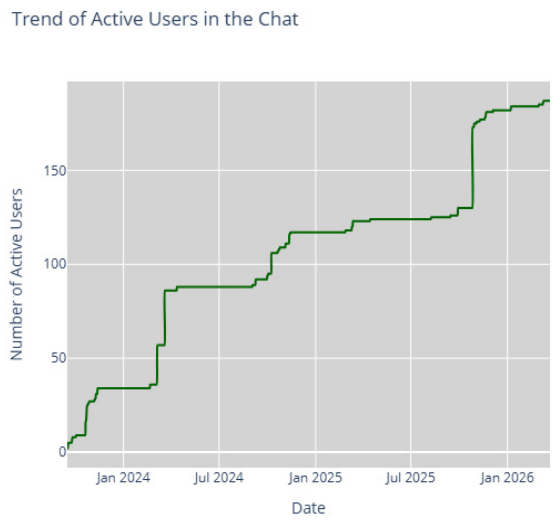

Figure 3: Growth of the core departmental noticeboard community (total members over time).

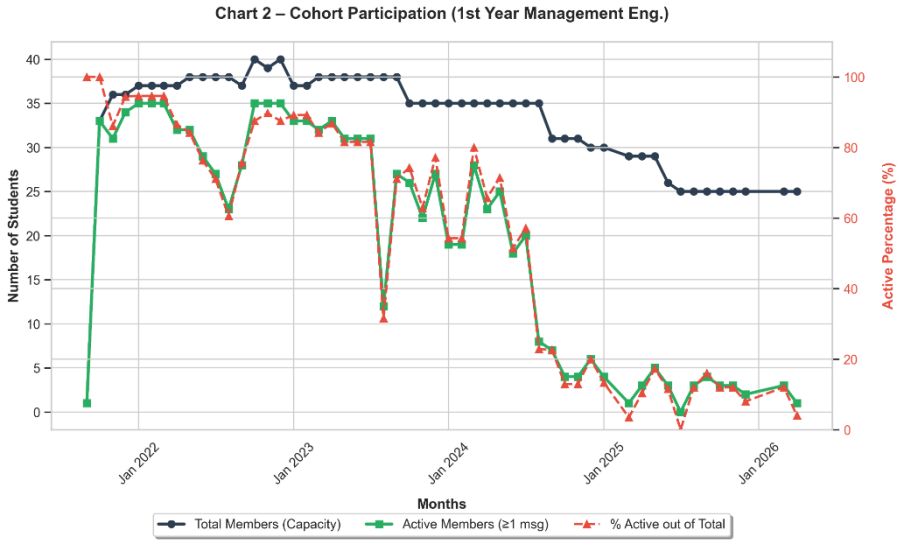

Figure 4: Total and active members in a first-year cohort community (students over time).

Figure 5 reports the monthly message volume in a project-oriented community. Activity peaks clearly align with key initiatives such as time-management workshops and entrepreneurship events, indicating that these smaller groups operate as intensive learning spaces where mentoring is tightly coupled with preparation, co-ordination and reflection around specific projects.

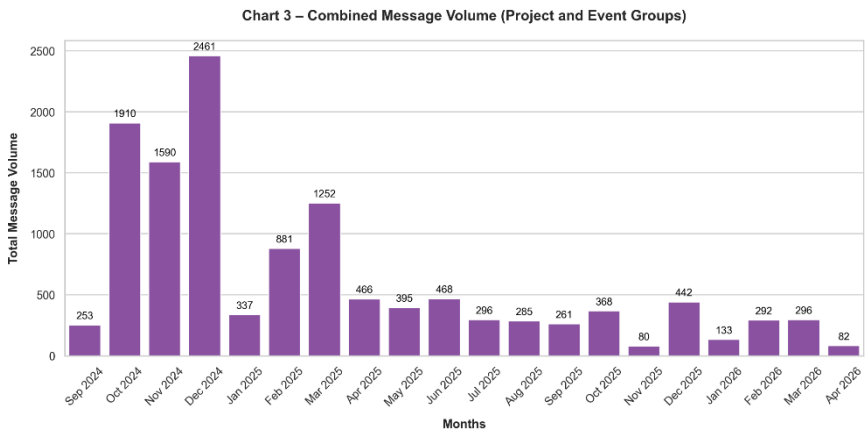

Figure 5: Monthly message volume in a project-oriented community within the mentoring ecosystem.

A preliminary semantic scan of messages across three representative communities – the core departmental noticeboard, a first-year cohort group and a project-oriented community – reinforces this interpretation. In the core community, the most frequent terms relate to schedules, deadlines, exams and institutional events, reflecting its role as a backbone for coordination and collective awareness. In the first-year cohort group, exam-related vocabulary and help-seeking expressions dominate, with recurrent references to “doubts”, “exams”, “notes” and “study groups”, indicating that students use this space as a low-threshold “safety net” to navigate early academic challenges and reduce the stigma of asking for support. In the project-oriented community, by contrast, the salience of terms such as “event”, “team”, “pitch” and “hackathon” points to a different function: these spaces concentrate the language of preparation, performance and external visibility, illustrating how the mentoring ecosystem also serves as a launchpad for participation in research and entrepreneurship initiatives beyond the classroom. Rather than offering a full semantic analysis, these patterns provide a first empirical glimpse into how different layers of the ecosystem host distinct but complementary knowledge and support flows.

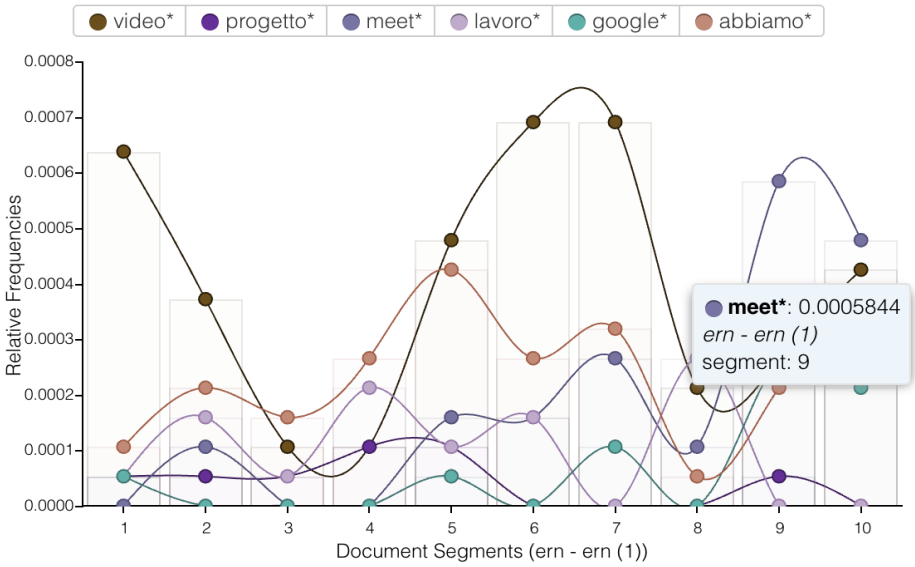

*Figure 6: Most frequent terms in mentoring-related community messages, highlighting dominant themes across coordination, help-seeking and project participation *(video,project,meet,job,google,we have)*

The two semantic views obtained with Voyant (FIgure 6 Cirrus and Figure 7 keyword trends) should be read as an exploratory “temperature check” of the mentoring ecosystem rather than as a full NLP analysis. The different community layers host distinct constellations of concerns and opportunities, opening a path for future work on systematic semantic monitoring of socio-digital mentoring ecosystems.

Figure 7: Word-cloud of the most frequent terms in mentoring-related community messages.

5 Theoretical Implications

The case extends mentoring research in at least three ways. First, it shows how formal, informal, peer and reverse-like mentoring practices can be configured not as separate interventions, but as layers of a coherent eco-system anchored in socio-digital infrastructures. While prior studies typically examine individual programmes or dyadic relationships in isolation, the LUM Engineering case illustrates how mentoring roles, community practices and digital tools can be orchestrated into a *continuous knowledge infrastructure* that spans cohorts, and transition points. This ecosystem perspective contributes to ongoing debates on how mentoring supports knowledge creation and sharing by highlighting the importance of persistent backbone communities and flexible satellite groups as complementary loci of learning.

Second, by combining communities-of-practice thinking with a multi-layered ecosystem lens, the study re-frames mentoring communities not only as informal networks emerging around shared concerns, but as deliberately cultivated socio-technical spaces where knowledge flows are shaped through light governance, role design and basic analytics. The growth and sustained activity of the core and cohort communities, together with the intensive exchanges in project-based groups, provide empirical grounding for the idea that digital communities can function as meso-level knowledge infrastructures that connect individual mentoring relationships with institutional strategies for student engagement and retention. This contributes to broader work on digital and entrepreneurial ecosystems by relocating the focus from firm–region dynamics to the micro-level of a university department.

Third, the preliminary use of activity metrics and semantic scans points to a promising avenue for integrating mentoring ecosystems with data-informed knowledge management. Rather than introducing sophisticated predictive models, the study suggests that simple indicators – such as participation rates, message volumes and dominant terms – can be mobilised as "temperature checks" of the mentoring ecosystem, helping educators monitor where support is flowing, where it may be lacking and how topics and concerns evolve over time. This opens up a research agenda on how AI-enabled tools and lightweight analytics can augment, rather than replace, human mentoring by providing new lenses for understanding and steering socio-digital knowledge infrastructures in engineering education and beyond.

6 Conclusions

This paper has argued that mentoring in an engineering education context can be fruitfully understood and designed as a sociodigital ecosystem that supports knowledge sharing, student success and participation in extracurricular initiatives. By documenting the *continuous mentoring* initiative at LUM's Engineering Department, the study has shown how a persistent core community, cohort-specific groups and project-oriented communities, supported by basic analytics and preliminary semantic scans, can be orchestrated into a coherent knowledge infrastructure. The case illustrates how this infrastructure lowers the threshold for asking questions, sustains everyday peer support and amplifies participation in opportunities such as research events and entrepreneurship competitions.

From a practical perspective, the paper has distilled three design principles for universities seeking to build mentoring-based knowledge infrastructures: anchor mentoring in a persistent core community that offers visibility and low-threshold access to help; cultivate flexible satellite communities around cohorts, courses and projects, where peer mentoring and experimentation can flourish; and augment, rather than replace, human mentoring with AI-enabled assistants and lightweight analytics for routine queries and ecosystem "health checks". Together, these principles highlight the importance of orchestrating people, practices and technologies as an integrated ecosystem rather than optimising isolated programmes.

Future research could extend this work in at least three directions. Longitudinal studies tracking student outcomes, such as retention, performance and early careers, would allow the effects of the mentoring ecosystem to be assessed more rigorously over time. Comparative analyses across institutions of different sizes, disciplines and national contexts could clarify which design principles are context-specific and which can be generalised beyond the LUM case. As AI-enabled tools and semantic analysis become more embedded in mentoring practices, further work should examine how chatbots, retrieval-augmented assistants and topic-sensitive dashboards reshape mentoring roles and knowledge codification, and how the exploratory semantic "temperature checks" used here can evolve into a more systematic method for monitoring topics, concerns and support needs across socio-digital communities

7 Ethics Declaration

This study draws on internal documents, project reports and anonymised digital traces from student communities within the Engineering Department. No sensitive personal data were collected, and no individual student is identifiable in the analysis. According to the current guidelines of the authors' institution, formal ethics approval was not required for studies based on organisational documents.

8 AI Declaration

AI tools (large language models) were used only at specific stages of the research process, namely to support the structuring and editing of the manuscript, to refine the wording of some sections (e.g. abstract, introduction and discussion) and to assist with the organisation and formatting of references. No AI tools were used for the conceptualisation of the research questions, research design, data collection, data preparation, data analysis or the generation of empirical findings. The authors reviewed and verified all AI-assisted outputs for accuracy and appropriateness, and cross-checked citations and bibliographic details against the original sources to avoid errors or misattribution.

AI Anxiety and Unemployment Anxiety: Moderating Role of Self-Efficacy in Cross-Cultural Study

Coşkun Akça[1], Albena Antonova[2], Anikó Csepregi[3], Zsuzsa Darida[3]
[1]Kastamonu University, Kastamonu, Turkey
[2]University of Sofia, Sofia, Bulgaria
[3]University of Pannonia, Veszprém, Hungary

Abstract

Artificial intelligence (AI) is rapidly transforming labour market structures, raising concerns not only about employment prospects but also about the broader psychological implications of technological change. Among university students, these concerns often emerge as heightened uncertainty regarding future employability. In this context, AI-related anxiety can be understood as a forward-looking stressor that shapes how individuals interpret knowledge about future work.

This study examines the relationship between AI anxiety and unemployment anxiety, with a particular focus on the moderating role of AI self-efficacy. A quantitative, cross-sectional design was applied using survey data collected from 510 university students in Turkey, Hungary, and Bulgaria. Established measurement scales were used to assess AI anxiety, AI self-efficacy, and unemployment anxiety. Data were analysed using SPSS and Hayes' PROCESS Macro (Model 1), alongside reliability, validity, and correlation analyses.

The results show that AI anxiety is positively associated with unemployment anxiety, suggesting that a large number of students tend to interpret AI-driven changes as potential threats to their future employment opportunities. Additionally, AI self-efficacy demonstrates a significant buffering effect: higher levels of perceived competence in using and understanding AI weaken the relationship between AI anxiety and unemployment anxiety. This points to the role of psychological resources in shaping how AI-related knowledge is cognitively and emotionally processed.

By integrating AI-related perceptions with perspectives on job insecurity, stress, and knowledge interpretation, the study contributes to the understanding of how technological change influences career-related anxiety. The findings suggest that AI anxiety should be conceptualised not merely as a technological attitude but as a mechanism through which individuals engage in sensemaking of AI-mediated knowledge about future employment.

From a practical perspective, the results underline the importance of strengthening AI-related competencies within higher education. Beyond technical skills, targeted interventions that enhance students' sense of control and interpretive capacity may play a key role in mitigating employment-related uncertainty in AI-driven labour markets.

Keywords: AI anxiety, AI self-efficacy, unemployment anxiety, university students

Paper type: Academic Research Paper

1 Introduction

In recent years, artificial intelligence (AI) has emerged not only as a technological innovation but also as a knowledge system that shapes the creation, interpretation, and use of knowledge (Hadjimichael et al., 2023; Mora et al., 2021). AI is recognised as a General-purpose technology with substantial economic and social effects (Crafts, 2021, Jain, 2025). Higher education provides a suitable context to examine this process, as it functions both as a knowledge ecosystem and as a setting for preparing students for the future labour market (Pandya and Wang, 2024). In this context, the growing diffusion of AI not only transforms modes of work but also influences how individuals make sense of and evaluate their future employment opportunities (Jin et al., 2024; Kim and Lee, 2024; Türk et al., 2025).

A stream of the literature examines the effects of AI mainly from automation, efficiency, or labour market displacement perspectives, emphasising the structural changes it triggers and their consequences (Erebak and Turgut, 2021; Chung et al., 2025). However, fewer studies examine how individuals make sense of AI-mediated knowledge, although organizational and cognitive research highlights the central role of sensemaking processes (Sandberg and Tsoukas, 2020; Whittle et al., 2023). A growing body of research shows that AI is not merely a source of information but a mediating system that shapes the structuring and sensemaking of knowledge (Jin et al., 2024; Kim and Lee, 2024; Li et al., 2025; Liu and Ye, 2026). This perspective reflects a shift from technological determinism to an interpretive view that foregrounds individual cognitive processing (Sandberg and Tsoukas, 2020).

Individual cognitive sensemaking processes are shaped by various subjective factors; therefore, uncertainty cannot be seen as determined solely by objective external conditions. Labour market uncertainty instead emerges as the outcome of individuals' sensemaking of knowledge, in which future-related information,

perceptions, and expectations are interconnected in complex ways (Shoss, 2017; Ganson et al., 2021; Chung et al., 2025). Prior psychological research shows that the perception of uncertainty is closely linked to cognitive processing and emotional responses, particularly anxiety, which can distort how information is interpreted and how future outcomes are inferred (Lamba et al., 2020; Sandhu et al., 2023). Several empirical studies confirm the relationship between AI-related anxiety and employment uncertainty (Erebak and Turgut, 2021; Uçar et al., 2025; Yaşar and Karagucuk, 2025), yet they do not examine in sufficient depth the underlying cognitive and psychological mechanisms behind this relationship.

Mechanism-based models that integrate knowledge management and human–AI cognition perspectives and explain how individuals make sense of AI-mediated knowledge, remain limited. Existing research highlights the role of self-efficacy as a cognitive resource and coping mechanism (Bandura, 2012; Peltier et al., 2022; Cabrera-Aguilar et al., 2023) and shows that AI-related competencies and attitudes influence the perception of anxiety (Kim and Lee, 2024; Li et al., 2025; Ren et al., 2025). However, these approaches rarely integrate sensemaking processes of AI-mediated knowledge and the emergence of uncertainty within a coherent theoretical framework.

This study addresses this gap by conceptualising AI as a knowledge-mediating system through which individuals make sense of their future employment opportunities, where cognitive and emotional mechanisms play a key role in the emergence of uncertainty. The study aims to examine how AI-related anxiety contributes to employment uncertainty and how AI-related self-efficacy moderates this relationship. The theoretical contribution lies in identifying the psychological mechanisms linking knowledge interpretation and the perception of uncertainty, and in integrating knowledge management and human–AI interaction perspectives within a coherent, mechanism-based model.

2 Theoretical Background

2.1 AI as a knowledge-based interpretive system

In the literature, artificial intelligence is traditionally viewed as a technology that automates tasks and improves efficiency (e.g., Bhargava et al., 2020; Pandya and Wang, 2024). However, a growing body of research shows that AI plays a more complex role in knowledge creation and interpretation (Hadjimichael et al., 2023; Sandberg and Tsoukas, 2020; Mora et al., 2021; Chester and Allenby, 2023). AI not only provides information but also mediates the creation, filtering, and sensemaking of knowledge, thereby shaping which information becomes accessible and how it is presented to individuals (Jin et al., 2024; Türk et al., 2025; Chester and Allenby, 2023). Consequently, AI can be understood as a knowledge-mediating infrastructure that shapes perception and decision-making (Chester and Allenby, 2023).

From a knowledge management perspective, knowledge is not merely objective information but a context-dependent phenomenon that emerges through sensemaking (Hadjimichael et al., 2023; Sandberg and Tsoukas, 2015). This view is particularly relevant for AI, where meaning-making occurs within sociomaterial interactions between technological systems and users (Mora et al., 2021). In this sense, AI is not simply a tool but functions as an extension of cognitive processes, shaping how individuals make sense of future labour market opportunities and risks (Chiriatti et al., 2025). Accordingly, AI can be understood as a knowledge-based interpretive system through which individuals interpret and structure future-oriented information, thereby shaping their perceptions of employment realities.

2.2 Psychological mechanisms of AI-mediated knowledge interpretation and human–AI cognition

The sensemaking of AI-mediated knowledge is not merely an information-processing activity but the result of complex cognitive and emotional mechanisms that shape how individuals respond to technological change (Sandberg and Tsoukas, 2020; Whittle et al., 2023; Jin et al., 2024; Erebak and Turgut, 2021). Among these mechanisms, self-efficacy, anxiety, and trust play a central role, jointly shaping human–AI cognition. This also highlights that meaning making is not a neutral process but unfolds through cognitive and linguistic mechanisms that shape how individuals make sense of information (Whittle et al., 2023).

Self-efficacy is a key determinant of behaviour, shaping the extent to which individuals feel capable of handling a given situation (Bandura, 2012). In the context of AI, it reflects a sense of competence and control in using the technology, enabling more structured and adaptive interpretation of knowledge (Kim and Lee, 2024; Ren et al., 2025). Prior empirical studies show that higher self-efficacy reduces anxiety and supports coping strategies, thereby stabilising the processing of AI-mediated information (Peltier et al., 2022; Cabrera-Aguilar et al., 2023; Li et al., 2025).

In contrast, anxiety distorts cognitive processes, particularly in uncertain situations. Research shows that anxiety impedes adaptive learning and accurate interpretation of information, leading to increased perceived uncertainty (Lamba et al., 2020; Sandhu et al., 2023). AI-related anxiety is especially important, as the rapid pace and unpredictability of technological change may be perceived as a threat, increasing employment uncertainty (Erebak and Turgut, 2021; Uçar et al., 2025; Yaşar and Karagucuk, 2025).

Trust also plays a key role in the sensemaking of AI-mediated knowledge, as it shapes the extent to which individuals rely on information generated by the technology. Trust is not merely a technical issue but a cognitive and social construct that emerges through interactions among the individual, the system, and the context (Afroogh et al., 2024; Li et al., 2024). An appropriate level of trust facilitates information acceptance and reduces perceived risk, whereas both excessive and insufficient trust may distort knowledge interpretation (Jiang et al., 2025).

These mechanisms jointly shape how individuals process AI-mediated knowledge and interpret its labour market implications. They can be understood as micro-level cognitive and emotional mechanisms that shape perceptions and decisions regarding future employment.

2.3 Career-related uncertainty as a knowledge-based construct

In traditional approaches, uncertainty is often viewed as a state determined by objective external factors; however, a growing body of research emphasises its cognitive and interpretive nature (Sandberg and Tsoukas, 2020; Hadjimichael et al., 2023; Whittle et al., 2023; Ferguson et al., 2024). Labour market uncertainty is not only a consequence of structural changes but also the result of how individuals make sense of information and expectations (Shoss, 2017; Chung et al., 2025).

Psychological research shows that the perception of uncertainty is closely linked to how individuals process available information and the meanings they assign to it (Ganson et al., 2021). In digital environments, this process is particularly complex, as uncertainty evolves dynamically through the integration of multiple information sources and signals (Ferguson et al., 2024; Bhargava et al., 2020). In addition, individual differences in information processing and tolerance for uncertainty may lead to substantial variation in perceptions (Sandhu et al., 2023).

In the context of AI, this means that the same technological environment may be interpreted differently by individuals, leading to varying levels of employment uncertainty (Bhargava et al., 2020; Pandya and Wang, 2024). Uncertainty is therefore not a direct outcome of AI's objective effects but rather the result of how individuals make sense of AI-mediated knowledge and future-oriented information.

2.4 Conceptual model and hypotheses

Based on the above theoretical considerations, this study proposes a mechanism-based model in which AI-related anxiety has a direct effect on employment uncertainty, while self-efficacy moderates this relationship. The model assumes that AI does not directly shape uncertainty but exerts its effects through sensemaking processes of AI-mediated knowledge.

AI-related anxiety may distort information processing and increase negative expectations about the future (Erebak and Turgut, 2021; Uçar et al., 2025), whereas self-efficacy can structure and stabilise these sensemaking processes (Bandura, 2012; Kim and Lee, 2024). Accordingly, self-efficacy influences not the effects of the technology itself but their interpretation, thereby playing a key role in the emergence of uncertainty.

Although the empirical model examines direct relationships, these reflect underlying cognitive and sensemaking processes that shape how AI-mediated knowledge is processed at a theoretical level. Accordingly, the model not only describes relationships between variables but also shows how technological change translates into individual-level uncertainty through sensemaking processes.

Based on these theoretical considerations, the following hypotheses are proposed:

- *H1: AI-related anxiety is positively associated with unemployment anxiety, as it may distort the sensemaking of AI-mediated information and reinforce uncertainty about the future.*
- *H2: AI-related self-efficacy weakens the relationship between AI-related anxiety and unemployment anxiety, as it enables more structured and controlled sensemaking of AI-mediated knowledge.*

The proposed model provides a framework for interpreting these relationships and examines how psychological responses to technological change translate into uncertainty about future employment (Figure 1). The model assumes that uncertainty does not arise directly from the effects of technology but from how individuals engage in sensemaking of AI-mediated knowledge, a process shaped by individual cognitive and psychological resources.

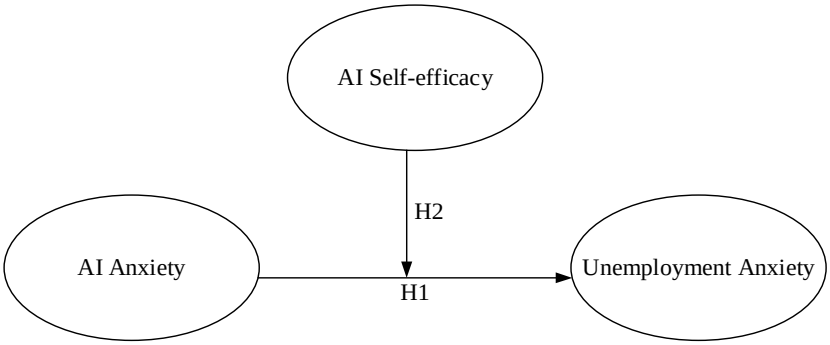

Figure 1: Interpretation-based research model

The model empirically represents direct relationships; however, at the theoretical level, these effects can be understood through cognitive and emotional mechanisms operating within the sensemaking of AI-mediated knowledge.

3 Methodology

This study used a cross-sectional survey design to examine the relationship between AI anxiety and unemployment anxiety among university students, with AI self-efficacy specified as a moderator. The data were collected in three countries (Turkey, Hungary, and Bulgaria), allowing the proposed relationships to be examined in a comparative higher education context rather than within a single national setting.

3.1 Research Sample

The sample consisted of 510 university students, with 170 respondents from each country. Data were collected through an anonymous online survey, and to ensure comparability across the three national subsamples, a balanced sampling approach was applied: from the initial 550 responses (Türkiye 180, Hungary 200, Bulgaria 170), 170 cases were retained from each country for the final analysis to ensure comparability across countries and to avoid potential bias resulting from unequal group sizes.

Participation was voluntary, and respondents were informed about the aim of the study before completing the questionnaire. Demographic characteristics are presented in Table 1. The final sample was predominantly female (n = 309), and the largest age group was 21–23 years (n = 265), which is consistent with the expected profile of the target population.

This design allows for a controlled comparison of AI-related perceptions across different higher education contexts.

Table 1**:** Demographic characteristics

Age			**Country**			**Total**
			Turkey	**Hungary**	**Bulgaria**	
18-20	Gender	Male	49	10	18	77
		Female	65	20	24	109
	Total		114	30	42	186
21-23	Gender	Male	22	36	37	95
		Female	24	84	62	170
	Total		46	120	99	265
24-26	Gender	Male	2	8	5	15
		Female	4	6	10	20
	Total		6	14	15	35
27+	Gender	Male	2	3	9	14
		Female	2	3	5	10
	Total		4	6	14	24
Total	Gender	Male	75	57	69	201
		Female	95	113	101	309
	Total		170	170	170	510

3.2 Measures

All items were assessed on a five-point Likert-type scale, and the questionnaire also included basic demographic variables such as gender, age, and country of residence. Unemployment anxiety was measured with the scale developed by Şanli et al. (2023), AI self-efficacy with the instrument proposed by Türk et al. (2025), and AI anxiety with the short-form measure developed by Batuk et al. (2025). In the case of the latter, only the AI anxiety dimension was used, as it was directly aligned with the focus of the present study.

Detailed psychometric properties of the original scales are not reproduced here; instead, the focus is on their performance in the current dataset.

All scales demonstrated satisfactory reliability in the current sample.

3.3 Analytical approach

All analyses were conducted using SPSS. The analysis proceeded in three steps. First, the measurement properties of the scales were assessed through exploratory factor analysis, reliability testing, and validity checks. Second, descriptive statistics and correlations were examined to identify the basic pattern of associations among the focal variables. Third, the hypotheses were tested using Hayes' PROCESS Macro (Model 1) to examine the moderating effect of AI self-efficacy on the relationship between AI anxiety and unemployment anxiety.

4 Results

4.1 Measurement validation

The measurement model showed satisfactory psychometric performance across all three constructs (see Table 2). Reliability and validity indicators supported the use of the scales in the subsequent analyses, confirming that AI anxiety, AI self-efficacy, and unemployment anxiety were empirically distinct constructs.

Table 2**:** Reliability and Validity Values

Variable	Factor Loading	Total explained variance	KMO	Bartlett's	Sig.	Alfa	AVE	CR
AI anxiety	798-882	71,625	,688	505,538	,000	,802	0.71	0.88
AI self-efficacy	767-887	68,256	,864	1356,309	,000	,880	0.68	0.91
Unemployment anxiety	539-863	56,177	,930	2834,822	,000	,910	0.56	0.92

4.2 Main relationships

The correlation analysis revealed a clear substantive pattern(see Table 3). AI anxiety was positively associated with unemployment anxiety, indicating that stronger concerns about AI tend to be accompanied by stronger concerns about future employment. By contrast, AI self-efficacy was negatively related to unemployment anxiety, suggesting that students with higher AI-related competence report lower levels of employment-related concern.

At the same time, AI anxiety and AI self-efficacy were not significantly related to each other, which implies that feeling anxious about AI is not simply the inverse of feeling competent in relation to it. This distinction is theoretically important because it suggests that the two constructs capture different psychological responses to the same technological environment.

Taken together, these findings move beyond a simple technology-effect explanation and indicate that unemployment-related concern is shaped both by threat-oriented perceptions of AI and by individuals' perceived capacity to cope with AI-related change.

Table 3**:** Descriptive Statistics, Correlation Matrix, and Discriminant Validity

Variable	N	Mean	SD	Skewness	Kurtosis	1	2	3
AI anxiety	510	2,9477	,87726	-,002	-,278	0.843		
AI self-efficacy	510	3,9027	,72059	-,598	1,103	,059	0.825	
Unemployment anxiety	510	3,1765	,90627	-,183	-,505	,176**	-,124**	0.748

4.3 Moderation effects

The moderation analysis supports the proposed relationships. AI anxiety had a significant positive effect on unemployment anxiety, while AI self-efficacy showed a significant negative direct effect. Importantly, the

interaction term was also significant, indicating that the relationship between AI anxiety and unemployment anxiety varies across levels of AI self-efficacy.

The pattern of conditional effects suggests a buffering mechanism. Among students with low AI self-efficacy, AI anxiety was strongly associated with unemployment anxiety. This relationship remained significant at average levels of self-efficacy, although with reduced strength. In contrast, at high levels of AI self-efficacy, the effect of AI anxiety was no longer statistically significant.

These results indicate that the impact of AI anxiety on employment-related uncertainty is contingent on individuals' psychological resources, particularly their perceived capability to interpret and manage AI-related information.

Table 4 presents the results of the moderation analysis.

Table 4**:** Hypothesis results

OUTCOME VARIABLE: Unemployment Anxiety						
Model Summary						
R	**R-sq**	**MSE**	**F**	**df1**	**df2**	**p**

Int_1: AI Anxiety X AI Self-Efficacy, **X**= AI Anxiety, **W**=AI Self-Efficacy, **SE** = Standard error.

The results consistently show that the effect of AI-related anxiety on perceived employment uncertainty is not uniform but depends on the psychological resources shaping how individuals interpret technological change, particularly AI self-efficacy.

5 Discussion

The findings confirm that the relationship between AI-related anxiety and employment uncertainty is not a direct effect but emerges through individuals' cognitive and sensemaking processes. This aligns with approaches suggesting that uncertainty does not arise directly from the external environment but is constructed through interpretive processes (Sandberg and Tsoukas, 2020). In this sense, AI is not merely a technological tool but a knowledge-mediating system that shapes perception and meaning-making (Jin et al., 2024; Kim and Lee, 2024).

Psychological mechanisms also play a key role. The positive effect of AI-related anxiety supports the view that anxiety distorts information processing and inferences about the future (Lamba et al., 2020; Sandhu et al., 2023). In contrast, self-efficacy not only directly reduces uncertainty but, through its moderating role, shapes how individuals make sense of AI-related information, consistent with Albert Bandura's (2012) theory and related empirical findings (Peltier et al., 2022; Ren et al., 2025).

One of the most important findings is that at higher levels of AI self-efficacy, the effect of AI anxiety disappears, suggesting that individuals interpret technological change differently. This confirms that uncertainty does not arise directly from technological change but is shaped through sensemaking (Sandberg and Tsoukas, 2020), a process driven by cognitive and contextual sensemaking mechanisms (Whittle et al., 2023). This goes beyond the traditional "technology → effect" logic and highlights the interpretive nature of uncertainty (Ferguson et al., 2024).

The paper contributes to the knowledge management literature by showing that knowledge is not merely information but acquires meaning through interpretation. In this sense, AI is not only a source of information but a knowledge system in which knowledge is context-dependent and emerges through sensemaking (Hadjimichael et al., 2023). Moreover, AI functions as a sociomaterial environment that shapes sensemaking

through the interaction of technological and social factors (Mora et al., 2021). The effects of AI-mediated knowledge are therefore not deterministic but depend on individual sensemaking processes.

For higher education institutions, the findings suggest that AI system design should not be treated as a purely technical decision but as a process that shapes the visibility and sensemaking of knowledge.

In addition, higher education institutions can contribute to reducing students' employment-related anxiety by fostering AI-related self-efficacy, thereby supporting a more confident transition into the labour market.

This may be supported through a combination of technical training and soft skill development initiatives, including communication, self-awareness, and career preparation programmes.

It is interesting to highlight that the relatively high levels of AI self-efficacy, observed among students, do not necessarily correlate with their actual competencies in using AI. A substantial number of students claim that had not taken any formal course of training on AI, but at the same time, they report to feel as confident and very confident AI users. Generative AI instruments have low learning curve, thereby reinforcing users' perceived capability. In line with social cognitive theory (Bandura, 2012), the positive experiences of students with AI tools are likely to strengthen self-efficacy beliefs even if they lack deep conceptual understanding of AI technologies. This distinction is important, as even the operational level self-efficacy may still function as a psychological buffer against anxiety, as evidenced in the findings, while not necessarily indicating readiness or preparation for more complex or high-stakes AI applications.

6 Conclusion

This study contributes to the literature by examining the effects of AI not as direct technological outcomes but through sensemaking of AI-mediated knowledge. The findings suggest that employment uncertainty arises not only from technological change but from how individuals engage in sensemaking of AI-mediated knowledge.

From a theoretical perspective, the study integrates knowledge management and human–AI cognition perspectives, showing that AI functions as an interpretive system that shapes perceptions of future employment (Hadjimichael et al., 2023; Sandberg and Tsoukas, 2020). The mechanism-based approach explains how psychological factors mediate the effects of technological change through sensemaking processes (Whittle et al., 2023).

From a practical perspective, the findings highlight the importance of developing AI-related self-efficacy (Bandura, 2012). Higher education institutions should focus not only on technical skills but also on supporting students' sensemaking capabilities and cognitive readiness in AI-based environments. The results help organizations and educational institutions address the psychological dimensions of AI-related uncertainty.

A limitation of the study is its cross-sectional design, which does not allow clear causal inference. Future research could use longitudinal and qualitative approaches to better capture the dynamics of sensemaking processes and the role of knowledge interpretation in the emergence of uncertainty.

7 Ethics declaration

The research reported in this paper involved human participants and required ethical approval. Ethical clearance was obtained from the University of Pannonia Research Ethics Committee, on 04/02/2026, under approval number KEB 2/2026 (02.04.) Participation in the study was voluntary, and respondents were informed about the purpose of the research prior to completing the questionnaire. All data were collected anonymously and handled in accordance with applicable data protection and ethical research standards.

8 AI declaration

AI-based tool (ChatGPT) was used during the development of this paper to support language refinement, structuring, and clarity of expression. The authors critically reviewed, edited, and validated all generated content. No AI tools were used for data analysis, interpretation of results, or generation of empirical findings. The authors take full responsibility for the content of the manuscript.

MatchIS: A Digital Platform Designed to Address Critical Gaps in Industrial Symbiosis Marketplaces

Giulia Lippi[1], Luca Colomba[2], Paolo Garza[2], Enrica Vesce[1]
[1]Department of Management, University of Turin, Turin, Italy
[2]Department of Control and Computer Engineering, Polytechnic of Turin, Turin, Italy

Abstract

Industrial Symbiosis is widely recognised as a key strategy for fostering the ecological transition of production systems. This model allows companies to reduce their environmental impacts by exchanging unused resources, whilst maintaining their economic competitiveness and lowering their operational costs. Despite the promising outcomes, its adoption is still hindered by several barriers. Informational gaps related to the lack of data-sharing among companies, technological lock-ins, unclear legislation, and difficulties in assessing the economic viability of symbiotic exchanges are some of the obstacles that companies face when engaging in Industrial Symbiosis. Within this context, digitalisation and, in particular, Information and Communication Technologies, may help to widen symbiotic possibilities and connect companies across broader geographical boundaries. This is testified by the rise of digital platforms promoting Industrial Symbiosis, which can be classified into three main groups according to their core functionalities: good practice repositories, marketplaces, and training solutions. However, most Industrial Symbiosis platforms are little used and often tend to become static spaces, especially in the case of open and public platforms.

The aim of this paper is to present the design of the MatchIS platform, which aims to foster Industrial Symbiosis adoption and help companies address their main challenges. The design of MatchIS was developed through a literature review of IS barriers and semi-structured interviews with representatives of business associations and Chambers of Commerce, which provided both theoretical grounding and empirical insights into the limitations of existing platforms. Building on these results, MatchIS is designed as an open, public, and integrated platform that combines marketplace functionalities with a multidisciplinary support system. The platform enables firms to exchange information on production residues and valorisation technologies, while also providing access to legal, economic, environmental, and certification-related guidance. Distinctively, the platform explicitly incorporates multiple symbiotic roles — producers, utilisers, and transformers — thereby overcoming the binary perspective that characterises most existing solutions.

The paper contributes to the literature by proposing an integrated and accessible platform model that addresses multiple IS barriers simultaneously, demonstrating that advanced support services typically associated with private platforms can be delivered within an open and publicly accessible environment. However, this study is conceptual and design-oriented, focusing on how the identified barriers to IS have been translated into specific platform features. Empirical validation of the platform's effectiveness is left for future research.

1 Introduction

The mounting environmental pressures associated with contemporary production and consumption systems render the transition to more sustainable economic models imperative. Institutions worldwide are advocating for new paradigms that can decouple economic growth from resource depletion and environmental degradation. Within this context, various production and consumption strategies and models oriented to sustainability have been consolidated under the overarching framework of the Circular Economy (Bocken et al, 2016). Indeed, this paradigm involves the sharing, leasing, reusing, repairing, refurbishing and recycling of existing materials and products to extend their lifespan. Circular strategies can be pursued and implemented at various levels, e.g., company, inter-firm, supply chain, municipal or regional scales. Among the various operational strategies underpinning the circular economy, Industrial Symbiosis (IS) has gained increasing attention as an effective approach to optimise resource use at the meso-level (Ghisellini, Cialani and Ulgiati, 2016), fostering collaboration among firms across different industrial sectors. The EU has recognised IS as a key circular operational tool to enable the ecological transition of manufacturing systems (European Commission, 2020). IS refers to a production strategy that connects different productive actors, belonging to different production segments, that establish physical synergies for the exchange and reuse of production residues and effluents (Lippi, Evola and Vesce, 2025). Therefore, IS enables circular integration across conventional supply chains by promoting resource optimisation before the consumption stage. Symbiotic exchanges are indeed limited to pre-consumer residues, such as by-products, waste, and end-of-waste materials arising from industrial

and manufacturing activities (Chertow and Ehrenfeld, 2012). In particular, IS allows companies to reduce their environmental burden whilst maintaining their economic competitiveness (Wadström, Johansson and Wallén, 2021). Companies engaging in symbiotic practices reduce their amount of waste or their reliance on virgin raw materials and, as a consequence, decrease the operational costs associated with input sourcing or waste management.

Symbiotic practices have been well documented for at least thirty years (Domenech et al., 2019; Neves et al., 2019), and some authors argue that they have always existed (Desrochers, 2004). Despite the recent acknowledgement of IS and the related diffusion, most companies, especially small and medium enterprises, struggle to adopt it (Akthar et al. 2022). Several barriers still hinder the diffusion of IS (Golev, Corder and Giurco, 2015). Among these, informational barriers play a central role (Lombardi, 2017). Firms often lack adequate knowledge of other companies' production processes, resulting in limited awareness of potential synergies involving the exchange of residual resources. This lack of visibility is further compounded by concerns related to confidentiality and the protection of sensitive information, which reduces firms' willingness to share data about their operations (Fraccascia and Yazan, 2018). Additionally, establishing symbiotic relationships requires a high level of coordination and trust among actors, which is often difficult to achieve, especially in fragmented industrial contexts (Velenturf and Jensen, 2015). Regulatory uncertainty, particularly regarding the legal classification of residues as waste or by-products, further complicates the implementation of IS initiatives (Lybæk, Christensen and Thomsen, 2021).

Within this context, digitalisation can play a crucial role in overcoming these barriers. Information and communication technologies (ICTs) offer new opportunities to facilitate data sharing, enhance transparency, and support the identification of potential symbiotic exchanges (Antikainen, Uusitalo, and Kivikytö-Reponen, 2018; Fraccascia and Yazan, 2018; Krom, Piscicelli, and Frenken, 2022). In particular, digital platforms can connect geographically dispersed actors, enabling the matching of supply and demand for residual resources and expanding the scope of IS networks beyond local industrial clusters. As a result, a growing number of digital solutions have been developed to support IS implementation. However, many existing IS platforms have struggled to achieve sustained engagement and tangible results (Maqbool, Mendez-Alva and van Eetvelde, 2018). Several initiatives remain underutilised or evolve into static databases with limited active exchanges among users. This gap between technological potential and practical effectiveness highlights critical shortcomings in current platform designs.

Against this backdrop, this paper presents the design of MatchIS, a digital marketplace aimed at facilitating IS among companies. Developed within the framework of the Digital and Sustainable North-West project funded by the Italian National Recovery and Resilience Plan, MatchIS has been conceived to address the main limitations of existing IS platforms by integrating a marketplace for resource exchange with dedicated helpdesks providing multidisciplinary support.

The remainder of the paper is structured as follows: the next section reviews the literature on IS barriers and existing digital platforms; Section 3 outlines the methodological approach adopted for the design of the platform; Sections 4 and 5 present and discuss the results. Particular attention is given to illustrating how the functionalities incorporated in MatchIS address the barriers identified in the literature.

2 Literature Review

2.1 Industrial Symbiosis

This section provides an overview of the IS concept and of the barriers that have to be overcome to operationalise it.

Adopting a material perspective, IS can be defined as the exchange of unused resources, such as byproduct, waste, residual energy and wastewater, among companies belonging to different production sectors (Chertow and Ehrenfeld, 2012; Lippi, Evola and Vesce, 2025). Therefore, the traditional symbiotic set-up foresees the material flow from one producer to one utiliser of the symbiotic resource. Those two are the main symbiotic roles, considering the binary synergy approach (Mendez-Alva et al. 2022). However, recent literature has acknowledged the necessity of intermediary actors that make the resource fit for further use (Patricio et al., 2022; Prosman and Wæhrens, 2019), thereby adding a new role within the symbiotic set-up: that one of the transformers. In order to activate IS material synergies, intermediate steps may be required to prepare or treat the residues (Chertow and Ehrenfeld, 2012). These steps may encompass upgrading the materials, cleaning, refurbishment and sometimes recycling. Transformation activities may be carried either by the producer or the utiliser, or by a third independent party. The intermediary actor is often referred to as upcycling tenant (Martin and Eklund, 2011; Oliveira Pavan et al., 2021), namely industrial plants taking and transforming wastes and by-

products from several other industries which otherwise would not be reusable, to create a new valuable intermediate product deployable by other productive processes.

Although IS implementation may be associated with a number of economic, environmental and social benefits, its establishment is challenged by a range of barriers including technological lock-ins, economic disincentives, informational gaps, regulatory hurdles, organisational, uncertainty and risk-related barriers (Domenech et al., 2019; Golev, Corder and Giurco, 2015; Neves et al., 2020). Barriers are perceived differently depending on the role and the sector of the company. Nonetheless, technological and economical obstacles are the most significant (Lombardi, 2017). Technological barriers refer to the technology readiness level (TRL) of the production process involving the use of productive residue. Existing technologies do not always allow for the activation of a byproduct synergy. Reuse, recovery, and recycling routes often face technological lock-ins, hindering the adoption of innovative solutions. Economic barriers mainly refer to timing mismatches between residue generation and demand and lack of economic incentives to support the secondary materials market. In fact, a significant economic disincentive stems from low raw material prices, which heavily influences the secondary market. Regarding risk-related barriers, the two mostly discussed refer to the possibility that long-term value chain partnerships may reduce companies' flexibility to respond to market changes and to the fact that increasing the inter-dependency among the industries can increase their vulnerability with respect to price and quantity variations (Herczeg, Akkerman and Hauschild, 2018). The regulatory dimension is of particular importance and has a twofold effect. Policy instruments can either facilitate IS formation or impose restrictions on industrial owners that hinder potential projects through policy fragmentation (Domenech, 2021; Lybæk, Christensen and Thomsen, 2021). Governments can play a key role by adopting programs like tax reductions or pollution control, directly or indirectly creating economic incentives for companies that incorporate IS in their production systems. At the same time, restrictive policies hinder the establishment of symbiotic exchanges by imposing strict requirements for residue quality. Likewise, a fragmented legislation may blur either the definition of IS or of different types of waste, imposing unclear administrative procedures. Table 1 provides a summary of the main barriers that should be addressed to promote IS. Particularly, the focus was set on those that can be tackled through digitalisation. As already mentioned, digitalisation can play a pivotal role in fostering data-sharing and support companies in evaluating their symbiotic possibilities.

Table 1. Barriers to the implementation of IS, according to the scientific literature.

Economic	Division of income and costs between organizations
	Different investment cycles
	Fluctuations in demand for a particular commodity or product
	Variation in cost of resources across regions
	Increase in operational costs (i.e. waste transportation and waste treatment costs)
Technical / Operational	Changing operations design
	Mismatch between demand and supply;
	vulnerabilities due to material fluctuations
	Variations in, or issues related to, waste quality
	Lack of technology and infrastructure readiness
Legislative	Restrictive environmental legislation
	Uncertain legislation or lack of guidance (on compliance criteria, best environmental practices, permit conditions, etc)
	Difficulties in obtaining approval for waste reuse projects from the regulatory authorities
Social/Informational	Social isolation between organizations
	lack of information about other companies' by-products and waste flows
	Lack of willingness to collaborate
	Lack of necessary information or data; lack of training for implementing IS
	Lack of awareness of IS concepts
	Lack of information sharing
Environmental	Unknown benefit

2.2 Existing Industrial Symbiosis platforms

The primary objective of this section is to provide a comprehensive overview of state-of-the-art digital platforms dedicated to IS. These platforms play a pivotal role in addressing the barriers outlined in the previous section, particularly those related to information asymmetries, partner identification, and coordination among actors. Across Europe, numerous initiatives—often supported by European Union funding—have contributed to

the development of IS digital platforms, characterised by diverse objectives, core functionalities, sectoral focus, and geographical scope.

Considering their functional configuration, three main core functionalities can be identified across existing IS platforms (van Capelleveen, Amrit, and Yazan, 2018; Krom, Piscicelli, and Frenken, 2022). The first concerns good practices repositories. Within these digital spaces, successful case studies and best practices related to IS and, more broadly, to the Circular Economy, are collected and disseminated. The primary role of this type of platform is to support knowledge sharing by providing companies with examples of waste reduction, by-product valorisation, and sustainable resource management practices. While valuable from an informational perspective, these platforms often remain descriptive in nature and do not directly facilitate operational exchanges among firms. The second functionality that can be identified is related to marketplaces and matching tools. Within these digital environments, companies can offer and acquire resources, materials, and by-products, while also identifying potential partners for symbiotic exchanges. Therefore, these platforms provide virtual spaces for trading residual resources, supported by features such as search tools, material classification systems, and matchmaking algorithms. By making both the supply and demand of residual resources visible, they directly address informational barriers and facilitate the identification of compatible exchanges. Depending on their level of sophistication, these platforms may also include additional services such as logistics coordination, preliminary feasibility assessments, or support in establishing business relationships. Finally, another recurring functionality consists of training programmes. Training platforms provide educational resources, guidelines, and capacity-building programmes related to IS. These platforms aim to enhance firms' knowledge and skills, supporting the adoption of circular practices through training materials, workshops, and digital learning tools.

Nonetheless, it is important to note that the above-mentioned functionalities are not mutually exclusive categories. Rather than representing distinct and isolated platform types, they reflect core functionalities that digital platforms may incorporate to varying degrees. In practice, many platforms combine multiple functionalities within a single digital environment, adopting a more integrated approach (Krom, Piscicelli, and Frenken, 2022).

In addition to functional classifications, IS platforms can also be distinguished based on their level of accessibility. Open platforms provide free and unrestricted access to information and services. Semi-open platforms require user registration to access advanced features or detailed information, thereby balancing openness with controlled data sharing. Finally, closed platforms are typically operated by private organisations or consultancy providers, offering specialised and often tailored services, such as the facilitation of symbiotic exchanges and the management of industrial networks. This classification partially overlaps with that based on ownership, which distinguishes between public and private platforms.

Another relevant dimension of analysis concerns the geographical scope of IS platforms. Some platforms are designed to operate within a clearly defined territorial context, such as eco-industrial parks or specific industrial districts, where physical proximity facilitates symbiotic exchanges. Others operate at a broader scale, including regional or national platforms, while some digital solutions do not impose explicit geographical constraints, potentially enabling interregional or even international exchanges.

In Italy, the platform landscape is particularly dynamic, reflecting the commitment to sustainability. A prominent example is the Italian Circular Economy Stakeholder Platform (ICESP), which primarily functions as a repository of best practices and a knowledge-sharing hub. Concurrently, several Chambers of Commerce have implemented platforms such as Elenco Sottoprodotti, aimed at supporting the exchange of unused resources among local companies. Alongside public initiatives, private actors also play a significant role in the Italian IS ecosystem. Companies such as Sfridoo and Circularity offer specialised digital services that combine multiple functionalities, including marketplace and matching features, consultancy, and training. These platforms contribute to bridging informational and organisational gaps by connecting firms with symbiotic opportunities, providing expert guidance, and supporting the practical implementation of circular strategies.

Overall, the coexistence of multiple functionalities within individual platforms, together with differences in accessibility, ownership, and geographical scope, highlights the heterogeneity of current IS digital solutions. Table 2 classifies some of the existing Italian platforms according to these dimensions. As mentioned in the introduction, most IS-related digital initiatives struggle to remain operative and to effectively promote the implementation of symbiotic practices. For instance, closed and private platforms limit access to data and make it difficult to assess their actual effectiveness in facilitating symbiotic exchanges. On the other hand, many of the public and open matchmaking tools have slowly become static repositories, given a decrease in participation.

Table 2. Characterisation of some Industrial Symbiosis platforms, including MatchIS

Name	Core Functionalities	Access	Ownership	Geographical scope
Elenco Sottoprodotti	Marketplace	Semi-open	Public	Regional
Symbiosis	Marketplace and matchmaking	Closed	Public	District
Sfridoo	Marketplace and Good Practice Repository	Closed	Private	National
Circularity	Marketplace, Training and Consultancy	Closed	Private	National
ICESP	Good Practice Repository	Open	Public	National
INSIGHT	Good Practice Repository and Training	Closed	Public	European
MATCHIS	Marketplace and Consultancy	Open	Public	Regional

3 Methodology

This study adopts a design-oriented research approach to develop the MatchIS platform. Particularly, the objective is to translate insights related to IS barriers and existing platforms' limitations into concrete design features. The methodological approach consists of three main phases, as illustrated in Figure 1. The first phase relies on a literature review to identify the most important barriers to IS implementation. Then, three semi-structured interviews were conducted with representatives of business associations and Chambers of Commerce. These actors were selected due to their strategic role in facilitating inter-firm collaboration and their direct knowledge of the challenges faced by companies in adopting IS practices. The interviews aimed to understand which of the identified barriers are most perceived by local companies and which are the most influential problems of existing IS platforms that have hindered their utilisation. These complementary sources enabled a comprehensive understanding of both theoretical and practical limitations affecting existing IS platforms. Furthermore, the insights drove the design requirements for MatchIS. Specific functionalities were developed to address the most important barriers. Therefore, the platform architecture adopts an integrated approach, combining more core functionalities.

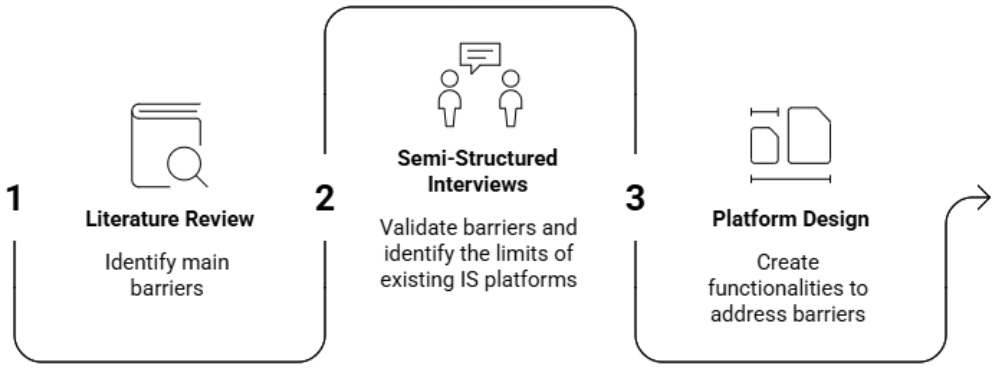

Figure 1. Methodological approach

4 Results

4.1 Existing Industrial Symbiosis platforms

The semi-structured interviews provided empirical support for several of the barriers identified in the literature. In particular, stakeholders consistently emphasised a limited awareness of IS among firms, especially small and medium-sized enterprises, which often lack a clear understanding of the practice as well as their potential symbiotic opportunities. This lack of awareness is closely linked to insufficient information on the availability and demand of specific resources, making it difficult for companies to identify suitable partners.

Regulatory uncertainty also emerged as a critical issue, particularly with regard to the distinction between waste and by-products. This ambiguity generates reluctance among firms to engage in symbiotic exchanges, especially within digital environments where concerns over legal compliance are amplified. Furthermore,

interviewees highlighted the difficulty in assessing the economic viability of IS practices, as companies often lack the necessary tools to evaluate potential cost savings.

Additional barriers include limited availability of technologies for waste valorisation, insufficient knowledge of possible valorisation pathways, and difficulties in quantifying and communicating environmental benefits. Overall, these findings confirm that IS implementation is hindered not only by informational gaps, but also by a broader lack of technical, economic, and regulatory support.

4.2 Critical gaps of existing platforms

The interviews also provided insights into the main limitations of existing IS platforms. First, good practice repositories, while useful for disseminating virtuous examples, often fail to provide sufficient detail to ensure replicability. As a result, they contribute only marginally to knowledge transfer and practical implementation.

Second, stakeholders expressed scepticism towards both open and closed marketplace platforms. On the one hand, companies are reluctant to share sensitive information on open platforms, particularly in the presence of regulatory uncertainty. On the other hand, closed platforms are often perceived as costly and restrictive, discouraging participation.

Third, most existing platforms adopt a binary approach to symbiotic exchanges, focusing exclusively on interactions between producers and utilisers. This perspective neglects the role of intermediary actors, thereby limiting the feasibility of more complex symbiotic configurations. Finally, only a limited number of platforms—typically private and closed—provide consultancy services or decision-support tools, which are, however, essential to assess the feasibility of IS initiatives.

In light of the above, the main objective is to design an open, public platform which combines a marketplace with a support system aimed at enhancing the feasibility and reliability of symbiotic transactions. In particular, the platform was designed to: (i) improve the visibility of supply and demand for production residues; (ii) explicitly include different symbiotic roles, such as producers, utilisers, and transformers; and (iii) provide access to specialised support services through a dedicated help-desk covering legal, economic, environmental, social, and certification aspects.

4.3 MatchIS design

This section presents the main outcomes of the research, namely the design and functional configuration of the MatchIS platform. As the platform has been recently deployed, the results are primarily conceptual and design-oriented, focusing on how the identified barriers to IS have been translated into specific platform features.

Building upon the findings illustrated in Section 4.1 and 4.2, MatchIS has been designed as an open, public, and integrated platform aimed at overcoming the identified barriers. Unlike many existing solutions, which either provide limited functionalities or operate as closed systems, MatchIS combines marketplace functionalities with a comprehensive support system, thereby adopting an integrated approach that is typically observed only in private platforms. This aspect represents a key distinguishing feature of MatchIS, as it delivers advanced services within an open and freely accessible environment.

The marketplace constitutes the core component of the platform and directly addresses informational barriers by enabling firms to publish structured advertisements related to both the supply and demand of production residues, as well as available valorisation technologies. The implementation of a standardised tagging system significantly enhances the visibility and comparability of information, allowing users to efficiently identify potential symbiotic opportunities based on material characteristics, quantities, and geographical proximity. The platform therefore incorporates filtering functionalities based on geographical and material criteria, and a semantic search function that allows users to navigate the marketplace efficiently.

Nonetheless, the key innovative feature of the MatchIS marketplace is the explicit inclusion of multiple symbiotic roles. In addition to producers and utilisers, the platform incorporates transformers, thereby overcoming the limitations of the traditional binary model. This enables the development of more complex and realistic symbiotic networks and facilitates the identification of valorisation pathways for materials that would otherwise remain unused. Not only producers and utilisers are allowed to publish advertisements, but also intermediary actors whose core business is the valorisation of waste. They can offer their technologies on the platform, enabling both knowledge transfer and the establishment of more sophisticated synergies. When publishing an advertisement, companies are required to specify the transformation needed and whether they perform such transformation and, if so, whether they are willing to act as intermediary for other companies.

Importantly, the platform separates the matching phase from the transactional phase, allowing companies to maintain control over negotiations and contractual agreements. This design choice contributes to reducing concerns related to confidentiality and trust, which emerged as critical barriers during the empirical analysis.

The marketplace is integrated with multidisciplinary helpdesks, which constitute a central element of the platform design. The helpdesks provide support across legal, economic, environmental, social, and certification domains. These services directly address several of the barriers identified in the literature and interviews. Within each helpdesk a list of frequently asked questions is presented, together with guidance on which public agencies can provide further consultancy. Therefore, these sections provide companies with structured guidance and practical information on key aspects of IS implementation. For instance, the legal helpdesk reduces regulatory uncertainty by clarifying the classification of production residues and the associated administrative procedures to be followed. Likewise, the certification helpdesk contains information on the schemes currently recognised by the European and Italian authorities to certify the engagement on IS, whilst the environmental helpdesk provides guidance on how to implement life cycle assessment analysis within the IS context. Of particular interest, within the economic helpdesk an automated mathematical modelling tool is proposed. The tool is based on linear programming and evaluates the costs that the utiliser has to bear in case of establishing a particular synergy. The model considers also logistics and transformation requirements. This tool enables firms to compare the economic convenience of using production residues instead of virgin raw materials, thereby supporting more informed decision-making.

Notably, these decision-support tools are freely accessible and designed to be user-friendly, lowering the entry barriers for companies with limited technical expertise. This represents a significant departure from existing platforms, where such services are typically restricted to private and fee-based solutions.

Overall, MatchIS represents an innovative and integrated approach to IS digitalisation, combining openness, accessibility, and advanced functionalities in a single platform. By simultaneously addressing informational, regulatory, economic, and organisational barriers, the platform contributes to enhancing both the feasibility and the scalability of IS practices.

5 Discussion

The results presented in the previous section provide several insights into the design of digital platforms for IS and their potential to address persistent implementation barriers. From a theoretical perspective, this study contributes to the literature by moving beyond the traditional classification of IS platforms based on isolated functionalities. Instead, this study supports the view that effective digital solutions should adopt a hybrid and integrated approach, combining multiple functionalities within a single platform. The design of MatchIS reflects this perspective, as it simultaneously incorporates marketplace, matching, and support-service features.

A second theoretical contribution concerns the explicit recognition of intermediary actors within IS systems. By introducing the role of transformers, the platform acknowledges that many symbiotic exchanges require additional processing steps before residues can be effectively reused. This expands the conventional binary perspective of IS interactions and provides a more realistic representation of industrial ecosystems.

Furthermore, the integration of multidisciplinary helpdesks highlights the importance of combining digital matching tools with expert knowledge. The findings suggest that the availability of information alone is not sufficient to enable IS adoption. Instead, firms require support in interpreting regulatory frameworks, assessing economic viability, and evaluating environmental implications. This reinforces the argument that digital platforms should not be conceived merely as information repositories or marketplaces, but as comprehensive service systems supporting decision-making processes. This is particularly relevant as integrated approaches combining digital marketplaces with consultancy services are more commonly associated with closed and private platforms, whereas MatchIS demonstrates the feasibility of delivering such functionalities within an open and publicly accessible system.

From a practical standpoint, the MatchIS platform offers several implications for policymakers, business associations, and companies. For policymakers and institutional actors, the platform provides a tool to promote IS practices at the territorial level, supporting the creation of local and regional symbiotic networks. For companies, particularly small and medium-sized enterprises, MatchIS reduces the complexity associated with identifying and implementing IS opportunities by centralising information and providing access to specialised support services.

At the same time, the study highlights some critical aspects that may influence the effectiveness of digital platforms for IS. User engagement emerges as a key factor, as the success of the platform depends on the active participation of firms and the continuous updating of information. In addition, issues related to trust and data sharing remain relevant, despite the design choices aimed at mitigating them. The decision to externalise the

transactional phase may reduce these concerns, but it also implies that the platform does not directly control or monitor the outcomes of symbiotic exchanges.

Finally, it is important to acknowledge that the present study is limited by the absence of empirical validation. While the platform design is grounded in both literature and stakeholder insights, its actual effectiveness in facilitating IS remains to be tested. Future research should therefore focus on evaluating the performance of MatchIS, analysing user behaviour, the number and quality of established exchanges, and the resulting environmental and economic benefits.

6 Conclusions

The study has presented the design of MatchIS. Building on the literature review of IS barriers and the gaps of existing platforms, the study aimed at addressing these obstacles for the design of a new, open, and public IS platform. The platform explicitly incorporates different symbiotic roles, including producers, utilisers, and transformers, and offers tools to assist firms in evaluating the economic, legal, and environmental feasibility of potential exchanges. In conclusion, the MatchIS platform represents a promising step towards more effective digital support for IS. Its integrated design addresses several of the key barriers identified in the literature, while also opening new avenues for research on the role of digital technologies in enabling circular economy transitions. Given the recent launch of the platform, this study focuses on its design and conceptual development. The empirical evaluation of its effectiveness is left for future research, which will assess its impact on the adoption of IS practices and its ability to overcome the identified barriers.

7 Ethics Declaration

No ethical clearance for the research was required for this study.

8 AI Declaration

DeeplAI was used for language editing during the final review. Figure 1 was created with NapkinAI.

The Roles of Arts in Knowledge Creation in Urban Planning

Mervi Hokkanen
LUT University, Lahti, Finland

Abstract

A changing society challenges municipalities and their partners. Factors such as climate change, diversification of the regional structure and an ageing population require new approaches to community and urban planning. This research explores how values of arts and arts-based initiatives (ABIs), frameworks developed by Giovanni Schiuma, can contribute to knowledge creation in urban planning, a phase in which environmental and social challenges can be addressed and more sustainable urban environments and futures can be envisioned. Traditional management and planning principles focus merely on efficiency and technical knowledge. This does not recognise the complex reality of planning, where different understandings of valid knowledge coexist and compete. Diverse ways of knowing are required. Through arts, emotional knowledge can be integrated into work practices, enabling environmental challenges to be addressed from more multi-perspectival viewpoints. The study was conducted as a qualitative case study in a company specialising in urban planning. ABIs (such as visual storytelling methods which combine drawings, text and told stories) were used to co-create the research materials. In collaboration with the company's planners, the study examined their perceptions of their own work processes and explored the potential roles of ABIs in organisational everyday work practices. As preliminary results of the study, four operational models for everyday work practices were developed, through which the values of arts and arts-based initiatives (ABIs) support the achievement of the company's strategic objectives. Three of the proposed operational models relate to the collaborative ideation process and the fourth model is based on a reflexive framework. These models were aligned with four values of arts supporting personal inspiration, learning, and the strengthening of professional networks. The study provided practical insights for knowledge management by highlighting the importance of everyday work practices as a means of integrating and mobilising the organisation's collective knowledge.

Keywords: value of arts, arts-based initiatives (ABIs), urban planning, knowledge creation, knowledge management

Paper type: Academic Research Paper

1 Introduction

The Association of Finnish Cities and Municipalities has stated that a changing society brings challenges to municipalities and their partners. Factors such as climate change, diversification of the regional structure and an ageing population require new approaches to community and urban planning. Municipalities are required to engage in multidimensional change management and to collaborate with a wide range of stakeholders. (Jarva and Toivonen, 2020).

The built environment is produced through the cooperation of actors from several different fields and under the influence of societal processes (Hytönen, 2020). Finnish urban planning and land-use planning are hierarchical, top-down-guided processes that involve several levels of planning. Planning is a participatory process, involving not only public authorities and various experts but also those affected by the plan, such as residents, associations, and other stakeholders.

In the organisational structures of Finnish municipalities, a comprehensive-rationalist planning culture is still strongly present. This assumes that the state of society can be managed through comprehensive data collection methods and knowledge grounded in facts and objectivity. (Bäcklund and Mäntysalo, 2009). Such an interpretation of the nature of knowledge, worldview, and legitimate decision making (Bäcklund and Mäntysalo, 2009) does not recognise the complex reality of planning where different understandings of the determinants of good democracy, legitimate planning and the roles of different actors in producing and managing valid knowledge coexist and compete (Bäcklund and Mäntysalo, 2010). In a complex reality urban planners encounter conflicts between economics, environmental, and social interest that cannot be resolved through visionary imagery (Campbell, 1996). If the constraints set by the environment are taken seriously, the nature of planning changes (Hytönen, 2020). In planning, a new understanding of the conceptions of knowledge, worldview and legitimacy in decision-making is needed (Bäcklund and Mäntysalo, 2010).

In urban planning, the traditional management and planning principles focused merely on efficiency and technical knowledge are still present. However, this is not sufficient for solving complex problems or creating new value; instead, diverse ways of knowing are also required. Through the arts, emotional knowledge can be

integrated into work practices, enabling environmental challenges to be addressed from more multi-perspectival viewpoints. (Carlucci and Schiuma, 2018).

Arts-based initiatives (ABIs) have a unique character in the increase of knowledge and skill (Carlucci and Schiuma, 2018), and long-term impacts are achieved when they are integrated into everyday life (Taylor and Ladkin, 2009; Pässilä, Oikarinen and Harmaakorpi, 2015). In the knowledge processes underlying ABIs the senses and emotions are emphasized alongside logical-rational knowledge (Darsø, 2004; Taylor and Ladkin, 2009; Schiuma, 2011). Researchers study these themes under the fields of organisational aesthetics (Darsø, 2004; Taylor and Ladkin, 2009; Schiuma, 2011), sensuous knowing (Taylor and Hansen, 2005) and emotive knowing (Schiuma, 2011). Central and common to these approaches is the role of the senses in knowledge acquisition, as well as the significance of emotions and aesthetic experience in the interpretation of information and the creation of knowledge (Schiuma, 2011; Taylor and Ladkin, 2009).

Schiuma (2011) situates his approach to the roles of arts in knowledge within a body of scholarship that conceptualises human cognitive and emotive knowledge processes as deeply intertwined and mutually influential. As a result, human action and behaviour are grounded in both rational and emotive modes of cognition. Emotional knowledge processes activate individuals' aesthetic, sensory and experiential dimensions of knowing. Emotions and aesthetics are reciprocally related: aesthetic experiences generate emotion, while emotions shape aesthetic experiences and perceptions. ABIs are connected to emotional and energetic processes in individuals. Art has the ability to influence people's emotions and energy through the senses, and to evoke aesthetic experiences. Aesthetic experiences can shape the attitudes through which we interpret situations and decide how to act. The actions determine the quality and condition of the organisation's performance. (Schiuma, 2011). Through this operational logic, it is possible to influence not only to the rational dimension of the thinking but also various forms of business performance. Schiuma emphasises that integrating emotional knowledge processes into organisational practices is essential for postmodern management in an increasingly complex world.

Schiuma (2011) has been exploring the benefits of arts through the framework of the Arts Value Matrix he developed. The Arts Value Matrix structures the types of value that can be achieved by integrating arts-based initiatives into individual and organizational learning and development. The Arts Value Matrix examines individual and organizational development at low, medium and high levels of intensity. The Arts Value Matrix covers nine categories, which are entertainment, galvanising, inspiration, reputation, environment, learning and development, investment, networking, and transformation.

To make these connections between arts and business visible, Schiuma (2011) draws on a knowledge-based understanding of organisational operations, where all the organisation's resources, activities, and products can be interpreted and classified as being the result of knowledge and expertise. Knowledge resources are constituted by people and their relationships, as well as by structures that can be either tangible - such as material artifacts, physical environments, and infrastructure – or intangible, such as organisational culture and identity. What distinguishes Schiuma's conception of knowledge resources from other knowledge management literature is that he also recognizes tangible resources as part of knowledge resources. Tangible resources contribute directly to organisational capabilities, while also influencing intangible resources through the networks of interdependencies among organisational resources. Both tangible and intangible resources are linked to the organisational and structural properties of the organisation. (Schiuma, 2011).

Schiuma also draws on performance management literature in developing the Arts Value Map framework, which elucidates how the operational logic of the arts can be translated into business performance outcomes. This framework enables the visualisation of relevant cause-and-effect relationships. ABIs can function as a platform for learning or as a means of developing an organisation's knowledge resources. These, in turn, influence the organisation's operational and dynamic capabilities, which affect organisational processes and, consequently, the achievement of the values the organisation aspires to create. ABIs influence people and structures in a distinctive, context-specific, temporal, and multilevel way. (Schiuma, 2011).

2 Research Objective

Interest in bringing artists and arts into planning processes has increased (Wiberg, 2022), but this is still an area of research that is just emerging (Carpenter and Horvath, 2022). This research explores how ABIs can contribute to knowledge creation in urban planning, a phase in which environmental and social challenges can be addressed and more sustainable urban environments and futures can be envisioned. The objective of this study is to investigate how the ABIs may be integrated into the everyday work practices of a Finnish company operating in the field of urban planning, while simultaneously supporting the attainment of the company's

strategic objectives. In addition, the study aims to develop operational models for embedding the values of arts and ABIs into everyday work practices.

Accordingly, the research question is formulated as follows:

How can ABIs be embedded with staff and managers in everyday organisational practices in ways that activate arts-driven value-creation mechanisms and thereby support the implementation of the company's strategic priorities?

3 Data, Method and Analysis

This study employs a qualitative research approach and is designed as a case study (Yin, 2018) in which ABIs were used within the everyday context of knowledge-creation practices. ABIs (such as visual storytelling methods which combine drawings, text and told stories) were used to co-create the research materials. In collaboration with the company's planners, the study examined their perceptions of their own work processes and explored the potential roles of ABIs in organisational everyday work practices.

3.1 Data collection process

Research data were collected in 2022 in a company operating in the urban planning sector. The data collection process consisted of two workshops, an orientation meeting prior the second workshops, and a concluding discussion at the end of process. The data were co-produced with the company's staff (12 people) and managers (4 people), all who work on planning projects. In the first workshop, managers described the strategic objectives of the company and the everyday work practices related to these objectives. These objectives and practices were identified and structured using the Arts Value Map developed by Schiuma (2011). Prior to the second workshop, an orientation meeting was held for staff and managers. The purpose of this meeting was to develop a preliminary shared understanding and to outline the themes to be addressed in the subsequent workshop. In the second workshop, staff and managers jointly described everyday work practices that managers had identified as strategically important. These practices were then analysed in terms of what functions well and what presents challenges. Following this description and analysis, participants engaged in an ideation phase focusing on how the Arts Values developed by Schiuma could be integrated into everyday work practices. The data collection process concluded with a discussion with managers, during which they reflected on the events and insights generated throughout the process.

3.2 Data and methods

In the study, various visual storytelling methods were used and combined as data collecting methods. Maps represent one of the oldest forms of non-verbal communication and serve as a powerful tool for visualising reality, relationships between entities, and the construction of meaning (Carlucci, Schiuma and Linzalone, 2017). For this reason, the workshop series began with the creation of an Arts Value Map. This framework is based on mapping practices and helps to understand how ABIs can be translated into business performance outcomes. (Carlucci et al., 2017).

Drawing functions as a catalyst for collective meaning-making as well as for sharing emotions and experiences (Ward and Shortt, 2018). In the data collection process, various drawing-based methods were employed. Participants drew visual stories depicting their everyday work practices. To support storytelling, guiding questions derived from the Work Stories storytelling method (Pässilä et al., 2013) were used. As well as the visualisation and narration of their own Work Stories, participants also listened to others' stories and created visual notes based on them, applying an evocative visual storytelling approach. Through this method, information is collected, the process is documented and tacit knowledge is given expression. The method also enables the visualisation of relationships between entities and supports the creation of shared understanding. (Benmergui, 2019). In addition, Work Stories were documented using the (maga)zine method. This is a flexible and three-dimensional approach that supports the visualisation of complex issues. (Biagioli, Pässilä and Owens, 2021).

In data collection methods, visual material was supported and completed through verbal means, including writing and interviews. In this way, the limitations of visual material were addressed with verbal explanations, while aspects that are difficult to express in words were more easily communicated through visualisation.

The research material consists of drawings, written texts, and verbal descriptions and discussions. This material captures both the present and desired future activities of the company. The material was analysed using Polkinghorne's (1995) narrative analysis approach. The collected data were classified and categorised, and these categories were made visible through the narratives constructed from the described Work Stories. Based

on the analysis of these narratives, proposals for operational models were developed for experimentation in the company. The analytical categories leading to the operational models were derived from the objectives, the knowledge resources, and the value of arts identified in the first workshop, as well as from the descriptions and analysis of current-state knowledge and the values of arts discussed in the second workshop. These categories were grounded in the frameworks of the Arts Value Map, the Arts Value Matrix and the concept of knowledge resources developed by Schiuma (2011).

4 Results

This study is work-in-progress. As preliminary findings of the study, four proposed operational models were developed for experimentation within everyday work practices. These models were aligned with four values of arts supporting personal inspiration, learning, and the strengthening of professional networks.

The strategic objectives and values identified in the study emphasised the company's aspiration to become a dream workplace for its employees as well as a forerunner in the field of urban planning. From the perspective of being a dream workplace, collaborative ideation was identified as a key everyday work practice. Ideation is a routine task in a planning office and a central component of the planner's professional role. The managers viewed this practice as particularly important, as it enables employees to experience success, a sense of community and commitment to the company. To achieve the strategic objective of forerunnership, informal and spontaneous encounters – such as coffee breaks and casual interactions in the office – were considered important contexts for sharing experiences and perspectives related to work. The following section presents three proposed operational models for integrating the values of arts into collaborative ideation, and one proposed operational model for integrating the values of arts into informal and spontaneous encounters.

Three arts-related values were linked to collaborative ideation to develop the forms of knowledge required in this practice. The first value was the galvanising value of the arts, which materialises when art can engage individuals in an intense, liberating, and meaningful experience that generates enthusiasm, joy, and energy (Schiuma, 2011). Schiuma (2011) further explains that the galvanising value of the arts can enhance people's motivation and commitment, as well as knowledge creation and sharing, creativity, and innovativeness. Through the galvanising value of the arts, the intention was to support the development of employees' personal competences and skills, such as imagination and creativity.

The first proposed operational model integrates the galvanising value of the arts into collaborative ideation as an everyday work practice. In this model, arts-based methods engaging multiple senses are incorporated into the ideation phase of collaborative design processes. During the workshops, merely ideating the use of different arts-based methods within the co-design process generated enthusiasm among participants, suggesting that the actual implementation of these methods is likely to produce a galvanising effect as well. These methods include the use of sound recording, photography, drawing, and the production of documentary films. Employees and managers can adapt, vary, and further develop these methods on a project-by-project basis to support ideation.

A second value of arts to be integrated into collaborative ideation was the inspirational value of the arts. According to Schiuma (2011), this value involves offering new perspectives, stimulating ideas, and inspiring action. The inspirational value of the arts is realised when it guides individuals toward self-reflection and deeper understanding, thereby transforming thinking and behaviour (Schiuma, 2011). Through the inspirational value of the arts, the intention was to support employees' personal competences and skills, as well as to develop the organisation's collaborative ideation knowledge management process, which forms part of the organisation's structural resources.

The second proposed operational model (Figure 1) integrates the inspirational value of the arts into collaborative ideation as an everyday work practice. This model is based on the creative process described by Taylor (2011). The inspirational value of the arts is realised within the creative process outlined by Taylor (2011), which emphasises processual progression and the development of deeper understanding as a foundation for idea generation. In addition to fostering individual deeper understanding, the process establishes a stepwise work practice that structures collaborative ideation.

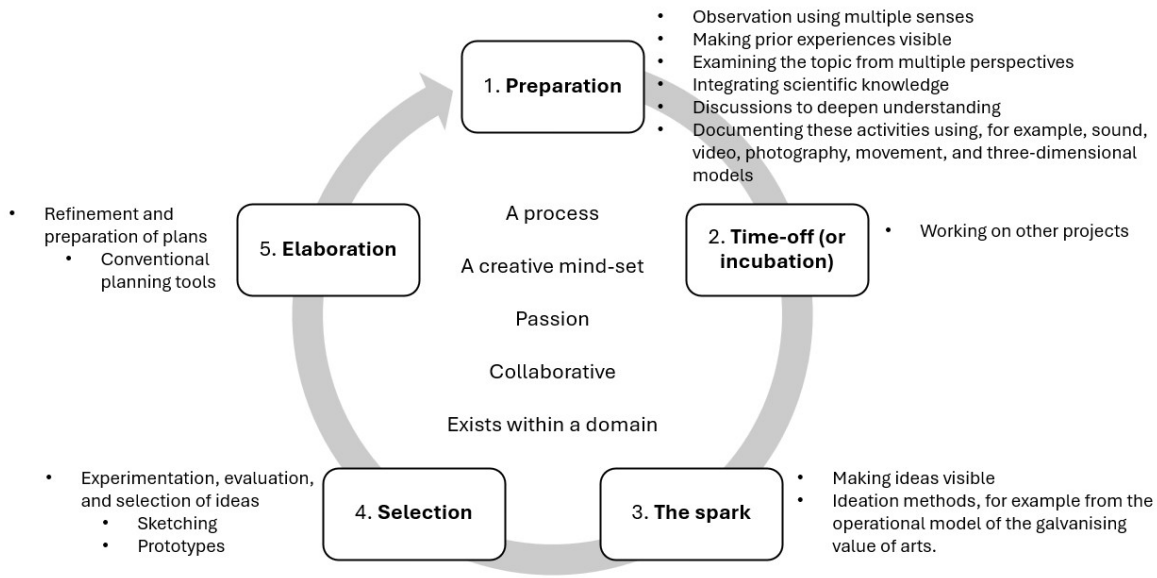

Figure 1: The proposed operational model: integrating the arts inspiration value into collaborative ideation.

The third value of arts to be integrated into collaborative ideation was the value of arts as networking. The value of the arts in networking is connected to the formation of shared understanding through dialogue, as well as to the activation and support of collaboration. Within this value domain, the arts can generate collective effects by bringing people together and stimulating dialogue that helps to build relationships as a foundation for cooperation (Schiuma, 2011). In the employees' narratives, challenges related to the quality of relational knowledge within multidisciplinary planning teams were highlighted. The ideation process defined and described by the managers was explicitly collaborative ideation, in which individual knowledge is transformed into shared knowledge.

The third proposed operational model (Figure 2) integrates the value of arts of networking into collaborative ideation as an everyday work practice. This model draws on the study by Sorsa et al. (2018) on the transformation of individual experience into collective collaboration and knowledge, which reflects the characteristics of the arts networking value described by Schiuma (2011). According to Sorsa et al. (2018), the foundation for collective dialogue lies in awareness of oneself and of others. They further argue that a materially mediated aesthetic experience is essential when bridging individual experience and collective collaboration (Sorsa et al., 2018).

The process examined by Sorsa et al. (2018) consists broadly of the following phases: self-awareness; doing individually; listening and taking the perspective of others; and doing together. In this process, aesthetic experience and material artifacts function as modes of communication, particularly in situations where issues are difficult to articulate verbally (Sorsa et al., 2018). The aim of the proposed operational model is to increase self-awareness and, through this, promote mutual understanding, attentive listening, the expression of diverse perspectives and approaches, improved collaboration, and the creation of shared understanding among participants regarding the project. These outcomes are intended to foster mutual trust and shared understanding, thereby improving the effectiveness of collaborative ideation. The aesthetic experience and materials employed may consist of previously ideated multisensory or other task-appropriate arts-based methods.

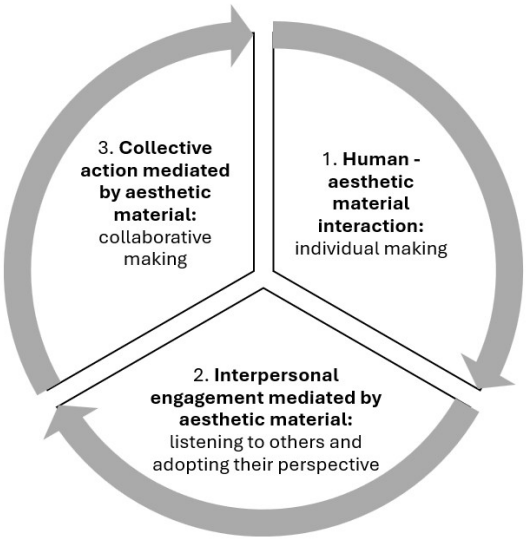

Figure 2: The proposed operational model: integrating the arts networking value into collaborative ideation.

The fourth proposed operational model and values of arts are linked to the strategic objective of forerunnership, for which informal and spontaneous everyday conversations were identified as important contexts for achievement. Four values of arts are associated with this objective: galvanising, inspiration, learning and development, and networking. The value of arts of learning and development activates and sustains experiential learning mechanisms in which the arts function through reflective learning processes. By practicing artistic skills or engaging with artistic competences, individuals' capabilities can be enhanced (Schiuma, 2011). The value of arts of networking is connected to the formation of shared understanding through dialogue, as well as to the activation and support of collaboration (Schiuma, 2011). The other values of arts have been presented in earlier sections.

Through these values of arts, the aim is to develop multiple organisational knowledge resources. The managers identified facilities, office culture, and trust as key forms of knowledge. In their development ideas, the employees emphasised the importance of personal experiences, interaction and collaboration, spaces and tools, and leadership. The significant and development-oriented forms of knowledge resources were found to relate to all categories of knowledge assets defined by Schiuma (2011): individual, relational, tangible, and intangible structures.

The fourth proposed operational model focuses on the more systematic integration of informal and spontaneous knowledge exchange into everyday work practices. This model draws on Biagioli's (2017) descriptions of the nature and significance of informal situations in organisations. Informal situations play an important role in organisational knowledge formation, particularly in relation to innovation. They are also significant for cultural understanding and organisational change. Informal situations provide contexts in which the transfer of tacit knowledge is especially activated, as formal practices do not guide action in these settings. In such situations, tacit knowledge is transferred and transformed through gestures, playfulness, informal learning, and embodied feelings associated with individual beliefs. (Biagioli, 2017).

The proposed operational model (Figure 3) is built around the reflexive model developed by Pässilä (2012) and aims to make visible and to construct the understanding that the case company perceives as emerging in spontaneous and informal situations. Through the values of arts, everyday experiences are rendered visible, multiple perspectives related to these experiences are shared, situations are interpreted in a polyphonic manner, new ways of acting are imagined, and novel practices are tested in action. Reflexive work practice should be given its own place within the company's structures and processes of knowledge creation and cultural understanding.

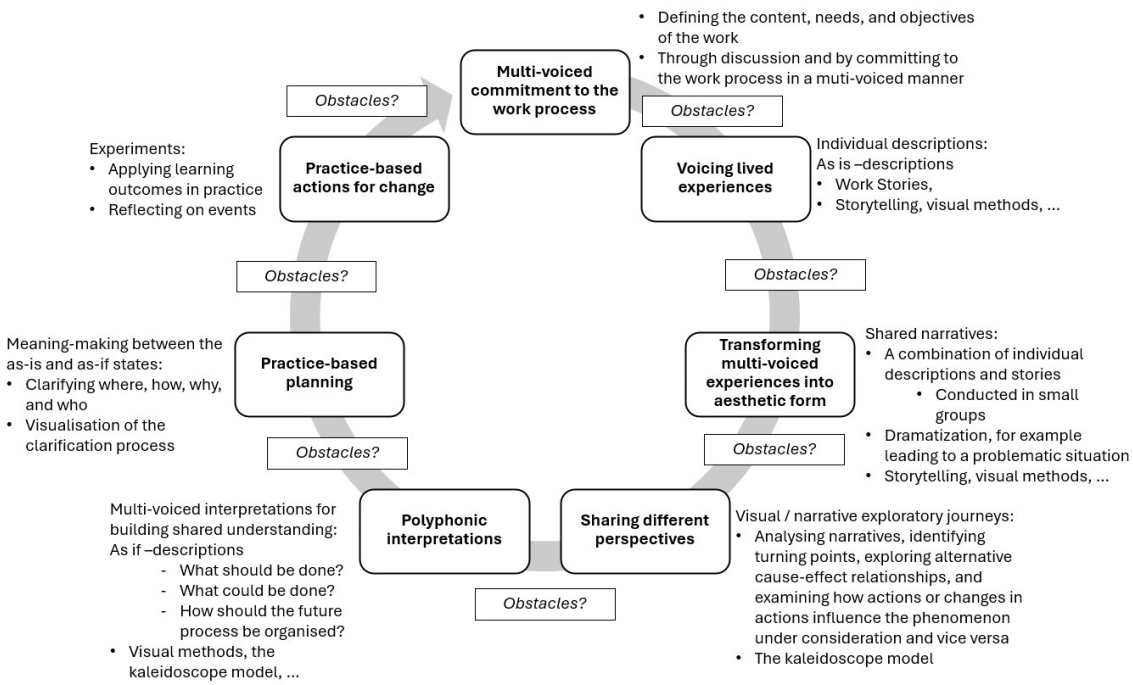

Figure 3: The proposed operational model: integrating the arts galvanising, inspiration, learning and development, and networking values into reflexive model.

The study provided practical insights for knowledge management by highlighting the importance of everyday work practices as a means of integrating and mobilising the organisation's collective knowledge. The frameworks developed by Schiuma (2011) support the structuring of how the values of arts and ABIs can be embedded within the organisation's strategic activities. To align values of arts and the ABIs that promote them with strategically significant everyday work practices, a shared description and analysis of these practices involving the entire organisation—including both staff and managers—is required.

Work practices comprise of multiple phases in which different forms of knowledge embedded in individuals and organisational structures are combined. The findings of this study indicate that ABIs are most effectively designed as operational models that integrate multiple values of arts, thereby enabling the simultaneous support and development of diverse knowledge forms. From a managerial perspective, it is also noteworthy that, based on the findings, informal situations within the organisation emerged as important arenas for knowledge creation.

5 Conclusions

This study examines the roles that the arts can play in urban planning, particularly from the perspective of knowledge creation. As preliminary results of the study, four operational models for everyday work practices were developed, through which the values of arts and arts-based initiatives (ABIs) support the achievement of the company's strategic objectives. Three of the proposed operational models relate to the collaborative ideation process, in which the galvanising, inspiration, and networking values of the arts are used to support employees' imagination and creativity, deeper self-reflection and understanding, and the transformation of individual experiences into collective collaboration and knowledge. The objective of these models is to achieve the strategic goal of becoming a dream workplace by supporting the development of employees' knowledge and competencies.

The fourth proposed operational model is based on a reflexive framework, in which the galvanising, inspiration, learning and development, and networking values of the arts are employed to render tacit knowledge visible and to generate new understanding. Through this model, knowledge creation occurring in informal situations within the company is provided with a dedicated platform, thereby supporting the attainment of the strategic objective of forerunnership.

The study is situated in Finland; however, planning structures and methods share similarities with those of many other European countries (Rantanen and Rajaniemi, 2020). This case study explored the roles of arts from

the perspective of an urban planning company and examined how arts influences professionals' everyday work practices.

In the next phase of the research, the focus will shift to investigating the roles that arts may play in articulating vulnerable residents' relationships with the city and in bringing their perspectives into the planning process. Differentiation in participation is evident both within residential areas and in participation in urban planning more broadly. A case study from Helsinki indicates that current planning practices have limited success in reaching socially vulnerable or otherwise marginalised groups. (Sjöblom and Niitamo, 2020). Future research will also find it relevant to examine the roles of third-sector organisations and municipal urban organisations, as well as how knowledge produced through arts-based methods can be utilised.

In addition to making emotional knowledge visible (Schiuma, 2011), arts (as an aesthetic approach) also have the potential to shape our aesthetic perceptions and our relationship with the environment (Lehtinen, 2021).

Using Intelligent Knowledge to Offer Digital Services: a Lean Startup Interpretation

Clara Filosa, Lara Agostini, Anna Nosella
Department of Management and Engineering, University of Padova, Vicenza, Italy

Abstract

Digital servitization (DS) enables manufacturing firms to transition from product-centric offerings to digitally enabled product-service systems (PSSs). Despite its strategic potential, DS represents a challenging transformation for incumbent manufacturers, characterized by technological, data-driven, and business model uncertainty. While prior research conceptualizes DS as a strategic and organizational shift, limited attention has been paid to the process mechanisms through which firms generate and leverage knowledge to navigate this transformation. In particular, the role of Intelligent Knowledge (IK) and the mechanisms through which firms act remain insufficiently understood.

This study investigates how IK evolves throughout the DS journey and how the Lean Startup approach helps firms manage uncertainty during this process. To do so, the research draws on a longitudinal multiple-case study of four global B2B manufacturing firms undergoing DS transformations.

Our findings reveal a three-stage pathway through which firms progressively develop and mobilize IK. In the first stage, experimentation enables firms to identify relevant customer problems and achieve problem-solution fit. In the second stage, accumulated insights support refinement and the achievement of PSS-market fit. In the third stage, IK expands to ecosystem-level knowledge, enabling outcome-based services and problem-solution fit.

The study contributes to the DS literature by introducing a knowledge-based perspective on the transformation process and by showing how Lean Startup experimentation functions as an adaptive mechanism to navigate the journey. For managers, the findings provide a structured roadmap for DS, highlighting how staged experimentation and progressive IK development can guide the transition toward scalable PSSs.

Keywords: Digital Servitization, Intelligent Knowledge, Lean Startup approach, Multiple case study.

Paper type: Academic Research Paper

1 Introduction

Digital servitization (DS), the transition from selling standalone physical products to offering digitally enabled and integrated product-service systems (PSSs), is increasingly recognized as a key pathway to generate competitive advantage. By leveraging digital technologies, firms can deliver adaptive solutions that continuously respond to evolving customer needs (Frank et al., 2019; Kohtamäki et al., 2020; Stonig et al., 2022). Despite these opportunities, DS represents a major challenge for incumbent manufacturers: organizational inertia, legacy infrastructures, and product-centric cultures often hinder the transition (Baines et al., 2020; Favoretto et al., 2022; Huikkola et al., 2022).

Beyond technological adoption, DS requires firms to generate, interpret, and act upon new forms of knowledge derived from connected products, digital platforms, and customer interactions. However, despite the central role of data and knowledge in DS, limited attention has been devoted to understanding how this evolves and supports decision-making throughout the servitization journey. In particular, little is known about how incumbents generate and use intelligent knowledge (IK), defined as a form of knowledge that emerges from processing and interpreting data and supports decision-making (North et al., 2018). As a result, scholars have called for new perspectives capable of capturing the dynamic and emergent nature of DS as it unfolds in practice (Kohtamäki et al., 2022).

In this context, the Lean Startup approach offers a promising lens for understanding how firms navigate uncertainty while progressively generating and acting upon new knowledge. Originally developed to guide startups operating under conditions of high uncertainty, Lean Startup emphasizes hypothesis-driven experimentation, iterative learning, and continuous customer feedback (Ries, 2011). Recent research suggests that Lean Startup may help incumbents manage innovation under uncertainty (Blank & Eckhardt, 2024; Ghezzi & Cavallo, 2020). However, how Lean Startup operates within DS transformations remains underexplored.

To address these gaps, this paper investigates how IK and Lean Startup evolve during DS transformations. Drawing on a longitudinal qualitative study of four B2B manufacturers undergoing DS transformations, we address two interconnected research questions:

RQ1: How does Intelligent Knowledge evolve along the digital servitization journey?

RQ2: How can the Lean Startup approach help firms navigate uncertainty throughout this journey?

Our findings reveal a three-stage pathway through which IK progressively evolves from early product-level insights to broader ecosystem-oriented knowledge. Across these stages, Lean Startup provides an adaptive approach that enables firms to translate emerging knowledge into iterative service development and BM transformation under uncertainty.

2 Theoretical Background

2.1 Digital servitization as a knowledge-intensive transformation

DS refers to the transformation through which manufacturing firms integrate digital technologies into their PSS offerings to develop data-enabled services and new value propositions (Frank et al., 2019; Kohtamäki et al., 2020).

At its core, DS requires profound business model (BM) transformation: manufacturers must reconfigure value creation, delivery, and capture mechanisms to support the development and provision of digitally enabled PSSs (Kohtamäki et al., 2020; Paiola et al., 2024).

This transformation is inherently knowledge intensive. Connected products and digital platforms enable firms to gather continuous data across the product lifecycle, supporting predictive services, remote monitoring, and data-driven optimization of customer operations (Baines et al., 2020). As a result, successful DS initiatives depend on new knowledge management capabilities, including data analytics, digital infrastructures, and cross-functional collaboration (Huikkola et al., 2022; Paiola & Gebauer, 2020).

Importantly, DS also expands knowledge processes beyond firm boundaries. Digital services often require collaboration with customers and partners, leading to data-driven service ecosystems in which knowledge is co-created and shared among multiple actors (Sjödin et al., 2020). Despite growing scholarly attention, however, limited research has examined how knowledge is generated and mobilized as DS transformations unfold, highlighting the need for perspectives capable of capturing their iterative and emergent nature (Sjödin et al., 2020).

2.2 Intelligent knowledge enabled by digital technologies

In DS contexts, digital technologies do not merely support operations but function as infrastructures for knowledge generation. IoT sensors and analytics platforms continuously generate data on product usage and performance. When processed and interpreted, these data generate insights that inform service delivery. Following North et al. (2018), we conceptualize this digitally enabled form of knowledge that supports data-driven decision-making as Intelligent Knowledge (IK).

In DS, IK is continuous and actionable. IK flows in real time, providing manufacturers with an uninterrupted stream of insights into product performance and customer behaviour (Solem et al., 2022). Moreover, IK is not merely descriptive but prescriptive, enabling firms to trigger proactive service interventions (i.e., predictive maintenance alerts, remote performance optimizations, automated anomaly responses) that translate insights into value (Kohtamäki et al., 2022; Sjödin et al., 2020).

IK enables DS by revealing actual rather than assumed customer usage patterns, by continuously identifying opportunities for value-adding interventions, and by enabling remote monitoring, automated diagnostics, and evidence-based service scheduling (Kohtamäki et al., 2022; Tian et al., 2022).

However, IK also introduces significant uncertainty and challenges. The huge volume, variety, and velocity of data generated by connected industrial assets create analytical and interpretive burdens for organizations (Hanelt et al., 2021). Raw data are not insights: transforming operational signals into actionable service knowledge requires significant investment in analytical capabilities, organizational routines, and governance structures for knowledge mobilization across functions (Kohtamäki et al., 2022). Moreover, as digital technologies evolve rapidly and become increasingly integrated, firms remain uncertain about the most appropriate digital infrastructure and technology combinations.

Consequently, IK simultaneously enables and complicates DS, producing a foundational tension that demands structured organizational responses.

2.3 Lean startup approach to manage digital servitization transformation

DS exposes incumbent manufacturers to multiple and interrelated forms of uncertainty. Technological uncertainty stems from the rapid evolution of digital technologies such as IoT, cloud infrastructures, and AI (Frank et al., 2019; Kohtamäki et al., 2020). Firms also face data-driven uncertainty regarding which technologies

to adopt and how to interpret the growing volume of data (Sjödin et al., 2020). Finally, DS introduces BM uncertainty, as manufacturers must experiment with new ways of creating, delivering, and capturing value through digitally enabled PSSs (Baines et al., 2020; Paiola & Gebauer, 2020).

In such contexts, the Lean Startup approach provides a useful framework for managing innovation under uncertainty. Originally developed for early-stage ventures, it emphasizes hypothesis testing, experimentation, and validated learning to progressively refine value propositions and BMs (Ries, 2011; Ghezzi, 2019). Recent studies suggest that these mechanisms can also support incumbent firms undergoing complex innovation-driven transformations (Ghezzi & Cavallo, 2020; Blank & Eckhardt, 2024).

A key mechanism within this approach is the Think-Make-Check cycle (Alvarez, 2017), through which firms formulate hypotheses about customer problems (Think), develop simplified experimental solutions (Make), and evaluate market feedback to validate or revise their assumptions (Check).

Despite these conceptual synergies, how Lean Startup approach operates within DS transformations remains empirically underexplored, particularly regarding how experimentation interacts with the generation and mobilization of knowledge along the servitization journey.

3 Methodology

To address the RQs, we adopted a qualitative multiple case study approach suitable for exploring complex phenomena (Yin, 2009). Multiple case studies enable cross-case comparison and robust analysis (Siggelkow, 2007). The investigation spans multiple time points (2023-2025), allowing the identification of changes and dynamics both retrospectively and in real time (Pettigrew, 1990).

Four global B2B manufacturers were selected based on the following criteria: being incumbent manufacturers actively engaged in DS projects, operating at different scales, and willing to provide regular access to data and participate in interviews and meetings. The sample includes Alpha (large firm, energy infrastructure), Beta (large firm, professional ovens), Gamma (medium firm, industrial thermal solutions), and Delta (medium firm, packaging machines), operating in diverse industrial contexts while sharing a common commitment to DS transformation.

Primary data were collected through semi-structured interviews and meetings with informants actively engaged in DS projects (Pettigrew, 1990). Secondary sources (i.e., company websites, internal presentations, and official documents) were incorporated to triangulate primary findings and ensure narrative completeness (Yin, 2009).

Interviews were recorded, transcribed, and rigorously coded to identify first-order categories grounded in informants' language. Connections among first-order categories were explored iteratively to derive second-order themes corresponding to distinct theoretical notions. Finally, a coding scheme aligned empirical findings with Lean Startup and IK.

4 Findings

Our cross-case analysis reveals that the DS process unfolds through three iterative stages, namely Hypothesis Framing and Initial Experiments, Solution Validation, and Extended and Ecosystem-Oriented Experiments, each characterized by a distinct configuration of IK and Lean Startup mechanisms. Across stages, IK progressively evolves from product-level operational data to ecosystem-level strategic intelligence, while Lean Startup mechanisms shift from basic hypothesis testing to complex partner co-development. Together, these dynamics illuminate how incumbent manufacturers adapt and transform their BMs under the compounding uncertainties of DS, successfully navigating the journey.

4.1 Stage 1: Hypothesis framing and initial experiments

In Stage 1, manufacturers initiate their DS journey by formulating hypotheses about customer problems and developing early-stage digital service configurations to test them on a limited scale. The emphasis is on learning what works and demonstrating value to selected customers. Firms begin the journey, without yet committing to full-scale transformation.

4.1.1 Intelligent knowledge evolution

In Stage 1, IK is product-centric and internally oriented. Firms invest in IoT sensors to capture operational data from their physical assets, generating a foundational layer of knowledge about product performance and usage conditions.

At Beta, connectivity is introduced to *"detect parameters such as temperature settings and water consumption to understand customer habits, optimizing and improving the product itself"* (Chief Information Officer - CIO). The data are initially accessible only to internal technicians, serving as a learning instrument about actual product usage rather than a vehicle for service delivery. Similarly, Delta equip its machines with sensors since 2017, noting that *"critical components were monitored to collect data throughout the asset lifecycle"* (Chief Operations Officer - COO).

Beyond product-level data, IK in Stage 1 begins to incorporate nascent customer knowledge, gathered through structured but preliminary interactions. Gamma leverage IoT data collected since 2015 to hypothesize digital service proposals: *"We actively involved selected customers through a targeted survey to validate our hypotheses on digital services and gather valuable feedback before moving into development"* (Service Specialist). Delta present an early-stage service concept at a major international trade fair, using customer reactions as a first-order signal of market interest: *"In 2018, at the most important trade fair for our sector, we presented the early-stage hypothesized concept to our key customers, testing their interest and gathering essential insights for its subsequent development"* (COO). These interactions represent the first steps in converting product-level IK into customer-relevant service intelligence, establishing the informational foundation for PSSs development.

4.1.2 Lean startup mechanisms

The dominant Lean Startup mechanism in Stage 1 is the Think-Make-Check cycle. In the Think phase, firms articulate and structure hypotheses about customer problems before committing to development. Beta hypothesize that lack of visibility on product use hampered quality improvements and service innovation. Gamma identifies that customers fail to recognize the value of previously free services and begins designing service contract: *"The idea was to make customers recognize the value and make them pay for the supporting activities"* (Service Specialist). Alpha hypothesize that customers need long-term operational reliability rather than transactional support: *"The time had come to expand the offer and think about how to constantly guarantee the continuity of the operational activities of our assets"* (Executive). This problem framing directs subsequent experiments.

In the Make phase, firms develop early-stage digital service configurations integrating physical products, connectivity, and service support. Alpha develops a data platform providing AI- and IoT-enabled asset diagnostics: *"IoT inspection data, photos and videos are collected in a component inspection repository; there is an assessment of the asset status, and recommendations are elaborated using AI and analytics tools"* (Executive). In parallel, Alpha develops a B2B e-commerce platform for spare parts and an advanced analytics suite for predictive maintenance and power forecasting. Beta extends its web and mobile monitoring platform - previously used only by internal technicians - to customers, offering remote oven monitoring and fleet management as a complimentary service: *"We combined the digitalized product with a service: a web and a mobile platforms that allow us to control the ovens at any time, even remotely, in real time"* (Chief Experience Officer - CXO). Gamma integrates a remote monitoring platform into its boiler service contracts *"to provide analysis at three levels: for the end customer, for service partners, and for the company which has full control and access to all information"* (CEO). Delta introduces preventive maintenance and anomaly detection services: *"We combined the tele-assistance and monitoring of the machine data... it makes sense to combine remote assistance and data monitoring"* (Operations Manager).

In the Check phase, PSSs are tested. To this end, all solutions are deliberately limited in scope. Beta offers its platform for free initially, treating it as a learning instrument rather than a revenue vehicle. Alpha positions its digital services as value-added components of existing contracts. Gamma and Delta conduct pilot projects with selected clients. As Gamma's President acknowledges: *"We began with prototype phases to thoroughly understand the needs and determine how to proceed"*. Delta's COO confirmes the same logic: *"The digital services developed underwent a testing phase with technicians on selected clients in Italy and Europe before expanding the offering"*. Thanks to this approach, firms gather feedback: customer responses to the new value propositions provide empirical signals about which service configurations generate value.

4.2 Stage 2: Solution validation

Following initial experiments, firms enter a solution validation phase in which they refine digital infrastructures and service functionalities. The emphasis shifts from testing whether PSSs create value to ensuring they do so effectively and in a scalable way.

4.2.1 Intelligent knowledge evolution

In Stage 2, IK evolves from product-level data toward richer forms of intelligence, including customer-behavioural and operational insights, which inform service refinement and progressively support BM optimization.

Beta illustrates this transition: its platform evolves from basic monitoring to an AI-enabled system that analyses usage patterns and automates operations: "*The platforms use AI to analyse usage patterns, provide consumption notifications, and automate certain operations*" (CXO). Similarly, Alpha consolidates fragmented digital platforms into a single interface to improve usability based on customer interaction data: "*We moved from a multichannel system to a single-sign-on platform that customers found easier to access*" (Executive). Gamma's GECO platform (GEnerators Characterization and Optimization) represents a further step in this integration process. The platform combines operational data, predictive analytics, and service interfaces within a single digital environment that "*supports boiler selection and predictive maintenance*" (Service Manager). By consolidating previously fragmented service and operational data into a unified analytical infrastructure, GECO enables multi-level insights for customers, service partners, and the focal firm simultaneously. Delta integrates edge computing capabilities with existing cloud and AI systems: "*While AI was initially employed to analyse data collected from IoT sensors in the cloud, it is now applied directly at the machine level - on the edge. This allows for faster, localized data processing and real-time decision-making, reducing latency and enabling immediate responses to anomalies*" (COO). This shift moves knowledge generation closer to operations, enabling faster responses to anomalies.

4.2.1 Lean startup mechanisms

The dominant Lean Startup mechanism in Stage 2 is validated learning applied to PSSs refinement. Customer feedback accumulated at the end of Stage 1 becomes the empirical basis for systematic service and infrastructure optimization.

Alpha unifies its fragmented platforms into a single cohesive interface with single sign-on access, directly responding to customer-reported usability barriers. Beta merges its separate web and mobile applications into one synchronized platform: "*Using the same code, we produced an application with two interfaces, one for the mobile version and one for the online one. In contrast to the past, when they were handled individually and might display different data, we now satisfy customer preference to have integrated applications that are always aligned*" (CIO). Beyond infrastructure consolidation, Beta introduces a new generation of smart ovens equipped with IoT sensors, AI-driven anomaly detection, and a connected control panel enabling direct remote intervention, exemplifying how product innovation and service innovation become tightly interwoven through validated learning. Gamma consolidates previously separated service functionalities into the GECO platform, making all insights and performance reports accessible through a unified, user-friendly interface that "*enhances transparency, usability, and customer engagement*" (Service Manager). Delta advances its AI capabilities to the edge level, streamlining service delivery and incorporating functionalities "*reflecting insights gathered from customer feedback*" (COO).

Next to value offering optimization, Stage 2 marks the critical transition from complimentary or experimental service access to sustainable recurring revenue models. Beta provides the clearest illustration: having offered its platform for free in Stage 1, it begins charging for the enhanced, feature-rich service, communicating to customers that "*to maintain it and ensure functionality, there is a cost the company must bear in terms of people and resources dedicated to the project... taking advantage of this type of feature implies a cost; to continue accessing it, a subscription is required*" (CXO). This transition is legitimized by the demonstrated value: customers who experienced the platform usefulness are willing to pay for its continued, enhanced availability. Gamma pushes multi-year service packages: "*The company is now pushing to sell packages with a duration of 3-5 years. In case of subscription for more than one year, the annual or monthly price remains fixed*" (Service Specialist). Delta moves toward subscription-based contracts coupled with machine sales: "*We are moving towards subscription-based contracts. The sales of the machines are coupled with a yearly-basis subscription fee*" (Operations Manager).

The validation implemented in Stage 2 provides the foundation for the more ambitious ecosystem-level experimentation that characterizes Stage 3.

4.3 Stage 3: Extended and ecosystem-oriented experiments

In Stage 3, manufacturers leverage the consolidated capabilities and validated BM configurations developed in Stages 1 and 2 to expand their service portfolios and engage in broader ecosystem collaborations, where value creation, delivery, and capture are no longer confined within the firm's boundaries but distributed across a

network of interconnected stakeholders. Empirical evidence for this stage mainly derives from Alpha and Beta, which progressed more rapidly in the DS journey; the same trajectory is nonetheless expected for medium-sized firms, albeit at a slower pace.

4.3.1 Intelligent knowledge evolution

In Stage 3, IK expands to ecosystem-level knowledge: it not only informs operational decisions within firms, but also shapes how value is co-created across partners and customers. As digital platforms open to external actors, the knowledge generated through connected assets becomes a shared resource that supports coordinated service delivery. For instance, Alpha progressively opens its digital platform to external partners and begins to monetize operational data, recognizing that *"We are part of an ecosystem where we need to connect our data to others and, the other way around, connect others into our ecosystem"* (Executive). Therefore, IK evolves from an internal analytical resource into a mechanism that supports ecosystem coordination and contractual governance: the continuous knowledge generated by connected assets provides the objective basis for measuring value delivery and managing long-term service relationships.

4.3.2 Lean startup mechanisms

Stage 3 reactivates the Think-Make-Check cycle at the ecosystem level, applying Lean Startup logic to a new form of experiments where the hypotheses being tested now require engagement with external stakeholders.

In the Think phase, firms engage in hypothesis-driven ideation about ecosystem-level PSSs. Alpha hypothesizes that opening its digital platform to third-party partners could unlock new service opportunities and revenue streams: *"At the industry level, several players operate around the company. We recognized the importance of becoming an active part of this broader ecosystem, staying open, avoiding silos, and fostering coordinated integration among stakeholders"* (Executive). This hypothesis involves framing data access and system interoperability as foundational to future value propositions. Beta begins questioning the limitations of the product sales model and hypothesizes an alternative BM based on usage: *"Some key customers indicated that their interest in purchasing ovens was starting to decline, while there was growing interest in rental programs"* (CXO). Critically, Beta's Think phase extends beyond customers to include dealers: *"We began moving in this direction by involving not only customers, to better understand how to design and develop this offering, but also the dealers who act as intermediaries between us and the customers. This step was crucial: engaging the dealers was essential to maintain their trust and ensure their collaboration, consequently safeguarding our market position"* (CXO).

In the Make phase, firms translate ecosystem hypotheses into new PSSs involving complex usage- and outcome-based contracts. Alpha operationalizes its ecosystem strategy by exposing APIs and enabling integration with customers' internal systems and third-party providers, co-developing services with ecosystem actors and embedding its solutions into broader customer workflows. In parallel, Alpha introduces performance-based contracts: *"We offer what we call 'power solutions': not just the uptime, but we also guarantee the output by collaborating with partners at the industry level"* (Executive). Beta operationalizes its rental hypothesis by launching a five-year oven rental model with pay-per-use pricing logic. The offering is built on a dedicated digital platform through which customers independently configure their rental, specifying expected usage that directly determine pricing: *"Through a dedicated platform, the customer independently selects the oven, including all desired features and optional accessories. Customers specify expected daily usage hours, which determine pricing. The system then automatically identifies the authorized resellers in the customer's area who have joined the program and generates a summary displaying the monthly installation fee, the required monthly payment, and the total value of services provided"* (Project Manager). The subscription fee includes not only the equipment itself but also predictive maintenance and full technical support throughout the contract period.

In the Check phase, firms engage in ecosystem-level test: rather than selected customers as in Stage 1, Stage 3 piloting involves assembling and testing multi-actor service delivery configurations, assessing not only customer acceptance but also partner coordination effectiveness. Beta's rental program is explicitly structured as a controlled ecosystem pilot: *"The oven rental project started as a pilot... we have currently selected a few dealers who are collaborating on the project, and now the rental service is available in specific regions. It is not yet a project that has been expanded nationwide"* (CXO). Alpha applies the same graduated approach to ecosystem engagement, explicitly recognizing the need for incremental partner involvement: *"We need to proceed through steps, involving the partners gradually and understanding the respective benefits"* (Executive).

Throughout the DS journey, firms have evolved from single-stream product sales to complex, data-enabled, ecosystem-distributed value capture systems, a transformation made possible through the iterative application of Lean Startup experimentation guided by progressively sophisticated IK.

5 Discussion and Conclusions

This study investigated how incumbent manufacturers navigate the DS process, introducing IK as a key enabler and presenting the Lean Startup approach as an interpretative lens. By analysing four B2B manufacturers, we identify a three-stage pathway in which IK and Lean Startup mechanisms co-evolve.

In Step 1, firms explore DS opportunities by testing hypotheses about customer problems. At this stage, experiments primarily aim to achieve problem-solution fit: firms identify relevant customer problems and test whether proposed digital solutions can effectively address them (Blank & Eckhardt, 2024), leveraging early forms of IK based on product usage data and initial customer interactions.

In Step 2, firms consolidate insights emerging from early experiments and refine PSSs accordingly. The accumulation and analysis of customer interaction data enable the development of more advanced forms of IK that guides PSSs improvements in terms of both digital infrastructure and service functions. Hence, firms move toward PSS-market fit, achieved since integrated PSSs demonstrate sustained adoption and willingness to pay.

In Step 3, firms build on the knowledge accumulated in earlier stages to engage ecosystem partners. Experiments continue but focus on expanding BMs within a wider ecosystem.

Overall, our findings show that IK is a key element in the DS journey, which can be interpreted through a Lean startup lens. Experiments generate knowledge about customer problems and service value, enabling the transition from problem-solution fit to PSS-market fit.

From a theoretical perspective, the study shows that Lean Startup functions as an adaptive learning mechanism for incumbents undergoing DS (Blank & Eckhardt, 2024; Ghezzi & Cavallo, 2020), thus expanding the applicability of this approach beyond startup contexts. Furthermore, it contributes to DS research by explaining how experiments and knowledge generation drive digital PSSs development (Kohtamäki et al., 2020; Sjödin et al., 2020).

From a managerial standpoint, our study shows that experiments enable firms to navigate DS uncertainty: first validating problem-solution fit through experimentation, then refining services to achieve PSS-market fit, and finally expanding digital offerings through ecosystem collaboration.

This study has limitations, including the small sample. Future research could examine broader contexts and factors influencing DS experimentation.

Leading Intelligent Knowledge Management for Data-Driven Sustainable Innovation: Micro-Practices that Build Human–AI Complementarities

Vittoria Magrelli[1], Isotta Vazzoler[1], Dario N. Palmucci[2], Luca Giraldi[2]
[1]University Gabriele D'Annunzio, Chieti-Pescara, Italy
[2]University of Turin, Turin, Italy

Abstract

Intelligent Knowledge Management (IKM) represents a shift from static knowledge repositories toward dynamic socio-technical arrangements in which data, human expertise, and algorithmic inference are continuously combined to support organisational action. While existing research has examined knowledge creation processes, analytics capabilities, and the implications of AI for decision-making, less attention has been paid to how leaders make these elements work together in practice—particularly in the context of sustainability-oriented innovation. Addressing this gap, this study explores how leadership is enacted through everyday practices that transform AI- and data-driven outputs into actionable organisational knowledge. Adopting a practice-theory perspective, the study conceptualises leadership as a set of situated micro-practices through which problems are framed, insights are interpreted, and learning is stabilised over time. Empirically, it draws on a qualitative, comparative case study of organisations engaged in AI-enabled knowledge work for sustainability. The research combines semi-structured interviews with senior leaders and analytics professionals, analysis of internal artefacts such as knowledge governance protocols and AI guidelines, and observational material where accessible. An abductive analytical approach is used to iteratively connect empirical patterns with theoretical insights from knowledge management, organisational learning, and human–AI augmentation literatures. The findings are expected to show that IKM becomes effective not through technology adoption alone, but through leadership practices that makes knowledge usable. These include framing sustainability-relevant problems in ways that guide analytical attention, curating and translating AI-generated outputs for diverse organisational audiences, fostering productive contestation that balances critical scrutiny with integration of experiential knowledge, and embedding insights into routines that sustain learning beyond individual projects. From a recombinant innovation perspective, these practices enable the continuous recombination of heterogeneous knowledge—spanning past and present, human and machine—thereby supporting cumulative rather than episodic innovation. By foregrounding leadership as a governance mechanism of intelligent knowledge, the study contributes to bridging knowledge management, digital transformation, and sustainability research, offering both theoretical refinement and practical guidance for organisations operating in complex, data-rich environments.

Keywords: Intelligence Knowledge Management; Leadership, Data-driven innovation; Sustainable innovation; Organizational learning; Recombinant innovation.

Paper type: Academic Research Paper

1 Introduction

Intelligent Knowledge Management (IKM) can be understood as a shift from knowledge management systems conceived as repositories toward socio-technical arrangements that continuously transform data, experience, and interpretation into knowledge that can be used (Alavi & Leidner, 2001; Nonaka, 1994). This shift is not primarily technological. It is managerial: it concerns how organisations frame problems, mobilise attention, coordinate across functions, and stabilise learning routines while integrating AI, advanced analytics, and natural language technologies into everyday work (Davenport & Kirby, 2016; Raisch & Krakowski, 2021). In this sense, IKM is best approached as a capability for orchestrating human judgement and machine-supported inference, rather than as the adoption of an additional tool (Raisch & Krakowski, 2021). The concept draws on and extends classical knowledge management theory, which distinguished between explicit and tacit knowledge and emphasised the social processes through which knowledge is created, shared, and institutionalised within organisations (Nonaka & Takeuchi, 1995; Grant, 1996). What distinguishes IKM from earlier frameworks is the integration of machine learning, natural language processing, and large-scale data analytics into these social processes, creating what some scholars describe as hybrid epistemic arrangements in which human and algorithmic inference are mutually constitutive (Faraj et al., 2018). This integration introduces both new opportunities and new governance challenges. On the opportunity side, AI-enabled systems can surface patterns in large, heterogeneous datasets that would be invisible to unaided human attention, extending the reach of organisational sensemaking and enabling more systematic exploration of innovation possibilities (Berente et al.,

2021). On the governance side, the very abundance of data and the opacity of algorithmic models can generate interpretive overload, introduce new forms of bias, and create a false sense of precision that undermines rather than supports deliberative decision-making (Cukier et al., 2021; Brynjolfsson & McAfee, 2017). Sustainability-oriented innovation increasingly depends on data-driven exploration and recombination: organisations search for new ways to reduce waste and resource intensity, redesign value propositions, and experiment with more durable forms of organising (Geissdoerfer et al., 2017; Bocken et al., 2014). The transition toward circular economy models, for instance, generates vast streams of product lifecycle, resource flow, and consumer behaviour data that require intelligent knowledge systems to be translated into actionable insights (Ellen MacArthur Foundation, 2013; Lacy & Rutqvist, 2015). Similarly, organisations pursuing science-based emissions targets or responsible supply chain commitments must develop the capacity to combine environmental performance data with operational and strategic knowledge in ways that inform innovation decisions across business units and value chain boundaries (Nambisan et al., 2017). Importantly, recombination is not only about producing novelty from "new" data; it also depends on how organisations retrieve, reinterpret, and redeploy dispersed knowledge over time. Recent process work on recombinant innovation shows how firms can mobilise "old" knowledge through distinct phases—recovering, reviving, and renewing—so that it becomes a platform for strategic renewal rather than a constraint (Magrelli et al., 2025). This reinforces a managerial point that is central to IKM: insights do not travel automatically, and AI outputs do not become organisational knowledge by themselves. They become actionable only when leaders shape the conditions under which they are interpreted, challenged, and translated into decisions and routines (Weick, 1995; Argote & Miron-Spektor, 2011). Therefore, as highlighted by recent studies, this makes leadership central (Palmucci & Ferraris, 2026; Palmucci et al., 2025): not as generic support for digital transformation, but as a set of micro-practices that govern how knowledge is produced, circulated, and used (Felin et al., 2015).

2 Research Gap and Purpose

Existing work offers strong foundations on (i) organisational knowledge creation and the socio-technical nature of knowledge systems (Nonaka, 1994; Alavi & Leidner, 2001), (ii) analytics capabilities and their organisational implications (Akter et al., 2016; Ferraris et al., 2019), and (iii) the automation–augmentation tension introduced by AI (Raisch & Krakowski, 2021). Scholarship on dynamic capabilities and knowledge-based views of the firm has further established that the ability to integrate, build, and reconfigure knowledge resources is a primary driver of competitive advantage and organisational resilience (Teece et al., 1997; Kogut & Zander, 1992). More recently, research on digital transformation has examined how AI and data analytics reshape organisational processes, competitive positioning, and value creation (Vial, 2019; Zuboff, 2019). What remains under-specified is how leaders *actually* make IKM work in practice when the strategic intent is sustainable innovation: how they build human–AI complementarities, prevent "data abundance" from turning into interpretive fragmentation, and convert analytics into cumulative organisational learning (Argote & Miron-Spektor, 2011; Weick, 1995). Building on a recombinant innovation lens, this also means explaining how leaders enable the organisation to recombine heterogeneous knowledge—new and old, human and machine-mediated—into a coherent innovation trajectory (Magrelli et al., 2025).

This study addresses the following research question: How do leaders enact Intelligent Knowledge Management in their day-to-day practice to enable data-driven sustainable innovation? This question is grounded in a practice-theory perspective that treats leadership not as a set of traits or styles but as something that is accomplished through situated, concrete activities—what strategy scholars have called "strategy-as-practice" and what organisation theorists describe as the microfoundations of collective action (Jarzabkowski, 2005; Felin et al., 2015). A practice lens is particularly suited to study IKM because the translation of data and AI outputs into organisational knowledge is fundamentally a social achievement: it happens in meetings, briefing sessions, review processes, and informal exchanges through which leaders frame what counts as relevant evidence, who is authorised to challenge a model's outputs, and how analytically derived insights are connected to organisational memory and strategy (Orlikowski, 2002). The empirical focus is on leadership micro-practices that (a) frame and prioritise sustainability-relevant innovation problems (Abdulmuhsin et al., 2025), (b) organise interpretation and contestation of AI- and analytics-based insights so that they become shared understandings rather than isolated outputs, (c) sustain cross-functional and cross-boundary knowledge flows that keep innovation efforts coordinated, and (d) institutionalise learning into routines and decision processes that endure beyond individual projects (Felin et al., 2015; Argote & Miron-Spektor, 2011).

3 Methodology

The study follows a qualitative, comparative case design (Eisenhardt, 1989). It investigates 10 organisations selected through purposive, theory-driven sampling to maximise variation in (i) firm size, (ii) sector, and (iii) geographical setting, while keeping cases comparable in terms of AI-enabled knowledge work for sustainability. The target organisations are European-headquartered firms (primarily Italy and other EU countries), where sustainability reporting and innovation programmes are increasingly institutionalised, and where comparable regulatory and market pressures support cross-case comparison. We focus mainly on medium-sized and large organisations (typically >250 employees)—as they are more likely to have formalised knowledge governance, dedicated analytics/AI roles, and routinised innovation processes—while including a limited number of smaller firms as contrast cases where such routines are still emerging. Sectorally, cases will be drawn from data-rich and/or resource-intensive industries in which sustainability-oriented innovation is salient (e.g., manufacturing and industrial supply chains, logistics/retail operations, energy/utilities, and consumer-facing circular economy domains such as agri-food/fashion). Eligible cases must have introduced AI- and analytics-enabled knowledge processes explicitly linked to sustainability-oriented innovation initiatives (e.g., circular experimentation, resource optimisation, sustainable supply-chain redesign, or data-enabled service innovation) (Bocken et al., 2014; Geissdoerfer et al., 2017).

Data collection combines semi-structured interviews with senior leaders and key knowledge/analytics roles, internal artefacts (knowledge protocols, AI use guidelines, analytics routines, training materials), and observational material where accessible. Interviews will follow a topic guide designed to elicit detailed accounts of how leaders respond to specific episodes in which AI- or analytics-generated insights were contested, reinterpreted, or integrated into innovation decisions. This approach draws on the critical incident technique (Flanagan, 1954) as a way of grounding leadership accounts in specific behavioural episodes rather than general attitudes or self-reports. Internal artefacts will be analysed as materialised traces of knowledge governance: they reveal how organisations formalise (or fail to formalise) the conditions under which data and AI outputs are to be interpreted and acted upon (Carlile, 2004). Observational material, where accessible, will allow direct observation of knowledge practices in situ, providing a triangulation point for interview and document data (Yin, 2018). The analysis will use an abductive approach to connect emergent leadership practices with mechanisms suggested by socio-technical KM theory, organisational learning, and human–AI augmentation perspectives (Alavi & Leidner, 2001; Raisch & Krakowski, 2021). Abductive analysis involves moving iteratively between empirical observations and theoretical concepts, allowing the study to both leverage existing frameworks and generate new theoretical insights where the data reveals patterns that existing theories do not adequately explain (Timmermans & Tavory, 2012). The coding process will combine deductive codes derived from the theoretical framework (e.g., framing, curation, contestation, institutionalisation) with inductive codes emerging from the data, following established protocols for qualitative case research (Gioia et al., 2013).

4 Expected Results and Contributions

The study aims to produce a practice-grounded model of IKM leadership micro-practices that explains how leaders make intelligent knowledge usable for sustainability-oriented innovation. Anticipated mechanisms include: (1) problem framing and attention design, through which leaders define which sustainability tensions deserve analytic investment and experimentation (Weick, 1995); (2) curation and translation, through which AI- and analytics-based outputs are rendered interpretable and relevant for heterogeneous stakeholders; (3) productive contestation, through which leaders create safe spaces to challenge model-driven insights and integrate them with experiential knowledge, avoiding both blind trust and defensive rejection (Raisch & Krakowski, 2021); and (4) institutionalising learning, through which insights are embedded into routines, cross-functional interfaces, and repeatable innovation practices (Argote & Miron-Spektor, 2011). A recombinant innovation perspective sharpens the contribution by showing how leaders enable recombination across time and levels—mobilising dispersed knowledge assets and connecting them to present data streams and AI-supported inferences—so that innovation becomes cumulative rather than episodic (Magrelli et al., 2025). The expected contribution is to reposition leadership as a governance mechanism of intelligent knowledge in data-driven sustainable innovation, showing how human judgement and AI can be designed as complements in everyday managerial work (Felin et al., 2015; Davenport & Kirby, 2016). Beyond the theoretical contribution, the study is expected to generate practical implications for managers and organisations navigating the integration of AI and analytics into innovation processes. Specifically, the resulting model of IKM micro-practices can inform the design of leadership development programmes, knowledge governance frameworks, and AI deployment guidelines that position human expertise and machine intelligence as complementary rather than competing sources of organisational capability (Brynjolfsson & McAfee, 2017; Berente et al., 2021). The study also

contributes to the IFKAD community's interest in intelligent knowledge as a resource for sustainable organising by providing an empirically grounded account of how data-driven knowledge practices can be institutionally designed to serve long-term sustainability goals rather than short-term efficiency gains (Calabrese et al., 2019). In doing so, it responds to calls for research that bridges knowledge management, innovation studies, and sustainability science in ways that are actionable for practitioners operating in complex, data-rich environments (Lichtenthaler, 2019).

5 Ethics Declaration

This paper reports an ongoing qualitative study based on semi-structured interviews, complemented by internal documents and observation where available. The research is subject to institutional ethical review and adheres to standard academic guidelines, ensuring informed consent, voluntary participation, confidentiality, and anonymisation of all data. Participants receive clear information prior to data collection, in line with European data protection standards. No sensitive personal data or vulnerable populations are involved, and no deceptive or high-risk procedures are used. Therefore, no additional ethical approval is required beyond standard institutional review.

6 AI Declaration

Artificial intelligence tools were used in a limited and non-systematic manner during the preparation of this paper. Their use was restricted to minor language refinement and English proofreading, without influencing the core ideas, analysis, or conclusions. All content, arguments, and interpretations remain the sole responsibility of the authors. AI assistance was applied only for fine-tuning purposes to improve clarity, readability, and overall linguistic accuracy.

Abstract

The packaging industry is currently undergoing a profound transformation driven by the Twin Transition, which combines environmental sustainability and digitalisation as key levers for industrial competitiveness and regulatory compliance. European policy frameworks, including the Ecodesign for Sustainable Products Regulation and the Circular Economy Action Plan, increasingly require firms to integrate eco-design principles, lifecycle thinking, and digital traceability tools into their production and decision-making processes. However, despite the strategic relevance of these developments, the actual level of adoption of green and digital strategies within the packaging sector remains uneven and insufficiently documented. This study aims to map the maturity level of green and digital strategy adoption in the packaging industry, adopting a knowledge-based perspective consistent with Eco-design and focus the study investigates how firms are operationalizing sustainability- and digital-related knowledge to transit their production processes towards a more green and sustainable strategies.
In the context of the transition toward a circular economy and industrial digitalization (Ghobakhloo et al., 2020), the packaging sector faces complex challenges related to environmental sustainability and technological innovation. Digital transformation, integrated with eco-design principles and traceability across the product lifecycle, emerges as a strategic lever to reduce environmental impacts and ensure regulatory compliance (Pagoropoulos et al., 2017; Kristoffersen et al., 2020). This study conducts an empirical, real-based analysis derived from a structured survey administered to entrepreneurs, scientist, consultant and operators in the packaging sector. The resulting mapping enables the identification criterias that allow to prioritize strategies for managing the end-of-life (EoL) phase of packaging materials, focusing on criteria such as environmental impact, economic feasibility, regulatory compliance, technological readiness, and stakeholder acceptance with Analytic Hierarchy Process (AHP) method derived from Multi-Criteria Decision Analysis (MCDA). The theoretical contribution lies in defining sustainability criteria for packaging in line with the new European regulations for Packaging and Packaging Waste. The expected results include a description of the state of the art on the twin transition and the structuring of sustainability criteria priorities among packaging producers and users in the management of end of life of packaging. This paper can help facilitate decision-making processes for packaging entrepreneurs in all the supply chain.

Keywords: Twin Transition, packaging industry, ecodesign, Multi-Criteria Decision Analysis, Analytic Hierarchy Process, survey

Paper type: Academic Research Paper

1 Introduction

In the context of the global transition toward circular economy (CE) models, the packaging sector represents a critical interface between industrial production systems and consumer behavior. Packaging has become a key target for systemic redesign in the shift to resource-efficient and sustainable production systems. Its prominent presence in consumer markets and significant contribution to post-consumer waste make it a pivotal intervention point for circular economy (CE) strategies (MacArthur, 2013). Regulations such as the European Union's Packaging and Packaging Waste Regulation (PPWR or 2025/40), effective from January 2025, impose stringent requirements whereby all packaging must be recyclable or reusable in technically and economically sustainable ways. However, the transition to circularity cannot be achieved solely through technological redesign; it also depends on active consumer involvement, whose preferences, awareness, and behavioral intentions determine the practical success of eco-designed solutions. To reduce the environmental impact associated with packaging, it is necessary to analyse production processes and materials involved, but particularly its end-of-life management. End-of-life packaging waste management has become a critical issue in pursuing sustainable development, especially in the European context, where environmental regulations and sustainability targets are stringent.

This paper presents:

- A systematised review to define the state of the art in the literature and thus the research questions and sustainability criterias that define decision making analysis.

- Application of AHP methodologies (Analytic Hierarchy Process (AHP) to construct a decision tree using the overall objective (strategy selection).

Following the bibliographic analysis, it emerged that neither the maturity level of packaging sector companies with respect to the Twin Transition nor the most relevant sustainability criteria to use in end-of-life packaging management are described in the literature. Moreover, there is a gap in business practices and a research gap in scientific publications on the application of AHP-based decision-making methods in end-of-life packaging design management. For this reason, this paper addresses the following two research questions (RQs):

- *RQ1: What is the maturity level of packaging sector companies with respect to the Twin Transition, i.e., the integration of green and digital strategies into their processes?*
- *RQ2: What are the sustainability criteria perceived as most relevant by companies in evaluating end-of-life packaging strategies?*

The work is developed to address these research questions. Current practices, policies, and technological innovations were examined in a sample of companies, professionals and academic researcher in the packaging sector.

Recent studies have highlighted that sustainable innovation is no longer purely a technological matter but a socio-technical process requiring coordination among various actors, including producers, designers, policymakers, and consumers (McDonough and Braungart, 2002). Co-design methodologies have proven effective in integrating stakeholder expertise and fostering cross-disciplinary mutual learning (Kirchherr, Reike, and Hekkert, 2017).

The main contribution of this study lies in its integrative analytical framework, which aims to bridge the intrinsic gap between company-driven design criteria and consumer-driven cognitive requirements regarding product sustainability. This comparative methodology was developed by mapping quantitative parameters derived from Multi-Criteria Decision Analysis (MCDA) such as AHP against qualitative insights from consumer behavior studies. In particular, the design criteria were selected through a literature review. Scientific articles were identified using the Scopus search engine with the keywords: circular packaging, technological innovation, customization end of life packaging, design for recycling, AHP method. The criterias have been submitted to a focus group of six experts from academy, association and industry for participatory discussion and to define those most appropriate for the packaging sector.

2 Theoretical Framework

The adoption of green and digital strategies in the packaging industry can be interpreted as a multidimensional and knowledge-intensive process, in which environmental, technological, regulatory, economic, behavioral, and strategic dimensions are deeply interconnected. Sustainable packaging does not simply derive from replacing one material with another; rather, it requires firms to evaluate the entire packaging system, from raw material sourcing and design to production, distribution, use, collection, recycling, recovery, or final disposal. In this perspective, life cycle thinking represents an essential theoretical foundation, as it allows for the identification of environmental impacts and trade-offs along the entire product system. Finnveden et al. (2009) highlight the importance of Life Cycle Assessment as a method to evaluate environmental impacts at different life cycle stages, while Laurent et al. (2014) show that, in waste management systems, environmental results are strongly influenced by system boundaries, treatment options, and methodological assumptions. This aspect is particularly relevant for packaging, where a solution that appears sustainable in one phase may generate negative effects in another. Jeswani, Krüger, and Russ (2021), for example, demonstrate that chemical recycling via pyrolysis, mechanical recycling, and energy recovery must be compared through a life cycle perspective, as none of these options can be considered ecologically less impactful regardless of the technological and systemic conditions in which it is applied.

Within this framework, the circular economy offers a broader conceptual perspective for interpreting the transition toward sustainable packaging. The shift from linear to circular models implies the redesign of packaging systems in order to reduce the use of virgin materials, increase recyclability, promote reuse, and close material loops. Hopewell, Dvorak, and Kosior (2009) show that plastic recycling represents both a great opportunity and a complex challenge, as its effectiveness depends on material properties, collection systems, contamination levels, sorting technologies, and the demand for secondary materials. Similarly, Lazarevic et al. (2010) highlight that plastic waste management must be evaluated from a life cycle perspective, as different recycling and recovery options entail uncertainty and environmental trade-offs. More generally, Geissdoerfer et al. (2017) define the circular economy as a new sustainability paradigm based on closing, slowing, and narrowing resource loops. Applied to the packaging industry, this paradigm suggests that sustainability cannot be achieved

solely through downstream recycling, but requires systemic redesign, supply chain coordination, and new forms of value creation.

However, the adoption of sustainable packaging solutions also depends on their technical and infrastructural feasibility. Ecologically preferable solutions can be implemented only when they are technologically mature, scalable, and compatible with production processes, logistics systems, and waste management infrastructure. Mankins (2009), through the concept of technology readiness assessment, provides a useful framework for evaluating whether a technology is sufficiently mature for industrial application. This is relevant for packaging innovations such as bio-based materials, biodegradable and compostable packaging, mechanical recycling, chemical recycling, reusable systems, and smart packaging, which may differ significantly in terms of maturity, reliability, and scalability. Furthermore, Yu et al. (2023) show that technological innovation toward sustainability is influenced not only by internal firm capabilities but also by external factors such as environmental regulation, public support, and financial development. This suggests that the feasibility of green packaging strategies depends on the interaction between internal knowledge, technological capabilities, and the broader institutional and infrastructural context.

The regulatory dimension further reinforces the need for a structured, knowledge-based approach. Packaging firms operate increasingly within a framework of environmental requirements concerning recyclability, recycled content, labeling, packaging minimization, waste prevention, and responsibility along the product life cycle. Weinrich et al. (2024), by analyzing decision-making processes regarding sustainable packaging options in the European food sector, show that packaging decisions are influenced by environmental, technical, economic, regulatory, and organizational considerations. In this perspective, the "Packaging and Packaging Waste Regulation – PPWR, Regulation (EU) 2025/40" assumes a central role, as it establishes a harmonized regulatory framework at the European level for packaging and packaging waste. The Regulation was published in the Official Journal of the European Union on January 22, 2025, entered into force on February 11, 2025, and will generally apply from August 12, 2026. It strengthens the centrality of requirements such as recyclability, minimum recycled content, reduction of superfluous packaging, waste prevention, reuse, refill systems, bio-based content, biodegradability and compostability of packaging, technical documentation, and harmonization of rules in the European internal market. Consequently, regulatory compliance no longer represents merely an administrative constraint, but becomes a driver of innovation, packaging redesign, and strategic adaptation. Firms must therefore not only understand regulatory obligations but also translate them into criteria for design, material selection, supplier management, reporting systems, traceability, and market communication.

Economic sustainability also plays a decisive role in the adoption of sustainable and digital strategies. Sustainable packaging solutions are more likely to be adopted when environmental improvements can be reconciled with cost efficiency, investment feasibility, and competitive value. Life cycle-based approaches can help firms identify environmental and economic trade-offs, for example, when higher material costs are offset by lower transportation, waste management, or regulatory compliance costs (Finnveden et al., 2009; Laurent et al., 2014). At the same time, circular economy strategies can generate value through resource efficiency, waste reduction, new business models, and increased resilience, although they often require investments in redesign, reverse logistics, and infrastructure (Geissdoerfer et al., 2017). Therefore, firms must evaluate sustainable packaging not only as an environmental or regulatory requirement but also as a potential source of long-term competitiveness.

Consumer behavior represents a further essential component of this transition. Packaging is a visible interface between firms and consumers, capable of influencing purchasing decisions, disposal practices, and trust in environmental claims. Testa, Iovino, and Iraldo (2020) show that information search mediates the relationship between the circular economy and consumer behavior in the purchase of circular packaging. This indicates that the acceptance of sustainable packaging by consumers depends on the availability, credibility, and clarity of information. Digital technologies can support this process through QR codes, smart labels, digital product passports, and traceability systems, which are capable of providing information on material composition, recyclability, environmental impact, and correct disposal. However, these tools are effective only if consumers perceive them as accessible and reliable.

Finally, sustainable packaging assumes strategic and reputational relevance. Packaging can strengthen brand positioning, stakeholder legitimacy, and competitive differentiation when environmental claims are credible and supported by evidence. Sharma, Soodan, and Chakraborty (2026) highlight the role of "green marketing" in promoting brand reputation, suggesting that sustainability-oriented communication can contribute to trust and competitive positioning. However, reputational value depends on the consistency between actual environmental performance and communication practices, as claims not supported by evidence can expose firms to accusations of greenwashing.

Overall, the theoretical framework suggests that the adoption of sustainable and digital strategies in the packaging industry must be interpreted as a knowledge-based process. Firms must integrate environmental knowledge derived from Life Cycle Assessment, circular economy knowledge related to material flows, technological knowledge regarding maturity and scalability, regulatory, economic, and organizational knowledge, consumer knowledge, and strategic communication knowledge. Digital technologies act as enabling mechanisms that support data collection, traceability, compliance monitoring, consumer communication, and strategic decision-making. In this sense, the adoption of sustainable packaging emerges as a complex process in which firms combine digital objectives and capabilities to redesign packaging systems, reduce environmental impacts, respond to regulatory pressures, create economic value, and strengthen market legitimacy.

3 Methodology

To construct the theoretical framework and identify the main dimensions influencing the adoption of green and digital strategies in the packaging industry in Europe market, this study adopted a systematized literature review conducted via the ScienceDirect database. The systematized review incorporates certain procedures typical of systematic reviews—such as explicit search criteria, transparent source selection, and structured synthesis of contributions—without claiming the same level of exhaustiveness as a full systematic review (Grant & Booth, 2009). The search focused on identifying contributions relevant to defining the study's main theoretical domains: Life Cycle Assessment, circular economy, plastic recycling, technological feasibility, European packaging regulation, consumer behavior, and green marketing. Priority was given to peer-reviewed articles published in journals indexed on ScienceDirect, selected based on their relevance to sustainable packaging, green and digital transitions, and the development of the empirical framework. These sources were complemented by institutional references to the Packaging and Packaging Waste Regulation (PPWR), Regulation (EU) 2025/40, as a central regulatory element for understanding the pressures driving the adoption of sustainable packaging solutions.

The literature synthesis was conducted narratively, in line with the heterogeneity of the selected contributions. The aim was not to aggregate quantitative results but to critically organize knowledge from diverse disciplinary fields and integrate it into a unified interpretive framework. Following Snyder (2019), the review thus served as a tool to develop the study's theoretical foundation, clarify key adoption factors, and highlight the role of digital technologies as enabling mechanisms. In this perspective, the systematized review provides the conceptual basis for the empirical analysis, while transparently acknowledging its primary limitation: it is structured and replicable in its general criteria but does not aim to exhaustively census all available literature on the topic.

The criterias defined in previous letterature analysis have been discussed with brainstroming method with 6 experts in packaging, from accademic, industry, associations, consulting company and finally used in AHP method in order to derive relative priorities. The Analytic Hierarchy Process (AHP) is a structured multi-criteria decision-making method that helps evaluate complex choices by breaking them into hierarchies of criteria, sub-criteria, and alternatives.

AHP, developed by Thomas L. Saaty in the 1970s, starts by modeling the decision problem as a goal-oriented hierarchy, with the top level as the main objective (e.g., optimal end-of-life strategy), middle levels as criteria like cost or environmental impact, and the bottom as options like recycling or composting. Experts then perform pairwise comparisons using a 1-9 scale (1 for equal importance, 9 for extreme preference) to derive relative priorities, forming judgment matrices whose eigenvalues yield normalized weights and eigenvector-based scores. A consistency ratio check (ideally under 0.1) ensures reliable judgments by measuring inconsistency against random indices.

AHP Key Steps are:

- Hierarchy construction: Decompose the problem into levels for tangible (e.g., costs) and intangible (e.g., sustainability) factors.
- Pairwise comparisons: Compare elements at each level to build matrices.
- Priority calculation: Compute weights via principal eigenvector; aggregate across levels for final rankings.
- Synthesis and sensitivity: Combine results and test robustness to input changes.

AHP excels in packaging waste management by integrating diverse factors like recyclability, biodegradability, regulatory compliance, and economic viability,critical for packaging materials. It handles stakeholder trade-offs. (e.g., environmental vs. cost priorities) in scenarios like filler selection or disposal optimization, providing transparent, defensible decisions amid EU regulations on microplastics and circular economy goals. AHP's flexibility with qualitative/quantitative data, consistency verification, and group decision support make it ideal for non-structured problems like end-of-life packaging, where multiple actors (producers, regulators) must

balance sustainability and feasibility. AHP will not replace the decision-making process itself but it will generate information needed to make the decision and will present it in a structured way. The AHP is a method of solving problems that involve prioritisation of alternative solutions and is based on the evaluation of a set of criteria.

4 Analysis Results

Decision-making techniques have been long dominated by the cost-benefit analysis that uses the criterion of maximum total net benefit to choose the optimum solution (Colorni et al., 1998). The main limitation of such an approach is that all the effects of an activity are evaluated in monetary terms, so that when aspects that cannot be quantified into monetary units (like social and environmental issues) are dominant, the method is completely inappropriate.

In the packaging sector, the final stage of the life cycle of a product, retirement, is one that has been often ignored. The retirement stage begins when the customer no longer wants the product. What happens to a product after the end of its usage is of growing importance to the producer because of consumer demands and other growing pressures such as new legislation that mandates recovery and recycling of some products by their manufacturers. Actually in the industry we have almost 4 alternative in management the end of life of packaging: reuse, mechanical recycling, organic recycling and chemical recycling.

In the AHP multicriteria analysis method used in this work, a hierarchical structure is formed using the overall objective (Selction of the optimal packaging end of life mangement strategy) as the root of the decision tree, with each main criterion placed as its child. Each criterion, in turn, is detailed to provide additional descendants. At the lowest level of the tree are the end-of-life options (reuse, mechanical, chemical, and organic recycling) assigned to each leaf node of the tree. We have created this decision tree in order to allow to the decision-maker performs pairwise comparisons at each level between criteria that share the same parent node and assigns them relative weights. In the next step after Fuzzification and defuzzification (Lee et al. 2010) is possible to convert fuzzy-set information into digital data evaluating all end-of-life options against each other in relation to each criterion, assigning them relative weights. All these comparisons lead to priority vectors that are propagated through the hierarchy to arrive at a final priority vector for the set of end-of-life options. The decision-maker is thus enabled to base their decision on various criteria to which they have themselves assigned weights.

The hierarchical structure of the criteria used in the AHP model in our study is represented in the following Figure, where the factors influencing the end-of-life management of packaging and the strategic alternatives considered are illustrated in decision tree.

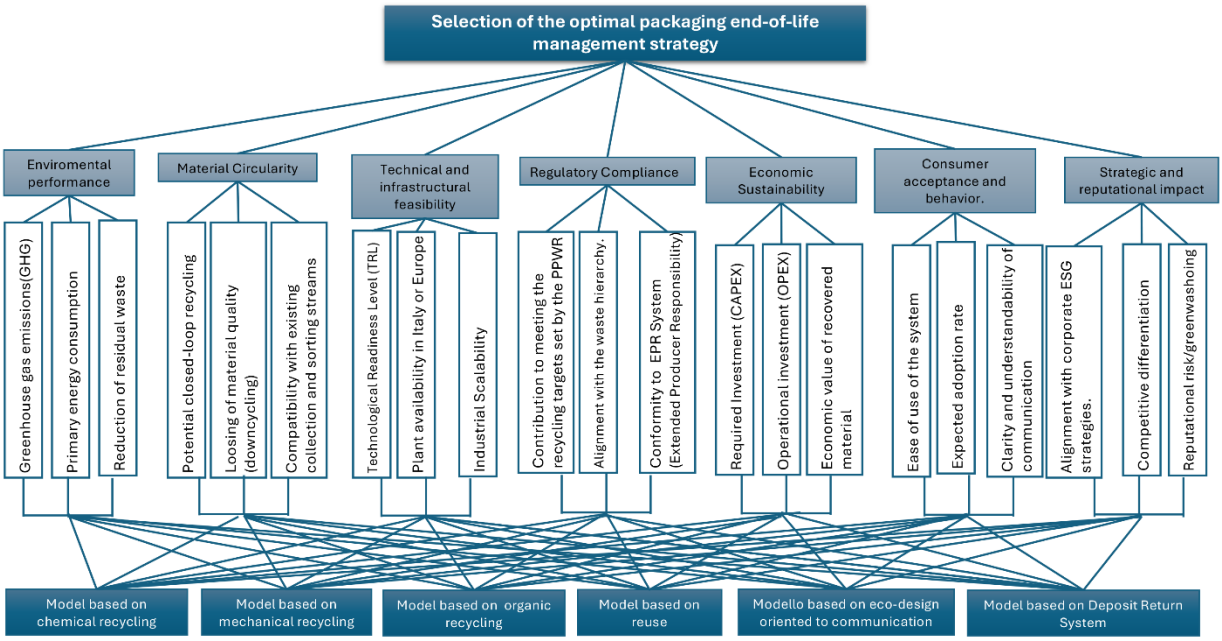

Figure 1: The hierarchical structure used by AHP in decision-making for end-of-life options for packaging: decision tree.

5 Conclusions

Decision-making for end-of-life of products, especially in packaging sector, is a difficult task. Many factors must be considered such as environmental, economic, social and so it becomes a multi- criteria decision problem. We have proposed one methodology, the AHP, that may help integrating all environmental, economic and social criteria in the decision-making process. The AHP is a simple and powerful tool that helps decision-makers structure and evaluate different alternatives. Incorporating environmental considerations, constraints stated by legislation and the voice of community in the decision-making process along with the economic judgements alters the decision for end-of-life of products. The main advantage of the AHP from the decision-maker point of view is that it s directly involved in the process. The decision-maker evaluates each pair of items he/she assesses. The result of the assessment is based only on the judgement of the decision-maker.In this paper we have demonstrate in the decision tree the criteria choosed and their connections.

When Traditional Knowledge Meets Digitalization: The Italian High-Quality Olive Oil Value Chain and The Platformized Markets

Sergio Conterjnic, Cristina Simone, Antonio Laudando
Sapienza, University of Rome. Rome, Italy

Abstract

The Agrifood sector is one of the recognized pillars of the Italian economy, generating 31,8 % of its GDP (Federalimentare, 2023) and providing labor to 17% of the Italian labor force (Istat, 2017). It is also one of the engines of the Italian exports, generating 8,1 % of annual Italian exports (Federalimentare, 2023). Some products are considered symbols of the agrifood "Made in Italy", such as pasta, olive oil, cheese, ham and wines. The agrifood sector has performed very well in the last decades, representing an excellent example of Italian food culture worldwide. In this paper, we will focus on the high-quality olive oil value chain. In 1960 the Italian government established the controlled appellation system for olive oils, designing the Protected Designation of Origin (PDO or DOP) and Protected Geographical Indicator (PGI or IGP). The support for this classification and certification is that the olive oil producers operating in a particular area owe their success primarily to the quality of their products and the inseparable link between these products and their *terroir*, i.e. the particular geographical area and environment that give their olive trees and olive oil their distinctive features (Vaudour, 2002; Conti et al., 2024). In addition to this classification, the production and designation of "Extra Virgin Olive Oil" was controlled and protected by European regulations.

This research will analyze the high-quality olive oil value chain, to identify its internal and external strengths and weaknesses. In particular, the aim is to provide an accurate analysis of the strategic successful factors of the high-quality olive oil value chain, as well as its challenges related to market forces, climate change and certification and quality processes and identification. Secondly, this research aims to explore the implications of the new digital technologies applied to the agribusiness sector, in particular, the high-quality olive oil sector. The paper focuses on the pivotal role of digital business platforms in enabling high-quality olive oil producers to expand their market reach, optimize supply chain efficiency, and respond dynamically to evolving consumer preferences.

Concerning scholars, the paper integrates the extant literature on high-quality olive oil, clearly identifying the sources of advantages of PDO and PGI olive oils in digital platformized markets. Concerning practitioners, the paper provides a multidimensional strategic framework of analysis to support the main stakeholders within the high-quality olive oil both in physical and digital ecosystems in adopting sustainable and regenerative practices for a higher co-creation of value in the value chain. Eventually, the paper will provide suggestions for future research paths.

Keywords: Agricultural Value Chains, Agrifood, High-Quality Olive Oil, Digital Platforms.

Paper type: Academic Research Paper

1 Introduction

The Agrifood sector is one of the recognized pillars of the Italian economy, generating 31,8 % of its GDP (Federalimentare, 2023) and providing labor to 17% of the Italian labor force (Istat, 2017). It is also one of the engines of the Italian exports, generating 8,1 % of annual Italian exports (Federalimentare, 2023). Some products are considered symbols of the agrifood "Made in Italy", such as olive oil, pasta, cheese, ham and wines. The agrifood sector has performed very well in the last decades, representing an excellent example of Italian food culture worldwide. In this paper, we will focus on the high-quality olive oil value chain.

This research will analyze each of the stakeholders in one of the most important and recognized Italian agrifood value chains (Porter, 1985, 2001; Davis & Goldberg, 1957; German et al., 2020): the high-quality olive oil value chain, to identify its internal and external strengths and weaknesses. In particular, the aim is to provide an accurate analysis of the strategic successful factors of this value chain, as well as its challenges related to market forces, climate change and certification and quality processes and identification. Secondly, this research aims to explore the implications of the new customers' concerns and demands relative to the product and the care of the environment, both in the domestic and international markets.

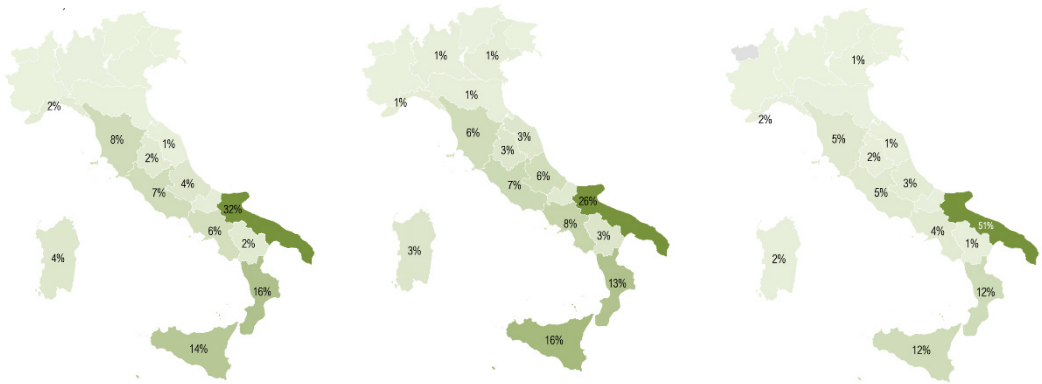
Regarding the first aim, a deep analysis of the vertical integration within the value chain will be performed. A cross-analyses of successful factors in the high-quality olive oil value chain will allow to discover the key strategic elements that made it to perform so well. Secondly, this research aims to explore on the pivotal role of digital business platforms in enabling high-quality olive oil producers to expand their market reach, optimize supply chain efficiency, and respond dynamically to evolving consumer preferences.

2 Italian Olive Oil Value Chain

Olive production and olive oil consumption was within the Italian heritage for millenniums, and it is one of the symbols of the agrifood "Made in Italy". Olive trees are planted all over the country, but for the Alps region. The total area is of 1,14 million hectares, mostly concentrated in the Southern regions: 62% – Puglia 32%, Calabria 16% and Sicily 14%.

The olive oil value chain consists of different stakeholders: (i) olive production (farmers), (ii) olive oil processing (mills, packing plants, refineries), (iii) marketing and distribution (supermarkets, small shops, gourmet food stores, exporters), (iv) consumers (domestic and international) and (v) government and services (consortiums, certification, etc.).

In Italy there are 619,000 olive producers and 4,240 olive mills. The pressing of the olives must be done within a day of harvesting, to avoid fermentation, so mills are in all the production areas. Producers are mostly small – average area of 1.8 hectares, 38% below 5 hectares – and mills are from small to medium capacity, mostly family or cooperatively run. Domestic consumption of olive oil is very high – 7.5 liters/person per year, due to the "Mediterranean diet", worldwide recognized for its health benefits.



(a) (b) (c)

Fig. 1: (a) Regional distribution of olive-growing area (average 2020-23), (b) Regional distribution of olive farms in 2020 and (c) Regional production (average 2020-23).

Source: Istituto di Servizi per il Mercato Agricolo-Alimentare (ISMEA) – Scheda del settore olio di oliva. Agosto 2025

Regarding mills, the larger producers have their own olive mill, sometimes with machinery for bottling and packing in different formats (cans or Tetra-Pack containers), while the small and medium producers bring their olives to an external mill, which can be managed privately or cooperatively. In both cases, those services are normally paid in kind, with a share of the oil. Small farmers use the oil for family consumption and for selling the extra to a network of relatives and clients. Some specialized bottlers buy bulk olive oil and bottle it with their own labels or with the private labels of large retailers.

Regarding the household domestic consumption, the two main retail channels are large retail chains (65%) and direct channels (farm and mill direct selling: 26%).

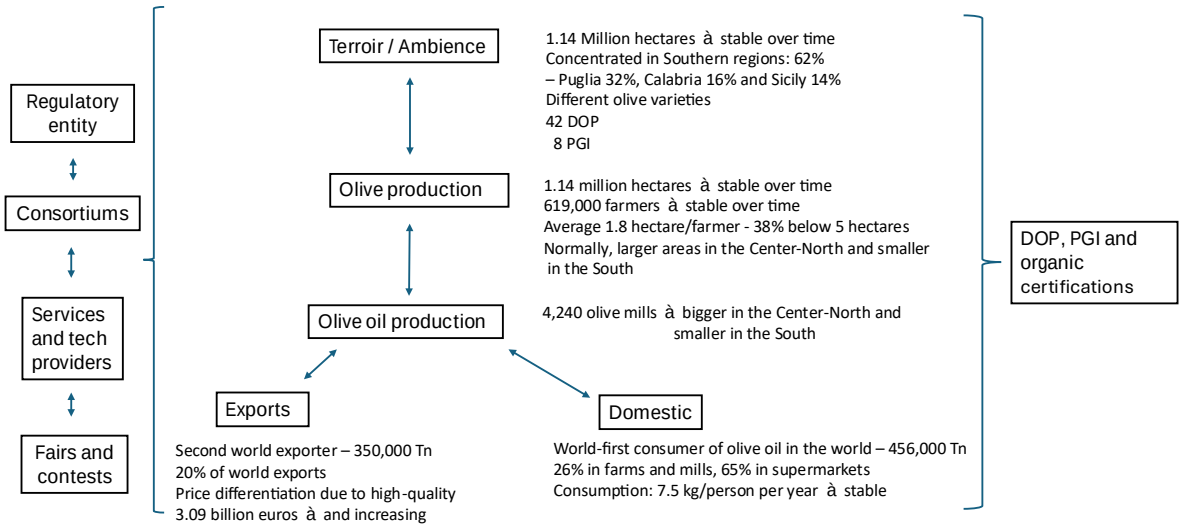


Fig. 2: Italian Olive Oil Value Chain.
Source: Self elaboration

Based on the average of the 4 campaigns 2021/22 to 2024/25, Italy is the world-first consumer of olive oil in the world – 456,000 Tn; second producer (after Spain) – 287,000 Tn; first importer – 524,000 Tn; and second exporter (after Spain) – 361,000 Tn, reaching 20% of world exports, but always with a price differentiation, due to quality recognition: the "Made in Italy" factor.

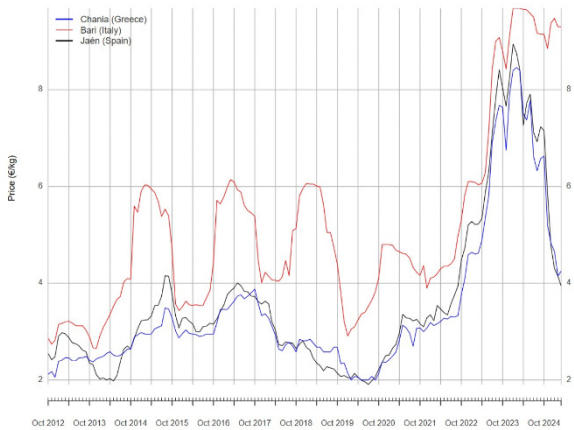

Fig. 3: Movements in producer prices (Oct 2012 / Mar 2025).
Source: International Olive Council: Olive sector statistics. March 2025

For the recognition of the different types and quality of olive oils and their identity, both in the domestic and international markets, the Italian government adopted in 1960 the controlled appellation system for olive oils, designing the Protected Designation of Origin (PDO or DOP) and Protected Geographical Indicator (PGI or IGP).

The effect of the PDO economy in Italian territories should not only consider the economic return of the productive sector, but to measure the value that "belongs" to those territories: the result of non-relocatable productions, expression of a collective heritage and a set of environmental, historical and cultural factors.

Regarding olive oil, there are 42 PDO and 8 PGI in Italy. These certifications apply only to 6.25% of the national production (13,000 Tn), while an impressive 24 % of the production is certified as "organic" – mostly due to the small area and natural production system, being this recognized by a price differentiation in the international markets for the Italian quality, in comparison with its competitors (Spain, Greece and Tunis). The quality and organic certification are important for customers in the international markets and in the big distribution

channels. As mentioned before, in Italy, a large volume of high-quality olive oil is sold directly from farmers and mills (26 %) showing that the closer the consumer to the producer, the less a certification is needed.

In the PDO-PGI market, a very interesting case is the region of Tuscany, that representing only 5% of national production is exporting 40% of the PGI olive oil, due to the international recognition of the region as high-quality food and wine provider.

In addition to this classification, the production and designation of "Extra Virgin Olive Oil" (EVOO) was controlled and protected by European regulations in the 'Art. 35 of EC Reg. 1513/2001 , which defines it as a product obtained from the first pressing of olives through mechanical processes, thus without the use of chemical processes or substances, under conditions that do not cause alterations in the oil and whose free acidity, expressed as oleic acid, is not more than 0.8 percent.

Organic production is to obtain foods and other agricultural products based on the use of processes with minimal impacts on the environment and the health of humans, plants and animals. Also, organic products are considered healthier and safer than conventional products, so it is not simply a matter of having a better taste and being more environmentally friendly. Income influences consumption of organic food, since are more expensive. The higher purchase of organically produced EVO oil is in gourmet food stores and, to a lesser extent, at farms gates or mills direct sales.

3 International Markets

In recent years, Italy has strengthened its role as the world's second-largest olive oil exporter, shipping in 2024/25 approximately 344,000 tons valued at over €3.09 billion. Major export markets are: the United States, Germany, France, Japan and Canada. The United States consume around 400,000 Tn/year (1.1 kg/person per year), but domestic production represents less than 2 per cent of consumption. The United States is the most important international customer, being Italy the larger supplier to the US (120,000 Tons, € 1billion): mostly Extra Virgin Olive Oil (89%), in small containers with private brands, reflecting quality recognition and price differentiation. This is a still-growing and high-price market for Italy.

4 The Platformization of the Italian High-Quality Olive Oil Value Chain

The growing adoption of digital business platforms is progressively reshaping the value chain of Italian high-quality olive oil, particularly with respect to traceability and commercialization (Parra-López et al., 2025; Muller et al., 2026). As a typical credence good, high-quality olive oil relies heavily on trust, origin, and quality attributes that are not directly observable by consumers (Sgroi et al., 2024). In this context, digital business platforms help reduce information asymmetries by integrating traceability systems, digital certifications, and product storytelling, thereby strengthening consumer trust and supporting price differentiation (Parra-López et al., 2025).

At the same time, digital platforms are becoming increasingly relevant for the commercialization of high-quality olive oil. While traditional channels still dominate the market, with large-scale retail accounting for approximately 65% of sales and direct channels for around 26% (ISMEA, 2025), a growing share of premium products is gradually shifting towards online and direct-to-consumer channels. This trend reflects broader dynamics in the Italian food sector: despite a recent stabilization, the combined value of online grocery and food delivery reached approximately €4.4 billion in 2023, underscoring the structural importance of digital channels for food consumption (Statista, 2025). Evidence from adjacent sectors, such as wine, highlights the magnitude of this transformation, with vertical platforms experiencing significant growth in recent years (Conterjnic et al., 2025). A similar, albeit less mature, dynamic can be observed in the olive oil sector, where vertical platforms are emerging. Examples include *Olive Oil Lovers* and *Citizens of Soil*, which focus on high-quality products and leverage digital channels to connect producers directly with consumers.

Although these platforms have not yet reached the scale observed in more mature sectors such as wine, they signal a clear process of platformization of the olive oil value chain, in which value creation increasingly relies not only on production and territorial embeddedness, but also on the ability to organize digital interactions, convey information, and orchestrate market access. In this evolving scenario, digital business platforms should therefore be interpreted not merely as additional sales channels, but as emerging infrastructural actors capable of reconfiguring coordination mechanisms, shaping consumer perception, and influencing the creation and appropriation of value along the value chain of Italian high-quality olive oil.

5 Conclusions

Extra Virgin Olive Oil (EVOO) is one of the most traditional Italian products, and its local production creates a virtuous circle of social and economic sustainability: supporting the viability of local economies, improving producers' incomes, and enhancing the quality of life within local territories. Furthermore, in recent decades, olive oil has also become one of the drivers of agrotourism, along with wine (Oil Routes, Towns of Oil, fairs and events), attracting tourists from all over the world into Italy's rural areas, generating income and labor opportunities.

However, the olive oil value chain is currently facing a set of structural challenges, including the impact of climate change, the spread of plant diseases, and the risk of declining production volumes (Fraga et al., 2020). These pressures are particularly critical in a sector characterized by high fragmentation, small-scale production, and strong territorial embeddedness (Martins et al., 2024).

In this evolving context, the findings of this paper suggest that digital transformation - particularly through the emergence of digital business platforms - is becoming an increasingly relevant dimension of competitiveness in the high-quality EVOO segment. Digital business platforms operate along two crucial and interrelated dimensions of value creation and appropriation. On the one hand, they enhance traceability and transparency by integrating digital certifications, data-driven information, and product storytelling, thereby strengthening trust mechanisms in a market where quality attributes are largely unobservable ex ante (Parra-López et al., 2025). On the other hand, they enable new forms of commercialization, allowing producers to access international markets more directly and enhance value capture through differentiation strategies (Conterjnic et al., 2025).

At the same time, this transformation contributes to a broader reconfiguration of the Italian olive oil value chain: from a predominantly linear, territorially bounded system to a more interconnected, platform-mediated ecosystem (Van Dijck et al., 2018; Poell et al., 2019; Barile et al., 2022). While this evolution creates new opportunities, particularly for small and medium-sized producers operating in the premium segment, it also introduces new structural tensions. In particular, the increasing reliance on digital business platforms tends to generate new forms of dependency, as market access, visibility, and competitive positioning become progressively mediated by digital intermediaries (Sauvagerd et al., 2024; Simone & Laudando, 2025; Simone et al., 2025).

Therefore, digital business platforms should not be interpreted merely as additional distribution channels, but as emerging infrastructural actors capable of reshaping coordination mechanisms, influencing consumer perception, and redefining value creation and appropriation within the olive oil sector (Podszun et al., 2021; Fletcher et al., 2024).

Building on these insights, future research could further investigate the role of digital business platforms in supporting quality recognition, traceability, and international positioning of high-quality Italian olive oil, as well as explore comparative analyses with other agri-food value chains, such as wine or cheese, to identify convergences and divergences in the process of platformization.

Knowledge Management in Sustainable Energy Transitions: An Exploratory Agent-Based Approach

Domenico Camarda[1], Maria Rosaria Stufano Melone[2]
[1] Polytechnic University of Bari, Italy
[2] CNR-ISTC Research Associate, Trento, Italy

Abstract

Sustainable energy transitions pose governance challenges that cannot be addressed through technological optimization alone: they require the management of heterogeneous forms of knowledge — technical, local, tacit, and institutional — distributed among actors with diverging interests and evolving over time. This work proposes an exploratory approach based on Agent-Based Modeling (ABM) as a proof of concept for decision-support architectures oriented toward territorial knowledge management. The application context is the Apulia region, with specific reference to the municipality of Giovinazzo as a conceptual testbed.

The model, developed in NetLogo with a 150-month horizon, simulates interactions between strategic and operational agents through two cumulative systemic states (ecosystem health and territorial consensus), interpreted as proxies of tacit environmental knowledge and distributed institutional trust. Feedback flows among agents affecting approval probability represent the main source of non-linearity in the system.

Three policy scenarios are compared by varying the operational mode of the regulatory authority: permissive, balanced, and conservative. Scenario A (environmentally permissive) maximizes land conversion but leads to the collapse of both indices, with institutional sensemaking effectively blocked and delayed social response. Scenario B (balanced) keeps both systemic states above critical thresholds through a mechanism that can be interpreted as double-loop learning, without maximizing any single objective. Scenario C (environmentally conservative) preserves ecological and social conditions at the expense of energy coverage, illustrating a mirrored form of selective blindness. A structural sensitivity analysis on three parameters — administrative capacity of the municipal technical office, composition of the landowner base, and institutional permeability to social knowledge — shows that the latter exhibits a non-linear response with an identifiable optimal window, a result that directly informs the priorities of a subsequent participatory phase.

The main contribution is the proposal of a framework connecting organizational knowledge management with computational modeling, rather than offering predictive claims, and focusing instead on how the cognitive assumptions underlying decision-making can be made explicit and compared. The framework is intended to be transferable to other sustainability domains where success depends on the ability to govern distributed knowledge under conditions of complexity and uncertainty.

1 Introduction

The transition toward sustainable energy systems represents one of the most complex governance challenges of our time. In real territorial contexts, it cannot be reduced to a matter of technological efficiency alone; rather, it involves forms of knowledge that are technically specialized, locally embedded, and institutionally mediated, distributed among actors whose interests only partially overlap, and subject to change over time (Geels, 2011; Turnheim et al., 2015). The fundamental difficulty lies not in a lack of information, but in the multiplicity of interpretive frames through which such information is perceived, filtered, and translated into action.

Local authorities are required to evaluate energy projects whose effects propagate across interconnected domains — land, ecosystems, economy, communities — generating trade-offs that are not immediately visible and feedbacks that are often delayed (Head and Alford, 2015). In this context, knowledge is not a fixed input to decision-making, but a resource that is co-produced and continuously reshaped through interactions among actors (Nonaka and Takeuchi, 1995; Wenger, 1998).

This paper proposes an exploratory approach based on Agent-Based Modeling (ABM), conceived as a proof of concept for possible knowledge-oriented decision-support architectures. The aim is not to build a predictive model, but to explore how different architectures of knowledge representation may reveal — or alternatively conceal — critical dynamics of energy transitions. The application context is the Apulia region, with a specific focus on the municipality of Giovinazzo as a conceptual testing ground. The scientific contribution lies in conceptualizing ABM as a knowledge governance device: not only an analytical tool for complex systems, but

also an infrastructure that allows the cognitive assumptions of actors involved in distributed decision-making processes to become explicit, comparable, and open to negotiation.

The work is part of a broader research program addressing, in parallel, both the architectural dimension of decision-support systems — including the integration of ontologies, multi-agent simulation, and artificial intelligence components — and the epistemic dimension of knowledge governance. The two strands share the same simulation base but pursue distinct questions: the former investigates how to design a multi-level DSS for policy development; this paper focuses instead on how distributed knowledge is structured and transformed within such a system. Scenario results are therefore shared for methodological reasons, while the knowledge management perspective represents the original contribution of this article.

2 Theoretical Framework

2.1 Distributed knowledge and sociotechnical transitions

The literature on sociotechnical transitions has consistently shown that the shift toward sustainability involves deep processes of cognitive and institutional reconfiguration (Geels, 2011). The Multi-Level Perspective highlights how technological regimes are stabilized by cognitive routines embedded in actors' practices, and how transitions require the destabilization of such patterns through processes of collective learning (Rip and Kemp, 1998). In this sense, technological change cannot be separated from changes in the structure of shared knowledge.

Nonaka and Takeuchi (1995) conceptualize knowledge creation as a conversion between tacit and explicit dimensions through cycles of socialization, externalization, combination, and internalization (the SECI model). In complex organizations — and even more so in multi-actor governance systems — this conversion does not occur smoothly. Structural resistances, power asymmetries, and interpretive barriers tend to slow down or distort the process. Zollo and Winter (2002) show that organizational dynamic capabilities depend on the ability to articulate tacit knowledge embedded in operational routines, transforming it into explicit rules that can be revised at the strategic level.

In the context of energy transitions, this tension appears as a misalignment between the strategic intentions of governance authorities and the operational practices of territorial actors (Kern and Smith, 2008). Public decision-makers formulate objectives in explicit and aggregated terms, while local communities develop their evaluations through tacit and context-dependent knowledge — perceptions of landscape, memory of past impacts, trust (or distrust) in institutions — which are difficult to translate into formats compatible with formal planning.

2.2 Collective sensemaking and boundary objects

The concept of sensemaking (Weick, 1995) refers to a retrospective and social process through which actors construct meaning by assigning interpretive frames to available information. In energy transition contexts, this process is inherently conflictual: different actors activate different frames — economic development, environmental protection, territorial identity — which are not easily comparable and often lead to misunderstanding or opposition that cannot be resolved simply by providing more information.

Ostrom (2009) has shown that the governance of complex socio-ecological systems requires forms of knowledge co-production between institutional actors and local communities. Wicked problems, such as those encountered in territorial energy planning, are characterized by the absence of a single optimal solution and by the contextual and interdependent nature of objectives (Head and Alford, 2015). The issue is therefore not to identify the 'right' knowledge, but to build processes that allow its continuous integration across different interpretive frames.

Within this perspective, the concept of boundary object (Star and Griesemer, 1989) becomes particularly relevant. Shared analytical tools — flexible enough to adapt to multiple frames, yet robust enough to maintain coherence across communities of practice — can play a key mediating role in distributed governance processes. Computational models such as the one proposed here aim to perform this function, providing a shared reference through which actors with different forms of knowledge can interact and compare positions.

2.3 ABM as an epistemic device

Agent-Based Modeling has been increasingly used in the study of energy transitions because of its capacity to represent complex adaptive systems with heterogeneous actors, non-linear dynamics, and emergent behavior (Chappin and Dijkema, 2010; Ringler et al., 2016). Unlike aggregated optimization models, ABM allows

for the explicit representation of individual decision logics, local interactions, and systemic feedbacks, making collective outcomes not reducible to the sum of individual actions.

From a knowledge management perspective, ABM can be seen as an epistemic device: it makes explicit the assumptions about how knowledge is structured among actors — who knows what, how beliefs are updated, how ambiguous signals are interpreted — and allows the exploration of the consequences of different cognitive architectures (Moglia et al., 2018; Robinson et al., 2012). The model proposed here follows this line, with a specific focus on institutional knowledge governance, exploring how different configurations of decision rules, institutional capacity, and social feedback mechanisms generate qualitatively different system trajectories.

Differently from traditional participatory modelling — where stakeholders are directly involved in model construction (Voinov and Bousquet, 2010) — the present approach uses simulation as a device of ex-post explicitation. Algorithmically generated scenarios act as a kind of reflective surface against which stakeholders' tacit knowledge can be articulated in a later phase. The contribution is not to replace actors' judgment, but to provide a formal structure that makes implicit governance assumptions visible, comparable, and open to discussion.

3 Model Architecture

3.1 General structure

The model is developed in NetLogo (Wilensky and Rand, 2015) and simulates a time horizon of 150 months (approximately 12.5 years), with each tick corresponding to three months. The role of parameter values is to generate comparable dynamics across scenarios, not to reproduce real-world magnitudes.

The development of the code benefited from generative AI tools as cognitive support during the prototyping phase, rather than as autonomous components of the model. A central design choice is the distinction between active agents and cumulative systemic states: agents act according to their decision rules at each tick, while state variables evolve cumulatively, incorporating memory and path dependency — a key feature of systems in which knowledge is embedded in institutional routines (Zollo and Winter, 2002). Knowledge is therefore not represented as a centralized database, but as a distributed set of localized rules, selective perceptions, and institutionalized routines.

3.2 Strategic and operational agents

The distinction between strategic and operational agents represents the main theoretical device of the model. Strategic agents — the regulatory authority (AC) and photovoltaic firms (FVE) — can adapt their policies in response to evolving signals. Operational agents — the municipal technical office (UTC), routine landowners, and rigid environmental associations — tend to follow predefined procedures, introducing a form of cognitive inertia that makes the translation of strategic intentions into concrete actions more difficult (Zollo and Winter, 2002).

The model includes seven agent types:

- FVE (firms): proposing agents with offers ranging from 5,000 to 15,000 monetary units, oriented toward maximizing installed capacity.
- Landowners (OWN): either speculative (acceptance threshold reduced by 10%) or aware (considering environmental and community impacts). Their proportion is controlled by speculator-owns.
- AC (authority): approval probability varies by mode — permissive (0.70), balanced (0.50), restrictive (0.35), conservative (0.20) — and is modulated by social mobilization through alpha-social (0.20).
- UTC: limited administrative capacity, with a growing backlog acting as a procedural bottleneck.
- AGR (agricultural land): distinguishes between traditional and agrivoltaic installations; subject to possible desertification.
- IND (industry): energy demand expressed as satisfaction on a 0–100 scale.
- AMB (environmental groups): either rigid (systematic opposition) or selective (evaluation based on technology and context), reflecting ideological versus contextual knowledge.

3.3 Cumulative systemic states as proxies of collective knowledge

ESY and COM are aggregated modelling constructs interpreted here as proxies of collective knowledge — a heuristic reading rather than an empirical claim.

- ESY (Ecosystem State): index of ecosystem health (initial value 1.0, critical threshold 0.55). Impact per installation: 0.010/tick (traditional), 0.004/tick (agrivoltaic); recovery rate 0.01/tick. ESY represents tacit

environmental knowledge embedded in the territory: its erosion signals the emergence of consequences not anticipated in collective decision-making.

- COM (Territorial Consensus): index of territorial consensus (initial value 1.0, opposition threshold 0.60). Similar dynamics to ESY. COM represents distributed trust in the governance system: its decline signals a failure of institutional sensemaking.

The feedback between ESY and COM on approval probability is the main source of non-linearity: when both fall below threshold, the system shifts regime in a way that is difficult to reverse (Argote and Miron-Spektor, 2011).

Social mobilization is updated at each tick in response to three triggers (development pressure > 25%, share of traditional PV > 60%, active AMB > 50%) and reduces AC approval probability through alpha-social. The structural asymmetry between the growth rate of mobilization (0.05) and its spontaneous decay (0.02) encodes the path-dependent nature of trust erosion.

4 Results: Knowledge Dynamics in Simulated Scenarios

4.1 Scenario design and epistemic caution

Three policy scenarios are compared over a 150-month period by varying the operational mode of the regulatory authority (ac-mode). The numerical values reported below are outputs of the model under its current assumptions. They do not represent empirical estimates of the real Apulian context, nor are they derived from field data. Their meaning is relative and comparative: they describe differences between scenarios, rather than absolute levels. In this sense, they should be read as indicative orders of magnitude, useful for reasoning about directions of change rather than precise quantities.

Table 1**:** Comparison of policy scenarios (150-month simulation)

Indicator	A scenario (Permissive)	B scenario (Balanced)	C scenario (Conservative)	Critical threshold
Land conversion	~61%	~45%	~21%	—
Main technology	Tradit. PV (~70%)	Agrivolt. PV (~54%)	Agrivolt. PV (~90%)	—
ESY (ecosystem health)	≈ 0.42 ⚠	≈ 0.68 ✓	≈ 0.91 ✓	0.55
COM (people consensus)	≈ 0.38 ⚠	≈ 0.73 ✓	≈ 0.94 ✓	0.60
Social mobilization	High	Moderate	Low	—
Energy coverage	High	Moderate	~21% ⚠	—
UTC backlog	High	Manageable	Low	—

4.2 Scenario A, permissive policy: blocked institutional sensemaking

With a permissive AC mode (baseline approval probability 0.70), the model produces the highest land conversion (around 61%) and a dominance of traditional PV installations (about 70%). At the same time, both ESY (≈ 0.42) and COM (≈ 0.38) fall below their critical thresholds.

From a knowledge management perspective, the AC agent does not incorporate into its decision mechanisms the signals of deterioration accumulating in the system. Local tacit knowledge — expressed through selective perceptions of environmental groups and aware landowners — fails to enter the formal approval process in a meaningful way. The UTC backlog progressively saturates, creating a misalignment between strategic intent and operational capacity: what is decided at the top cannot be effectively translated into practice. This could represent a failure in tacit-to-explicit knowledge conversion (Nonaka and Takeuchi, 1995), an interpretation that would require empirical verification.

The high level of social mobilization observed in later stages emerges as a bottom-up adaptive response: the community gradually develops collective knowledge about the impacts of installations and translates it into political pressure. However, because collective sensemaking is inherently retrospective (Weick, 1995), this response occurs too late, when system degradation is already advanced.

4.3 Scenario B, balanced policy: dynamic equilibrium

With a balanced AC mode (baseline approval probability 0.50), the model generates moderate land conversion (around 45%), a more even technological mix (agrivoltaic ~54%), and keeps both ESY (≈ 0.68) and COM (≈ 0.73) above their thresholds. Social mobilization remains present but manageable.

In this configuration, the AC acts as a kind of cognitive filter, introducing friction into the approval process and indirectly favoring diversification. The ESY–COM feedback remains active and prevents the system from drifting toward collapse. Under the model's assumptions, this behavior can be interpreted as a form of double-loop learning (Argyris and Schön, 1978): the system does not simply correct errors within fixed rules, but adjusts those rules in response to feedback.

No single objective is maximized in this scenario. Instead, all dimensions remain within acceptable ranges. Within the model's assumptions, no single objective dominates; instead, all dimensions remain within acceptable ranges, suggesting a form of maintained balance.

4.4 Scenario C, conservative policy: inverse selective blindness

With a conservative AC mode (baseline approval probability 0.20), land conversion remains low (around 21%), agrivoltaic installations dominate (~90%), and both ESY (≈ 0.91) and COM (≈ 0.94) remain high. However, energy coverage is insufficient (around 21%).

This scenario represents a mirror image of Scenario A. Here, the system systematically privileges environmental and social knowledge, but does so at the expense of economic and technological considerations. The result is another form of cognitive failure — not due to excess permissiveness, but due to over-correction. What the model cannot determine — and what would require empirical investigation — is whether this over-correction reflects a genuine institutional pathology or a rational response to past permissiveness. The simulation encodes it as symmetric failure, yet reality may be more ambiguous.

4.5 Cognitive thresholds and irreversibility dynamics

The critical thresholds of ESY (0.55) and COM (0.60) act not just as indicators, but as behavioral discontinuities. When crossed, the system shifts into a different regime, with consequences that are difficult to reverse. This reflects the path-dependent nature of organizational learning (Argote and Miron-Spektor, 2011): losses in cognitive capital — both environmental knowledge embedded in the territory and institutional trust — do not recover in a linear way.

The comparison across scenarios suggests that preventive governance — maintaining conditions above thresholds — may be more effective than reactive governance, which intervenes only after degradation has occurred. This remains, however, a hypothesis that would require further validation in the participatory phase.

4.6 Structural sensitivity analysis

In the absence of multiple empirically calibrated runs, the qualitative robustness of the model is assessed by analytically deriving the expected directions of response when varying three parameters that are theoretically relevant for the KM framework: the administrative capacity of the UTC (κ), the proportion of speculative landowners (σ), and the weight of social mobilization on the approval probability of the AC (α).

Unlike a statistical sensitivity analysis based on multiple simulation runs, this approach analytically derives the expected directions of system response. The objective is not to measure output variance, but rather to verify the structural coherence of the model with the theoretical assumptions of the KM framework, and to identify which parameters produce qualitative regime shifts rather than simple scale variations.

4.6.1 Experiment 1 — UTC administrative capacity (κ)

With low κ (e.g. 1), the UTC backlog grows faster than it can be processed: fewer installations slow down the erosion of ESY and COM, but the accumulated development pressure fuels social mobilization independently. With high κ (e.g. 6), the flow is faster but more exposed to stochastic variability in approvals.

Expected direction: κ↓ → ESY/COM moderately higher but higher mobilization; κ↑ → faster convergence toward asymptotic values of the baseline scenario.

The qualitative structure of scenarios remains robust with respect to κ: the parameter regulates the speed of the trajectory, not its final regime. From a KM perspective, this highlights that UTC administrative capacity is an autonomous cognitive variable — not simply a multiplier of AC policy.

4.6.2 Experiment 2 — Composition of the landowner base (σ).

As σ increases, the acceptance rate of offers rises, as does the volume of applications entering the UTC backlog, with direct impact on ESY and COM. A relevant aspect is that, since the technological choice between traditional and agrivoltaic installations is determined by the AC rather than by landowners, σ does not affect the technological mix but influences overall volume.

Expected direction: σ↑ → greater erosion of ESY and COM, earlier mobilization; σ↓ → slower system, more favorable profiles.

The qualitative structure is robust: σ acts as an acceleration factor, not as a regime-shifting variable. From a KM perspective, this indicates that the cognitive composition of the landowner base represents an independent source of systemic risk.

4.6.3 Experiment 3 — Weight of social mobilization (α).

α modulates the reduction of approval probability as a function of active mobilization. With α = 0, the system becomes insensitive to social feedback: ESY and COM converge toward worse values because the self-regulation mechanism is deactivated. With α ≥ 0.35, mobilization acts as a brake that blocks decisions without proportionally improving the indices.

The response is non-linear, with an optimal window between 0.10 and 0.25 — neither deaf nor paralyzed — consistent with the notion of double-loop learning (Argyris and Schön, 1978).

α represents institutional permeability to social knowledge: its non-linearity is the most theoretically relevant result of the analysis, because it directly informs the priority questions of the participatory Phase 2.

Table 2**:** Structural sensitivity analysis (baseline scenario: ac-mode = balanced)

Parameter	**Levels explored**	**ESY/COM Expected direction**	**Unchanged qualitative structure?**	**Relevance for KM frameworks**
κ (UTC capacity)	1 / 3* / 6	κ↓ → Higher ESY/COM, higher mob.; κ↑ → faster convergence	Yes — κ regulates speed, not regime	Operational inertia as an autonomous KM variable
σ (speculator-owns)	20% / 50%* / 80%	σ↑ → greater ESY/COM erosion and earlier mob.; σ↓ → slower trajectory	Yes — acceleration factor, not regime change factor	Cognitive composition of micro-actors as systemic risk
α (alpha-social)	0 / 0.20* / 0.40	α=0 → Lower ESY/COM (deaf system); moderate α → preserves thresholds; high α → decision block	No — non-linear; optimal window 0.10–0.25	Institutional permeability: the most critical parameter of the framework

** = Baseline values for scenarios A/B/C. Directions derived analytically from NetLogo procedures; they do not constitute output from simulated runs.*

The comparison across the three experiments reveals an overall pattern consistent with the KM framework assumptions. For κ and σ, the qualitative structure of scenarios is robust: both parameters affect the speed of trajectories rather than their regime. For α, instead, the response is non-linear — institutional blindness at low values, decision paralysis at high values — with an identifiable optimal window. This represents the most relevant theoretical result of the structural analysis and directly guides the key questions for the participatory phase.

5 Implications for Research and Practice

5.1 Operational hypotheses for local authorities

The model formulates, within its own assumptions, three operational hypotheses that can be explored empirically in the participatory Phase 2. The fact that they are hypotheses rather than prescriptions does not make them less useful: structuring precise questions is already a contribution to knowledge governance.

UTC administrative capacity. Within the model assumptions, an under-dimensioned UTC does not simply produce procedural delays, but introduces a structural decoupling between the strategic intentions of the AC and the operational action of the institutional system. This decoupling erodes the coherence of public action and fuels development pressure even in the absence of new approvals. Investing in administrative capacity can therefore be interpreted, in KM terms, as investing in the system's ability to learn from its own decisions — transforming tacit knowledge embedded in bureaucratic practices into explicit and updatable operational competences.

Technological differentiation. Agrivoltaic installations generate structurally lower impacts on ESY and COM (0.004 vs 0.010/tick), contributing to the preservation of future approval conditions. Technological choice is therefore not neutral with respect to system trajectories: it produces long-term effects on institutional trust and ecosystem health that do not emerge from short-term analysis. The model suggests that incentivizing this choice through differentiated regulatory mechanisms may, from a systemic perspective, function as a strategy for preserving the cognitive and social capital of the territory.

Asymmetry of consensus. The structural asymmetry between mob-k-up (0.05) and mob-k-down (0.02) encodes in the model a dynamic widely recognized in the literature: trust builds slowly and is lost quickly. This implies that policies aimed at restoring consensus — once eroded — are structurally more costly than policies aimed at preserving it.

Precautionary governance approaches — building continuous structures of dialogue and knowledge co-production before tensions accumulate — may therefore be more effective than reactive approaches that intervene only when mobilization is already visible.

5.2 The model as a knowledge co-production infrastructure

The model is conceived as a potential boundary object (Star and Griesemer, 1989): a shared but flexible representation through which actors holding different forms of knowledge can reflect on assumptions, explore trade-offs, and compare alternative framings, without requiring full agreement on problem definitions or solutions. Its value does not lie in predictive accuracy, but in its capacity to structure complex conversations and make otherwise opaque dynamics visible.

This potential is articulated through a two-phase approach. Phase 1 — documented in this work — produces simulated scenarios that function as structured hypotheses: plausible configurations of the system, derived from explicit assumptions and comparable with one another. Phase 2, envisaged as a subsequent development, involves the critical confrontation of these scenarios with the tacit and contextual knowledge of local stakeholders — municipal authorities, agricultural operators, environmental associations, and communities — in structured participatory workshops.

Knowledge is not transferred from the model to stakeholders, but co-produced through their critical interaction (Argote and Miron-Spektor, 2011). This process also helps to reveal potential mismatches between model assumptions and real-world dynamics, making such divergences analytically useful rather than simply problematic.

5.3 Limits and future directions

The model has limitations that need to be explicitly acknowledged. The decision rules of agents are simplified compared to the real complexity of institutional and individual behaviors: in particular, the binary distinction between speculative and aware landowners does not capture the continuous range of real positions. Impact parameters (esy-impact-trad, com-impact-trad) are hypothetical-exploratory and require empirical calibration using real territorial data — GIS analysis on the Apulia region, cadastral data, and administrative data on the municipality of Giovinazzo.

The spatial dimension is treated in a simplified way, without accounting for landscape and infrastructural interdependencies. Finally, the model does not incorporate inter-period learning dynamics of institutional agents: AC and UTC operate with fixed parameters throughout the simulation, whereas in reality institutions may update their routines in response to accumulated experience.

Future directions include: the integration of ontological frameworks to formalize concepts, relations, and assumptions (Borgo et al., 2021), improving transparency and replicability; the introduction of adaptive learning capacities in institutional agents; and the extension of the framework to adjacent sustainability domains — water governance, forest planning, waste management — where similar problems of distributed knowledge governance arise under conditions of complexity and uncertainty.

6 Conclusions

This work has explored the use of Agent-Based Modeling (ABM) as a knowledge management tool in sustainable energy transitions, with a focus on the mechanisms through which distributed knowledge is represented, mediated, and transformed within a complex territorial governance system. The proposed model, applied in an exploratory way to the context of the Apulia region, makes it possible to render visible informational misalignments, cognitive thresholds, and alternative trajectories that would otherwise remain opaque to formal decision-making processes.

The main contribution is a framework that connects organizational knowledge management with computational modeling. This connection is not purely methodological, as it raises questions about how knowledge is represented and transformed across the two domains.

Within the assumptions of the proof of concept, the sustainability of the energy transition does not emerge from the optimization of single objectives, but from the maintenance of a dynamic balance between different and competing forms of knowledge: energy-related, environmental, social, and institutional. The critical

thresholds of ESY and COM identify discontinuities beyond which the system loses the capacity to learn from its past experience, entering regimes that are difficult to reverse.

The structural sensitivity analysis further indicates that institutional permeability to social knowledge (α) exhibits a non-linear response with an identifiable optimal window — a result that directly informs the priority questions for the participatory Phase 2 and represents the most theoretically relevant hypothesis of the framework.

Although grounded in the energy sector and in the Apulian context, the framework is intended to be transferable to other domains of sustainability in which success depends on the capacity to govern distributed knowledge under conditions of complexity and uncertainty. Sustainable transition cannot be reduced to a purely technical problem; it also involves a cognitive dimension, particularly where different forms of knowledge need to be articulated and negotiated over time.

7 Ethics declaration

This research is of a theoretical and computational nature and does not involve human subjects, personal data, field surveys, or direct interaction with communities or individuals. The municipality of Giovinazzo is used exclusively as a conceptual testbed for model parameterization; no empirical data concerning identifiable persons or organizations was collected or processed. Accordingly, no formal ethical clearance was required for the conduct of this study. The authors acknowledge, however, that the envisaged Phase 2 — involving participatory workshops with local stakeholders — will require appropriate ethical review prior to implementation, in accordance with applicable institutional and national guidelines.

8 AI declaration

Generative AI tools (specifically, large language model-based assistants) were used during the research process as cognitive support in two distinct phases: (1) during the prototyping of the NetLogo simulation code, where AI assistance contributed to the iterative drafting and debugging of agent procedures — as explicitly acknowledged in Section 3.1; and (2) during the drafting of portions of this manuscript, where AI tools were used to support textual editing, structural organization, and bibliographic consistency checks.

In both cases, all conceptual choices, theoretical framings, parameter definitions, scenario interpretations, and conclusions remain the sole responsibility of the authors. AI-generated content was critically reviewed, substantially revised, and integrated into an original argumentative structure developed independently by the authors. No AI tool was used as a source of scientific claims or bibliographic references.

Managing Circular Innovation Ecosystems through Knowledge Recombination: Assessing Ecosystem Health and ESG Outcomes in Phytoremediation-Based Circular Economy Models

Mercedes Grijalvo Martín[1], Joaquín Ordieres-Meré[1], Lorna Anguilano[2,3]
[1] Universidad Politécnica de Madrid, Department of Industrial Engineering, Madrid, Spain.
[2] Phyona Ltd., Stamford, UK
[3] Experimental Techniques Centre, Brunel University. Kingston Ln, Uxbridge UB8 3PH, UK.

Abstract:

The transition to a circular economy depends not only on technological innovation, but on the ability of innovation ecosystems to integrate diverse knowledge, coordinate interdependent actors, and deliver credible environmental, social, and governance (ESG) outcomes. Yet many circular initiatives remain fragmented and struggle to scale or demonstrate measurable impact. This paper addresses this challenge by advancing an ecosystem-level perspective grounded in knowledge management, focusing on how knowledge recombination enables effective circular innovation.

The study adopts a qualitative case study approach based on the Phyona/CSTO2NE use cases, which combine phytoremediation, phytomining, biomass valorisation, and green construction materials. In this ecosystem, contaminated land is reframed as a productive resource, where hyperaccumulator plants extract metals while generating biomass that can be further valorised into high-value applications. The case illustrates how environmental remediation, resource recovery, and material innovation are interconnected through complex knowledge flows spanning plant science, soil chemistry, materials engineering, and sustainability assessment.

The paper's main contribution is the development of an ecosystem health framework. Ecosystem health is defined as the capacity of a circular innovation ecosystem to sustain knowledge diversity, enable knowledge connectivity, coordinate actors, support adaptive learning, and ensure ESG credibility. These dimensions explain how circular systems evolve from isolated experimentation to scalable and legitimate solutions. ESG outcomes are conceptualised not as ex-post indicators, but as emergent properties of ecosystems capable of aligning environmental performance, social value, and governance over time.

The findings contribute to circular economy and knowledge management literature by positioning knowledge recombination as a core mechanism for system-level sustainability transitions. The framework also provides actionable guidance for managers and policymakers, highlighting the need to design circular initiatives as coordinated ecosystems supported by robust knowledge infrastructures and transparent assessment practices. By linking ecosystem health with ESG outcomes, the study offers a structured approach to evaluate and govern circular innovation in emerging sustainability domains.

Paper Type: Academic Research Paper

1 Introduction

The transition towards a circular economy requires more than replacing linear production processes with recycling or recovery practices. It depends on the capacity of innovation ecosystems to coordinate heterogeneous actors, integrate diverse knowledge domains, and transform environmental liabilities into sources of value. Circular economy models are therefore knowledge-intensive systems in which value emerges through the recombination of scientific, technological, organizational, and regulatory knowledge (Geissdoerfer et al., 2017; Scuotto et al., 2022).

Contaminated land and metal-rich waste streams represent both a challenge and an opportunity in this transition. Conventional remediation approaches treat contaminated soils as liabilities, while resource-intensive extraction processes continue to generate environmental impacts. Nature-based solutions such as phytoremediation and phytomining offer an alternative by enabling metal recovery from degraded land while contributing to ecological rehabilitation (Nti Nkrumah et al., 2016; van der Ent et al., 2015).

This paper examines a Phytomining-based circular ecosystem in which metal-rich biomass obtained from phytoecosystems grown on retired mines or other retired industrial sites, becomes a platform for multiple value pathways, including metal recovery, nanoparticle production, fertiliser generation, and potential applications in construction materials. These interconnected processes highlight the need to move beyond firm-level

innovation towards an ecosystem perspective, where value depends on coordinated knowledge flows and interdependencies among actors (Adner, 2017; Jacobides et al., 2018).

From a knowledge management perspective, such systems require the recombination of diverse knowledge bases, enabling the transformation of distributed expertise into scalable sustainability outcomes (Grant, 1996; Nonaka et al., 1996). However, existing ESG approaches often focus on outputs rather than the underlying conditions that enable long-term impact.

This paper addresses this gap by proposing ecosystem health as an intermediate construct linking knowledge recombination with ESG outcomes. Drawing on the Phyona/CSTO2NE case, it develops a framework to assess how circular innovation ecosystems generate credible and scalable sustainability value.

2 Theoretical Background

2.1 Circular economy as a knowledge-intensive transition

Circular economy represents a systemic transformation that requires coordination across actors, knowledge integration, and new business models (Kirchherr et al., 2017). Its effectiveness depends not only on material recovery, but on the ability to connect previously separated activities, resources, and value logics.

Sustainable business model literature shows that circular transitions require reconfiguration of value creation, delivery, and capture mechanisms (Bocken et al., 2014; Boons & Lüdeke-Freund, 2013).

For the purposes of this paper, circular economy is therefore approached as a knowledge-intensive transition. Its success depends on the ability to mobilize scientific, technical, organizational, regulatory, and market knowledge across ecosystem boundaries. This is particularly important in emerging circular economy fields, where technologies are still developing, markets are uncertain, and sustainability impacts must be demonstrated credibly. The Phyona/CSTO2NE use cases are consistent with this challenge because they connect phytomining, contaminated land regeneration, biomass valorisation, nanoparticle recovery, and green construction materials within a single circular innovation logic.

2.2 Knowledge management and knowledge recombination

Knowledge management provides a useful theoretical lens for understanding how circular economy ecosystems create value from heterogeneous resources. The knowledge-based view argues that knowledge is one of the most strategically significant resources of organizations, especially when it is specialized, distributed, and difficult to imitate (Grant, 1996). In complex innovation settings, value creation depends less on the possession of isolated knowledge assets and more on the ability to integrate knowledge held by different actors, disciplines, and organizations.

Nonaka et al. (1996) theory of organizational knowledge creation is also relevant because it emphasizes the dynamic interaction between tacit and explicit knowledge. Circular innovation depends on both codified knowledge, such as technical data, environmental assessments, standards, and experimental results, and tacit knowledge, such as field experience, stakeholder understanding, process know-how, and practical judgment. The interaction between these forms of knowledge enables organizations and ecosystems to generate new solutions under conditions of uncertainty.

In the context of circular economy ecosystems, knowledge recombination is especially important. Knowledge recombination refers to the process through which existing knowledge elements are connected in new ways to generate novel applications, processes, or value propositions. Circular economy initiatives often require such recombination because they seek to create value from materials, sites, or outputs previously treated as waste or externalities.

Absorptive capacity further explains how organizations identify, assimilate, and apply external knowledge (Cohen & Levinthal, 1990). This is important in circular innovation ecosystems because no single actor typically holds all the knowledge required to deliver a complete circular solution. The ecosystem's capacity to create value therefore depends on the ability to absorb and recombine knowledge across organizational boundaries.

From this perspective, knowledge management is not simply a support activity. It is a central orchestration mechanism through which circular economy initiatives become technically feasible, economically meaningful, and socially legitimate. In the case examined in this paper, knowledge management enables the translation of phytomining and phytoremediation knowledge into multiple circular pathways, including metal recovery, nanoparticle production, biomass valorisation, and material applications. The central theoretical issue is therefore not only whether the ecosystem possesses valuable knowledge, but whether it can recombine that knowledge into scalable and credible ESG outcomes.

2.3 Innovation ecosystems and interdependent value creation

Innovation ecosystem theory provides a complementary perspective by shifting attention from individual firms to systems of interdependent actors. Adner (2017) defines ecosystems as structures of alignment among partners that need to interact for a focal value proposition to materialize. This view is particularly useful for circular economy initiatives, where value creation often depends on the coordination of multiple actors who contribute different resources and capabilities. In contrast to linear value chains, ecosystems involve complementarities, mutual dependencies, and coordination challenges that cannot be fully managed through traditional hierarchical control.

(Jacobides et al., 2018) argue that ecosystems emerge when groups of organizations coordinate around complementarities that are not easily governed through markets or vertical integration. This is relevant to circular economy systems because they often require actors to collaborate around uncertain technologies, emerging standards, shared infrastructures, and evolving value propositions. The viability of the ecosystem depends on whether actors can align roles, manage interdependencies, and coordinate activities without necessarily belonging to a single organization.

These interdependencies mean that circular value creation cannot be attributed to any single actor. Instead, it emerges from the configuration of roles, relationships, and knowledge flows across the ecosystem. This is why an ecosystem perspective is appropriate for the present qualitative case study.

Dynamic capabilities theory also strengthens this argument. (Teece et al., 1997) define dynamic capabilities as the ability to integrate, build, and reconfigure internal and external competences in response to changing environments. Circular economy ecosystems require similar capabilities, but at an interorganizational level. They must sense opportunities in contaminated land and residual biomass, seize them through new technological and business model configurations, and reconfigure relationships as technical evidence, regulatory expectations, and market opportunities evolve. In this sense, ecosystem-level dynamic capabilities are essential for moving from isolated experimental activities to scalable circular economy models.

2.4 Ecosystem health as an intermediate construct

Although circular economy and innovation ecosystem literatures provide important insights, assessing the performance of circular innovation ecosystems remains challenging. Conventional performance indicators often focus on firm-level outputs, financial results, or environmental metrics. ESG frameworks, meanwhile, frequently emphasize reporting outcomes after activities have taken place. While such indicators are important, they may not fully capture whether the ecosystem has the underlying capacity to sustain circular value creation over time.

This paper therefore introduces ecosystem health as an intermediate construct between knowledge management capabilities and ESG outcomes. Ecosystem health refers to the capacity of an innovation ecosystem to maintain effective knowledge flows, coordinate interdependent actors, adapt to technological and regulatory change, and align value creation with environmental, social, and governance objectives. The concept is useful because it shifts attention from isolated outputs to the conditions that make long-term circular impact possible.

In the context of a circular innovation ecosystem, ecosystem health can be understood through several dimensions. First, knowledge diversity refers to the presence of multiple knowledge domains required to address complex sustainability challenges. Second, knowledge connectivity refers to the mechanisms through which actors exchange, translate, and integrate knowledge. Third, coordination capacity refers to the ability to align roles, responsibilities, incentives, and expectations across the ecosystem. Fourth, adaptability refers to the capacity to respond to new evidence, site-specific conditions, regulatory requirements, and technological constraints. Fifth, legitimacy refers to the ability to demonstrate credible environmental and social value to stakeholders.

These dimensions are particularly relevant to phytoremediation-based circular economy models. The effectiveness of such models depends on biological processes, environmental conditions, material properties, downstream applications, and stakeholder acceptance. If knowledge is fragmented, if actors are poorly coordinated, or if ESG claims cannot be substantiated, the circular model may remain experimental or fail to scale. Conversely, a healthy ecosystem can support learning, experimentation, validation, and diffusion across multiple use cases.

Ecosystem health also helps connect qualitative case study evidence with theory development. Rather than treating the case as a simple illustration of circular economy principles, the ecosystem health lens enables a structured analysis of how knowledge assets are mobilized, where coordination challenges arise, and how ESG outcomes become more or less credible. This supports theory-building because it identifies the mechanisms through which knowledge recombination contributes to circular economy performance.

2.5 ESG outcomes as emergent properties of circular ecosystems

ESG outcomes in circular ecosystems are better understood as emergent properties of knowledge, coordination, and governance processes rather than isolated reporting indicators. Environmental impacts relate to remediation effectiveness and resource recovery; social outcomes to land regeneration and stakeholder engagement; and governance to transparency and compliance. Their credibility depends on the ecosystem's capacity to integrate technical validation, environmental assessment, and stakeholder communication.

The relationship between circular economy and ESG is therefore mediated by ecosystem health. A circular initiative may have strong environmental potential, but weak governance or poor stakeholder engagement can undermine its legitimacy. Similarly, technical feasibility does not automatically translate into social value unless the ecosystem develops mechanisms for inclusion, communication, and benefit distribution. This is particularly important in cases involving contaminated land, recovered materials, and emerging nature-based technologies, where public trust and regulatory acceptance are essential.

Life cycle assessment and related sustainability assessment methods can strengthen ESG credibility by providing quantitative evidence of environmental impacts. However, such methods depend on data availability, methodological assumptions, allocation choices, and system boundaries. Therefore, they must be understood as part of a broader knowledge infrastructure rather than as standalone proof of sustainability. In circular ecosystems, ESG assessment becomes a learning mechanism that helps actors identify hotspots, compare alternatives, and improve the design of processes and value propositions over time.

In the case considered in this paper, ESG outcomes are linked to several interconnected pathways: contaminated land remediation, metal and nanoparticle recovery, fertiliser production, residual biomass valorisation, and potential applications in lower-carbon construction materials. These pathways require different forms of evidence and different stakeholder relationships. The credibility of the overall circular model therefore depends on the ecosystem's ability to integrate technical validation, environmental assessment, governance mechanisms, and stakeholder communication.

2.6 Implications for the qualitative case study

The theoretical background developed above supports the qualitative case study approach adopted in this paper. Case study research is appropriate when the aim is to understand complex, context-dependent phenomena in which boundaries between the phenomenon and its context are not clearly separable (Yin, 2018). It is also suitable for theory development when the research seeks to explain mechanisms, relationships, and emerging constructs rather than test predefined hypotheses (Eisenhardt, 1989).

The Phyona/CSTO2NE case is theoretically relevant because it combines several features that are central to circular innovation ecosystems. It involves a nature-based remediation and resource recovery model, the transformation of contaminated, or better actually, metal-rich biomass into multiple value streams, the potential integration of residual fibres into construction materials, and the need to substantiate ESG outcomes. It also requires collaboration across scientific, industrial, regulatory, and market domains. These features make it a suitable case for examining how knowledge recombination supports ecosystem health and ESG value creation.

Based on the literature reviewed, the paper adopts three guiding theoretical assumptions. First, circular economy initiatives should be analysed as systemic and knowledge-intensive transformations rather than as isolated technical solutions. Second, knowledge recombination across organizational and disciplinary boundaries is a core capability for circular innovation ecosystems. Third, ESG outcomes emerge from the health of the ecosystem, understood as its capacity to coordinate actors, sustain knowledge flows, adapt to uncertainty, and provide credible evidence of impact.

These assumptions guide the subsequent case analysis. The focus is not only on what the Phyona/CSTO2NE ecosystem produces, but on how knowledge assets are mobilized and recombined across the ecosystem to support circular value creation. In doing so, the paper contributes to knowledge management and circular economy literature by proposing ecosystem health as a conceptual bridge between knowledge-based capabilities and measurable ESG outcomes.

3 Research Design and Case Context

3.1 Research design

This study adopts a qualitative case study design to examine how knowledge recombination supports ecosystem health and ESG value creation in a phytoremediation-based circular economy ecosystem. A case

study approach is appropriate when the research objective is to understand a contemporary, context-dependent phenomenon in which the boundaries between the phenomenon and its setting are not clearly separable (Yin, 2018). It is also suitable for theory development where the aim is to identify mechanisms, relationships, and emergent constructs rather than to test predefined hypotheses (Eisenhardt, 1989; Siggelkow, 2007).

The case is treated as a revelatory and illustrative case because it brings together several features that are central to circular innovation ecosystems: nature-based remediation, critical material recovery, biomass valorisation, green construction applications, and sustainability assessment. Rather than analysing a single technology in isolation, the study examines the configuration of actors, knowledge assets, and value pathways that connect contaminated land, phytomining, bioprocessing, nanoparticle production, residual biomass, and cementitious material development. This ecosystem-oriented framing follows the logic of qualitative research in which complex empirical settings are used to refine conceptual understanding and generate theoretically meaningful insights (Dubois & Gadde, 2002; Gioia et al., 2013).

The empirical basis of the study consists of documentary and technical case material related to the Phyona/CSTO2NE use cases. The analysis focuses on identifying how knowledge flows across technical, organizational, environmental, and material domains, and how these flows contribute to the development of circular value propositions and ESG outcomes. The purpose is not to provide a full technical validation of each process, but to interpret the use cases as evidence of an emerging circular innovation ecosystem.

The analytical strategy follows an abductive logic, moving iteratively between theory and case evidence (Dubois & Gadde, 2002). The initial theoretical categories were derived from the literature on circular economy, knowledge management, innovation ecosystems, and ESG assessment. These categories were then refined through the case material, with particular attention to four dimensions: knowledge recombination, ecosystem coordination, circular value creation, and ESG credibility. This approach enables the paper to develop ecosystem health as a conceptual bridge between knowledge management capabilities and sustainability outcomes.

3.2 Case context: the Phyona/CSTO2NE circular innovation ecosystem

The focal case is centred on Phyona's phytoremediation- and phytomining-based circular economy model, commercialised by Phyona Ltd (www.phyona.co.uk) and further developed to integrate innovation for the decarbonisation of the construction sector in connection with CSTO2NE use cases. The extended abstract frames the case as a circular innovation ecosystem in which plant-based technologies are used to treat contaminated soils, extract heavy metals, and support the production of high-value nanoparticles. Rather than treating soil contamination as a residual environmental problem, the model reframes degraded land and metal-rich biomass as sources of regenerative value. This makes the case especially relevant for examining how circular economy initiatives can integrate remediation, resource recovery, and advanced material production within a broader socio-technical system.

The phytomining use case describes a workflow that integrates soil characterisation, plant selection, agronomic optimisation, biomass processing, and metallurgical recovery. Soil characterisation is used to assess contamination, metal bioavailability, and expected recovery potential, while plant selection and cultivation rely on hyperaccumulator species and agronomic practices that improve biomass yield and metal uptake. Downstream processing then converts metal-rich biomass into recoverable resources, although the use case also highlights biomass processing as a bottleneck for field-scale deployment because of the technical and economic challenges associated with transforming variable biomass into concentrated metal feedstock.

The environmental and ESG relevance of the case is reinforced by the life cycle assessment material included in the phytomining use case. Phyona Ltd commissioned an assessment covering three sites: Salford, Barnsley, and a hypothetical scaled future site. The study used a cradle-to-gate approach and considered climate change, water consumption, land use, and mineral resource scarcity. It also defined three functional outputs: one kilogram of filtered and dried nanoparticles, one kilogram of organic fertiliser, and one hectare of decontaminated land. This is important for the present paper because it shows that ESG outcomes are not treated as abstract claims, but as impacts that require system boundaries, allocation choices, functional units, and environmental indicators. Such use of life cycle thinking is consistent with established sustainability assessment practice, where environmental impacts must be assessed across defined product systems and life cycle stages (Huijbregts et al., 2016; ISO/TC 207/SC 5, 2006, 2022).

The CSTO2NE green cement use case extends the circular logic by examining how biomass and fibres can contribute to lower-carbon construction materials. The consortium has worked on two complementary approaches: bio-inspired composite design using bio-derived reinforcement materials and carbon-sink green mortars derived from phytomining biomass. The first approach explores natural fibres and carbonated matrices, while the second investigates residual fibres from the bioprocessing of metal-rich phytomining biomass. These

fibres are assessed for their reaction with mortar matrices and their potential use as reinforcement or functional additives that may improve workability, reduce Portland cement and water demand, and support lower embodied carbon construction materials.

The technical material also indicates that phytomining-derived fibres were characterised through chemical and microstructural methods and integrated into mortar formulations with varying water-to-cement ratios and fibre contents. The CSTO2NE methodology included sourcing biomass from hyperaccumulator plants, bioprocessing through Phyona's proprietary method for metal recovery, size fraction mapping of fibre residues, SEM/EDS, FTIR and TGA-PKM characterisation, mechanical testing under compression and flexure, and evaluation of thermal insulation potential. This reinforces the interpretation of the case as a knowledge-intensive ecosystem in which plant science, soil chemistry, bioprocessing, materials characterisation, construction technology, and sustainability assessment must be connected.

The case also involves a multi-actor configuration. The phytomining use case identifies collaboration among Phyona Ltd, Brunel University London, Silesian University of Technology, CPBI, and DTU, while the green cement use case consolidates contributions from Brunel University London, Phyona Ltd., University of Lleida, and Silesian University of Technology. These actors contribute different forms of expertise, including phytomining bioprocessing, fibre characterisation, mortar formulation, analytical testing, and market-oriented assessment. The case therefore provides a suitable empirical setting for analysing ecosystem health as the capacity to coordinate diverse actors and recombine distributed knowledge into credible circular and ESG outcomes.

Overall, the Phyona/CSTO2NE case is not examined as a finished commercial system, but as an emerging circular innovation ecosystem. Its analytical value lies in showing how environmental remediation, metal recovery, residual biomass valorisation, and construction material innovation can be connected through knowledge recombination. This makes it possible to explore how ecosystem health develops, where coordination challenges arise, and how ESG value can become more credible through technical validation, environmental assessment, and cross-sector collaboration.

4 Ecosystem Health Framework

Building on the Phyona/CSTO2NE case, this paper proposes ecosystem health as an intermediate construct linking knowledge recombination capabilities with credible ESG outcomes. Health refers to the capacity of the ecosystem to sustain knowledge flows, coordinate interdependent activities, adapt to uncertainty, and translate circular value creation into verifiable environmental, social, and governance outcomes.

The proposed framework is structured around five interrelated dimensions: knowledge diversity, knowledge connectivity, coordination capacity, adaptive learning, and ESG credibility.

First, knowledge diversity captures the breadth of expertise required to generate circular value. Phytomining-based circular models combine plant science, soil chemistry, microbiology, materials science, environmental assessment, construction technology, regulatory knowledge, and business model design.

Second, knowledge connectivity refers to the mechanisms through which distributed knowledge is exchanged, translated, and recombined across actors. Knowledge diversity alone does not produce ecosystem-level value unless actors are able to communicate across disciplinary and organizational boundaries. In the case analysed, laboratory characterization, soil intelligence, fibre testing, life cycle assessment, and material performance evaluation act as boundary objects that allow different partners to interpret and use each other's knowledge.

Third, coordination capacity concerns the ability of the ecosystem to align roles, responsibilities, incentives, and decision points. Circular innovation ecosystems are inherently interdependent: remediation activities affect biomass characteristics; bioprocessing affects metal recovery and residual fibre quality; material applications influence performance requirements; and ESG assessment depends on data generated throughout the system. Coordination capacity is therefore necessary to avoid fragmented innovation, where each actor optimizes its own contribution without strengthening the overall circular value proposition. This dimension is consistent with ecosystem theory, which emphasizes that value creation depends on the alignment of complementary actors around a shared value proposition (Adner, 2017; Jacobides et al., 2018).

Fourth, adaptive learning reflects the ecosystem's ability to respond to experimental evidence, site-specific conditions, regulatory constraints, and market feedback. Phytomining and biomass valorisation are not standardized processes; they depend on soil composition, plant performance, biomass variability, processing conditions, and downstream application requirements. The case material shows that different water-to-cement ratios, fibre sizes, and fibre concentrations affect the morphology and mechanical behaviour of cementitious formulations, while life cycle assessment identifies energy-related hotspots in the bioreagents preparation stage.

Finally, ESG credibility refers to the capacity to substantiate sustainability claims through transparent evidence and governance mechanisms. Circular economy initiatives can easily generate appealing narratives, but their legitimacy depends on whether environmental and social benefits can be demonstrated. In the Phyona/CSTO2NE case, ESG credibility is supported by the articulation of functional outputs, such as kilograms of nanoparticles, kilograms of organic fertiliser, and hectares of decontaminated land, as well as by environmental indicators including climate change, water consumption, land use, and mineral resource scarcity. Such assessment practices strengthen the connection between circular innovation and measurable impact.

Taken together, these five dimensions position ecosystem health as a practical and conceptual tool for assessing circular innovation ecosystems. A healthy ecosystem is not simply one that produces technically viable outputs, but one that can continuously recombine knowledge, coordinate actors, learn from evidence, and maintain the credibility of its ESG claims. This framework is especially relevant for emerging circular economy models, where technologies, markets, regulations, and stakeholder expectations are still evolving.

5 Discussion

The case analysis suggests that phytomining-based circular economy models should be understood as knowledge-intensive innovation ecosystems rather than as isolated environmental technologies. The Phyona/CSTO2NE case demonstrates that value creation emerges through the recombination of multiple knowledge domains: ecological knowledge concerning contaminated soils and hyperaccumulator plants; technical knowledge related to bioprocessing, metal recovery, and nanoparticle production; materials knowledge concerning residual fibres and cementitious matrices; and sustainability knowledge related to life cycle assessment and ESG reporting.

This finding contributes to knowledge management literature by showing that knowledge recombination is not only a driver of product or process innovation, but also a mechanism for circular value creation. In this case, circularity depends on the ability to reinterpret contaminated land and residual biomass as knowledge-enabled resources. What counts as “waste” or “contamination” changes when actors can connect plant-based remediation, metal recovery, biomass processing, and construction material development within a coherent ecosystem. Knowledge management therefore acts as an orchestration capability that enables the ecosystem to convert dispersed expertise into new circular value pathways.

The paper also contributes to circular economy literature by emphasizing the role of ecosystem health as a condition for credible circular impact. Much circular economy research focuses on material loops, business models, or environmental indicators. These are important, but they do not fully explain how circular systems become scalable, legitimate, and adaptive. The proposed framework suggests that circular economy initiatives require a healthy ecosystem capable of sustaining knowledge diversity, connectivity, coordination, adaptive learning, and ESG credibility. This perspective helps explain why promising circular technologies may fail to scale when governance, knowledge integration, or stakeholder alignment is weak.

Figure 1 illustrates the proposed ecosystem health framework. Knowledge recombination acts as the enabling mechanism through which diverse actors and knowledge bases are integrated. Ecosystem health is reflected in five dimensions (knowledge diversity, knowledge connectivity, coordination capacity, adaptive learning, and ESG credibility) which together support environmental, social, and governance outcomes in phytoremediation-based circular innovation ecosystems.

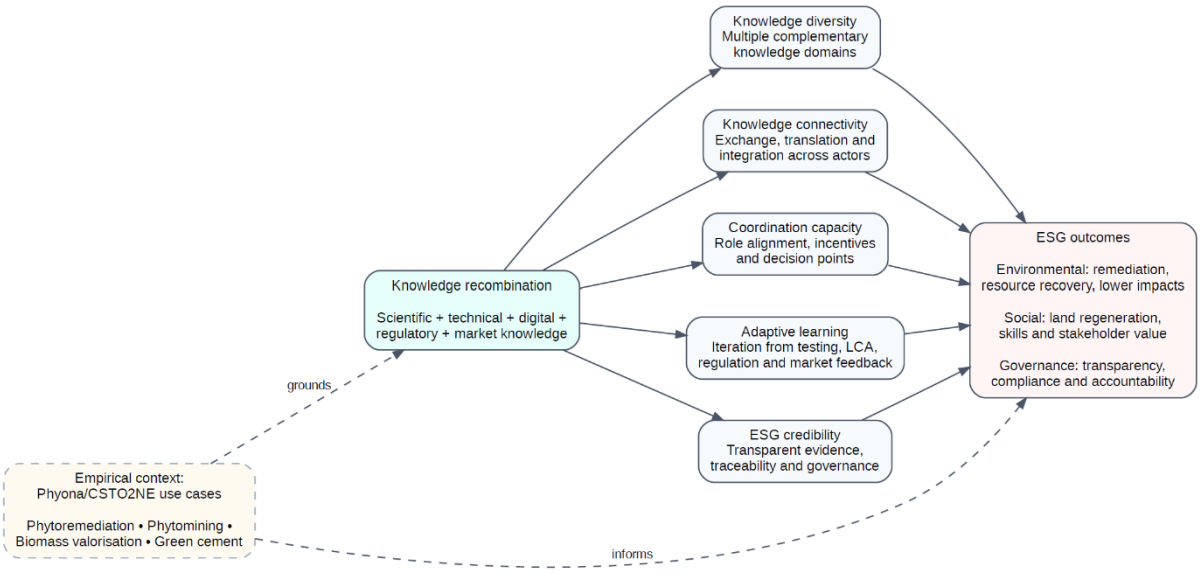

Figure 1. Ecosystem health framework for phytoremediation-based circular innovation

For managers, the framework highlights the importance of designing circular initiatives as ecosystems from the beginning. This means identifying not only technical partners, but also the knowledge interfaces required to connect them. Managers should pay attention to how data, test results, environmental assessments, and operational learning move across organizational boundaries. They should also treat ESG assessment as a learning process rather than as a final reporting exercise. In emerging circular systems, life cycle assessment, material testing, and site-specific monitoring can help identify hotspots, refine processes, and strengthen the credibility of sustainability claims.

For policymakers, the case illustrates the importance of supporting circular innovation ecosystems that connect environmental remediation with industrial valorisation. Contaminated land, mine residues, and marginal sites can be reframed as strategic assets when combined with appropriate knowledge, regulation, and market development. Policy support should therefore not focus only on individual technologies, but also on enabling infrastructures, testing facilities, data standards, certification pathways, and cross-sector partnerships. This is particularly relevant for critical raw materials, low-carbon construction, and nature-based solutions, where public legitimacy and regulatory confidence are essential.

The case also has implications for ESG practice. ESG outcomes in circular ecosystems should not be treated as isolated indicators attached to a finished product. They emerge from the way the ecosystem is organized and governed. Environmental outcomes depend on remediation effectiveness, resource recovery, carbon impacts, and material substitution. Social outcomes depend on land regeneration, local engagement, skill development, and the creation of new opportunities around degraded sites. Governance outcomes depend on transparency, traceability, role clarity, and credible evidence. Ecosystem health therefore provides a useful bridge between operational circularity and ESG performance.

However, the study also has limitations. The analysis is based on qualitative documentary and technical case material rather than longitudinal observation or primary interviews with all ecosystem actors. The case should therefore be interpreted as theory-building and exploratory rather than as a basis for statistical generalization. In addition, several technical pathways remain under development, particularly regarding the large-scale performance of phytomining-derived fibres in cementitious materials and the commercial scalability of biomass processing. Future research could extend this work through longitudinal case studies, comparative ecosystem analysis, stakeholder interviews, and quantitative assessment of ecosystem health indicators.

6 Conclusions

This paper examined how knowledge recombination supports ecosystem health and ESG value creation in a phytoremediation-based circular economy ecosystem. Grounded in the Phyona/CSTO2NE use cases, the paper argued that circular innovation should not be analysed only as a technical process of material recovery, but as an ecosystem-level phenomenon requiring the coordination of heterogeneous actors, knowledge domains, and value pathways.

The central contribution is the proposal of an ecosystem health framework for circular innovation. The framework identifies five dimensions: knowledge diversity, knowledge connectivity, coordination capacity,

adaptive learning, and ESG credibility. These dimensions explain how circular economy ecosystems can move from fragmented experimentation towards scalable and legitimate impact. In the case analysed, contaminated land, hyperaccumulator plants, recovered metals, nanoparticles, residual biomass, and cementitious materials are connected through knowledge flows that enable new forms of circular value creation.

The paper contributes to knowledge management research by positioning knowledge recombination as a core capability for circular innovation ecosystems. It contributes to circular economy literature by showing that ecosystem health can act as an intermediate construct linking knowledge management practices with ESG outcomes. It also offers practical guidance for managers and policymakers seeking to design, govern, and assess circular economy initiatives that combine nature-based solutions, resource recovery, and industrial applications.

Overall, the study suggests that credible circular economy transitions require more than technical feasibility. They require healthy ecosystems capable of learning, coordinating, adapting, and demonstrating impact over time.

7 Ethics Declaration

Ethical clearance was not required for this research, as the study is based on documentary analysis, technical use-case material, and non-human-subject research. No personal data, interviews with human participants, or sensitive individual-level information were collected or analysed.

8 AI Declaration

Generative AI tools were used to improve the linguistic flow and grammatical accuracy of this manuscript, as the authors are non-native English speakers. However, the final content has been thoroughly reviewed and edited by the authors, who take full responsibility for the integrity and accuracy of the published work.

Economic Potential of ESCO Financing Models in Public Lighting: Evidence from Hungary

Nikolett Deutsch[1], László Berényi[2]

Abstract

The technical capacity of LED street-lighting retrofits to achieve energy savings and reduce operating and maintenance costs is well established in the literature. This study contributes to the field of municipal energy-efficiency financing by presenting a two-sided discounted cash-flow analysis of public lighting modernization, comparing direct public financing with the ESCO-based model. Unlike most existing studies, which focus on either technical optimization or financing structures, this research models municipal and ESCO cash flows separately and examines their interaction within a unified financial framework for Hungarian municipalities. This issue is highly relevant in Hungary, where street lighting constitutes a major operational expense for municipalities with limited investment capacity and debt constraints. Regulatory and ownership limitations, lack of experience, uncertainty regarding realized savings, and weak procurement capacity further impede municipal retrofit activities. The analysis demonstrates that financial attractiveness depends not only on energy-saving potential as well as on tariff structures, contract duration, and contractor fees. The findings indicate that energy-efficient LED retrofits may remain financially unattractive for municipalities under direct self-financing, whereas the ESCO model can improve municipal outcomes by shifting upfront investment burdens, even if it reduces the provider's return. The results show that key contractual parameters primarily redistribute economic value rather than alter the underlying savings potential, which helps explain the frequent emergence of conflicts of interest in ESCO contracts. By quantifying these trade-offs and identifying threshold values at which municipal and ESCO incentives diverge or align, this study improves understanding of when and under what conditions ESCO financing constitutes a viable solution for small Hungarian municipalities. These insights prove particularly relevant for policy design and contract structuring in contexts characterized by budget constraints, tariff uncertainty, and limited local investment capacity.

Keywords: Energy Service Company, business model innovation, financial analysis, sustainability.

Paper type: Practical Paper

1 Introduction

Public lighting refers to the continuous, regular, fixed location artificial illumination of public spaces, such as roads, squares, parks, and private areas open to public traffic, operated according to a predefined schedule. Its primary purpose is to ensure traffic safety and protect public and private property at night. Municipalities are responsible for providing safe, reliable, lawful, and affordable public lighting services. At the same time, they are increasingly expected to improve energy efficiency, reduce greenhouse gas emissions, and mitigate environmental impacts such as light pollution. Thus, municipalities face a multi-objective challenge in public lighting management, and often struggle to deliver these services consistently due to several financial, technical, organizational, and regulatory obstacles. As Mercado et al. (2018) stress, public lighting services account for 30-50% of total municipal electricity consumption, and their share of municipal budgets varies with settlement size, ranging from 5-10% in larger cities to as much as 20% in smaller locations. As budgetary constraints restrict investment capacity as well as strategic flexibility, and municipalities are particularly exposed to energy price shocks, they tend to favour short-term solutions that give immediate cost reductions (Polzin et al., 2018). While increasing energy prices may strengthen the economic grounds for efficiency investments, they can also render decision-making more reactive and politically constrained (Lockwood & Selwyn, 2011). Due to aging systems, higher O&M costs, limited local expertise, procurement issues, and stricter regulatory and data reporting requirements, modernizing existing infrastructure is challenging. Although LED technology and adaptive lighting systems can deliver notable energy savings (Tsankov et al., 2025), the relatively high investment costs can delay implementation (Doulos et al., 2019; Balázs et al., 2023). Some authors (Valentiny, 2008; Pintér et al., 2018) also call attention to the fact that municipalities must operate under strict constraints on borrowing capacity, ownership structures, and tariff regulation, and in many cases, public funding schemes are insufficient, poorly targeted, or poorly aligned with the specific conditions of local projects. Polzin et al. (2016b) emphasize that procurement, implementation, and long-term management often exceed local governance capacities, making it more difficult for municipalities to implement retrofit projects. Similarly, Plepys and Richter (2016) highlight that

knowledge gaps, fragmented responsibilities, and risk-averse interpretations of procurement regulations hinder the uptake of innovative lighting solutions.

Municipal street lighting retrofits can be financed in many ways. Novikova et al. (2017) summarize options for municipalities, highlighting their advantages and disadvantages. Self-financing relies on revenues or grants, sometimes supplemented by internal contracting or revolving funds to ease taxpayer burden. However, limited revenues or weak capacity hinder project development, leading local governments to seek external financing like debt, municipal bonds, or institutional investment, with repayments from taxes or energy savings. Private contractors support retrofit projects through contractual schemes, covering design, financing, and implementation. Large infrastructure projects may involve private ownership and operation under leasing or concession agreements, with ownership reverting later. Funding often uses project finance via special-purpose vehicles, or crowdfunding for community involvement. Nowadays, there is a shift toward third-party financing models such as PPPs, ESCO schemes, and EPCs, in which investments are repaid from energy savings, either guaranteed or shared.

According to Bertoldi and Rezessy (2005), energy service companies develop, implement, and finance energy-efficiency or renewable energy projects, with project costs, including investment expenditures, recovered from the income stream generated by energy savings or renewable energy production. Bertoldi et al. (2014, p. 5) describe ESCOs as entities that guarantee energy savings or provide the same service at lower costs, with remuneration tied to savings and the ability to finance or help arrange financing for energy systems. Municipalities transfer financial responsibility for infrastructure updates to ESCOs via contracts, which include fees for planning, financing, and implementation. Operational activities are managed separately (Wardhana, 2024). This arrangement allows off-balance-sheet investment and simplifies procurement by enabling authorities to hire specialized service providers.

Business models, or financing schemes used for public energy efficiency projects, are well described in the relevant literature. Several case studies (World Bank, 2015; Marques & Geddes, 2019; Kurniawan & Kurniawan, 2022; Patra et al., 2025) evaluate how these options operate in practice, examining financing methods, asset ownership, and risk-sharing arrangements. Within the EPC and ESCO literature, public lighting is often seen as a promising application area, as LED-based renovations are relatively simple in technical terms, their benefits are easy to communicate, and the investment logic is often more transparent than in other energy-efficiency applications (Novikova et al., 2017). However, the empirical literature on public lighting is predominantly case-based, which limits the comparability and generalizability of the results. Quantitative studies on street lighting modernization primarily use techno-economic optimization or multi-criteria decision-making approaches. These papers often focus on the comparative assessment of replacement strategies, technology selection, and investment alternatives (Carli et al., 2018; Hermoso-Orzáez et al., 2019; Juričić et al., 2020; Gordić et al., 2021). Although these approaches play a major role in improving technical efficiency and decision support, they mostly neglect detailed analysis of project-level financing structures, contractual pricing mechanisms, and financial risk and benefit-sharing between the parties. A further branch of the literature examines ESCO and EPC structures primarily from a legal, institutional, and accounting perspective, with particular attention to public procurement rules, public debt classification, and state aid constraints (Polzin et al., 2016a,b). This approach provides an important analytical framework for understanding the institutional and regulatory feasibility of projects, but it is not intended to model in detail the project-level cash flows, tariff structures, or profitability profiles associated with specific technological uses. However, surveys of large-scale Western European projects show that while reducing energy and maintenance costs improves economic prospects, overall profitability remains sensitive to investment and financing costs (Campisi et al., 2017; Campisi et al., 2018). Studies based on German and Scandinavian cases show that municipalities often use EPC to reduce their investment needs and financial risks. This is especially important for municipalities with limited internal capital, technical expertise, or project management capacity (Polzin et al., 2016a,b; Aasen et al., 2016; Jensen et al., 2013). Studies focusing on Central and Eastern European countries mainly highlight the barriers and risks of third-party financing, and place greater emphasis on procedural feasibility, procurement structures, and legal frameworks than on detailed financial analysis of projects (Mikuŝová et al., 2020; Wacinkiewicz & Słotwiński, 2023). Furthermore, some authors (Bobbino et al., 2014; Kurowska-Pysz & Kunikowski, 2021; Wacinkiewicz & Słotwiński, 2023) argue that EU regulations on EPC, public accounting, and state aid strongly affect whether ESCO contracts are recorded on municipal balance sheets. In addition, financial analysis in many studies focuses primarily on institutional and accounting compliance issues, while the actual project-level cash flow structures are mostly only partially or implicitly reflected. While numerous business models, financing, and contracts for public lighting modernization are documented, much of the literature focuses on case studies or institutional issues. So it can be stated that there is still a lack of transparent, generalizable analyses that model municipal and ESCO cash flows, tariffs, savings sharing, and transaction costs in a unified framework.

This paper explores the ESCO model's potential to boost energy efficiency and cost savings for Hungarian municipalities facing limited funds, debt, aging infrastructure, and a lack of expertise. A Hungary-specific model integrating street lighting retrofits with ESCO financing is proposed as a decision-support tool. The research develops a hypothetical business model and an Excel-based decision analysis to replace fixtures with LED luminaires, using indicators such as NPV, ROI, and IRR to evaluate feasibility from municipal and utility perspectives. Cost data and forecasts support legislative and engineering considerations. Sensitivity analyses examine how variables such as energy charges, grants, contractor fees, payments, and contract length affect savings for both parties.

The structure of the paper is as follows: Section 2 outlines the model development and main assumptions. Section 3 presents the results of the financial and sensitivity analyses. Section 4 discusses the key findings in relation to the relevant literature. The conclusion provides a summary and final remarks.

2 Research Design

Hungary has achieved a substantial reduction in energy intensity over the past decade, with a 23.28% decline since 2015, according to Eurostat data. In parallel with this trend, an increasing number of municipalities have begun upgrading obsolete public lighting infrastructure by replacing traditional luminaires with energy-efficient technologies. As illustrated in Figure 1, these modernization efforts contribute to a measurable reduction in the overall electricity consumption of public lighting. While these trends are positive, they also mask persistent structural challenges. Energy intensity in Hungary remains well above the EU average, suggesting considerable untapped energy efficiency potential, particularly in the public sector and municipal infrastructure. In these areas, old systems and limited investment capacity continue to constrain modernization efforts (European Commission, 2025). Hungarian municipalities face a layered challenge, as they are under strong pressure to reduce electricity expenditure, a burden that is especially pronounced in smaller settlements. Local Hungarian governments must manage aging infrastructure, budgetary constraints, a lack of expertise, and a regulatory environment that does not always correspond to technically optimal solutions (Vidovszky Németh & Schanda, 2011; OECD, 2023; Vasvári & Longauer, 2024; Gellén & Horváth, 2026). Pintér et al. (2018) demonstrate that for many small municipalities, the upfront investment costs of lighting retrofits are prohibitively high without external funding, rendering several modernization pathways financially unviable in the absence of non-repayable public support. Drawing on international experience, ESCO-type intermediation can offer a mechanism for delivering financing, technical expertise, and risk management to Hungarian municipalities.

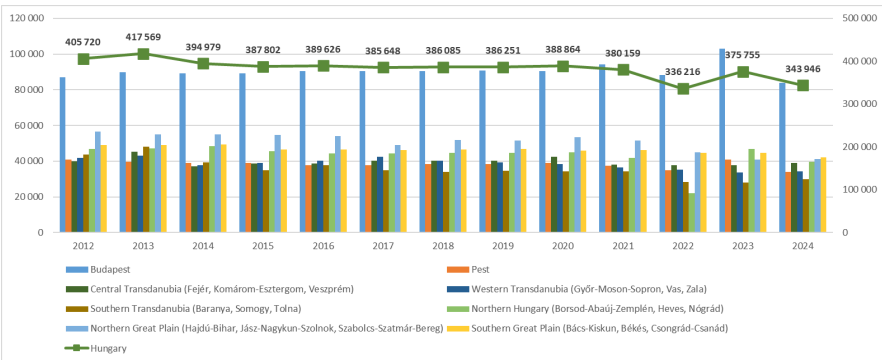

Figure 1. Energy consumption for public lighting - Regional distribution (in 1000 kWh)

This paper evaluates the financial viability of energy-efficiency investments using an ESCO financing model, focusing on modernizing municipal public lighting systems in Hungary. A hypothetical case study examines upgrading the public lighting system in a small Hungarian settlement with LED luminaires under an ESCO agreement. Based on an engineering review, it proposes a complete redesign using LED technology to reduce light pollution, improve lighting, and diminish energy use by 20%. Tables 1 and 2 show the technical details. The Excel-based decision model assumes that, under an ESCO scheme, the municipality's financial burden shifts to an energy service company via a contractual agreement. The service provider covers planning, financing, and retrofit costs, while lighting operation is managed under a separate contract. To assess the value of the ESCO model, the feasibility was evaluated for two options:

- Option 1 - Direct Investment by the municipality: The municipality, in collaboration with the energy company, modernizes its public lighting system by replacing existing luminaires with LED units. The full project cost is paid by the municipality in the year of the investment.

- Option 2 - ESCO-Based Model: The energy company handles the investment and operation. The municipality repays the cost over time in accordance with the ESCO financing agreement. The municipality repays the investment amount (including VAT) over 8 years. The initial payment at project start is zero, and from the second year, the municipality pays 1% of the investment amount annually as a contractor fee.

The common underlying assumptions of the feasibility analyses conducted for the options can be summarized as follows:

- Only luminaire replacement considered (no pole changes).
- Project lead time: 1 year.
- No investment subsidy or loans are assumed.
- Investment cost: 52 675 EUR.
- ESCO revenue includes only contractor fees and maintenance profits.
- Depreciation calculated linearly over investment cost.
- Residual value considered at the end of the analysis period.
- Energy company subsidiary responsible for operation and maintenance.
- O&M costs on the energy company's side are 90% of O&M fees.
- O&M costs saved due to modernization: 25%
- Identical external conditions: VAT = 27%, inflation = 3.00%, required return = 5.83%, corporate tax = 9%, analysis period = 15 years.
- Identical energy, transmission, and distribution tariffs for old and new systems.
- Tariffs increase according to inflation.

Table 1: Description of the current system

System elements	Quantity (Nr.)	Electrical energy (W)	Consumption (Wh)
Na lamp 400W	9	400	432

3 Results and Discussion

3.1 Financial Results for the business options

The financial analysis used traditional indicators such as NPV, IRR, payback period, and ROI. Without ESCO financing (see Table 3), modernizing public lighting would require upfront costs for the municipality. The first year shows a net cost of EUR 48,918.78, based on an EUR 52,675 investment, only partly offset by savings from reduced electricity and 25% lower O&M costs due to improved energy efficiency. Despite operational savings, all key financial indicators remain negative, and the project does not cover initial costs over 15 years. For the energy company, the NPV of revenues from operational and maintenance cash flows, excluding electricity sales, is about EUR 2253.513.

Table 3. Financial results for the partners under Option 1

Indicator	Municipality	Energy Company
Total discounted savings/revenue (EUR)	-1 824.295	2253.513
Yearly discounted savings (EUR/y)	-121.62	150.24
Discounted internal rate of return	-0.53%	Not interpretable
Discounted payback period	Not interpretable	0
ROI	-3.00%	Not interpretable

Under the ESCO model, the municipality collaborates with an energy company to modernize public lighting by replacing existing lighting with LED luminaires. The energy company finances the upgrade, and the municipality repays over an eight-year period, starting from the second year, with an annual fee of 1% of the investment. The project reaches financial breakeven in year 12, with total discounted savings of EUR 6,354.21. From the energy company's view, the investment does not break even within 15 years, resulting in a net present value of EUR -6,150.27 and a discounted internal rate of return of -3.92%.

Table 3. Financial results for the partners under Option 2

Indicator	Municipality	Energy Company
Total discounted savings (EUR)	6354.205	-6150.27
Yearly discounted savings (EUR/y)	423.61	410.02
Discounted internal rate of return	5.66%	-3.92%
Discounted payback period	12	Not interpretable
ROI	58.00%	Not interpretable

In sum, the financial analysis indicates that, under the baseline assumptions, the LED modernization of the public lighting system is not economically viable when financed solely by the municipality. Under the ESCO model, the project becomes financially attractive to the municipality but fails to generate a sufficient return for the energy company. However, these results are highly sensitive to a range of external factors that are uncertain at the start of the project or may evolve over time, as well as to contractual parameters that may be subject to negotiation between the parties. Consequently, conclusions drawn from the baseline options alone are insufficient to provide robust and well-founded guidance for decision-making.

3.2 Financial results for the business options

To illustrate how traditional and ESCO models respond to changes in assumptions on exogenous variables or contractual elements, one and two-way sensitivity analyses were conducted. The existing literature stresses that public lighting retrofit projects are sensitive to energy charges (Beccali et al., 2018; Campisi et al., 2017), subsidies (World Bank, 2015), contractor fees, and contract length (Guo & Zhang, 2020; Tupikina & Rozhkova, 2020; Martiniello et al., 2020). Energy charge changes directly impact savings: higher charges boost benefits, while steady or falling prices weaken financial viability. Grant support reduces initial costs and improves financial indicators. One-way analyses on energy charges and grants were performed for Options 1 and 2. As shown in Figure 2, under Option 1, municipal savings increase if energy charges fall below EUR 0.03827/kWh. With grants, savings break even at a 3.46% grant rate.

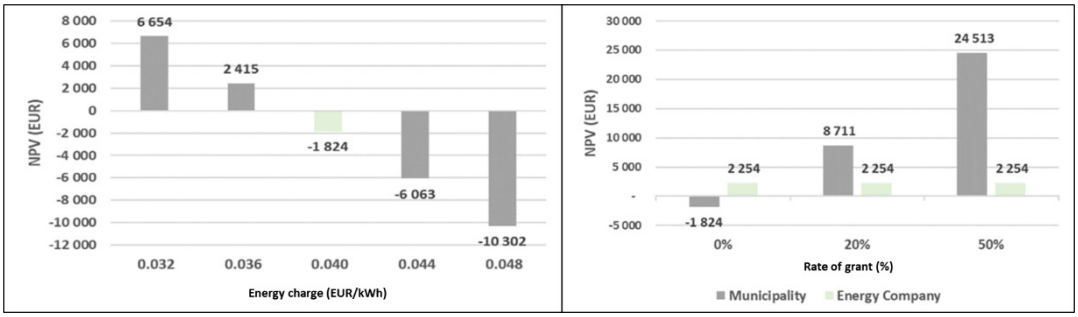

Figure 2. Sensitivity analysis for Option 1 - Energy charge (EUR/kWh) & Availability of public grants (Rate of grant in the investment cost, %)

In the case of Option 2 (see Figure 3), the municipality breaks even over the evaluation period at an energy charge of EUR 0.046/kWh. Beyond this level, the investment is no longer financially beneficial for the municipality. This suggests that higher energy charges alone are sufficient to eliminate municipal financial gains. The availability of public grant improves the economic results for both parties, but not to the same extent. Even at a high subsidy rate of 50%, the energy company is still unable to fully recover its investment over the evaluation period, although its net present value improves to EUR -1,372. By contrast, the municipality benefits more strongly from grant funding. Under these conditions, the investment is effectively recovered in the year of implementation, resulting in total discounted cost savings of EUR 28,602.

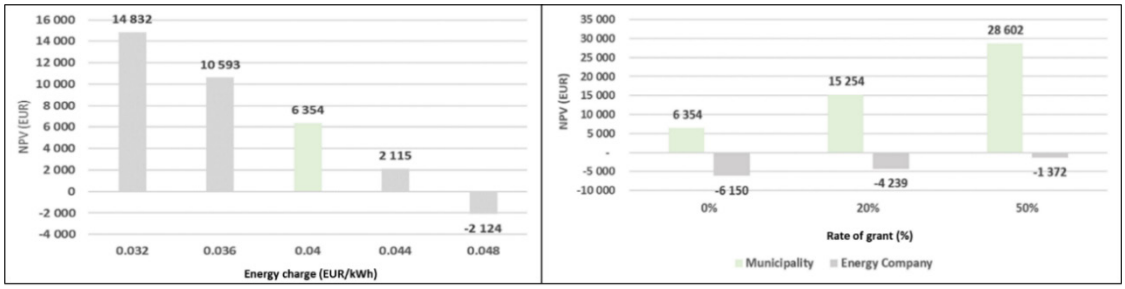

Figure 3. Sensitivity analysis for Option 2 - Energy charge (EUR/kWh) & Availability of public grants (Rate of grant in the investment cost, %)

The municipality's ESCO financial results are sensitive to contractual parameters. Small changes in fees can significantly impact net present savings: a 1% fee increase without grants can make the NPV negative. Conversely, this boosts the energy company's NPV to EUR -4,488.3. The project becomes profitable for the energy company once the contractor fee exceeds 4.63%, while municipality savings turn negative above 3.77% (Figure 4). Contract duration and initial repayment rate are key, affecting how returns are shared. Longer contracts ease annual pressure and help recover costs, while higher initial repayments improve the energy company's liquidity but increase early costs for the municipality. Longer repayment periods with higher first-year payments can increase the municipality's discounted savings but reduce the energy company's return.

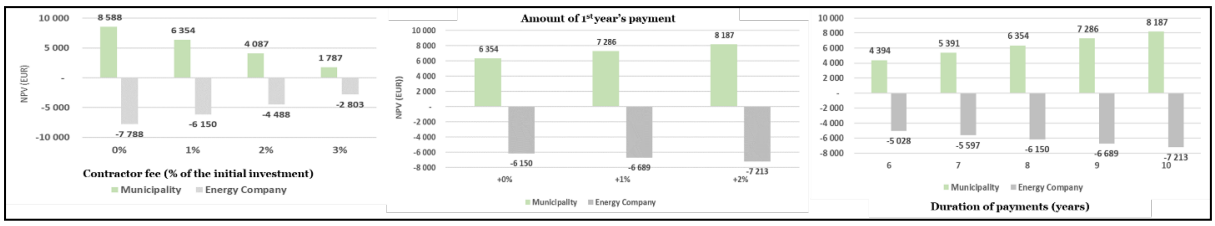

Figure 4. Sensitivity analysis for Option 2 - Contractor fee, Amount of 1st year's payment & Duration of payments

The two-way sensitivity analysis (see Figure 5) examines how changes in public grants and contractor fees affect the project's net present value, helping determine when investment is attractive to municipalities without harming the ESCO's finances. Results show that with only contractual fee and O&M income, and no grants, no contractor fee yields positive returns for both parties, revealing a conflict of interest in the ESCO model without public support. However, if subsidies exceed 30%, municipal savings stay positive across all fees, showing grants can turn an unviable project into a financially sustainable one, enabling mutually acceptable outcomes.

4 Discussion

In the relevant literature, only a limited number of studies explicitly examine municipal and ESCO cash flows in parallel or compare direct public financing with ESCO-based delivery using a unified discounted cash flow framework. According to prior studies, municipalities can realize considerable energy savings through street lighting modernization despite failing to recoup investment costs (Tähkämö et al., 2012; Beccali et al., 2018). It can also be stated that these economically desirable outcomes are highly context-specific and depend on local tariff structures, engineering and maintenance assumptions, lighting standards, capital costs, and financing conditions (Jiang et al., 2015; Campisi et al., 2018). The results of the present study are fully consistent with these statements, confirming that under self-financing, financial savings often materialize too slowly to offset upfront costs, particularly in the absence of subsidies or favorable tariffs (Polzin et al., 2016a; Novikova et al. 2017). At the same time, the relevant literature treats ESCO-based models as a means of improving public street lighting due to their predictable savings, moderate technical complexity, and relatively reliable baseline consumption (Šeba & Mušec, 2018). Nevertheless, both prior findings and our results emphasize that ESCO financing does not eliminate costs but redistributes them over time through contractor fees, contract duration, and risk allocation (Tupikina & Rozhkova, 2018; Martiniello et al., 2020). Consistent with earlier empirical and modeling research, our study shows that low contractor fees may preserve positive municipal savings while undermining ESCO viability, whereas small increases in fees or contract length can rapidly shift returns toward service providers (Guo et al., 2019; Guo & Zhang, 2020). Overall, these findings reinforce contract design and savings sharing as the central determinants of balanced and sustainable ESCO business models.

5 Conclusions

Although the technical effectiveness of LED street-lighting retrofits is well established, their financial performance becomes less certain once financing arrangements and contract design are considered. This study uses a two-sided discounted cash-flow approach to compare direct public financing with ESCO-based implementation. The results show that viability depends not only on energy savings, but also on tariffs, contract duration, fees, and subsidies. Even energy-efficient LED projects may be financially unattractive under direct financing, while ESCO models can relieve municipal budget pressure, often at the expense of provider profitability. In the examined cases, balanced outcomes for both parties occur only when public investment subsidies exceed 30 percent. Generalization of our key findings is not possible because the analysis is based on a hypothetical Hungarian case with a specific technical, economic, and institutional context. Although exploratory and context-specific, the analysis helps clarify when ESCO financing can offer a financially sustainable path for public lighting modernization.

Abstract

A central challenge in regional innovation and sustainability transitions research is to explain why the twin innovation transition — understood as the joint advancement of green and digital technological specialisation — emerges only in some regions and only at specific moments in time. While Evolutionary Economic Geography has offered powerful concepts to analyse regional path development, much of this literature has focused on the emergence of new growth trajectories, paying less attention to situations in which path-development potential stabilises, remains latent, episodic, or insufficiently converted into transformative innovation outcomes.

This paper addresses this gap by developing a configurational panel framework that links regional path development mechanisms to twin innovation outcomes across European NUTS-2 regions over the period 2007–2019. Drawing on regional path development theory and sustainability transitions research, we argue that twin innovation is not the result of a single enabling factor, but of place-specific combinations of structural assets, innovation capabilities, external linkages, policy support, and institutional conditions. At the same time, the absence of twin innovation should not be interpreted simply as a lack of capabilities, but may reflect incomplete conversion processes, weak cross-domain coupling, or path-development dynamics that remain temporally unstable.

Methodologically, the paper applies panel fuzzy-set Qualitative Comparative Analysis to distinguish between cross-sectional variation across regions and longitudinal variation within regions. This allows us to assess not only which configurations are sufficient for twin innovation, but also whether they display temporal stability or instead appear as episodic alignments. The findings show that regional innovation performance constitutes an important baseline condition across the identified configurations, but is not sufficient on its own to generate twin innovation outcomes. Moreover, the mechanisms most commonly associated with cumulative regional development, such as extension and branching, do not emerge as sufficient pathways to twin innovation. Instead, the results point to a limited number of highly place-specific configurations, often concentrated in Northern and Western European regions, whose empirical relevance is frequently episodic rather than stable over time.

The paper contributes to the literature in two ways. Conceptually, it refines the link between regional path development and sustainability transitions by distinguishing between path-development potential, path activation, and path realisation. Empirically, it provides systematic panel evidence on the spatial selectivity and temporal fragility of twin innovation trajectories in Europe, with implications for place-based innovation policies aimed at supporting not only regional capabilities, but also their effective conversion into green-digital transformation.

Paper type: Academic Research Paper

1 Introduction

Regional economies across Europe have undergone substantial transformation over the past two decades, driven by intensifying pressures towards green and digital technological change (Bachtrögler-Unger et al., 2023). Among the multiple dimensions of this transformation, the joint advancement of green and digital technological specialisation within regions — what we term twin innovation — plays a particularly strategic role. It is through the simultaneous generation and adoption of knowledge in both domains that regions build the capabilities required to navigate long-term structural change (Mäkitie et al., 2023). Yet this process remains deeply uneven across space and over time. A growing body of research has begun to examine regional innovation trajectories, highlighting how structural heterogeneity shapes both the capacity and the mode of regional response to transformative pressures (Fazio et al., 2024; Montresor & Vezzani, 2023). While this heterogeneity has been examined in its spatial dimension (R. Boschma et al., 2017), its temporal dynamics — including whether underlying configurations persist, transform, or emerge only episodically — have largely remained a black-box in transitions research (Strambach & Pflitsch, 2020).

Evolutionary Economic Geography provides a powerful framework for analysing how regional economies transform their innovation base over time (R. A. Boschma & Frenken, 2006; Martin & Sunley, 2006). Its typology of path development mechanisms — creation, importation, upgrading, diversification, branching, and extension — offers a systematic basis for understanding regional structural change (Grillitsch et al., 2018; Hassink et al.,

2019; Isaksen, 2020). However, this literature has predominantly focused on the emergence of new growth trajectories, paying limited attention to situations in which path-development potential remains latent, episodic, or insufficiently converted into transformative innovation outcomes. More fundamentally, the link between regional path development mechanisms and twin innovation trajectories has not been systematically established — neither for configurations that succeed, nor for those that remain stable yet fail to generate green-digital co-specialisation over time.

This paper addresses these gaps by developing a configurational panel framework linking regional path development mechanisms to twin innovation outcomes across European NUTS-2 regions over 2007–2019. By combining insights from sustainability transitions theory and Evolutionary Economic Geography (Fuenfschilling & Truffer, 2014; Köhler et al., 2019; Loorbach et al., 2017), and applying panel fuzzy-set Qualitative Comparative Analysis, the analysis disentangles cross-sectional structural diversity from temporal dynamics, highlighting the extent to which regional pathways reflect durable structures or transient alignments of conditions.

The remainder of the paper is structured as follows. Section 2 reviews the theoretical background. Section 3 presents the methodology. Section 4 presents the analytical model. Section 5 reports the empirical findings. Section 6 discusses their theoretical and policy implications and concludes the paper.

2 Background

Understanding why twin innovation trajectories unfold so unevenly across regions requires unpacking the place-specific configurations that shape regional innovation systems and their capacity for transformation over time. Regions can be conceptualised as territorially embedded systems of firms, knowledge organisations, and institutions whose interactions shape processes of knowledge creation, diffusion, and use (Asheim et al., 2011). These systems are embedded in multi-scalar dynamics that connect local developments to broader socio-technical transformations (Coenen et al., 2012; Truffer & Coenen, 2012), and are shaped by institutional environments that co-evolve with technological specialisation and industrial structures. As a result, regional transitions tend to follow differentiated and context-specific trajectories, reflecting place-dependent configurations of capabilities and institutional arrangements (Affolderbach & Schulz, 2016; Gibbs & O'Neill, 2017). A growing body of work at the intersection of sustainability transitions research and Evolutionary Economic Geography has highlighted precisely this multiplicity — emphasising how the pace, direction, and stability of regional transformation are shaped by place-specific configurations rather than by universal mechanisms (R. Boschma et al., 2017; Hodson et al., 2017).

The EEG literature provides a well-established framework for analysing how regional economies evolve through processes of path development, emphasising the cumulative and path-dependent nature of regional transformation shaped by the interaction between existing capabilities, institutional structures, and external linkages (R. Boschma & Martin, 2010). The literature identifies a range of mechanisms through which regional industrial and innovation structures evolve over time — path creation, importation, upgrading, diversification, branching, and extension (Grillitsch et al., 2018; Hassink et al., 2019) — as synthesised in Table 1.

Table 1. Types and mechanisms of regional industrial path development

Type of path development	Definition
Path creation	Emergence of entirely new industries, driven by novel technologies, institutional change, and entrepreneurial agency, often requiring the transformation of the local knowledge and innovation system.
Path branching	Emergence of new industries related to existing regional knowledge, based on the redeployment of existing assets by incumbent firms or spin-offs.
Path diversification	Emergence of new industries based on unrelated combinations of knowledge, involving a greater degree of novelty and cognitive distance.
Path importation	Establishment of industries new to the region but not new to the world, driven by exogenous actors and potentially embedded through local linkages (Karlsson, 2008).
Path upgrading	Transformation within existing paths via (i) functional upgrading in global value chains, (ii) technological or organisational renewal, or (iii) niche development based on symbolic knowledge.
Path extension	Continuity of existing industrial path through incremental innovation along established technological trajectories

Source: own elaboration

Yet this classification, while analytically useful, tends to conceptualise path development mechanisms as distinct and relatively stable processes. To assess the empirical grounding of this limitation, we conducted a

structured review of studies explicitly applying path development typologies across European regional contexts — presented in detail in Section 3. The review confirms that existing studies have largely adopted descriptive approaches focused on a limited number of case studies, offering only partial insight into how multiple mechanisms interact, overlap, and reconfigure over time (Blažek et al., 2020). This empirical orientation contrasts with the sustainability transitions literature, which conceptualises transformation as the outcome of co-evolving technological, institutional, and social dynamics unfolding through region-specific configurations of industrial structures and actor constellations (Geels, 2012; Hansen & Coenen, 2015; Markard et al., 2012; Truffer & Coenen, 2012). What remains insufficiently understood is how multiple path development mechanisms combine and evolve over time — and whether the resulting configurations are durable structures or transient alignments that dissolve before generating transformative outcomes.

This gap is particularly salient in the context of twin innovation, which requires the simultaneous development and coupling of green and digital knowledge domains within the same regional system over time. While both domains have been widely studied in isolation, the link between regional path development mechanisms and twin innovation trajectories has not been systematically established — neither for configurations that succeed in generating green-digital co-specialisation, nor for those that remain stable yet fail to convert path-development potential into twin innovation outcomes. Against this background, the paper addresses the following research question: How do configurations of regional path development mechanisms evolve over time across European regions, and what conditions determine whether these temporal patterns support, constrain, or prevent the emergence of twin innovation trajectories?

3 Methodology

Investigating how configurations of regional path development mechanisms evolve over time and under which conditions they support, constrain, or prevent twin innovation trajectories requires a methodological approach capable of addressing two forms of complexity simultaneously: the geographical heterogeneity of regional systems and the temporal dynamics of their transformation. Neither regression-based models nor structural equation modelling are well suited to this purpose, as they estimate net effects of individual conditions and are ill-equipped to capture conjunctural causation, equifinality, and causal asymmetry (Ragin, 2000, 2008). The analysis therefore adopts a two-step design that combines a structured literature review with a panel fuzzy-set Qualitative Comparative Analysis (fsQCA).

The first step consists of a structured review of empirical studies explicitly applying path development typologies across regional contexts. Following a multi-stage protocol, we queried Scopus using a combination of relevant keywords — including "regional innovation", "path development", "branching", "diversification", "upgrading", "importation", and "creation" — restricted to peer-reviewed articles in English. Abstracts were screened for references to European countries and NUTS-2 regions, and studies from unrelated disciplines were excluded. Additional papers were included based on the research team's expert judgement. The resulting cases were systematically classified according to their dominant path development trajectory by applying the taxonomy drawn from Grillitsch et al. (2018) to the mechanisms explicitly described by the original authors. This step provided the empirical foundation for the second step.

The second step adopts a configurational approach grounded in a conceptualisation of regional innovation systems as complex adaptive systems — dynamic structures characterised by non-linearity and emergent properties arising from interactions among heterogeneous agents (Cooke, 2013). FsQCA builds on set-theoretical principles and Boolean algebra, and draws on an understanding of causal complexity structured around conjunctural causation, equifinality, and causal asymmetry (Rihoux & Ragin, 2009). Unlike regression approaches, fsQCA identifies how multiple conditions combine in shaping an outcome rather than estimating their net individual effects — a distinction that is particularly relevant for economic geography, where conditions often matter only in conjunction with others (Woodside, 2013). Causal asymmetry is equally important here: the configurations associated with the presence of twin innovation outcomes are not simply the mirror image of those associated with their absence (Fiss et al., 2013).

To extend this configurational logic to the temporal dimension, the analysis adopts a panel fsQCA approach, which extends set-theoretic reasoning to longitudinal data and makes it possible to distinguish cross-sectional variation across regions from longitudinal variation within regions (Garcia-Castro & Ariño, 2016). This makes it possible to assess not only which configurations are sufficient for twin innovation, but also whether they display temporal stability or appear as episodic alignments. Following Bhattacharya (2023), panel-data QCA modelling proceeds through case knowledge, model specification, set calibration, directional expectations, and tests of necessity and sufficiency. Pooled, between, and within consistency and coverage scores are computed to distinguish cross-regional from within-region temporal variation.

4 The model

This section presents the analytical model used to investigate how combinations of regional path development mechanisms shape twin innovation outcomes across European NUTS-2 regions over 2007–2019.

The selection of causal conditions draws on both theoretical insights from EEG and the review presented in Section 3. Table 2 presents the full set of causal conditions, their operational definitions, and data sources.

Table 2. Causal Conditions

Label	Dimension	Index	Source
UV	Unrelated Variety	Unrelated Variety	Eurostat
EKIA	Structural complexity	Employment in Knowledge-intensive activities	Regional Innovation scoreboard
FDI	FDI Intensity	FDI inward stock % GDP	OECD
ICOLL	Collaborative R&D activity	Innovative SMEs collaborating with others	Regional innovation Scoreboard
PS	Policy Support	Historic EU payments annual timeseries - modelled	Cohesion Data
RII	Innovation Performance	Regional Innovation Index	Regional Innovation Scoreboard
NEWB	Entrepreneurial Activity	Business entries	OECD Data Explorer

The outcome is constructed using Revealed Technological Advantage (RTA), a proxy for regional technological specialisation derived from patent data (Balland et al., 2019). RTA captures the extent to which a region is oriented towards a specific technological domain relative to the overall European patenting structure. Yearly RTAs were calculated using OECD REGPAT data. Green technologies refer to the OECD "environment-related technologies" domain, while digital technologies include patents classified under "ICT" and "artificial intelligence-related technologies". RTA is calculated as follows:

$$RTA_{r,d} = \frac{P_{r,d}}{P_r} \Big/ \frac{P_d}{P_T}$$

where:

- $P_{r,d}$ is the number of patent applications in domain d filed in region r,
- P_r is the total number of patent applications filed in region r,
- P_d is the total number of patent applications in domain d across all regions,
- P_T is the total number of patent applications in all domains and regions.

The twin innovation outcome is constructed at the region-year level as the minimum between green and digital RTA:

$$RTA_Twin_{r,t} = \min\left(RTA_Digital_{r,t}, RTA_Green_{r,t}\right)$$

This reflects the directional and conjunctural nature of twin innovation: a regional transition path can be considered twin-oriented only when green and digital specialisation are jointly present. The resulting values are calibrated into fuzzy-set membership scores, while temporal stabilisation or fragility is assessed through the panel fsQCA analysis.

To ensure the reliability of RTA values, we applied a two-level filtering strategy. At the country level, only countries with at least 1,000 patent applications over the reference period were retained, following Cantwell (2010) and Vertova (2001). At the regional level, we excluded NUTS-2 regions with fewer than 50 patent applications per year and required at least 10 patents in either the green or digital domain, adapting the criteria proposed by Pinheiro et al. (2022) to the twin innovation context. These filters reduce small-number distortions while preserving regions specialised in at least one transition domain. The final dataset includes 82 NUTS-2 regions across 12 European countries for 2007–2019.

The regional nomenclature follows the classification used in the Regional Innovation Scoreboard.

5 Results

The necessity analysis shows that no individual condition reaches the conventional consistency threshold of 0.90. Regional innovation performance has the highest consistency value (0.815), but remains below the threshold, indicating that it is relevant but not necessary for twin innovation. This supports the need for a configurational analysis. Summary results are reported in Table 4.

Table 3. Necessity analysis for the twin transition outcome.

Causal Condition	Consistency	Coverage
EKIA	0,733	0,529
ICOLL	0,708	0,526
NEWB	0,635	0,486
FDI	0,695	0,503
UV	0,757	0,514
PS	0,625	0,491
RII	0,815	0,498

The sufficiency analysis identifies six configurations associated with the twin innovation outcome, with overall coverage of 0.91 and consistency of 0.75. Table 3 reports the configurations, fit parameters, covered cases, and path-development interpretation. Regional innovation performance (RII) appears as a core condition across all six configurations, confirming its role as a baseline structural requirement — a necessary floor below which no configuration is sufficient, but which alone does not generate twin innovation outcomes.

The combination of moderate raw coverage and very low unique coverage scores — ranging from 0.002 to 0.029 — indicates that the identified configurations cover largely overlapping sets of cases, each explaining only a marginal share of the outcome independently. More importantly, the outcome membership scores of covered cases reveal that the large majority display weak twin innovation membership, typically between 0.10 and 0.40. These are better understood as deviant consistency cases in the sense of Oana and Schneider (2018): regions whose structural conditions align with a sufficient configuration, yet fail to convert that alignment into realised twin innovation outcomes. Cases with high outcome membership are rare, geographically concentrated in a small number of Northern and Western European regions, and tend to appear only in isolated time windows. This pattern constitutes the empirical signature of what this paper terms episodic alignment — configurations that are formally sufficient yet dissolve before stabilising into durable twin innovation trajectories across institutional fields and over time (Strambach & Pflitsch, 2020).

This prevalence of deviant consistency cases carries broader theoretical meaning. It suggests that the absence of twin innovation should not be treated as a residual category, but as an empirical signal of path-development dynamics that remain weakly converted, structurally blocked, or insufficiently coupled across domains. In this sense, the findings speak directly to the debate on the dark side of regional path development (Blažek et al., 2020): while the analysis does not directly measure trajectories of decline, it shows that identifiable path-development mechanisms may still produce incomplete or non-transformative transition trajectories when they fail to generate the simultaneous green-digital co-specialisation that twin innovation requires. The critical mechanism is not the absence of path development activity, but the failure of cross-domain coupling — the incapacity of regional systems to stabilise green and digital knowledge trajectories within the same institutional and temporal space.

Interpreted through the lens of regional path development theory (Grillitsch et al., 2018), the six configurations point to different empirical expressions of path-development potential, rather than to neatly separated path types. M1 stands apart as the only configuration without an identifiable path development mechanism, driven instead by policy support and innovation performance alone. The deviant consistency cases associated with this configuration display among the lowest outcome membership scores in the solution, suggesting that policy-induced activation without an underlying path-development mechanism produces at best transient alignment.

The remaining configurations reflect increasingly complex path dynamics, since their empirical profiles do not always map perfectly onto single theoretical mechanisms. This suggests that regional path development mechanisms may overlap in practice. M2 reflects an upgrading, where collaborative R&D activity and policy support sustain incremental transformation within existing knowledge structures, yet in the absence of entrepreneurial dynamism and structural complexity, the resulting twin innovation engagement remains weak and episodic. M3 points to an unrelated diversification, where cognitive variety activates cross-domain recombination in contexts of strong collaborative capacity — a more disruptive mechanism that nonetheless produces only partial conversion, as the absence of FDI and entrepreneurial activity limits the anchoring of new knowledge combinations within the regional system. M4 is best read as a hybrid configuration located at the intersection of creation and unrelated diversification, suggesting a route based on exogenous recombination and cognitively distant knowledge combinations. M5 is an importation-oriented configuration with elements of unrelated diversification, where external anchoring combines with structural complexity and cognitive variety.

M6 offers the clearest empirical signal of a realised twin innovation pathway. What distinguishes this configuration from the others is the density of its enabling conditions that co-occur in a mutually reinforcing constellation. This suggests that twin innovation does not emerge from the activation of any single path development mechanism in isolation, but requires the simultaneous stabilisation of endogenous agency, external knowledge anchoring, and cognitive variety within the same regional system. The concentration of high-membership cases among French regions points to the place-specific and institutionally thick character of this configuration.

Two findings deserve particular theoretical attention. First, path extension and branching — the mechanisms most widely documented in the EEG literature — are entirely absent from the sufficient configurations. This does not imply that these mechanisms are irrelevant to regional development in general, but that in this empirical setting they do not generate the cross-domain coupling required for twin innovation. Incremental, relatedness-based path dynamics are insufficient to bridge the cognitive and institutional distance between green and digital knowledge domains simultaneously. Second, the configurations that do support twin innovation are those involving the greatest degree of structural complexity, cognitive distance, and exogenous knowledge flows, pointing to the importance of hybrid path dynamics as drivers of twin innovation trajectories.

6 Conclusions

This paper has developed a configurational panel framework linking regional path development mechanisms to twin innovation outcome across European NUTS-2 regions over 2007–2019. By combining insights from Evolutionary Economic Geography and sustainability transitions research, and applying panel fuzzy-set Qualitative Comparative Analysis, the analysis has addressed a gap that neither tradition had systematically confronted: the conditions under which regional path development mechanisms support, constrain, or prevent the emergence of twin innovation trajectories.

Three findings stand out. First, twin innovation trajectories are rare, episodic, and geographically concentrated — not for lack of path-development activity, but because of the structural difficulty of coupling green and digital knowledge domains simultaneously within the same regional system over time. Second, incremental mechanisms such as path extension and branching — the most widely documented in the EEG literature — prove insufficient to generate this coupling. Only configurations combining endogenous recombination, external knowledge anchoring, and cognitive variety produce realised twin innovation trajectories, and even these remain temporally fragile. Third, the prevalence of deviant consistency cases reveals that path-development potential is widespread, but its conversion into twin innovation outcomes is systematically incomplete — a pattern that speaks to the dark side of regional path development and the limits of policy-induced activation without underlying structural depth.

These results carry direct implications for place-based innovation policy. Supporting twin innovation requires not only the development of regional capabilities in green and digital domains separately, but the deliberate cultivation of the cross-domain coupling conditions — relational, institutional, and cognitive — that allow these trajectories to stabilise and co-evolve within the same regional system over time.

Knowledge Management and Artificial Intelligence: Governance and Liability in Business Management

Claudio D'Alonzo
Catholic University Our Lady of Good Counsel, Tirana, Albania

Abstract

The purpose of this paper is to analyse the role of artificial intelligence in corporate management. Since the topic does not concern only the digital sector, the research is conducted from a legal perspective. Consequently, the methodological approach adopted considers both the existing legal framework and the relevant legal doctrine; however, it does not seem possible to make reference to case law. As a result, this article has a theoretical character and adopts a conceptual approach to the subject matter.

In Italy, not only does the AI Act apply, but also Law No. 132 of 23 September 2025, which emphasises the strategic importance of artificial intelligence for the national economy. The foregoing considerations suggest that companies are required to undertake a profound review of their organisational and operational models.

The findings highlight that it is possible to identify three distinct levels of interaction between corporate law and artificial intelligence tools. The first concerns support for the decision-making process of the management body. The second relates to the use of artificial intelligence to improve dialogue with shareholders and third parties in general. Finally, artificial intelligence is considered a tool for the external assessment of a company's functioning.

One of the specific issues that arises concerns the need to assess the extent to which artificial intelligence can be integrated into the organisation of a company. This raises the question of whether the use of AI is necessary to such an extent that failure to adopt it would result in inadequate corporate structures.

Finally, the study highlights that the issue of adequate organisational structures must enable directors to continuously monitor the adopted artificial intelligence system from the moment of its selection through to its use, also in order to prevent undesirable outcomes. Clearly, AI does not replace directors, but it serves as a support tool for them.

Keywords: artificial intelligence, knowledge management, corporate management, organisational structures, existing legislation

Paper type: Academic Research Paper

1 Introduction

Knowledge is one of an organisation's most valuable resources and forms the basis for the creation and development of the organisation's innovative capacity. In company law, knowledge plays a key role as a fundamental element of organisational structures and decision-making processes, directly impacting the obligations of proper management and the liability of directors. In this context, a pivotal role is played by new technologies (Nascimento et al., 2021), particularly artificial intelligence (AI). AI appears to be a fundamental element of knowledge management (KM) thanks to improved information collection, development, and dissemination, as well as its efficient implementation within organisations (He and Burger-Helmchen, 2025).

The recent increase in popularity of AI and its diffusion across various sectors has radically changed the role of KM, which has been transformed into a complex discipline aimed at improving decision-making and increasing value creation (Sanzogni et al., 2017; Al Mansoori et al., 2020; Leoni et al., 2024). To achieve this, it is essential to establish a solid relationship between existing knowledge (Iqbal, 2023) and the AI tools that support KM practices (Arias-Pérez et al., 2022).

The purpose of this paper is to analyse the role of AI in corporate management. Since the topic does not concern only the digital sector, the research is conducted from a legal perspective. Consequently, the methodological approach adopted takes into account both the existing legal framework and the relevant legal doctrine; however, it does not seem possible to make reference to case law. As a result, this article has a theoretical character and adopts a conceptual approach to the subject matter. The findings show that AI is part of the organisation of a company and that directors are required to monitor the adopted AI system constantly, also in order to prevent undesirable outcomes.

The paper is organised as follows. Section 2 deals with KM in a business. Section 3 presents the existing regulatory framework. Sections 4, 5, and 6 address the skills of directors and the integration of AI in a business. Section 7 concerns the liability of directors. The last part presents the conclusions.

2 KM in a Business

The convergence of AI and KM is not a new concept in the scientific field nor in the business world; in fact, modern businesses are investing significantly in KM. In business law, KM can be understood as the set of tools, techniques, and strategies for storing, analysing, organising, improving, and sharing entrepreneurial experience (Groff and Jones, 2003). The evolution of many businesses in recent times is closely linked to the increasingly widespread use of AI (Abriani, 2022), which has rapidly spread across various sectors such as healthcare and finance. Beyond the risks that may arise from the use of this technology (for example, biases and discrimination), there is a need to assess the consequences for companies that use AI to carry out their business.

Intelligent knowledge, i.e., the synergistic integration of human cognitive capabilities and AI-based tools, is transforming business law, both nationally and internationally. However, KM remains a constant challenge due to multiple factors, such as the risk of losing tacit knowledge or information overload (Jarrahi et al., 2023). For this reason, companies are required to transform continuously; as a consequence, innovation becomes a goal, and not just a way of thinking, to be absorbed in terms of culture, best practices, and initiatives.

The relationship between innovation and law has never been simple, but AI has made this debate even more urgent and complex. Business law is at a crossroads: on the one hand, it must adapt to the new operating methods introduced by intelligent technologies; on the other, it must remain linked to the principles that guarantee the integrity of the legal system and the protection of collective interests.

In an era of digital acceleration and AI-driven transformation, businesses must not focus exclusively on technology as the primary driver of innovation; this is because innovation is not just a technological issue, but above all a cultural and human one. To achieve a true advantage, businesses are required to evolve towards intelligent systems, where organisation is viewed as a living organism capable of learning and adapting. From this perspective, knowledge is not a static asset (stored in a database), but a dynamic flow that constantly feeds decision-making processes.

3 The Existing Regulatory Framework

The existing regulatory framework for AI has significant impacts on businesses and their organisations. Therefore, it seems useful to examine the role AI plays in the life of a business, considering that current legislation, both at the European and national levels, promotes the correct, responsible, and transparent use of this tool; all from a perspective that places the human being at the centre.

As is well known, the increasingly prominent role played by AI has led the European lawmaker to enact the European Artificial Intelligence Act (AI Act). The scope for national discretion left by European legislation has been promptly incorporated into Italian law through Law No. 132 of 23 September 2025, in which information, and consequently the management and dissemination of knowledge, play a fundamental role. Italy is the first EU Member State to have adopted a national legislative instrument dedicated exclusively to the regulation of AI, anticipating the operational implementation of the AI Act (Sottoriva and Vetrugno, 2025). In this way, the Italian law stands out for promoting a national strategy capable of reconciling technical, ethical and social requirements (Pesucci, 2026). The legislation issued sets out key principles such as transparency, data protection, and security (Raganelli, 2025). In this context, with a view to initiating a transformation of corporate compliance systems and internal governance (Sottoriva and Vetrugno, 2025), Italian law provides, amongst other things, that the State and other public authorities shall promote the development and use of AI as a tool to improve human-machine interaction.

The law provides detailed and sector-specific provisions that build on the existing regulatory framework, particularly regarding compliance, transparency, accountability, and governance. Consequently, businesses are required to modify their organisational models both to integrate AI systems into decision-making, management, and production processes, and to address the risks arising from the use of such systems, avoiding liability for non-compliance with current legislation.

4 The Skills of Directors

The above considerations lead to reflecting, albeit briefly, on the impact that AI has on corporate governance. Indeed, AI directly influences the way management functions are exercised. First, it seems possible to state that AI and KM, together, may enable a company to improve its results, increase its profitability, and enhance its market competitiveness. It follows that AI serves, first and foremost, as a tool to support the organisation of a company and make it more competitive on the market.

The first perspective from which the interaction between corporate management and AI may be examined concerns the possibility of providing support in the identification of potential directors (Rimini, 2024). In this

regard, it is worth noting that there has been a past attempt to automate the administrative body through the so-called DAO Project (Picciau, 2021), based on the ambitious and provocative idea that company management could be more efficient if entrusted to intelligent computers rather than to humans (Rimini, 2024; Abriani, 2022). Although it was not successful and it seems unlikely that AI will lead to the disappearance of a company's management body or make the delegation of functions to one or more directors superfluous (Benedetti, 2025), the proposal highlights the attempt to innovate the principles of corporate governance through a functional replacement of decision-making roles.

Under current legislation, even though directors are not required to have high levels of technological expertise, it seems clear that the use of AI requires at least a basic understanding of such systems, as well as the ability to understand their limitations, risks, and potential. Therefore, the specific technical skills of individual candidates should be adequately assessed when appointing directors. Consequently, it seems appropriate for a company's administrative body to consist of at least one member with IT expertise, who can contribute to any preliminary discussions prior to a specific decision and broaden the discussion within the board (Ruffolo and Amidei, 2025; Paccoia, 2025; Enriques and Zorzi, 2023; Pacileo, 2022). This solution does not appear illogical, being it normal for the board of directors of a medium-large company to be composed of several different professional figures with specific skills. From this perspective, it is essential that directors undergo continuous training through appropriate programs that focus on digital innovation and the risks associated with it (Mäntymäki, 2023).

In light of the above, it is necessary to consider how human intelligence and AI might interact. The adoption of AI-based tools by businesses calls for a re-examination of governance issues, whilst ensuring compliance not only with current legislation but also with ethical standards (Rahul, 2025).

5 The Integration of AI into a Business

It is possible to identify three distinct levels of interaction between corporate law and AI tools; this is because AI may be used primarily to support the activity carried out (De Nadai, 2024; Montagnani, 2020). AI has long been present in the life of a company, inserting itself into the decision-making processes and influencing the choices of the management bodies (Enriques and Zorzi, 2023). Although the current legislation is aimed at humans (Lucarelli Tonini, 2023), given that AI systems are not legal persons, it is necessary to recognise that management decisions no longer depend exclusively on human will (Rimini, 2024). In fact, the use of AI may support both the day-to-day management of a company and the guidance and evaluation phase of the administrative body (Abriani, 2022; Benedetti, 2025). Examples include the examination of complex contracts, financial documents, and other critical information quickly and with a high degree of reliability. This does not mean predicting the outcomes of every operation (Enriques and Zorzi, 2023), but understanding the risk factors that could expose a business to potential uncertainties, such as legal, financial, or reputational liability. It follows that the integration of AI and business requires a profound change in the way directors fulfil their duties.

The legislative introduction of transparency and traceability criteria for AI systems used by companies leads to new disclosure requirements. This aspect is particularly relevant in all companies operating in the AI, cybersecurity, and instrumental technologies sectors. In this way, digitalisation paves the way for Italy's technological strengthening, at least within Europe. The duty of transparency falls on managing directors, who must inform the board of directors as well as shareholders. It seems possible to argue that the general obligation to act in an informed manner requires an assessment not only of the choices made through the use of AI tools, but also of the specific characteristics of the system used (Rimini, 2024); of course, the duty to provide information varies with the model used and must be inevitably fulfilled more rigorously where the chosen system is provided or managed by a third party.

However, the question arises as to whether a company's governing bodies must necessarily adhere to the instructions received or whether they can deviate from them. The most preferable solution appears to be to adopt a comply-or-explain approach, meaning that when the AI's instructions are not followed it is necessary to specify why that happened (Picciau, 2021). Therefore, every decision made by the governing body must be not only transparent and accountable (Štrukelj and Gajšt, 2025), but must also allow for an assessment of the logical path followed.

The second level of connection between business and AI concerns the use of AI to improve the organisation and functioning of a company's governing bodies, to ensure compliance with legal and statutory obligations, and to foster dialogue with shareholders and third parties in general (Abriani, 2022). On this point, it seems worth noting that KM and its transmission within a company are sensitive issues, as it is not always possible to share information among the various bodies that make up a company. Although a continuous flow of information among those responsible for managing and supervising the company is normal and it is natural that their rotation

is followed by the transfer of information, it is not necessarily the case that this information should be made available to the shareholders. However, the possibility that AI could be used as a tool to strengthen the dialogue between directors and shareholders, reducing information asymmetries between these two bodies, seems not remote. Likewise, AI could be helpful in assessing the impact that any changes to the administrative and financial rights of company shares may have on ownership structures (Montagnani, 2021). This creates a new scenario in which companies are required not only to evaluate the cost-benefit ratio in day-to-day management and in their relationships with shareholders, but also to address new challenges, including liability arising from the use of these new digital tools, known as Corporate Digital Responsibility (Wade, 2020; Lobschat et al., 2021; Abriani and Schneider, 2020; Valiante et al., 2023).

Finally, AI is being considered as a tool for assessing a company's performance from an external perspective. This approach is justified by the fact that improved information flows between directors and shareholders may inevitably be followed by increased communications directed at third parties (Abriani, 2022).

6 AI and Business' Structure

The integration of AI within a business raises fundamental questions regarding the duties assigned to the administrative body. In Italy, pursuant to Article 2086 of the Italian Civil Code, directors are required to *"establish an organisational, administrative, and accounting structure appropriate to the nature and size of the company, also with a view to the timely identification of business crises and the loss of business continuity"*.

One of the main questions posed by the current legislative and social landscape concerns the role that AI solutions can play within an appropriate organisational, administrative, and accounting structure. It seems undeniable that the assistance offered by AI tools favours the inclusion of such systems within the organisation of a company (Ruffolo and Amidei, 2025).

Therefore, not only does AI become an integral part of the organisational, administrative, and accounting structure, but it also contributes to compliance with the law and internal regulations (De Nadai, 2024; Enriques and Zorzi, 2023). In particular, with regard to this last aspect, the inclusion of AI in a company's organisation may help identify the concrete possibilities for business continuity and the effective sustainability of its debts.

Obviously, the integration of AI into a business organisation raises the question of whether its use is so necessary that failure to adopt it would result in the inadequacy of the corporate structure (Abriani, 2022; Enriques and Zorzi, 2023). If this were the case, this would have implications for directors' liability. It seems safe to say that the answer to this question is not unequivocal, but varies based on the nature of the business performed and the size of the company (Benedetti, 2025; Montagnani, 2020). The function of AI is to ensure compliance with the law and to support directors in fulfilling their duties, but there is no obligation to use it. However, where this occurs, it is essential that the administrative body use a reliable and transparent AI system (Bruner, 2021), without prejudice to the need to evaluate the response provided and decide whether or not to carry out a specific operation. The arrangements in place must allow directors to constantly monitor the AI system adopted from the moment of its selection until its use, also in order to prevent undesirable outcomes (Pacileo, 2022).

In any case, it seems essential to diversify the administrative bodies by establishing specific committees (De Nadai, 2024) which, based on the nature and size of a company, adopt procedures suitable for the appropriate use of AI and the management of the risks associated with it, such as regulatory, technical and ethical ones (Abriani, 2022; Moerel, 2020); in this perspective, the creation of a technology committee (Rimini, 2024), possibly composed of independent directors (Enriques and Zorzi, 2023), which deals with the choice of AI systems and their monitoring, could be useful (Pacileo, 2022); although a committee of this type plays a strategic role within a company, it remains understood that it is not vested with management powers and that every decision is up to the board of directors as a whole.

In addition to the creation of a specific committee, it would also be useful to appoint a data protection officer who could play a central role in AI governance to ensure compliance in the handling of personal data.

It follows that administrative bodies should not only be made up of adequately experienced and competent figures in AI, but should also recruit cybersecurity professionals and ensure that there is a flow of information with them. AI must be embedded within the organisational structure of a company, so that it can act as a powerful cognitive technology and adequately manage all the information at its disposal.

7 Directors' Liability

It has been said that AI has become an integral part of businesses and their decision-making processes. Decisions made by the board of directors are characterised by a high degree of discretion, as they are the final stage of a complex process that requires the evaluation of a series of factors that are not easily measurable.

Although the use of AI may be necessary in some cases, the board of directors must not be passive, relying entirely on its decisions without any critical evaluation. Instead, it is always necessary to maintain an active role and engage directly in the decision-making processes. Otherwise, directors could be held liable for failing to act diligently and for abdicating their role in favour of the results obtained by the adopted AI system. The foregoing considerations lead to the belief that the role of AI in the organisation of a company is similar to that of external consultants who provide opinions or recommendations (Ruffolo and Amidei, 2025); AI is an aid for directors, who must evaluate whether or not to proceed with a specific transaction, taking into due consideration that they may incur liability towards the company if they do not use the required diligence.

It remains clear that decisions taken do not need to be justified and that the principle of the business judgment rule applies, whose purpose is to prevent the transfer of business risk from shareholders to directors (Pacileo, 2022). On this point, it may be useful to note that directors must be able to prove that they acted in an informed manner, in good faith, and in the company's best interest. However, where a decision is made using AI tools, only in the presence of specific information on the AI system used, its level of transparency, and the role it played in making certain decisions will it be possible to exclude directors' liability, even where the transaction had a negative outcome for the company (Ruffolo and Amidei, 2025; Montagnani, 2020; Rimini, 2024).

The issue of liability appears to intersect with that of administrative, organisational, and accounting structures (Pacileo, 2022; Perrino, 2025). It seems fair to say that the duty to create an organisational structure adequate for the activity carried out cannot be subject to stringent judicial oversight and, consequently, is covered by the business judgment rule. It follows that the violation of the obligation to establish adequate organisational, administrative, and accounting structures cannot be an independent cause for liability of the administrative body, but only a contributing cause to be examined together with other charges (Paccoia, 2025). With reference to the issue of AI, in order to benefit from the protection of the business judgment rule, directors will have to ensure that AI-based structures are adequate also in terms of general reliability (Enriques and Zorzi, 2023). From this perspective, it seems necessary to document the characteristics of the technology used and the instructions given in written and comprehensible form. In other words, the administrative body is responsible for disclosing the AI system used and its operating methods. The need to track AI decisions not only appears appropriate from a corporate law perspective, but also complies with the provisions of the applicable legislation, which establishes transparency, traceability, and clarity (Ruffolo, 2025).

8 Conclusions

As mentioned, AI is a tool that enables the transmission of various branches of knowledge and may become essential both for facilitating decision-making processes and for providing decision makers with a broader range of possible solutions. The use of AI in corporate law strikes a delicate balance between opportunities and pitfalls. AI is a formidable innovation tool, capable of optimising resources, simplifying decision-making processes, and increasing market competitiveness. The automation of administrative functions, predictive analytics, and the ability to access automated systems are strategic advantages for businesses. AI also influences a company's governance structure, shifting the focus of decision-making toward automated tools that require constant human oversight.

The competitive skill of a modern company lies, first and foremost, in its ability to manage and govern knowledge. KM directly impacts the innovative capacity of a company as an organisation, considering that innovation is not solely linked to the adoption of advanced digital tools, but also (and above all) to the cognitive dynamics that form its structural foundation.

AI can be an integral part of a company's organisation, albeit within certain limits. First, AI can assist the board of directors in day-to-day management, but it cannot replace human judgment in strategic decisions. In other words, AI does not replace directors, but rather supports them. This means that directors must not take the results obtained for granted, trusting in a high probability of accuracy and reliability (Pacileo, 2022). It follows that despite the entry of new technologies into corporate life, its management still requires a human-centric approach in which AI is a tool and not a solution (Sacco Ginevri, 2021). This interpretation is justified by the fact that computers and information systems, however efficient, lack typically human characteristics such as flexibility, adaptability, and communication skills (Picciau, 2021). What has been said so far is in line with current national and European legislation, which emphasises that AI's role is to assist humans in decision-making processes and not to replace them. The crucial role entrusted to directors and their specific skills also in terms of technological innovation are the key to avoiding the total transfer of business management to AI, including the establishment of organisational structures.

Between Heritage and Change: Value-Oriented Digital Transformation in European Theatres

Dóra Horváth
Corvinus University of Budapest, Budapest, Hungary

Abstract

This study examines how theatres interpret, govern, and strategically integrate digital technologies and knowledge practices in the context of mission-driven value creation. While digital transformation is often associated with efficiency gains and technological change, less attention has been paid to how digital knowledge is embedded in organizational practices and contributes to cultural and social value in non-profit contexts. Drawing on 28 semi-structured interviews with theatre professionals across Europe, the study applies an inductive qualitative approach inspired by grounded theory to explore how digitalization unfolds in practice. The findings show that digitalization is primarily embedded in operational and support activities, where digital tools function as knowledge infrastructures that enhance communication, coordination, and audience engagement. Rather than being driven mainly by efficiency, these practices contribute to public value by extending access, sustaining relationships, and reinforcing theatres' cultural missions. At the same time, digital transformation remains incremental and selective. More advanced forms of transformation - defined as the strategic integration of digital knowledge into governance and value creation - are limited, as digital practices are typically embedded within existing institutional frameworks shaped by legacy structures and public value orientations. Digital experimentation supports organizational learning but remains largely project-based and weakly institutionalized. Overall, the study shows that digital transformation in theatres primarily reinforces existing value creation logics rather than redefining them. It contributes to the literature by conceptualizing digital transformation as a knowledge-based, value-oriented process shaped by governance, institutional logics, and organizational capacities, offering insights into how mission-driven organizations navigate digital change beyond market-based contexts.

Keywords: cultural organizations, non-profit organizations, cultural heritage, mission-driven, digital transformation

Paper type: Academic Research Paper

1 Introduction

In the current phase of digital transformation, the central challenge for organizations is not simply whether digital technologies improve efficiency, but how efficiency gains are integrated into broader processes of value creation and organizational practice shaped by digital knowledge. In this sense, digital technologies increasingly influence how knowledge is integrated into strategic decision-making, accountability, and relationships with stakeholders, thereby altering organizational priorities and forms of legitimacy (Matt *et al.*, 2015; Vial, 2019; Wessel *et al.*, 2021). These dynamics are particularly consequential for non-profit, public organizations, where digital transformation intersects directly with mission fulfilment, public responsibility, and the production of cultural and social value rather than market-based returns (Bakhshi and Throsby, 2012). In such contexts, digital systems do not operate as neutral infrastructures but as structuring forces that shape governance arrangements and organizational identities (Hanisch *et al.*, 2023), while their integration remains conditioned by historically embedded institutional logics and path-dependent practices (Johnson, 2007).

Theatre organizations represent a distinctive case within this broader transformation. As historically embedded cultural institutions, theatres are deeply rooted in traditions of live presence, artistic autonomy, and cultural heritage. They operate predominantly as non-profit or publicly supported organizations, shaped by strong institutional legacies and path-dependent routines that prioritize continuity, legitimacy, and public responsibility (Bonet and Schargorodsky, 2018; Johnson, 2007; Schreyögg *et al.*, 2011). At the same time, theatres are increasingly exposed to digital pressures that affect the entire cultural value chain, from artistic creation and production to dissemination, audience engagement, and organizational coordination (Ford and Mandviwalla, 2020; De Voldere *et al.*, 2017). This creates a structural tension between digital transformation as a force of organizational reconfiguration and theatres as tradition-oriented, mission-driven organizations. Digital technologies such as audience data systems, digital archives, streaming platforms, and hybrid performance formats actively shape organizational learning, redefine relationships with audiences, and introduce new forms of knowledge-based coordination (Saarikko *et al.*, 2020). However, their integration is mediated by institutional logics centered on authenticity, embodied co-presence, and cultural continuity, which constrain radical or

disruptive change (Lampel *et al.*, 2000). From a theoretical perspective, digital transformation in theatres unfolds primarily through selective and negotiated integration. Digital knowledge systems reshape value creation beyond profit by extending access, supporting cultural preservation, and enabling more inclusive and knowledge-informed governance, while remaining embedded in historic missions and public value logics (Ford and Mandviwalla, 2020; Hawthorne, 2023). Despite these contributions, existing research offers limited empirical insight into how digital transformation is strategically governed and knowledge is mobilized for value-oriented outcomes in historically embedded, mission-driven cultural organizations such as theatres, particularly beyond isolated digital practices or technology-specific interventions.

To address this gap, the study adopts a qualitative research design based on semi-structured interviews with theatre leaders and key professionals across Europe. A total of 28 in-depth interviews were conducted with executive directors, artistic directors, marketing and communication managers, financial leaders, innovation managers, artists, researchers, and digital service providers. The interviews examined how theatres interpret, govern, and strategically integrate digital technologies and knowledge practices to reconcile efficiency gains with mission-driven value creation, public responsibility, and long-term cultural relevance. The interview data were analysed using an inductive qualitative approach inspired by grounded theory (Gioia *et al.*, 2013; Glaser and Strauss, 1967). Through iterative coding and constant comparison, recurring patterns were identified across organizational, strategic, and institutional dimensions, enabling an integrated understanding of how theatres navigate intelligent digital transformation as mission-driven and hybrid organizations.

2 Theoretical Background

Digital transformation is increasingly conceptualized as a multidimensional process that extends beyond the mere adoption of digital technologies, encompassing changes in how organizations create value, organize knowledge, and structure decision-making processes (Matt *et al.*, 2015; Vial, 2019; Wessel *et al.*, 2021). In this context, it is essential to distinguish between related concepts that capture different levels of change. Digitization refers to the technical conversion of analog information into digital form, while digitalization describes the application of digital technologies to improve and reorganize existing processes (Brennen and Kreiss, 2016; Saarikko *et al.*, 2020). Digital transformation, in contrast, involves the deeper integration of digital technologies and knowledge into organizational strategy, governance, and value creation, potentially reshaping organizational identity and purpose (Berman, 2012; Matt *et al.*, 2015; Wessel *et al.*, 2021).

However, recent research suggests that digital transformation does not necessarily lead to radical or disruptive change in all contexts. Instead, organizations often adopt digital technologies in incremental and selective ways, embedding them into existing structures and practices (Baiyere *et al.*, 2023; Plekhanov *et al.*, 2023). From this perspective, digital transformation is not a uniform process but one that unfolds through different dynamics. Wang et al. (2021) conceptualize this through reinforcing and differentiating mechanisms: digital technologies may either strengthen existing organizational logics and practices or enable new forms of value creation and interpretation. This distinction is particularly relevant in contexts where organizational identity and value are closely tied to historically embedded practices.

These dynamics are especially pronounced in non-profit and public organizations, where value creation extends beyond economic outcomes. Cultural institutions operate within public value frameworks that emphasize accessibility, participation, cultural preservation, and social impact (Bakhshi and Throsby, 2012). In such settings, digital technologies influence not only efficiency but also how knowledge is generated, shared, and embedded in organizational processes, as well as how relationships with stakeholders are managed (Hanisch *et al.*, 2023; Saarikko *et al.*, 2020). As a result, digital systems function as structuring elements that shape governance arrangements and organizational priorities, rather than acting as neutral technological tools.

Theatre organizations represent a distinctive case within this broader transformation. As historically embedded cultural institutions, they are strongly shaped by institutional legacies, artistic traditions, and path-dependent routines that prioritize continuity, legitimacy, and public responsibility (Bonet and Schargorodsky, 2018; Johnson, 2007; Schreyögg *et al.*, 2011). These characteristics create a structural tension between the transformative potential of digital technologies and the preservation of theatre as a live, embodied, and co-present art form (Lampel *et al.*, 2000). Consequently, the adoption and integration of digital practices are mediated by institutional logics that balance artistic integrity with organizational adaptation.

In this context, digitalization in theatres is often associated with the use of digital tools to support communication, audience engagement, and the dissemination of cultural content, while more comprehensive transformation remains limited. Digital innovation - such as streaming, hybrid formats, or digitally mediated performances - introduces new possibilities for engagement and experimentation but does not necessarily imply a fundamental reconfiguration of organizational identity or value creation (Antonopoulou and Begkos, 2020;

Jiao *et al.*, 2025). As previous studies suggest, such developments frequently remain project-based and unevenly integrated into institutional structures (Mosse *et al.*, 2022).

Building on these perspectives, this study conceptualizes digital transformation in theatres as a knowledge-based and value-oriented process shaped by institutional conditions, governance capacity, and organizational learning. Rather than assuming disruptive change, it examines how digital technologies are selectively integrated into existing practices, and how this integration contributes to cultural and social value creation within mission-driven organizational contexts.

3 Methodology

This study adopts a qualitative research design to examine how theatres interpret, govern, and strategically integrate digital technologies and knowledge practices in the context of mission-driven value creation. Rather than treating digitalization as a purely technological or efficiency-driven process, the research focuses on how digital knowledge is embedded into organizational practices, governance structures, and cultural value creation. Particular attention is given to how theatres navigate the tension between continuity and change, and how digital transformation unfolds through selective and context-dependent integration.

Given the exploratory nature of the research and the limited empirical understanding of digital transformation in mission-driven cultural organizations, the study applies an inductive approach inspired by grounded theory Glaser and Strauss (1967) and the Gioia methodology (Gioia *et al.*, 2013). This approach enables the systematic development of theoretical insights from empirical data, while maintaining transparency and rigor in the analysis. Data collection and analysis were conducted iteratively, allowing emerging themes to inform subsequent data gathering until theoretical saturation was reached.

3.1. Data collection

Data were collected through 28 semi-structured interviews conducted between December 2023 and November 2024, and in November 2025. The sample includes a diverse group of professionals from the European theatre sector, such as theatre directors, executive and financial managers, marketing and communication specialists, artists, researchers, and digital service providers. This diversity ensured a comprehensive understanding of how digitalization is interpreted and implemented across different organizational roles and institutional contexts.

Participants were selected using purposeful sampling (Palinkas *et al.*, 2015) to identify individuals with relevant experience in digital initiatives, organizational strategy, and artistic production. Attention was paid to institutional diversity, including both large, publicly funded theatres and smaller, independent or experimental organizations. This approach made it possible to capture variations in digitalization practices shaped by differences in resources, governance structures, and audience orientation.

The interviews lasted 45-60 minutes and were conducted both online and offline. All interviews were audio-recorded, transcribed verbatim, and anonymized to ensure confidentiality. An interview guide was used to structure the conversations around key themes, including organizational background, digital practices, strategic approaches, governance structures, and perceived challenges and opportunities related to digital transformation. The semi-structured format allowed flexibility while ensuring comparability across interviews.

To enhance the credibility of the findings, additional publicly available materials - such as organizational websites, reports, and digital content - were reviewed to support data triangulation.

3.2. Data analysis

The data analysis followed an inductive, iterative process based on the Gioia methodology (Gioia *et al.*, 2013). First, open coding was conducted using NVivo software, focusing on how participants describe and interpret digitalization, digital transformation, and related practices. These first-order concepts closely reflected the language and experiences of interviewees.

In the next stage, second-order themes were developed by grouping and interpreting these concepts through relevant theoretical lenses, including institutional logics, public value, and knowledge-based perspectives on digital transformation. This step enabled the identification of recurring patterns related to operational digitalization, selective integration, organizational learning, and governance.

Finally, these themes were aggregated into higher-level dimensions that structure the findings. This process revealed how digitalization in theatres operates primarily as a knowledge-based, value-oriented process embedded in existing institutional frameworks, and how transformation is shaped by organizational capacities, governance arrangements, and historically embedded practices.

Through this approach, the analysis provides an empirically grounded understanding of how theatres navigate digital transformation as mission-driven and hybrid organizations, where change emerges not through disruption but through the gradual integration of digital knowledge into existing value creation logics.

4 Results

The findings reveal how theatres interpret and implement digitalization as a knowledge-based and value-oriented process embedded in existing organizational practices. Rather than unfolding as a uniform or technology-driven transformation, digitalization appears across multiple, interconnected dimensions, ranging from operational applications to strategic integration and organizational learning. The following sections present these patterns by examining (1) the role of digitalization in operational and support activities, (2) the selective and limited nature of digital transformation, (3) the function of digital experimentation in organizational learning, (4) the importance of governance and leadership, and (5) the reinforcing dynamics that shape value-oriented digital transformation in theatres.

4.1 Digitalization as operational knowledge infrastructure

The findings indicate that theatres primarily interpret and implement digitalization within operational and support activities, including communication, ticketing, audience management, marketing, and administrative coordination. This pattern was further accelerated during the COVID-19 pandemic, when digital tools became essential for maintaining communication, coordination, and audience engagement under conditions of restricted physical access. In these areas, digital technologies function as knowledge infrastructures that structure information flows, improve transparency, and enable continuous interaction with audiences, partners, and internal stakeholders.

Rather than being driven mainly by efficiency considerations, these practices contribute to cultural and social value creation. By broadening access to performances, maintaining institutional visibility, and supporting ongoing audience relationships, digitalization reinforces theatres' public missions and their role as cultural intermediaries. Digital platforms and communication tools, for instance, extend the reach of performances and facilitate engagement beyond physical attendance, while also supporting the dissemination and preservation of cultural content.

At the same time, digitalization remains incremental and uneven. It is shaped by legacy systems, resource constraints, uneven digital capabilities, and the cyclical nature of theatrical production processes. While the pandemic intensified the use of digital tools, it did not fundamentally alter these structural conditions. As a result, digital practices are typically embedded into existing routines without significantly transforming organizational structures or value creation logics. This reflects a pattern of adaptation in which digital technologies are integrated in ways that support continuity rather than enable systemic change.

4.2. Selective integration and limited digital transformation

More advanced forms of digital transformation - understood as the strategic integration of digital knowledge into organizational priorities, governance arrangements, and value creation processes - are less prevalent across theatres. Instead of pursuing disruptive or technology-driven change, theatres tend to adopt selective and adaptive approaches that embed digital tools within established institutional frameworks.

This pattern is closely linked to the sector's value orientation. Theatres operate within a context where legitimacy, continuity, artistic integrity, and responsibility toward audiences and funders are central. As a result, digital initiatives are evaluated not only in terms of efficiency or innovation, but also in relation to their alignment with cultural missions and public value. This often limits the scope of transformation, as radical change may conflict with institutional identity or stakeholder expectations.

Digital technologies are therefore primarily used to complement and extend existing practices rather than redefine them. Even when new tools are introduced, they are typically integrated in ways that preserve established governance structures and artistic processes. Consequently, digital transformation remains partial, gradual, and strongly conditioned by institutional logics.

4.3. Digital experimentation and organizational learning

Digital experimentation plays a significant role in how theatres engage with emerging technologies and practices. Hybrid formats, streaming, and digitally mediated artistic productions create opportunities to explore new forms of audience engagement, collaboration, and cultural expression. These initiatives contribute to

organizational learning by generating knowledge about how digital tools can support both artistic and managerial processes.

However, such experimentation is typically project-based and loosely connected to core organizational structures. It often depends on individual initiatives, temporary funding, or specific productions rather than long-term strategic planning. As a result, the knowledge generated through these experiments is only partially integrated into governance, limiting its broader organizational impact.

This highlights a key finding: intelligent transformation in theatres depends less on the availability of technology and more on the ability to absorb, interpret, and strategically integrate digital knowledge. Without mechanisms to institutionalize learning, experimentation remains isolated and its transformative potential underutilized.

4.4. Governance, leadership, and value-oriented transformation

Leadership and governance capacity emerge as critical enabling conditions for bridging operational digitalization and broader transformation. Where digitalization is explicitly framed as a tool for mission fulfilment, knowledge sharing, and long-term public value creation, it is more likely to be embedded in strategic thinking and cross-functional collaboration.

In such cases, digital practices support not only operational efficiency but also organizational learning and stakeholder engagement. They become part of a broader reflection on how theatres create and sustain cultural relevance in a digitally mediated environment.

Conversely, fragmented governance structures, unclear responsibilities, and limited strategic coordination constrain the integration of digital knowledge. These conditions reinforce incremental, path-dependent practices and limit the potential for more comprehensive transformation. This suggests that governance is not only a structural issue but also a key determinant of how digitalization is interpreted and enacted within the organization.

4.5. Reinforcing dynamics and intelligent transformation

Across the findings, digitalization in theatres primarily operates through reinforcing dynamics that extend and stabilize existing value creation logics. Digital tools and practices are most consistently embedded in operational and support activities, where they enhance communication, coordination, and audience engagement without fundamentally altering core organizational structures or artistic processes.

In this context, digital knowledge systems contribute to the preservation and dissemination of cultural value by improving accessibility, supporting participation, and maintaining relationships with audiences and stakeholders. These practices strengthen institutional continuity and public mission fulfilment, rather than driving disruptive or large-scale transformation.

At the same time, the limited integration of digital initiatives into strategic governance and decision-making processes constrains the emergence of more transformative dynamics. While digital experimentation introduces new forms of engagement and generates organizational knowledge, its project-based and weakly institutionalized nature reduces its influence on long-term value creation and organizational priorities.

These patterns indicate that digitalization in theatres is predominantly aligned with existing institutional logics, where legitimacy, continuity, and responsibility toward audiences and funders shape how digital tools are interpreted and applied. As a result, digital transformation tends to unfold as a gradual and selective process, in which new practices are incorporated in ways that reinforce rather than redefine organizational identities.

The findings further show that the extent to which digitalization moves beyond reinforcing dynamics depends on organizational capacities to absorb, interpret, and strategically integrate digital knowledge. Where such capacities are limited, digital practices remain fragmented and operationally focused; where they are more developed, digitalization is more likely to be connected to broader processes of reflection, coordination, and value-oriented development.

5 Conclusion

This study examined how theatres interpret, govern, and integrate digital technologies and knowledge practices in the context of mission-driven value creation. The findings show that digitalization is primarily embedded in operational and support activities, where digital tools function as knowledge infrastructures that enhance communication, coordination, and audience engagement. These practices contribute less to efficiency alone and more to cultural and social value by improving access, sustaining relationships, and reinforcing theatres' public missions.

At the same time, digitalization remains incremental and uneven, shaped by legacy systems, limited capabilities, and the cyclical nature of theatrical production. More advanced forms of digital transformation—defined as the strategic integration of digital knowledge into governance and value creation—are less prevalent. Instead, theatres adopt selective and adaptive approaches that embed digital tools within existing institutional frameworks, reflecting an orientation toward continuity, legitimacy, and public responsibility rather than disruptive change.

Digital experimentation plays a role in organizational learning, particularly through hybrid formats and streaming, but remains largely project-based and weakly institutionalized. As a result, its impact on long-term governance and strategy is limited. Across these patterns, the findings indicate that intelligent transformation depends less on technology itself and more on organizational capacities to absorb, interpret, and strategically integrate digital knowledge.

Overall, digital transformation in theatres primarily reinforces existing value creation logics rather than redefining them. Digital knowledge systems extend access, support cultural preservation, and strengthen audience relationships, contributing to institutional resilience while maintaining the core characteristics of theatre as a live, mission-driven art form. These findings highlight that in non-profit and hybrid contexts, digital transformation unfolds as a value-oriented, knowledge-based process shaped by governance, institutional logics, and public mission.

UX-Driven Digital Architecture for Knowledge Integration in Social-Ecological Systems

Anna Maria Crespino, Marco Lucio Sarcinella, Lorenzo Quarta
Naica Società Cooperativa, Lecce, Italy

Abstract

In the polycrisis triggered by Xylella fastidiosa in the Salento area, Italy, the regeneration of social-ecological systems depends not only on data availability, but on the ability to integrate, interpret and operationalize heterogeneous knowledge produced by multiple institutional and territorial actors. Despite the abundance of environmental data and scientific outputs, a persistent information–action gap limits the capacity of stakeholders to make coordinated and informed decisions.

This paper investigates how UX-Driven Digital Architecture can support knowledge integration and decision-making in complex socio-ecological contexts. The study adopts a qualitative case study approach combined with a research-through-design methodology, focusing on the development of the DAJS Atlas, a web-based decision-support platform for landscape regeneration.

The findings show that structuring information through actor–action–goal pathways enables users to navigate complex datasets more effectively, reduces informational fragmentation, and supports coordination among stakeholders with different objectives and knowledge frameworks. By organizing heterogeneous resources into decision-oriented flows, the platform aligns scientific, institutional, and local knowledge within shared scenarios of territorial regeneration.

The contribution of the study is twofold. Empirically, it presents a practical model for designing digital platforms that support regenerative strategies in social–ecological systems. Conceptually, it advances the understanding of User Experience as a strategic component of digital architectures, positioning UX as a systemic layer for knowledge integration, coordination, and long-term transformation in polycrisis contexts.

Keywords: Regenerative approach; Social-Ecological Systems; Decision Support System; User Experience and Research; Resilient Innovation Ecosystem.

Paper type: Practical Paper

1 Introduction

The spread of *Xylella fastidiosa* in the Salento area, located in the Apulia region (Southern Italy), has generated a condition of systemic disruption affecting ecological processes, productive structures, and territorial governance. Beyond the immediate agronomic impact, the crisis has altered the relationships between landscape management, local economies, and institutional decision-making, exposing structural fragilities in how knowledge is produced, shared, and used across stakeholders.

In this context, a significant information–action gap has emerged. Despite the availability of large volumes of environmental data, GIS-based analyses, and scientific reports, stakeholders often struggle to translate such information into coordinated and context-sensitive decisions. This gap reflects a broader challenge in knowledge systems, where the usability of information depends on its credibility, salience, and legitimacy (Cash et al., 2003).

Effective responses in social–ecological systems require the integration of heterogeneous forms of knowledge across institutional and disciplinary boundaries, particularly under conditions of uncertainty and complexity (Moallemi et al., 2023). However, this integration is often hindered by the fragmentation of data sources, the diversity of stakeholder perspectives, and the lack of mechanisms to align information with real decision-making contexts.

Digital platforms and decision-support systems are increasingly used to address complexity in social–ecological systems. However, many of these systems remain focused on data integration and visualization, while providing limited support for knowledge interpretation, coordination, and action. As a result, decision-making processes remain fragmented, particularly in multi-actor environments characterized by diverse objectives and epistemic perspectives.

This paper investigates how UX-Driven Digital Architecture can contribute to addressing this challenge by positioning User Experience (UX) as a strategic component of digital knowledge infrastructures. Rather than focusing solely on usability, this approach leverages UX principles to structure information architectures, interaction flows, and decision-making pathways that enable knowledge integration and coordination across stakeholders.

The study adopts a qualitative case study approach combined with a research-through-design methodology, focusing on the DAJS Atlas, a web-based decision-support platform developed to support landscape regeneration in the post-Xylella context. The platform integrates heterogeneous datasets related to environmental, agricultural, and socio-economic conditions, and serves as an empirical setting to explore how UX-driven design can transform data availability into actionable knowledge.

The contribution of this paper is twofold. First, it provides empirical evidence on how UX-centred design can support knowledge integration and coordinated decision-making in complex social–ecological systems. Second, it advances a conceptual interpretation of UX as a systemic design layer within digital architectures, enabling alignment between scientific, institutional, and local forms of knowledge in polycrisis contexts.

2 Background and Related Works

2.1 Knowledge Integration in Social-Ecological Systems

Social–ecological systems (SES) are complex and adaptive systems in which ecological processes, social dynamics, and institutional arrangements are deeply interconnected. Addressing challenges such as climate change, biodiversity loss, and resource management therefore requires integrative approaches capable of bridging disciplinary and sectoral boundaries. This need is emphasized by Moallemi et al. (2023), who argue that effective responses in human–natural systems depend on combining multiple forms of knowledge within decision processes under uncertainty.

However, knowledge integration in SES remains difficult. Different disciplines rely on distinct conceptual vocabularies, methods, and evaluative criteria, often producing semantic ambiguities and epistemic misalignments. A foundational contribution to this problem is Star & Griesemer (1989), who introduced the concept of boundary objects as artifacts flexible enough to adapt to local needs while robust enough to retain a common identity across communities.

Building on this perspective, the literature on sustainability and science–policy relations shows that knowledge integration is not only a matter of communication, but of designing systems that make knowledge usable across contexts. In Cash et al. (2003) argue that effective knowledge systems must balance credibility, salience, and legitimacy if they are to inform action across science, policy, and practice.

At the same time, integrating scientific, expert, and local knowledge introduces further complexity because these knowledge forms may generate divergent interpretations of the same phenomenon. Recent work on co-production stresses that such divergence should not be treated as noise to eliminate, but as a condition to be managed through iterative and collaborative processes. This is the central argument of Norström et al. (2020).

From a governance perspective, collaborative arrangements are increasingly seen as essential for enabling knowledge integration and supporting resilience in SES. Yet collaboration alone is insufficient if it does not translate into effective coordination and action. Wyborn (2015) reframes adaptive governance as a co-productive process shaped by social, contextual, and normative relations rather than by formal coordination alone.

Overall, the literature suggests that knowledge integration in social–ecological systems is not merely a technical issue of aggregating data, but a systemic challenge involving epistemic alignment, stakeholder coordination, and governance design. This creates the need for approaches that can structure heterogeneous knowledge into meaningful and actionable forms, bridging the gap between information availability and effective decision-making.

2.2 Digital Platforms as Knowledge Infrastructures

Digital platforms and decision-support systems (DSS), particularly those applied to environmental and territorial contexts, have become central tools for addressing complexity in social–ecological systems. These systems enable the integration, visualization, and analysis of heterogeneous datasets, supporting planning and decision-making processes across multiple domains. However, despite their technical potential, many environmental decision-support systems face significant limitations in terms of usability, adoption, and long-term effectiveness. As highlighted in Walling & Vaneeckhaute (2020), a large proportion of DSS initiatives are underused or abandoned, often due to a mismatch between system design and stakeholder needs, as well as insufficient support for real-world decision processes.

These limitations reflect a broader issue in the design of digital systems, where the emphasis is placed on data availability and analytical capabilities rather than on how information is structured, interpreted, and operationalized by users. In complex decision-making environments, the availability of data does not

automatically translate into actionable knowledge, particularly when users must navigate large volumes of heterogeneous information and reconcile multiple objectives.

To address this gap, recent research suggests that digital platforms should be understood not merely as tools or applications, but as knowledge infrastructures that is, socio-technical systems composed of people, technologies, and institutional arrangements that collectively enable the production, sharing, and use of knowledge. As discussed in Borgman & Groth (2025), knowledge infrastructures shape how data are interpreted, reused, and transformed into knowledge, influencing the capacity of different actors to engage with information and participate in decision-making processes.

This perspective builds on earlier work on knowledge infrastructures, which conceptualizes them as the underlying frameworks that sustain knowledge production and coordination across communities (Edwards, P. N. et al., 2013). Within this framework, digital platforms are not neutral containers of data, but active components of socio-technical systems that structure interactions, define access to information, and influence how knowledge is mobilized.

Recent studies in platform research further reinforce this view by conceptualizing digital platforms as infrastructural systems that embed social, technical, and institutional relations. In Pierson (2021), platforms are described as deeply embedded in social practices, shaping not only communication and coordination but also trust, governance, and value creation.

At the same time, research on environmental governance highlights that the effectiveness of decision-making processes depends not only on access to information, but on the quality of stakeholder interaction and participation. As shown in Newig et al. (2023), meaningful participation is associated with improved environmental outcomes, suggesting that systems supporting decision-making must enable not only access to data but also shared understanding and coordination among actors.

Despite these advances, many digital platforms still struggle to support knowledge integration and coordinated action in multi-stakeholder environments. This limitation reflects a persistent gap between data availability and its practical usability, where information is not adequately structured to support sense-making and decision-making processes.

These challenges highlight the need to move beyond a purely data-centric view of digital platforms toward an approach that emphasizes how knowledge is structured, navigated, and made meaningful for different users. In this sense, digital platforms should be conceived as environments that support sense-making, coordination, and alignment across stakeholders, laying the groundwork for design approaches that position interaction and user experience (UX) as central components of knowledge infrastructures.

2.3 From User Experience to UX-Driven Digital Architecture

UX-Driven Digital Architecture refers to the use of UX principles to structure information architectures, interaction flows, and decision-making pathways to enable knowledge integration and coordination in complex systems. This perspective extends traditional Human–Computer Interaction approaches Dix, A. (2026) by shifting the focus from interface usability to system-level orchestration of meaning, where interaction design becomes a mechanism for organizing distributed knowledge and supporting collective decision processes.

In complex socio-technical environments, usability alone is insufficient when users must interpret heterogeneous and uncertain datasets. Building on Cash et al. (2003), knowledge becomes actionable across disciplinary and institutional boundaries only when it satisfies three conditions: credibility, salience, and legitimacy. This implies that digital systems must be designed to align how information is structured and the contexts with how it is interpreted and used.

From this perspective, UX-Driven Digital Architecture can be conceptualized as comprising three interrelated components:

- Information structuring layer, which organizes heterogeneous datasets into coherent and meaningful configurations aligned with user needs and decision contexts;
- Interaction layer, which defines how users navigate, access, and interpret information through guided flows rather than isolated data exploration;
- Decision pathways layer, which connects user intentions (actor–action–goal) with relevant data, indicators, and knowledge resources, enabling coordinated and context-aware decision-making.

These components operate together to transform fragmented information environments into structured knowledge systems that support sense-making and coordination across stakeholders.

Furthermore, this approach aligns with principles of knowledge co-production Szetey et al. (2023), where different forms of knowledge are integrated through iterative and collaborative processes. In this sense, UX-Driven Digital Architecture can be interpreted as an operational translation of co-production principles into

design practice, enabling the alignment of scientific, institutional, and local knowledge within shared decision frameworks.

Rather than functioning as a layer of interface optimization, UX becomes a systemic design strategy that enables coordination across actors, datasets, and institutional boundaries, particularly in contexts characterized by high uncertainty and fragmentation.

3 Research Design and Methodological Approach

3.1 Research aims and steps

To extend the current state of the art of User Experience into the domain of social–ecological systems, this study investigates how UX-Driven Digital Architecture can support knowledge integration among multiple institutional and territorial actors operating within the polycrisis triggered by Xylella fastidiosa in Salento. The aim is to explore how UX can be repositioned as a strategic component in the design of digital systems supporting knowledge integration and decision-making in complex social–ecological contexts. Specifically, the study examines how a UX-Driven Digital Architecture can contribute to structuring heterogeneous knowledge, enabling coordination among stakeholders, and supporting decision-making processes.

To address this objective, the research adopts a qualitative case study approach combined with a research-through-design perspective. A case study is a suitable method to explore a problem and how to solve it in a real organizational setting (Creswell & Creswell, 2018). This approach allows the investigation of a real-world design process while simultaneously generating conceptual insights grounded in practice. The case study focuses on the development of a UX-Driven Digital Architecture within the DAJS project, providing an empirical context to analyse how design choices influence knowledge integration and system usability. The research is structured into the following steps:

1. An exploratory phase was conducted to understand the complexity of the context and to identify the main challenges related to knowledge integration and decision-making. This phase included the analysis of existing data sources, system requirements, and stakeholder roles within the project.
2. A design-oriented phase was carried out through qualitative data collection involving semi-structured interviews with domain experts and selected end-users. This phase aimed to elicit use situations, user needs, and perceived barriers in accessing and using available information. The qualitative data collection involved a purposive sample of domain experts and end-users, including representatives from agriculture, public administration, and technical domains. A total of 21 semi-structured interviews were conducted, each lasting approximately 60 minutes. The collected data were analysed through an iterative coding process, combining open and axial coding to identify recurring patterns in user needs, decision contexts, and information use. This process led to the identification of actor–action–goal structures that informed the design of the information architecture.
3. In the implementation phase, the UX-Driven Digital Architecture translated these insights into a structured design solution, operationalised within the DAJS Atlas, where the identified patterns were systematically embedded into the system's information architecture and interaction flows.
4. A validation phase is currently being conducted through iterative feedback sessions and usability-oriented evaluations with stakeholders. This phase aims to assess the system's capacity to support knowledge integration, improve information accessibility, and facilitate coordinated decision-making. Preliminary observations indicate that structuring information through actor–action–goal pathways enhances users' ability to navigate complex datasets, reduces the need to manually assemble fragmented information, and supports more informed and coordinated decisions across stakeholder groups. This phase is still ongoing and is focuses on collecting qualitative feedback, usage insights, and interaction patterns to inform further refinement of the platform and support its progression toward a higher Technology Readiness Level (TRL).

Through this structured process, the research combines empirical investigation and design practice to generate both practical and conceptual contributions, demonstrating how UX can function as a strategic layer within digital knowledge infrastructures.

4 Social-Ecological Context

The research is situated within the socio-ecological crisis triggered by Xylella fastidiosa in the Salento region (Southern Italy), one of the most severe plant disease outbreaks affecting Mediterranean agro-ecosystems in recent decades. The spread of the bacterium has caused the widespread destruction of olive groves, generating

profound ecological, economic, and cultural impacts across the region (*Figure 1*). Recent studies highlight the scale of this crisis, estimating significant long-term economic losses and structural transformations in olive production systems (Schneider et al., 2020). Beyond its direct agricultural impact, the Xylella outbreak has triggered a systemic disruption affecting the relationships between landscape, local identity, agricultural practices, and regional economies. This configuration reflects the characteristics of complex social–ecological systems, where environmental, social, and institutional dimensions are deeply interconnected and evolve dynamically over time. In such contexts, effective responses require the integration of heterogeneous forms of knowledge and the coordination of multiple actors operating across different scales.

The Salento context is characterized by a high degree of complexity, both in terms of environmental variables and data availability. A large volume of information is generated through environmental monitoring systems and Geographic Information Systems (GIS), covering aspects such as soil conditions, water availability, climate dynamics, ecosystem services, and agricultural suitability. Recent research emphasizes how advanced monitoring technologies contribute to the generation of high-resolution datasets for tracking the spread and impact of Xylella fastidiosa, further increasing the volume and heterogeneity of available information (Hadjichristodoulou et al., 2024). However, the availability of data does not automatically translate into actionable knowledge. Information is often distributed across multiple institutional platforms and technical systems, requiring advanced expertise to be accessed and interpreted. This fragmentation creates significant barriers for stakeholders who need to make informed decisions, particularly in contexts where time-sensitive interventions and long-term planning must coexist.

Figure 1: Impact of Xylella fastidiosa on olive landscapes in the Salento area. The widespread dieback of olive trees illustrates the ecological and socio-economic disruption caused by the outbreak. Sjor, CC BY-SA 4.0 <https://creativecommons.org/licenses/by-sa/4.0>, via Wikimedia Commons.

More specifically, three main criticalities can be identified: (i) data fragmentation across platforms and institutions limits the possibility of constructing a coherent and integrated understanding of the territory; (ii) the technical complexity of available tools restricts their usability to a limited number of expert users, excluding non-specialist stakeholders such as farmers or local decision-makers; (iii) the absence of structured decision-support mechanisms hinders coordination among actors, each operating according to different objectives, priorities, and knowledge frameworks. These challenges are further amplified by the multi-actor nature of the system. The regeneration process involves a wide range of stakeholders, including farmers, researchers, public administrations, policy makers, and technical experts. Each of these actors contributes different forms of knowledge and operates within distinct institutional and operational logics. As highlighted in recent studies on environmental governance, the effectiveness of decision-making processes depends not only on access to information, but also on the quality of stakeholder interaction and coordination (Newig et al., 2023).

In this context, existing digital platforms often function primarily as data repositories or visualization tools. While they provide access to large volumes of information, they do not necessarily support its interpretation, integration, or operationalization. As a result, decision-making processes remain fragmented, reactive, and poorly coordinated. The DAJS Atlas was developed within this context as a digital platform aimed at integrating heterogeneous datasets and supporting territorial regeneration processes. It provides access to multi-scalar information, scenario-based analyses, and thematic datasets related to environmental, agricultural, and socio-economic conditions. However, while the availability of an integrated platform represents a necessary step, it is

not sufficient to ensure effective knowledge integration. The key challenge lies in how information is structured, navigated, and aligned with the cognitive and operational needs of different users. Within this complex socio-ecological context, the UX-Driven Digital Architecture approach is introduced to transform data availability into actionable knowledge, by structuring information architectures and interaction flows that support sense-making, coordination, and shared decision-making across stakeholders.

5 Case Study: UX-Driven Digital Architecture in the DAJS Atlas platform

5.1 Context: the post-Xylella landscape

The DAJS Atlas case emerged within a context where ecological collapse was accompanied by operational and governance complexity. Following the spread of Xylella fastidiosa, large portions of the Salento olive landscape experienced severe degradation, creating urgent needs for replanting strategies, land-use reconfiguration, economic diversification, and environmental restoration. These needs generated multiple technical questions that could not be addressed through a single disciplinary lens.

Stakeholders required access to heterogeneous information sources, including soil suitability data, hydrological constraints, climatic trends, biodiversity indicators, energy infrastructure, agricultural productivity, protected areas, and regulatory constraints. These datasets existed across separate institutional repositories, often in incompatible formats and with different update cycles. While technically available, they were difficult to combine into coherent decision processes.

At the same time, actors operated with divergent priorities. Farmers needed practical guidance on crop substitution, irrigation feasibility, and economic viability. Public administrations required evidence for territorial planning, incentives, and compliance procedures. Technical professionals needed spatial diagnostics and normative references. Researchers sought exportable datasets and analytical continuity. As a result, the core challenge was not merely data scarcity, but the absence of an accessible architecture capable of translating distributed information into coordinated action.

Existing GIS environments were largely oriented toward expert use. They exposed map layers, technical metadata, and complex controls, but rarely reflected how non-specialist users formulate problems in practice. Users typically reasoned in terms such as “What can I cultivate here?”, “Which constraints apply to this parcel?”, “Where are similar successful cases?”, or “How will climate conditions evolve?”. The mismatch between system logic and user logic created a persistent information–action gap.

The post-Xylella landscape therefore represented an ideal setting to test whether UX-driven architectural principles could reorganize complex territorial knowledge into navigable decision pathways aligned with real stakeholder intentions.

5.2 UX-Driven Digital Architecture configuration

The UX-Driven Digital Architecture was implemented in DAJS Atlas as a modular web platform composed of three interconnected functional domains: (a) a scenario exploration module (DSS), (b) an interactive territorial intelligence module (WebGIS), and (c) a documentary knowledge repository.

- The first module, DSS (Decision Support Scenarios), was designed as an entry point for users who do not start from datasets but from intentions. Instead of navigating technical categories, users are guided through progressive selections based on actor profile, intended action, and expected objective. This interaction logic transforms user needs into structured queries linked to relevant territorial information (Figure 2).
- The second module, WebGIS, provides map-based exploration of the territory. It includes geospatial layers related to land use, ecosystem services, logistics, agricultural potential, climatic dynamics, and simulation outputs. However, unlike conventional GIS systems, access to layers is mediated through decision scenarios and task-oriented navigation rather than purely thematic menus (Figure 3).
- The third module, Repository, aggregates reports, scientific studies, crop sheets, regulatory documents, and practical guidelines related to sustainable regeneration. Search and filtering mechanisms allow users to retrieve documentary evidence connected to spatial contexts and decision pathways (Figure 4).

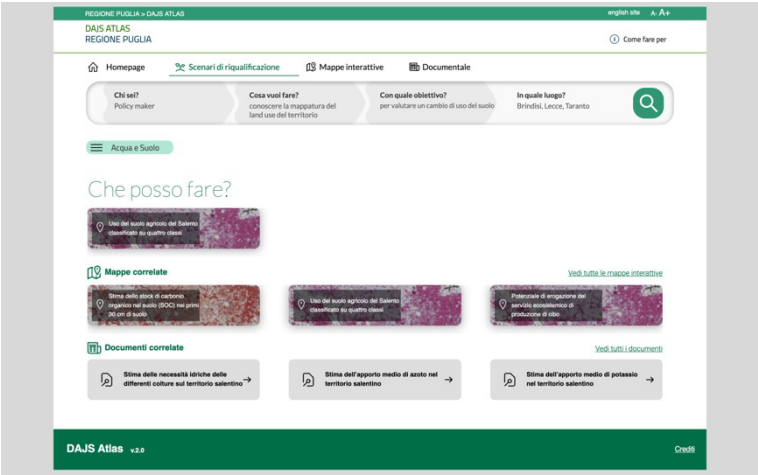

Figure 2: Component acting as a decision dashboard that guides the user in selecting the most appropriate regeneration strategies based on stated needs.

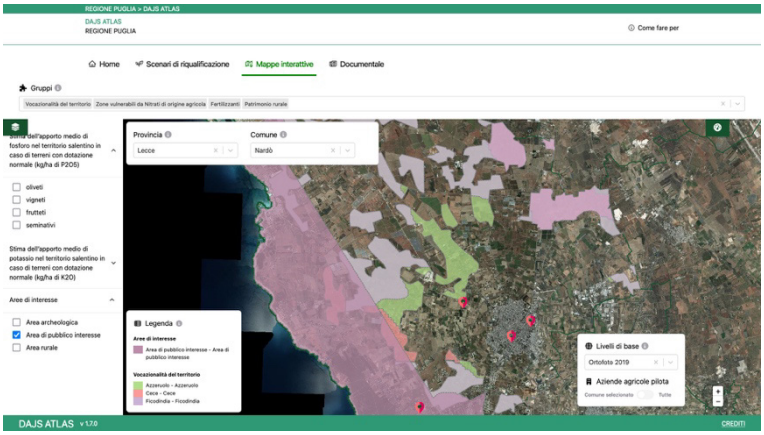

Figure 3: Interactive Maps component showing an example of the dataset of Areas of Public Interest according to the PPTR, overlaid with the dataset of potential tree and shrub species suitable for planting.

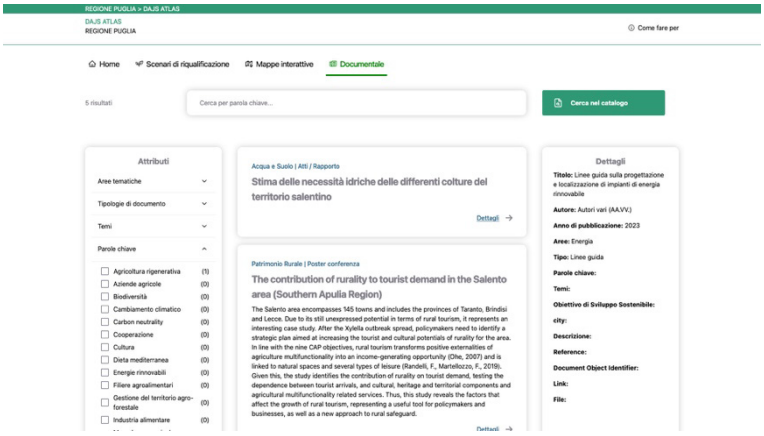

Figure 4: Repository component for searching and filtering documents related to sustainable regeneration.

From an architectural perspective, the platform was configured around dependency logic between activities. For example, geographic search enables map navigation; map navigation enables consultation of territorial constraints and case studies; case studies enable access to guidelines; map-based analysis enables forecasts and simulations; simulations enable data export for external tools. This sequencing reflects progressive knowledge acquisition rather than isolated functions.

5.3 Structuring decision-making for knowledge integration and coordination

The core design mechanism of the platform was the transformation of qualitative user research into reusable actor–action–goal pathways. Interviews and iterative design phases revealed recurring decision situations across stakeholder categories. These were converted into structured flows connecting user intentions with relevant datasets, indicators, documents, and analytical tools.

The architecture therefore combines three design principles:

- *Intentional access*: users enter through goals rather than datasets.
- *Progressive complexity*: advanced tools are revealed after contextual orientation.
- *Cross-module continuity*: maps, documents, scenarios, and analytics are linked within coherent flows.

As an example, the following connections are provided to stakeholders.

A farmer could ask which crop alternatives are viable in a damaged olive area. The system connects parcel location, pedological data, climatic suitability, irrigation availability, and cultivation guidelines.

A policy maker could evaluate where regeneration incentives should be prioritized. The platform combines land abandonment indicators, ecosystem service deficits, logistics accessibility, and socio-economic vulnerability.

A technical consultant could verify whether a land-use transition is feasible. The system links administrative boundaries, environmental constraints, normative references, and comparable case studies.

A researcher could obtain simulation outputs for external modelling. The platform enables export of forecast and KPI data generated within the system.

These pathways reduce the need for users to manually assemble fragmented information across institutions. They also create shared reference frames among actors whose objectives differ but intersect territorially. For instance, the economic resilience sought by farms, the ecological restoration sought by environmental actors, and the planning rationality sought by administrations can be examined through common geographies and evidence bases.

In this sense, UX design functions here as a translation layer between heterogeneous epistemic communities.

6 Discussion

The case extends conventional interpretations of UX by positioning it as an infrastructural capability rather than a front-end optimization practice. In complex social–ecological systems, usability alone is insufficient because the central challenge is often epistemic fragmentation: data exist but remain disconnected from decision contexts.

The DAJS Atlas suggests that UX can contribute to three higher-order functions.

First, UX can structure knowledge through pathways based on actor goals, allowing the system to filter what is relevant at specific moments.

Second, UX can support mediation among different actors interpreting the same territory through different lenses. A shared architecture enables the coexistence of these perspectives without collapsing them into a single logic.

Third, UX can enhance coordination capacity. By linking actions, data, and objectives across modules, interaction design contributes to governance performance.

This supports the broader proposition that digital platforms in sustainability transitions should be analysed not only as technologies, but as socio-technical architectures where UX plays a strategic role in aligning cognition, institutions, and action.

The DAJS Atlas case provides several practical implications for territorial governance, policy design, and digital platform development in polycrisis contexts.

For territorial systems, it demonstrates how digital infrastructures can operationalize regenerative strategies by translating fragmented datasets into decision pathways aligned with local priorities. The actor–action–goal framework offers a method to transform spatial data into actionable insights that support context-specific planning, crop diversification, and adaptive land-use transitions. This approach helps municipalities and local consortia move from reactive crisis management toward anticipatory and regenerative governance.

For decision-makers, the platform highlights the need to redesign governance mechanisms around information accessibility and interpretability. By aligning scientific outputs with institutional workflows, DAJS Atlas supports evidence-based decisions, facilitates interdepartmental coordination, and strengthens accountability across multi-level governance structures. It suggests that post-crisis regeneration policies should invest not only in data collection but also in mediation capacities that enable shared sense-making and cross-sectoral learning.

For digital platform design, the case illustrates the strategic value of UX as a governance instrument rather than a mere usability enhancement. Embedding participatory inquiry and qualitative coding into the design

process enables platforms to reflect the real cognitive and operational needs of diverse stakeholders. This reframes digital tools as dynamic knowledge infrastructures that mediate between scientific, administrative, and local forms of knowledge.

7 Conclusions

This paper examined how UX-Driven Digital Architecture can support stakeholder engagement and knowledge integration in the post-Xylella regeneration of Salento. The DAJS Atlas case shows that the main challenge in polycrisis environments is often not lack of data, but the inability to convert dispersed information into coordinated decisions.

By organizing heterogeneous resources through actor–action–goal pathways, the platform transformed GIS layers, reports, simulations, and regulatory content into navigable decision structures tailored to multiple stakeholder groups. In doing so, UX operated as a strategic layer for territorial coordination, reducing fragmentation and supporting regenerative planning.

The contribution is twofold. Empirically, the study documents a practical model for designing decision-support platforms in stressed territorial systems. Conceptually, it advances the view of UX as an infrastructural practice for aligning knowledge, institutions, and long-term transformation goals.

Future research may evaluate longitudinal impacts on adoption, inter-organizational coordination, and measurable regeneration outcomes, as well as test transferability of the model in other climate, biodiversity, or agricultural crisis contexts.

8 Acknowledgements

This contribution is the result of a collective reflection by the authors on the outcomes of the Research and Development Project “Sustainable Regeneration of Agriculture in Territories Affected by Xylella fastidiosa”, promoted by the Jonico-Salentino Agro-Food Quality District (DAJS) and funded by the Italian Ministry of Agriculture, Food Sovereignty and Forestry (MASAF).

A Multidimensional KPI-Based Framework for Evaluating AI-Driven Cybersecurity Solutions

Mariangela Lazoi, Marianna Lezzi, Nicolò Gianmauro Totaro
University of Salento, Lecce, Italy

Abstract

Artificial Intelligence (AI)-powered cybersecurity is increasingly adopted in complex and data-intensive environments, particularly in Internet of Things (IoT) settings, where traditional rule-based approaches struggle to cope with dynamic and unforeseen threats. While AI-based solutions demonstrate high detection accuracy, responsiveness, and operational efficiency, their evaluation remains dominated by technical performance indicators such as precision, recall, false-positive rates, and computational efficiency. This focus provides a partial view of the suitability of AI-based cybersecurity solutions, ignoring relevant issues related to energy consumption, carbon footprint, organizational impact, accountability, and regulatory compliance. To addresses this limitation, the paper adopts a conceptual and design-oriented research approach to propose a multidimensional key performance indicators (KPI)-based framework for comparing AI-driven cybersecurity solutions, considering technical, environmental, social, economic, and governance dimensions. The framework operationalises evaluation through a structured pipeline that combines three main elements: the AI-based cybersecurity solutions under evaluation, a baseline set of KPI, and expert judgements on the relative importance of the five evaluation dimensions. The framework operationalises evaluation through a structured pipeline. Heterogeneous KPIs are classified according to their direction of preference and normalised onto a common scale to ensure comparability. Normalised indicators are aggregated within each dimension to generate dimensional performance scores. Expert judgements are processed to derive dimension weights reflecting contextual priorities. Dimensional scores and weights are combined through weighted aggregation to produce both a composite sustainability-performance index and a multidimensional performance profile for each solution. The contribution of the paper lies in moving beyond accuracy-centric benchmarking by providing a transparent and replicable evaluation logic that makes trade-offs across dimensions explicit. Rather than treating sustainability as an external factor or an additional descriptive element, the framework integrates it directly into the evaluation process, enabling more balanced and context-sensitive comparison among AI-driven cybersecurity solutions. The proposed framework provides a methodological foundation for future empirical applications and supports more informed decision-making in the selection and governance of AI-based cybersecurity technologies.

Paper type: Academic research paper

1 Introduction

The increasing digitalisation of organisational processes has intensified exposure to cyber threats, particularly in complex environments such as those based on the Internet of Things (IoT) (Mohamed, 2025; Uddin et al., 2025). In response to this growing complexity, traditional cybersecurity approaches are increasingly complemented or replaced by Artificial Intelligence (AI)-powered solutions that rely on machine learning and deep learning techniques to detect anomalies and adapt to evolving attack patterns (Alansary et al., 2025; Mohamed, 2025). AI-based cybersecurity solutions can significantly outperform traditional approaches in terms of detection accuracy, with reported values exceeding 99% in controlled intrusion detection benchmarks (Shan, 2025; Yang et al., 2024). These performance gains are often accompanied by reductions in false-positive rates and analyst workload, contributing to more efficient Security Operations Centre (SOC) operations (BustamanteV et al., 2025; Shan, 2025). However, detection performance may degrade in heterogeneous and real-world IoT environments, where data diversity and evolving attack behaviours increase system complexity (Rafique et al., 2024). This variability highlights the limitations of evaluating AI-driven cybersecurity solutions solely through benchmark-based technical metrics (Mohamed, 2025; Rawat, 2025).

Sustainability has emerged as a key dimension of digital transformation strategies, extending beyond environmental efficiency to encompass social, economic, and governance considerations (Lezzi et al., 2025; Yu et al., 2025). However, current practices for evaluating technological solutions remain largely focused on technical performance indicators such as accuracy, precision, recall, false-positive rates, and computational efficiency (Mohamed, 2025; Rawat, 2025). Although these metrics are essential for assessing detection effectiveness, they are insufficient for revealing the impacts associated with AI-based security solutions, especially as model complexity and computational demands increase (Agarwal and Gupta, 2025; De Vries, 2023).

Concerns regarding energy consumption, carbon footprint, operational costs, transparency, and governance are still rarely integrated into cybersecurity evaluation frameworks (Achuthan et al., 2025; De Vries, 2023). Accuracy-centric assessment approaches risk overlooking environmental, social, and organisational implications that are critical for long-term sustainability (Lezzi et al., 2025; Priebe et al., 2023).

AI-driven solutions are increasingly recognised as both enablers of sustainable digital practices and sources of new sustainability challenges (Achuthan et al., 2025; Bhimavarapu, 2025). On the one hand, AI-based automation can enhance resource efficiency and organisational resilience; on the other hand, the growing computational footprint of advanced models raises concerns related to energy use, electronic waste, and unequal access to advanced infrastructures (Brevini, 2020; Gómez et al., 2023; Le Goff, 2025). Since current approaches to evaluating AI-driven cybersecurity rarely integrate these sustainability dimensions in a systematic and operational manner, the literature offers fragmented assessment practices (Henao et al., 2025; Rawat, 2025; Usman et al., 2025).

To fill this gap, this study proposes a conceptual framework based on key performance indicators (KPIs) for the multidimensional comparison of AI-driven cybersecurity solutions that integrates technical performance with environmental, social, economic, and governance considerations. The framework aims to support more balanced, transparent, and sustainability-aware evaluations of AI-based cybersecurity.

2 State-of-the-Art

Recent research on AI-driven cybersecurity has mainly examined how machine learning and deep learning techniques can improve the detection, classification, and prediction of cyber threats in increasingly complex digital ecosystems. Applications include intrusion detection, anomaly detection, malware classification, and threat intelligence, where AI models are used to identify non-linear patterns and evolving behaviours that are difficult to capture through static rule-based systems (Alansary et al., 2025; Hamid and Rahman, 2025; Uddin et al., 2025). Within this stream of research, IoT and industrial environments represent particularly relevant application contexts, due to their high connectivity, data heterogeneity, and exposure to dynamic attack surfaces (Mohamed, 2025; Uddin et al., 2025).

Evaluation practices in this literature remain primarily centred on technical effectiveness. Most studies assess AI-based cybersecurity solutions through indicators such as accuracy, precision, recall, false-positive and false-negative rates, latency, and computational efficiency (Mohamed, 2025; Rawat, 2025). These metrics are essential for demonstrating detection capability and operational feasibility, and several experimental studies report very high performance levels in benchmark-based intrusion detection scenarios (Shan, 2025; Yang et al., 2024). However, recent contributions also show that such results are often context-dependent, as model performance can be affected by data heterogeneity, deployment conditions, and evolving attack behaviours in real-world environments (Rafique et al., 2024). For this reason, optimisation-driven and hybrid approaches increasingly attempt to balance detection accuracy with latency, resource consumption, and deployment constraints in operational settings such as SOCs and industrial control systems (Ranpara et al., 2025).

While technical performance remains the dominant evaluation focus, recent studies increasingly acknowledge the relevance of sustainability considerations in AI-driven cybersecurity (Achuthan et al., 2025; Lezzi et al., 2025). The study by (Lezzi et al., 2025) emphasizes the distinction between “green cybersecurity”, which focuses primarily on environmental efficiency, and the broader notion of “sustainable cybersecurity”, which adopts a multidimensional perspective integrating environmental, social, economic, and governance dimensions. Green cybersecurity approaches concentrate on reducing energy consumption and carbon footprint through lightweight models and resource-aware optimisation, often without extending evaluation beyond technical and environmental indicators (Bhimavarapu, 2025; Rawat, 2025).

From an environmental perspective, increasingly complex AI models can entail significant energy consumption and associated carbon emissions, particularly during training and retraining cycles (Brevini, 2020; De Vries, 2023). In response, green AI approaches propose techniques such as model compression and adaptive learning to mitigate environmental impact while maintaining acceptable performance levels (Gupta et al., 2025; Rawat, 2025). Nevertheless, these approaches generally remain focused on technical optimisation, without explicitly connecting environmental indicators to broader organisational or societal evaluation frameworks.

The social dimension of AI-driven cybersecurity is comparatively underexplored and is typically addressed at a conceptual rather than operational level (Achuthan et al., 2025; Henao et al., 2025). Issues such as privacy protection, trust in automated decisions, workforce implications, and risks of bias, are discussed but rarely translate these concerns into measurable indicators suitable for comparative evaluation (Arpaci, 2024; Dr. Varsha, 2023). As a result, social considerations remain marginal in evaluation practices despite their relevance for responsible AI adoption.

Similarly, governance aspects, including accountability, transparency, explainability, robustness, and regulatory compliance, are increasingly recognised as critical for sustainable AI-driven cybersecurity deployment (BustamanteV et al., 2025; Usman et al., 2025). However, governance principles are seldom operationalised through explicit evaluation metrics or integrated with technical performance indicators, limiting their role in organisational decision-making (Königstorfer and Thalmann, 2022; Mohamed, 2025).

From an economic standpoint, several studies address trade-offs between detection performance, computational cost, and operational efficiency, particularly in relation to total cost of ownership and resource allocation in cybersecurity operations (Azrour et al., 2025; Ranpara et al., 2025). Nevertheless, economic considerations are often treated implicitly or in isolation, rather than being systematically integrated into multidimensional evaluation frameworks.

Overall, the literature reveals a fragmented evaluation landscape in which technical performance is extensively measured, while environmental, social, economic, and governance dimensions are addressed inconsistently and rarely integrated within a unified assessment logic (Achuthan et al., 2025; BustamanteV et al., 2025; Rawat, 2025). This fragmentation limits the ability of organisations to systematically assess trade-offs between AI effectiveness and sustainability-related impacts, reinforcing the need for a multidimensional evaluation framework.

3 Research Approach

This study adopts a conceptual and design-oriented research approach (Gregor and Hevner, 2013; Hevner et al., 2004) to develop a structured framework for evaluating AI-powered cybersecurity solutions from a multidimensional sustainability perspective.

Specifically, the approach is grounded in research on AI-driven cybersecurity evaluation and sustainable digital systems, which highlights the limits of accuracy-centric assessments and the need to account for environmental, social, economic, and governance considerations (Lezzi et al., 2025; Mohamed, 2025). Accordingly, the framework is derived through a twofold process. First, technical KPIs are identified from the AI-driven cybersecurity evaluation literature, where performance assessment is commonly based on indicators such as detection accuracy, false positives, and computational efficiency (Mohamed, 2025). Second, the environmental, social, economic, and governance dimensions are developed as author-defined KPI categories, conceptually informed by recurrent concerns discussed in recent literature on sustainable cybersecurity, responsible AI, and digital governance. Rather than being directly adopted from existing frameworks, these KPIs are formulated and adapted to the specific evaluation context of AI-driven cybersecurity solutions. This process allows the baseline KPI architecture to translate heterogeneous literature-based concerns into a parsimonious set of operational indicators suitable for cross-dimensional comparison of AI-based cybersecurity solutions.

The aim is to design an evaluation artefact that supports organisational decision-making by integrating heterogeneous criteria within a coherent structure (Belton and Stewart, 2002; Gregor and Hevner, 2013). To do this framework draws on multi-criteria evaluation and decision-support research for comparing alternatives characterised by multiple, potentially conflicting objectives (Belton and Stewart, 2002; Keeney and Raiffa, 1993). The scope is intentionally delimited. The framework supports transparent, context-aware evaluation by making trade-offs between technical performance and sustainability dimensions explicit (Montibeller and Von Winterfeldt, 2015; OECD et al., 2008). The framework provides a conceptual foundation that can be instantiated and assessed in future work, for example through case studies or expert-based evaluations (Belton and Stewart, 2002; Lezzi et al., 2025).

The baseline KPI set adopted in this study is conceived as a reference configuration derived from the convergence between two literature streams: technical evaluation of AI-driven cybersecurity and sustainability-oriented assessment of digital systems. The technical KPIs are directly derived from the cybersecurity and AI literature, whereas the remaining KPIs are inspired by the sustainability, responsible AI, and AI governance literature and subsequently adapted to the specific evaluative context of AI-enabled cybersecurity solutions. The selection of fifteen KPIs, equally distributed across five dimensions, reflects a parsimonious design choice aimed at ensuring structural symmetry, interpretability, and comparability across alternatives. This choice is consistent with composite-indicator construction guidelines, which emphasise the need for a clear theoretical structure, analytically meaningful indicator selection, and transparent comparison across units of analysis (OECD et al., 2008). The KPI set is not intended as an exhaustive list, but as a balanced operational baseline that captures the minimum evaluative architecture required to jointly assess technical performance and sustainability impacts in AI-enabled cybersecurity solutions. In line with the scope of the framework, the selected indicators focus primarily on the operational use phase of AI systems, combining technical, environmental, social, economic, and governance measures that are both organisationally relevant and operationally measurable. However, the

framework remains modular: depending on specific evaluation needs, users may add, substitute, or refine indicators, including more explicitly AI-specific or lifecycle-oriented KPIs related to phases such as training, fine-tuning, retraining, or dataset curation, while preserving the underlying evaluation logic of the framework.

4 A Multidimensional Framework for Evaluating AI-Powered Cybersecurity

4.1 Input layer: evaluation scope, KPIs, and expert knowledge

The proposed framework is designed to support the systematic comparison of AI-powered cybersecurity solutions through a structured, KPI-driven architecture. As illustrated in Figure 1, the framework explicitly defines its evaluation scope by identifying the elements that enter the assessment process and by structuring them into a coherent input layer. This design choice ensures that the evaluation process is transparent from the outset and that all subsequent analytical steps can be traced back to clearly specified inputs.

The primary unit of analysis within the framework is an AI-based cybersecurity solution to be evaluated, such as an intrusion detection system, anomaly detection model, or integrated cybersecurity platform deployed within an organisational or infrastructural context. Each solution is assessed within a common evaluation space defined by a predefined baseline set of KPIs.

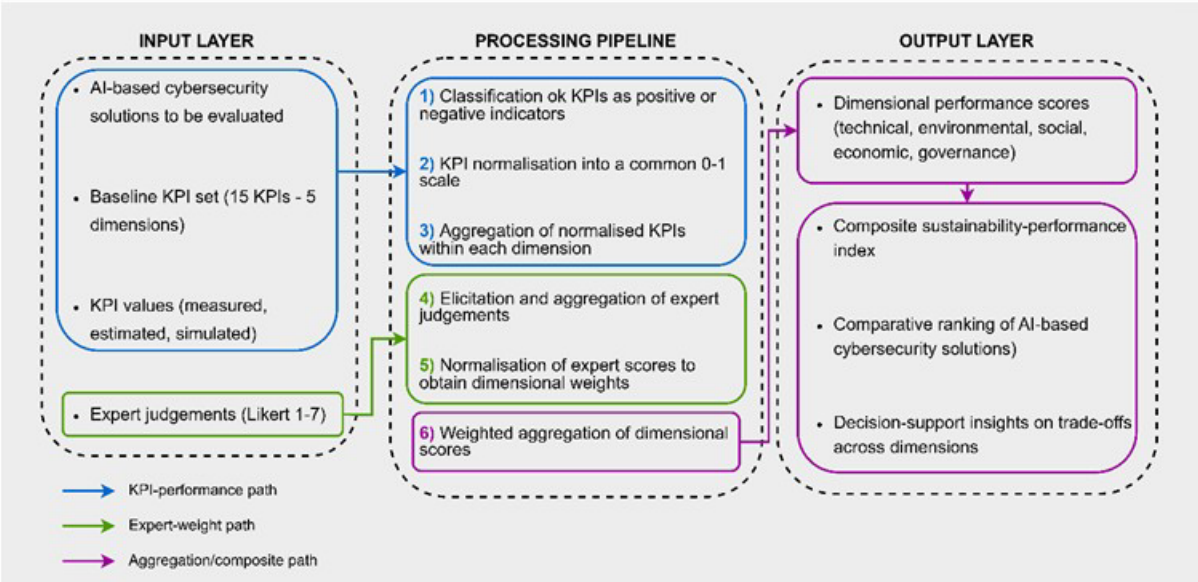

Figure 1: Framework design

The baseline KPI set is structured along five evaluation dimensions: technical, environmental, social, economic, and governance. This structure ensures consistency and comparability across all solutions under evaluation, in line with methodological recommendations for constructing composite indicators based on clearly defined dimensions and indicators (OECD et al., 2008). The framework requires that KPI values may be empirically measured, analytically estimated, or simulated, depending on data availability and evaluation context. This flexibility reflects the practical constraints of cybersecurity evaluation, where access to complete and homogeneous performance data is often limited and security metrics are typically context-dependent (Pendleton et al., 2017).

For the technical dimension, the framework considers *detection accuracy*, namely the ability of the solution to correctly identify malicious activities; *false positive rate*, namely the frequency with which legitimate events are classified as threats; and *computational efficiency*, namely the ability to maintain performance with limited computational resources (Mohamed, 2025). For the environmental dimension, the selected KPIs are *inference energy intensity*, referring to the energy consumed by the AI component during operation; *energy-to-performance ratio*, referring to the extent to which the AI component achieves detection performance relative to the energy consumed during operation; and *operational carbon intensity*, referring to the emissions associated with AI inference and model-serving activities. For the social dimension, the framework includes *sensitive-data minimisation*, namely the extent to which the solution limits the use, retention, or exposure of sensitive data in operational processing; *explanation usefulness for analysts*, namely the degree to which system outputs provide understandable and actionable support to human operators; and *human override and feedback*

support, namely the extent to which operators can supervise, contest, and intervene in system behaviour. For the economic dimension, the selected KPIs are AI *operating cost intensity*, referring to the cost attributable to the AI component during operation; *analyst productivity gain*, namely the extent to which the solution reduces triage effort and investigation time; and *cost per validated alert*, namely the average operational cost associated with generating and processing a validated security alert. Finally, for the governance dimension, the framework considers *model lineage and traceability*, namely the extent to which model versions, thresholds, data dependencies, and decision logs are documented and traceable; *drift monitoring and control readiness*, namely the ability to detect, monitor, and respond to model degradation over time; and *AI compliance and audit readiness*, namely the degree to which the solution supports auditable evidence for cybersecurity and AI-related governance requirements.

The baseline KPI set should therefore be interpreted as a general-purpose and literature-grounded reference configuration. Its role is to provide a stable and comparable evaluative structure across heterogeneous AI-driven cybersecurity solutions, while remaining sufficiently flexible to accommodate context-specific refinements. This is particularly relevant in the AI domain, where some applications may require the integration of lifecycle-specific indicators related to training, validation, deployment, monitoring, drift management, or retraining.

In addition to KPI values, the framework explicitly incorporates expert knowledge as a distinct and formalised input. Experts are asked to express judgements on the relative importance of the evaluation dimensions using a Likert scale ranging from 1 to 7, preserving interpretability and discriminative capacity in evaluative judgement tasks (Dawes, 2008; Finstad, 2010). These expert responses capture contextual priorities, such as organisational risk tolerance, regulatory sensitivity, or strategic emphasis on sustainability objectives, that cannot be inferred directly from KPI values alone.

4.2 KPI processing and dimensional scoring

The framework applies a structured KPI processing pipeline aimed at transforming heterogeneous performance indicators into analytically consistent and comparable scores. This processing phase represents the core analytical component of the framework, where raw inputs are systematically converted into dimensional performance assessments. Within this logic, the framework distinguishes between a stable evaluation architecture and context-specific implementation choices. The five dimensions and the baseline KPI structure constitute the stable backbone of the framework, while the operational instantiation may vary depending on data availability, sectoral requirements, and organisational priorities.

The first step of KPI processing consists of classifying each indicator as either a positive or a negative KPI, depending on whether higher values correspond to better or worse performance. This classification is a necessary precondition for ensuring interpretability during subsequent transformations and avoids ambiguities when aggregating indicators with opposite performance orientations, such as detection accuracy and energy consumption, as required in composite-indicator construction processes (OECD et al., 2008).

Once classified, KPI values are normalised onto a common 0-1 scale (step 2). Normalisation serves to eliminate scale effects across indicators that may originally be expressed in different units, magnitudes, or measurement ranges. By mapping all KPIs onto a shared scale, the framework ensures that no indicator dominates the evaluation solely because of its numerical properties. Importantly, the framework does not prescribe a specific mathematical normalisation formula, allowing evaluators to adopt approaches consistent with data availability and contextual constraints, provided that the directionality and relative meaning of each KPI are preserved.

Normalised KPIs are then aggregated within their respective evaluation dimensions to obtain dimensional performance scores (step 3). This intra-dimensional aggregation captures trade-offs among KPIs belonging to the same dimension. At this stage, each dimension is represented by a single score that summarises its internal performance profile, while remaining traceable to the underlying KPIs.

In parallel to KPI aggregation, expert judgements collected at the input stage are processed to derive dimension weights (step 4). Individual expert responses on dimensional importance are first aggregated and then normalised to ensure comparability across respondents. This process yields a set of weights that reflect the relative importance assigned to each dimension within a specific evaluation context, making the framework sensitive to organisational priorities without embedding fixed or universal assumptions.

A key design feature of this processing step is the explicit separation between performance scoring and importance weighting (step 5). KPI-based dimensional scores are computed independently of expert preferences, ensuring that performance evidence is not distorted by value judgements during early stages of analysis.

Through this structured KPI processing and dimensional scoring logic, the framework establishes a rigorous and traceable bridge between heterogeneous input data and higher-level evaluation outputs, preparing the ground for cross-dimensional aggregation and comparative assessment.

Once dimensional performance scores and corresponding weights have been derived, the framework proceeds to cross-dimensional aggregation (step 6). This step combines empirically grounded dimensional scores with context-specific importance weights to generate integrated evaluation outputs for each AI-based cybersecurity solution.

The first outcome of this step is the calculation of a composite sustainability-performance index, obtained through weighted aggregation of dimensional scores. Each dimension contributes to the overall index proportionally to its normalised importance weight. This structure ensures that the final composite value reflects both objective performance evidence (through KPI-derived dimensional scores) and contextual priorities (through expert-defined weights).

The framework does not collapse evaluation results into a single opaque metric. Alongside the composite index, it preserves dimensional performance scores, allowing evaluators to compare solutions at multiple analytical levels and distinguish between alternatives that achieve similar overall scores through different performance configurations. This dual-output structure supports scenario analysis and sensitivity checks, since changes in dimensional weights can show how alternative strategic priorities reshape comparative outcomes.

5 Discussion and Conclusions

This study contributes to AI-powered cybersecurity evaluation by addressing the predominance of accuracy-centric and technically focused assessment approaches. By introducing a structured, KPI-based framework that integrates technical, environmental, social, economic, and governance considerations, the proposed approach advances evaluation from isolated benchmarking towards a multidimensional and sustainability-aware perspective.

The framework enables comparative ranking and benchmarking across alternative AI-based cybersecurity solutions. Since all KPI values are normalised and aggregated according to a consistent procedure, resulting scores are directly comparable within the same evaluation exercise. This supports structured benchmarking across different models, architectures, or deployment configurations under identical evaluative assumptions, useful to provide explicit decision-support insights on trade-offs across dimensions.

The aggregation logic maintains full traceability from composite index back to dimensional scores and ultimately to underlying KPIs. This traceability strengthens interpretability and supports auditability, particularly in regulated or high-stakes cybersecurity contexts. The framework produces not only a ranking outcome, but a structured performance profile that supports informed, transparent, and reproducible evaluation of AI-based cybersecurity solutions.

From a theoretical standpoint, the framework contributes to the literature by operationalising sustainability in AI-driven cybersecurity evaluation without reducing it to a qualitative checklist or abstract principle. While prior research has highlighted sustainability-related concerns in AI-driven cybersecurity, these dimensions are often addressed in a fragmented or dimension-specific manner (Lezzi et al., 2025).The proposed framework embeds them within a coherent evaluation architecture that explicitly links KPIs, dimensional scores, expert judgement, and aggregation logic. This integration represents a methodological contribution that bridges research on AI performance evaluation, sustainable digital systems, and multi-criteria decision support, while remaining grounded in the specific requirements of cybersecurity contexts.

A key strength of the framework lies in its explicit separation between performance evidence and value-based judgement. By computing KPI-based dimensional scores independently from expert-defined importance weights, the framework avoids implicit or opaque weighting schemes that often characterise composite indicators. As a result, the framework supports reasoned deliberation rather than automated optimisation, which is particularly appropriate in cybersecurity settings characterised by uncertainty, high stakes, and regulatory constraints. This facilitates scenario analysis and sensitivity exploration, allowing organisations to examine how changes in strategic priorities, such as increased emphasis on environmental sustainability or governance robustness, alter comparative outcomes.

The framework also enables a more nuanced understanding of trade-offs inherent in AI-driven cybersecurity adoption. The dual output structure, namely dimensional profiles alongside a composite index, makes trade-offs explicit and analysable. This feature is especially relevant for organisations facing competing objectives, such as maximising detection effectiveness while minimising environmental impact or ensuring compliance with governance requirements. By preserving traceability from composite scores back to KPIs, the framework facilitates auditability and supports accountability in evaluation processes.

The framework exhibits some limitations. The framework is conceptual, and it has not yet been empirically validated through real-world case studies or comparative deployments. These limitations reflect deliberate design decisions aimed at preserving flexibility and generality, but they also point to clear directions for future research. In particular, the current KPI configuration should be understood as a transferable baseline rather than as a definitive taxonomy of AI-specific indicators. Future work may therefore extend the framework through empirical validation in different cybersecurity contexts, refinement of KPI sets for specific application domains, and the incorporation of more explicitly AI-specific or lifecycle-oriented indicators, for example related to training, validation, deployment, monitoring, and retraining. Such extensions would further strengthen the practical applicability of the framework while preserving its core conceptual structure.

Ethics declaration

This study does not involve human participants, personal data, or sensitive information. Ethical approval was therefore not required.

AI declaration

AI tools were used to support language editing and clarity of expression. The intellectual content, structure, and scientific arguments were entirely developed by the authors.

Territorial Development as Resource for Firm Growth Strategies: A Conceptual Framework

Stefano Marciano, Raffaele Fiorentino, Rosita Capurro, Francesca Peluso
University of Naples Parthenope, Naples, Italy

Abstract

This study aims to investigate the role that territorial development can assume within firm growth strategies. Specifically, the study aims to provide an in-depth analysis of territorial development for firms' value creation processes and the achievement of the competitive advantage. In order to achieve this aim, the study analyze the literature on the Resource-Based View Theory, dynamic capabilities and territorial development. Thus, the study has developed a conceptual framework, grounded in the Resource-Based View Theory, aimed at clarifying the conditions under which territorial development can acquire strategic relevance within firm growth strategies. The findings support the idea that territorial resources become strategically relevant when they are aligned with the firm's objectives, business model and strategic trajectory; when they present the features of durability and limited transferability and replicability; and when the firm is able to capture the value generated. In this perspective, territorial development does not contribute to firm growth simply because some resources are available within a given territory. Its strategic value depends on the firm's capability to identify and activate such resources and transform them into a coherent basis for competitive advantage.

The paper provides relevant contributions in theory and practice. From a theoretical perspective, the results contribute to the strategic management literature by extending the Resource-Based View Theory to the interpretation of territorial development as a strategic resource for firm growth. From a practical perspective, the study offers a conceptual framework useful for entrepreneurs, executives, managers and policy-makers to identify, evaluate and exploit territorial resources. However, as a theoretical and literature-based study, the proposed framework requires empirical validation and further investigation across different sectors, territorial settings and firm types in order to assess its explanatory power and practical applicability in heterogeneous business contexts. Future studies should integrate the theoretical analysis with empirical investigations in specific territorial contexts.

Keywords: Territorial development; strategic management; Resource-Based View; firm growth.

Paper type: Academic Research Paper

1 Introduction

Territorial development has become an increasingly relevant issue in contemporary strategic and managerial debates, as it lies at the intersection of economic growth, sustainability, territorial planning and firms' competitiveness (Porter, 2000; Delgadillo et al., 2021; Morretta et al., 2021). From this perspective, territorial development can be understood as a multidimensional configuration of tangible and intangible resources, social relations, traditions and knowledge dynamics that shape value creation processes (Allais et al., 2015; Torre, 2025).

In many cases, firms are embedded in territorial contexts where access to human capital, infrastructures, local institutions, social capital and place-based knowledge affects both strategic choices and competitive trajectories. The access to these territorial resources often can generate significant competitive benefits, as it can enhance firms' value creation processes, support the achievement of competitive advantage and contribute to the development of more sustainable growth paths (Oerlemans and Meeus, 2005).

Although the growing interest devoted to this topic in the literature (Bianchi and Richiedei, 2023; Fiorentino, 2023; Fiume et al., 2025; Capurro et al., 2025), there has been limited attention given to interpreting territorial development through a strategic management lens, particularly as a resource for firm growth. Despite their potential strategic relevance, territorial resources are often under-exploited by firms, even when they can support the achievement of competitive advantage (Storper, 1997; Porter, 2000; Allais et al., 2015).

In order to bridge the gap, the study aims to investigate the role that territorial development can assume within firm growth strategies. More specifically, the study addresses the following research question: which is the role of territorial development for firm growth strategies from a Resource-Based View perspective? To answer this question, the study aims to provide an in-depth analysis of territorial development and advances a conceptual framework grounded in the Resource-Based View (RBV), with particular reference to Grant's resource and capability-based approach to strategy formulation (Grant, 1991). This perspective is especially suitable because it makes possible to move beyond a static interpretation of territorial resources and to focus

instead on the conditions under which they become strategically relevant, contribute to competitive advantage and enable the appropriation of value.

The paper is structured as follows. Section 2 presents the theoretical background. Section 3 develops the proposed conceptual framework. Section 4 discusses the main findings and implications emerging from the framework. Finally, Section 5 concludes the paper by summarizing the main contributions, outlining the practical implications and suggesting avenues for future research.

2 Theoretical Background

2.1 Resource-based view

The RBV has emerged as one of the most influential frameworks in strategic management for understanding how firms achieve and sustain competitive advantage. Originally developed by Barney (1991, 2001) and expanded by other scholars (Grant, 1991; Peteraf, 1993; Sirmon et al., 2007), RBV advances that a firm's competitive advantage derives from its resources and capabilities and from the way these are organized to support strategy formulation. While Barney's contribution has been pivotal in emphasizing the role of valuable, rare, inimitable and non-substitutable resources, Grant's perspective is particularly relevant in highlighting that strategy is grounded in the match between the firm's resources and capabilities and the opportunities arising in its external environment.

The evolution of RBV theory has been marked by increasing complexity in understanding resource heterogeneity and its relationship to performance, moving from static conceptions of resource possession to dynamic understandings of resource orchestration and reconfiguration (D'oria et al. 2021). The foundational premise of RBV emphasizes that competitive advantages arise primarily from internal resources and capabilities. This theoretical shift has profound implications for strategic management practice, redirecting managerial attention from competitive analysis to internal resource and capability development.

The integration of RBV with other theoretical perspectives, particularly Dynamic Capabilities Theory (Grant, 1991; Teece et al., 1997; Teece, 2007), has enriched our understanding of how firms must continuously adapt and reconfigure their resources to maintain competitive advantages in dynamic environments.

Dynamic Capabilities Theory addresses a critical limitation of traditional RBV by explaining how firms maintain competitive advantage in rapidly changing environments. While RBV emphasizes the possession of valuable resources, dynamic capabilities focus on the firm's ability to identify opportunities and threats, exploit promising opportunities and transform resource configurations in response to environmental changes.

Firms that successfully combine possession of resources with robust dynamic capabilities achieve superior and more sustainable performance outcomes (Wilden et al., 2016). This perspective has particular relevance for understanding how firms can leverage territorial development.

In line with the RBV and dynamic capabilities perspective, territorial development cannot be interpreted as a static resource; rather, it represents an evolving configuration that requires active management, continuous strategic scanning of emerging territorial opportunities and the purposeful reconfiguration of firm–territory engagement strategies.

2.2 Territorial development

The concept of territorial development exhibits a broad and multidimensional nature that encompasses economic, social, environmental and institutional components (Allais et al., 2015). As it has been defined by Torre (2025), territorial development can be understood as a process that aims to improve the well-being and wealth of a territory's stakeholders through cooperation and competition, collective initiatives, governance processes and territorial innovation dynamics. In this sense, territory is a relational space in which a community recognises itself and uses it as a reference point for its individual and collective actions, contributing to the orientation of its development trajectories (Maillat, 1995; Banini et al., 2021). Consistently, territory can also be understood as an evolving and complex combination of actors and geographical space, shaped by the ways in which such actors use, organise and manage it (Allais et al., 2015; Moine, 2006).

In this sense, development is not solely grounded in sectoral dynamics, but also in the territory as a context for coordination, learning and collective action, where the valorisation of local resources and the construction of social capital play a decisive role (Shucksmith, 2010). More precisely, social capital, defined as a set of trust, reciprocity and networks of cooperation, is a vital territorial resource because it enhances the territory's ability to effectively utilise its material and immaterial resources (Portes, 2000; Tura and Harmaakorpi, 2005). In addition, territorial value can be seen as arising from the interaction among multiple interconnected

components, including natural ecosystems, anthropic infrastructures, industrial systems and social spaces, each of which provides both tangible and intangible resources (Allais et al., 2015; Moine, 2006). In particular, social spaces contribute with elements such as common culture, local history and identity, all of which can shape how territorial resources are perceived, mobilised and transformed into value (Allais et al., 2015; Moine, 2006).

This leads to a strategic interpretation of territory as a driver of economic and entrepreneurial development, in which firms, resources and knowledge are closely intertwined and embedded with the territorial context (Darroch, 2005). From this view, territorial characteristics can affect firm performance. This suggests that territorial capital can be interpreted as a resource for competitive advantage of firms (Morretta et al., 2020).

Moreover, territorial resources are often under-exploited by firms, despite their potential to generate competitive advantage through the use of local tangible and intangible resources, such as specialised competences and excellence clusters (Porter, 2000; Allais et al., 2015).

2.3 Territorial development from a RBV perspective

The conceptualization of territorial development as a resource reflects an important theoretical extension of RBV that recognizes the strategic importance of local and regional contexts. Geographic proximity creates both tangible advantages - such as reduced transportation and logistics costs, improved supply chain coordination, access to specialized labour markets, shared infrastructure and proximity to suppliers and key inputs - and intangible benefits including knowledge, institutional support and cultural alignment (Oerlemans and Meeus, 2005). Research on industrial clusters demonstrates that geographic concentration of firms within specific industries creates unique competitive environments where territorial factors significantly enhance firm performance and innovation capacity (Storper, 1997; Porter, 2000).

Contrasting passively accepting a geographic location, strategic territorial development involves active engagement with regional economies, community stakeholders and institutional actors to enhance the strategic value of territorial resources (Morretta et al., 2020). This management approach recognizes that territorial advantages require continuous cultivation; firms have to invest in building relationships, improving infrastructure, developing knowledge networks and engaging with institutions to fully realize the value potential of territorial resources.

Territorial development management has evolved as a central strategic function for firms operating in sectors strongly tied to place-based resources, such as tourism and creative industries. In such contexts, firms are actors embedded within geographically bounded systems of relationships, where performance depends on the ability to access, combine and leverage territorial resources and capabilities (Boschma, 2005). Effective territorial management involves orchestrating relationships between multiple stakeholders' groups to create an environment that fosters success (Freeman, 1984).

3 Conceptual Framework

In light of the theoretical background, this study proposes a conceptual framework designed to interpret territorial development within the RBV, with particular reference to Grant's resource and capability-based approach to strategic management (Grant, 1991). The framework was developed through literature analysis and a process of synthesis aimed at identifying the key concepts and theoretical relationships emerging from RBV, dynamic capabilities and territorial development (Capurro et al., 2024).

Territorial resources do not automatically constitute strategic assets; their strategic relevance depends on the firm's ability to recognize their meaning, evaluate their potential and effectively integrate them with its internal resource and dynamic capabilities.

The proposed framework is grounded in a fundamental distinction between territorial resources and firm dynamic capabilities. The former encompasses the set of tangible and intangible resources embedded within a given territorial context, whereas the latter refer to the firm's ability to access, coordinate and integrate such resources with its internal resource and dynamic capabilities (Barney, 1991; Grant, 1991, Teece 1997; 2007).

The achievement of competitive advantage depends on the firm's ability to translate access to territorial resources into an effective basis for strategic action. Territorial development does not constitute a capability per se; it represents a pool of potentially strategic resources whose value is realized only when the firm develops the capabilities of absorption, integration, coordination and orchestration. The potential value-creation of territorial development can be examined along three closely interrelated dimensions: their capacity to generate competitive advantage, their ability to sustain such competitive advantage over time and their effectiveness in enabling the appropriation of the value created (Grant, 1991).

The first dimension advances that a resource gets strategic significance when it exhibits two fundamental characteristics: relevance to the market's critical success factors and scarcity. From a territorial development

perspective, a territorial resource becomes strategic insofar as it concretely contributes to the achievement of the firm's objectives. Accordingly, not all territorial resources can be considered, per se, as sources of competitive advantage, only those resources that are closely aligned with the firm's business model and strategic trajectory assume strategic relevance. This is the case, for instance, with a local pool of highly skilled labour, place-based know-how developed within a specific production tradition, close access to specialised suppliers and service providers, supportive local institutions, dense networks of trust and collaboration and a territorial reputation that enhances the firm's legitimacy and market positioning (Darroch, 2005; Allais et al., 2015; Moine, 2006; Torre, 2025).

Alongside strategic relevance, scarcity assumes a distinctive meaning. It should be interpreted primarily in terms of differential accessibility. Territorial resources are inherently location-specific and unequally distributed across space; however, their scarcity also derives from the fact that, although potentially accessible by multiple actors, access is not equally guaranteed to all firms operating within the same context. The ability to effectively leverage such resources depends on the firm's degree of local embeddedness, its legitimacy and its capacity to integrate into local networks of cooperation (Tura and Harmaakorpi, 2005).

The second dimension of the framework concerns the sustainability of competitive advantage over time. Such sustainability depends on three key properties: durability, transferability and replicability.

The durability of territorial resources comes from their origin in long-term historical, cultural and institutional processes. Social capital, territorial reputation, productive traditions, the quality of relationships between firms and institutions and the accumulation of knowledge are all elements that develop gradually and, for this reason, tend to exhibit strong persistence over time (Portes 2000, Allais et al., 2015; Moine, 2006). This implies that competitive advantages grounded in such resources can present greater resilience compared to those based on market-acquired assets.

The limited transferability of territorial resources further reinforces this advantage. Their strategic relevance lies, in part, in their location-specific nature, which makes them difficult to relocate or transfer without a significant loss of value. In the case of territorial resources, this constraint is even more pronounced as they depend on a contextual configuration that cannot be easily reproduced elsewhere. While firms can be able to relocate certain tangible assets, they cannot transfer with the same effectiveness the complex set of relationships and coordination mechanisms that underpin the strategic value of a given territorial context.

This is completed by the limited replicability of territorial resources. Even when competitors are able to observe the factors that make a territory advantageous, reproducing the same configuration in a different context remains highly challenging. Territorial resources do not derive from a single component; instead, they emerge from an intricate combination of material and immaterial, relational and institutional, formal and informal elements. Such complexity makes imitation difficult, as what ultimately matters is not the presence of individual assets, but the way in which they are combined and mutually reinforced over time. Consequently, competitive advantage lies in the firm's ability to operate within a complex territorial configuration whose replication by competitors faces substantial barriers.

The third dimension concerns the appropriation of the value generated. The availability of a resources does not automatically imply the ability to capture the returns that it produces. This issue becomes even more critical in the case of territorial resources, which are typically not directly owned by the firm. Elements such as the skills diffused within a community, reputation, relationships with local institutions, availability of shared knowledge and social capital of a territory constitute resources to which firms can gain access, but which they rarely full control.

Therefore, the strategic challenge lies in accessing these resources and transforming such access into economic, competitive and reputational advantages and, more broadly, into value (Gereffi et al., 2005; Darroch, 2005). The appropriation of territorial value depends, first, on the presence of appropriability mechanisms, specifically in formal and informal arrangements capable of strengthening the link between the value generated within the territory and the firm's performance. These mechanisms can take the form of contractual agreements, partnerships, specific investments or territorial branding initiatives.

Second, the firm's relative bargaining power within the territorial system plays a crucial role (Porter, 1979). Firms operating within the same territory do not possess equal capacity to take the benefits arising from territorial resource. This capacity tends to increase when a firm occupies central positions within local networks, controls critical nodes of the value chain, possesses distinctive capabilities complementary to territorial resources or enjoys a high degree of legitimacy among key stakeholders. Finally, the degree of territorial embeddedness is a key determinant.

The more deeply a firm is embedded in local economic, social and institutional networks, the greater its access to resources and its capacity to transform that access into relationships, reputation and economically

returns. From this perspective, embeddedness operates both upstream, as a condition enabling access to territorial resources and downstream, as a factor influencing the firm's capacity to capture the value generated.

The conceptual framework is presented in Figure 1.

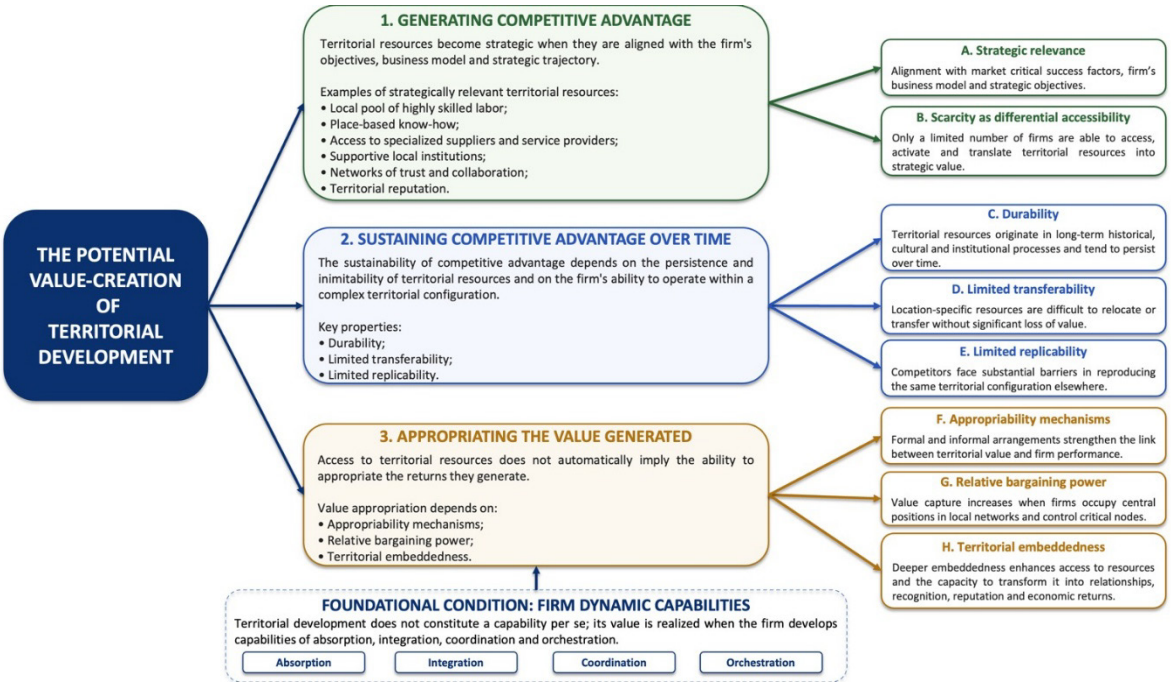

Figure 1: The potential value-creation of territorial development: a resource-based framework

4 Discussion

From the elaboration of the conceptual framework, several findings emerge regarding the role of territorial development in firm's growth strategy.

Primarily, the analysis shows that territorial development cannot be interpreted as an external condition that is generally favourable to the firm, nor as a capability per se; it should be seen as a set of potentially strategic territorial resources, whose value is neither intrinsic nor automatic, but depends on the firm's ability to recognize their relevance, assess their potential and integrate them with its own resource and dynamic capabilities. In this regard, the primary finding of this study is to shift the focus from the territory as a contextual backdrop to the territory as a source of resources that can be strategically exploited.

With regard to the nature of the relationship between the firm and its territorial context, the framework highlights that competitive advantage does not arise from the availability of local resources - since these are, in principle, accessible to all firms operating within the same area - but from the firm's ability, first, to effectively access such resources and, subsequently, to transform them into strategic resources.

This step is particularly relevant, as it enables a clearer distinction between local endowments and strategic value. The presence within a given context of human capital, knowledge, infrastructure, supporting institutions and networks of cooperation does not automatically translate into competitive advantage. The framework emphasizes that such resources become strategically relevant only when they are aligned with the firm's objectives, its business model and its strategic trajectory. Therefore, the strategic value of a territory is often selective: it depends on what the territory "possesses," and on the degree of alignment between the territory's characteristics and the firm's competitive capabilities. The concept of scarcity is closely linked with this perspective. The framework demonstrates that, in this context, scarcity should be understood primarily as differential accessibility. Territorial resources are inherently location-specific and unevenly distributed; however, their strategic relevance also derives from the fact that, even when they are embedded within the same geographical context, not all firms are equally able to access, activate and transform them into value. Territorial scarcity, therefore, depends on the firm's degree of embeddedness, its legitimacy and its capacity to integrate into local networks of cooperation. This represents a theoretically significant insight, as it enables a shift beyond a strictly proprietary interpretation of the RBV, highlighting that, in the case of territorial resources, competitive advantage is grounded in mechanisms of access and activation. In this perspective, scarcity coincides with the fact that only a limited number of firms are able to effectively exploit the territorial resources.

With regard to the sustainability of competitive advantage over time, the requirements of durability, transferability and replicability highlight that territorial resources can serve as a particularly robust foundation for sustainable advantage. Their durability derives from their embedding in long-term historical, cultural and institutional processes, while their limited transferability and replicability stem from their inherently territorial nature, which renders them difficult to relocate and challenging to reproduce. Therefore, the competitive advantage grounded in territorial resources can exhibit greater resilience than advantages based on assets that can be acquired on the market. From this perspective, the most significant insight is that the sustainability of such advantage resides in the overall territorial configuration and in the firm's ability to effectively operate within it.

Another key finding concerns value capture. The framework shows that, in the case of territorial resources, the strategic challenge extends beyond access to resources to the firm's ability to capture the returns generated by their use. This is a crucial point, since many territorial resources are not directly owned by the firm. Value capture depends on the presence of appropriability mechanisms, the firm's relative bargaining power within the territorial system and its degree of embeddedness in local networks. Consequently, embeddedness operates as a key factor shaping the firm's ability to transform such access into stable relationships, recognition, reputation and economic returns. From this perspective, the territory tends to reward firms that occupy central positions within networks, control critical nodes of the value chain, possess complementary capabilities and enjoy higher levels of legitimacy among key stakeholders.

These findings lead to understand that the contribution of territorial development to firm growth derive from the firm's ability to develop a set of dynamic capabilities oriented toward the absorption, integration, coordination and orchestration of territorial resources.

5 Conclusions

This study investigates the role that territorial development can assume for firms' growth strategies. Starting from the limited attention in the literature to territorial development from a RBV perspective, the paper developed a conceptual framework to clarify under which conditions territorial resources can acquire strategic relevance and contribute to the generation of sustainable competitive advantage and to the firm growth.

The findings make it possible to answer the research question by showing that territorial development acquires strategic relevance only under specific conditions. More precisely, territorial resources become a potential source of firm growth when they are consistent with the firm's objectives, business model and strategic trajectory and when the firm is able to appropriate the value generated. In this perspective, the framework clarifies that the contribution of territorial development to firm growth derive from firm's ability to recognize their strategic relevance, to access and activate them selectively and to integrate them with its internal resources and dynamic capabilities. From this perspective, territorial development emerges as a source of value and competitive advantage, whose impact on growth derives primarily from the firm's capacity for absorption, integration, coordination and orchestration.

The paper provides contributions to theory and practice.

From a theoretical perspective, the results contribute to the strategic management literature streams, by showing that territorial resources, although external to the firm in a strict ownership sense, can be incorporated into the firm growth strategy when they are strategically activated and combined with internal capabilities. In addition, it contributes to the debate on the relationship between firms and territory by clarifying that competitive advantage is not primarily grounded in the ownership of territorial resources, but in the firm's ability to access and exploit them selectively through embeddedness, legitimacy and network positioning.

Although the paper is mainly theoretical, it also offers some practical implications. The advanced framework can support entrepreneurs, managers and policy-makers in interpreting territorial development as a potential strategic driver. More specifically, the framework suggests that firms should identify which territorial resources are most consistent with their strategic trajectory, assess the conditions under which such resources can generate competitive advantage and strengthen the capabilities required to absorb, integrate, coordinate and orchestrate them. Moreover, it provides an initial analytical tool for interpreting territorial development within strategic decision-making processes.

Thus, the study presents some limitations that should be acknowledged. The paper does not include an empirical validation of the proposed framework. As a consequence, the identified relationships between territorial resources, dynamic capabilities and firm growth remain at a theoretical level and require further testing in real firm contexts.

The paper opens future research opportunities. The advanced framework should be empirically tested through further investigations aimed at verifying how firms actually recognize and exploit territorial resources

within their growth strategies. In addition, future studies would apply the framework to concrete territorial contexts in order to explore how place-based resources, institutional settings and local networks interact in shaping competitive advantage. In this regard, within a regional based research project founded by "Regione Campania" two Italian promising empirical settings concern the "Agro Nocerino-Sarnese" and the "Valle dell'Ufita", both of which represent local value chains where territorial development can be observed as a strategic resource in relation to distinctive productive, institutional, and socio-economic dynamics.

Measuring the Unmeasurable? A Systematic Literature Review of University Technology Transfer Efficiency

Miklós Verseghi-Nagy, András Nemeslaki
Budapest University of Technology and Economics, Budapest, Hungary

Abstract

Innovation has become central to achieving high-value growth, particularly in economies seeking to escape the middle-income trap where competitiveness still rests on low wages and process cost-cutting. In triple helix innovation ecosystems, technology transfer is seen as a crucial link enabling public–private value co-creation. Yet the efficiency of these processes remains poorly understood. University technology transfer efficiency (UTTE) — the relationship between inputs devoted to transferring research into commercial applications and resulting outputs — poses significant conceptual and measurement challenges. Inputs are ambiguous and multidimensional (research expenditure, technology transfer office resources, organizational capabilities); outputs are heterogeneous (patents, licenses, spin-offs, licensing income, broader impacts); and no consensus exists on which efficiency concept should formally link them. Despite a substantial body of empirical literature, UTTE measurement remains fragmented across incompatible units, anchored to transactional proxies, and disconnected from the economic outcomes that justify the investment. What is being measured is not what matters; what matters is not being measured.

This paper investigates whether the existing literature offers an adequate conceptual and empirical basis for measuring UTTE — and if not, what is missing. Our systematic review examines 71 peer-reviewed studies published between 2006 and 2026, analyzing: (a) how inputs and outputs are defined and operationalized; (b) which methodological frameworks relate inputs to outputs; (c) how studies address data limitations and cross-institutional comparability; and (d) to what extent emerging metric frameworks from professional associations (e.g., ASTP) are reflected in recent empirical work.

We find that DEA-type non-parametric frontiers dominate methodologically, with stochastic frontier analysis providing a parametric alternative; that data limitations severely constrain cross-institutional and cross-country comparability; and that emerging professional frameworks have only partially penetrated empirical practice. Taken together, these findings reveal a field built around what is measurable and institutionally available rather than what is theoretically adequate — and point toward a reoriented research agenda that moves upward in aggregation level, from institutions to ecosystems; forward in the value chain, from transfer outputs to enterprise outcomes; and deeper in explanatory mechanism, from quantitative proxies to qualitative process understanding.

Keywords: Social Impact Measurement, University Technology Transfer Efficiency

Paper type: Academic Research Paper

1 Research methodology: protocol and reporting

The review includes peer-reviewed journal articles published between 2006 and 2026 that: conceptualize UTTE as an explicit input-output transformation (e.g., via DEA, frontier models, or maturity frameworks); use universities, groups of universities, or TTOs as the unit of analysis; explicitly identify both input variables (e.g., R&D expenditure, staff, TTO resources) and output variables (e.g., patents, licenses, spin-offs, licensing income); and apply a quantitative efficiency framework or clearly specified perceptual constructs of TTO performance. Studies were excluded if they described technology transfer outcomes without an explicit efficiency framework, or focused solely on determinants of performance without measuring the input-output relationship itself.

Web of Science Core Collection and Scopus were searched using two concept dimensions combined in titles, abstracts, and keywords: university technology transfer ("university technology transfer" OR "technology transfer office") and efficiency ("efficiency" OR "productivity" OR "performance"). Only English-language peer-reviewed articles were included. Initial searches yielded 253 unique records; after title/abstract screening and independent crosschecking against eligibility criteria, 71 articles were retained. Data extraction followed PRISMA 2020 requirements, covering UTTE definitions, input–output configurations, and methodological approaches.

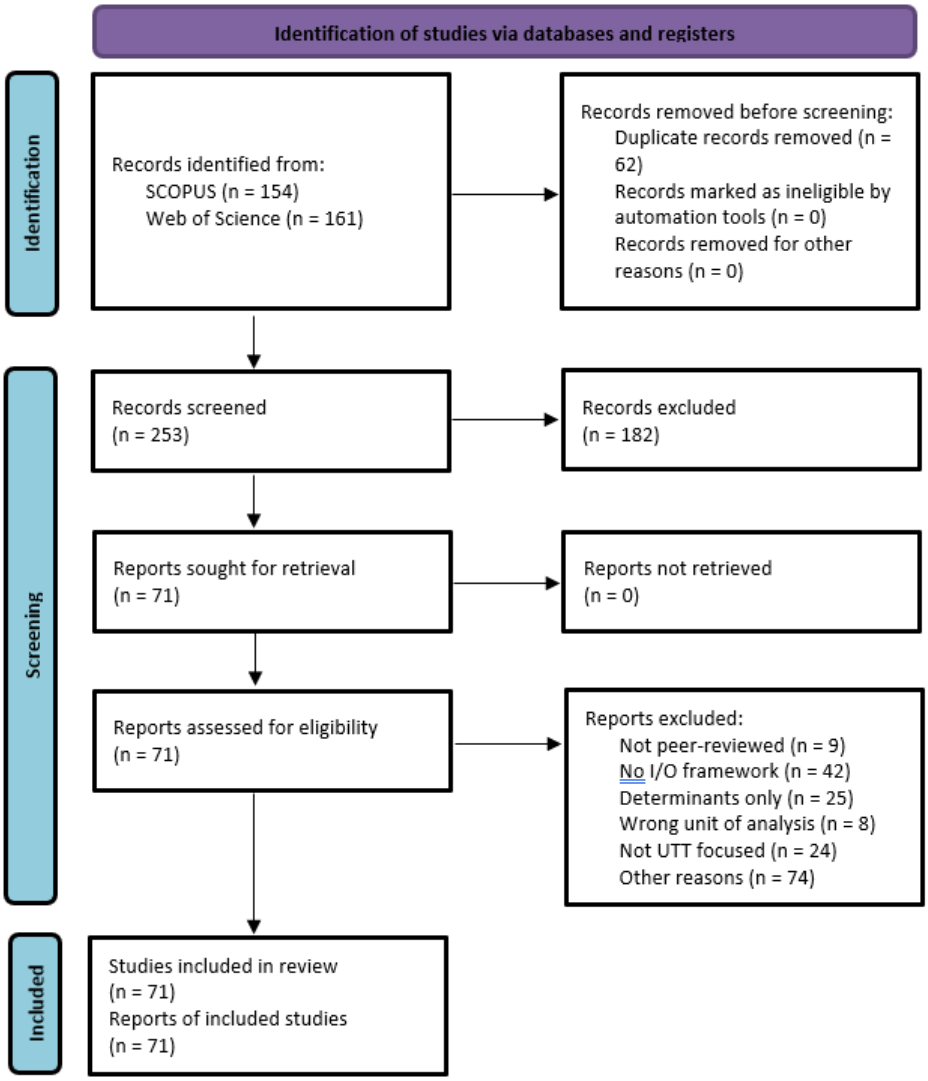

Figure 1: Identification of studies via databases and registers

2 Results

Methodologically, the field's foundations rest on early stochastic frontier and non-parametric analyses of TTO efficiency (Siegel, Waldman and Link, 2003; Chapple et al., 2005), the latter offering one of the first systematic parametric–non-parametric comparisons for UK universities. Within the review period, Anderson et al. (2007) refined DEA by introducing weight restrictions for benchmarking US institutions, Curi et al. (2012) applied DEA-based efficiency analysis to French universities, Bradley et al. (2013) synthesised university technology transfer models and empirical methods, and Lafuente and Berbegal-Mirabent (2019) incorporated portfolio complexity into TTO productivity analysis.

Across the 71 reviewed studies, four structural patterns emerge — in how inputs and outputs are modelled, in the methodological frameworks applied, in how data limitations are managed, and in the geographical scope of the evidence base.

3 Discussion

The UTTE literature has not yet produced a coherent basis for measuring university technology transfer efficiency. Four structural dimensions point toward a common problem: UTTE research has been built around what is measurable and institutionally available rather than what is theoretically adequate. Patents, licenses, and spin-off counts are tractable; the economic value they generate is not. DEA frontiers are rigorous; the efficiency scores they produce are local and context-specific. The sections that follow discuss each of these features in turn — not only to establish what is missing, but why it is missing. The common thread is a

transactional paradigm: the literature models technology transfer as a unilateral production process rather than the reciprocal, translational interaction that Triple Helix theory describes.

3.1 How inputs and outputs are currently modeled

The reviewed studies converge on three input and four output dimensions.

Common input dimensions

- Research capacity: R&D expenditure, R&D personnel, research intensity (Hülsbeck et al., 2013; Xia et al., 2020; Barra and Zotti, 2018).
- TTO resources/capabilities: staff numbers, experience, seniority, organizational structure, embeddedness, IP management capabilities (Caldera and Debande, 2010; Cartaxo and Godinho, 2017; Prónay et al., 2022; Secundo et al., 2017; Hülsbeck et al., 2013; Conti and Gaulé, 2011; Feng et al., 2012; Heisey and Adelman, 2011; Fernández-Alles et al., 2025; Iacobucci et al., 2021; Modic and Suklan, 2022; Sallan and Lordan, 2025).
- Intellectual capital: human, structural and relational capital of universities and TTOs (Secundo et al., 2017; Feng et al., 2012; Kreiling and Bounfour, 2020).

Common output dimensions

- IP & deals: invention disclosures, patent applications/grants, licenses, options, license income (Caldera and Debande, 2010; Lafuente and Berbegal-Mirabent, 2019; Hülsbeck et al., 2013; Vinig and Lips, 2015; Curi et al., 2012; Heisey and Adelman, 2011; Anderson et al., 2007; Tseng and Raudensky, 2014a; Tseng and Raudensky, 2014b; Showalter and Jensen, 2019).
- New firms: spin-offs/startups with/without university equity (Fadeyi et al., 2019; Lafuente and Berbegal-Mirabent, 2019; Kim, 2013; Vinig and Lips, 2015; Djokovic and Souitaris, 2008; Iacobucci et al., 2021; Lee and Jung, 2024; Lynskey, 2008).
- Broader commercialization: contract research, collaborative projects, consulting, science park benefits, job creation (Caldera and Debande, 2010; Fadeyi et al., 2019; Kim, 2013; Wang and Zhao, 2022; Kurman, 2011; Weis et al., 2018; Villasalero, 2014; Bigliardi et al., 2015; Li and Tan, 2020; Pujotomo et al., 2025).
- Perceptual/intangible performance: academics' willingness to cooperate, industry engagement, perceived TTO effectiveness (Prónay et al., 2022; Secundo et al., 2017; Secundo et al., 2019; Stankevičienė et al., 2017).

Three structural problems follow from this configuration. First, relying on patents and licenses as primary outputs risks introducing a disciplinary bias: science and engineering universities may appear more efficient partly because their outputs are more patent-intensive, not necessarily because they transfer more knowledge overall (Caldera and Debande, 2010; Curi et al., 2012). Second, organizational capabilities — embeddedness, networking depth, TTO maturity — shape observed efficiency yet are rarely measured directly, meaning that institutions pursuing non-IP channels are penalized by metrics that cannot capture those choices (Cartaxo and Godinho, 2017; Prónay et al., 2022; Secundo et al., 2017). Third, highly skewed distributions mean that DEA best-practice frontiers are often defined by a few structurally exceptional institutions, against which the majority are benchmarked (Kim, 2013; Kurman, 2011; Weis et al., 2018). Together, these problems suggest the input-output framework generates precise but potentially misleading efficiency assessments for much of the university population.

3.2 Main methodological frameworks linking inputs, outputs and efficiency

Across UTTE studies, non-parametric frontier methods dominate, complemented by parametric frontiers, index and multicriteria approaches. The choice of framework shapes what "efficiency" means in practice: frontier models yield relative rankings against a best-practice envelope, while index and structural approaches offer more diagnostic insight into specific performance drivers.

Frontier efficiency / productivity models

DEA dominates, modelling TTOs and universities as multi-input–multi-output production units from which relative efficiency scores are derived (Anderson et al., 2007; Kim, 2013; Wang and Zhao, 2022; Curi et al., 2012; Curi et al., 2015; Ma et al., 2022; Huang et al., 2011; Chen, K. et al., 2024a; Chen, X. et al., 2024b; See et al., 2023; Liu et al., 2026; Zarea et al., 2025; Lee et al., 2023). Variants — CCR/BCC, Slack-Based Measure, and Malmquist indices — extend the model to handle returns to scale, slack analysis, and productivity change over time. SFA offers a parametric alternative separating inefficiency from statistical noise, though far less used (Juárez and Montoro-Sánchez, 2019; Coupet and Ba, 2022; Siegel et al., 2008; Lee and Jung, 2021; Barra and Zotti, 2018).

The dominance of DEA is consequential: it yields relative rankings within a sample, not an absolute benchmark — leaving cross-system comparison structurally constrained.

Index and meta-data approaches

Index-based "health" measures: h-index–like commercialization, job-creation, and licensing-speed indices capturing skewed outcome distributions and time dynamics rather than simple counts (Kurman, 2011). Meta-data potential vs. realized transfer: uses research output to estimate a university's potential for transfer, then relates this to actual patents, licenses and spin-offs to derive a performance ratio (Vinig and Lips, 2015).

Multicriteria decision & structural models

Multicriteria decision methods (FARE + TOPSIS): build weighted composite performance scores from multiple TT indicators (e.g., patents, contracts, spin-offs) and rank universities (Stankevičienė et al., 2017; Belgin et al., 2025; Ustundag et al., 2011). Structural Equation Modeling / PLS-SEM: relate TTO resources and activities to multiple performance outputs via latent constructs rather than an efficiency frontier (Cartaxo and Godinho, 2017; Hwang et al., 2023).

The following table summarizes the main quantitative approaches, and the studies in which they occur.

Table 1: Main quantitative approaches to UTTE assessment

Approach	What it measures	Example use	Citations
DEA / SBM / Malmquist / SFA	Non-parametric and parametric efficiency frontiers	Nigeria, France, US, UK, China, TTO benchmarking	Fadeyi et al., 2019; Lafuente and Berbegal-Mirabent, 2019; Kim, 2013; Sutopo et al., 2019; Sutopo et al., 2022; Wang and Zhao, 2022; Curi et al., 2012; Siegel et al., 2008
Index-based (h-index analogues)	"Health" of commercialization, job creation, speed	US institutions	Kurman, 2011; Weis et al., 2018
Meta-data potential vs. realized transfer	Normalizes outputs by research-output-based potential	Dutch universities	Vinig and Lips, 2015
Maturity / capability models	TTO process maturity and capability as efficiency drivers	European TTOs	Kreiling and Bounfour, 2020; Scanlan, 2018
Configurational / fsQCA	Causal configurations for high transfer performance	China	Wang, 2025; Huang et al., 2025; Yang and Chen, 2025

3.3 Data limitations and cross-institution comparability

Across UTTE research, data are often incomplete, non-standardized, and context-specific, and most studies only partially address these constraints. The tension between internal validity (restricting to comparable units) and external validity (generalizing across systems) runs through virtually all empirical UTTE work.

Three coping strategies recur: harmonizing indicators via shared survey templates (AUTM or national equivalents) to stabilize definitions within a country (Kim, 2013; Weis et al., 2018); restricting samples to single countries or homogeneous institutional types to limit cross-country definitional differences (Curi et al., 2012; Lafuente and Berbegal-Mirabent, 2019); and augmenting sparse data through direct institutional contact (Vinig and Lips, 2015). These are pragmatic workarounds, not solutions: they preserve internal validity at the cost of generalizability, leaving cross-system comparison structurally out of reach.

Table 2: Common comparability problems and how addressed

Issue	Typical treatment	Citations
Incomplete / inconsistent reporting	Explicitly noted; missing years, partial disclosure, student spin-offs often excluded	Vinig and Lips, 2015; Stankevičienė et al., 2017
Cross-country heterogeneity	Frequently acknowledged; most empirical work remains single-country; few true multi-country datasets	Prónay et al., 2022; Secundo et al., 2017; Fadeyi et al., 2019; Juárez and Montoro-Sánchez, 2019
Non-comparable institutional contexts	Recognized as confounding efficiency scores (field mix, TTO age/mandate, national IP regimes)	Prónay et al., 2022; Lafuente and Berbegal-Mirabent, 2019; Curi et al., 2012; Cartaxo and Godinho, 2017

3.4 Alignment with emerging professional frameworks

ASTP and similar associations have developed harmonized metric frameworks (Barjak et al., 2025), but empirical practice has adopted them only partially, continuing to rely on patent- and license-based indicators.

Some convergence is visible: multi-stage pipelines echo ASTP's value-chain logic (Weis et al., 2018; Lafuente and Berbegal-Mirabent, 2019), and recent European and Japanese TTO work explicitly incorporates intangible dimensions — embeddedness, marketing capabilities — aligning with ASTP's push for holistic assessment (Prónay et al., 2022). What remains absent is direct adoption of ASTP's framework: most studies rely on AUTM definitions or ad-hoc indicator sets (Bradley et al., 2013; de Falani and Torkomian, 2024; Gulbrandsen and Rasmussen, 2012; Sorensen and Chambers, 2008), societal outcomes remain weakly represented, and cross-country harmonization in line with ASTP/EU guidelines is only partially realized (Prónay et al., 2022; Weis et al., 2018).

3.5 Geographical coverage of UTTE studies

The literature is dominated by single-country analyses benchmarked against the United States. National systems studied include Spain (Caldera and Debande, 2010; Lafuente and Berbegal-Mirabent, 2019), Italy (Ramaciotti and Rizzo, 2015), Taiwan (Hsu et al., 2015; Zhang and Zeng, 2025), Indonesia (Sutopo et al., 2019), China (Wang and Zhao, 2022; Li and Fu, 2021), the US (Kim et al., 2008; Anderson et al., 2007; Showalter and Jensen, 2019), South Korea (Lee and Jung, 2021; Hwang et al., 2023), Japan (Modic and Suklan, 2022), Brazil (Leite et al., 2023), Australia (Nugent and Chan, 2023), Canada (Moroz et al., 2008), Turkey (Ustundag et al., 2011; Belgin et al., 2025), South Africa (Gumbi, 2010), and Norway (Gulbrandsen and Rasmussen, 2012), many narrowed to small institutional samples. The one multi-continent exception — a Europe–Japan survey of 18 countries — explicitly notes that single-country work and US-centric benchmarking dominate the field (Prónay et al., 2022; Lee and Jung, 2024; de Falani and Torkomian, 2024). Efficiency benchmarks calibrated to Bayh-Dole-era US institutions are weakly comparable when applied to European contexts.

4 Conclusion

This systematic review of 71 studies reveals a field constrained by four structural limitations: single-country scope that precludes cross-system comparison; supply-side framing that ignores downstream economic value; continued reliance on patent and licensing proxies despite calls for broader impact metrics; and weak measurement of the organizational mechanisms — capabilities, embeddedness, trust — that shape transfer outcomes.

These findings carry a theoretical implication. The dominant paradigm models technology transfer as a unilateral production process, yet Triple Helix theory frames it as reciprocal interaction between university, industry, and government. What the literature measures as efficiency is better understood as a transactional proxy for a translational process oriented toward co-creating value across organizational boundaries. The gap between available metrics and theoretically relevant outcomes suggests the field requires a reconceptualization of what UTTE means in a demand-side perspective.

These findings carry practical implications. TTO managers should recognize that current benchmarking tools may systematically undervalue offices pursuing non-IP channels such as contract research or collaborative development. Policymakers designing performance frameworks — particularly in EU widening countries — should adopt ASTP-type harmonized metrics rather than importing US-centric indicators. University administrators should look beyond patent counts toward broader commercialization outcomes and relational capabilities. We propose three research directions: shifting the unit of analysis to the national innovation ecosystem using European Innovation Scoreboard data to relate input configurations to outcome measures across EU member states; examining innovation-driven enterprises as downstream recipients of transferred knowledge; and qualitative inquiry into the micro-level mechanisms that macro-level analysis cannot capture.

5 Ethics Declaration

This study is based on a systematic review of published peer-reviewed literature and does not involve human subjects, personal data, or primary data collection. No ethical clearance was required.

6 AI Declaration

Two AI tools were used in developing this paper. Consensus AI was used to support the analysis of the reviewed literature and to identify patterns across studies. Claude AI (Anthropic) was used to assist in constructing the analytical framework and methodology, and for text revisions including language editing, reference formatting, and structural refinement. In all cases, the authors retained full responsibility for the intellectual content, interpretation of findings, and argumentation.

A Hybrid RAG Architecture for Knowledge Management in Urban Digital Twins

Giovanni Felle, Antonio Arcadi, Davide Storelli, Valentina Chetta, Rosaria Lovecchio, Elisa De Bellis
Engineering Ingegneria Informatica S.p.A., Italy

Abstract

Urban Digital Twins (UDTs) have emerged as strategic instruments for urban planning and governance, generating unprecedented volumes of heterogeneous knowledge assets — policy documents, municipal acts, citizen reports, and sensor data streams — that overwhelm traditional Knowledge Management (KM) frameworks. Conventional AI-driven systems struggle to deliver accurate, traceable responses on complex, multi-domain queries, exhibiting persistent hallucination and insufficient contextual grounding: benchmarking studies reveal that advanced LLMs achieve only 34% accuracy on complex queries, standard Retrieval-Augmented Generation (RAG) improves this to merely 44%, and state-of-the-art solutions answer only 63% of questions without hallucination. These limitations are particularly critical in regulated public governance contexts where transparency, provenance, and temporal consistency are fundamental requirements. This paper presents a Hybrid Retrieval-Augmented Generation (H-RAG) architecture for knowledge management in UDT environments, integrating vector-based semantic retrieval with Knowledge Graph-grounded reasoning. Following a Design Science Research (DSR) methodology, we describe the end-to-end architecture of a Knowledge Management System (KMS) comprising six interconnected modules: heterogeneous document ingestion, parsing and normalisation, transformer-based embedding generation, incremental Knowledge Graph construction, hybrid multimodal indexing, and context-fused retrieval and generation. A Knowledge Intake Guard (KIG) ensures semantic consistency and deduplication prior to graph ingestion, preventing knowledge base fragmentation as the document corpus evolves. The KMS adopts a microservices-oriented pattern with asynchronous processing (message broker and task queue) and multimodal storage (object store, vector database, graph database, and search engine), enabling scalable ingestion of structured and unstructured municipal document corpora. Unlike batch-oriented graph approaches, the proposed system supports incremental knowledge enrichment without requiring periodic full reconstruction of the knowledge base. An illustrative case study based on a municipal traffic ordinance demonstrates how the architecture supports cross-silo knowledge integration, serving both citizens submitting natural-language queries and technical operators requiring entity-centric relational retrieval. Benchmarking evidence from the literature confirms substantial accuracy improvements in Knowledge Graph-augmented retrieval settings, with a corresponding significant reduction in hallucinations. The proposed KMS is developed within the AVANT IPCEI-CIS project and contributes: (i) a conceptual framework for hybrid knowledge retrieval in dynamic urban environments; (ii) a replicable DSR-grounded design approach applicable to public administration KM; and (iii) architectural guidelines and design principles for integrating governance-oriented KM capabilities into multi-silo UDT contexts.

Keywords: Hybrid RAG (H-RAG), Urban Digital Twins, Knowledge Graph (KG), Urban Knowledge Management, Evidence-Based Governance.

Paper type: Practical Paper

1 Introduction

Urban Digital Twins (UDTs) have emerged as strategic instruments for urban planning and governance, generating unprecedented volumes of heterogeneous knowledge artifacts including policy documents, citizen science data, analytical reports, and real-time sensor datasets (Deren, Wenbo and Zhenfeng, 2021). Managing this dynamic and multi-domain knowledge ecosystem poses significant challenges for traditional KM frameworks, which often struggle to maintain pace with the rapid evolution and sheer volume of unstructured data distributed across administrative silos.

RAG has become a standard architectural pattern for incorporating domain-specific knowledge into AI-powered applications (Gao et al., 2023). However, benchmarking studies reveal significant limitations: advanced LLMs achieve only 34% accuracy on complex queries, while standard RAG improves this to merely 44%, and state-of-the-art solutions answer only 63% of questions without hallucination (Yang et al., 2024). Moreover, recent comparative evaluations of RAG versus GraphRAG confirm that graph-augmented approaches provide qualitatively distinct capabilities for entity-centric and relational queries (Han et al., 2025). These limitations hinder the adoption of AI-driven KM systems in regulated urban governance contexts where transparency, provenance, and temporal consistency are fundamental requirements. In particular, the digitisation of municipal administrative acts — decrees, resolutions, ordinances — presents significant challenges for searchability and

interoperability that standard retrieval paradigms cannot fully address, as these documents create intricate webs of regulatory dependencies and cross-references that demand structured relational reasoning.

While existing literature has explored RAG and GraphRAG separately, few studies have addressed their systematic integration for urban knowledge bases. This paper addresses these limitations by proposing a Hybrid RAG (H-RAG) architecture for UDT environments, developed within the AVANT IPCEI-CIS project. The system targets three primary user profiles: public administrators, citizens, and technical operators requiring decision support grounded in verified, traceable urban knowledge.

The following research question guides this work: To what extent can a hybrid architecture integrating semantic, lexical, and graph-based retrieval address the knowledge fragmentation challenge across administrative silos in Urban Digital Twin environments?

2 Related Work

2.1 Knowledge Management and AI-Augmented Systems

Knowledge Management (KM) is broadly defined as the deliberate, integrated process of identifying, capturing, and leveraging collective organisational knowledge to support effective action and decision-making. KM efforts revolve around four interdependent processes — creation, storage and retrieval, sharing, and application — forming the KM lifecycle (Alavi and Leidner, 2001). The adoption of AI-based approaches has significantly expanded the capacity of KM systems to handle unstructured data and complex retrieval tasks (Jarrahi et al., 2023). In the UDT context, KM challenges are compounded by the multi-domain, temporally layered nature of urban knowledge spanning multiple administrative silos.

2.2 From Information Retrieval to Hybrid Retrieval

The evolution of information retrieval traces from the Vector Space Model and probabilistic BM25 ranking (Robertson and Walker, 1994), through Latent Semantic Indexing (Deerwester et al., 1990), to dense neural retrieval powered by transformer-based embeddings (Devlin et al., 2019; Reimers and Gurevych, 2019; Karpukhin et al., 2020). Hybrid retrieval approaches combining dense vector search with sparse keyword search have demonstrated superior performance over single-paradigm retrieval on heterogeneous document collections (Kiran, 2025), motivating their adoption in the proposed architecture.

2.3 Retrieval-Augmented Generation and Knowledge Graph Augmentation

RAG architectures were introduced to mitigate LLM limitations — hallucination and static knowledge cutoffs — by conditioning generation on dynamically retrieved document passages (Lewis et al., 2020). Recent surveys synthesise the rapidly expanding RAG landscape and its variants (Gao et al., 2023; Fan et al., 2024). Recent research has extended RAG toward semantic compression (Raja and Vats, 2025) and multimodal retrieval for industrial applications (Riedler and Langer, 2024).

Knowledge Graphs (KGs) provide structured, explicit representations of entities and semantic relationships, enabling deterministic graph traversal for multi-hop queries. The integration of KGs with LLM-based retrieval reduces hallucination rates and improves accuracy on complex enterprise knowledge tasks: Agrawal et al. (2024) confirm that KG grounding substantially reduces hallucinations in LLMs, while Sequeda, Allemang and Jacob (2023) report an accuracy increase from 16.7% to 54.2% when KG grounding is combined with LLM-based retrieval. Sarmah et al. (2024) propose HybridRAG as a practical integration pattern combining KG and vector retrieval, and Edge et al. (2024) extend this paradigm to graph-based query-focused summarisation. Neural-symbolic hybrid approaches further combine the interpretability of symbolic graph reasoning with the robustness of neural embeddings (Futia and Vetrò, 2020; Zhang et al., 2021). To the authors' knowledge, no prior work has specifically addressed the design of an H-RAG architecture tailored to the multi-silo UDT environment and the governance requirements of public administration KM.

3 Methodology

This research follows the Design Science Research (DSR) methodology as formalised by Hevner et al. (2004) and Peffers et al. (2007). DSR is particularly suited to the development and evaluation of innovative IT artifacts in contexts requiring both technical rigour and practical relevance. The methodology proceeds through five iterative phases: problem identification, objectives definition, design and development, demonstration, and evaluation.

Three core design requirements, derived from analysis of the AVANT project's governance and operational context, guide the artifact's design:

- R1: Support for heterogeneous, incrementally ingested document types without requiring periodic full knowledge base reconstruction.
- R2: Transparent, provenance-anchored responses for regulated decision-making, ensuring every generated answer is traceable to specific source documents.
- R3: Cross-silo semantic integration across urban administrative domains, enabling multi-hop reasoning over entities and relationships distributed across multiple document collections.

The system is currently in a prototypical phase deployed in a controlled test environment, with ingestion and end-to-end pipeline validation underway on a corpus of municipal administrative acts.

The demonstration phase, instantiated through the case study presented in Section 5, provides evidence of the architecture's applicability to realistic urban governance scenarios. Full empirical evaluation is planned as part of the AVANT First Industrial Deployment (FID) phase, scheduled for July 2026.

4 Proposed KMS Architecture

4.1 Architecture Overview

The proposed KMS implements a knowledge management infrastructure designed for large-scale municipal document ingestion, semantic processing, and hybrid retrieval in Urban Digital Twin environments. The platform adopts a microservices-oriented pattern with asynchronous processing and a multimodal storage strategy to support scalability and data integrity. At this stage, the implementation prioritises architectural integration and end-to-end data-flow validation over performance optimisation.

The system is organised into six functionally distinct layers, each responsible for a stage of the document lifecycle: ingestion, parsing, vectorisation, indexing, graph construction, and information retrieval.

The three design requirements introduced in Section 3 are addressed as follows: R1 (incremental ingestion without full reconstruction) is realised through the asynchronous pipeline and the Knowledge Intake Guard; R2 (provenance-anchored responses) is enforced through persistent metadata tagging at ingestion and CITES relationships in the Knowledge Graph; R3 (cross-silo semantic integration) is delivered by the hybrid retrieval layer combining vector, lexical, and graph-based search.

Figure 1 illustrates the end-to-end architecture described in the following subsections.

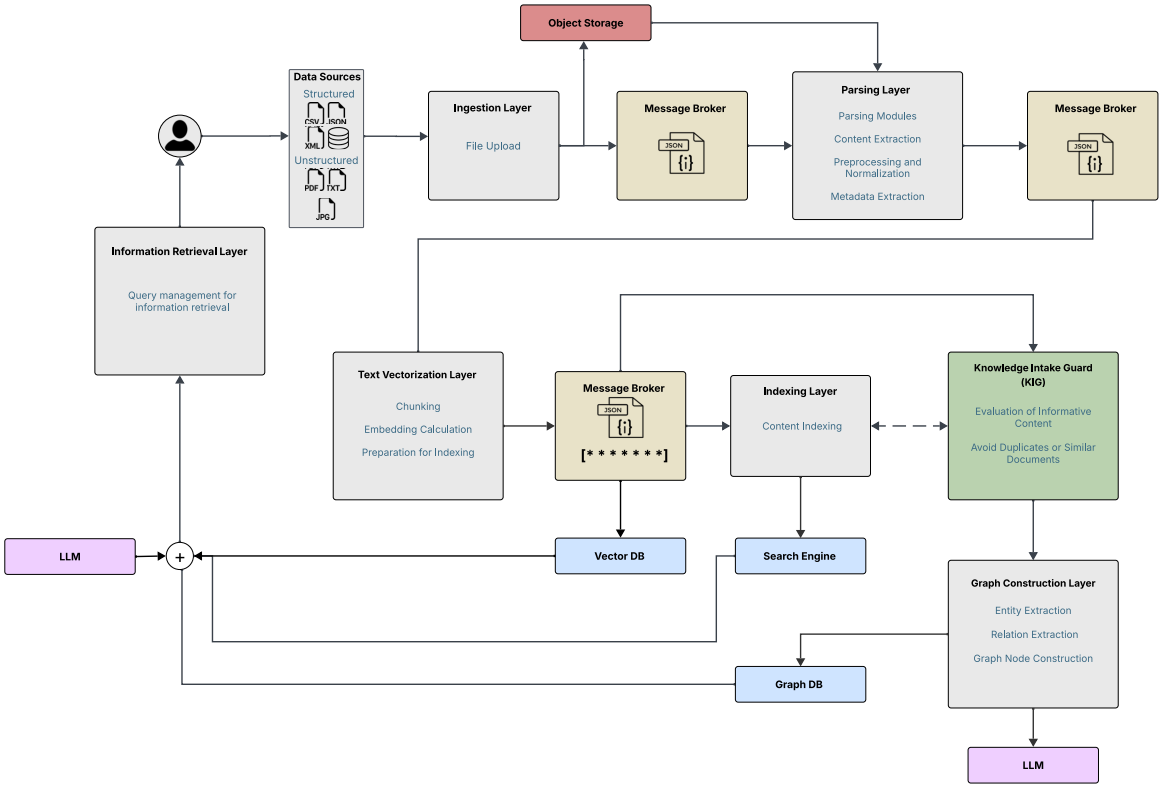

Figure 1: The KMS Architecture

4.2 Technical Description of the KMS Architecture

The workflow originates at the frontend interface, where user sessions and security are managed by a central Identity and Access Management (IAM) layer based on standard authentication and authorisation protocols. This layer enforces role-based access control policies consistently across services.

Data enters through the Ingestion Layer, which exposes a high-throughput API gateway for both structured (CSV, JSON) and unstructured (PDF, TXT) sources. The ingestion service validates schemas, captures core metadata and relationships, and persists raw assets in an S3-compatible object store that acts as the system's source of truth.

To avoid blocking request/response latency, the KMS adopts a producer-consumer pattern: the ingestion service publishes events to a distributed, fault-tolerant message broker, and downstream workers consume and execute pipeline stages asynchronously.

The refined data then moves to the Text Vectorisation Layer, where text is partitioned into optimised chunks before being transformed into high-dimensional vectors.

To handle large documents, the engine implements a sliding window chunking strategy.

The embedding is calculated using a transformer-based model optimised for semantic similarity tasks, producing high-dimensional dense vector representations. This model is specifically designed to capture contextual meaning across heterogeneous textual sources.

Before embedding, chunks undergo light normalisation (whitespace/encoding) to improve consistency for semantic retrieval.

These vectors are indexed in a vector database optimised for ANN search that leverages Hierarchical Navigable Small World (HNSW) graphs to enable efficient approximate nearest neighbour search. The collection is configured with a cosine distance metric consistent with the model's embedding dimensionality, supporting compatibility with semantic similarity computations. Each vector is stored alongside a structured payload containing document metadata (e.g., source, type, creation date), enabling metadata-aware retrieval and post-filtering.

Parallel to the vector indexing, the system populates a Knowledge Graph that extends the retrieval pipeline with structured relational capabilities through a "Text-to-Triple" architecture based on semantic extraction (via an LLM and prompt engineering) and graph-based persistence. Each chunk is processed by an extractor that identifies entities and relations based on a specific Urban Digital Twin ontology.

Extracted triples undergo a strict validation phase. This process cross-references the initial output with the allowed ontology, performing:

The final stage automates the insertion into a graph database.

- *(Document)-[:CITES]->(Entity)*
- *(Entity)-[:RELATED {type: "..."}]->(Entity)*

The presented knowledge graph is an experimental component designed for future GraphRAG capabilities. This process is also governed by the Knowledge Intake Guard, which evaluates information density and utilises deduplication logic to maintain the integrity of the graph. Parallel to vector indexing, the system executes a dedicated Search Engine Layer, where the content is indexed for traditional full-text search and keyword-based retrieval.

To support keyword-based retrieval and structured filtering, the Search Engine relies on a custom index schema designed to align with the document processing pipeline. The index mapping defines both textual and structured fields, enabling hybrid search and metadata-aware querying.

Each document is uniquely identified and enriched with contextual attributes, including source, file path, and ingestion metadata. The full textual content is indexed for traditional inverted-index search, while additional fields support filtering, provenance tracking, and chunk-level granularity.

In particular, the system adopts the following index structure:

- Document Identification: id (keyword) ensures unique document referencing.
- Content Representation: content (text) stores the processed textual chunks, while filename and content_type provide descriptive context.
- Data Provenance and Filtering: Fields such as source, path, and created_at enable traceability and temporal queries.
- Chunk-Level Processing: chunk_id allows fine-grained indexing aligned with the embedding pipeline.
- Metadata Enrichment: metadata (object) stores flexible, schema-less attributes extracted during ingestion.
- Vector Representation: The embedding field is defined as a knn_vector, enabling integration with approximate nearest neighbour (ANN) search algorithms.

- Integrity Control: A hash field is used to detect duplicate content and helps ensure consistency across ingestion cycles.

This schema enables the search engine to operate not only as a full-text engine but also as a complementary component in the hybrid retrieval strategy, supporting filtering, ranking, and alignment with vector-based results.

The final stage of the architecture is the Information Retrieval Layer, which executes a hybrid search strategy. Upon receiving a user query, this layer orchestrates synchronised retrieval across the Search Engine (keyword precision), the Vector DB (semantic similarity), and the Graph DB (relational context). Although vector fields can also be hosted in the search engine for moderate-scale workloads, the architecture includes a dedicated vector database to provide improved performance and operational flexibility for high-dimensional embeddings; this also enables future comparative evaluation between alternative deployment options. During query time, the system encodes the user input into the same vector space and performs similarity search with tuned HNSW parameters to balance recall and latency.

To support document-level relevance, retrieved chunks are aggregated and deduplicated by their originating document, retaining the highest-scoring segment per document as a primary signal while leaving room for future extensions (e.g., multi-segment aggregation via mean pooling or reciprocal rank fusion).

To combine heterogeneous retrieval signals, the system adopts a late-fusion strategy based on score normalisation and weighted aggregation. Similarity scores from semantic (vector-based) and keyword (BM25-based) retrieval are independently normalised (max-score) and then merged through a weighted linear combination, enabling fine-grained control over the ranking process. Overall, the approach balances contextual understanding with lexical precision to support both semantically rich questions and exact-match search scenarios.

Results are dynamically filtered according to the user profile before reaching the Chatbot Layer. In this final phase, the system employs a LLM for high-precision re-ranking, selecting the most relevant document segments to generate a grounded, natural language response that cites its sources directly, providing a seamless and verifiable end-user experience.

5 Illustrative Case Study: Processing A Municipal Traffic Ordinance

This section operationalises the architectural components described in Section 4, illustrating how ingestion, hybrid retrieval, and graph augmentation interact in a realistic scenario drawn from the municipal administration domain. The reference document is Traffic Ordinance No. 118/2026 (Municipality of Fictional City), a synthetic but realistic municipal ordinance, constructed to reflect the structure and language of typical Italian administrative acts, and used here solely for illustrative purposes. It regulates the temporary closure of Via Roma for urban regeneration works. Three distinct interaction scenarios — corresponding to an administrator, a citizen, and a traffic engineer — are used to exercise complementary subsystems of the architecture and to ground the design choices in concrete operational outcomes.

5.1 Document Ingestion and Processing

An administrator with the *document_manager* role uploads the ordinance as a PDF through the frontend interface. The ingestion layer validates the document structure and persists the raw file in the object store before dispatching an asynchronous processing event to the message broker. The subsequent pipeline executes without further human input.

The ordinance exhibits structural characteristics typical of Italian administrative acts: a legal preamble citing antecedent resolutions, a normative body organised as an ordered list of provisions, and a closing monitoring clause. In this case study, chunking follows these structural boundaries; when boundaries are not reliably detected or when cross-paragraph context must be preserved, the system applies a sliding-window overlap strategy. This produces five semantically coherent segments:

- *Chunk A*: preamble and legal references (Resolution No. 42/2026, public safety rationale)
- *Chunk B*: full closure of Via Roma between Piazza Verdi and Via Milano
- *Chunk C*: mandatory traffic deviations (Via Milano eastbound, Via Garibaldi westbound)
- *Chunk D*: signage, barriers, and access exceptions (residents, emergency vehicles, authorised providers)
- *Chunk E*: enforcement period (5 May – 20 June 2026) and daily traffic monitoring provision

Each chunk is embedded and indexed in the Vector DB and Search Engine alongside its metadata payload (source: "ordinance_118_2026", content_type: "traffic_regulation", created_at: "2026-04-15"). In parallel, the Knowledge Graph component extracts the following representative triples via the Text-to-Triple pipeline:

Table 1: Sample extracted triples from the Text-to-Triple pipeline.

Extracted Triples		
Subject	Relation	Object
Ordinance_118_2026	Restricts	Via_roma
Via_roma	Located_in	Fictional_city
Via_roma	Affects	Vehicular_traffic
Resolution_42_2026	Authorises	Ordinance_118_2026
Via_milano	Serves_as	Eastbound_deviation
Via_garibaldi	Serves_as	Westbound_deviation

All entity nodes are linked to the source document via a CITES provenance edge, ensuring full traceability from graph traversal results back to the originating ordinance.

5.2 Scenario 1 — Semantic Retrieval (Citizen Query)

A citizen authenticated with the *citizen* role submits the following query:

"Can I drive through Via Roma next month?"

The query contains no administrative terminology, no reference to the ordinance identifier, and no explicit mention of a closure or regulation. The retrieval layer encodes the query into the shared vector space and performs ANN search. The resulting vector is geometrically proximate to Chunk B and Chunk C, as the embedding model captures the underlying intent — movement restriction on a named road — independently of lexical overlap with the indexed text. The BM25 component contributes results anchored to the surface term "Via Roma", partially overlapping with the semantic signal. After late fusion and per-document deduplication, Chunk B is ranked first, followed by Chunk C and Chunk E.

The IAM filter confirms that the ordinance falls within the access scope of the *citizen* role. The chatbot layer generates the following grounded response:

"Via Roma is closed to vehicular traffic between Piazza Verdi and Via Milano until 20 June 2026, due to urban regeneration works (Ordinance No. 118/2026). Eastbound traffic is diverted via Via Milano, westbound via Via Garibaldi. Residents and emergency vehicles retain controlled access."

This scenario illustrates how semantic retrieval enables effective resolution of natural-language queries over regulatory content even in the absence of lexical overlap with the source document—a capability that purely keyword-based retrieval would not reliably provide in this instance.

5.3 Scenario 2 — Relational Retrieval (Technical Query)

A traffic engineer with the *technical_staff* role submits a structured query:

"Which ordinances issued in 2026 impose restrictions on Via Roma?"

This query favours keyword and structured retrieval: BM25 matches on "Via Roma" and "ordinances", while metadata filtering on *created_at* and *content_type* narrows the candidate set. However, neither vector search nor full-text indexing can resolve this relational dimension with sufficient precision, as the association between via_roma and its restricting ordinance is not co-located in any single chunk. By contrast, the Knowledge Graph provides explicit entity grounding and deterministic relation traversal, enabling the system to answer "which ordinances restrict Via Roma" even when evidence is distributed across chunks or implicit in cross-document references.

The Knowledge Graph resolves this directly: starting from the node *via_roma*, the system traverses the restricts relation in reverse and returns *ordinance_118_2026* as the source entity, enriched with its provenance metadata. In a realistic multi-document setting, the same traversal would return a set of ordinances linked to the entity *via_roma*, enabling comparative analysis across multiple regulatory acts. This result is incorporated into the fusion stage alongside the keyword and semantic signals, producing a ranked response that identifies the ordinance, its enforcement period, and its principal provisions.

This scenario highlights how graph augmentation provides qualitatively distinct retrieval capabilities for entity-centric and relationship-oriented queries—particularly in cases involving implicit or cross-chunk relational dependencies that neither keyword search nor vector similarity can resolve independently.

5.4 Observations

The ordinance use case highlights three operational properties of the KMS that are particularly significant in the public administration domain.

The case study suggests that semantic retrieval extends the effective recall of the system beyond what lexical methods alone can achieve: citizen queries formulated in natural, non-technical language are correctly resolved against regulatory documents that share no significant vocabulary with the query surface form. At the same time, BM25 remains valuable for queries with precise terminological anchors, motivating the hybrid fusion strategy over either paradigm in isolation.

The Knowledge Graph is not merely complementary to vector retrieval but provides structurally distinct query capabilities. Relational queries that require traversing implicit associations between entities — such as identifying all regulations affecting a specific road — are not reliably addressed by semantic similarity or inverted-index lookup, regardless of chunking granularity or embedding quality. The graph layer addresses precisely this class of query.

The provenance mechanism — source citation in the chatbot response and CITES edges in the graph — ensures that every system output remains traceable to its originating document. In a public-sector context, this traceability is a necessary condition for institutional trust and accountability, independent of retrieval effectiveness.

Although the scenario uses a single ordinance, the architecture scales to multi-document corpora, enabling aggregation and comparison across regulatory sources.

6 Discussion and Conclusion

This paper presents a H-RAG architecture for knowledge management in Urban Digital Twin environments, investigating to what extent a hybrid integration of semantic, lexical, and graph-based retrieval can mitigate knowledge fragmentation across administrative silos. Following a DSR methodology, the proposed KMS is designed around three core requirements—incremental ingestion (R1), provenance-anchored responses (R2), and cross-silo semantic integration (R3)—and demonstrated through an illustrative case study based on a municipal traffic ordinance. The research offers three main contributions: (i) a conceptual framework for hybrid knowledge retrieval in dynamic urban environments; (ii) a replicable DSR-based design approach for public administration; (iii) architectural guidelines for integrating governance-oriented KM into UDT contexts.

The case study illustrates how hybrid retrieval can extend recall beyond what lexical methods alone achieve for citizen-facing natural-language queries, while Knowledge Graph augmentation enables structurally distinct capabilities for entity-centric and relational queries that neither semantic similarity nor keyword matching can resolve independently.

From a scientific perspective, the paper advances understanding of how structured and unstructured knowledge can be jointly managed under governance constraints, extending the H-RAG literature to a domain—municipal governance—that has received limited attention in existing research.

Expected outcomes and practical impact are targeted at three stakeholder groups:

- Public administrators and urban data managers → faster, evidence-based access to regulatory knowledge with end-to-end provenance traceability (answer-to-source), supporting accountable decision-making.
- Citizens → natural-language access to complex administrative information without requiring domain expertise, improving accessibility of public services.
- IT architects and platform owners → a modular, microservices-oriented reference architecture for integrating hybrid retrieval and governance-oriented KM capabilities into Digital Twin platforms.

The system is currently deployed as an early-stage prototype, with the primary objective of validating architectural feasibility, interoperability, and end-to-end data flow consistency rather than optimising performance. Evaluation is framed as a progressive, multi-stage process, given the non-stationary ingestion corpus, the heterogeneous retrieval paradigms, and the structural variability of municipal documents.

Accordingly, future work will pursue a structured evaluation roadmap covering retrieval effectiveness (precision, recall, nDCG) across lexical, semantic and hybrid configurations, ablation studies on individual retrieval layers, validation of graph extraction against curated ground-truth subsets, latency and scalability analysis under increasing ingestion and query loads, and end-to-end testing in realistic user-query scenarios.

This staged strategy supports the incremental development of a robust infrastructure for structuring municipal knowledge. Overall, the proposed architecture represents a foundational step toward knowledge-driven access to complex administrative information systems.

7 Acknowledgment

This work is framed within the Project “AVANT” — Project no. IPCEI-CL_0000005 — Application protocol no. 108421 of 14/05/2024 — CUP B89J24002920005 — Grant decree no. 1322 of August 8, 2024 — financed by the European Union — NextGenerationEU (IPCEI Funding).

8 Ethics Declaration

This research did not require ethical clearance, as it does not involve the collection or processing of personal data from human participants. The municipal administrative document corpora referenced in the illustrative case study are synthetic and constructed solely for demonstration purposes.

9 AI Declaration

AI tools (specifically, Claude by Anthropic) were used to support the drafting, structural organisation, and language editing of portions of this paper. All technical content, architectural decisions, scientific claims, and bibliographic references were developed, verified, and validated by the authors. The authors take full responsibility for the accuracy of all content.

A Knowledge-Based Life-Cycle Framework for Sustainable Restoration Decision-Making

Stefano Abbate, Anna Scotto di Santolo
Pegaso University, Naples, Italy

Abstract

Cultural heritage represents a key driver of social identity, cultural continuity, and local economic development, yet it is increasingly exposed to environmental, anthropogenic, and climate-related threats. In this context, restoration and conservation interventions require selecting materials and techniques that ensure technical performance while addressing broader sustainability objectives. However, decision-making in cultural heritage restoration is often based on fragmented criteria, with limited integration of environmental, economic, and social dimensions across the entire life cycle. This study addresses this gap by developing a multi-criteria life-cycle framework to support the selection and prioritisation of sustainable restoration techniques in cultural heritage. The research adopts a systematic literature review (SLR) methodology to identify and analyse contributions on Life Cycle Assessment (LCA), Life Cycle Costing (LCC), and Social Life Cycle Assessment (S-LCA) within the heritage conservation domain. A final sample of 45 peer-reviewed articles was examined through descriptive and content analyses to extract relevant indicators, methodological approaches, and decision variables. The output is a structured multi-criteria life-cycle framework that integrates sustainability indicators across environmental, economic, and social dimensions, including, for example, Global Warming Potential (GWP), natural resource depletion, water footprint, equipment and energy costs, health and safety, employment stability, and community well-being. This set of indicators constitutes a coherent, multidimensional taxonomy that underpins a flexible, replicable decision-support framework, enabling transparent, systematic comparison of alternative restoration strategies. The study offers relevant implications for both practice and policy, supporting more informed resource allocation and the development of sustainability-oriented guidelines for cultural heritage conservation. The proposed framework is explicitly designed to provide a solid knowledge base for future empirical applications, making it an operational tool for decision-makers. By integrating multi-criteria decision-making techniques, it will be possible to weight the heterogeneous criteria identified and prioritise restoration interventions under conditions of uncertainty. Future developments should also focus on empirical validation through case studies and on incorporating stakeholder perspectives to enhance the framework's applicability and robustness.

Keywords: cultural heritage restoration, life-cycle thinking, sustainability

Paper type: Academic Research Paper

1 Background

Cultural heritage represents a fundamental component of collective identity and regional development, embodying historical, social, and symbolic values that extend beyond its material dimension (Vadrucci, 2025). Archaeological sites contribute to cultural continuity, foster social cohesion, boost tourism, and support local economies (Chen and Tan, 2025). However, these heritage assets face increasing threats, including material degradation, climate change-related hazards, urban development pressures, and anthropogenic impacts. Restoration and consolidation efforts in cultural heritage increasingly rely on a wide range of materials and techniques, including traditional methods, innovative consolidants, and advanced composite or nano-engineered formulations. Recently, significant research has focused on enhancing the mechanical performance, durability, and compatibility of these materials with historic substrates, aiming to improve structural stability while preserving the authenticity of heritage assets (Dal Pozzo et al., 2024). Preventive conservation methods and low-impact treatments are also gaining prominence, as they can reduce the frequency and invasiveness of interventions throughout the entire life cycle of cultural heritage sites (Menegaldo et al., 2023). As a result, the growing availability of alternative materials and restoration techniques has introduced new challenges for decision-makers. Solutions that perform well technically or mechanically may differ substantially in terms of environmental impact, long-term economic effects, or social acceptance. For instance, innovative consolidants might reduce maintenance needs but require energy-intensive manufacturing, whereas traditional materials may promote cultural harmony but result in higher long-term costs or environmental impacts. Despite this complexity, selecting restoration strategies often still relies on isolated performance criteria, with limited consideration of life-cycle environmental, economic, and social impacts. Balancing these often-competing goals is one of the most pressing challenges in contemporary cultural heritage restoration (Angrisano et al., 2024).

By employing a systematic literature review, this study aims to develop a structured, replicable, knowledge-driven evaluation system to support decision-making for the restoration and consolidation of cultural heritage assets. Specifically, it seeks to build a multidimensional assessment framework that serves as a basis for comparing different restoration techniques, materials, and intervention strategies, incorporating environmental, economic, and social sustainability perspectives. The system is based on life-cycle thinking and integrates indicators from Life Cycle Assessment (LCA), Life Cycle Costing (LCC), and Social Life Cycle Assessment (S-LCA) to capture the full range of impacts associated with heritage restoration over time. Consequently, this study introduces a useful knowledge-based tool for practitioners, researchers, and policymakers, thereby contributing to more sustainable, transparent, and well-informed conservation strategies in cultural heritage restoration.

2 Methodology

This study employs a systematic literature review (SLR) structured according to established frameworks for evidence synthesis in management and sustainability research (Cerchione and Esposito, 2016; Greenhalgh and Peacock, 2005). The SLR methodology ensures transparency, reproducibility, and methodological rigour in documenting the search, screening, and selection procedures (Centobelli et al., 2017). The review process was organised into two main phases. The initial phase focused on identifying, gathering, and selecting scientific and technical literature related to sustainability assessment in cultural heritage conservation. The second phase involved a descriptive and content analysis of the final sample of articles to identify and incorporate life-cycle–based sustainability indicators related to maintenance and restoration of cultural heritage assets. These indicators were then integrated into a single decision-support tool designed to prioritise interventions.

2.1 Data collection and selection

The sample of articles was retrieved from the Scopus database, chosen for its extensive coverage of engineering, environmental assessment, and sustainability research (Abbate et al., 2023). Peer-reviewed articles and reviews formed the main evidence base. We obtained an initial sample of 71 documents. Subsequently, following PRISMA recommendations (Page et al., 2021), a preliminary title and abstract screening was conducted. Notably, only documents demonstrating sufficient clarity regarding the methodological framework, relevance to the cultural heritage sector, and alignment with life-cycle–based sustainability assessment principles were retained in the review. During this phase, 30 studies were excluded. The remaining 41 papers were analysed in full text, and six were excluded because they employed non-sustainability-focused approaches. Therefore, 35 papers were considered eligible for inclusion in the final sample. In addition to these core studies, a snowballing approach was used (Greenhalgh and Peacock, 2005). This resulted in the identification of 10 additional relevant publications, primarily on multi-criteria decision-making methods and case studies of life-cycle sustainability assessments in cultural heritage settings. As a result, the final sample consists of 45 articles, as shown in Figure 1.

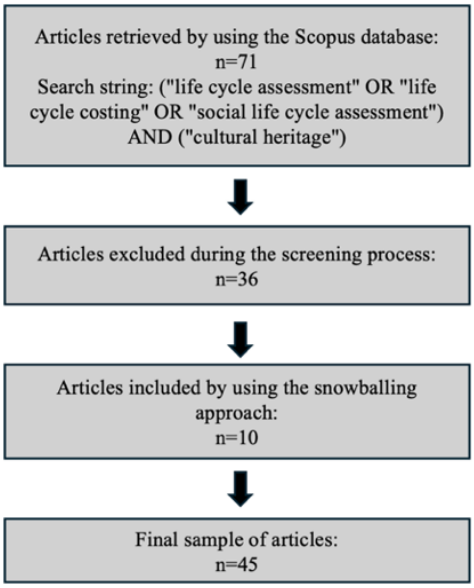

Figure 1. Data collection and selection process

3. Results

3.1 Descriptive statistics

The growing number of publications over time indicates that sustainability in heritage conservation has become an increasingly important research focus. This trend is driven by the global shift towards climate-oriented strategies, efficient use of resources, and the demand for more sustainable conservation approaches. Notably, the increasing application of LCA, LCC, and more recently, SLCA in conservation studies shows a shift from merely technical restoration techniques to broader assessment frameworks that support sustainable decision-making.

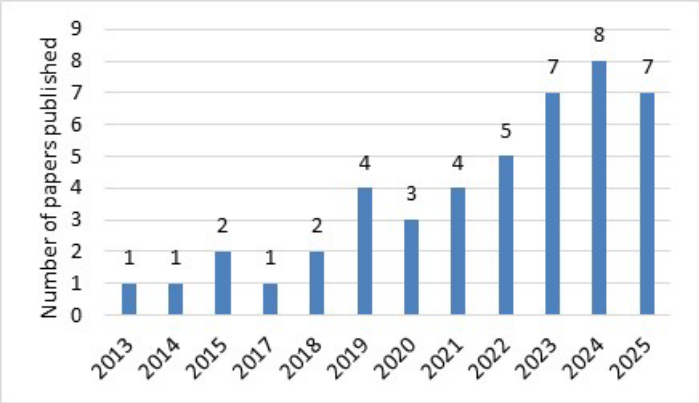

Figure 2. Papers published over time

The analysis of the methodological approaches in the selected publications reveals a predominant use of environmental assessment techniques. Notably, 52% of the papers employ LCA as their primary evaluation tool, confirming its position as the most frequently used sustainability assessment method in the cultural heritage sector. Only 3% of publications combine LCA and LCC, while another 3% integrate LCA with SLCA. Notably, only 7% employ a comprehensive approach that includes LCA, LCC, and SLCA, indicating that a full multidimensional sustainability assessment remains limited and not yet widely adopted. In addition, LCC is used alone in only 3% of the contributions, indicating that economic sustainability is often underrepresented compared to environmental issues. Likewise, only 3% of the papers use SLCA as a standalone method, with the same percentage comprising conceptual studies, which emphasises the necessity for more empirical frameworks. Furthermore, 3% of the publications employ mixed-method approaches, incorporating multi-criteria decision-making (MCDM) techniques; 10% are based on simulation models; and 13% present systematic or narrative literature reviews. This distribution indicates that studies on the topic remain mainly focused on environmental aspects. Economic and social aspects are less commonly examined, and when addressed, they are rarely integrated into a unified assessment framework. The limited adoption of LCC and SLCA, whether used independently or in combination with LCA, highlights a fragmented approach to assessing sustainability in restoration decision-making.

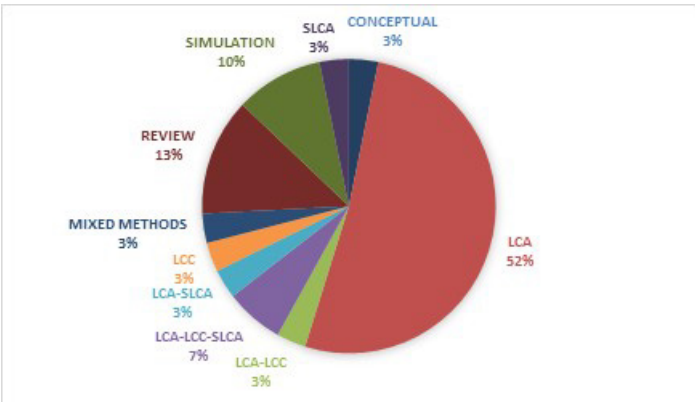

Figure 3. Distribution of papers by methodology

An analysis of publication venues reveals a wide range of journals, underscoring the interdisciplinary character of sustainability assessment in cultural heritage. However, a few journals publish most contributions, as listed in Table 1, including those with at least 2 publications on this topic. Prominent among these are the International Journal of Life Cycle Assessment, Resources, Conservation and Recycling, Journal of Cleaner Production, and Building and Environment, all of which emphasise environmental sustainability and life-cycle perspectives. Sector-specific journals such as the Journal of Cultural Heritage, Heritage Science, and the Journal of Cultural Heritage Management and Sustainable Development also play significant roles, reflecting the importance of heritage conservation. This pattern affirms that sustainability assessment in cultural heritage is a multidisciplinary field that intersects environmental science, materials and building engineering, and heritage management.

Table 1. Distribution of papers across journals

Journal	Papers published
International Journal of Life Cycle Assessment	3
Resources, Conservation and Recycling	3
Journal of Cleaner Production	2
Journal of Cultural Heritage	2
Building and Environment	2
Cleaner Environmental Systems	2
Journal of Cultural Heritage Management and Sustainable Development	2
Journal of Building Engineering	2
Heritage Science	2
Energy Reports	2
Journal of the American Institute for Conservation	2

3.2 Content analysis

The analysis of the selected studies reveals several coherent thematic trends that demonstrate how sustainability assessment is increasingly integrated into cultural heritage conservation. First, many studies use LCA to assess the environmental implications of restoration materials and associated conservation products. Dal Pozzo et al. (2024) employ LCA to compare different consolidants used in the restoration of weathered carbonate substrates, aiming to identify formulations with reduced life-cycle impacts. Their results indicate that an innovative treatment with an aqueous diammonium hydrogen phosphate (DAP) solution outperforms commercial options. Similarly, Turk et al. (2017) assess three eco-friendly calcium carbonate-based consolidants. Their LCA study reveals that calcium acetoacetate has a lower environmental impact than the others, with 1 kg of the consolidant associated with 0.32 kg of CO2-equivalent emissions. Other articles employed LCA to assess conservation-related materials and products, including innovative nanomaterials for the preventive conservation of cultural assets (e.g. Menegaldo et al., 2023). Additional research examines the environmental effects of treatments aimed at slowing the degradation of oxygen-sensitive materials or objects in cultural heritage (e.g. Sanchez et al., 2023). Overall, these studies indicate that LCA is increasingly used as a decision-making tool for selecting restoration materials, highlighting the need to incorporate environmental performance criteria into conservation efforts alongside traditional technical and aesthetic factors.

A smaller but significant number of contributions use LCC, either alone or in combination with LCA, to analyse the economic dimension of conservation. Menegaldo et al. (2023) employ an integrated LCA–LCC methodology to assess the potential of innovative nanotechnologies for the preventive conservation of cultural objects. Their findings highlight a substantial impact linked to raw material sourcing, especially transportation. Hromada et al. (2024) apply LCC to maintenance planning in historic buildings, demonstrating that deferred maintenance increases long-term costs and risks. Their findings suggest that heritage asset management should adopt a life-cycle cost approach rather than short-term budgeting. Together, these studies emphasise the lack of economic analysis in heritage sustainability research and highlight the importance of LCC for long-term financial planning.

The social dimension remains underexplored, yet various studies broaden sustainability assessments to include social impacts. Arcese et al. (2015) aim to develop a framework for assessing social impact in the cultural heritage sector by integrating existing SLCA tools with data from social assessments of how cultural services relate to stakeholders. They propose that heritage projects can bring community benefits, including improved identity and increased employment, but also pose risks such as gentrification and unequal access. Mohaddes Khorassani et al. (2019) integrate LCA and SLCA to assess cultural heritage restoration scenarios. Their LCA findings highlight that the most impactful phases involved reconstructing materials and elements that could not be recovered because the originals were too damaged. The SLCA results show that the restoration brought

several benefits, particularly in addressing social issues within the local community. These findings indicate that incorporating social assessment into heritage sustainability analysis is still a developing area, but it remains crucial for understanding community impacts.

A final group of studies includes conceptual frameworks and systematic reviews. Flyen et al. (2020) examine how socio-cultural values can be integrated into sustainability assessments, highlighting that purely technical evaluation methods might overlook significant heritage meanings. Calabrò et al. (2024) suggest that using monitoring technologies, such as drones, can significantly improve the accuracy of initial cost estimates for cultural heritage restoration. Chelazzi et al. (2024) introduce the GREENART project, highlighting innovative, eco-friendly solutions for conserving cultural heritage, such as protective coatings, foams, and consolidants, that support broader sustainable conservation efforts. Elnaggar (2024) offers an overview of LCA applications in cultural heritage, emphasising the benefits and challenges of these life-cycle-based approaches in heritage science, and offering recommendations to guide the field towards more sustainable, eco-friendly practices.

As a result, during the content analysis phase, a systematic data extraction process was conducted. Each study was analysed to identify methodological characteristics related to the application of LCA, LCC, or SLCA, including system boundaries, functional units, data sources, and modelling assumptions, as well as the impact categories considered, the temporal horizon of the assessment, and the sustainability indicators reported. This analytical phase identified recurring sustainability indicators and decision variables across the environmental, economic, and social dimensions. These findings provided the empirical basis for developing a structured, knowledge-based, multidimensional evaluation framework to support material selection and intervention planning in cultural heritage conservation, aligned with life-cycle thinking (Table 2).

4 Conclusions, Implications and Future Research Directions

The main contribution of this study is the definition and organisation of a multidimensional taxonomy of life-cycle–based indicators, enabling a more holistic understanding of the impacts of cultural heritage restoration interventions. It is a flexible, replicable decision-support framework adaptable to diverse cultural heritage contexts and site-specific constraints, helping to overcome the fragmented nature of existing approaches, which often focus on single dimensions of sustainability without adopting a comprehensive life-cycle perspective. The framework organises life-cycle indicators into a coherent knowledge structure that supports transparent, informed decision-making.

Building on this foundation, the framework can be further developed into an operational decision-support tool through empirical applications using multi-criteria decision-making techniques, such as the fuzzy Analytic Hierarchy Process (AHP) and the fuzzy Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). These methods would allow the weighting of heterogeneous criteria and the prioritisation of alternative interventions under conditions of uncertainty and limited data availability, which are typical of cultural heritage

contexts. Through this integration, the framework can shift from a descriptive structure to a prescriptive tool that supports concrete decision-making processes.

This research design entails relevant practical and policy implications. From a managerial perspective, it would support practitioners and heritage managers in allocating resources more effectively and in identifying intervention strategies that balance performance across multiple sustainability dimensions. From a policy standpoint, it provides a robust analytical basis for developing guidelines, evaluation criteria, and funding mechanisms aligned with life-cycle sustainability principles. Moreover, by enhancing transparency and comparability, the framework can contribute to more accountable, evidence-based decision-making in the cultural heritage sector.

Opening the Black Box of Incubation: Governance Archetypes and the Moderating Role of Regional Innovation Ecosystems in Start-up Growth

Antonio Sonetto, Silvia Tommaso, Antonio Ricciardi
University of Calabria, Arcavacata di Rende (CS), Italy

Abstract

Start-ups are widely recognised as key drivers of national competitiveness, contributing to economic growth and technological progress through their ability to innovate, adapt, and generate new markets. However, despite their strategic relevance, they face substantial barriers in the stages of development, including limited financial, organisational, and managerial resources, which constrain their ability to successfully commercialise innovations. As a result, firm survival remains a critical challenge, with a large share of start-ups exiting within a few years and only a minority achieving long-term sustainability. In this context, business incubators (BIs) have become widely adopted policy and managerial instruments aimed at supporting start-ups' development. They provide a combination of tangible and intangible resources, including physical infrastructure, advisory services, managerial support, and access to external networks, with the objective of improving start-up survival and growth prospects. However, despite their diffusion, existing research provides mixed evidence regarding their actual effectiveness, often conceptualising incubation as a *"black box"* with heterogeneous and context-dependent outcomes. This study addresses this gap by examining how public and private BI governance archetypes and regional innovation ecosystem development jointly shape start-up performance. Using a sample of 659 innovative start-ups hosted in 62 certified BIs in Italy, the analysis employs OLS regression models with clustered standard errors, integrating firm-level data from the Italian Business Register (IBR) and AIDA database for the period 2023-2024. The findings indicate that start-ups supported by private BIs achieve significantly higher revenue growth compared to those hosted in public BIs. However, this performance gap is not uniform across contexts. The level of regional innovation development positively moderates the effectiveness of public BIs, reducing their performance disadvantage in more advanced ecosystems. While private BIs exhibit robust performance regardless of territorial conditions, public BIs appear more dependent on external ecosystem quality. Finally, this research provides implications for managers, entrepreneurs, and policymakers.

Paper type: Academic Research Paper

1 Introduction

Start-ups are key to a nation's competitive advantage, driving economic growth and technological innovation through their adaptability, risk-taking, and ability to create new industries with significant societal and economic impact (Audretsch *et al.*, 2020). However, start-ups face significant obstacles in bringing innovations to market due to limitations in size, resources, expertise, and organizational capabilities (Spender *et al.*, 2017). Therefore, start-up survival remains a major concern: research indicates that 40-80% of new ventures fail within the first five years (Colombelli *et al.*, 2016; Yang and Aldrich, 2012), and only 10-20% survive beyond ten years (Ebert *et al.*, 2019; Kalyanasundaram *et al.*, 2021), underscoring the challenge of achieving long-term sustainability (Wang and Zhou, 2022). In response to these challenges, business incubators (BIs) have emerged as important tools to support start-up creation and growth (e.g., Aernoudt, 2004), offering facility-related services, consulting and management support, and access to networks (Abduh *et al.*, 2007). BIs serve as a critical resource for facilitating start-ups' knowledge management (KM) processes (e.g., Gao *et al.*, 2021), encompassing the creation, sharing, and application of both tacit and explicit knowledge, and thereby enhancing their learning, innovation capacity, resilience, and overall organizational and financial performance. Therefore, BIs can be interpreted as intelligent KM infrastructures.

Despite the growing prevalence of BIs, empirical evidence on their effectiveness remains scarce and inconclusive (Bergman and McMullen, 2022; Cohen *et al.*, 2019; Hausberg and Korreck, 2020).

While several contributions document positive effects on firm survival, employment, sales growth, and innovation (e.g., Colombo and Delmastro, 2002; Löfsten and Lindelöf, 2002; Soetanto and Jack, 2016; Stokan *et al.*, 2015), others report no significant differences between incubated and non-incubated firms (e.g., Ferguson and Olofsson, 2004; Pena, 2004; Schwartz, 2013; Vásquez-Urriago *et al.*, 2016), or even negative effects on financial performance and growth (e.g., Dvouletý *et al.*, 2018; Ensley and Hmieleski, 2005; Schwartz, 2009). Lukeš *et al.* (2019) show that incubation negatively affects sales growth in the short term, while generating positive

effects in the long run. Additional evidence suggests that participation in venture incubation programs can increase the likelihood of firm closure and reduce the amount of funding raised (Schwartz, 2013; Yu, 2020).

These mixed findings highlight the need for further research to identify the conditions under which incubation generates meaningful outcomes (Braun and Suoranta, 2025). There is a need for studies that move beyond survival and examine start-up growth (Del Sarto *et al.*, 2020). Therefore, the lack of clear and consistent theories on how incubation operates has led scholars to describe BIs as a *"black box"* (Hackett and Dilts, 2004). The majority of the literature has primarily focused on tenant firms, paying limited attention to how the nature and intensity of BI support vary across different types of BIs (Breivik-Meyer *et al.*, 2020). Consequently, there is limited clarity regarding the relative benefits for venture development associated with different incubation program configurations. Moreover, a further promising explanation for these inconsistent findings is that incubation outcomes are contingent upon territorial and contextual factors, such as local economic conditions, institutional quality, industry clustering, and the maturity of regional innovation systems. Although several studies have emphasized the importance of incorporating these dimensions into empirical analyses (e.g., Ratinho and Henriques, 2010; Van Rijnsoever, 2020), systematic evidence remains scarce. Addressing these gaps, this study investigates how public and private BI governance archetypes influence start-up growth and how these effects vary across territorial contexts. Therefore, we defined the following research question:

RQ: To what extent do public and private incubator governance archetypes influence tenants' performance outcomes, and how does regional institutional thickness moderate these effects?

2 Hypothesis Development

Building on the framework proposed by Grimaldi and Grandi (2005), we distinguish among public BIs (business innovation centres) and private BIs (independent private incubators and corporate private incubators). Public BIs generally operate as non-profit organisations, as they are established by public institutions with the primary aim of fostering local economic development. In contrast, private BIs are profit-oriented entities, created and managed by private actors with explicit objectives of financial return. Prior research has found no statistically significant differences in start-up growth outcomes associated with the public or private ownership of BIs (Barbero *et al.*, 2012; Lukeš *et al.*, 2019). However, private BIs tend to be more performance and market driven than their publicly operated counterparts, which are more commonly guided by objectives related to social welfare and employment preservation (e.g., Grimaldi and Grandi, 2005). For private BIs, the success of their tenant firms, unlike in the case of public BIs, represents a necessary condition for their economic and entrepreneurial sustainability (Boschetti *et al.*, 2011). Therefore, we formulate the following hypothesis:

H_1: Start-ups supported by privately operated BIs exhibit higher revenue growth than those supported by publicly operated incubators.

Based on Bade (2026), the direct support provided by BIs, namely the services delivered internally to start-ups such as office space, targeted mentorship, and legal assistance, is encapsulated within the incubation program and primarily contingent on the intrinsic quality of the BI itself. Consequently, this dimension is not expected to vary with the level of development of the surrounding regional innovation ecosystem. In contrast, bridging mechanisms, i.e., the processes through which BIs connect start-ups to essential external resources such as networks, knowledge, and financial capital, are strongly dependent on the characteristics of the territorial context in which the BI operates. Given that the primary objective of public BIs is to foster regional development and safeguard employment by compensating for institutional voids through the creation of missing linkages and the bridging of knowledge and financial gaps (Grimaldi and Grandi, 2005; Harper-Anderson and Lewis, 2018; Mrkajic, 2017), we argue that such BIs are more externally embedded than their private counterparts, which tend to be more inward-oriented and rely predominantly on internal capabilities and privately cultivated networks. Accordingly, we posit that the effectiveness of public BIs relative to private ones is more strongly contingent upon the level of development of the surrounding territorial ecosystem. Therefore, we hypothesize:

H_2: The level of regional development positively moderates the relationship between public BI support and start-up growth performance.

3 Data and methods

3.1 Sample and data collection

This study is based on the analysis of data on BIs and start-ups located in Italy. The dataset was constructed by combining information retrieved from the Italian Business Register (IBR) and the AIDA database. Data

extraction was carried out in January 2026. The sample of BIs consists of the list of BIs certified by the Ministry of Enterprises and Made in Italy, which has also been considered in prior studies as the most reliable population of BIs in the Italian context (Bonfanti *et al.*, 2025). The total number of certified BIs included in the sample is 69. The start-up sample consists of innovative start-ups listed in the IBR, amounting to 11,742 firms. The legal requirements to obtain the qualification of innovative start-up or certified BI are illustrated in Figure 1.

Requirements to be a "certified" Business Incubator *Article 25, paragraph 5, of Italian Decree-Law No. 179 of October 18, 2012, converted with amendments by Law No. 221 of December 17, 2012*
• Availability of adequate facilities for hosting innovative start-ups, including spaces for testing, experimentation, or research • Presence of suitable equipment for start-up activities, such as ultra-broadband internet access, meeting rooms, and prototyping/testing machinery • Management by individuals with recognized expertise in business and innovation, supported by a permanent technical and managerial structure • Established collaborations with universities, research centres, public institutions, and innovation-oriented financial partners • Documented experience in supporting innovative start-ups
Requirements for qualification as an "innovative start-up" *Growth Decree 2.0 (Decree-Law No. 179/2012)*
• Incorporation as a limited liability company (e.g., S.r.l., S.p.A., S.a.p.a., or cooperative) • Main activity focused on development, production, or commercialization of high-tech goods or services, regardless of sector • Company age not exceeding 5 years, annual turnover below €5 million, and non-distribution of profits • Non-origin from extraordinary corporate transactions (e.g., mergers, demergers, or business transfers) • Evidence of innovative character through at least one of the following: significant R&D expenditure (at least 15% of the higher of total costs and total value of production), highly qualified personnel, or ownership/licensing of patents or registered software

Figure 1: Legal requirements for qualification as innovative start-up and certified BI (authors' elaboration)

Subsequently, for both samples, firm-level and financial data were retrieved from AIDA and merged with the information extracted from the IBR. While the number of BIs remained unchanged, the number of innovative start-ups decreased from 11,742 to 11,618 due to missing data.

As done in prior literature (Arcuri *et al.*, 2025; Lukeš *et al.*, 2019), we reconstructed the set of start-ups hosted within Italian BIs. Specifically, the list was generated by extracting the relevant information from the IBR, considered relatively up to date, as start-ups are required to update their records at least annually, and triangulating it with data collected from the official websites of the 69 BIs. In many cases, these websites provide updated lists of currently incubated start-ups as well as alumni. This process allowed us, on the one hand, to fill in missing information from the IBR and, on the other hand, to correct potential inaccuracies by excluding firms that were listed as incubated in the IBR but appeared as alumni on BI websites. This procedure enabled the construction of a reliable estimate of start-ups that were actively incubated at the beginning of the year. However, consistent with Lukeš *et al.* (2019), the absence of longitudinal information prevents identification of the duration of incubation.

The number of incubated start-ups thus amounted to 1,065. However, due to data availability constraints within AIDA, specifically, financial records being updated only through the 2024 fiscal year, the final analytical sample was restricted to 659 start-ups distributed across 62 BIs. 22.58% of the BIs are public, while 77.42% are private. Moreover, 11.29% of the BIs have a university affiliation. Regarding start-ups, 41.73% are hosted by public BIs and 58.27% by private ones. Additionally, 22.00% of the start-ups are incubated within BIs that have a university affiliation.

3.2 Variables and methodology

Table 1 reports the list of variables used in this study, identified on the basis of prior literature (e.g., Arcuri *et al.*, 2025; Lukeš *et al.*, 2019; Sansone *et al.*, 2020). To mitigate potential endogeneity issues arising from both self-selection (whereby more promising start-ups choose specific BIs) and cherry-picking (whereby high-performing BIs systematically select only the most promising candidates), we included several proxies for initial firm quality as control variables. By holding these factors constant, our model accounts for the observed heterogeneity at the time of entry.

Table 1: Description of the regression variables.

Type	Name	Definition	Source
Dependent	Tenant_growth	log (1 + tenant revenues 2024) - log (1 + tenant revenues 2023)	AIDA
Predictors	Public_Inc	Dummy variable = 1 if at least 50% of the BI's shareholders are public entities.	
	Regional_innovation_scoreboard	Mean-centered	Eurostat
Control - BIs	Inc_university_affiliation	Dummy variable = 1 if the BI is associated with a university	AIDA
	Inc_age	log (Difference between 31/12/2023 and BI founding date, divided by 365.25)	
	Inc_size	log (1 + BI total assets) as of 31/12/2023	
Control - Tenants			
	Tenant_age	log (Difference between 31/12/2023 and tenant founding date, divided by 365.25)	
	Tenant_initial_capital	log (tenant first year equity – tenant first year net income)	
	Tenant_size	log (1 + tenant total assets)	
	Tenant_qualified_team	Dummy variable = 1 if the team is composed of at least two-thirds master's degree holders, or at least one-third PhD students, PhD holders, or individuals with at least three years of certified research experience	IBR
	Tenant_R&D_intensity	Dummy variable = 1 if R&D expenditures represent at least 15% of the higher value between total production value and total costs	
	Tenant_intellectual_property	Dummy variable = 1 if the firm holds or licenses industrial property rights or owns registered software	
	Tenant_female_dominant_team	Dummy variable = 1 if the average of (i) percentage of female shareholders and (ii) percentage of female board members exceeds 50%	
	Tenant_young_dominant_team	Dummy variable = 1 if the average of (i) percentage of young shareholders and (ii) percentage of young board members exceeds 50%	
	Tenant_foreign_dominant_team	Dummy variable = 1 if the average of (i) percentage of foreign shareholders and (ii) percentage of foreign board members exceeds 50%	
	Regional_FE	BI region (NUTS 2 Italy)	AIDA
	Industry_FE	Tenant sector (NACE 2)	

Given the unavailability of panel data and the fact that the dependent variable is continuous rather than binary, the hypotheses are tested using an OLS regression model (Angrist and Pischke, 2009). Moreover, since multiple tenants are located within the same BI, the observations are not independent. Therefore, we employ BI-clustered standard errors to obtain valid and reliable p-values.

4 Preliminary results

Table 2 presents a descriptive statistical summary of the quantitative variables.

Table 2**:** Descriptive statistics for quantitative variables

Variables	Mean	SD	Min	Max
Tenant_growth	1.088652	3.631955	-11.69546	12.93785
Regional_innovation_scoreboard	-.1162569	8.018221	-21.00897	10.06103
Inc_age	2.566976	.8545125	-.0894411	4.136999
Tenant_age	.5995083	.7279528	-3.335633	2.01841
Tenant_initial_capital	9.604024	1.985973	0	14.77981
Tenant_size	11.53733	1.526032	5.451038	15.18722
Inc_size	15.5847	2.350215	11.3923	20.81247

Moreover, we conducted a correlation analysis to examine potential relationships among the independent variables (Table 3).

*$p < 0.05$

The results indicate that most correlation coefficients are low to moderate. The highest statistically significant coefficient is 0.6202 (between Public_Inc and Inc_university_affiliation), which remains below the critical threshold of 0.70; similarly, the corresponding VIF value is below the commonly accepted cutoff of 5 (4.33). This relatively higher correlation can be explained by the Italian context, where the majority of university-affiliated BIs are public in nature. Despite this correlation, the inclusion of both variables in the model is justified. From a theoretical perspective, they capture two distinct mechanisms of start-up support: while Public_Inc reflects the BI's governance structure and strategic mission, Inc_university_affiliation captures access to specific knowledge networks, R&D infrastructure, and technology transfer capabilities. From an empirical standpoint, retaining both variables allows us to isolate the *"pure"* effect of public governance on start-up growth, holding academic embeddedness constant. Excluding Inc_university_affiliation would lead to omitted variable bias, conflating the impact of public ownership with the benefits derived from academic resources. Additionally, a moderate and statistically significant negative correlation is observed between Tenant_qualified_team and Tenant_intellectual_property (−0.5855), as well as between Tenant_qualified_team and Tenant_R&D_intensity (−0.5097). This pattern can be explained by the institutional framework defining innovative start-ups in Italy, where these three variables represent alternative eligibility criteria. By law, firms are required to satisfy at least one of these conditions to be classified as innovative start-ups. This reporting behaviour generates a statistical substitution effect in the IBR data, thereby explaining the observed negative correlations. Finally, a moderate-to-low positive correlation is found between Public_Inc and Inc_age (0.3665). This relationship reflects the fact that public BIs tend to be older, as they are funded by public (national or regional) resources, which ensure greater financial stability and longevity compared to private BIs that are more exposed to market dynamics.

Table 4 reports the results of the econometric models. Overall, they show a progressive increase in explanatory power as additional controls and fixed effects are introduced.

With respect to H1, the coefficient associated with Public_Inc is consistently negative and statistically significant across most specifications. In particular, in Models (2), (4), (5), and (6), the coefficient ranges from −2.10 to −0.80, with significance levels between 1% and 10%: the magnitude of the effect decreases when additional controls are included, but remains statistically significant, confirming the robustness of the result. Therefore, H_1 is supported, suggesting that privately managed BIs are more effective in fostering start-up growth, potentially due to stronger market orientation, efficiency incentives, and performance-driven selection mechanisms.

Regarding H_2, Model (6) introduces both the Regional_innovation_scoreboard and its interaction with Public_Inc. While the direct effect of Regional_innovation_scoreboard is not statistically significant, the interaction term (Public_Inc × Regional_innovation_scoreboard) is positive and statistically significant at the 5% level (β = 0.086). This indicates that the negative effect associated with public BIs is attenuated as the level of regional innovation ecosystem development increases. Therefore, in more developed regions, publicly operated BIs become relatively more effective in supporting start-up growth. This finding provides support for H_2, highlighting a moderating effect whereby the institutional and economic environment enhances the performance of public BIs. This result can be interpreted through the distinction between internally provided services and externally oriented bridging mechanisms: while the former are largely independent of the regional context, the effectiveness of the latter, on which public BIs rely more heavily, is inherently contingent upon the quality of the surrounding innovation ecosystem. Accordingly, in more developed regions, where networks, knowledge flows, and financial resources are more accessible, public BIs are better able to activate these bridging mechanisms, thereby improving their relative impact on start-up growth. However, the estimated turning point for the Regional_innovation_scoreboard (» 12.23 based on coefficients from Model (6)) lies outside the observed range of the data (-21.01 and 10.06), implying that the moderating effect of Regional_innovation_scoreboard is not strong enough to reverse the performance gap between public and private BIs within the sample. Instead, it facilitates a progressive reduction of the growth disadvantage associated with public governance.

For start-ups incubated by private BIs, the quality of the regional ecosystem does not appear to significantly affect performance, as the coefficient for Regional_innovation_scoreboard (β2) from Model (6) is not statistically significant. This suggests that private BIs rely on sufficiently robust business models and well-established networks that enable them to generate growth for their tenants regardless of the surrounding regional development level, whether in less developed areas or in highly advanced innovation ecosystems.

Turning to the control variables, several relevant patterns emerge. Among BI characteristics, Inc_university_affiliation shows a positive and statistically significant coefficient in multiple models, suggesting that access to academic resources, knowledge networks, and technology transfer mechanisms positively influences start-up growth. Conversely, Inc age is negatively associated with start-up performance in some specifications, indicating that older BIs may be less dynamic or less aligned with current entrepreneurial needs. Inc size is consistently positive and highly significant, implying that larger BIs benefit from economies of scale and more extensive support services.

At the start-up level, Tenant_age exhibits a strong and consistently negative effect across all models, indicating that younger firms tend to grow faster, in line with typical life-cycle dynamics. The remaining start-up characteristics, including initial capital, size, team composition, R&D intensity, and intellectual property, do not display statistically significant effects, suggesting that, within this sample, BI-related factors play a more decisive role than internal firm attributes.

5 Conclusions and Limitations

From a theoretical perspective, this study helps open the *"black box"* of incubation by moving beyond the simple incubated versus non-incubated dichotomy. By explicitly distinguishing between public and private governance models, the analysis shows that incubation outcomes vary systematically according to the strategic orientation of the BI. Moreover, the research responds to calls for greater contextualization in incubation research: by incorporating the moderating role of the regional innovation ecosystem, it demonstrates that the effectiveness of incubation is not context-neutral, but it is influenced by the institutional thickness of the surrounding environment.

For BI managers, the results highlight the importance of aligning strategies with the characteristics of the territorial context. Public BIs operating in less developed regions should not rely exclusively on local networks, which are often fragmented or incomplete. Instead, they should actively strengthen external bridging activities through inter-regional partnerships and structured open innovation programmes. At the same time, public BI management should focus not only on expanding networks but also on improving selection and support mechanisms for start-ups, mitigating potential bureaucratic constraints. Greater managerial autonomy and the adoption of performance-oriented evaluation systems could help reduce the gap with private BIs.

The findings also carry implications for policymakers. The lower performance of public BIs relative to private ones raises questions about the efficiency of public resource allocation. Policymakers should reconsider the key performance indicators used to evaluate public BIs, shifting towards more market-oriented performance indicators and encouraging more flexible, efficiency-driven management models. Moreover, innovation policy should be systemic rather than isolated: investment in incubation infrastructure must be complemented by broader regional innovation ecosystem-building interventions, including the improvement of technology transfer mechanisms, investment in innovation infrastructures and intermediaries, and the promotion of inter-firm collaboration through targeted incentives, such as funding programmes supporting innovations developed through the establishment of consortia.

This study is no without limitations. First, consistent with prior literature (e.g., Arcuri *et al.*, 2025), the analysis is affected by survivorship bias. The lack of historical data from the IBR implies that the available dataset likely overrepresents start-ups that survived until the data extraction date, while excluding those that failed in earlier stages. Second, due to data availability constraints, the absence of longitudinal information prevents the identification of the exact duration of the incubation period for individual start-ups, limiting the ability to capture dynamic effects over time (e.g., Lukeš *et al.*, 2019).

This work is currently at an early stage and is intended as a basis for further development. In future extensions, we plan to enrich the empirical framework by incorporating additional performance indicators, such as the amount and types of funding received and alternative measures of regional development. Moreover, we aim to strengthen the empirical strategy by implementing a broader set of robustness checks and alternative econometric specifications to validate the stability of the results across different modelling approaches.

Business Incubation as a Support Mechanism for the Circular Transition: Evidence from Italy

Antonio Ricciardi, Antonio Sonetto, Silvia Tommaso, Patrizia Pastore
University of Calabria, Arcavacata di Rende (CS), Italy

Abstract

Circular start-ups play a central role in the transition toward a Circular Economy (CE), due to their capacity to generate innovative solutions for resource recovery, waste minimisation, and regenerative value creation. However, their development is hindered by several constraints, such as limited access to financial and human resources, weak managerial skills, fragile market legitimacy, fragmented value chains, and complex regulatory environments. Within this context, business incubators (BIs) are expected to act as key enablers of entrepreneurial development, although their specific role in fostering circular entrepreneurship remains under-researched and not yet fully understood. To fill this gap, this study, based on a case analysis of a public certified Italian BI, explores how a CE-oriented incubation model supports the formation and development of circular business models, as well as the main constraints affecting its effectiveness. Primary data were collected through an interview with a BI manager and questionnaires administered to the incubated start-ups. The results show that circular incubation extends beyond traditional support mechanisms for start-ups, requiring highly customised and specialised services designed to address the specific challenges of circular start-ups. In particular, the analysed BI provides a combination of physical infrastructure, tailored business development support (especially mentoring and coaching focused on business model design and validation), financial capability enhancement, facilitation of investor relations, internationalisation support, and structured networking activities that promote industrial symbiosis and access to complementary capabilities within the ecosystem. Moreover, the findings highlight that the development of a CE-oriented incubation model has required substantial organisational and infrastructural investments, particularly to reinforce advanced mentoring competences and to upgrade physical and technical facilities suitable for experimentation and prototyping. The study advances the growing body of research on CE-focused incubation by offering empirical insights into how these models function in real-world settings. It goes beyond purely conceptual perspectives, developing a more operational understanding of how incubation processes are adapted to foster regenerative business approaches.

Keywords: business incubators, circular economy, circular start-ups, circular economy-oriented incubation model, case study

Paper type: Academic Research Paper

1 Introduction and theoretical background

Circular start-ups play a crucial role by developing innovative circular business models (e.g., Henry *et al.*, 2020; Sharma *et al.*, 2024), aimed at narrowing, slowing, closing, and regenerating resource flows (Bocken and Geradts, 2022; Konietzko *et al.*, 2020), and characterized by greater flexibility than incumbent firms (Han *et al.*, 2023; Henry *et al.*, 2020). These start-ups generate solutions that can be scaled, adopted, or integrated by established firms, enabling systemic circular transformation. However, they face significant challenges in designing scalable, replicable, and economically viable circular business models, as well as in their implementation (e.g., Gaurav *et al.*, 2019; Sharma *et al.*, 2024). Their growth is constrained by limited access to resources and capabilities (e.g., Baldassarre *et al.*, 2020) and difficulties in securing funding, as investors often remain sceptical, reinforcing financing gaps in circular transitions (Kahupi *et al.*, 2021; Kanda *et al.*, 2024). Additional barriers arise from industry-specific constraints, business model features, and idea maturity (Kanda *et al.*, 2024; Kasana *et al.*, 2024; Van Opstal and Borms, 2023). Moreover, weak market demand, driven by low environmental awareness, dependence on incumbents, and inadequate regulation, further limits their success (Engzell and Kambanou, 2024; Kanda *et al.*, 2024; Kasana *et al.*, 2024; Van Opstal and Borms, 2023; Von Kolpinski *et al.*, 2023). Consequently, their success depends on the ability to navigate these internal and external challenges (Engzell and Kambanou, 2024; Von Kolpinski *et al.*, 2023) while mobilizing resources and capabilities effectively.

Business incubators (BIs) can support circular start-ups across planning, development, and scaling phases (Millette *et al.*, 2020). Incubation is defined as *"an interactive development process where the aim is to encourage people to start their own business and to support start-up companies in the development of innovative products"* (Aernoudt, 2004, p. 127). According to Abduh *et al.* (2007), BI services include: (i) infrastructure (workspace and shared facilities), (ii) advisory and managerial support to strengthen entrepreneurial capabilities, and (iii) access to internal and external networks connecting investors, partners, and markets.

However, traditional incubation models often lack the competencies needed to support circular business models, limiting effectiveness in areas such as material flows, reverse logistics, and industrial symbiosis (Hull *et al.*, 2021; Millette *et al.*, 2020). To address this, Millette *et al.* (2020) propose a CE-oriented incubation framework aligned with CE requirements, involving multiple stakeholders (government, academia, entrepreneurs, BI management, Non-Governmental Organizations). Unlike traditional models, it is proactive, supporting entrepreneurs in identifying sustainable opportunities. A central element is Entrepreneurial Orientation (EO), which helps select entrepreneurs capable of transforming ideas into market-ready solutions, alongside Industrial Symbiosis (IS), which fosters inter-firm collaboration to optimize resources and reduce costs through exchanges. Accordingly, conventional BIs are increasingly required to integrate CE principles, such as waste reduction, resource circularity, and product life-cycle redesign (Klofsten *et al.*, 2024). Key support mechanisms include mentoring by experts in CE, sustainable supply chains, stakeholder engagement, and impact mitigation (Kanda *et al.*, 2024; Millette *et al.*, 2020), as well as tailored training programs, regulatory support, and marketing strategies to increase consumer awareness (Bank and Kanda, 2016; Klofsten *et al.*, 2024). Similarly, Surana et al. (2020) emphasize alignment with SDGs, cross-initiative coordination, performance monitoring, and multi-level capacity building. In university business incubators (UBIs), effective circular transition further requires collaboration with faculty, CE-focused training, digital repositories, and financial incentives (Kambanou *et al.*, 2025).

Nevertheless, BI literature remains underdeveloped and fragmented (Sohail *et al.*, 2023). In particular, the role of BIs in the CE context is still insufficiently explored, highlighting the need for research that informs adaptation of incubation programmes (e.g., Kambanou *et al.*, 2025; Klofsten *et al.*, 2024). Existing studies mainly assess conventional BIs' ability to support circular initiatives, often emphasizing structural and operational limitations, while dedicated analyses of CE-oriented BIs remain scarce. Similarly, research on circular start-ups is still emerging and requires further development (Suchek *et al.*, 2022).

To address these gaps, this study analyses a CE-oriented incubation model to identify key operational levers supporting circular entrepreneurship and the constraints limiting it. Accordingly, we defined the following research question:

RQ: How do CE-oriented BIs support incubated start-ups in the development of their business models?

2 Methodology

This research adopts a descriptive-exploratory single-case study design (Yin, 2018). The empirical context is Italy, a particularly suitable setting due to its advanced CE performance. Italy ranks among Europe's leaders, with a recycling rate of 72%, well above the EU average of 58% (Circular Economy Network, 2025). It also reports a circular material use rate of 20.8%, nearly double the European average of 11.8%. To ensure a high-standard context characterized by advanced incubation services, the selected BI was drawn from the list of Italian certified BIs recognized by the Ministry of Enterprises and Made in Italy and registered in the Business Register as of 26 November 2025.

Requirements to be a "certified" Business Incubator *Article 25, paragraph 5, of Italian Decree-Law No. 179 of October 18, 2012, converted with amendments by Law No. 221 of December 17, 2012*
• Availability of adequate facilities for hosting innovative start-ups, including spaces for testing, experimentation, or research • Presence of suitable equipment for start-up activities, such as ultra-broadband internet access, meeting rooms, and prototyping/testing machinery • Management by individuals with recognized expertise in business and innovation, supported by a permanent technical and managerial structure • Established collaborations with universities, research centres, public institutions, and innovation-oriented financial partners • Documented experience in supporting innovative start-ups

Figure 1: Legal requirements for qualification as certified BI (authors' elaboration)

Case selection followed a structured procedure. A systematic analysis of Italian certified BIs was conducted using triangulated data from official websites, internal documents, public reports, and press materials, with the aim of identifying organizations explicitly oriented toward the CE. The selected case is a public BI located in Northern Italy, hereafter referred to as a Green Business Incubator (GBI). Among Italian certified BIs, GBI is a distinctive benchmark as it is the only one explicitly and exclusively focused on green and CE principles since its inception.

Data collection relied on multiple sources to enhance methodological rigor and enable triangulation, thereby reducing potential bias and increasing the robustness of the findings (Bowen, 2009). Primary data were gathered through a semi-structured interview, lasting approximately one and a half hours, with a BI manager. Additionally, questionnaires are currently being administered to the incubated start-ups. To date, the survey has been completed by three incubated start-ups. Secondary data included publicly available documentation related to the BI and incubated start-ups, such as content from their official website, published reports, and relevant press articles.

3 Preliminary Results

3.1 A brief overview of GBI

GBI operates as *the "green hub"*, hosting firms in sustainability-related sectors and supporting circular start-ups. This specialization enables knowledge exchange, sector-specific networking, and shared cognitive frameworks among firms facing similar technological and regulatory constraints. Its role is embedded in a broader public policy strategy aimed not only at start-up creation but also at territorial development (e.g., Grimaldi and Grandi, 2005). GBI supports sustainability, renewable energy, circular production, resource efficiency, and environmental technologies, rather than a single niche: over-specialization could constrain entrepreneurial emergence in the regional system. Its mission is to implement a people-centred incubation model oriented to social value creation, supporting start-up growth and local development. A key feature is the co-location of early-stage start-ups with established innovative SMEs, generating mutual benefits: SMEs provide legitimacy, networks, and industrial linkages, while start-ups contribute innovation, experimentation, and flexibility.

GBI's selection process begins with evaluation of the start-up's mission, which must show a clear sustainability orientation. Projects must also align with regional development priorities, as admission decisions are embedded in territorial policy objectives. Territorial and infrastructural compatibility is also decisive. Start-ups involving heavy processing, emissions, hazardous materials, combustion processes, or large-scale logistics are excluded regardless of technological potential. Priority is given to initiatives aligned with local resource endowments; for example, regional hydropower tradition supports firms in energy management and renewable optimisation. In contrast, large-scale solar or wind projects are constrained by land availability and landscape protection rules. Finally, strong emphasis is placed on the entrepreneurial team (EO assessment) and long-term viability. Given the early-stage nature of applications, evaluation is forward-looking and interpretative, focusing on their potential. GBI's public mandate also allows greater risk tolerance than private BIs, enabling support for less mature but promising start-ups.

GBI incubation duration consists in four-year cycles, renewable if necessary. On average, start-ups remain for three to four years, while innovative SMEs may stay longer due to their ongoing ecosystem contribution.

3.2 GBI's Perspective on Challenges in Start-ups' Circular Business Models

From the perspective of GBI, and consistently with prior literature (e.g., Kanda *et al.*, 2024; Klofsten *et al.*, 2024; Lit *et al.*, 2024), circular start-ups encounter several recurring barriers, which GBI seeks to mitigate through targeted support services.

First, many start-ups experience difficulties in clearly articulating their value proposition in terms that are understandable to economic and institutional stakeholders. In several cases, early-stage circular initiatives tend to prioritise environmental or social objectives without adequately demonstrating their underlying economic feasibility. Translating environmental intent into tangible economic outcomes, such as resource recovery, cost reductions, or identifiable revenue streams, is therefore crucial. This translation enhances the credibility and readability of start-ups from a market perspective, thereby improving their ability to attract investment and easing the resource constraints that typically affect them.

A second challenge concerns market uncertainty. Highly innovative technologies rarely face pre-existing demand conditions and often require the deliberate creation of market legitimacy and acceptance.

Third, the lack of established circular supply chains represents a further constraint. The necessary inter-organisational connections are frequently absent and must therefore be actively developed by the start-ups themselves. As a result, start-ups are required not only to develop their own products or services but also to construct an ecosystem of actors who have not traditionally regarded specific waste streams as valuable economic inputs. This process entails continuous networking, brokerage, regulatory interpretation, and

negotiation with both public and private stakeholders, making business development closely intertwined with ecosystem building.

Finally, circular start-ups face significant structural complexity arising from regulatory frameworks governing supply chains. Even in cases where waste producers are willing to transfer materials at no cost, regulatory classifications and compliance obligations, such as permits for special waste, certified transport requirements, and administrative procedures, can significantly delay transactions. These constraints are often rooted in regulatory systems designed around disposal-oriented logics rather than reuse, thereby generating bureaucratic and procedural frictions despite the existence of clear economic incentives for material exchange.

3.3 GBI's service offering

3.3.1 Physical Infrastructure

GBI provides dedicated facilities through subsidised rental schemes well below market rates. In line with its public mandate, this generates immediate liquidity advantages for incubated firms, particularly early-stage start-ups with unstable revenues and limited financial buffers, by lowering fixed costs and extending their financial runway for experimentation.

Beyond cost savings, the infrastructure has a strong functional role. The BI offers an integrated package of services-utilities, security, logistics, maintenance, and mobility support-that reduces non-core operational burdens for resident firms. This decreases managerial complexity in early growth stages and limits coordination costs typically associated with independent site selection in industrial contexts, allowing start-ups to focus on product development, partner acquisition, and market testing.

In addition, the green campus environment enhances the symbolic legitimacy of hosted start-ups, strengthening their credibility with investors, public institutions, and strategic partners (e.g., Grilli and Marzano, 2023).

3.3.2 Business Development Support

A core element of GBI's incubation model is the structured provision of business development support through coaching and mentoring, aimed at transforming early-stage ideas into viable business models. This aligns with the importance of specialised mentoring in circular incubation contexts (Kanda *et al.*, 2024; Millette *et al.*, 2020), particularly for business model design and refinement (Bank and Kanda, 2016; Klofsten *et al.*, 2024).

A distinctive feature is its dual mentoring system, combining internal and external support. Each start-up is assigned an internal mentor ensuring continuity and acting as the main contact point with the BI. This is complemented by external mentors from academia, industry, and specialised sectors, selected based on start-up specific needs. While internal mentoring provides stability and oversight, external mentoring contributes specialised, domain-specific expertise, resulting in a hybrid and tailored support structure.

Support is also differentiated by start-up maturity. Many incoming start-ups, often research-based, have strong technological foundations but limited managerial capabilities for market translation. In early stages, support therefore focuses on core entrepreneurial skills, including business planning, value proposition design, customer segmentation, revenue model definition, and go-to-market strategies. This is particularly relevant for circular start-ups, where technical feasibility does not ensure commercial viability and value creation must align with value capture and stakeholder adoption conditions (e.g., Pieroni *et al.*, 2019).

As start-ups mature, support shifts from foundational training to validation-oriented assistance. Once core business elements are established, advisory activities focus on testing assumptions, refining business models, identifying market entry barriers, and strengthening commercial pathways. This is operationalised through *"Tractor"* programmes, targeting start-ups with a minimum viable product (MVP) but limited validation. Selected start-ups near market readiness receive structured guidance on validation strategies, early customer acquisition, and milestone definition, particularly for longer development cycles. Overall, business model development is treated as an iterative, evidence-based validation process rather than a static design activity.

Incubated start-ups perceive the support received has generally been adequate to address the main pre-entry competency gaps, which primarily concern commercial, managerial, financial, and regulatory aspects.

3.3.3 Financial Support

GBI acts as an intermediary between entrepreneurial projects and multiple funding sources, providing structured financial support instruments to enhance access to external capital. This is particularly relevant for CE initiatives, which often struggle to attract investment due to perceived long payback periods, uncertain demand trajectories, and complex value chains (Kahupi *et al.*, 2021; Kanda *et al.*, 2024).

Well-structured circular and sustainable start-ups are evaluated on comparable terms to conventional firms. In this context, the ability to clearly articulate business logic and scalability is crucial. Moreover, the increasing presence of ESG-oriented investors introduces actors willing to integrate sustainability into value assessment and accept longer investment horizons in exchange for measurable environmental and social impact, complementing more risk-averse non-ESG investors.

Start-ups receive support in preparing fundraising documentation. This helps founders, often focused on technological or environmental outcomes, understand how investors assess risk, milestones, scalability, and returns.

Start-ups are prepared for interactions with investors through structured activities aimed at refining pitch materials, clarifying strategic priorities, and emphasising investment-relevant business model aspects. GBI stages investor engagement only once sufficient organisational maturity is achieved, improving communication effectiveness and reducing reputational risk.

As public BI, tenants benefit from facilitated access to regional, national, and European programmes, which often co-finance prototyping and pre-market development, particularly in early-stage, pre-commercial phases.

Incubated start-ups highlight that this type of support is fundamental for their business model development. They report relying mainly on public funding and private investors, particularly venture capital.

3.3.4 Internationalization Support

Within GBI, support for internationalization is a core function. The process starts with an internal assessment to determine whether foreign market entry is strategically appropriate and operationally feasible. Before any external action, the BI conducts a diagnostic evaluation of target market attractiveness, organisational readiness, and unresolved structural weaknesses. Internationalisation is therefore not automatic but contingent on sufficient internal coherence. This screening is particularly relevant for circular start-ups, as foreign contexts differ significantly in regulatory regimes, waste management systems, energy infrastructures, procurement frameworks, and sustainability incentives (e.g., Chabowski *et al.*, 2025).

Once strategic alignment is established, support shifts to facilitation and network activation. GBI leverages its relational capital to connect start-ups with chambers of commerce, regional intermediaries, and institutional networks that help reduce entry barriers in unfamiliar markets. This brokerage function is especially critical for early-stage start-ups, which typically lack the legitimacy and reputation needed to independently develop international partnerships. Institutional ties thus partially compensate for limited reputational capital and reduce uncertainty in early foreign market entry phases (e.g., Kanda *et al.*, 2024).

3.3.5 Networking

A central component of GBI's incubation model is its structured networking strategy, which goes beyond informal interaction and is oriented toward intentional, goal-driven collaboration. The BI actively engages national and international technical and financial networks to identify partners supporting start-up development through technology transfer, open innovation, scaling, and access to funding. These networks are systematically leveraged to translate external capabilities into concrete opportunities for resident firms, mitigating resource and scaling constraints, particularly in CE contexts. In this regard, GBI fosters both external and internal innovation networks (e.g., Soetanto and Jack, 2013).

Externally, collaborations with large industrial groups enable start-ups to access technology transfer and challenge-based innovation projects. Through these channels, start-ups gain access to industrial infrastructure, specialised expertise, mentoring, and testing environments that would otherwise be inaccessible, while incumbents benefit from start-ups' innovative capacity. The BI acts as an intermediary, coordinating objectives, facilitating resource allocation, and overseeing project development. Partnerships with universities and research centres are also key, supporting the transformation of scientific knowledge and intellectual property into market-oriented solutions and enabling validation of entrepreneurial ideas. In addition, GBI's fosters links with governmental entities. As noted in Section 3.3.3, the BI also connects start-ups with public and private investor networks to facilitate access to financial resources.

Internally, collaboration among resident firms is reinforced by the coexistence of start-ups and more mature innovative SMEs. This proximity allows established firms to provide legitimacy, technical know-how, and relational capital, strengthening early-stage start-ups and improving overall ecosystem performance.

For circular start-ups in particular, these networking dynamics also support industrial symbiosis by enabling resource exchange opportunities, co-development activities, and collaborative use of materials among resident firms and industrial partners.

Incubated start-ups report a high perceived usefulness of networking services, both with external partners and with other tenants within the BI. Firms highlight GBI's strong commitment to fostering partnerships with

external actors (both established firms and start-ups), other incubated start-ups, universities and research centres, and public administrations. Start-ups also confirm GBI's active role in organising periodic networking events to facilitate connections with external partners, including both general and one-to-one formats. In addition, the BI supports participation in national and international trade fairs and sector-specific events. Co-working spaces are consistently regarded as important, as they enable both structured and spontaneous interactions among incubated start-ups.

Two out of three start-ups report having established collaborations with other tenants: one experienced no particular difficulty in forming such partnerships, while the other highlighted concerns related to the reluctance to share sensitive information, particularly regarding core technological developments.

Regarding external partnerships, two start-ups did not report significant difficulties, whereas one pointed to excessively slow decision-making processes among external partners compared to start-up requirements for timely decision-making. In this case, GBI played an important intermediary role in mitigating the issue.

Finally, one start-up reports engaging in industrial symbiosis collaborations, for which GBI played an active role in supporting their development.

3.4 Challenges in Developing a CE Incubation Model

The manager stresses that circular start-ups do not inherently require more intensive support than conventional start-ups, as the core incubation architecture remains broadly similar. However, supporting these initiatives has required GBI to address specific operational challenges and progressively develop additional technical and organizational capabilities.

A first challenge concerns infrastructural availability. When start-ups introduce highly sustainable and innovative technologies, patents or novel ideas alone are insufficient; adequate laboratories, dedicated spaces, and specialised equipment are often required to ensure safe and effective experimentation. GBI has therefore progressively developed the capacity to invest in and configure environments suitable for technically demanding innovation trajectories, particularly where experimentation involves non-standard production conditions.

A second challenge relates to business development support. When start-ups are led by highly specialized inventors, often researchers commercializing advanced patents, it becomes difficult to identify mentors capable of providing direct technological guidance, as founders may already possess rare domain-specific expertise. The BI has therefore expanded its mentor network over time to address highly specialized cases. In parallel, it has strengthened relationships with international investors able to provide external validation for highly uncertain circular projects.

Finally, institutional constraints stem from GBI's integration within a public organization. Because support must comply with formal procedures, public calls, ranking systems, and administrative verification processes, bureaucratic delays become a significant constraint (e.g., Von Bloh, 2021). As a result, decision-making is slower due to eligibility checks, appeals, and administrative procedures. This temporal mismatch is particularly critical as start-ups require rapid decisions, timely resource allocation, and managerial flexibility. Consequently, regulatory simplification is identified as a key policy priority.

4 Conclusions

From a theoretical perspective, the study contributes to the emerging literature on CE-oriented incubation by providing evidence on how such incubation models operate in practice, moving beyond conceptual definitions toward a functional understanding of how incubation processes are reconfigured to support regenerative business logics.

From a managerial perspective, the findings indicate that supporting circular start-ups requires incubation models that integrate specialised mentoring, enable collaborative linkages within the ecosystem, and foster investor readiness. More broadly, managers of traditional BIs should interpret circular incubation as an adaptive reconfiguration of existing incubation logics rather than a simple addition of sustainability-oriented services.

For policymakers, the results highlight the need to support both start-ups and BIs, strengthening incubation processes through targeted investments. They also underline the importance of developing sustainable innovation ecosystems that foster collaboration among actors, a critical condition in the CE context. Regulatory simplification remains essential, as administrative barriers continue to slow circular start-up development despite strong technological potential.

This research is still exploratory. Its main limitation is the single-case design and the fact that current evidence reflects primarily the BI perspective. In the future, we expect to obtain additional responses from recently administered questionnaires to incubated start-ups, further deepening the analysed topics through

interviews with founders and managers. Moreover, we plan to conduct further interviews with additional members of GBI's management team to gain broader insights and complementary perspectives on the topic.

Learning to Scale: What Mentoring Really Does for Startups

Luca Simone Macca[1], Alain Daou[1,2]

[2]Olayan School of Business, American University of Beirut, Lebanon

Abstract

This study examines how entrepreneurial mentoring interaction processes shape founders' interpretations and enactment of scalability during early venture development. While prior research has established that mentoring positively influences entrepreneurial outcomes, such as self-efficacy, opportunity recognition, and strategic decision-making, it has largely treated mentoring as an input and focused on its effects rather than the interactional mechanisms through which influence unfolds. At the same time, research on scalability has predominantly emphasised structural and organisational dimensions, overlooking how founders come to adopt, or resist, a scalability-oriented mindset. Addressing this gap, the present study conceptualises mentoring as a sensegiving–sensemaking process through which meanings of scalability are constructed, negotiated, and translated into action. The study draws on a qualitative multiple-case design involving five early-stage startups participating in a structured pan-European mentoring program. The analysis is based on twenty mentoring sessions, complemented by follow-up interviews and secondary data. This dataset enables an in-depth examination of how mentoring unfolds over time as an interactional process. The findings show that mentoring introduces a conceptualised scalability evaluative regime, which emerged as a set of externally oriented criteria that redefine what counts as legitimate progress, viable growth, and credible venture development. This regime operates by shifting attention toward investor-oriented metrics, reducing dependence on founder time, enforcing representational clarity, and emphasising narrative coherence and distribution channels. However, findings from the founders' perspective show that founders do not merely accept these criteria passively. Instead, they engage in boundary work, actively interpreting mentoring inputs through four recurring responses: acceptance, negotiation, identity-protective resistance, and deferral. These interaction dynamics give rise to three distinct scalability trajectories: (1) relabeling, where existing activities are reframed as evidence of scalability; (2) systematising, where ventures are restructured into bounded, repeatable systems; and (3) narrativising, where growth is pursued through strengthened positioning and legitimacy-building channels. The study demonstrates that scalability is not simply a structural capability but an interpretive accomplishment emerging through ongoing interaction. By shifting attention from outcomes to processes, this research contributes to entrepreneurship literature by integrating mentoring, entrepreneurial cognition, and scalability.

Keywords: Entrepreneurial mentoring; entrepreneurial learning; scalability; early-stage startups.

Paper type: Academic Research Paper

1 Introduction

In contemporary entrepreneurial ecosystems, early-stage ventures are increasingly exposed to strong pressures to demonstrate scalability, legitimacy, and investment readiness at very early stages of development (Stein et al., 2026; Spigel, 2017; Troise et al., 2022). Mentorship programs have emerged as a central mechanism through which startups are guided in navigating these pressures, particularly in accelerator- and university-affiliated settings (Eesley and Lee, 2021; Lall et al., 2023; Sarkar et al., 2019; Seitz et al., 2024). Prior research positions mentoring as a key mechanism through which early-stage founders gain access to experiential knowledge, strategic feedback, and social capital, thereby helping them cope with uncertainty and resource constraints (Yusubova & Knoben, 2025; Wu & Tsao, 2025). Empirical studies consistently show that founders value mentoring highly and often cite it as a primary reason for participating in structured support programs (Kirsch et al., 2025; Yusubova & Knoben, 2025).

The dominant stream of mentoring research adopts an outcome-oriented perspective. Quantitative, experimental, and survey-based studies link mentoring to outcomes such as entrepreneurial self-efficacy, opportunity recognition, strategic goal attainment, and major strategic decisions including pivoting (Kirsch et al., 2025; Pereyra et al., 2021; St-Jean and Tremblay, 2020). Recent work further demonstrates that the framing of mentor feedback matters, showing that concrete feedback increases the likelihood that entrepreneurs act on advice compared to more abstract guidance (Welbourne & Miller, 2026). While these studies establish that mentoring can influence entrepreneurial behaviour, their findings are often context-dependent, and similar mentoring interventions frequently produce heterogeneous outcomes across ventures.

To address these limitations, a growing body of research conceptualises mentoring as a relational and cognitive process embedded in ongoing interaction. For example, drawing on socially situated cognition and sensemaking perspectives, Kaffka et al. (2021) highlight how feedback from mentors and other stakeholders can

disrupt entrepreneurs' existing assumptions and trigger new sensemaking through reframing, questioning, and reinterpretation. Process-oriented studies of entrepreneurial learning similarly show that entrepreneurs dynamically shift between exploratory and exploitative learning strategies in response to uncertainty and feedback, with learning trajectories shaped by situational conditions and interactional contexts (El-Awad, 2023; McKevitt and Marshall, 2015). A similar stream of research on sustainability-driven enterprises further demonstrates that entrepreneurs engage in different patterns of sensemaking depending on the ambiguity and urgency of the issues they face (Zeng et al., 2026).

Despite these advances, mentoring interactions themselves remain underexplored. Most studies rely on retrospective accounts, experiments, or surveys, rather than examining mentoring interactions as they unfold over time. This aspect follows an evident need to investigate and learn more about how the mentor-mentee relationship transforms in scalability and business model transformation. While research on scaling, pivoting, and platform growth identifies key drivers of venture growth and strategic reorientation (Granot et al., 2026; Macca et al., 2025; Nagy et al., 2025), it largely focuses on outcomes rather than on how founders learn to think in scalable terms. This lack of knowledge is especially evident for early-stage ventures, where scalability requires cognitive, strategic, and identity transformations (Liu et al., 2026; Somaya and You, 2024). In this regard, the literature points to a need for longitudinal, interaction-level research that examines how mentoring shapes founders' sensemaking and scalability thinking over time.

Building on the above literature, this study conceptualises mentoring as an interactional process through which meanings about venture development are constructed, negotiated, and enacted. Specifically, it explores how mentoring interactions influence how founders interpret and operationalise scalability during early venture development. Drawing on a qualitative multiple-case study of five startups participating in a pan-European mentoring program, this study analyses twenty mentoring sessions to uncover how mentors introduce evaluative criteria and how founders respond to them over time. Each startup was supported through multiple semi-structured mentoring sessions, generating a rich dataset of recorded and transcribed interactions that captures both mentor interventions and founder responses as they unfolded. Data collection was also supported by documentary and observational evidence (e.g., mentoring policy statements, guidelines and procedures, company websites and business plans), which were useful in validating the startup's development phase and identifying milestones.

Our preliminary findings show that: (1) mentoring consistently installed what we conceptualise as a scalability evaluative regime. Through repeated interactions, mentors introduced external evaluative criteria aligned with investor, partner, and market expectations, thereby shifting attention away from internally meaningful indicators such as effort, creativity, or early traction; (2) founders did not respond uniformly to this evaluative regime: instead, they engaged in active sensemaking and boundary work as they interpreted and translated mentoring input into action; (3) over successive interactions, these sensemaking responses stabilised into three distinct emergent scalability trajectories (i.e., relabeling trajectory, systematising trajectory, narrativising trajectory), which illustrate that scalability is not a singular outcome but an emergent process shaped by how evaluative criteria are enacted in practice.

The contribution of this study is threefold. First, it advances entrepreneurial mentoring research by providing a more nuanced understanding of why similar mentoring interventions can produce heterogeneous results across ventures. It highlights the cognitive and relational mechanisms through which scalability is constructed and offers insights into how mentoring influences strategic orientation in early-stage startups. Second, it contributes to the entrepreneurship and scalability literature by showing that scalability emerges through multiple trajectories rather than converging on a single dominant model. Third, it offers practical implications for the design of mentorship and accelerator programs by highlighting the unintended consequences of evaluative regimes and the importance of recognising founder sensemaking dynamics.

2 Theoretical Background

Entrepreneurial mentoring is widely recognised as a core component of entrepreneurial ecosystems, providing founders with access to knowledge, networks, and legitimacy (Pauwels et al., 2015). Within accelerators and incubators, mentoring functions as a key mechanism through which ventures receive strategic guidance and validation (Cavallo et al., 2025; Seitz et al., 2024). Prior research has linked mentoring to improved entrepreneurial outcomes, including enhanced self-efficacy and opportunity recognition (Baluku et al., 2019; Kirsch et al., 2025).

However, much of this literature treats mentoring as an input and evaluates its effectiveness through measurable outcomes, leaving underexplored the interactional processes through which mentoring exerts influence. Recent studies have begun to reconceptualise mentoring as a relational and cognitive process

embedded in ongoing interaction (Bergman & McMullen, 2022; Kaffka et al., 2021). In this view, mentors act as sensegivers who introduce evaluative perspectives, while founders engage in sensemaking processes that shape how these inputs are interpreted and enacted.

This perspective aligns with broader research on entrepreneurial learning, which emphasises that cognition evolves through interaction with external actors and feedback (El-Awad, 2023; Lynch & Corbett, 2023). Founders interpret mentoring advice through the lens of their prior experiences, identity, and contextual constraints, which explains variation in responses to similar mentoring interventions (Kirsch et al., 2025). Thus, mentoring effectiveness depends not only on the quality of advice but also on how it is interpreted and negotiated in interaction.

Scalability has become a central evaluative concept in entrepreneurship, particularly in technology-driven and high-growth ventures (Coviello et al., 2024). It is commonly defined as the ability to expand output or market reach without proportional increases in costs or resources (Nielsen & Lund, 2018). Achieving scalability requires alignment between technological infrastructure, organisational design, and business model logic (Granot et al., 2026; Nagy et al., 2025).

Existing research primarily examines scalability as a structural or organisational capability, focusing on business model innovation, experimentation, and ecosystem dynamics (Foss & Saebi, 2018; Sanasi, 2023). While these studies provide valuable insights into the drivers of growth, they tend to overlook the cognitive processes through which founders come to adopt a scalability-oriented mindset.

Importantly, scalability is also an evaluative construct shaped by expectations from investors, mentors, and markets (Cavallo et al., 2025). Founders must interpret these expectations and translate them into strategic decisions, often navigating tensions between short-term survival and long-term growth (Wu & Tsao, 2025). This interpretive dimension of scalability remains underexplored.

Bringing together these perspectives highlights an important gap: while mentoring research emphasises outcomes and scalability research emphasises structure, neither fully explains how founders come to interpret and enact scalability through interaction. Mentoring introduces evaluative criteria that define what constitutes a scalable venture, but founders actively negotiate these criteria rather than simply adopting them.

This study addresses this gap by conceptualising mentoring as a process through which a scalability evaluative regime is introduced and interpreted over time. This perspective enables a process-level understanding of how mentoring influences entrepreneurial cognition and how different scalability trajectories emerge from interaction dynamics.

3 Methodology

To investigate how mentoring interactions influence founders' interpretations of scalability, this study adopts a qualitative multiple-case study design. This approach is particularly suitable for examining processual phenomena and capturing the complexity of interaction dynamics over time (Eisenhardt, 1989; Yin, 2014). Unlike survey-based or experimental studies, which focus on outcomes, this design allows for in-depth analysis of how mentoring unfolds in practice. An inductive theory-building approach (Eisenhardt & Graebner, 2007; Glaser & Strauss, 1967) was employed, given the exploratory nature of our research and the limited prior theory explaining how mentoring influences interpretations of scalability (Goffin et al., 2019). By analysing multiple mentoring sessions across different ventures, the study captures both recurring patterns and meaningful variations in interaction processes.

The empirical setting consists of a structured mentoring program within a pan-European entrepreneurial support initiative. The program involved collaboration between higher education institutions, accelerators, and research organisations, providing a diverse and institutionally rich context for mentoring interactions. Five early-stage startups were selected using purposive sampling to ensure variation in business models, sectors, and developmental stages. This diversity allowed for theoretical replication and facilitated comparison across different contexts in which scalability might be interpreted differently. Each startup participated in four mentoring sessions over a three-month period, resulting in a dataset of twenty sessions. Mentors were drawn from a pool of thirteen individuals with diverse backgrounds, including entrepreneurs, investors, consultants, and academics. This diversity introduced variation in evaluative perspectives and enriched the interaction dynamics.

The primary data consist of audio and video recordings of mentoring sessions, which were transcribed and analysed. These recordings capture real-time interactions, including questions, feedback, disagreements, and moments of alignment. This level of detail enables a nuanced understanding of how mentoring unfolds as an interactional process. To complement the primary data, secondary materials were collected, including venture

documents, pitch decks, and publicly available information. Follow-up interviews were also conducted to clarify interpretations and gain additional insights into founders' perspectives.

Data were analysed inductively using grounded theory and Gioia methodology principles (Gioia et al., 2013). The analysis progressed from first-order coding to second-order themes and aggregate dimensions (Strauss & Corbin, 1990). Three key dimensions emerged: (1) the introduction of a scalability evaluative regime, (2) founder sensemaking as boundary work, and (3) emergent scalability trajectories.

4 Preliminary Results

The preliminary findings of this study indicate that entrepreneurial mentoring exerts a structured yet dynamic influence on how founders interpret and enact scalability during early venture development. Rather than functioning as a simple transfer of knowledge, mentoring interactions consistently introduce what can be conceptualised as a scalability evaluative regime, a set of externally oriented criteria that redefine how venture progress, viability, and legitimacy are assessed.

A first key insight concerns how mentoring reframes legitimacy. Across cases, mentors systematically shifted founders' attention away from internally meaningful indicators of progress, such as effort, creativity, or early traction, toward externally evaluable signals aligned with investor and market expectations. This included emphasising the distinction between activity and scalability, particularly highlighting the limitations of revenue streams dependent on founder time. Founders were encouraged to demonstrate that value creation could persist independently of their direct involvement, thereby repositioning scalability as a prerequisite for legitimacy rather than a future aspiration.

A second important finding relates to the quantification of viability. Mentoring interactions repeatedly foregrounded the importance of metrics such as customer acquisition cost, lifetime value, and measurable value propositions. Rather than treating metrics as optimisation tools, mentors framed them as gatekeeping mechanisms that determine whether a venture can be considered scalable. This introduced a shift from intuitive or narrative-driven reasoning toward evidence-based evaluation. Notably, pilots and early experiments were reframed as measurement infrastructures designed to generate quantifiable proof of value, reinforcing the expectation that scalability must be demonstrated rather than assumed.

A third insight concerns the enforcement of representational discipline. Mentors consistently challenged founders to translate broad visions into concrete, bounded representations, such as clearly defined use cases, system architectures, and investor-facing artefacts. This process reduced ambiguity and increased the legibility of ventures to external audiences. Founders were required to move from abstract descriptions of "platforms" or "solutions" to detailed explanations of how their systems function in practice. This emphasis on clarity suggests that scalability is not only a structural or operational challenge but also a representational one, dependent on how effectively ventures can be communicated and evaluated.

A fourth finding highlights the role of narrative and channels in scaling. Mentors emphasised that scalability depends on the ability to articulate a clear and compelling value proposition and to position the venture within credible distribution channels. In particular, narrative clarity was framed as a mechanism for growth, enabling ventures to be understood quickly by external stakeholders. Similarly, access to established platforms and intermediaries was presented as a means of "borrowing legitimacy," reinforcing the relational nature of scalability within entrepreneurial ecosystems.

Importantly, founders did not respond uniformly to these evaluative pressures. Instead, they engaged in ongoing sensemaking processes characterised by boundary work. Some founders accepted mentoring frames and rearticulated their ventures accordingly, adopting investor-oriented language and reframing existing activities as scalable evidence. Others negotiated these frames by adapting them to local market conditions or operational constraints, resulting in partial adoption. In certain cases, founders resisted mentoring inputs when they conflicted with core identity commitments, such as maintaining a boutique brand or preserving personalised service delivery. Finally, some founders deferred the integration of scalability criteria, prioritising immediate survival concerns and postponing evaluation to later stages.

These varied responses gave rise to distinct scalability trajectories. The relabeling trajectory involved reframing existing activities to align with scalability expectations without substantial structural change. The *systematising trajectory* entailed simplifying and formalising operations into reusable and scalable systems. The *narrativising trajectory* focused on strengthening brand coherence and leveraging channels to enhance legitimacy and growth. Together, these findings demonstrate that scalability emerges not as a uniform outcome but as a negotiated and interactionally constructed process shaped by mentoring dynamics.

5 Conclusions

This study contributes to entrepreneurship research by shifting the focus from mentoring outcomes to interaction processes. It demonstrates that mentoring influences entrepreneurial cognition through sensegiving–sensemaking dynamics rather than direct advice adoption. It also extends research on entrepreneurial cognition by highlighting the role of boundary work in interpreting external inputs (Kaffka et al., 2021).

Furthermore, the study contributes to scalability research by conceptualising scalability as an interpretive accomplishment rather than solely a structural capability. This perspective complements existing work on business model dynamics and growth (Macca et al., 2025).

For mentors, the findings emphasise the importance of making evaluative criteria explicit and recognising variation in founder interpretation. For support organisations, mentoring should be designed as an iterative process allowing reflection and adaptation. For policymakers, mentoring programs should incorporate diverse perspectives to support varied venture trajectories.

Overall, the study demonstrates that scalability is not merely a structural outcome but a socially constructed orientation emerging through interaction. By integrating mentoring, entrepreneurial cognition, and scalability, it provides a comprehensive explanation of how early-stage ventures navigate growth within entrepreneurial ecosystems.

Accounting-Mediated Knowledge Management in Agrifood Supply Chains: Insights from Participant Observation on How Quality, Traceability and Cost Knowledge is Produced and Coordinated

Gaetano Rago
University of Salerno, Fisciano, Italy

Abstract

Agrifood supply chains are characterised by high levels of complexity, biological variability and increasing regulatory and societal pressures for transparency, traceability and sustainability. In such contexts, knowledge management (KM) plays a critical role in enabling coordination among heterogeneous actors, including farmers, processors, quality managers, accountants and auditors. However, existing literature has largely conceptualised KM in supply chains in abstract terms, focusing on information sharing and integration, while paying limited attention to the everyday practices through which knowledge is produced, translated and made actionable.

This study addresses this gap by examining how knowledge is managed in practice within an agrifood supply chain and by exploring the role of accounting and auditing artefacts in mediating this process. Drawing on an ethnographic research design based on one year of participant observation within a large Italian agrifood processing firm and its network of partners, the study provides a fine-grained analysis of the micro-practices through which knowledge is transformed into organizationally relevant forms.

The findings show that knowledge management is not a linear process of data transfer, but a situated and ongoing accomplishment. Three key mechanisms are identified. First, translational practices convert tacit and experiential knowledge into standardized categories and inscriptions, such as quality classifications, traceability records and cost analyses. Second, accounting and auditing artefacts operate as boundary objects that enable coordination across different communities of practice while shaping visibility and accountability. Third, governance routines, including audits, meetings and performance reviews, serve as arenas in which knowledge claims are validated and stabilised.

The study contributes to knowledge management literature by demonstrating that knowledge conversion is materially mediated by calculative and documentary practices. It also extends accounting research by showing that accounting functions as a knowledge infrastructure linking quality, traceability, cost and sustainability. Overall, the paper advances an accounting-mediated view of KM, highlighting the central role of accounting and auditing artefacts in making knowledge visible, credible and actionable in complex agrifood supply chains.

Keywords: Knowledge management; agrifood supply chains; accounting artifacts; Management accounting; ethnography.

Paper type: Academic Research Paper

1 Introduction

Agrifood supply chains represent one of the most complex and highly regulated organizational fields in contemporary economies. Their complexity stems from the interplay between biological processes, environmental variability, and socio-economic constraints, combined with increasing demands for food safety, traceability, and sustainability (Trienekens *et al.*, 2012; Busch, 2011). Unlike industrial supply chains, which are typically characterized by standardization and predictability, agrifood systems must continuously adapt to uncertain production conditions, product perishability, and fluctuating demand patterns. In such a context, Knowledge Management (KM) becomes central to understanding how dispersed competencies are generated, translated, and mobilized across the supply chain (Corso et al., 2010).

A significant portion of the knowledge circulating within agrifood systems is tacit and deeply embedded in practice. Assessments of field conditions, agronomic decisions, product freshness, and production constraints largely rely on professional judgment and locally situated experience (Wenger, 1999). However, such knowledge cannot easily traverse organizational boundaries unless it is translated into forms that are mobilizable within decision-making processes. Existing literature on supply chain management has extensively emphasized the importance of information sharing and integration as drivers of performance (Mentzer *et al.*, 2001; Hult *et al*, 2007). Similarly, studies on inter-organizational relationships have highlighted the role of trust, collaboration, and governance mechanisms in facilitating coordination (Fawcett *et al*., 2008; Caglio and Ditillo, 2008). However, these perspectives often conceptualise knowledge in relatively abstract terms, focusing on systems,

technologies, or formal agreements, while overlooking the everyday practices through which knowledge is produced, negotiated, and made actionable.

This gap is particularly evident in accounting research. While management accounting has increasingly been recognized as a key mechanism for coordinating inter-firm relationships (Mouritsen and Thrane, 2006; Caglio and Ditillo, 2008), limited attention has been paid to how accounting artefacts mediate knowledge flows in complex supply chain settings. Yet, in agrifood contexts, many of the objects through which coordination is achieved, such as traceability records, quality indicators, and cost reports, are inherently accounting-based or accounting-mediated. These artefacts do not simply represent reality; they actively construct it by defining categories, establishing comparability, and allocating responsibility (Miller, 2020).

The increasing emphasis on sustainability and ESG disclosure further intensifies these dynamics.

Agrifood firms are now required to demonstrate not only economic performance but also environmental and social impacts, thereby expanding the scope of knowledge that must be produced, validated, and communicated (Gray, 2010; Burritt and Schaltegger, 2010). This raises critical questions about how different forms of knowledge are integrated and governed across organizational boundaries.

Building on these considerations, the research question guiding this study is as follows: *how is knowledge managed through everyday practices within an agrifood supply chain, and what role do accounting and auditing artifacts play in translating and legitimising knowledge among heterogeneous actors?*

To answer this question, the study adopts an ethnographic approach based on one year of participant observation within a large processing firm and its supply network. By focusing on micro-level practices, the research seeks to uncover the "invisible work" through which knowledge is transformed into actionable organizational facts, shedding light on the situated processes through which coordination is practically accomplished.

The remainder of the paper is organised as follows. The next section develops the theoretical framework by integrating KM perspectives on tacit and explicit knowledge conversion (Nonaka, 1994) and communities of practice (Wenger, 1999). The methodology section outlines the ethnographic research design and analytical approach. The results and discussion section examines the mechanisms through which accounting and auditing artifacts mediate KM practices and elaborates on their implications. Finally, the concluding section discusses the limitations of the study and suggests avenues for future research.

2 Theoretical Framework

KM has been widely recognised as a critical driver of organizational effectiveness, particularly in contexts characterised by uncertainty, interdependence, and distributed expertise (Grant, 1996; Nonaka, 1994). In supply chain environments, knowledge is inherently fragmented across multiple actors, each possessing distinct capabilities, interests, and interpretive frameworks. This fragmentation is especially pronounced in agrifood supply chains, where biological variability, environmental uncertainty, and regulatory pressures require continuous coordination among heterogeneous stakeholders (Trienekens *et al.*, 2012). In such contexts, KM cannot be reduced to the mere exchange of information; rather, it involves the ongoing production, translation, and validation of knowledge that is both locally situated and organizationally actionable.

Nonaka's (1994) theory of knowledge creation provides a foundational lens for understanding these dynamics. The SECI model conceptualises knowledge as emerging from the interaction between tacit and explicit dimensions, emphasising processes of socialisation, externalisation, combination, and internalisation. In agrifood supply chains, this interplay is particularly salient, as much of the relevant knowledge, such as farmers' experiential understanding of cultivation conditions or quality inspectors' sensory assessments, remains tacit and embedded in practice. For such knowledge to travel across organizational boundaries, it must be externalised and transformed into standardized representations that can be communicated, compared, and acted upon. This process is not merely technical but inherently social and interpretive, involving negotiation and sensemaking among actors with different perspectives (Boland and Tenkasi, 1995).

Wenger's (1999) concept of communities of practice further enriches this perspective by highlighting the situated and collective nature of knowing. Knowledge is not simply possessed by individuals but enacted through participation in shared practices. Agrifood supply chains can thus be understood as constellations of overlapping communities of practice (farmers, agronomists, quality managers, procurement specialists, accountants), each with its own norms, languages, and evaluative criteria. Coordination across these communities requires mechanisms that enable alignment without erasing differences, allowing actors to collaborate despite divergent forms of expertise. Prior research has shown that such inter-organizational knowledge sharing can generate significant performance benefits (Hult *et al.*, 2007; Dyer and Nobeoka, 2000), but it is also fraught with challenges related to trust, power asymmetries, and cognitive distance (Fawcett *et al.*, 2008).

Within this complex landscape, accounting emerges as a central yet often under-theorised mechanism for mediating knowledge. Moving beyond its traditional representational view, accounting has increasingly been conceptualised as a performative practice that actively shapes organizational realities (Hopwood, 2013).

Calculative devices, such as cost reports, performance indicators, traceability records, and sustainability metrics, do not merely capture pre-existing phenomena; they construct them by defining categories, establishing comparability, and structuring attention. In doing so, accounting contributes to determining what is considered relevant, credible, and actionable knowledge within and across organizations.

This performative role is particularly evident in inter-organizational settings, where shared understandings cannot be taken for granted. Research on management control in inter-firm relationships has highlighted how accounting systems facilitate coordination by providing common metrics and evaluation frameworks (Caglio and Ditillo, 2008). Mouritsen and Thrane (2006) argue that accounting acts as a mediating instrument that enables collaboration while simultaneously embedding governance structures and power relations. In supply chains, accounting thus operates as both a coordinating and a disciplining mechanism, enabling alignment while shaping the distribution of responsibilities and decision rights.

The concept of boundary objects (Star and Griesemer, 1989) offers a particularly useful lens for understanding how accounting artefacts perform this mediating role. Boundary objects are artefacts that are sufficiently robust to maintain a common identity across different social worlds, yet flexible enough to accommodate diverse interpretations. In agrifood supply chains, artefacts such as traceability documents, quality standards, cost analyses, and audit reports function as boundary objects that enable coordination among heterogeneous actors. These artefacts allow different communities of practice to interact and align their activities without requiring full consensus, thereby supporting cooperation in contexts characterised by epistemic diversity. At the same time, they embed specific assumptions and priorities, influencing how problems are framed and how solutions are evaluated.

The increasing emphasis on traceability and sustainability further expands the scope of these dynamics. Traceability systems, initially developed to ensure food safety and regulatory compliance, have evolved into broader infrastructures for transparency and accountability (Trienekens *et al.*, 2012). They generate detailed data on product origins, production processes, and logistical flows, enabling organizations to monitor and communicate information across the supply chain. Simultaneously, the rise of sustainability accounting has extended the boundaries of what is measured and reported, incorporating environmental and social dimensions alongside economic performance (Burritt and Schaltegger, 2010; Gray, 2010). In agrifood contexts, this includes issues such as resource use, emissions, labour conditions, and ethical sourcing.

The integration of these diverse knowledge domains introduces significant challenges, as different stakeholders may hold divergent expectations regarding what constitutes relevant and legitimate knowledge. Regulators, certification bodies, consumers, and supply chain partners often demand different forms of evidence, leading to potential tensions and trade-offs. As a result, organizations must develop mechanisms to translate, align, and legitimise multiple forms of knowledge, ensuring that they are simultaneously credible, comparable, and operationally useful. Accounting and auditing artefacts play a crucial role in this process, as they provide the infrastructures through which such knowledge is stabilised and rendered auditable. Building on these perspectives, this study conceptualises agrifood supply chains as “knowledge ecologies” in which multiple forms of knowledge interact through a combination of social practices and calculative infrastructures. Within this ecology, accounting is not merely a supporting tool but a central mediating mechanism that enables the translation, circulation, and validation of knowledge across organizational boundaries. By focusing on the everyday practices through which these processes unfold, the study advances an accounting-mediated view of KM, highlighting the constitutive role of calculative artefacts in shaping coordination, accountability, and decision-making in complex supply chain environments.

3 Methodology

The study adopts a qualitative research design based on participant observation as an ethnographic field research approach (Spradley, 1980). This approach is particularly suitable for investigating everyday practices, informal coordination and the situated use of accounting and auditing artefacts in organizational life (Ahrens and Chapman, 2006). The empirical investigation was conducted from September 2024 to September 2025 within a large Italian agrifood processing firm and involved the observation of its interactions with selected upstream and downstream partners. The researcher was immersed in key organizational settings, including procurement planning, quality control, production scheduling, sustainability practices, audit preparation and performance review meetings. This allowed the study to capture both routine activities and critical episodes, such as quality deviations, traceability issues and supplier negotiations.

The researcher adopted the role of participant observer, combining direct involvement in the field with continuous analytical distance. This position enabled close access to everyday interactions, informal exchanges and documentary practices that would have been difficult to capture through interviews alone. At the same time, the researcher maintained a reflexive stance, recording not only observed practices but also contextual interpretations and potential effects of their own presence in the field. Informed consent was requested from the organization and from the actors involved in the research process. Confidentiality and anonymity were ensured by removing identifying details concerning individuals, the firm and its supply chain partners.

Data collection relied on three main sources: participant observation, informal conversations and documentary analysis. Fieldnotes were written throughout the research process to record observed interactions, contextual details and emerging interpretations (Emerson *et al.*, 2011). Informal conversations with managers, quality technicians, procurement officers, controllers and other organizational actors helped clarify the meaning of observed practices and reconstruct the rationale behind everyday decisions (Musante and DeWalt, 2010). In addition, the analysis considered relevant artefacts, including quality reports, traceability records, audit checklists, dashboards, cost and margin analyses and sustainability-related documentation.

Data analysis followed an iterative and abductive logic, moving between empirical material and theoretical concepts. Particular attention was given to critical episodes in which knowledge was contested, negotiated or stabilised. The analysis was informed by concepts such as knowledge conversion (Nonaka, 1994), communities of practice (Wenger, 1998), boundary objects (Star and Griesemer, 1989) and the performative role of accounting, while remaining grounded in the empirical material.

The methodological design also presents limitations. First, the study is based on a single organizational setting, which limits statistical generalisation. Second, participant observation may be influenced by the researcher's position, interpretations and access to specific situations. Third, some informal exchanges and sensitive organizational dynamics may have remained only partially visible. Nevertheless, prolonged field engagement, triangulation across multiple data sources and reflexive interpretation strengthened the credibility of the analysis and supported a rich understanding of how accounting and auditing artefacts mediate knowledge management in practice.

To enhance the methodological rigour, the study combined prolonged field engagement, triangulation across multiple data sources and reflexive interpretation. Although the ethnographic design limits statistical generalisation, it provides a rich understanding of the micro-practices through which accounting and auditing artefacts mediate KM in agrifood supply chains.

4 Results and Discussion

The ethnographic evidence shows that knowledge management within the observed agrifood supply chain is not enacted through the linear transfer of information, but through situated practices in which heterogeneous forms of knowledge are progressively translated, stabilised and made actionable. In line with the theoretical framework, the supply chain operates as a "knowledge ecology" in which multiple communities of practice interact and where accounting and auditing artefacts play a central mediating role. Knowledge moves from tacit, local and experiential forms to explicit, standardised and auditable representations; however, this movement is neither neutral nor automatic, as it is shaped by calculative practices, documentary requirements and governance routines.

A first finding concerns the translation of tacit knowledge into organisational facts. Observations in the receiving area and during quality inspections show that product evaluation initially relies on embodied and sensory judgement. Quality technicians assess colour, consistency, defects and freshness through experience-based evaluation before any formal classification is entered into the system. As one technician explained during an informal conversation, "you understand certain things before writing them down, but if they are not written down, they do not exist for the rest of the company". This statement captures a central feature of the observed setting: tacit knowledge becomes organisationally relevant only when it is translated into a recognised category, such as a quality grade, a deviation report or a traceability entry.

For example, a batch described informally as "*not uniform*" during initial inspection became actionable only once it was codified as a quality deviation within the inspection sheet. Once documented, the assessment could travel beyond the receiving area and be used by procurement to discuss supplier performance, by production to adjust processing decisions and by accounting to evaluate yield and cost implications. This pattern resonates with Nonaka's (1994) notion of knowledge conversion, but the findings refine it by showing that externalisation is not merely cognitive or communicative. It is materially mediated by artefacts that impose specific formats, categories and thresholds on knowledge. Accounting and quality-related documents therefore act as translation

devices: they make tacit knowledge mobile, but they also reshape it according to managerial, regulatory and economic logics.

A second finding concerns the role of accounting and auditing artefacts as boundary objects. Traceability records, quality reports, cost analyses and audit checklists were repeatedly mobilised by actors belonging to different communities of practice. Their value did not lie in producing a single interpretation, but in allowing different actors to coordinate around a shared object. During one traceability review, the same file was used by the quality manager to verify compliance, by the production planner to reconstruct batch sequences, by procurement to check supplier codes and by administrative staff to assess whether the documentation would be sufficient in case of a customer claim. As one manager noted informally, "*the same document speaks different languages depending on who is reading it*".

This finding supports the concept of boundary objects developed by Star and Griesemer (1989). The traceability file remained stable enough to coordinate action while flexible enough to accommodate different professional concerns. However, the fieldwork also shows that such artefacts are not neutral. They privilege what can be documented, measured and audited. What is recorded becomes defensible; what remains experiential becomes more fragile. This dynamic was evident in several informal conversations, where actors repeatedly emphasised that "*knowing is not enough; you must be able to prove it*". Accounting and auditing artefacts therefore enable coordination, but they also structure visibility, legitimacy and accountability.

A third finding relates to the performative role of accounting in reframing organisational issues. During performance review meetings, technical and operational problems were frequently translated into economic terms through cost and margin analyses. Variability in raw material quality, initially discussed as an agronomic or production issue, became a matter of yield loss, increased unit cost and margin pressure once represented in financial reports. In one observed discussion, the production manager explained the slowdown of the line by referring to the variability of incoming raw material. When the controller presented the corresponding cost impact, the discussion shifted. As one participant commented after the meeting, "*when the number appears, the problem changes level*".

This episode illustrates the performative role of accounting. The margin analysis did not merely describe an operational issue; it altered its organisational relevance. Once translated into cost and margin effects, the issue became more visible to senior management and more likely to generate corrective action. This supports the view of accounting as a calculative practice that shapes organisational attention, relevance and accountability (Hopwood, 1987). At the same time, the findings show the ambivalence of this process: accounting makes problems governable, but it may also narrow attention to what can be economically quantified.

A fourth mechanism concerns governance routines. Meetings, audits, performance reviews and informal cross-functional interactions were the arenas in which knowledge claims were tested, negotiated and stabilised. Documents alone did not produce certainty. They had to be interpreted, questioned and connected to situated explanations. During audit preparation, for instance, the quality team did not simply collect evidence; it reconstructed sequences of events, checked dates, compared forms and added explanations to make the documentation intelligible to external evaluators. As one quality manager observed, "*the auditor does not only want the document; they want to understand the story behind the document*".

This finding is particularly important because it shows that auditability is not equivalent to data availability. Auditability requires coherence, chronology and credibility. The organisation must be able to demonstrate not only that procedures were followed, but also that events can be reconstructed in a plausible and verifiable way. Governance routines therefore function as sites of knowledge validation, where documentary evidence and situated explanations are brought together. This extends Wenger's (1998) view of knowing as socially embedded by showing that, in regulated supply chains, knowledge becomes legitimate through collective practices of verification and justification.

Finally, the analysis shows that sustainability knowledge entered the supply chain through the same accounting-mediated mechanisms. Sustainability was not observed as a separate domain detached from operational and accounting practices. Rather, it appeared in supplier evaluation, quality standards, certifications, customer requirements and cost discussions. In one informal conversation, a procurement manager stated that "*price is no longer the only variable; now every supplier also brings a documentation burden*". Similarly, a controller noted that "*sustainability requirements always arrive with a cost implication, even when they are presented as values*".

These observations suggest that sustainability, quality, traceability and cost are not separate knowledge domains in practice. They are bundled together and made governable through the same calculative and documentary infrastructures. A supplier decision may simultaneously concern origin, certification, price, reliability and environmental or social requirements. This confirms that sustainability accounting expands the

scope of organisational knowledge beyond traditional financial performance (Gray, 2010; Burritt and Schaltegger, 2010), while also showing that such expansion must be integrated into existing routines of calculation, documentation and accountability.

Overall, the findings suggest that transparency in agrifood supply chains is not produced simply by collecting more information. It is a practical accomplishment generated through translation, documentation, discussion and validation. Traceability systems and accounting reports provide the infrastructure, but transparency emerges only when actors can connect inscriptions to events, explanations and responsibilities. In this sense, knowledge management in agrifood supply chains is fundamentally accounting mediated. Accounting and auditing artefacts stabilise knowledge, make it transferable across communities of practice, and define the conditions under which it becomes visible, credible and actionable.

Theoretically, the study contributes to KM literature by showing that knowledge conversion in supply chains is materially mediated. While Nonaka's (1994) framework explains the movement between tacit and explicit knowledge, and Wenger's (1998) communities of practice illuminate the social embeddedness of knowing, this study shows that knowledge becomes actionable through accounting and auditing artefacts that format and legitimise it. The study also contributes to accounting research by extending the role of accounting in inter-organizational relationships. Prior studies show that accounting supports coordination and control across firm boundaries (Mouritsen *et al*., 2001; Caglio and Ditillo, 2008). This study adds that accounting also operates as a knowledge infrastructure, linking operational events, traceability, sustainability and financial consequences.

Practically, for managers the findings indicate that improving knowledge management in agrifood supply chains does not simply mean introducing more sophisticated digital tools or increasing the quantity of data collected. It requires designing routines and artefacts that support meaningful translation across professional communities. Quality reports, cost analyses, traceability records and sustainability indicators should be treated as interconnected devices rather than isolated reporting instruments. Their effectiveness depends on the capacity of actors to interpret them jointly and to connect them to situated operational knowledge. Finally, for policy makers and certification bodies, the findings suggest caution against overly formalistic approaches to transparency and accountability. Standards and reporting requirements are essential, but they must be accompanied by an understanding of the practical work through which evidence is produced. The credibility of agrifood disclosure depends not only on the presence of records, but on the organizational routines that make those records reliable, interpretable and auditable.

5 Conclusion

This study examined how knowledge is managed within agrifood supply chains and how accounting and auditing artefacts contribute to translating and legitimising knowledge among heterogeneous actors. Drawing on participant observation, the analysis shows that KM is not merely a matter of information sharing, but a situated process through which tacit, experiential and local knowledge is transformed into actionable organizational knowledge.

The study also presents some limitations that should be acknowledged. First, its ethnographic design is based on participant observation within a single large processing firm and a selected number of supply chain partners. This choice allows for an in-depth understanding of everyday practices but limits the possibility of statistical generalisation. Second, the analysis focuses primarily on accounting and auditing artefacts, while other infrastructures, such as digital platforms, informal relationships and data-driven technologies, are considered only marginally. Third, the findings are situated within a specific agrifood context and may vary across different products, institutional settings and supply chain configurations.

Future research could address these limitations by developing comparative studies across different agrifood supply chains, sectors and countries. Longitudinal research would also be valuable to examine how accounting-mediated knowledge practices evolve over time, especially in response to regulatory changes, sustainability pressures and technological innovation. Further studies could investigate how blockchain, artificial intelligence and advanced data analytics reshape traceability, sustainability accounting and inter-organizational accountability. This would help clarify whether digital technologies reinforce existing accounting-mediated knowledge practices or generate new forms of visibility, control and coordination.

Overall, this study suggests that KM in agrifood supply chains is fundamentally accounting mediated. Accounting and auditing artefacts do not simply document knowledge after it has been produced; they actively participate in making knowledge visible, credible and governable across organizational boundaries.

6 Ethics Declaration

Informed consent was obtained from the organization and the individuals involved in the study.

Confidentiality and anonymity were ensured by removing identifying details related to participants, the firm and its supply chain partners. Data were handled securely and used only for research purposes. Given the participant observation design, the researcher maintained a reflexive stance to minimise interference with everyday activities and to avoid disclosing sensitive commercial information.

7 AI Declaration

AI tools, specifically ChatGPT, were used solely to support language editing, enhance clarity, and refine the academic style of the manuscript.

How Does Innovation Activity Impact Firm Competitiveness? Evidence from Hungarian Firms

Anett Dobos, Zoltán Soma Kárpáti, Márk Recskó
Corvinus University of Budapest, Budapest, Hungary

Abstract

Innovation has long been recognized as a key driver of firm competitiveness; however, the mechanisms through which different innovation activities translate into performance remain insufficiently understood, particularly in Central and Eastern European contexts. While prior research has established a generally positive relationship between innovation and firm performance, empirical findings remain heterogeneous, and the underlying capability and knowledge-based mechanisms are not fully clarified. This paper investigates how innovation activities influence firm competitiveness through capability-based and knowledge-driven processes.

Building on the resource-based view (RBV) and the dynamic capabilities framework, the study extends existing approaches by incorporating a knowledge-based perspective, conceptualizing innovation as a process of knowledge creation, integration, and recombination. The empirical analysis is based on a sample of 332 Hungarian medium-sized and large firms. Using partial least squares structural equation modelling (PLS-SEM), the study examines the direct and indirect effects of process innovation, product and service innovation, and intellectual property ownership on firm competitiveness, measured by the Firm Competitiveness Index.

The results show that process innovation and intellectual property ownership positively influence competitiveness, primarily through operational excellence and organizational adaptivity. In contrast, product and service innovation activities exhibit a negative relationship with adaptivity and no significant positive effect on performance. These findings suggest that innovation does not translate into performance uniformly. Instead, its effects are mediated by the firm's ability to transform knowledge into capabilities.

From a knowledge-based perspective, process innovation enhances internal knowledge integration and efficiency, while intellectual property supports knowledge protection and recombination. Conversely, market-facing innovation may impose coordination and knowledge integration challenges that weaken adaptive capabilities, particularly in manufacturing-dominated contexts.

The study contributes to the IFKAD discourse by demonstrating that firm competitiveness is fundamentally capability-driven and rooted in knowledge asset management. The findings also have important managerial implications, suggesting that firms should sequence innovation investments by first strengthening internal capabilities before engaging in market-facing innovation activities.

Paper type: Academic Research Paper

1 Introduction

Innovation has been a central topic in economic and management research since Schumpeter (1934), who emphasized its role in driving economic development. Subsequent research has consistently linked innovation activities to firm performance and competitive advantage (Prajogo, 2006; Gunday et al., 2011). However, empirical findings remain heterogeneous, particularly across different institutional and regional contexts. In Central and Eastern Europe, empirical evidence on the innovation–performance relationship is relatively scarce. This gap is particularly relevant given the structural characteristics of these economies, where firms often operate under resource constraints and rely heavily on incremental innovation and capability development (Lukovszki et al., 2020).

This paper examines how innovation activities influence firm competitiveness through capability-based mechanisms. Building on the resource-based view (Barney, 1991) and the dynamic capabilities framework (Teece et al., 1997), the study adopts a knowledge-based perspective, interpreting innovation as a process of knowledge creation and recombination. In this framework, innovation does not directly lead to performance outcomes; rather, its impact is mediated through capabilities that enable firms to exploit and adapt their knowledge base. The paper focuses on three types of innovation activities: process innovation, product and service innovation, and intellectual property ownership. These are linked to two key capability dimensions: operational excellence and adaptivity, which together determine firm competitiveness.

The study contributes to the literature in three ways. First, it provides empirical evidence from a Central European context; second, it advances theoretical understanding by integrating innovation, capabilities, and knowledge assets into a unified framework. Third, it contributes to the IFKAD discourse by explicitly linking innovation activities to knowledge-based capability development.

2 Theoretical background

2.1 Innovation as a knowledge-based process

Innovation is commonly defined as the implementation of new or significantly improved products or processes (OECD, 2018). However, beyond this outcome-oriented definition, innovation can be interpreted as a knowledge-based process involving the creation, integration, and application of knowledge within the firm (Baregheh et al., 2009). From a knowledge-based view, firms achieve competitive advantage by effectively managing their knowledge assets (Grant, 1996). Innovation activities represent structured mechanisms through which knowledge is recombined and transformed into value. Different types of innovation reflect distinct knowledge processes. Process innovation enhances internal knowledge efficiency, product and service innovation relies on external and market knowledge, while intellectual property represents codified and protected knowledge.

2.2 Resource-based view, dynamic capabilities and knowledge assets

The resource-based view explains firm performance differences through resource heterogeneity and the possession of valuable, rare, inimitable, and organizationally embedded resources (Barney, 1991). However, in dynamic environments, static resources are insufficient to sustain competitive advantage. The dynamic capabilities framework extends the RBV by emphasizing the firm's ability to integrate, build, and reconfigure resources (Teece et al., 1997). Dynamic capabilities enable firms to respond to changing environments through sensing, seizing, and transforming activities (Teece, 2007). Integrating a knowledge-based perspective, capabilities can be interpreted as mechanisms through which knowledge is mobilized and transformed into performance outcomes. Operational excellence reflects the efficient exploitation of existing knowledge, while adaptivity represents the ability to explore and integrate new knowledge.

2.3 Innovation and firm competitiveness

A substantial body of empirical research demonstrates a positive relationship between innovation and firm performance (Prajogo, 2006; Gunday et al., 2011). However, this relationship is not uniform. The performance effects of innovation depend on how innovation activities are embedded within organizational processes and capabilities (Jin and Choi, 2019). Recent research increasingly emphasizes that innovation influences performance indirectly by shaping firm capabilities (Chikán et al., 2022). In this perspective, competitiveness is a multidimensional construct reflecting the combined effects of resources, capabilities, and strategic choices. Figure 1 illustrates the conceptual framework of the study, highlighting the direct and capability-mediated relationships between different types of innovation activities and firm competitiveness.

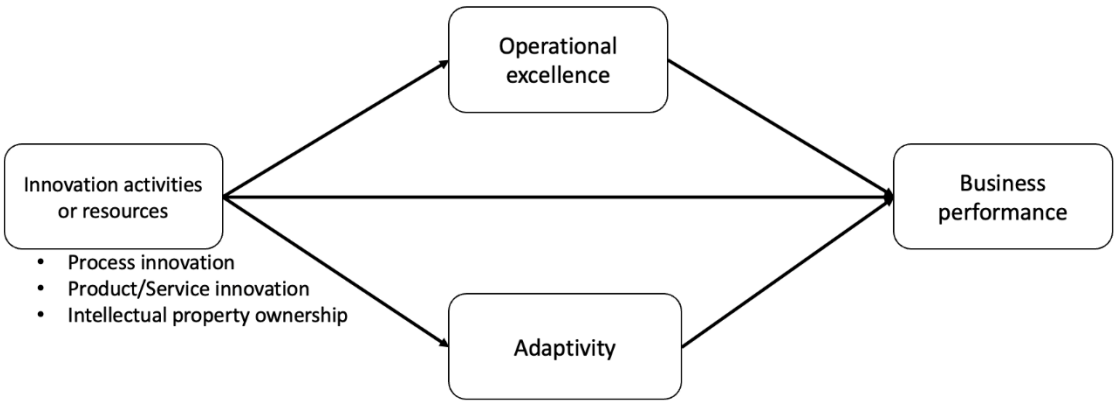

Figure 1: The relationship between innovation and firm performance.
Source: Author's own compilation

Based on the theoretical framework, the study examines the following hypotheses:

- *H1: Process innovation activities have both a significant direct and an indirect positive effect on firm competitiveness, with the indirect effect being mediated by operational excellence and adaptivity*
- *H2: Product/service innovation activities have both a significant direct and an indirect positive effect on firm competitiveness, with the indirect effect being mediated by operational excellence and adaptivity.*
- *H3: Intellectual property ownership (IPO) activities have both a significant direct and an indirect positive effect on firm competitiveness, with the indirect effect being mediated by operational excellence and adaptivity.*

3 Methodology

The empirical analysis is based on a survey conducted among Hungarian firms with more than 50 employees. The final sample consists of 332 firms across multiple sectors, including manufacturing, trade, and transportation. Firm competitiveness is measured using the Firm Competitiveness Index (Chikán et al., 2022), which captures both operational and dynamic capability dimensions. Operational excellence reflects efficiency and quality, while adaptivity captures the firm's ability to respond to environmental changes. Innovation activities are measured using composite indices constructed from binary indicators, following established methodological approaches (Eurostat, 2022). This allows capturing the breadth and intensity of innovation activities.

Table 1: Sample demographics. Source: Author's own compilation.

Characteristic	Description	Frequency	Percentage
Firm size	No. of employees in 2024		
	50-249	290	87.35%
	>250	42	12.65%
Ownership			
	Hungarian owned	301	90.66%
	Foreign owned	31	9.34%
	Family business	122	36.75%
Sectors			
	Manufacturing	162	48.80%
	Construction	33	9.94%
	Wholesale and retail trade; repair of motor vehicles	86	25.90%
	Transportation and storage	51	15.36%
Export activity			
	Export activity	202	60.84%
	No export activity	130	39.16%

Partial least squares structural equation modelling (PLS-SEM) is used to test the hypothesized relationships (Hair et al., 2022). This method is particularly suitable for exploratory models and complex relationships among latent constructs. To address potential robustness concerns, firm size and ownership structure are included as control variables. In addition, the analysis considers the potential influence of sectoral composition and reverse causality. While the cross-sectional nature of the data limits causal inference, the capability-mediated structure of the model provides theoretical support for the proposed relationships.

4 Results

The results indicate that operational excellence and adaptivity both have a significant positive effect on firm competitiveness (Figure 2). Process innovation exhibits a strong positive effect on both capability dimensions, which in turn translate into improved performance. Intellectual property ownership shows a significant positive effect on adaptivity, suggesting that codified knowledge assets enhance the firm's ability to respond to environmental changes. However, its direct effect on performance is not significant, indicating that its impact is primarily indirect. In contrast, product and service innovation activities do not have a significant positive effect on performance. Moreover, a negative relationship is observed between these activities and adaptivity, suggesting that market-facing innovation may impose coordination and integration challenges.

5 Discussion

5.1 Results of the analysis

In this study, we explored how firms' innovation activities affect business performance both directly and indirectly through the mediating roles of operational excellence and organizational adaptivity. While the relationship between innovation and performance has been widely examined in the literature, empirical evidence from the Central and Eastern European region remains relatively scarce and insufficiently theorized. To contribute to this gap, we analysed data from 332 Hungarian firms and found that process innovation and intellectual property–related assets have a strong and positive influence on both operational excellence and adaptivity, thereby supporting hypotheses H1 and H3. However, our results did not support the second hypothesis. We observed a significant negative association between market-oriented innovation activities—such as product, service, and technology-related innovation—and adaptivity. At the same time, no statistically significant direct effect was identified between operational excellence and business performance. These findings indicate that different types of innovation do not contribute equally to capability development or performance outcomes, suggesting a more nuanced relationship between innovation and competitiveness.

The results are particularly meaningful in the Hungarian and broader Central European context, where both medium-sized and large firms account for a substantial share of employment and play a critical role in the economy (Hungarian Central Statistical Office, 2025). Our analysis underscores the importance of innovation activities, especially process innovation and intellectual property ownership, in shaping firm-level competitiveness. Considering that manufacturing firms make up a large proportion of the sample (over 48%) and that the Hungarian economy is relatively labor-intensive, it is both theoretically and economically reasonable that firms benefit more from improvements in internal processes and operational capabilities than from market-facing product or service innovation.

5.2 Theoretical contribution

The study contributes to the literature by integrating innovation, capabilities, and knowledge assets into a unified framework. It demonstrates that innovation does not directly drive performance; instead, its effects are mediated through capabilities that transform knowledge into value. This finding aligns with the dynamic capabilities perspective and extends it by emphasizing the role of knowledge integration and recombination. The results also contribute to the IFKAD discourse by highlighting the central role of knowledge-based capabilities in achieving firm competitiveness. Overall, the results support a capability-driven view of competitiveness, where innovation influences performance indirectly through capability development.

5.3 Managerial implications

Given that process innovation and intellectual property ownership were shown to have a significant impact on operational excellence, adaptivity, and overall business performance, these areas should be treated as strategic priorities by Hungarian firms. The combined development of process-oriented innovation and the acquisition or protection of intellectual property can contribute to achieving sustainable competitive advantage. Accordingly, managers need to deliberately invest in strengthening the underlying capabilities that support these activities.

Although innovation often involves substantial costs, the results suggest that such investments can generate long-term returns. To realize these benefits, firms must systematically build organizational and firm-level capabilities that enable continuous innovation and the development of dynamic capabilities. This is not an immediate outcome but rather a long-term process that requires sustained effort over several years, during which capability building itself can be interpreted as a strategic objective (Hutton, Demir & Eldridge, 2021). In practice, this implies that managers need to adopt a dynamic capabilities perspective, focusing on their ability to sense emerging opportunities, seize them, and reconfigure existing resources accordingly (Teece, 2016).

Organizations that perform strongly across these capability dimensions are more likely to generate higher-level and more transformative innovations (Ellonen, Wikström & Jantunen, 2009). Achieving this also requires firms to actively seek and utilize knowledge beyond their organizational boundaries. Establishing and maintaining collaborations with universities, research institutes, and other external partners can significantly enhance firms' innovation potential (Lin et al., 2020).

In addition, firms need to continuously integrate external knowledge into their operations, reflecting the importance of absorptive capacity within the knowledge-based view. This also depends on the firm's ability to attract and retain highly skilled professionals, particularly in research and development roles. In the Hungarian context, this represents a considerable challenge, as companies face ongoing labour shortages, outward migration of talent, and increasing competition for qualified employees in international markets. These findings reinforce the role of knowledge assets as the underlying drivers of capability development and firm competitiveness.

6 Conclusions

This study offers a comprehensive examination of how various types of innovation activities influence firm competitiveness through the mediating roles of operational excellence and organizational adaptivity. Based on a large sample of Hungarian medium-sized and large enterprises, the results indicate that the relationship between innovation and business performance is neither direct nor uniform. Rather, the impact of innovation is primarily indirect, unfolding through the development of internal capabilities related to efficiency and adaptability.

From an empirical perspective, the findings emphasize the importance of process innovation and intellectual property–related resources in enhancing both operational excellence and adaptivity, thereby contributing to higher levels of firm competitiveness. These results support the assumptions of the resource-based view and the dynamic capabilities framework, demonstrating that sustained performance advantages arise not only from innovation outcomes themselves but from the firm's ability to translate innovation activities into effective organizational capabilities. In contrast, innovation activities that are oriented toward markets—such as product, service, and technology innovation—do not necessarily lead to improved performance and may, in some cases, place additional pressure on adaptive capacities, highlighting potential trade-offs in firms' innovation strategies.

Furthermore, the analysis reveals that the relationships identified between innovation, capabilities, and performance remain consistent across different firm sizes and ownership structures. Neither firm size nor foreign ownership significantly modifies these core relationships, suggesting that the underlying mechanisms operate similarly across organizational contexts. This consistency enhances the robustness and broader applicability of the proposed model within the Hungarian economy and, more generally, in the Central and Eastern European region.

7 Ethics Declaration

The research reported in this paper was conducted with prior ethical approval granted by the Research Ethics Committee of Corvinus University of Budapest. The approval was issued under file number KRH/181/2025 for the research project "Competitiveness Research Center – Firm competitiveness research 2025–2027".

The study is based on survey data collected from company representatives. Participation in the research was voluntary, and informed consent was obtained from all respondents prior to data collection. Respondents were

contacted by a professional data collection provider, and they were fully informed about the purpose of the research, the voluntary nature of participation, and their right to withdraw at any time. All data were collected and processed in accordance with applicable data protection regulations. The dataset was anonymized prior to analysis, and no individual firm or respondent can be identified. Researchers had access only to aggregated and anonymized data, ensuring confidentiality and compliance with ethical standards.

The research did not involve vulnerable groups, sensitive personal data, or any procedures that could pose physical, psychological, or social risks to participants. The study adhered to the ethical principles and institutional guidelines of Corvinus University of Budapest throughout the research process.

8 AI Declaration

The authors declare that Grammarly was used during the preparation of this manuscript for language checking and to improve grammar, clarity, and readability.

The use of this tool was limited to linguistic refinement only. All substantive elements of the research, including the research design, data analysis, interpretation, and conclusions, were developed solely by the authors, who take full responsibility for the content of the paper. No AI tools were used for data analysis, empirical modelling, or the generation of research findings.

Accounting Standardization and Circular Knowledge Frictions in Cooperative Banks

Andrea Comandé, Olga Ferraro
University of Calabria, Italy

Abstract

This research investigates the organizational and strategic transformation of Cooperative Credit Banks (CCBs) under the pressure of increasing regulatory standardization. In the contemporary European banking landscape, the transition toward hard data metrics (e.g., Basel Regulation, EBA guidelines) poses a significant challenge to the traditional business model of CCBs, which is historically rooted in 'Relational Capital' and the processing of 'soft information'. The study aims to analyse how this exogenous regulatory shock acts as a catalyst for internal reconfiguration, shifting these hybrid organizations from a model of 'Circular Knowledge' toward one of 'Linear Efficiency'. The paper adopts an inductive qualitative methodology based on a multiple-case study design. The proposed research setting is enabled by a strategic partnership with a pilot CCB, complemented by a comparative analysis of additional cases selected through specific control. Drawing on Transaction Cost Economics (TCE) as the primary theoretical lens, the study employs semi-structured interviews with top management and internal document analysis to map the shift in decision-making authority and credit-granting processes. As a research-in-progress, this study proposes a theoretical framework to be further validated through the ongoing empirical phase. By moving beyond a purely normative view of regulation, this study aims to contribute to Knowledge Management and Organization Studies by illustrating how measurement frictions can structurally alter the boundaries and the identity of hybrid financial institutions. The findings will provide both scholars and practitioners with a critical understanding of the unintended organizational costs of systemic banking supervision.

Keywords: Cooperative Credit Banks, Relational Capital, Circular Knowledge, Banking Biodiversity

Paper type: Academic Research Paper

1 Introduction

Hybrid organizations, such as Cooperative Credit Banks (CCBs), represent a distinct organizational paradigm characterized by a dual logic: pursuing economic objectives while fulfilling a social mission (Bruni and Zamagni, 2004; Ferraro et al., 2024). Following an evolutionary economic perspective (Williamson, 1985), markets tend to select organizational forms that minimizes transaction and ownership costs most efficiently. While institutional factors – such as regulatory protections, tax exemptions, or public subsidies - can distort this mechanism, the historical persistence of CCBs must be explainable by a specific relative advantage that justifies their existence in purely economic terms. Particularly, we argue that the core of this advantage lies in what this study defines as Relational Capital. We specialize this definition conceptualizing it as a strategic informational asset generated through an iterative learning process wherein qualitative data extracted by means of repeated, localized interactions materialize into implicit contracts and reputational constraints, thereby enabling the design of optimal contracts and enforcement schemes.

By circumscribing their activities to localized areas, these institutions specialize in high frequency, lower complexity financial transactions. Within this framework, relational capital functions as a primary informational resource, as it addresses information asymmetries through mechanisms that fundamentally differ from market signals (Scott et al., 2001). The accumulation over time of knowledge and uncodified data (soft information), enabled by the embedded nature of these organizations, defines a distinct specialization model whereby relational proximity and repeated interaction efficiently substitute formal quantitative metrics in assessing creditworthiness. In this context, the CCB functions as a node in a circular system of knowledge: local savings are reinvested locally, fuelled by a continuous feedback loop of soft information that enables the efficient mitigation of information asymmetries, continuously generating knowledge that create the condition for this specific organizational configuration to optimally operate in the market.

However, the banking institutional environment in Europe is marked by a pervasive process of regulatory standardization driven by a calculative logic intended to minimize monitoring and agency cost in the European financial system. By means of standardized accounting metrics (such as Basel Regulation and the EBA NPL guidelines) regulators establish a formal evaluative scaffolding to reduce informational gaps at the systemic level. This process mirrors what has been described in sociological literature as 'commensuration' (Espeland and Stevens, 1998): the synthesis of highly specific, relationship-reducing mechanisms into defined categories

to ensure visibility and comparability at the expense of the relevance of the local context. That is, displacing soft information – although fundamental for an accurate assessment of a prospective borrower's true risk profile – prioritizing hard information, as the latter can be seamlessly integrated into a uniform and objectively verifiable supervisory system (Behn et al., 2016). In doing so, these mechanics create a formal evaluative foundation to manage uncertainty and incomplete informational sets, reflecting the regulator's need to stabilize decision-making processes and thoroughly monitor risks across the financial system.

We argue that by imposing standardized metrics onto relationship governed by implicit contracts, the regulatory framework introduces steep measurement cost over CCBs. In particular, our argument posits that an approach failing to account for the idiosyncratic nature of local lending might disrupt the circularity of information among delimited boundaries, and in turn this may lead CCBs to abandon their specialized informational technology, reassessing their perceived mission in the market and ultimately their behaviour. Centralized accounting regimes significantly restrict managerial discretion by displacing relational logics, ultimately emerging as the sole legitimate foundation for defining and measuring variables relevant to investment decisions. The evaluative scaffolding systematically excludes those intangible assets, remaining outside the visibility of conventional reporting framework.

Sociological and Critical Accounting perspectives provide valuable complementary insights. Indeed, when regulators impose standardized metrics to minimize their own monitoring costs, accounting acts as a powerful mechanism of commensuration (Espeland and Stevens, 1998). In this view, accounting is not merely a neutral, technical recording of economic facts, but an institutional practice that shapes organizational reality by altering what is rendered visible to decision makers (Hopwood, 1987). Indeed, once established, these standardized metrics tend to acquire a self-justifying force (Espeland and Sauder, 2007), where the necessity to continuously evaluate organizational outcomes against them drives a shift in organizational behaviour, promoting homogenization and displacing other types of authority and judging systems (Mennicken and Espeland, 2019), ultimately redefining what action can be considered legitimate. The magnitude of this progressive alignment will depend on the intensity of the coercive pressure and the critical need to comply with these metrics to preserve operational legitimacy (Meyer and Rowan, 1977). The basic idea of this research, that will inform the formulation of the propositions, is that when managerial discretion is displaced by rigid decision-making processes, the resources invested in cultivating Relational Capital are no longer capitalized.

Through a critical analysis of these valuative frictions, this paper intend to investigate over the frictional costs of regulatory homogenization for decentralized financial ecosystems. Particularly, whilst broader macro-trends, such as digitalization, concurrently affect bank-customer interactions, this paper focuses strictly on the organizational impact of these accounting and regulatory pressures. Methodologically, the study adopts a theory-building approach grounded in case study research (Eisenhardt, 1989). Within this framework, our research objective is twofold; that is: *i)* investigating how standardized accounting alters the regime of organizational visibility; *ii)* examining the consequences of isomorphic dynamics in these contexts, informing an initial set of propositions regarding the potential for "mission drift" (Battilana and Dorado, 2010).

Following Eisenhardt's iterative methodology, the case study will not be employed merely to validate these *a priori* hypotheses. Rather, it will serve as an empirical setting to test and continuously refine the theoretical framework, allowing the initial constructs to be modified or expanded in response to the specific organizational dynamics that emerge from the data.

2 The Architecture of Soft Information: Local Knowledge and the Cooperative Advantage

In localized settings, economic transactions are rarely isolated events; rather, they unfold within a dense network of repeated interactions among a defined set of actors. Because information about past behaviour is shared in local boundaries, historical interactions and mechanisms of reciprocity function as credible commitments. Consequently, opportunistic behaviour is deterred by the implicit threat of social ostracism and reputational damage, thereby facilitating sustainable, long-term economic cooperation (Coleman, 1988). The proximity of the relationship may, for instance, translate into greater contractual flexibility, allowing for discretion and renegotiation according to particular circumstances; more effective monitoring of collateral and contractual covenants, or an expansion of credit provision in cases where the rents derived from the expected value of the relationship compensate for the costs of financing projects that are initially unprofitable (Boot, 2000).

In support of our argument, we align with Hayek's identification of the primary economic problem: the adaptation to localized "circumstances of time and space". Although Hayek's concern was primarily epistemological, he underlined the need for recognizing the complexity in idiosyncratic, local knowledge, that by its very nature resists aggregation into standardized statistical measures and yet constitutes the essential

basis for economic adaptation within specific contexts (Hayek, 1945, 1967; Williamson, 1985). While literature has widely documented the advantages of 'relationship lending' dynamics in terms of enhanced resilience and risk management in financial markets (Petersen and Rajan, 1994; Boot, 2000; Ferri et al., 2014), the deep reliance on proprietary soft information requires specific organizational architectures for the continuous accumulation of uncodified data (soft information), defining a distinct specialization path.

For instance, Stein (2002) argues that relatively flat organizational structures are more efficient when dependent upon *soft information* (or equivalently, if the organization is specialized in soft data collection). This perspective helps explain the historical resistance of German and Italian Cooperative Banks to the centralizing pressures of the European Central Bank toward centralization. The resulting compromise - like the aggregation within comprehensive groups in Italy with sub-banks who own the group and retain varying degree of autonomy - internalized the tension transforming the central holding into a transmission mechanism for regulatory pressures, allowing for a general reduction of Monitoring costs for the ECB.

In vast, complex, and interconnected markets, transaction costs are minimized through formal institutional rules that are necessary to manage information asymmetry and to constrain opportunistic behaviour among distant agents where defining and enforcing agreements is costly (North, 1991). For example, Agarwal et al. (2014), argue that centralized regulators are bound to remain detached from local socio-economic dynamics, adopting a generalized evaluative posture that ensures systemic consistency and significantly lower economic costs. In particular, local supervisory forbearance - often driven by the intent to shield regional economies - correlates with delayed recognition of problem loans and higher bank failure rates.

However, albeit relationship lending in closed, auto-referential settings theoretically exposes the institution to severe agency costs, cronyism, rent-seeking and exposes borrowers to hold-up problems (Sharpe, 1990; Rajan, 1992; Uzzi, 1997; Weinstein and Yafeh, 1998), the cooperative architecture is functional to the mitigation of these dynamics. In particular, micro-prudential regulation has been devised to solve specific agency problem inherent to commercial banking, to prevent the moral hazard stemming from limited liability and institutional safety nets, by means of rigid capital requirements and standardized (risk-weighted) metrics (Freixas and Rochet, 2008). In the case of CCBs, the 'common bond' (Hansmann, 1996) - such as territorial or associative proximity - reduces adverse selection and moral hazard through incentive alignment that constrain opportunistic behaviour drawing upon social pressures, the credible threat of reputational loss within the business community, and informal peer sanctions (Stiglitz, 1990; Banerjee et al., 1994). For the analytical purpose of this study, we assume this organizational form as our theoretical baseline to isolate the specific frictions generated by exogenous regulatory commensuration.

2.1 Regulatory standardization as an exogenous shock

Following from the Hansmann (1996) arguments, the persistence of the cooperative form can be viewed as an efficient organizational response to minimize transaction costs associated with locally rooted information asymmetries. However, regulatory homogenization through the widespread implementation of impersonal logics onto CCBs generates two structural frictions, particularly: *i)* replacing soft information with metrics based on hard data prevents the assessment of physiologically "opaque" subjects (e.g., micro-enterprises, artisans) thereby leading to systemic credit rationing for local borrowers; and at a more aggregate level *ii)* the reduction of "banking biodiversity" by imposition of isomorphic logics.

The methodological architecture of traditional financial accounting operates on a linear, transactional logic. That is, it excels at measuring standardized, hard data, but inherently lacks the vocabulary to capture the effects of facts pertaining to the creation and maintenance of relational capital into commensurable metrics. This limitation stems, obviously, from the structural difficulty of codifying phenomena that are predominantly qualitative in nature, highly specific to a certain relationship or network and poorly transferable (Petersen and Rajan, 1994). By collapsing vast amounts of idiosyncratic information into standardized metrics, this process drastically diminishes the relevance of local context, rendering the very definitions of what is considered legitimate and rational strictly dependent on what can be quantitatively measured (and maximized), anchoring decision-making to an institutional discourse reframing the foundations upon which what is considered "optimal" is established.

The exogenous imposition through institutional pressures also carries a dominant societal discourse regarding what constitutes a legitimate organization (Meyer and Rowan, 1977). As the domain of what is visible shifts to comply with these exogenous rules, it directly alters the incentive structure guiding managerial behaviour (Mennicken and Espeland, 2019). For example, it becomes costly to produce knowledge that cannot be credibly transmitted along the hierarchy, anticipating that the effort will be wasted since it will not inform standardized capital allocation procedures (Stein, 2002). As organizations adhere to and start to privilege

standardized metrics, the immediate costs of investing in relational capital will appear more certain in the relative outcome, with more specific effects distributed in shorter time horizons. The proximity and clarity of such causalities, entails consequences for how resources are allocated across space and time. Furthermore, increasing salience of measurable attributes of transaction constrains managerial discretion, since decision making rely on information that can be formally validated, reducing the role of tacit knowledge and local judgement.

As these changes becomes the basis for the activities carried out by the organization, structures tend to adapt following resulting changes in transaction (that is, resource allocation) to align with the dominant evaluative framework. This may include increased centralization, formalization of procedures and a shift toward transactional forms of interaction. Consequently, time and resources invested by organizations - such as CCBs in cultivating soft information to maintain a capillary territorial presence, engaging in continuous face-to-face qualitative listening – are not capitalized as strategic assets.

The friction between what is measurable and what remains invisible within accounting systems directly intersects with the challenge of quantifying non-financial ESG outcomes. Insofar as we conceptualize the 'social dimension' of CCBs - traditionally defined by mutuality and territorial ties – as a circular knowledge infrastructure, in this framework tacit knowledge extracted from the local environment is analysed and reinvested within the same boundaries, creating a closed-loop feedback systems that fuels local sustainable investment.

2.2 The friction between local knowledge and systemic metrics

Historically, particularly within the European Context (such as in Italy and Germany), cooperative banks emerged as a local response to community needs, as a mean for financial inclusion and emancipation from local monopolistic practices, such as usurious interest rates. Over decades, the continuous refinement of processes tailored to these specific local needs sedimented a distinct organizational culture which is fundamentally misaligned with purely profit-maximizing logics of commercial banking in competitive settings. Oftentimes, this kind of institution tends to promote themselves as agents fundamentally different from traditional banks, tied to the local community in which they operate and to a general set of ethical value, such as the ones defined by the International Cooperative Alliance (ICA), in which they recognizes themselves and that ideally should characterize their daily operations, governance and stakeholder relations.

However, the macro-institutional environment has historically shifted to structurally alter the competitive landscape in which CCBs operate. The introduction of modern banking regulations and deposit insurance schemes (e.g., FITD in Europe or FDIC in the US) has artificially lowered the contracting and transaction costs for depositors of traditional commercial banks by providing a systemic safety net, implicitly subsidizing the moral hazard inherent in the commercial model, and ultimately harming the competitive advantage that historically attracted depositors to cooperative institutions (Hansmann, 1996). The imposition of standardized regulatory regimes can be conceptualized as institutional interventions that potentially reconfigure the transaction cost structure of credit intermediation, introducing significant informational frictions when applied to relational lending models by altering the measurement and monitoring costs. In turn, changes to the nature and characteristics of transactions follows changes in governance that should efficiently minimize transaction costs (Williamson, 1985). Again, this logical sequence might explain the organizational transformations across Europe of Cooperative Credit sector following the imposition of new ECB/EBA's requirements.

By tracing a parallel with the idea of social structure premised in the Economic Sociology, Uzzi (1997) acknowledges that organizations that build their competitive advantage upon embedded ties face a substantial risk of failure when institutional changes rationalize the basis of, or preclude the formation of new ones. To sustain these arguments, we can recur to two examples. Firstly, the evaluative structure of supervisory frameworks structurally privileges hard information (e.g., audited financial statements, standardized collateral) (Power, 2004). Consequently, credit relationship that are implicitly sustained by continuous interaction history and mutual trust may be interpreted as 'opaque' within this framework, thereby assigning higher Risk-Weighted Asset coefficients, and forcing CCBs to set aside greater amounts of costly regulatory capital with respect to a theoretical risk profile that may diverge from the actual, artificially driving up the cost of local credit allocation. For instance, Berger and Udell (2006) find that, although there are transactional technologies specifically designed to evaluate and serve this kind of clients by recurring to hard data diverse from financial statements, rigid rules and aggregative logics as for Basel II implicitly encourage the adoption of such technologies at the expense of relationship lending based on soft information. We can also pose a symmetrical reasoning where this dynamic operate counterfactually as a constraint: credit may simply be rationed and not granted at all, as the regulatory capital requirements disincentivize the transaction from the outset (Peek and Rosengren, 1995; Aiyar

et al., 2014). What is important here is that, in more general terms, to changes in operational target correspond modifications on the feasible set of credit allocation choices available within the banking sector. Secondly, recent regulatory approaches to Non-performing Loans such as the EBA's calendar provisioning mandates, impose automatic, time-bound write-downs of impaired credit. This mechanical accounting treatment disregards the flexibility and localized recovery strategies that CCBs historically employed to manage borrowers facing temporary liquidity shocks. By forcing premature loss recognition, the regulation actively disincentivizes lending to economic actors who may exhibit irregular cash flows despite the possibility of private information regarding the actual long-term solvency. The specific value of idiosyncratic knowledge is depreciated in front of the imposition of automatic write-downs and forced asset sales (Moretto and Parigi, 2025) or by disregarding the role of managerial discretion in the forward-looking recognition of credit risk (Bushman and Williams, 2012).

Although these metrics are introduced with the legitimate goal of reducing systemic risk and ensuring transparency across financial systems, they are designed for contexts of impersonal exchange as a mean for creating public, impartial knowledge (Porter, 1995). The issue can be most succinctly summarized by the idea that, because regulatory apparatus discourse lacks the vocabulary to measure the value of soft information in these settings, it prudentially assumes that such information does not exist other than in its indirect consequences, and the ultimate outcome is that of reintroducing one of the primary frictions the cooperative model emerged to cope with.

3 Proposed Research Design

Whilst it is beyond the scope of this paper to normatively assess the social optimality of these mechanics, our research objective is strictly positive. We aim to empirically investigate whether and how exogeneous increase in measurement and compliance costs for the CCBs, may entail internal rearrangements with respect to the specificity of transactions, that we contend may be different in nature and scope because of the resulting changes in the incentives structure that ultimately defines and constrain economic behaviour in the market.

3.1 Empirical strategy and data sources

Methodologically, this study benefits from an immersive research setting facilitated by a formal research partnership with a prominent Cooperative Credit Bank. While such proximity necessitates rigorous analytical protocols to mitigate researcher bias, it grants unprecedented access to multiple organizational layers and rich data collection to build inductive theory. To ensure systematic data triangulation, the empirical investigation relies upon qualitative organizational routines and institutional outputs. Namely:

- *Qualitative Data*: the inductive process relies on field observations and semi-structured interviews with top management, risk officers and local branch managers. This ethnographic immersion is corroborated by access to archival data, such as internal credit committee minutes (where available), allowing us to trace how soft information is debated and utilized in credit allocation policies, tracing decision-making process from policy-setting by the Board of Directors to execution by Executive Committees.
- *Secondary Archival Data*: to contextualize and verify the consistency of narration, interview data will be cross-referenced with institutional documentation. This includes the analysis of group-level credit policies, annual mission reports and aggregated financial statements.

Ideally, the juxtaposition of these sources is intended to neutralize idiosyncratic biases, allowing for the isolation of governance rearrangements following exogenous regulatory shock.

3.2 Analytical focus and theoretical sampling

We focus our empirical setting on the Italian Cooperative Credit System (Banche di Credito Cooperativo), adopting a multiple-case study approach that draws on Eisenhardt's (1989) protocol. That is, we employ theoretical sampling to isolate the effect of the regulatory shock from confounding factors. In particular, the selected CCBs are controlled along the following dimensions:

- *Size (Total Assets)*: to ensure that organizational changes are not the result of scale economies (Berger and Udell, 2005), the selected institutions operate within a similar dimensional threshold.
- *Historical NPL Ratio (as a proxy of pre-shock health)*: to avoid attributing organizational rearrangements to restructuring operations or excessive focus on costs saving (Berger and DeYoung, 1997). The sample focuses on CCBs that exhibit sound financial health over time.
- *Macroeconomic Context:* the sample focuses on economic institutions operating within comparable socio-economic environments, aiming at neutralizing variations due to local credit demand fluctuations (Guiso et al., 2004).

- *Leadership Stability:* since modifications in the organizational governance may be due to changes in the Top Management (Cuñat and Garicano, 2010).
- *Banking Group Affiliation:* to control for internal policies the selected cases belong to the same Cooperative Banking Group.

4 Expected Propositions and Implications

This study develops a set of analytical propositions to guide the empirical investigation. They are not intended as deterministic predictions, but as theoretically informed expectations subject to refinement through inductive analysis. In particular:

- *Internal Centralization and Bureaucratization*: following Stein (2002), regulatory mandates for standard metrics to flatten the comparative advantage of decentralized structures, leading to an elongation of the internal hierarchies and counter-balancing discretionary power of local branch managers with central risk and compliance departments.
- *Measurement Frictions and Cost-Income Dynamics:* the mandatory translation of idiosyncratic soft information into standardized regulatory categories acts as a severe transactional friction. This artificially inflates measurement and compliance costs, driving a structural upward pressure on the Cost-Income ratio of CCBs.
- *Transactional Shift*: as the internal cost of processing soft information rises, CCBs face structural incentives to crowd-out relationship lending, progressively shifting their credit portfolios toward standardized, transactional financial products.
- *Depreciation of the "Common Bond"*: we aim to observe how internal governance mechanisms autonomously adapt beyond formal compliance. Particularly, we expect that peer-monitoring and reputational constraints (Hansmann, 1996; Stiglitz, 1990) intrinsic to bounded settings - such as a cooperative community – are progressively marginalized in formal credit approval processes.

These dynamics may suggest that regulatory commensuration may reshape not only operational processes but also the informational foundations of cooperative banking. This raises a potential trade-off between systemic comparability and the preservation of locally embedded informational advantages, with implications for both regulators and practitioners.

5 Ethics Declaration

This study does not require an Ethics Committee Approval.

Intelligent Knowledge Management Systems for Human-AI Collaboration in Financial Decision-Making: A Behavioural Finance Perspective on Value Creation Beyond Profit

Wahala Thanthrige Navini Madhushani Perera[1], Jaki Erika[2]
[1] Doctoral School, Budapest University of Economics and Business, Hungary
[2] Budapest University of Economics and Business, Hungary

Abstract

This theoretical paper examines how intelligent knowledge management systems (IKMS) enable human–AI collaboration in financial decision-making and how such collaboration contributes to value creation beyond profit. The study addresses a theoretical gap at the intersection of behavioural finance, artificial intelligence in finance, knowledge management, and organisational innovation. Behavioural finance has demonstrated that financial judgement is shaped by biases, heuristics, emotions, and bounded rationality, while AI research in finance has largely emphasised automation, predictive accuracy, efficiency, and performance optimisation. However, less attention has been paid to how human cognition and algorithmic intelligence interact within organisational knowledge processes, and how this interaction reshapes financial decision-making in ways that affect trust, accountability, sustainability, and innovation. Using a conceptual framework-building approach, the paper positions IKMS as the central organisational layer through which human and AI cognition are integrated. Financial decision-making is conceptualised as a knowledge-intensive organisational process involving knowledge retrieval, knowledge integration, knowledge interpretation, and knowledge application. Within this process, AI contributes computational capacity, pattern recognition, prediction, and scalable knowledge synthesis, while human actors contribute contextual judgement, ethical reasoning, experience-based interpretation, and responsible oversight. The framework argues that human–AI collaboration becomes valuable not when AI replaces human judgement, but when IKMS enable complementarity, augmentation, validation, and continuous learning between human and machine intelligence. A central contribution of the paper is to show that AI does not eliminate behavioural bias in financial decision-making. Rather, biases may be redistributed, amplified, or transformed within hybrid human–AI knowledge systems. For example, AI-supported financial recommendations may reduce some forms of human overconfidence while creating new risks of automation bias, anchoring on algorithmic outputs, or excessive trust in model-generated classifications. The framework therefore identifies governance, explainability, trust calibration, ethical alignment, and feedback mechanisms as critical boundary conditions for responsible and effective human–AI collaboration. The paper conceptualises value creation beyond profit across four interrelated dimensions: cognitive value, reflected in improved decision quality, bias recalibration, and enhanced risk insight; institutional value, reflected in transparency, accountability, and stakeholder trust; societal value, reflected in ethical alignment, financial inclusion, sustainability, and long-term stability; and organisational innovation, reflected in improved knowledge recombination, adaptive learning routines, and more responsive financial decision processes. By integrating behavioural finance with intelligent knowledge management systems, the study contributes to a more comprehensive understanding of how AI-supported financial institutions can create trustworthy, sustainable, and innovation-oriented value beyond narrow economic performance.

Keywords: Intelligent knowledge management systems, human-AI collaboration, behavioural finance, organisational innovation, value creation beyond profit, sustainable and ethical AI
Paper type: Academic research paper (Theoretical)

1 Introduction

Over the past decade, artificial intelligence (AI) has significantly transformed financial decision-making (Aldasoro et al., 2025; Li et al., 2024), reshaping how information is processed, interpreted, and applied within financial institutions. In organisational terms, financial decision-making is not only an analytical activity but also a **knowledge-intensive process** (Hartvigsen, 1992) that depends on the acquisition, integration, interpretation, and use of dispersed forms of expertise and information (Richardson & Courtney, 2006). In line with Jarrahi et al. (2023), AI-enabled tools increasingly function as intelligent knowledge management systems by supporting core knowledge management activities such as retrieval, synthesis, sharing, augmentation, and application across organisational decision contexts (see also Böhm & Durst, 2025). This raises a broader question: how can human and AI cognition be integrated within organisational knowledge systems to generate not only performance gains but also innovation and sustainable value creation?

Despite the growing use of machine learning, predictive analytics, and algorithmic systems in finance, much of the literature continues to emphasise efficiency, predictive accuracy, and performance optimisation, often within a broader profit-oriented logic (Goodell et al., 2021; Pattnaik et al., 2024). This emphasis reflects the assumptions of traditional finance, where value is commonly framed in terms of market efficiency, shareholder

wealth, and risk–return optimisation (Fama, 1970; Stulz, 2025; Doeswijk et al., 2025). By contrast, behavioural finance (BF) has shown that financial decision-making is systematically shaped by cognitive limitations, heuristics, and emotional influences rather than strict rationality (Ackert, 2022; Kahneman & Tversky, 1979; Thaler, 1980). However, while BF has deepened understanding of human bias and judgment under uncertainty, it has largely treated decision-makers in isolation, with limited attention to how these behavioural dynamics are reconfigured when human cognition is embedded in AI-enabled organisational knowledge systems.

At the same time, research on AI in finance has often treated algorithms as tools of automation or optimisation (Goodell et al., 2021; Back, 2023), implicitly assuming that technological sophistication reduces or neutralises human bias (Hasan et al., 2024). Yet AI systems are not neutral actors: they may inherit, amplify, or reshape biases embedded in data, models, and institutional settings (Barocas & Selbst, 2016; Brynjolfsson & McAfee, 2017). As a result, an important theoretical gap remains. We still lack an integrated explanation of how human cognition and algorithmic intelligence interact within intelligent knowledge management systems, and how this interaction affects organisational knowledge processes, value creation, and innovation in financial institutions. This gap matters because contemporary financial organisations are increasingly expected to generate not only economic returns but also broader institutional and societal value, including transparency, trust, ethical alignment, and long-term sustainability (Freeman, 1984; Porter & Kramer, 2011; Dev et al., 2025; Jiang & Lin, 2026).

This paper addresses that gap by developing a theoretical framework that reconceptualises human–AI collaboration through a behavioural finance lens while placing intelligent knowledge management systems (IKMS) at the centre of the analysis. Rather than viewing AI as a substitute for human judgement, the paper conceptualises it as a cognitive complement that interacts with human cognition through an integrated human–AI cognition layer embedded in organisational knowledge processes. Within this framework, IKMS functions as the system layer through which human and AI capabilities are translated into core knowledge processes, namely knowledge retrieval, integration, interpretation, and application.

From this perspective, value does not arise solely from computational efficiency, but from the interaction between human interpretation, behavioural judgement, and AI-supported knowledge capabilities within hybrid knowledge systems. The paper argues that this interaction generates value beyond profit across three interrelated dimensions: i) cognitive value, reflected in improved decision quality, bias recalibration, and enhanced risk perception; ii) institutional value, reflected in transparency, accountability, and trust; and iii) societal value, reflected in ethical alignment, sustainability, and long-term financial stability. The framework further suggests that such systems may also support organizational innovation through improved knowledge integration, more adaptive decision processes, and enhanced learning routines in financial institutions.

Importantly, the paper also argues that AI does not eliminate behavioural bias; rather, it redistributes and reshapes bias within hybrid knowledge systems. This makes governance, explainability, trust, and ethical alignment central boundary conditions for effective and responsible human–AI collaboration. In this sense, the paper contributes not only to behavioural finance, but also to the literature on intelligent knowledge management systems by showing how human and AI cognition interact through organisational knowledge processes in financial decision-making. As a theoretical study, the paper does not test these relationships empirically; instead, it develops propositions to guide future research on human–AI collaboration, knowledge processes, value creation, and innovation in financial organisations.

2 Literature Review

2.1 Behavioural finance, AI in finance, and the limits of isolated decision models

Traditional financial theory assumes that rational agents operate in efficient markets where prices reflect available information (Fama, 1970; Lo, 2007). Recent work has refined this view by showing that market efficiency depends on information costs and distribution, rather than functioning as a frictionless benchmark (Lee, 2025). In this perspective, value creation is usually linked to profit maximisation, optimal allocation, and market performance. Behavioural finance (BF) challenged this assumption by showing that financial decisions are shaped by cognitive bias, bounded rationality, and emotions rather than strict rational calculation (Kahneman & Tversky, 1979; Thaler, 1980; Barberis & Thaler, 2003; Corzo, 2024). It identified recurrent patterns such as overconfidence, loss aversion, anchoring, and herd behaviour (Agudelo et al., 2024; Lonkani et al., 2025; Bai, 2024). However, BF has mainly examined human decision-makers, with less attention to how behavioural dynamics change when decisions are mediated by AI-enabled systems (Agudelo et al., 2024; Hasan et al., 2024; Klingbeil et al., 2024).

At the same time, AI-in-finance research has grown rapidly in areas such as algorithmic trading, credit scoring, fraud detection, and portfolio management (Goodell et al., 2021; Vuković et al., 2025). This literature largely emphasises efficiency, predictive accuracy, scalability, and personalization (Goodell et al., 2021; Pattnaik et al., 2024), often treating AI as an autonomous decision technology rather than part of a broader organisational knowledge environment. Emerging studies suggest that AI may inherit, amplify, or redistribute bias through data, models, and feedback loops (Barocas & Selbst, 2016; Aldasoro et al., 2025), while hybrid AI systems combine predictive power, contextual reasoning, and system design to improve financial decisions (Asemi et al., 2025). This reveals a limitation in both traditions: BF has paid limited attention to AI-mediated cognition, while AI-in-finance research has insufficiently examined how human judgement, bias, and organisational knowledge processes interact in hybrid decision systems.

2.2 Human–AI collaboration in organisational knowledge processes

Recent research has shifted from viewing AI as a substitute for human expertise toward understanding it as a complement to human cognition (Jarrahi, 2018; Simón et al., 2024; Cui et al., 2024; Byun, 2024; Bai, 2024; Back, 2023). This perspective emphasises complementarity, where human judgement and machine intelligence jointly improve decision-making outcomes (Daud et al., 2022). In organisational settings, this is best understood as human–AI collaboration embedded in knowledge processes. Humans provide contextual interpretation, ethical reasoning, practical judgement, and adaptive sensemaking, while AI contributes computational power, pattern recognition, retrieval speed, and consistency (Jarrahi, 2018; Cui et al., 2024). However, behavioural finance has paid limited attention to AI-mediated cognition, while AI-in-finance research has only recently examined how human judgement, bias, and organisational knowledge processes interact in hybrid decision systems (Hasan et al., 2024; Simón et al., 2024; Do Khac et al., 2025).

From this perspective, human–AI collaboration should be treated not merely as a technical arrangement but as a knowledge-organising mechanism for organisational value creation (Jarrahi, 2018; Simón et al., 2024). AI-enabled systems support knowledge augmentation through retrieval, synthesis, and pattern detection, while human actors remain central to interpretation, validation, and responsible application (Jarrahi et al., 2023; Cui et al., 2024). This is particularly relevant in finance, where decisions combine quantitative analysis with qualitative judgement under uncertainty (Back, 2023). Yet such interaction also creates behavioural and organisational challenges, including overreliance, algorithm aversion, shifting accountability, and trust calibration (Dietvorst et al., 2015; Do Khac et al., 2025). Thus, human–AI collaboration depends not only on better tools but on how cognitive and algorithmic capabilities are integrated within organisational knowledge systems.

2.3 Intelligent knowledge management systems, organisational learning and innovation

Intelligent knowledge management systems (IKMS) are central to understanding AI-supported decision-making in organisations. They can be understood as AI-enabled knowledge infrastructures that support knowledge retrieval, integration, interpretation, and application across organisational processes (Jarrahi et al., 2023; Böhm & Durst, 2025). In knowledge-intensive contexts such as financial institutions, IKMS do not merely automate information handling; they reshape knowledge flows, influence how expertise is combined, and structure decision support.

By improving access to dispersed knowledge, strengthening synthesis, and supporting interpretation, IKMS can enhance organisational learning and adaptive capability (Yan et al., 2026). Their relevance therefore extends beyond efficiency to organizational innovation, as they enable knowledge recombination, learning routines, responsive decision cycles, and better alignment between analytical systems and expert judgement (Simón et al., 2024; Cristache et al., 2025; An et al., 2024). Innovation should therefore be viewed as an organisational outcome of how knowledge is structured, shared, and applied through AI-enabled systems. However, these outcomes depend on system design and governance. Without transparency, human oversight, and knowledge validation, IKMS may reproduce weak judgements, reinforce flawed assumptions, or scale biased knowledge across the organisation (Olan et al., 2022; Rezaei, 2025).

2.4 Value creation beyond profit in AI-enabled knowledge systems

The concept of value creation in finance has traditionally been dominated by economic returns and shareholder wealth. More recent perspectives, however, emphasise that financial organisations are also expected to generate wider institutional and societal value, including trust, transparency, responsibility, and sustainability (Freeman, 1984; Porter & Kramer, 2011; Lim, 2024; Jiang & Lin, 2026; Pizzi et al., 2024). In AI-

enabled knowledge systems, value creation should therefore be understood as multidimensional rather than purely financial.

From a knowledge management perspective, value is generated not only through improved outcomes but through improved knowledge processes. When human judgement and AI capabilities are effectively integrated, organisations may create cognitive value through better decision quality and bias recalibration, institutional value through greater accountability and trust, and societal value through ethical alignment and long-term sustainability (Simón et al., 2024; Rezaei, 2025). In addition, such systems may also support organizational innovation by enabling more adaptive routines, stronger learning capability, and new forms of service, process, or business model development grounded in improved knowledge integration and application (Cristache et al., 2025; Yan et al., 2026; An et al., 2024). This suggests that value beyond profit in financial institutions is not separate from knowledge management; rather, it is increasingly produced through the design, governance, and application of intelligent knowledge systems.

2.5 Literature gap and theoretical positioning

Taken together, the literature points to four unresolved issues. First, behavioural finance explains human bias but does not adequately theorise AI as an active participant in organisational decision systems (Agudelo et al., 2024; Hasan et al., 2024). Second, AI-in-finance research explains technological capability but pays more limited attention to knowledge processes, human oversight, and behavioural dynamics (Goodell et al., 2021; Aldasoro et al., 2025; Rezaei, 2025). Third, the emerging literature on human–AI collaboration has not yet been sufficiently integrated with intelligent knowledge management systems and organisational learning (Simón et al., 2024; Do Khac et al., 2025; Yan et al., 2026). Fourth, the relationship between IKMS-enabled human–AI collaboration, value creation beyond profit, and organizational innovation remains undertheorized (Jarrahi et al., 2023; Simón et al., 2024; Cristache et al., 2025). This paper addresses these gaps by developing a framework that integrates behavioural finance with intelligent knowledge management systems in order to explain how human and AI cognition jointly shape knowledge-intensive financial decision-making and generate cognitive, institutional, and societal value beyond profit.

3 Conceptual Framework Development

3.1 Research design

This study adopts a conceptual design to develop an integrated framework explaining how intelligent knowledge management systems (IKMS) enable human–AI collaboration in financial decision-making and generate value beyond profit. This approach is appropriate because behavioural finance, AI-enabled decision-making, and knowledge management remain insufficiently integrated, especially regarding knowledge processes, governance conditions, and organizational innovation. Following guidance on conceptual article design, the study uses a framework-building approach to integrate fragmented streams (Jaakkola, 2020; Lim, 2026).

The paper applies a methodology suited to theory synthesis across behavioural finance, AI in finance, IKMS, knowledge processes, and multidimensional value creation (Jaakkola, 2020). It explains how human cognition and AI capabilities interact within financial institutions.

The framework was developed through three stages. First, literature synthesis identified constructs and tensions. Second, conceptual integration positioned human cognition and AI capabilities as interdependent sources of intelligence: humans contribute biases, heuristics, emotions, and expertise, while AI contributes data processing, prediction, learning, and reasoning. Their interaction links judgement and algorithmic intelligence in organisational decision-making (Jarrahi, 2018; Simón et al., 2024; Cui et al., 2024). Third, framework construction specified how these elements operate within IKMS. IKMS enables financial decision-making as an organisational knowledge process and supports knowledge-based value creation (Jarrahi et al., 2023; Simón et al., 2024). Human and AI cognition support retrieval, integration, interpretation, and application, enabling collaboration (Jarrahi et al., 2023; Rezaei, 2025).

3.2 Framework development

More specifically, the model distinguishes four interrelated knowledge processes through which human and AI capabilities can be translated into organisational decision support: i) knowledge retrieval refers to accessing internal and external data, information, and expertise relevant to financial decision-making, consistent with prior work showing that AI increasingly supports storage, retrieval, and situated knowledge application in

organisations (Jarrahi et al., 2023); ii) knowledge integration refers to the synthesis of heterogeneous inputs and the identification of patterns across sources, reflecting the broader challenge of combining dispersed organisational and domain knowledge within AI-enabled systems (Miedema et al., 2026); iii) knowledge interpretation refers to the sensemaking process through which integrated knowledge is contextualised, evaluated, and given practical meaning, particularly under conditions of uncertainty (Malik et al., 2025); iv) knowledge application refers to decision support, action recommendations, and the practical use of knowledge in financial decisions, in line with the KM literature that treats AI as increasingly relevant to knowledge use and implementation (Jarrahi et al., 2023; Rezaei, 2025).

Through these stages, IKMS does not merely automate information handling; it structures how knowledge is generated, combined, interpreted, and applied within financial institutions, while also introducing design and governance challenges that shape the quality of organisational outcomes (Jarrahi et al., 2023; Rezaei, 2025).

The framework further assumes that the operation of IKMS is shaped by a set of boundary conditions, namely governance, explainability, trust, and ethical alignment. These conditions influence whether human–AI cognition integration leads to effective and responsible collaboration or instead reproduces opacity, misalignment, or biased outcomes (Papagiannidis et al., 2025; Do Khac et al., 2025; Miedema et al., 2026). In this sense, the framework does not assume that AI eliminates behavioural bias. Rather, it recognises that biases may be reshaped, redistributed, or amplified within hybrid knowledge systems, making system design and oversight central to value creation (Barocas & Selbst, 2016; Xia et al., 2026; Kim et al., 2026).

Within this structure, human–AI collaboration is conceptualised as the immediate organisational mechanism emerging from the interaction of human cognition, AI capabilities, and IKMS-enabled knowledge processes. This view is consistent with prior work that treats human–AI collaboration not merely as technological interaction, but as an organisational arrangement through which human and algorithmic capabilities are combined for value creation (Jarrahi, 2018; Simón et al., 2024; Do Khac et al., 2025). This collaboration is characterised by complementarity, augmentation, and oversight, meaning that AI supports but does not replace human judgement. The model therefore treats collaboration not simply as technical coexistence, but as a knowledge-based mode of interaction in which human and AI capabilities jointly shape decision quality and organisational outcomes.

On this basis, the framework conceptualises value creation outcomes across four dimensions: i) cognitive value refers to improved decision quality, bias recalibration, and enhanced risk insight; ii) institutional value refers to transparency, accountability, and trust in AI-supported systems; iii) societal value refers to ethical alignment, sustainability, and long-term stability. In addition, the model includes a fourth dimension iv) organizational innovation as an important outcome, reflected in new processes, services, business models, and enhanced organisational learning and adaptive routines. This is consistent with emerging work suggesting that human–AI teaming and knowledge management can generate value not only through performance improvements, but also through trust-building, learning, and organisational adaptation (Simón et al., 2024; Cristache et al., 2025; Jiang & Lin, 2026). Accordingly, the framework assumes that intelligent knowledge management systems may generate not only better decisions, but also broader innovation-related benefits for financial institutions.

The framework further assumes that feedback and continuous improvement are integral to the operation of IKMS, such that the results of human–AI collaboration inform subsequent rounds of knowledge retrieval, integration, interpretation, and application (Yan et al., 2026; Zheng et al., 2025). In this sense, human–AI collaboration evolves through iterative learning, adaptive refinement, and ongoing recalibration of both system outputs and human judgement, consistent with organisational learning perspectives on AI capability development (Yan et al., 2026; Ritala et al., 2024).

Figure 1 presents this conceptual framework. It shows that value creation and organizational innovation do not emerge directly from either human cognition or AI alone, but from their interaction as embedded in intelligent knowledge management systems and mediated through organisational knowledge processes. The figure also highlights that feedback and continuous improvement are integral to the model, reinforcing the idea that human–AI collaboration evolves through ongoing learning, refinement, and adaptive innovation.

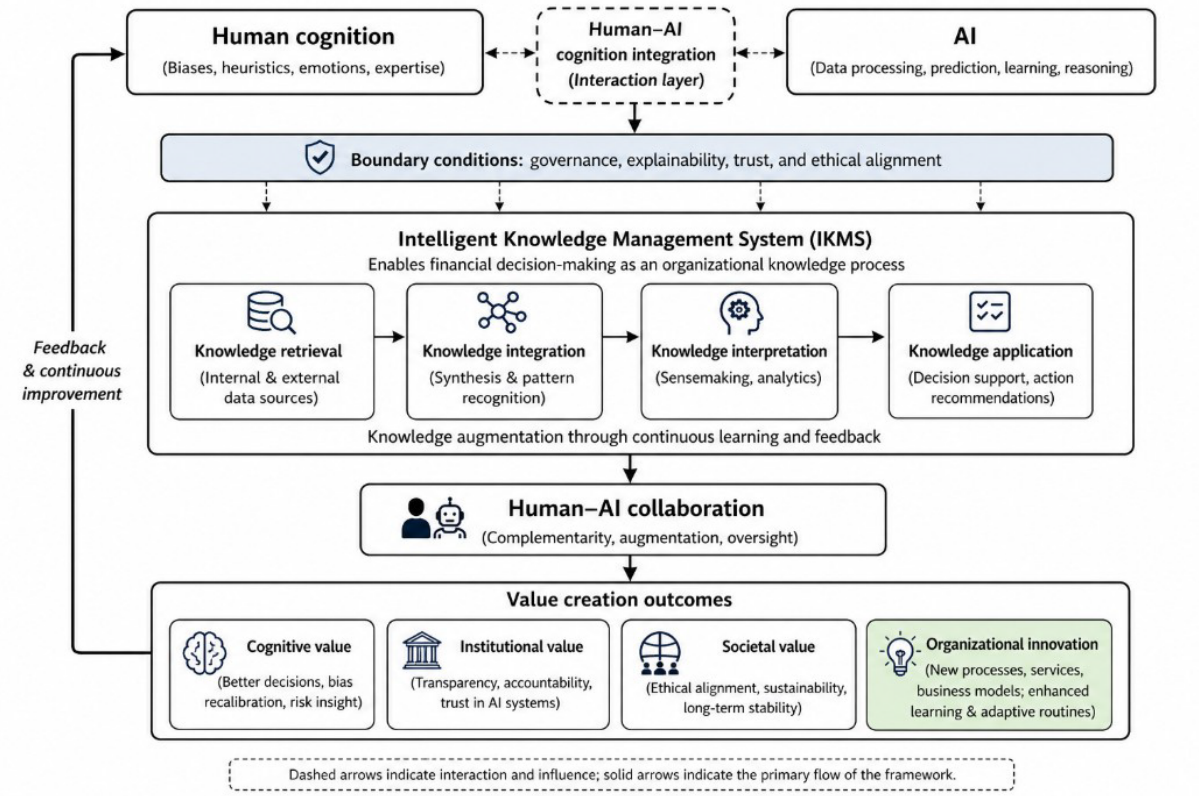

Figure 1: Conceptual framework

3.3 Proposition development

Based on the conceptual framework, the study develops five propositions specifying how human cognition, AI capabilities, intelligent knowledge management systems, organisational knowledge processes, and boundary conditions jointly shape value creation beyond profit in financial institutions.

P1: Human–AI cognitive complementarity within intelligent knowledge management systems enhances cognitive value through improved decision quality, enhanced risk insight, and bias recalibration.

P2: Intelligent knowledge management systems that effectively support knowledge retrieval, integration, interpretation, and application are more likely to enable effective human–AI collaboration in financial decision-making.

P3: Governance, explainability, trust, and ethical alignment act as boundary conditions that strengthen the positive relationship between human–AI collaboration and institutional and societal value.

P4: Feedback and continuous improvement mechanisms within intelligent knowledge management systems strengthen human–AI collaboration by enabling iterative learning and adaptive refinement of both system outputs and human judgement.

P**5:** Intelligent knowledge management systems that successfully integrate human and AI cognition are more likely to generate organizational innovation through improved knowledge recombination, adaptive learning routines, and more responsive decision processes.

These propositions suggest that the value of intelligent knowledge management systems lies not only in technological capability, but in how human and AI cognition are organised through knowledge processes, shaped by boundary conditions, and developed through iterative learning within financial institutions.

4 Discussion

The central contribution of this paper is to show that value creation in financial decision-making is not solely a technical or financial outcome, but the product of human–AI cognition integration embedded in intelligent knowledge management systems. By integrating behavioural finance, AI in finance, human–AI collaboration, and IKMS into a single framework, the study responds to a fragmented literature that has largely examined these domains separately. The framework suggests that financial decision-making should be understood as a knowledge-intensive organisational process in which value emerges through retrieval, integration, interpretation, and application rather than through technological capability alone. A first implication of the

framework is that human–AI collaboration is best understood as cognitive complementarity rather than substitution, as reflected in P1 and P2. AI contributes retrieval, synthesis, and pattern recognition, while human actors remain central to interpretation, validation, judgement, and responsible use. These propositions suggest that cognitive value depends both on the complementarity between human and AI capabilities and on the extent to which IKMS effectively support the underlying knowledge processes. Decision quality therefore becomes the outcome of hybrid cognition rather than isolated human judgement. A second implication is that bias must be analysed at the level of hybrid knowledge systems rather than at the level of individual decision-makers alone, which is captured in P3. The framework suggests that AI does not eliminate behavioural bias, but may redistribute, reshape, or amplify it through data, models, feedback loops, and patterns of organisational use. Governance, explainability, trust, and ethical alignment therefore function as boundary conditions that shape whether human–AI collaboration generates institutional and societal value or instead reinforces opacity and misalignment. A third implication is that human–AI collaboration should be treated as an iterative learning process rather than a static decision arrangement, as proposed in P4. By incorporating feedback and continuous improvement, the framework highlights that both system outputs and human judgement can be recalibrated over time. This feedback logic is especially important in financial institutions, where the quality of future decisions depends on whether prior outcomes are translated into organisational learning and system refinement. A fourth implication is that organizational innovation emerges as a systemic consequence of how IKMS structure knowledge processes, as formalised in P5. Better-designed human–AI knowledge systems do more than improve isolated decisions: they enable stronger knowledge recombination, more adaptive routines, and more responsive decision cycles. In this sense, organizational innovation is not external to value creation beyond profit, but one of its core organisational expressions.

These propositions generate three focused contributions. The paper extends behavioural finance toward hybrid knowledge systems, reframes AI in finance as an organisational knowledge process rather than a purely technical capability, and positions IKMS as the mechanism linking human–AI collaboration to multidimensional value creation and organizational innovation. For practice, the implication is equally clear: financial institutions should evaluate AI not only in terms of predictive performance, but also in terms of governance, knowledge quality, learning capacity, and the extent to which AI strengthens rather than weakens human judgement.

5 Conclusion

This paper examined how intelligent knowledge management systems (IKMS) enable human–AI collaboration in financial decision-making and how this collaboration contributes to value creation beyond profit. By integrating insights from behavioural finance, AI in finance, and knowledge management, the study showed that financial decision-making should be understood not only as a technical or analytical activity, but as a knowledge-intensive organisational process. The framework argues that AI functions not as a substitute for human judgement, but as a cognitive complement embedded in organisational knowledge processes of retrieval, integration, interpretation, and application.

The paper makes three main contributions. First, it extends behavioural finance by incorporating AI as an active participant in hybrid knowledge systems. Second, it reframes AI-supported decision-making in finance as a process shaped by knowledge governance, trust, explainability, and ethical alignment rather than by performance alone. Third, it shows that IKMS may generate not only cognitive, institutional, and societal value, but also organizational innovation through improved learning, knowledge recombination, and adaptive decision routines. Overall, the study suggests that the future of financial decision-making lies not in full automation, but in the development of well-governed intelligent knowledge management systems that support more trustworthy, adaptive, and innovation-oriented financial organisations.

Assessing Knowledge Management Maturity in Public Sector Organizations: Model Development and Case-Based Validation

Ingrida Girnienė, Laura Valiukevičienė
Vilnius University, Faculty of Communication, Vilnius, Lithuania

Abstract

Knowledge management (KM) maturity has become increasingly relevant as organizations seek to improve operational reliability, support digital transformation, and prepare for the responsible use of artificial intelligence (AI). However, existing KM maturity models are often discussed as generic frameworks and are less frequently adapted and empirically applied in specific organizational and public-sector contexts. This paper develops and applies a context-adapted KM maturity assessment model in a Lithuanian public-sector transport organization. The study addresses the question of how KM maturity can be purposefully assessed through a model that is sensitive to organizational, sectoral, and contemporary digital-transformation conditions, and what level of maturity characterizes the selected case organization. The model was constructed through a comparative analysis of established KM maturity models, including Siemens KMMM, G-KMMM, APQC, KNM 2.0, and IT-CMF, and was aligned with ISO 30401:2018 principles. In response to the growing role of AI in KM, the model distinguishes between innovation-enabled high maturity and AI-supported maturity at the highest stage. The empirical research applies a case-study strategy combining strategic document analysis and semi-structured interviews with managers from different functional areas. Findings show that KM is present in the organization, but is not explicitly formalized as an independent strategic priority. The strongest dimensions are culture, people, and technology: employees generally experience a cooperative environment, learning systems are available, and multiple digital tools support knowledge storage and communication. However, KM processes remain fragmented, knowledge ownership is unclear, search and taxonomy are weak, and KM performance indicators are absent. The paper contributes by proposing a diagnostic model that is both descriptive and prescriptive: it assesses the current maturity state and indicates development priorities for progression. Managerially, the study highlights the need to formalize KM policy, clarify ownership, integrate KM objectives with technology and AI initiatives, and introduce KM performance measurement.

Keywords: knowledge management maturity; public sector; maturity model; digital transformation; artificial intelligence

Paper type: Academic Research Paper

1 Introduction

Knowledge has long been recognized as a strategic organizational resource, but its managerial importance has intensified amid digital transformation and artificial intelligence. Organizations increasingly rely on accurate, accessible, and reusable knowledge to make decisions, redesign processes, support service quality, and retain expertise when employees move between roles or leave. In the public sector, where continuity, accountability, and service reliability are especially important, knowledge management (KM) is not only a managerial tool, but also a condition for institutional resilience and public value creation.

The relevance of KM maturity has grown because digital and AI-enabled transformation depends on the availability, quality, and governance of organizational knowledge. Recent discussions of AI adoption emphasize that value is achieved not only through technology acquisition, but through redesigned workflows, data and knowledge governance, human validation, measurable outcomes, and organizational adoption practices (McKinsey & Company, 2025; Gartner, 2024). In this sense, KM maturity is not treated as a separate technological capability in this paper. It is conceptualized as an organizational capability that conditions how well technology and AI can be used for knowledge creation, storage, sharing, and application.

Although KM maturity models offer structured ways to assess such capability, the literature also identifies several limitations. Many models have been designed for broad or large-scale corporate use, emphasize only selected dimensions, and are difficult to apply directly in specific national, sectoral, or organizational contexts (Escrivão and Da Silva, 2019; Bougoulia and Glykas, 2023). Empirical applications in public-sector organizations remain comparatively limited. In Lithuania and the Baltic context, KM maturity assessment is particularly underdeveloped, with only isolated prior applications and limited evidence about how maturity models should be adapted to local organizational realities (Šajeva and Jucevičius, 2010).

This study therefore aims to develop and empirically validate a context-adapted KM maturity assessment model that enables systematic evaluation of KM practices in a public-sector organization and supports the identification of development priorities. The study is situated in organizational, public-sector, and contemporary

digital-transformation contexts. It is an organizational context, because the model is adapted to the selected case organization and its existing practices. It is a public-sector context, because the organization performs strategically important passenger transport functions and operates under public accountability and service-continuity expectations. It is a contemporary digital-transformation context because the model explicitly considers technology, performance measurement, and AI-supported maturity.

The main research question in the paper is: how can KM maturity be assessed in an organization through a context-appropriate maturity model? The contribution is both theoretical and practical. Theoretically, the paper integrates classical KM maturity logic with ISO 30401:2018 and digital-transformation considerations. Practically, it proposes a diagnostic model that identifies strengths, weaknesses, and improvement pathways.

2 Literature Background

KM is commonly understood as a set of organizational processes through which knowledge is created, stored, shared and applied to support organizational objectives (North and Kumta, 2018; Alavi and Leidner, 2001; Dalkir, 2021). Early KM research emphasized the socio-technical nature of KM systems: technologies can support knowledge processes, but their effectiveness depends on people, culture, organizational structure, and managerial priorities. Nonaka and Takeuchi (1995) similarly argued that knowledge creation requires interaction between tacit and explicit knowledge, making organizational culture and social practices central to KM performance.

Maturity models emerged as tools to assess how systematically an organization manages a particular capability. The Capability Maturity Model logic influenced many KM maturity frameworks by introducing staged development from informal and reactive practices to optimized and continuously improved processes (Paulk et al., 1993; Rios, Rodríguez-Elias and Pino, 2011). KM maturity models apply this logic to knowledge-related activities, helping organizations diagnose their current state and plan improvement.

Several established KM maturity models were analyzed in this study. The Siemens KMMM by Ehms and Langen (2002) offers a socio-technical assessment across multiple areas, including strategy, people, culture, knowledge structures, technology, and processes. The G-KMMM integrates people, processes, and technology and defines sequential maturity levels from initial to optimizing (Pee and Kankanhalli, 2009). The APQC model emphasizes standardized assessment and benchmarking across areas such as people, process, content, technology, and strategy (APQC, 2016; Hubert and Lemons, 2019). KNM and KNM 2.0 offer a more detailed assessment with dimensions and indicators that can be converted into maturity indices (Hsieh, Lin and Lin, 2009; Hsieh et al., 2020). IT-CMF extends the discussion toward the digital age by emphasizing that KM maturity must account for analytics, digital tools, information overload and the capacity to learn dynamically (Thornley et al., 2016).

The comparison of these models indicates some important outcomes:

- people, processes and technology are foundational and appear in nearly all models;
- culture, strategy and performance measurement are often decisive for the sustainability of KM, but are not always sufficiently explicit;
- digital transformation and AI require maturity models to move beyond technology availability toward integration, governance, quality control, human oversight and measurable value.

ISO 30401:2018 reinforces this broader view by framing KM as a management system aligned with organizational context, leadership, planning, support, operation, evaluation and improvement (ISO, 2018; Carlucci et al., 2022).

The literature also shows a gap between model design and empirical use. Escrivão and Da Silva (2019) identify fragmentation and the need for models that reflect organizational complexity rather than isolated technological indicators. Bougoulia and Glykas (2023) argue for more holistic frameworks aligned with ISO 30401 and for stronger implementation orientation. This is especially relevant for public-sector organizations, where KM may be embedded in HR, quality, digitalization or operational routines without being labelled as KM.

3 Model Development

The adapted model developed in this study includes seven dimensions: people, processes, technology, culture, strategy and management, performance management, and results (Figure1). The model is context-adapted because these dimensions were selected through a synthesis of classical KM maturity models, ISO 30401:2018 requirements and the empirical characteristics of the selected organization. It does not assume that KM must be managed through a separate department; instead, it assesses whether KM practices are sufficiently visible, coordinated, measurable and value-generating across organizational routines.

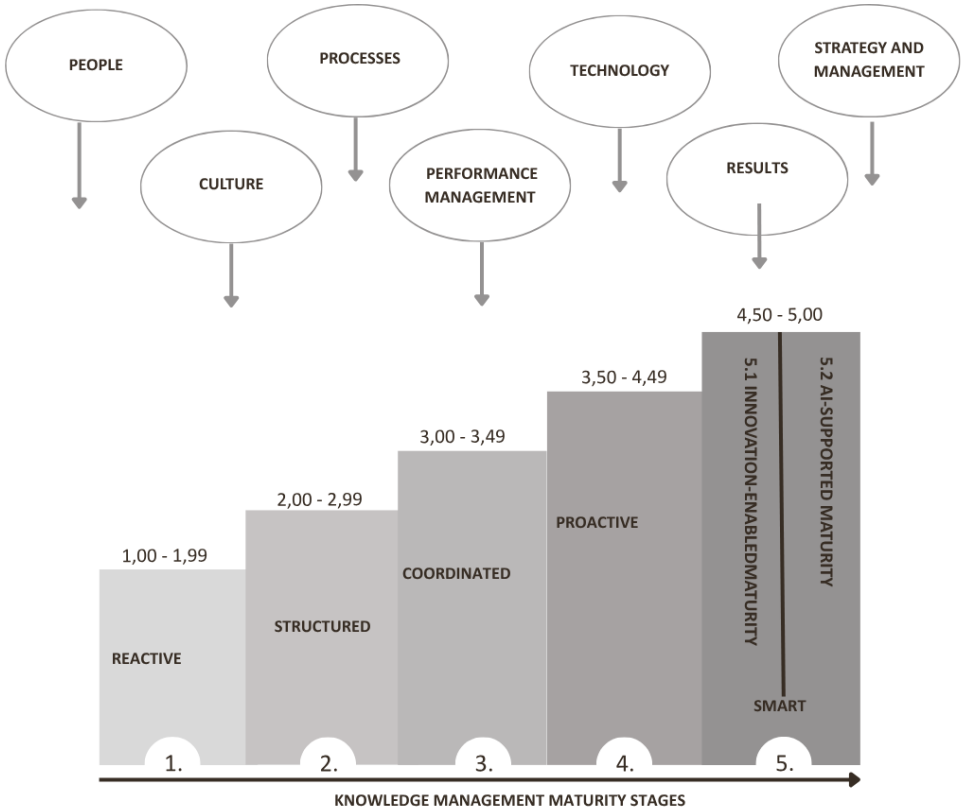

Figure 1 : Knowledge Management adapted model

The people dimension assesses competence development, motivation, roles, leadership, and knowledge-sharing behaviour. The processes dimension assesses the documentation, storage, searchability, repeatability, updating, and control of knowledge processes. The technology dimension evaluates the availability, usability, and integration of digital tools, including AI-related initiatives. The culture dimension assesses trust, openness, collaboration, learning from mistakes, and managerial role modeling. The strategy and management dimension evaluates the alignment of KM with organizational objectives, policy, governance, and resources. The performance management dimension assesses whether KM indicators, audits, and feedback mechanisms exist and are used for improvement. The results dimension evaluates whether KM creates visible organizational value, for example, faster onboarding, improved decisions, fewer errors, process efficiency, or innovation.

The maturity scale consists of five main stages. Level 1, reactive, describes organizations where KM is largely unrecognized, and knowledge is managed informally. Level 2, structured, indicates the existence of initial practices, documents or tools, but with limited coordination. Level 3, coordinated, describes organizations where core KM practices exist across several areas but are not fully integrated strategically or measured consistently. Level 4, proactive, indicates systematic KM practices, clear responsibilities, managerial support and continuous improvement. Level 5 describes smart maturity and is divided conceptually into two subtypes: 5.1 innovation-enabled maturity, where KM is integrated into innovation and advanced digital tools; and 5.2 AI-supported maturity, where AI is embedded in knowledge search, classification, reuse, recommendation, validation or real-time application. The sublevels are not scored separately in this paper; they clarify the difference between classical high maturity and AI-enabled KM maturity.

The model is primarily diagnostic, but also prescriptive. It is descriptive because it assesses the current level of maturity in each dimension. It is prescriptive because each level implies a development path: for example, an organization at Level 2 in performance management must define KM indicators and evaluation routines before it can claim Level 3 or Level 4 maturity.

4 Methodology

The empirical study adopts a qualitative case-study strategy, supported by structured scoring. A case study is appropriate because KM maturity is a complex organizational phenomenon embedded in routines, practices, documents, and managerial interpretations (Yin, 2018). The selected case is a Lithuanian public-sector

organization. The case was selected purposively for its strategic public-service role, operational complexity, digitalization agenda, emphasis on service quality, and reliance on coordinated knowledge across functions.

Two data sources were used (Figure 2). First, a strategic document analysis was conducted using the 2024 annual report, the 2025 first-half report, and the 2029 organizational strategy. The document analysis identified explicit and implicit references to the seven model dimensions. Repeated content across at least two documents was treated as stronger evidence of stable organizational practice, while isolated references were considered supplementary. Second, seven semi-structured interviews were conducted with managers from different functional areas: project management, operational efficiency, customer service, business support, international development, technical project development, and human resources. The informants represented both strategic and tactical perspectives and had organizational experience ranging from less than one year to eighteen years.

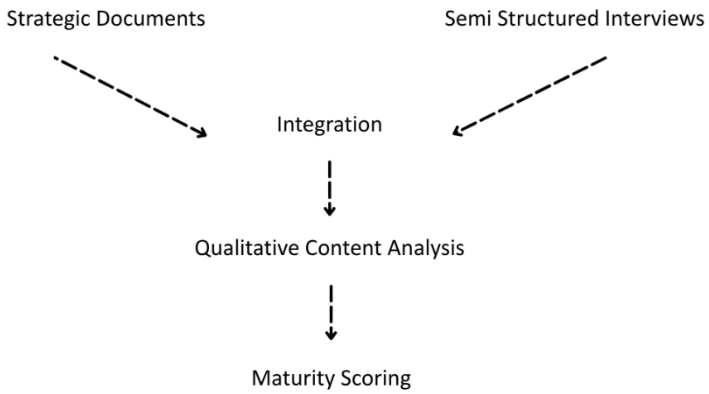

Figure 2: Data source integration

Interview questions were structured around the seven model dimensions. Seven interviews were conducted remotely and in person, recorded, and transcribed. The analysis followed qualitative content analysis. Evidence was coded into categories and subcategories, such as knowledge storage, role clarity, learning systems, searchability, knowledge-sharing culture, strategic alignment, and performance measurement. The qualitative findings were then translated into maturity scores for each dimension using the adapted maturity scale. The final score was calculated as the arithmetic mean of the dimensional scores. This scoring approach was used not to claim statistical generalizability, but to make the diagnostic interpretation transparent and comparable across dimensions.

5 Findings

The strategic document analysis shows that KM is not explicitly articulated as an independent strategic priority in the organization. There is no separate KM policy, no explicit KM objectives, and no formalized KM performance measurement system. Nevertheless, several KM-related elements appear implicitly in the organization's strategic language and operational initiatives. The strongest documentary evidence relates to people, culture, and technology. The documents repeatedly emphasize improvement, cooperation, employee development, inclusion, and digitalization. Programs such as onboarding, recognition initiatives, learning platforms, and competence evaluation indicate that knowledge-related activities are embedded in HR and organizational development routines.

The people dimension received a score of 3, corresponding to a coordinated level. The organization has a competence management center, learning systems, mandatory and additional training, mentoring-like practices, and recognition mechanisms. Managers confirm the existence of a learning management system and formal competence-development practices. However, knowledge ownership is not always clear, and some employees, particularly in operational roles, may hesitate to document their knowledge because tacit expertise is perceived as a means of protecting individual replaceability. This creates a risk of knowledge loss and shows that people-related KM practices, while present, are not yet fully systematic.

The processes dimension received a score of 2.5, indicating a maturity between structured and coordinated. Formal processes exist for onboarding, training, and repeated tasks, and employees use templates, forms, and established documents. At the same time, knowledge storage and retrieval remain fragmented. Knowledge is stored across SharePoint, Teams, document management systems, and other tools, but there is no unified taxonomy or reliable search logic. Managers report that keyword searches do not always lead to the most current or relevant information. Knowledge capture is being addressed through planned pilot initiatives, such as

a professional-mastery project, but these initiatives are not yet institutionalized. Process control is weak: KM processes are not evaluated as KM processes, and general audits do not substitute for systematic knowledge-process assessment.

The technology dimension received a score of 3, indicating a coordinated level of maturity. The organization uses multiple digital tools, including a document management system, learning management system, SharePoint, Microsoft Teams, SAP-related competence tools, and JIRA. These tools enable information storage, communication, learning, and task coordination. Technology, therefore, supports KM, but mainly as infrastructure. The tools are not sufficiently integrated, and users experience search, usability, and taxonomy problems. AI use is emerging but not yet embedded in KM. Some managers use Microsoft Copilot individually, and a project for transforming the knowledge base with AI is planned. However, AI currently supports individual productivity rather than an integrated organizational KM system.

The culture dimension received the highest score, 4, corresponding to proactive maturity. Interviews indicate a generally open, friendly, and cooperative environment. Managers describe employees as willing to help one another, and leadership is perceived as modeling information sharing. Recognition practices and public acknowledgment of knowledgeable employees support positive knowledge-sharing norms. This finding aligns with strategic documents emphasizing cooperation, development, and respectful working conditions. However, the cultural score is not 5 because knowledge hoarding persists in some roles and because the link between cultural values and formal KM routines is incomplete.

The strategy and management dimension received a score of 2, corresponding to structured maturity. The organization has a long-term strategy, clearly communicated values, and strategic development cycles, but KM is not named as a strategic priority. Interviewees explicitly note that there is no separate KM policy. Knowledge sharing is visible through values and inter-organizational cooperation, including learning from partner organizations, but these practices remain embedded in general strategy rather than governed as KM. Resources are not allocated specifically to KM, and ownership of some knowledge processes remains unclear.

The performance management dimension received the lowest score, 1, corresponding to reactive maturity. The organization uses feedback tools and competence-evaluation practices and collects general operational indicators. However, there are no KM-specific indicators, no systematic evaluation of knowledge creation, sharing, reuse, or loss, and no measurement of the value created by KM initiatives. This creates a major barrier to maturity progression. Without measurement, the organization cannot reliably determine whether knowledge processes improve decision-making, reduce repeated errors, accelerate onboarding, or support innovation.

The results dimension received a score of 2, indicating a structured level of maturity. Managers recognize knowledge and experience as highly valuable and directly related to strategic goals. One interviewee emphasized that achieving the organization's strategic aspiration requires improving knowledge transfer and KM practices. However, KM results are not measured directly. Benefits are identified only indirectly through general performance, service improvement, competence development, and strategic projects. Knowledge risks are also visible: outdated content, weak searchability, and insufficient documentation may reduce the reliability and speed of decision-making.

Overall, the organization's KM maturity is assessed at 2.5 out of 5, indicating a structured and coordinated level. The organization has important foundations for KM: learning systems, digital tools, cooperative culture, and managerial awareness. Yet these foundations remain only partly integrated. KM is not formalized strategically, processes are fragmented, technology is not fully interoperable, and performance measurement is absent.

Table 1: Summary of maturity scores

Dimension	Score	Maturity interpretation	Main evidence
People	3.0	Coordinated	Competence management, LMS, training, and mentoring are in place; role clarity and knowledge capture remain uneven.
Processes	2.5	Structured/coordinated	Templates, onboarding, and training processes exist; storage, search, taxonomy, and control are fragmented.
Technology	3.0	Coordinated	Multiple tools support KM; integration, usability, and AI embedding remain limited.
Culture	4.0	Proactive	Cooperative, open environment and leadership support; some knowledge hoarding persists.
Strategy and management	2.0	Structured	A long-term strategy and values exist, but KM policy, objectives, and resources are not explicitly defined.

Dimension	Score	Maturity interpretation	Main evidence
Performance management	1.0	Reactive	General indicators and feedback exist, but KM indicators and evaluation are absent.
Results	2.0	Structured	Knowledge value is recognized, but KM benefits and risks are not systematically measured.

6 Discussion

The findings confirm that KM maturity in the selected public-sector organization is not absent, but it is implicit, fragmented, and unevenly developed. This supports the argument that KM in contemporary organizations often appears through HR, quality management, digitalization, and operational routines rather than through explicit KM policies. The case, therefore, illustrates why generic maturity models need contextual adaptation. A model limited to technology, for example, would overestimate maturity because many tools are available. A model limited to culture would also overestimate maturity because the organization demonstrates strong collaboration. Conversely, a model incorporating strategy, performance management, and results reveals that KM has not yet become a systematically governed capability.

The study also clarifies the relationship between KM maturity, AI, and digital transformation. AI is represented in the model in two ways. First, it appears in the technology dimension, where the empirical assessment examines whether AI tools are used, integrated, and connected to organizational knowledge repositories. Second, AI is incorporated into the highest maturity level, where AI-supported KM is distinguished from general innovation-enabled maturity. In the case of an organization, AI is not yet a maturity driver; it is an emerging initiative. This finding is important because it avoids treating AI adoption as proof of maturity. AI-supported KM requires reliable knowledge bases, governance, taxonomy, quality control, human validation, and performance measurement. Without these foundations, AI may accelerate access to poorly governed knowledge rather than improve KM maturity.

The novelty of the paper lies in three elements. First, it proposes a seven-dimensional maturity model that combines classical KM maturity dimensions with ISO-aligned governance, performance, and results dimensions. Second, it adapts the maturity scale to digital transformation by separating innovation-enabled and AI-supported maturity at the highest level. Third, it empirically applies the model in a Lithuanian public-sector context, where KM maturity studies are limited. This responds to calls for more grounded and context-sensitive KM maturity research (Escrivão and Da Silva, 2019; Bougoulia and Glykas, 2023).

Theoretical implications arise from the model's multidimensional character. The study demonstrates that KM maturity should be evaluated as an organizational configuration rather than a single capability. High maturity requires alignment among culture, process, technology, strategy, and measurement. The case shows that strong culture and technology do not compensate for weak performance management. This finding supports socio-technical views of KM and extends them by emphasizing measurement and AI-readiness as contemporary maturity conditions.

Managerial implications are also clear. The organization should formalize KM as a strategic objective or policy area, without necessarily creating a separate bureaucratic unit. Knowledge ownership should be clarified for critical documents, processes, and repositories. A unified taxonomy and semantic search approach should be developed to improve knowledge accessibility. AI initiatives should be aligned with KM objectives and governed by quality, responsibility, and human-validation rules. KM indicators should be introduced, such as time required to find critical knowledge, onboarding duration, reuse of documented lessons, frequency of content updates, knowledge-loss incidents, and employee perceptions of knowledge accessibility. These steps would move the organization from a structured/coordinated maturity level to a proactive maturity.

7 Conclusions

This paper developed and applied a context-adapted KM maturity assessment model in a public-sector organization. The study shows that KM maturity can be purposefully assessed by combining established maturity-model logic with context-sensitive dimensions and empirical evidence from documents and managerial interviews. The proposed model is both descriptive and prescriptive: it identifies the current maturity level and indicates what must be improved to progress to higher maturity.

The organization has a strong collaborative culture, established learning practices, and multiple digital tools. However, KM is not explicitly defined in strategy, processes are fragmented, knowledge search and taxonomy are weak, AI is not yet embedded in KM, and KM performance is not measured. The most important maturity barrier is therefore not the absence of knowledge-related activity, but the absence of systematic integration and evaluation.

The study contributes to KM maturity literature by offering a model suitable for public-sector and digitally transforming organizations. AI-supported KM requires prior development of governance, knowledge quality, process integration, and measurement. Future research could apply the model across multiple organizations, compare public and private sector cases, and test the scoring instrument quantitatively using a larger sample.

8 Ethics Declaration

The empirical research was conducted with voluntary participation from managers. Interviewees were anonymized, and findings are reported in aggregated form to avoid disclosure of personal or sensitive organizational information.

9 AI Declaration

AI tools were used to support language editing, structuring, and academic drafting based on the author-provided research material. The author is responsible for verifying the accuracy, validity, and appropriateness of the final paper.

The Role of Servant Leadership and Technology in Driving Organizational Citizenship Behaviour

Silvia Martelo-Landroguez, Jerónimo García-Fernández, Gabriel Cepeda-Carrión
Universidad de Sevilla, Seville, Spain

Abstract

The continuous change process in which today's society is immersed increasingly requires leaders to behave ethically and consider all stakeholders in the company (Al-Asadi et al., 2019). As a result, leadership has evolved from approaches that are more focused on how the personality of the leader influences individuals (e.g., transactional or transformational leadership) to more holistic approaches to leadership, such as servant leadership (SL), which is more focused on the individuals themselves (Panaccio et al., 2015).

Previous research has generally indicated a positive effect of SL on employee outcomes (Bavik, Bavik, and Tang, 2017; Lu, Falahat, and Cheah, 2024). However, more work is necessary to ascertain how and through what mechanisms SL influences such outcomes (Lu et al., 2024). In this regard, we have identified a fundamental element: technological adaptation. For many years, there has been a trend towards the digital transformation of companies, a process that has been accelerated by the COVID-19 pandemic situation. As the need for technological adaptation of companies is affecting most industries, the role that technology assumes for all parties in firms must be considered today.

This study examines the influence of SL and technological adaptation capability (TAC) on employees' organizational citizenship behaviour (OCB), using a sample of 53 leaders and 481 knowledge workers responsible for sports training activities that require advanced knowledge and empathy in fitness centres in Spain.

Our results indicate that establishing a TAC, by which knowledge workers encourage subordinates to make their own technological tool choices, is feasible and positively mediates the relationship between SL and OCB. The identification of SL as a catalyst for knowledge-sharing behaviour is largely consistent with the conclusions of authors such as Srivastava, Bartol and Locke (2006), who assert that servant leaders provide guidance and recognition to employees, thereby creating the context in organizations for sharing knowledge.

Keywords: Leadership, technology, employee outcomes, citizenship behaviour, knowledge sharing.

Paper type: Academic Research Paper

1 Introduction

Knowledge workers are highly qualified employees with highly specialized knowledge who become the primary driver of innovation within companies. As the environment change, they and their organizations must adapt to meet new challenges by keeping their team members motivated, confident, and aligned with the organization's goals through leadership (Alvesson, 2019).

The ongoing societal transformation process requires leaders to behave ethically and consider all stakeholders in the company (Al-Asadi et al., 2019). Traditional leadership styles fail to generate the intrinsic motivation that is currently leading to a higher level of organizational performance (Su et al., 2020). As a result, leadership has evolved from leader-focused approaches (e.g., transactional, or transformational leadership) to more holistic approaches, such as SL, which emphasizes individuals (Panaccio et al., 2015). Leaders must secure employee commitment by being the first to be committed to the organization (Djibo, Desiderio, and Price, 2010), focusing on follower development and achieving a sustainable competitive advantage that will allow organization survival in today's markets.

Previous research has generally indicated a positive effect of SL on employee outcomes (e.g., Bavik et al., 2017; Lu et al., 2024). Although OCB has been identified as a contributor to a more positive work environment, leading to increased organizational performance, lower turnover, and greater productivity, its underlying mechanisms are poorly understood (Koning and Van Kleef, 2015; Newman et al., 2017). The link between SL and OCB is still considered a black box (Addisu, Abebe, and Assefa, 2024). Several mediators have been proposed between SL and OCB, such as employee empathy, perceptions of leaders' ethics, perceived procedural justice and trust, and group service climate (Qiu and Dooley, 2022; Reiley and Jacobs, 2016). However, more work is necessary to ascertain how and through what mechanisms SL influences both organizational and individual-level outcomes (Lu et al., 2024). Servant leaders should cultivate an organizational culture that motivates employees to engage in OCB because they want to and not because they expect external rewards (Thomas, Ambrosini, and Hughes, 2019).

In this regard, TAC is key. For many years, there has been a trend towards the digital transformation of companies. COVID-19 pandemic situation has accelerated this process. Hence, the role that technology assumes for all parties in firms must be considered today. Suppose that employees perceive that leaders adopt technological systems to aid their job performance. In that case, they will experience higher levels of participation, which will motivate them to perform OCB. Specifically, our research question is: to what extent do SL and TAC significantly influence the OCB of employees? This aspect has been treated poorly in the management domain and the context of sports (Welty Peachey et al., 2015). Therefore, technology is incorporated into the proposed model to analyse whether SL can encourage its use and influence employee behaviour.

2 Theoretical Background

2.1 Organizational citizenship behaviour (OCB)

OCB has been conceptualized in many ways (Klotz et al., 2018). Williams and Anderson (1991) developed the most popular conceptualization, distinguishing between organization-focused OCB (i.e., actions aimed at the compliance with organizational rules and norms) and individually-focused OCB (i.e., actions explicitly aimed at helping individuals). This study uses such division into categories in terms of the target or direction of behaviour.

OCB includes behaviours that are of benefit to an organization but are outside the formal requirements of the job and rewards (Koning and Van Kleef, 2015). In this vein, Organ (1997) contends that employee behaviour does not need to be discretionary or voluntary to be considered an act of citizenship, it only needs to be contextual because it contributes to the organizational context supporting task performance. These behaviours are also referred to as extra-role behaviours, which are behaviours that cannot be required of employees for a particular job (Morrison, 1994). In any organization, at any given moment, any knowledge worker could do something that, albeit unrequired, could be helpful for other knowledge workers or the organization itself (Yam et al., 2017). Finding ways to encourage such behaviour in knowledge workers without directly requesting is essential.

2.2 Servant leadership (SL)

The growing level of knowledge in society (i.e., regarding people and employees) means that leadership styles associated with direct supervision are, in many cases, no longer effective and have bowed to other more successful approaches related to empowerment (Zu, 2019).

Greenleaf (1970) coined the term 50 years ago, and since then, numerous literature reviews have been conducted on SL (e.g., Parris and Welty Peachey, 2013; van Dierendonck, 2011). However, there is still a need to reach a consensus on its definition or theoretical framework (Mcquade, Harrison, and Tarbert, 2021). The seminal definition of SL proposed that: “The servant leader is servant first... it begins with the natural feeling that one wants to serve, to serve first. Then conscious choice brings one to aspire to lead” (Greenleaf, 1970, p. 7). We take the definition by Eva et al. (2019) as a reference, providing a solid basis for operationalizing the measures of SL that our analysis requires (Qiu and Dooley, 2022). We refer to SL as “an other-oriented approach to leadership, manifested through one-on-one prioritization of follower individual needs and interests, and outward reorienting of their concern for self towards concern for others within the organization and the larger community” (Eva et al., 2019, p. 114).

2.3 Technological adaptation capability (TAC)

The COVID-19 pandemic has changed our understanding of the world, affected the daily life of knowledge workers, and forced organizational structures to adapt to the latest technological formulas. Technology and its outputs (such as databases, files, and protocols) enable organizations to retain and make use of their valuable technology skills (Gold, Malhotra, and Segars, 2001). This study refers to technology as all the hardware and software that a company needs to use to achieve its goals (Laudon and Laudon, 2013). Technology can also be seen as all the products, methods, inventions, and standards that can be used to generate and share information (Kroenke, 2013) or as a tool for the management, storage, and dissemination of structured knowledge. Therefore, TAC refers to the firm’s ability to use technology to support work practices and improve working conditions (Ipe, 2003).

TAC constitutes an essential element of the structural dimension necessary for the mobilization of social capital to create new knowledge. Such capability is helpful because it supports better communication and collaboration, facilitates the organization and search for knowledge, and stimulates innovation (Alavi and

Leidner, 2001). If an organization aims to make its workers more willing to share what they know, it should first increase their interest in the use of technology (Tseng, 2017). Therefore, it should be kept in mind that if a firm wants to make its knowledge workers more willing to use technology, then the leader's involvement is critical.

3 Development of Hypotheses

As previously stated, SL refers to managing organizational challenges by subordinating the leader's personal interests to those of stakeholders (van Dierendonck, 2011). According to Otero-Neira, Varela-Neira and Bande (2016), SL promotes the development of employees as servants and the display of positive organizational behaviour.

It should be noted that if someone wants team members to develop certain behaviours, it must first be shown. One cannot ask someone to do something one would not do oneself (Cai et al., 2022). If knowledge workers showed OCB, their followers could understand its intrinsic value (Brown, Treviño, and Harrison, 2005), emulate their behaviours and engage in other servant behaviours. For example, they could share knowledge for the development of others (Tripathi et al., 2021).

There is a stream of studies related to the effects of SL on the relationship between employees and organizations (e.g., Addisu et al., 2024; Panaccio et al., 2015). Social learning theory and social exchange theory are mainly used to explain the relationship between these variables (Yang and Wei, 2018). Social learning theory (Bandura, 1977) states that individuals learn to behave in an appropriate manner through the observation of the behaviour of credible role models and imitating this behaviour. Under this framework, servant leaders are plausible models (Bavik et al., 2017; Tripathi et al., 2021). According to social exchange theory (Blau, 1964), once individuals benefit from the activities and actions of a firm, they are committed to seeking compensation and reciprocity. Social exchange theory suggests that individuals need to reciprocate when a servant leader cares about their needs. Therefore, we propose the following hypothesis:

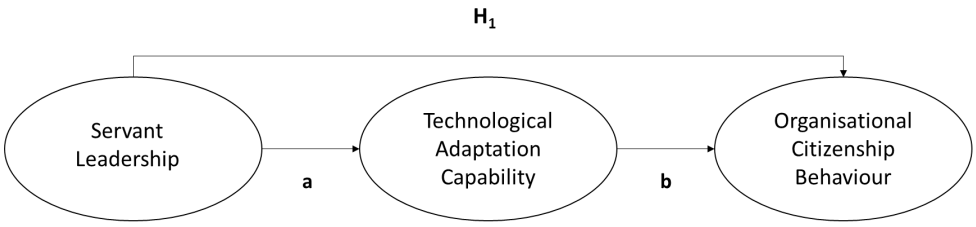
H1: SL positively influences OCB.

One of the consequences of the COVID-19 pandemic has been that people who had never used technologies have started to use them, motivated by necessity and social pressure (Batra, 2020). The importance of technology nowadays in organizations of any type requires the search for variables that promote technological transformation. In this regard, SL have been identified as a leadership style that positively influences technological adaptation (Hanif, Baloch, and Baig, 2020; Tseng, 2017). Therefore, TAC could strengthen the influence of SL on OCB by motivating knowledge workers to perform in the workplace (Zhou, Wang, and Breedlove, 2021). To the best of our knowledge, previous research focused only on how leaders can influence the adoption and implementation of technologies (Neufeld, Dong, and Higgins, 2007). The effect of TAC on employee behaviour has yet to be tested.

These arguments suggest that many organizations have used information technology to better cope with the challenges of operating in a turbulent environment (Sigala, 2003). The effective use and management of technology (i.e., TAC) constitute essential qualities for a company that could directly influence OCB and mediate the indirect relationship between SL and OCB. A possible explanation for this rests on the need to maintain knowledge within the organization and make it accessible to workers (Cepeda-Carrion et al., 2012). From this point of view, the leader leads by example using the company technologies, with technological adaptation of subordinates being a result of supervisor's SL and a mechanism by which servant leaders enhance employees' OCB. Therefore, we propose the second hypothesis:

H2: TAC positively mediates the relationship between SL and OCB.

The proposed relationships between the variables are shown in Figure 1.



H_2= Servant Leadership→ Technological Adaptation Capability → Organisational Citizenship Behaviour = a*b

Figure 1: Research model

4 Methodology

4.1 Research context

Fitness centres have been chosen as a suitable context due to its unique characteristics. Their management is a complicated task. Among the main errors, we would highlight: 1) needing more precise positioning and medium-term planning, 2) not using analysis and control tools, and 3) needing to work as a team. One way to overcome these problems is by a leadership style aligned with continuous changes in the organizational environment (Woo, 2018).

Fitness centres have adapted to COVID-19 pandemic by digitalizing their management and sports services (Batra, 2020). This digital transformation, while emphasized during the pandemic, constitutes a change over recent years (Jones, Ratten, and Hayduk, 2020). Fitness industry trends, demanding more excellent training and the applicability of technological skills in employees, influence this situation.

Fifty-three fitness centre leaders and 481 employees of 4 Spanish fitness chain participated in this study. Most of the respondents were women (56.7%), aged between 20 and 40 years (78.2%), and had a university degree (70.4%).

4.2 Measures

The executive SL scale proposed by Reed, Vidaver-Cohen and Colwell (2011), with 25 items, was chosen to measure SL. This scale includes the five Greenleaf's (1970) factors: interpersonal support, community building, altruism, egalitarianism, and moral integrity. The Lee and Allen's (2002) 16-item scale was chosen to measure the two target-based OCB dimensions: OCBO and OCBI. According to Yin and Yang (2010), TAC was measured by asking whether the information technology (IT) system is easy to use and helpful in performing the required tasks. Employees were also asked about the support of managers when using the IT system and about the availability of resources needed to use it.

4.3 Data analysis

We used PLS-SEM to test the proposed model since every measure was operationalized as composites (Cepeda-Carrion, Cegarra-Navarro, and Cillo, 2019). Our PLS-SEM analysis is explanatory and predictive (Henseler, 2018), focusing on testing the hypotheses and considering the predictability of indicators of the dependent variable (i.e., OCB). Model assessment with PLS-SEM involves the evaluation of the measurement and the structural model (Hair, Sarstedt, and Ringle, 2019). SmartPLS 3.3.9 was utilized to obtain results from the data analysis (Ringle, Wende, and Will, 2005). To prevent problems of common-method variance (CMV), the Kock and Lynn (2012) test of erratic collinearity was applied. This test is based on VIF values, whereby VIF values greater than 3.3 indicate collinearity problems. A maximum VIF of 1.04 was found, implying no CMV problems.

5 Results

5.1 Measurement model

We addressed individual reliability, which is confirmed by the fact that all constructs' standardized loadings exceed 0.7. Composite reliability measures are all higher than 0.8. The convergent validity threshold of 0.5 is surpassed by the average variance extracted (AVE) values. Both the criterion proposed by Fornell and Larcker (1981) and the HTMT ratio, provide evidence of discriminant validity (Henseler, Ringle, and Sarstedt, 2015).

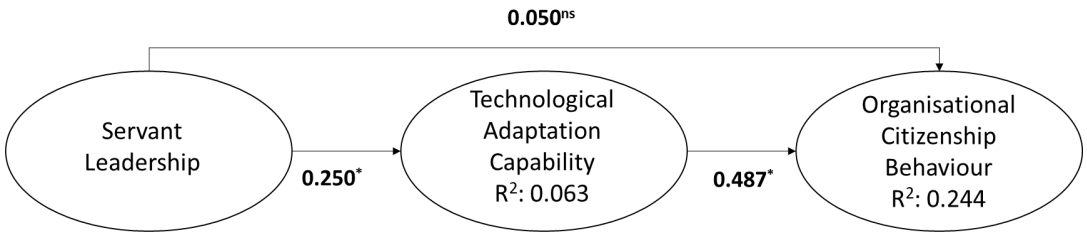
5.2 Structural model

After evaluating the absence of any collinearity issues between the constructs (Hair et al., 2019), the assessment of the path coefficients' sign, magnitude, and significance was carried out. Bootstrapping with 5,000 resamples was used to obtain confident intervals for evaluating the statistical significance of the path coefficients (Chin, 1998).

Our mediation hypothesis is analysed following Nitzl, Roldan and Cepeda's (2016) procedure. A full mediation of TAC was found in the relationship between SL and OCB. No control variables that influence our model were found. The percentile bootstrap at the 95% confidence interval was used to test hypotheses (Table 1). The effect size f^2 is reported, enabling the extent to which the explained variance of the dependent variables R^2 changes to be ascertained if a specified construct is absent from the model. Figure 2 shows the outcomes of the structural model.

Table 1: Structural Model (Bootstrapping)

Path	Path Coefficient	5%	95%	p-value	R^2	f^2
SL → OCB	0.050	0.029	0.149	0.182	0.244	0.003
SL → TAC	0.250	0.227	0.330	0.030	0.063	0.067
TAC → OCB	0.487	0.422	0.546	0.000	0.244	0.290
SL → TAC → OCB	0.122	0.108	0.163	0.030	0.244	0.357



* p<0.05; ns non-significant

Figure 2: Model results

R^2=0.244 confirmed model predictability for OCB. The PLSpredict procedure was also run, following Shmueli et al. (2019) (Table 2), which, in line with R^2, indicated high predictive power because all OCB dimensions exhibit lower residual errors for PLS-SEM than for the linear model (LM).

Table 2: PLSpredict

PLS			LM		PLS-LM	
	RMSE	Q^2_predict		RMSE		RMSE
OCBO	0.998	0.008	OCBO	0.999	OCBO	-0.001
OCBI	0.999	0.005	OCBI	1.003	OCBI	-0.006

6 Discussion

Knowledge workers can exercise a positive influence on how other people understand and interact with each other. To achieve this, it is essential to foster an attitude and mindset that is more receptive to new technology and the opinions of subordinates. In doing so, servant leaders play a crucial role in improving TAC while helping those affected by technological developments to adjust to these changes. One possible explanation of why SL is so essential for knowledge workers is that while only the leader's actions characterize other leadership styles, servant leaders are characterized by their willingness to serve others (Newman et al., 2017).

Organizations should encourage employees to display OCB due to its importance (Koning and Van Kleef, 2015). In this vein, our results support a direct and positive relationship between TAC and OCB. A possible explanation for this result would be that advances in the digital age are leading us towards new brain-technology interfaces that are changing our mental abilities and behaviours when interacting with others. For example, writing an email allows people to be more rational and control their emotions when expressing their ideas, especially when they are upset.

An interesting result is the nonsignificant direct relationship between SL and OCB. This circumstance invites us to believe that emotions, mixed feelings, and frustrations of not seeing themselves reciprocated can emerge among knowledge workers when their subordinates do not understand them or have different viewpoints. Our findings also confirm the critical role of TAC and support that it mediates the relationship between SL and OCB. It confirms what is said by authors such as Cepeda-Carrion et al. (2012), when they argue that since the various actors are forced to use a common language, TAC could deal with differences and agree on different views.

Based on the above, employees need internal motivation to show suitable behaviour. However, these behaviours cannot be easily acquired. This is the reason why organizations should find ways to encourage their employees to be good citizens (Khalili, 2017). Indeed, employee's engagement in OCB and how to encourage them to do so has been the subject of considerable research (Koning and Van Kleef, 2015). Empirical evidence suggests that leaders who serve their followers will create a more satisfied, committed, and empowered workforce with higher performance (Mayer, Bardes, and Piccolo, 2008). That is, employees will react to how their leader treats them. Therefore, servant leaders' care and commitment inspire employees to mimic this behaviour (Trong Tuan, 2017), facilitating the emergence of OCB.

6.1 Practical implications

First, we suggest that leaders must not only manage the environment in the organization and the employees directly but also be responsible for developing specific organizational capabilities. According to Tseng (2017), the leadership style is related to adaptability to technology and knowledge sharing. In this framework, knowledge workers will support the use of technology in the organization and enhance knowledge sharing among employees.

Second, TAC exerts an impact on the organizational environment, and it is, therefore, necessary to develop this capability among subordinates. Thus, the objective should be to design user-friendly information systems (i.e., allowing individuals with little experience to interact successfully with the system that influences employee satisfaction and motivation to perform better).

Third, the organizational environment will be improved by enhancing SL and TAC. Individuals are more likely to exhibit OCB in settings where suitable SL is combined with an appropriate TAC.

Fourth, managers can improve the TAC of their organizations through SL, which will result in OCB. For example, when leaders care about the employees and make their job easier, employees are more likely to be committed to the organization and perform for the benefit of the organization and other individuals because they want to, not just because they are asked to do so.

Furthermore, this change in employee behaviour and commitment will be a reward for the effort involved in the technological transformation. That could encourage the adaptation of this leadership style and the implementation of technology in more reluctant companies.

6.2 Limitations and future research

Future studies should be aligned to avoid the following limitations. First, there are self-report data for which concern arises regarding social desirability and the veracity of participant responses. Consistent with research suggesting that leaders overestimate their leadership abilities (Foster, Clarke, and Packard, 2018), future studies should use employee ratings of leadership. Second, the scales used in the study have been developed in the general business context and are relatively novel in the sports context. Future studies should combine organizations from different industries and countries to generalize the findings.

7 Conclusions

The first contribution of this research is to question existing models that manage the relationship between SL and OCB. Previous models have been applied from person to person. We now propose a person-to-person model through the means of technology. Our results indicate that establishing a TAC, whereby knowledge workers encourage subordinates to make their own technological tool choices, is possible and positively mediates the relationship between SL and OCB. The study also helps predict OCB through SL and TAC. This is largely consistent with the conclusions of authors such as Srivastava et al. (2006), who assert that servant leaders provide guidance and recognition to employees, thereby creating the context in organizations for sharing knowledge. Furthermore, our research model helps to predict OCB in innovative organizations such as fitness centres due to the increasing importance of technology in this sector, especially during COVID-19 lockdown.

Abstract

Technology adoption in higher education (HE) constitutes a complex process that goes beyond access to digital tools, this process involves individual competences, academic practices and sociodigital and cultural skills. This study focused on students in higher education from two countries in Latin America: Mexico and Ecuador, considering their paper of the digital and sociocultural skills in the development of the significant learning practices in the educative multicultural ecosystems.

For the analysis of the results, an exploratory design of mixed methods was used, with the application of a questionnaire with a Likert scale, who consist in a 150 sample, which one 100 was from Mexico and 50 from Ecuador. The data analysis was carried out in two stages, firstly, started with the descriptive analysis and the instrument reliability with Statgraphics® software, evaluating the internal consistency and the validity of analytical dimensions. Secondly, Structural Equation Modelling was employed based on partial minimum square (PLS-SEM) using SmartPLS® 4, with the principal objective of examining the structural relationships between the four dimensions and the capability of the model. The analytical model consists in four dimensions: digital and sociocultural skills, academic use of technology, ethical and responsible use of technology, and institutional conditions. For the analysis of the results, it used a conceptual model of technology which show four directional relationships between the constructs, such as, 1) Digital and sociocultural skills-academic use of technology, 2) Institutional conditions-academic use of technology, 3) Academic use of technology-ethical and 4) Responsible use of technology and digital and sociocultural skills- ethical and responsible use of technology. In this model, technology enhances learning and ethical practices from a transversal STEM perspective.

The results show that the digital and sociocultural skills impact significantly in the academic use of technology in both contexts, while the academic use of technology emerge as the principal predictor of their ethic and responsible use. In contrast, the direct relationship between the sociocultural skills and the ethical and responsible use of technology is not meaningful, which confirms the mediator role of the use of technology. Empirical evidence shows that the technology adoption in higher education must understanding as a mediated process with oriented learning and conditioning by institutional context.

Keywords: Technology adoption, sociodigital skills, Knowledge management, learning ecosystems

Paper type: Academic Research Paper

1 Introduction

The digital transformation in higher education (HE) is experiencing an unprecedented phenomenon marked by the convergence of Artificial Intelligence (AI), demographic changes, and the redefinition of job skills. This process goes beyond the incorporation of emerging technologies, as it raises the need for a thorough review of the ways in which learning, knowledge and skill formation are conceived, questioning not only how, but also why and what is learned in contemporary digital environments (European Commission, Joint Research Centre, 2022).

International frameworks such as DigComp 2.2 have reframed digital transformation as a people-centered process rather than merely technological infrastructure. From this perspective, digital competence involves the critical and responsible use of technology through the integration of knowledge, skills, and attitudes developed through educational processes (Vuorikari, Kluzer, Punie, 2022).The emphasis on skills training is justified by the need to thrive in an unstable environment, where, in the world of "infodemia" and misinformation, HE must train professionals capable of assessing the credibility and reliability of data sources. In this sense, the DigComp framework allows students to identify their own digital gaps and seek opportunities for self-development to stay updated with constant technological evolution (Cosgrove, Cachia, 2025).

Farias-Gaytan (2023) identifies a significant gap between the incorporation of technological tools and the effective development of digital skills in higher education institutions. In this context, digital transformation involves not only the digitalization of educational activities, but also cultural, organizational, and pedagogical changes aimed at strengthening advanced digital competences. Despite increasing interest in educational technologies, many academic programs still lack systematic strategies to develop digital literacy and promote the effective pedagogical integration of technology among teachers and students (Macías-Galeas, 2024).

In this context, digital transformation in HE is a process that transcends the incorporation of technologies, being deeply conditioned by the institutional culture, and the learning ecosystems in which it develops. In this framework, characterized by cultural diversity and institutional heterogeneity, technological adoption is configured as a complex phenomenon in which pedagogical practices, digital infrastructures and socio-digital skills focused on critical use interact, ethical and collaborative of knowledge interact (Macías-Galeas, 2024). However, a gap remains in empirical evidence about how these cultural and educational dimensions mediate technological adoption in multicultural learning ecosystems, particularly in HE. In response to this gap, the present research analyzes the adoption of digital technologies in university students from the perspective of socio-digital and cultural skills, so, to understand this process as a contextualized educational practice oriented, towards creation and management of knowledge.

2 Justification of the Research

Nowadays, there is a need to deepen approaches that support technological adoption in higher education, due to the accelerated growth of digital transformation. While digital transformation has promoted a broad incorporation of technologies in educational processes, there remains a limited understanding of the role that socio-digital and cultural skills play in the meaningful adoption of such technologies within complex learning ecosystems.

This study is justified by the growing need to understand technological adoption in higher education beyond the simple incorporation of digital tools. Although digital transformation has expanded the use of technologies in educational processes, there is still limited understanding of how socio-digital and cultural skills influence the meaningful, critical, and responsible use of technology within complex learning ecosystems. From a knowledge management perspective, these skills are essential for the creation, validation, and application of knowledge in digital environments.

From an empirical perspective, there is limited research analyzing the relationship between technological adoption, socio-digital competences, and cultural dimensions in higher education, particularly in Latin America. In this sense, the comparison between Mexico and Ecuador provides contextualized evidence within multicultural educational ecosystems. Furthermore, the study contributes to the development of educational strategies and institutional policies aimed at strengthening socio-digital skills and promoting meaningful and ethical technology use in higher education.

3 Research Problem Statement

In today's education environment, the need for digital transformation has become highly necessary, mainly because of continued technological progress and its impact on society. In 2024, the World Economic Forum revealed that 87% of companies anticipate using digital transformation in their processes, but only half believe they are prepared. This disparity underscores the urgent need for institutions, particularly higher-level institutions, to reconsider their operating models to remain relevant. According to UNESCO, digital innovation can support and improve education, helping to accelerate progress toward universal access to quality learning, as outlined in Sustainable Development Goal 4. Digital transformation in higher-level institutions involves the incorporation of new technologies and the transformation of practices, business models, and processes. This is directly related to the development of new and improved pedagogical approaches (Bucăţa et al., 2022).

Higher education institutions have increasingly adopted educational technologies such as digital platforms, e-learning systems, and AI-based tools. However, technology adoption does not necessarily guarantee the development of critical, transferable, and ethical digital competences among students. Existing research suggests that meaningful technology use depends on socio-digital skills, pedagogical integration, and institutional conditions that mediate the relationship between technology and learning processes (Feng et al., 2025). In addition, several institutions, particularly in developing countries, continue to face barriers related to digital infrastructure, connectivity, and digital literacy gaps among teachers and students (Alenezi and Akour, 2023).

In this context, the present study analyzes the adoption of digital technologies among higher education students in Mexico and Ecuador, considering these settings as multicultural learning ecosystems shaped by

sociocultural and institutional diversity. The study approaches technological adoption as a mediated process influenced by socio-digital and cultural skills that support the critical, ethical, and meaningful use of technology in learning and knowledge management processes.

4 Research Objectives

The general objective of this research is to analyze technological adoption in higher education students in two countries: Mexico and Ecuador, considering the role of socio-digital and cultural skills in developing meaningful learning practices within multicultural educational ecosystems.

5 Theoretical framework

Today's society lives in what is known as a "digital age", where the products and technological practices can quickly become essential parts of everyday life. These changes have impacted on how people communicate, consume information, and organize their life. These have repercussions in how learning is performed, how knowledge is created, and how people expect to be taught. This makes sense in the educational sector, who is reinvented under a technological light, where digital systems and networks are integral to the management and operation of modern institutions. This has obvious consequences for schools, universities, and other educational institutions (Selwyn, 2016).

5.1. Technological adoption in higher education

In the XX century, knowledge was seen as a final product or result of education, most of the time like a change in the conductivist conception of learning. This notion of learning as a product remains a common-sense way of understanding. Many students (and some educators) continue to view learning as largely acquiring knowledge and filling empty containers or ideas that Bereiter (2002) described as the "popular" theories of learning.

However, alternative perspectives have increasingly challenged this notion of learning. In a seminal study, Säljö (1979) identified different ways in which adults understand learning:

- Learning as a quantitative increase in knowledge
- Learning as memorization
- Learning as the acquisition of facts, skills and methods that can be retained and used as needed.
- Learning having meaning or abstract the meaning, that is, learning that involves relating parts of the subject to each other and with the real world.
- Learning how to interpret and understand reality in a different way

These two latter descriptions of learning as a continuous process highlight the role of prior experiences, reflection, and contextual interaction on knowledge construction. This conception of learning provides a perspective where digital technologies acquire educational value not through their mere presence, but through their integration into academic practices that support meaningful learning, problem solving, and knowledge application. Consequently, the use of technology for academic purposes becomes a central mechanism through which learning processes are mediated, and through which ethical and responsible practices can emerge.

From this perspective, technological adoption in higher education is understood as a mediated and context-dependent process, rather than a direct consequence of digital skills alone. Socio-digital and cultural competencies provide a necessary foundation for their integration into academic practice that meaningful and ethical technology use emerges (Kolmos, 2017; OECD, 2021). In this sense, the academic use of technology operates as a central mediating mechanism through which individual skills are transformed into ethical and responsible technology use. This view is closely aligned with transversal STEM educational approaches, which emphasize problem solving, interdisciplinary learning, and the practical application of knowledge as core learning processes. Within such approaches, technology functions not merely as a tool, but to support reflective and responsible engagement with real-world challenges. This process is further shaped by institutional conditions that enable or constrain opportunities for pedagogically meaningful engagement with technology, reinforcing the need to understand technological adoption within educational ecosystems rather than as an individual or purely technical phenomenon (Schiuma, 2011; Kozma, 2011)

Based on the theoretical perspective, technological adoption in higher education can be analytically structured through four interrelated dimensions that reflect the interplay between individual competencies, academic practices, ethical outcomes and institutional context. First, digital and sociocultural skills represent the foundational competencies that enable students to critically engage with digital technologies, integrating technical abilities with cognitive and social awareness (UNESCO, 2018; Redecker, 2017). Second, the academic

use of technology captures the extent to which digital tools are embedded into meaningful learning processes, supporting problem solving, knowledge construction, and application, particularly within STEM-oriented and practice-based learning environments (Kolmos, 2017; OECD, 2021). Third, ethical and responsible use of technology is conceptualized as a formative outcome that emerges through sustained academic engagement, reflecting students' capacity to use digital technologies in a reflective, responsible, and socially aware manner (Selwyn, 2016; Floridi et al., 2018). Finally, institutional conditions represent the contextual dimension that shapes access, opportunities, and pedagogical support for technology integration, highlighting the role of educational ecosystems in enabling or constraining technological adoption (Schiuma, 2011; Kozma, 2011). Together, these four dimensions provide a coherent framework for understanding technological adoption as a mediated process in which competencies, practices, ethics, and context interact dynamically.

5.2. Integrative conceptual model

Building on the four analytical dimensions identified, this study proposes an integrative conceptual model to explain the technological adoption in higher education. Considering the socio-constructivist and critical perspectives on educational technology, a model emerges that assumes that educational value of digital technologies is produced through their integration into academic practices and is shaped by broader institutional environments. This suggests that technological adoption in higher education is a mediated and context-dependent process, rather than a direct result of digital skills.

Contemplating the ethical and responsible use of technology, this is conceived as an outcome that arises from sustained academic engagement rather than as an attribute inherent to people with digital skills. So, in this context, ethical practices are framed as a formative result of technology-mediated learning experiences supported by institutional contexts, rather than as a direct consequence of technical competence alone. Together, this conceptual model integrates socio-digital skills, the academic and ethical use of technology, as well as institutional conditions, providing a coherent theoretical basis for analyzing technological adoption in higher education as a dynamic process shaped by individual competencies, academic practices and institutional ecosystems.

6 Methodology

Given the exploratory nature of the research and the complexity of the phenomenon under investigation, this study adopts an exploratory mixed-method research design, to capture contextual dynamics and actors' perspectives. Data was collected through an online questionnaire administered using Google Forms, which combined open-ended questions with a Likert scale item. The instrument was designed to explore students' experiences, perceptions, and practices related to technology use in academic contexts. The questionnaire was structured around four analytical dimensions derived from the literature and the theoretical framework:

- Digital and socio cultural skills
- Academic use of technology
- Ethical and responsible use of technology
- Institutional conditions

These dimensions enable a structured interpretation of the empirical material and support systematic analysis of students' technological adoption processes. The sample consisted of 150 students enrolled in university institutions from two Latin American countries: Mexico and Ecuador. Specifically, data were collected from 100 students in Mexico, from the University of Aguascalientes, University of Guanajuato and National Polytechnic Institute, and 50 students in Ecuador from the University of Cuenca. The sampling strategy was non-probabilistic and based on convenience, as participants were selected according to accessibility and institutional collaboration. This approach is consistent with exploratory research designs aimed at identifying structural patterns rather than achieving statistical representativeness.

The analysis was guided by an integrative analytical framework derived from the literature on digital competences, pedagogical ICT integration, digital sustainability, and 21st century skills. The four analytical dimensions provided a structured basis for interpreting the empirical material and analysing students' technological adoption processes. In particular, the dimension of academic use of technology was informed by UNESCO's digital competence frameworks and STEM-oriented educational approaches, conceptualizing technology use to support problem solving, interdisciplinary learning, and the practical application of knowledge.

Data analysis was conducted using Statgraphics® and SmartPLS 4 software, the first software analyzed the Likert scale items to summarize students´ responses and identify general patterns related to the four analytical

dimensions. SmartPLS 4 was employed for the exploration analysis of relationships among the dimensions, supported by the examination of technological adoption as a multicultural construct.

7 Analysis and Results

The results obtained from the four dimensions' analysis were interpreted as a structured process of technological adoption rather than isolated statical associations. This analysis integrates descriptive findings obtained through statistical analysis, emphasizing contextual similarities and differences between Mexico and Ecuador. Figure 1 represents the structural model of technological adoption of this research, which is integrated into four dimensions represented in blue circles and their respective indicators, represented by yellow rectangles. The directional relationships between these constructs illustrate a sequential and mediated process. Digital and sociocultural skills and institutional conditions act as antecedents that enable academic use of technology, which in turn functions as the central mechanism leading to ethical and responsible use. While a direct relationship between skills and ethical use is included, the model highlights that ethical practices primarily emerge through academic engagement. Overall, the model reflects a process-oriented and context-dependent interpretation of technological adoption, consistent with transversal STEM educational approaches.

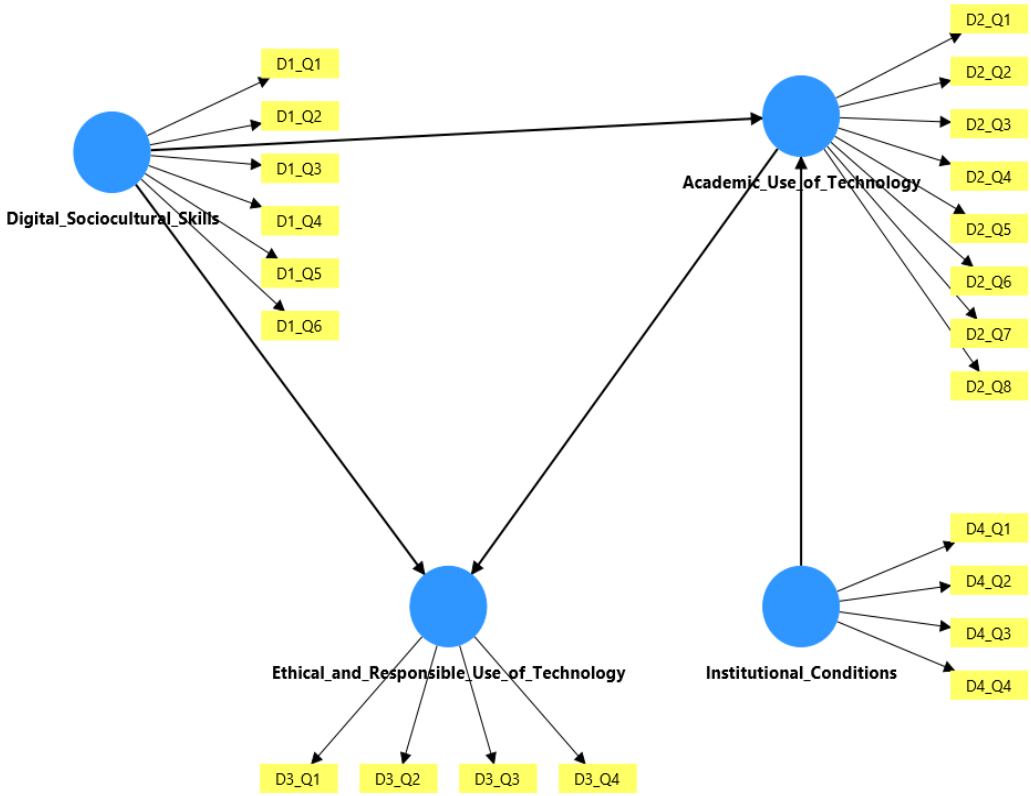

Figure 1: Conceptual model of technology-enhanced learning and ethical practices from a transversal STEM perspective. Source: SmartPLS 4.

The conceptual model proposes four directional relationships that collectively describe technological adoption in higher education as a mediated and context-dependent process. Rather than assuming linear or purely skill-based effects, the model emphasizes the interaction between individual competencies, academic practices, and institutional environments to shape meaningful and ethical use of technology. This model shows the four directional relationships between the constructs:

- Digital and sociocultural skills --- > Academic use of technology
  - This construct indicates that students' digital and sociocultural skills directly influence their ability to integrate technology into meaningful academic practices.
- Institutional conditions --- > Academic use of technology
  - This construct reflects the facilitating role of the institutional environment in the academic use of technology, highlighting the importance of the educational context as an enabler of digital learning.

- Academic use of technology --- > Ethical and responsible use of technology
    - This relationship makes the academic use of technology a central mechanism, suggesting that digital ethics emerge from structured learning experiences.
- Digital and sociocultural skills --- > Ethical and responsible use of technology
    - This direct relationship represents an alternative path between skills and ethics of the responsible use of technology.

Prior to examining the structural relationships among constructs, the reliability of the measurement instrument was assessed to ensure the robustness of the analytical dimensions. This analysis indicates acceptable internal consistency across all dimensions in both samples (Mexico and Ecuador). The table 1 shows the Cronbach's alpha values who meet or exceed recommended thresholds for exploratory research. Convergent validity, assessed through Average Variance Extracted (AVE), is satisfactory for most constructs. Although the AVE value for digital and sociocultural skills in the Ecuadorian sample is slightly below the conventional threshold, it remains acceptable within an exploratory and cross-national research design.

Table 1**:** Reliability and Average Variance Extracted (AVE) of the dimensions

Dimensions	**Items**	**Mexico**		**Ecuador**	
		Cronbach's α	**AVE**	**Cronbach's α**	**AVE**
Digital and sociocultural skills	6	0,807	0,506	0,697	0,430
Academic use of technology	8	0,906	0,605	0,874	0,540
Ethical and responsible use of technology	4	0,831	0,660	0,771	0,587
Institutional conditions	4	0,702	0,512	0,748	0,553

Source: Own elaboration

Once the reliability of the measurement instrument was determined, determination coefficient is considered, which considers the determination of a dependent variable, which is explained by the set predictors of the model (Kuehl, 2000). The results in Mexico indicate that the model explains a substantial proportion of variability in the endogens constructs, the use of technology (R^2= 0,572) and ethical and responsible use of technology (R^2= 0,623). For the case of Ecuador, the academic use of technology shows a R^2= 0,648 and for the ethical and responsible use of technology 0,629, this is significant superior for the dimension 2 in the case of Mexico.

Although the magnitude of some relationships varies between Mexico and Ecuador, the overall structure of the model remains consistent with the technological adoption, which follows a similar formative process within multicultural higher education ecosystems, despite contextual differences. The table 2 shows the structural relationship between the dimensions of the technological adoption in Mexico and Ecuador.

Table 2**:** Structural relationships of the technological adoption model across Mexico and Ecuador.

Construct	**Mexico**			**Ecuador**		
	Route coefficient (β)	**p-value**	**t-value**	**Route coefficient (β)**	**p-value**	**t-value**
Digital and sociocultural skills ---> Academic use of technology	0,569	0,000	8,712	0,686	0,000	6,969
Institutional conditions ---> Academic use of technology	0,310	0,000	4,335	0,202	0,072	1,800
Academic use of technology ---> Ethical and responsible use of technology	0,761	0,000	10,041	0,638	0,000	5,171
Digital and sociocultural skills ---> Ethical and responsible use of technology	0,040	0,680	0,413	0,187	0,164	1,392

Source: Own elaboration

The results of the relationship between the dimensions show a consistent patron of technological adoption in both national contexts, although with variations in some of the constructs. For first instance, the digital and sociocultural skills revel a positive effect on the use of academic technology in Mexico (β= 0,569, $p < 0.05$) and Ecuador (β= 0,686, $p < 0.05$), who confirms the central role of the individual competences in the integration of technology in learning practices. This result confirms the literature who highlights the digital alphabetization and

sociocultural dimension as necessary conditions for a pedagogical use in technologies in universities (UNESCO, 2018; Redecker, 2017).

The construct of academic use of technology, emerges as the principal predictor of the ethical and responsible use of technology in both countries with the highest coefficients in México ($\beta = 0.761$, $p < 0.05$) and Ecuador ($\beta = 0.638$, $p < 0.05$). This supports the idea that the ethical practices in the use of technology doesn't develop in isolation, but build through structured academic experiences focused on learning, problem solving and knowledge application, in line with STEM and meaningful learning approaches ((Kolmos, 2017; OECD, 2021).

Empirical evidence revels that the institutional conditions represent an influence in the academic use of technology in Mexico, while in Ecuador ($\beta = 0{,}202$, $p = 0{,}072$), the relationship is weak and is not enough to achieve the level of conventional statistical significance. This difference suggests that, although the institutional conditions act as a facilitator of academic use, their influence depends on the specific educational context. Enhancing the fact that the technology adoption must understand as a perspective of the educational ecosystems more than a homogenous process (Schiuma, 2011; Kozma, 2011).

In contrast, the digital and sociocultural skills and the ethical and responsible use of technology didn't result as statistically significant in Mexico and Ecuador. This reinforces the idea that the digital competences, by his own, doesn't guarantee responsible practices, although these competences must work through the academic use of technology for generate ethical behaviours. Floridi, et al. (2028) highlights the importance of have a mediator of the academic use of technology, pointing it out as the central mechanism who articulates the individual competences, institutional context and formative results.

The qualitative analysis of results shows that, both in Mexico and in Ecuador, technological adoption is perceived as a process that goes beyond the technical domain of digital tools. Students' narratives confirm that academic use of technology is the key element that transforms digital skills into meaningful learning experiences and ethical, responsible practices. This perception highlights that technological value is not derived from mere access or technical competence, but from the ways in which digital tools are incorporated into academic activities such as problem-solving, research, collaboration, and applied learning. In both contexts, students associate the ethical and responsible use of technology with situations where technology is deliberately integrated into learning tasks and guided by academic expectations.

At the same time, narratives reveal that institutional conditions - such as availability of infrastructure, access to specialized software, and pedagogical support - shape the depth and quality of this academic commitment. which contributes to the contextual differences between Mexico and Ecuador. In general, these perspectives reinforce the conceptualization of technological adoption as a mediated and ecosystem-dependent process, aligned with cross-cutting STEM approaches that emphasize learning by doing, responsible reflection and engagement with real-world challenges.

8 Conclusions

The main objective of this study was to analyze technological adoption in higher education (HE) students from Mexico and Ecuador, considering the role of digital and sociocultural skills, academic and ethical use of technology, as well as institutional conditions in the development of meaningful learning practices within multicultural educational ecosystems. Based on the integrative conceptual model and a PLS-SEM analysis, the results identified that technological adoption is not a linear process or a direct result of the possession of digital skills, but a mediated, contextual and fundamentally formative phenomenon.

The results show that digital and sociocultural skills form the necessary basis for academic use of technology in both national contexts. However, these skills do not automatically translate into ethical and responsible practices. In this sense, the academic use of technology emerges as the central mechanism that links individual competencies with formative outcomes, confirming that digital ethics is built through structured learning experiences oriented to the pedagogical use of technology, and not as a direct consequence of technical mastery.

Also, the results show that institutional conditions play a relevant role in technological adoption, although their influence varies between Mexico and Ecuador. This variability reinforces the relevance of analyzing technological adoption from an educational ecosystem perspective, in which institutions act as enablers or limiters of academic use of technology, without altering the overall structure of the identified adoption process. Considering the STEM approach of transversal effect, the results underline the importance of conceiving technology as a means for active learning, problem-solving, and application of knowledge in significant academic contexts. In this framework, the ethical and responsible use of technology is not conceived as an isolated competition, but as an emerging result of educational practices that promote reflection, informed decision-making, and connection to real issues.

Finally, this study provides empirical and conceptual evidence to understand how technological adoption is generated in higher education as a process mediated by the academic use of technology and conditioned by the institutional context. These findings have relevant implications for higher education institutions, pointing to the need to strengthen pedagogical and organizational strategies that intentionally integrate technology into the curriculum, promoting meaningful digital learning and ethical practices within multicultural educational ecosystems.

9 Ethics declaration

This study was conducted in accordance with the ethical standards for participation of higher-level students. The data were collected through a voluntary questionnaire administered to higher education students in Mexico and Ecuador. All participants were informed about the purpose of the study and their right to withdraw at any time without consequences. Participation was anonymous, and no personally identifiable information was collected. The data was used exclusively for academic and research purposes, ensuring confidentiality and responsible handling of the data throughout the research process.

10 AI declaration

Artificial intelligence tools used specifically to assist with language refinement, clarity of expression, and structural editing of the text. The use of AI did not involve data analysis, generation of results, or interpretation of empirical findings. All theoretical content, methodological decisions, data analyses and conclusions remain the sole responsibility of the authors.

Beyond Profit, Through Data: How AI-Driven Academic Spin-offs Enact Public Value in Knowledge Ecosystems

Silvana Revellino
University of Salerno, Fisciano, Italy

Abstract

Artificial intelligence (AI) is increasingly positioned as a key driver of digital transformation, enabling organizations to enhance performance, decision-making, innovation and stakeholder engagement. However, for public, hybrid, and mission-driven organizations, the critical issue is not only how AI improves efficiency, but how it contributes to value creation beyond profit (Moore, 1995; 2013; Battilana and Lee, 2014). This paper investigates how AI-driven academic spin-offs enact public value within digital knowledge ecosystems.

Drawing on public value theory (Moore, 1995; 2013), the sociology of valuation (Stark, 2009; Dussauge et al., 2015; Kornberger et al., 2015), knowledge management literature (Davenport and Prusak, 1998; Zack, 1999), and research on AI and entrepreneurship (Shepherd and Majchrzak, 2022; Fossen et al., 2024), the study conceptualizes public value as a dynamic process of (dis)aggregation, where multiple and conflicting value regimes coexist and are negotiated through evaluative practices. This allows us to explain not only the multiplicity of value generated by such organizations, but also the tensions, asymmetries, and exclusions through which that value comes into being.

The paper is based on an exploratory qualitative case study of Kebula S.r.l., an academic spin-off operating in data engineering and AI. Adopting a valuographic approach (Dussauge et al., 2015), the analysis examines how value is constructed, justified, and governed through everyday practices. Findings show that AI systems act as infrastructures of valuation that reorganize what counts as legitimate impact, redistributing visibility across economic, social, and knowledge domains. Public value emerges as a contested and relational accomplishment rather than a stable outcome. The paper contributes to knowledge management, public value theory, and AI-entrepreneurship literature by showing that intelligent transformation shapes not only how value is created, but also how it is made visible, accountable, and legitimate. Empirically, the case highlights how digital knowledge systems mediate innovation, learning, failure, and infrastructural flexibility in a hybrid university-based organization over time and across organizational contexts.

Keywords: Academic spin-offs; Artificial Intelligence; Public value; Valuography; Knowledge ecosystems

Paper type: Academic Research Paper

1 Introduction

Artificial intelligence (AI) is increasingly celebrated as a strategic lever of digital transformation. Across sectors, AI promises to improve decision-making, accelerate innovation, enhance prediction, and unlock new forms of organizational intelligence (Agarwal et al., 2021; Shepherd and Majchrzak, 2022; Fossen et al., 2024). Yet, the expansion of AI also raises a deeper question that cannot be reduced to efficiency or competitiveness alone: what kinds of value are being produced through AI-mediated knowledge processes, for whom, and through which evaluative infrastructures? This question is especially pressing for organizations that operate at the intersection of economic, scientific, and societal mandates, such as academic spin-offs (Iacobucci and Micozzi, 2015; Miranda et al., 2018).

Academic spin-offs occupy a distinctive position in contemporary knowledge economies. They translate scientific research into entrepreneurial initiatives, but they also remain tied to broader public missions associated with universities, including education, research, and territorial development (Abramo et al., 2012; Li et al., 2022). They are therefore not simply firms; they are hybrid organizational forms embedded in knowledge ecosystems where universities, businesses, students, technologies, investors, and public institutions interact (Battilana and Lee, 2014; Mele et al., 2023). In such settings, the creation of value cannot be reduced to profit, growth, or market share. It also concerns the circulation of expertise, the formation of talent, the enhancement of teaching and research, the reshaping of local capabilities, and the production of organizational and societal futures (Davenport and Prusak, 1998; Zack, 1999).

This paper argues that AI intensifies and complicates these dynamics. It does so not merely by augmenting entrepreneurial decision-making, but by actively reconfiguring the knowledge practices through which value is enacted, made visible, and judged (Shepherd and Majchrzak, 2022; Fossen et al., 2024). AI does not simply process data. It participates in the construction of what counts as relevant knowledge, meaningful performance, legitimate impact, and actionable opportunity (Miller, 1998; Mouritsen et al., 2009). This is why it is insufficient to speak of AI as a neutral enabler of innovation. Instead, AI must be understood as part of the evaluative

infrastructures through which organizations know, decide, justify, and govern (Kornberger et al., 2015; Dussauge et al., 2015).

To capture these dynamics, the paper draws on public value theory and the sociology of valuation. Public value theory has long emphasized that organizations, especially those connected to public institutions, generate value beyond economic returns (Moore, 1995; 2013; Bracci et al., 2019). However, the concept of public value remains ambiguous and often overly normative (Steccolini, 2019). The sociology of valuation helps unpack this ambiguity by shifting the analytical focus from value as an object to valuing as a situated practice (Stark, 2009; Dussauge et al., 2015). Combining these perspectives, the paper conceptualizes public value as a process of (dis)aggregation. Value is continuously assembled through narratives, metrics, classifications, and infrastructures, but it is also disassembled through exclusions, failures, trade-offs, and forms of invisibility (Miller, 1998; Carruthers and Kim, 2011; Kornberger et al., 2015). What is omitted or backgrounded is not external to value creation; it is constitutive of it.

This argument is developed through an exploratory case study of Kebula S.r.l., an academic spin-off of the University of Salerno specializing in data engineering, analytics, and artificial intelligence. Kebula is a particularly revealing case because it sits at the intersection of university-based knowledge production and market-facing AI solutions. Its activities range from data platforms and analytics to audience measurement, recommendation systems, and process automation. In this context, AI is not only a technical capability but a mode of organizing, a way of making knowledge travel, and a mechanism through which different forms of value are articulated and contested.

The paper shows that AI-driven academic spin-offs generate public value not because they harmoniously combine economic and social goals, but because they operate as sites where multiple value regimes are continuously negotiated. In doing so, they reveal both the promise and the tensions of intelligent transformation in hybrid knowledge organizations.

2 Theoretical background

2.1 Public value beyond stable outcomes

Public value theory emerged as an attempt to rethink the role of public organizations and public managers beyond narrow efficiency criteria (Moore, 1995; 2013). Rather than focusing exclusively on compliance, output measures, or incentive alignment, the notion of public value emphasizes the broader benefits that organizational action can generate for society (Bracci et al., 2019; Steccolini, 2019). Yet, despite its appeal, public value remains an unstable and often elusive construct. It is difficult to define, difficult to operationalize, and difficult to separate from the evaluative practices through which it is claimed and recognized.

This instability matters. Public value is often invoked as if it were self-evident: a desirable societal outcome that organizations can pursue, measure, and report. However, such a view risks reifying value into a fixed object. As a growing body of work in public sector accounting and management suggests, public value is not simply "there" waiting to be captured. It is actively constituted through managerial, political, and calculative practices (Miller, 1998; Bracci et al., 2019; Steccolini, 2019). Budgets, indicators, rankings, targets, reports, and impact frameworks do not merely describe value; they participate in its production (Mouritsen et al., 2009; Carruthers and Kim, 2011).

From this perspective, public value is not only plural but also contested. It involves multiple stakeholders with different evaluative principles. What counts as valuable for a university manager, a public policymaker, a spin-off founder, a student, or a local ecosystem actor may not coincide. This multiplicity makes public value less a coherent outcome than an arena of negotiations, compromises, and tensions.

2.2 Valuation and the (dis)aggregation of value

The sociology of valuation provides conceptual tools to address this complexity. Rather than assuming that value is an intrinsic property of things or actions, valuation studies examine the practices through which value is enacted (Stark, 2009; Dussauge et al., 2015; Kornberger et al., 2015). This includes the devices, classifications, tests, attachments, and infrastructures that make things count (Dussauge et al., 2015). The central analytical move is to shift from asking "what is value?" to asking "how does valuing happen?"

This move is especially useful for understanding public value in hybrid contexts such as academic spin-offs. These organizations are subject to multiple evaluative logics at once. They are judged as businesses, as knowledge transfer vehicles, as educational spaces, as territorial development actors, and as embodiments of the university's third mission. Each of these logics carries its own criteria, temporalities, and forms of visibility.

To capture this multiplicity, this paper mobilizes the concept of (dis)aggregation. Value is aggregated when elements are connected, grouped, and represented as contributing to a broader social good. But value is also disaggregated when some elements are left out, purified, deferred, or rendered invisible. (Dis)aggregation does not simply mean fragmentation. It refers to the constitutive work of separation through which value formation becomes possible. In other words, every value claim is sustained by a corresponding background of exclusions, silences, and ambiguities.

This is why additive models of value, such as some versions of blended value thinking, are only partially helpful. They correctly recognize that economic and social values are connected, but they often assume that these values can be harmoniously combined (Emerson, 2003; Nicholls, 2009). The valuographic perspective adopted here is more skeptical. It assumes that value regimes may nourish one another, but also clash, overflow, and destabilize each other (Stark, 2009; Kornberger et al., 2015).

2.3 Knowledge management beyond resource metaphors

Knowledge management literature has long stressed the importance of knowledge as a strategic asset (Davenport and Prusak, 1998; Zack, 1999). Classic contributions frame knowledge as something that can be captured, codified, transferred, and leveraged for competitive advantage (Davenport and Prusak, 1998). This literature has been highly influential in highlighting the organizational centrality of learning, expertise, and intellectual capital. Yet, it has also often relied on a relatively stable image of knowledge as a resource that exists independently of the practices through which it is recognized and mobilized.

More practice-oriented perspectives complicate this picture by suggesting that knowledge is not simply stored and moved but enacted in situated activities (Mouritsen et al., 2009; Kornberger et al., 2015). What counts as valid knowledge depends on organizational routines, interpretive frames, technologies, and material infrastructures (Dussauge et al., 2015). Knowledge is thus inseparable from organizational forms of valuation. To know is also to rank, classify, prioritize, and render some signals more consequential than others.

This point becomes crucial in AI-intensive settings. AI systems are not external tools acting upon stable pools of knowledge. They participate in the production of knowledge by selecting, cleaning, weighting, predicting, and recommending (Shepherd and Majchrzak, 2022; Fossen et al., 2024). Accordingly, intelligent knowledge systems must be understood not only as knowledge infrastructures but also as evaluative infrastructures (Mele et al., 2023).

2.4 AI and entrepreneurship beyond augmentation

Emerging research on AI and entrepreneurship highlights how AI can assist opportunity recognition, market analysis, experimentation, and business model development (Shepherd and Majchrzak, 2022; Fossen et al., 2024). Entrepreneurs can use AI to process more information, simulate scenarios, identify patterns, and accelerate strategic choices (Fossen et al., 2024). This literature is important because it moves beyond purely technical accounts of AI and shows how AI affects entrepreneurial cognition and organizing.

However, much of this literature still treats AI primarily as an enhancer of pre-existing entrepreneurial processes. The underlying assumption is that entrepreneurship remains fundamentally human, while AI improves speed, accuracy, and scope. Such an approach risks underestimating the performative role of AI.

AI systems do not simply help entrepreneurs discover opportunities; they shape what becomes intelligible as an opportunity in the first place (Shepherd and Majchrzak, 2022). They do not only support decision-making; they configure the informational environments within which decisions become thinkable and defensible (Miller, 1998; Mouritsen et al., 2009). They do not merely optimize action; they participate in defining what should be optimized.

This is where insights from performativity and calculative practices become useful. If calculative devices can act at a distance by rendering distant phenomena knowable and governable, then AI can be seen as a particularly powerful extension of such capacity. Yet, unlike conventional accounting devices, AI introduces forms of prediction, automation, and opacity that intensify both the promises and the ambiguities of organizational valuation.

3 Methodology

3.1 Research design

This study adopts an exploratory qualitative case study design (Yin, 2018). A case study is appropriate because the phenomenon under investigation is complex, context-dependent, and difficult to isolate from the

organizational and institutional settings in which it unfolds (Yin, 2018). The aim is not statistical generalization, but analytical development: to generate theoretically informed insights into how AI-driven academic spin-offs enact public value in practice.

The selected case is Kebula S.r.l., an academic spin-off of the University of Salerno. Academic spin-offs are particularly relevant for examining knowledge transfer, innovation, and local development because they operate at the boundary between academic research and entrepreneurial activity (Iacobucci and Micozzi, 2015; Miranda et al., 2018). Kebula is registered as an innovative start-up and operates in the fields of data engineering, analytics, and AI. The case was chosen because it is strongly embedded in the university's entrepreneurial ecosystem while simultaneously operating in highly data-intensive and market-facing sectors, including media and broadcasting. This makes it particularly suitable for exploring how AI-mediated knowledge practices intersect with public value creation.

The data were analysed through a valuographic lens (Dussauge et al., 2015). Valuography does not assume stable categories of value in advance. Instead, it follows how actors describe, justify, prioritize, and contest what matters (Dussauge et al., 2015; Stark, 2009).

3.2 Empirical context

The case emerges from the local environment of the University of Salerno and from the role of intermediary structures supporting technology transfer and spin-off development. Like many university-based entrepreneurial initiatives, Kebula sits in a space where academic research, entrepreneurship, and institutional support intersect. It is therefore not simply a business venture but part of a broader ecology of innovation, training, and public investment.

Kebula's mission is to help clients "datafy" their businesses. This means transforming unprocessed data into structured, analyzable, and strategically useful information. Its work includes the development of end-to-end data platforms, AI-enabled analytics, machine learning models, automation solutions, and content-related tools. In the broadcasting sector, for instance, the company has worked on audience analytics and data infrastructures for major players such as RTL 102.5.

3.3 Data collection and analysis

The analysis draws on semi-structured interviews with founders and key organizational actors engaged in the spin-off's activities. These interviews focused on the origin of the spin-off, its technological practices, its relationship with the university, and the various forms of value perceived to be generated through its work. Interview material was complemented by contextual analysis of the company's activities, its positioning, and its project descriptions.

The data were analysed through a valuographic lens (Dussauge et al., 2015; Stark, 2009), which follows how actors describe, justify, prioritize, and contest what matters.

The analytical process proceeded iteratively. First, interview material was read to identify explicit and implicit references to value, impact, and public significance. Second, these references were grouped into recurring themes, including knowledge transfer, innovation, talent formation, failure, educational payback, research enhancement, infrastructural flexibility, and bureaucratic tension. Third, these themes were interpreted as interrelated value regimes rather than isolated outcomes. Finally, the analysis examined how AI and data practices mediated the enactment of these regimes.

4 Findings

4.1 Innovation as knowledge translation and public contribution

A first dimension of public value concerns the translation of academic knowledge into organizational practice. Interviewees repeatedly stressed that the spin-off was not engaged in "business as usual." This expression signalled more than a start-up ethos. It pointed to a form of entrepreneurship rooted in experimentation, co-engineering, and the mobilization of specialized knowledge for broader organizational and societal purposes.

The CTO articulated this clearly:

"The most immediate public value we contribute to is the transfer of experiences and expertise, an entire technical and cultural baggage to the productive world. The aim is to innovate, create new opportunities. This is also what is considered as the substantial value justifying the university's third mission."

What is striking in this statement is that innovation is not framed narrowly as product development or firm performance. It is framed as transfer, opportunity creation, and contribution to the university's public mission. The value of the spin-off resides not only in its capacity to commercialize knowledge but in its role as a conduit through which academic expertise acquires broader relevance.

This suggests that innovation itself is being valued in a public register. The spin-off's work is understood as contributing to a larger ecosystem of organizational learning and capability building (Zack, 1999; Mele et al., 2023). The public value claim therefore does not emerge after the fact through ex post measurement; it is embedded in the very narrative through which the organization makes sense of its existence.

4.2 Datafication, AI, and the construction of actionable reality

A second key finding concerns the role of datafication and AI as practical means through which value is enacted. Kebula's core activity is not simply to analyse data, but to construct datafied organizational realities. This involves collecting heterogeneous sources of information, structuring them into meaningful categories, and rendering them available for decision-making.

The company's activities span big data analysis, machine learning, process automation, and content-related applications. In the broadcasting sector, for example, Kebula's work includes audience analysis, content recommendation, and the development of data platforms capable of integrating signals from production, contribution, packaging, distribution, and consumption.

The spin-off developed a data platform intended not merely to gather data, but to create a new model of radio audience measurement. This is analytically important because audience measurement is not a neutral task. It does not simply reveal what listeners do. It defines what counts as an audience, which interactions matter, how engagement is represented, and what signals become strategically consequential. In other words, AI and data platforms do not merely describe organizational reality; they participate in formatting it.

4.3 Failure as ecosystem learning and redistributed value

A particularly interesting finding concerns the revaluation of failure. In conventional entrepreneurial discourse, failure is often treated as value destruction. By contrast, interviewees suggested that failures in spin-off activity can still generate public value when viewed from a systemic perspective.

The CTO observed:

"Increasing the probability of success in financing a spin-off initiative is undoubtedly an advantage because it allows more people to approach these challenges. Even if spin-offs were to fail, they wouldn't actually be failures because such failures would be absorbed by the system. Providing opportunities for Italian talents to express themselves in an environment close to the market through a spin-off… represents comprehensive value because those individuals, even if the spin-off were to fail, remain within the ecosystem and become a valuable resource."

This passage is theoretically significant. It shows that value is being redistributed away from the isolated unit of the firm toward the broader ecosystem. Failure is no longer evaluated solely at the level of business performance. It is reinterpreted as a mechanism through which learning, exposure, and capability building are retained within the environment.

This challenges linear and firm-centric models of entrepreneurial evaluation. Public value here emerges precisely through disaggregation: what appears as failure at one level may become productive at another. This also suggests that conventional metrics such as turnover, cash flow, or profit may be insufficient for evaluating the public significance of AI-driven academic entrepreneurship (Moore, 2013; Bracci et al., 2019).

4.4 Anti-bureaucratic flexibility and the politics of infrastructure

A final major finding concerns the role of the spin-off as an anti-bureaucratic mechanism. Interviewees emphasized that the organizational form of the spin-off allowed greater flexibility than a university department would permit, especially in relation to computing infrastructure and cloud-based resources.

The CTO put it bluntly:

"If today I wanted, within the Italian university, to purchase a cloud service from Google or Amazon, this would be practically impossible because, normatively, it's considered public expenditure… But once I have this machine, if I don't use it at full capacity, I'm destroying value… less structure, less bureaucracy, and more action help create value!"

This statement makes visible a central tension in AI-intensive public value creation. Governance arrangements designed to ensure accountability can inhibit the very flexibility needed to deploy AI effectively.

The spin-off form becomes a workaround: an organizational infrastructure that absorbs friction and enables experimentation (Battilana and Lee, 2014; Miranda et al., 2018).

This finding reveals that value creation beyond profit depends not only on entrepreneurial intent or technological capability, but also on the material and regulatory infrastructures that make action possible. Public value is therefore intertwined with the politics of organizational form.

5 Discussion

5.1 AI as infrastructure of valuation

The findings show that AI-driven academic spin-offs should not be understood merely as knowledge transfer vehicles or innovation intermediaries. They are sites where value is continuously made, tested, redistributed, and contested. This process is deeply mediated by AI and data infrastructures.

AI acts here as an infrastructure of valuation in at least three senses. First, it structures visibility. Through data collection, model building, dashboards, and analytics, AI foregrounds certain dimensions of organizational life and renders them actionable. Listener behaviour, process efficiency, engagement signals, predictive patterns, and usage dynamics become visible in standardized formats. Yet, what AI makes visible is never neutral. It depends on prior choices about what to measure, how to measure it, and what to optimize.

Second, AI extends organizational action at a distance. Once translated into data and models, audiences, processes, and organizational states can be monitored and acted upon remotely. This echoes classic analyses of calculative infrastructures, but AI intensifies these capacities by combining scale, speed, prediction, and automation. In the Kebula case, action at a distance is not abstract. It is materialized in audience analytics, content recommendation, and platform-based representations that travel across organizational boundaries.

Third, AI produces a paradoxical combination of transparency and opacity. On the one hand, metrics and dashboards increase traceability and comparative visibility. On the other hand, the very complexity of AI systems can obscure how specific outputs are generated. Responsibility becomes more difficult to assign, not less. Accountability is redistributed across data engineers, algorithms, clients, and infrastructures.

5.2 Public value as (dis)aggregation rather than harmony

These findings support a reconceptualization of public value as a process of (dis)aggregation. Public value is not a stable stock of benefits produced by the spin-off and then measured by external observers. It is a precarious accomplishment constituted through the alignment, tension, and partial reconciliation of multiple value regimes.

This is where the paper departs from additive or harmonizing accounts. Economic value, social value, educational value, research value, and infrastructural value do not simply accumulate. They interact in uneven ways. Sometimes they reinforce one another, as when industrial engagement improves teaching and research. Sometimes they conflict, as when performance-oriented data systems marginalize less measurable dimensions such as editorial judgment or cultural plurality. Sometimes they are redistributed across levels, as when apparent firm-level failure generates ecosystem-level learning.

The concept of (dis)aggregation allows us to see these movements without forcing them into a unified metric. It also helps explain why public value is so difficult to stabilize conceptually: because it is generated precisely through the coexistence of complementarity and contradiction.

5.3 Contributions to knowledge management

The paper contributes to knowledge management by arguing that AI-mediated knowledge processes are inseparable from valuation processes. Traditional knowledge management often emphasizes capture, sharing, transfer, and leverage. These remain important concerns, but the present analysis shows that what counts as knowledge in AI-driven settings depends on evaluative infrastructures.

In Kebula's case, datafication is not only about extracting knowledge from organizational reality. It is about formatting reality into knowledge that can circulate, be optimized, and justify action. Data platforms, model outputs, and KPIs are not simply knowledge containers. They are valuation devices that rank some forms of knowing over others.

This implies a more critical view of intelligent knowledge systems. Their significance lies not only in improving knowledge flows but in reorganizing the criteria through which knowledge becomes relevant. Knowledge ecosystems, in turn, are not merely networks of exchange. They are arenas where epistemic and evaluative orders are continuously produced together.

5.4 Contributions to public value theory

The paper contributes to public value theory by moving away from a normative and outcome-focused understanding of public value toward a relational and processual one. Rather than asking whether an organization creates public value in the abstract, the analysis asks how value is enacted through concrete practices, and which forms of visibility, exclusion, and redistribution sustain those claims.

This move is important because it prevents public value from becoming an empty managerial slogan. If public value is treated as a self-evident organizational aspiration, it becomes difficult to analyse critically. By contrast, treating public value as (dis)aggregation makes it possible to study how claims of public benefit are assembled, how they travel, and what they leave aside.

The paper also shows that public value in hybrid organizations is not merely a matter of balancing market and mission. It is an effect of socio-technical organizing. AI infrastructures, cloud services, educational feedback loops, talent retention mechanisms, and entrepreneurial narratives all participate in making public value plausible and durable.

5.5 Contributions to AI-entrepreneurship literature

The AI-entrepreneurship literature has rightly emphasized the promise of AI for opportunity recognition and venture development. This paper adds a critical dimension by showing that AI does more than enhance entrepreneurial cognition. It actively configures the evaluative environments within which entrepreneurship unfolds.

In this sense, AI is not just an aid to entrepreneurship but part of the organizational politics of value. It influences which opportunities are seen, which outcomes are prioritized, and which forms of legitimacy are available. This is particularly consequential in academic entrepreneurship, where ventures are accountable not only to markets but also to universities, students, and public narratives of innovation.

6 Conclusion

This paper has examined how an AI-driven academic spin-off enacts public value within a knowledge ecosystem. Drawing on public value theory, valuation studies, knowledge management, and AI-entrepreneurship literature, it has argued that public value is best understood not as a stable or additive outcome but as a process of (dis)aggregation.

The paper makes three main contributions. First, it contributes to knowledge management by showing that intelligent knowledge systems are inseparable from valuation processes. Second, it contributes to public value theory by conceptualizing public value as a relational and contested accomplishment. Third, it contributes to AI-entrepreneurship research by showing that AI actively shapes the evaluative infrastructures through which entrepreneurship becomes meaningful and legitimate.

Towards an Integrated Digital Twin Maturity Assessment Framework for Coastal Cultural Heritage Resilience

Abstract

Coastal and underwater cultural heritage is increasingly exposed to climate-driven stressors, including sea-level rise, shoreline erosion, salinization, extreme weather events, and marine environmental change. These pressures are accelerating the degradation of vulnerable archaeological sites and historic coastal assets, while also exposing the limits of conventional documentation and conservation approaches based on periodic surveys and fragmented datasets. In this context, Digital Twins (DTs) are emerging as a promising paradigm for heritage monitoring and preservation, as they can integrate digital representation, sensor-based observation, environmental information, and predictive analysis within a dynamic and potentially interoperable system. However, current applications in cultural heritage remain uneven and frequently technology-centred, with limited attention to institutional embedding, environmental coupling, and long-term knowledge continuity. To address this gap, this study proposes a multidimensional maturity assessment framework for Digital Twins in coastal and underwater cultural heritage. The research adopts a sequential mixed-method design. First, a bibliometric analysis of 346 publications published between 2010 and 2025 was conducted using Scopus and Bibliometrix in RStudio to identify thematic trends, research fragmentation, and underrepresented dimensions in the literature. The results show a rapidly growing field, but still organized around weakly connected clusters, especially between digital representation, environmental modelling, and governance- or knowledge-related themes. Second, these findings were translated into a five-dimensional maturity framework comprising Technical, Structural, Environmental, Governmental, and Social dimensions. The proposed framework redefines DT maturity as a multidimensional preservation condition rather than a purely technological stage. It enables the assessment of whether a DT can function not only as a digital model, but also as an interoperable, governable, and sustainable preservation system. The findings indicate that current initiatives are advancing more strongly in technical and structural terms, while environmental, governmental, and social dimensions remain significantly underdeveloped. The framework, therefore, offers an evidence-based tool for identifying implementation gaps, supporting strategic planning, and guiding the more balanced development of Digital Twins for long-term heritage preservation.

Keywords: Digital Twins, Coastal Cultural Heritage, Risk Management, Maturity Assessment, Knowledge Sharing

Paper type: Academic Research Paper

1 Introduction

Underwater and coastal cultural heritage (U&C-CH) (including shipwrecks, submerged settlements, harbours, and maritime fortifications) constitutes an integral part of the cultural heritage of humanity and preserves unique evidence of past societies, maritime connections, and long-term human–environment interactions. As recognized by the 2001 UNESCO Convention (UNESCO, 2001), these evidences from the past are not only archaeological resources but also shared cultural assets whose preservation should be prioritized in situ whenever possible. Today, however, U&C-CH is increasingly exposed to climate-driven hazards, including sea-level rise, coastal flooding, erosion, storm intensification, ocean warming, and acidification, all of which can accelerate material decay, destabilize seabeds, and increase the physical vulnerability of both coastal and submerged sites. These pressures are particularly urgent in the Mediterranean, where coastal heritage is densely concentrated and where exposure to flooding and erosion is projected to increase substantially during the twenty-first century (Gregory et al., 2022; Reimann et al., 2018; UNESCO, 2001). Conventional conservation approaches, typically based on periodic surveys, isolated documentation campaigns, and reactive interventions, are increasingly inadequate for addressing hazards that are cumulative, dynamic, and spatially interconnected. Recent reviews show that research on climate change and cultural heritage has grown rapidly, yet the field remains fragmented across disciplines, institutions, and regions, and only a limited proportion of studies is effectively translated into adaptation planning, management protocols, or long-term monitoring strategies. For underwater heritage in particular, the challenge is amplified by site inaccessibility, the scarcity of baseline datasets, and the difficulty of integrating environmental observations with archaeological documentation to

support timely decision-making and risk prioritization (Gregory et al., 2022; Orr et al., 2021). Digital Twins (DTs) are emerging as a relevant framework for monitoring and managing heritage assets, as they integrate geometric and semantic data, sensor inputs, environmental information, and simulation models within a continuously updated digital representation. In cultural heritage, the transition from HBIM (Heritage-Building Information Modeling) to DTs marks a shift from static documentation to dynamic systems that support condition assessment, predictive maintenance, and scenario analysis, enabling more timely and informed conservation decisions, particularly in rapidly changing environments (Grazianova & Mesaros, 2024; Hou et al., 2024). However, current applications remain uneven and generally immature. Key challenges include managing heterogeneous data, structuring semantic information, integrating enabling technologies, and embedding DTs into operational workflows. Recent studies also highlight that maturity depends not only on technical capabilities, but on interoperability, institutional adoption, and effective knowledge exchange (Hou et al., 2024; Klar et al., 2024). To address this gap, this research develops a multidimensional maturity assessment framework for Digital Twins in coastal resilience and U&C-CH. Rather than evaluating DTs development only through technical deployment, the framework considers the interdependence of technical, structural, environmental, governmental, and social dimensions. Grounded in a bibliometric review of 346 publications, the framework is intended to support archaeologists, engineers, heritage managers, and policymakers in assessing not only whether a DT can be built, but whether it can function as an interoperable, governable, and sustainable system for long-term heritage preservation.

2 Background

2.1 Digital twins: definition, architecture, and heritage applications

Digital Twins (DTs) are commonly understood not as generic 3D models, but as systems in which a physical asset and its digital counterpart are connected through automated data exchange. In the literature, a DT is commonly distinguished from a simple digital model, which has no automated link with the physical asset, and from a digital shadow, in which data flow is unidirectional. A DT, by contrast, implies at least the possibility of continuous or recurrent synchronization between physical and digital states. Although DT architectures vary across domains, most definitions converge on a recurring set of elements: a physical asset, a digital representation, data acquisition systems, data storage and processing layers, communication infrastructure, and analytical or simulation services supporting visualization, monitoring, and prediction (Fuller et al., 2020). In cultural heritage, this distinction is especially important because many systems described as “digital twins” are, in practice, advanced documentation environments rather than fully synchronized twins. Current research consistently indicates that HBIM can provide a crucial basis for DT development by structuring geometric, historical, and semantic information, but that HBIM alone should not be equated with a DT. What distinguishes a heritage DT is the integration of documentation with monitoring, updating, analysis, and decision support, so that the digital environment can assist conservation practice rather than merely record the asset. In this sense, DTs extend heritage documentation toward condition assessment, predictive maintenance, and operational management (Grazianova & Mesaros, 2024; Hou et al., 2024). For cultural heritage applications, the real added value of DTs lies less in visual replication alone than in the capacity to integrate heterogeneous information (e.g. survey outputs, monitoring records, diagnostics, conservation data, and interpretive knowledge), within a coherent and interoperable information environment. This issue has become central in recent work on the Heritage Digital Twin ontology, which proposes a CIDOC CRM–based (CIDOC Conceptual Reference Model) semantic framework capable of linking diverse documentation systems while preserving interoperability across institutions and research domains (Niccolucci et al., 2023). Such an approach can become particularly relevant for underwater and coastal cultural heritage, where archaeological evidence, environmental observations, and conservation actions are often fragmented across incompatible datasets, tools, and organizations.

2.2 Existing maturity assessment frameworks: capabilities and limitations

A range of maturity assessment frameworks can inform the evaluation of Digital Twin development, but each addresses only a partial dimension of the problem. Technology Readiness Levels (TRLs) remain useful for measuring the progression of technology from early research to operational deployment (European Commission. Directorate General for Research and Innovation, 2017). The Capability Maturity Model Integration (CMMI) focuses instead on organizational capability and process improvement (Chrissis et al., 2003) while BIM maturity models or matrix evaluate the quality, repeatability, and predictability of information modelling practices (Underwood & Isikdag, 2010). These frameworks are therefore valuable as reference points, but they

were not originally designed to assess the combined technical, semantic, environmental, and organizational demands of heritage-oriented DT systems. This limitation becomes clearer in heritage applications. Reviews of DT adoption in heritage facilities management describe the field as still preliminary and identify recurring implementation bottlenecks (Grazianova & Mesaros, 2024; Hou et al., 2024): the need to manage very large and heterogeneous datasets, the difficulty of building structured semantic databases, the integration of HBIM with IoT, etc. In other words, technical deployment alone does not provide a reliable indicator of maturity. A system may include advanced modelling and sensing components, yet remain weak in interoperability, documentation structure, routine usability, or institutional uptake (Hou et al., 2024; Niccolucci et al., 2023). More broadly, the aforementioned studies' maturity argues that interoperability should be treated as a defining feature of advanced digital twins rather than as a secondary add-on. This observation is highly relevant for coastal and underwater heritage, where effective preservation depends on the coordinated use of environmental monitoring, spatial analysis, semantic documentation, and multi-actor management. At the same time, climate-change and heritage research have repeatedly shown that fragmentation across disciplines, institutions, and adaptation practices remains a major barrier to effective action. For this reason, a maturity model for heritage DTs cannot be limited to technical readiness or geometric richness alone, but should also consider structural coherence, environmental coupling, organizational preparedness, and knowledge sharing across stakeholders (Klar et al., 2024).

2.3 Research gap: multidimensional assessment framework for heritage digital twins

In the context of cultural heritage, Digital Twins should operate not only as technical systems but also as long-term infrastructures (Barzaghi et al., 2024; Gabellone, 2022) for documentation, monitoring, interpretation, and decision support across heterogeneous actors and datasets. A major gap concerns interoperability and information continuity. Recent work on FAIR-by-design (Findibale, Accesible, Interoperable, Reusable) digital twins in cultural heritage has shown that long-term usability depends on much more than 3D acquisition quality: it also requires pre-structured workflows, provenance tracking, open standards, and metadata models capable of supporting reuse across platforms and institutions (Barzaghi et al., 2024). Likewise, emerging ontology-based approaches for cultural heritage preservation emphasize that static documentation models are insufficient when the objective is predictive monitoring and preventive conservation. Frameworks such as PANOPTES have therefore been developed to integrate sensor observations, diagnoses, risk predictions, and conservation decisions within a common semantic environment (Pavlidis et al., 2025). These contributions make clear that maturity in heritage DTs cannot be reduced to modelling sophistication alone, but must include the ability to sustain interoperable, traceable, and operational data ecosystems.

Against this background, the present study addresses the following research questions:

- *RQ1. Which dimensions are necessary to assess the maturity of Digital Twins for coastal and underwater cultural heritage beyond conventional measures of technological readiness?*
- *RQ2. How can a multidimensional maturity framework support heritage practitioners and decision-makers in identifying implementation gaps, comparing initiatives, and guiding the sustainable deployment of Digital Twins in real-world preservation contexts?*

These research questions directly motivate the DTs' five dimensions proposed in this study. The Technical dimension addresses data acquisition, sensing, updating workflows, simulation, and risk-processing capabilities. The Structural dimension evaluates the quality of geometric representation, semantic enrichment, provenance, and interoperability of the digital asset. The Environmental dimension assesses the extent to which a Digital Twin incorporates dynamic coastal or underwater observations, hazard indicators, and predictive environmental modelling. The Governmental dimension considers governance arrangements, stakeholder coordination, organizational readiness, and the integration of a Digital Twin into decision-making processes. Finally, the Social dimension captures documentation quality, training, knowledge transfer, and the capacity of institutions and practitioners to maintain and reuse the system over time.

3 Research Methodology

This study adopts a sequential mixed-method design to develop a multidimensional maturity assessment framework for Digital Twins (DTs) in coastal and underwater cultural heritage. The research was therefore structured in two consecutive phases: (i) a bibliometric analysis to identify thematic patterns and implementation gaps in the literature, and (ii) the development of a multidimensional framework grounded in those findings. Additionally, a weighted scoring method is proposed to compute the overall maturity score.

3.1 Data source and search strategy

The bibliometric dataset was compiled from Scopus in February 2026, which has been selected for its multidisciplinary coverage and suitability for reproducible bibliometric analysis (Mongeon & Paul-Hus, 2016). The search strategy combined terms related to Digital Twins, maturity, BIM/HBIM/GIS, cultural heritage, and related monitoring and preservation domains, employing the following query after several iterations aimed to properly address sources related with the field of investigation: TITLE-ABS-KEY(("digital twin*" or "digital shadow" or "cyber-physical system*") AND ("maturity" or "readiness" or "capabilit*") AND ("BIM" or "HBIM" or "GIS" or "BIM/GIS" OR "cultural heritage" OR "climate change" or "sea level")). The time window covered publications from 2010 to 2025. Following a screening of records to exclude incorrect data (e.g., Conference Review records), the final dataset included 346 publications. The records were analysed in Rstudio using the Bibliometrix package (Aria & Cuccurullo, 2017). The bibliometric phase served two purposes. First, it mapped the growth and thematic configuration of the field through annual scientific production and keyword co-occurrence analysis. Second, and more importantly, it was used to detect structural gaps in the literature. The analysis showed that research on heritage DTs remains fragmented across partly disconnected domains, particularly between digital representation, monitoring technologies, environmental modelling, and decision-making or governance-related issues. This fragmentation provided the empirical justification for moving beyond technology-centred maturity models toward a broader evaluative structure.

3.2 Framework proposal development

Existing DT frameworks in heritage contexts primarily address technical and structural maturity; our proposed framework extends this to encompass the social, governance, and environmental dimensions essential for sustainable heritage preservation. Drawing on Lovell et al. (2023), this research incorporates the "Usefulness" concept to ensure HBIM development aligns with stakeholder requirements. This governance and social perspective prevent overdesign by prioritizing models that fulfill specific needs without unnecessary complexity or excessive detail. The second phase translated the bibliometric findings into a multidimensional maturity framework. The derivation logic was functional rather than merely classificatory: a DT for coastal and underwater heritage should be considered mature only if it can operate as a preservation-oriented system rather than as an isolated digital model. This assumption is consistent with recent work showing that heritage DTs depend not only on 3D modelling quality, but also on interoperable workflows, semantic consistency, provenance, environmental responsiveness, and decision-support capacity (Barzaghi et al., 2024; Niccolucci et al., 2023). On this basis, five interdependent dimensions were defined. The Technical dimension addresses data acquisition, sensing, updating workflows, and analytical or predictive capabilities, and is conceptually anchored to Technology Readiness Levels (TRLs) as a reference for progression from experimental to operational systems (Mankins, 2009). The Structural dimension evaluates geometric reliability, semantic enrichment, provenance, and interoperability of the digital representation, drawing on BIM/HBIM maturity and Level of Development (LOD) principles (Underwood & Isikdag, 2010). The Environmental dimension considers the integration of coastal or underwater monitoring data, hazard variables, and predictive environmental modelling, in line with the management-oriented logic of ISO 14001 (ISO, 2015). The Governmental dimension assesses governance arrangements, stakeholder coordination, accountability, and organizational readiness, using ISO 38500 (ISO, 2024) as a conceptual anchor for governance principles. Finally, the Social dimension captures documentation quality, training, knowledge transfer, and the long-term capacity of institutions to maintain and reuse the system, consistently with the broader responsibility and stakeholder orientation reflected in ISO 2600 regarding Social Responsibility (ISO, 2010). These standards were not adopted as complete maturity models in their original form. Rather, they were used as interpretive anchors to define dimension-specific criteria while preserving a heritage-oriented perspective. This choice was intended to avoid the direct transfer of industrial or corporate maturity logic to cultural heritage, while still ensuring conceptual rigor and inter-domain comparability.

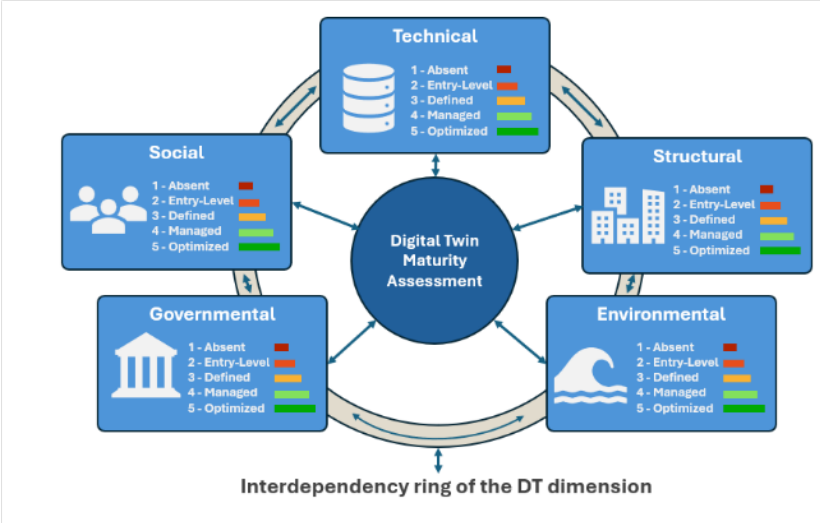

Figure 1 – DT Maturity framework assessment proposal

The proposed framework (Figure 1) operationalizes five interdependent dimensions for assessing Digital Twin (DT) maturity within the specialized context of coastal heritage preservation. This multidimensional approach moves beyond purely technical metrics to encompass the structural, environmental, governmental, and social facets of heritage management.

3.3 Maturity levels and scoring logic

Each dimension is assessed on a five-level ordinal scale (0–4): 0 = Absent, 1 = Entry Level, 2 = Defined but static, 3 = Managed, and 4 = Optimized. This scale was designed to balance simplicity and interpretability while still distinguishing between experimental, operational, and advanced DT implementations. An overall maturity score is calculated through a weighted aggregation of the five dimensions:

$$DT_{Score} = \frac{\sum_{i=1}^{5} w_i * D_i}{\sum_{i=1}^{5} w_i}$$

Where D_i represents the score of each dimension and w_i its relative weight. In the present study, equal weighting is assumed as the default condition to avoid arbitrary prioritization at this stage. However, the framework allows future calibration through expert-based methods such as the Analytical Hierarchy Process (AHP) or related multi-criteria decision-making approaches (Saaty, 1987). The aggregated score is intended as a diagnostic and comparative indicator, not as a substitute for expert judgement: the framework assumes only partial compensability across dimensions, it means that high technical or structural performance should not be interpreted as sufficient maturity when environmental integration, governance capacity, or knowledge continuity remain weak. The main output of the methodology is a multidimensional maturity assessment framework that can support the evaluation, comparison, and staged development of DT initiatives for coastal and underwater cultural heritage. Rather than ranking projects in purely technological terms, the framework is intended to identify implementation gaps and guide the transition from isolated digital products to interoperable, governable, and sustainable preservation systems

4 Findings

4.1 Bibliometric findings

Bibliometric analysis of annual publication output (2010–2025) demonstrates a significant growth (+25.63% with a strong peak in the latest years) in scientific research productivity within this domain (Figure 2).

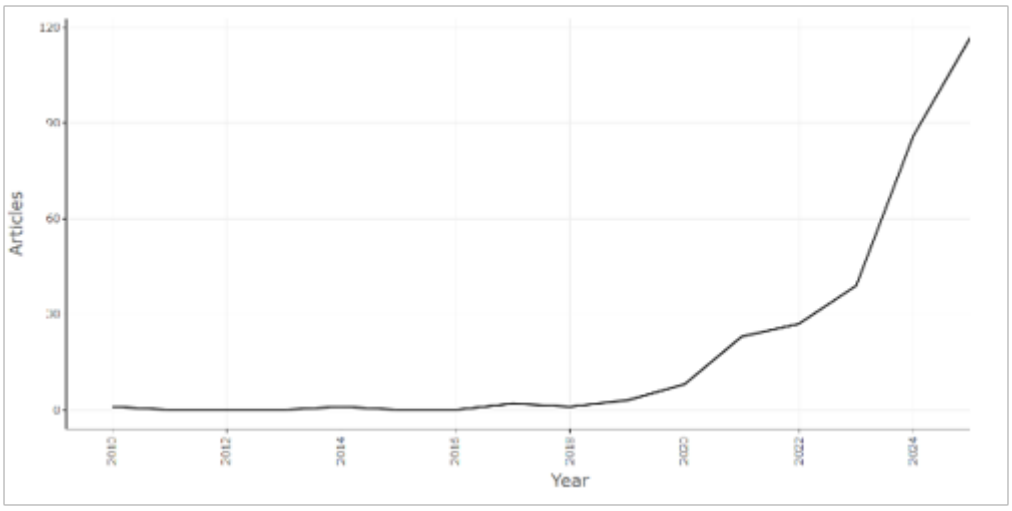

Figure 2 Annual Scientific production (Information produced by the Authors through Bibliometrix Software)

The analysis identifies three distinct temporal phases: a dormancy phase (2010–2017) characterized by minimal publication activity (average 2.1 articles/year), a growth acceleration phase (2018–2023) with gradually increasing publication rates (average 8.3 articles/year), and an emergence phase (2024–2025) exhibiting accelerated publication dynamics (peak of 120 articles in 2024). The cumulative publication growth from 2017 to 2024 represents a significant increase, indicating rapid field maturation and mainstream research adoption.

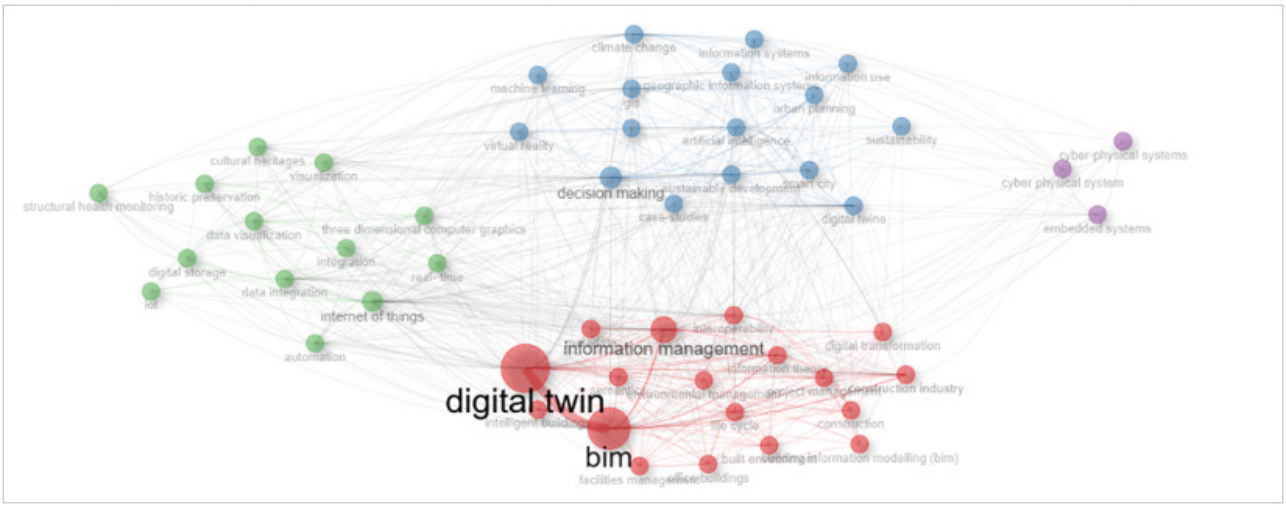

Figure 3: Keyword co-occurrence network

Keyword co-occurrence network analysis (Figure 3) demonstrates Digital Twin and BIM as dominant research nodes (red cluster, central position). Four distinct research topics emerge: information management (red), sustainability and GIS (blue), IoT and sensors (green), and Cyber-Physical Integration and Control Systems (purple). Weak inter-cluster connectivity indicates significant research fragmentation. This pattern substantiates the necessity for comprehensive maturity assessment frameworks integrating these isolated research domains. The analysis also highlights a limited overlap between core research domains. Only a small proportion of the reviewed literature explicitly combines HBIM, GIS, and Digital Twin approaches, while governance and knowledge-transfer themes remain significantly underrepresented. This finding supports the advanced argument in the previous sections: although the DT concept is gaining visibility in heritage research, its operational maturity is still constrained by fragmentation across technical systems, data environments, and institutional practices. Taken together, these bibliometric findings suggest the need for a multidimensional maturity framework. They show that the central challenge is no longer the visibility of the DT paradigm itself, but the absence of integrated evaluation criteria capable of linking representation, monitoring, environmental responsiveness, governance, and long-term usability within a single assessment structure.

4.2 Multidimensional maturity findings

Technical dimension findings

The literature shows that the Technical dimension is among the most advanced. Many projects already integrate multiple sources of digital documentation and environmental data, and several studies report the use of sensor-based acquisition, remote sensing, or interoperable data streams. In maturity terms, most current implementations can be positioned between Level 2 and Level 3, meaning that technical procedures are increasingly standardized and, in some cases, operational. However, fully automated, continuously updated, and real-time DT environments remain limited to a relatively small number of advanced research initiatives.

Structural dimension findings

The Structural dimension also shows comparatively strong development. Three-dimensional surveying, photogrammetry, laser scanning, and HBIM-based representations are now well established across a broad part of the heritage literature. As a result, many initiatives achieve Level 2–3 maturity in terms of geometric reliability and basic semantic structuring. Nevertheless, the transition from accurate digital representation to richly interconnected semantic environments remains incomplete. Provenance, ontology-based enrichment, and full interoperability with external information systems are still not systematically implemented, which limits the capacity of DTs to function as long-term knowledge infrastructures.

Environmental dimension findings

The Environmental dimension remains one of the least mature, despite being fundamental for coastal and underwater heritage protection. The reviewed literature shows that robust environmental maturity requires the integration of hydrodynamic, wave, and morphodynamic simulations able to capture water levels, currents, temperature, salinity, sediment transport, shoreline evolution, and site-specific marine forcing. Models such as ADCIRC, NEMO, ROMS, SCHISM, and SHYFEM for hydrodynamics (Fox-Kemper et al., 2019) demonstrate that high-resolution environmental forecasting is technically feasible when supported by downscaled Copernicus and EMODNET data. However, these capabilities are still only weakly integrated into most heritage DT applications, where environmental information often remains static, partial, or disconnected from structural documentation and conservation planning.

Governmental dimension findings

The Governmental dimension remains underdeveloped, even though the reviewed material shows that environmental modelling becomes operationally valuable only when translated into decision-support processes. Numerical simulations and Digital Twin environments can support adaptation planning, maintenance prioritization, and risk-informed intervention, but this requires the active involvement of public authorities, infrastructure operators, and other institutional stakeholders. In this respect, governance maturity depends not only on stakeholder presence but on the existence of procedures capable of transforming environmental evidence into coordinated action, best-practice guidelines, and policy-relevant responses. Current DT initiatives rarely demonstrate this degree of institutional embedding, which suggests that governance still lags behind technical capability.

Social dimension findings

The Social dimension shows similarly low maturity. The reviewed material suggests that Digital Twins become socially meaningful only when complex technical outputs, such as flood forecasts, erosion trends, or environmental risk simulations, are made usable for non-specialist actors and heritage practitioners. This implies not only communication and dissemination, but also documentation, training, and transferable operational knowledge. The production of best practices, replicable workflows, and accessible decision-support tools therefore becomes central to long-term sustainability. Yet these elements remain limited in current heritage DT initiatives, which still depend heavily on expert-led research settings and only rarely provide structured mechanisms for broader knowledge transfer or durable institutional learning.

5 Discussion

The findings reveal a structural paradox in the current development of heritage Digital Twins. On the one hand, the field has made clear progress in data acquisition, 3D representation, and technical modelling. On the other hand, these advances have not yet translated into equally mature systems of environmental integration, institutional governance, and knowledge continuity. This confirms that DT maturity in coastal and underwater heritage cannot be equated with modelling sophistication alone. A technically advanced system may remain immature if it cannot support risk-informed decision-making, coordinated management, and long-term operational use. From this perspective, the framework proposed in this paper helps reposition Digital Twins from a technology-centered paradigm to a preservation-centered one. Its main value lies in making explicit the dimensions that are usually treated as external or secondary to DT development. In particular, the

environmental dimension is decisive for coastal and underwater heritage because exposure to erosion, flooding, salinization, and marine dynamics directly affects the relevance of any monitoring architecture. Likewise, the governmental and social dimensions make visible the institutional and human conditions under which a DT can remain functional after the completion of a research project. A second implication concerns the interdependence of the five dimensions. The results suggest that maturity should not be understood as a linear accumulation of features, but as a relational condition in which weaknesses in one dimension constrain the system's overall usefulness. For example, strong structural modelling cannot compensate for the absence of environmental forecasting, and high technical readiness cannot substitute for weak governance or missing knowledge-transfer mechanisms. For this reason, the proposed framework encourages a parallel and coordinated development of all five dimensions from the early phases of project design. More broadly, the framework offers a practical contribution for heritage managers, archaeologists, engineers, and policymakers. It provides a common reference for identifying implementation gaps, prioritizing investment, and comparing initiatives beyond purely technological criteria. In doing so, it supports a shift from isolated digital outputs toward interoperable and sustainable systems capable of informing conservation strategies under conditions of accelerating climate risk.

6 Conclusion

This study proposed a multidimensional maturity assessment framework for Digital Twins in coastal and underwater cultural heritage. Grounded in a bibliometric analysis of 346 publications and in the synthesis of current literature, the framework was developed to address a central gap in the field: the lack of evaluative models capable of linking technical maturity with structural quality, environmental responsiveness, governance capacity, and knowledge sustainability. The results show that current DT initiatives are progressing unevenly. Technical and structural components are becoming increasingly mature, while environmental, governmental, and social dimensions remain significantly underdeveloped. This imbalance limits the practical effectiveness of DTs as tools for long-term heritage preservation, especially in coastal and underwater contexts where climate-related pressures and institutional fragmentation are particularly acute. The main contribution of the paper is therefore not only the definition of five assessment dimensions, but the reframing of DT maturity as a multidimensional preservation condition rather than as a purely technological stage. In this sense, the framework may support more consistent project design, more transparent evaluation, and more sustainable implementation pathways for initiatives such as ARCHAEOSAFE. Future research should focus on empirical validation through case studies, indicator refinement, and expert-based calibration of dimension weights.

Abstract

The integration of Artificial Intelligence (AI) and Generative Artificial Intelligence (GenAI) is transforming Knowledge Management. Digital technologies are evolving from passive information repositories into active knowledge co-constructors capable of supporting knowledge generation, recombination, dissemination, interpretation, and application. This study examines the emerging relationship among Knowledge Management, AI, and GenAI, focusing on their implications for firms operating in increasingly data-intensive, uncertain, and knowledge-driven environments. A key difference exists between AI-enabled Knowledge Management and current systems. As technology and society evolve, businesses learn, make decisions, generate new ideas, compete, and govern in new ways. This research employs a bibliometric methodology centered on Scopus data, keyword co-occurrence networks, and ensemble MCA-based community detection techniques. A consensus community detection method combines multiple algorithms and merges their outputs using dimensionality reduction and hierarchical clustering to enhance methodological rigor. This approach allows the analysis to move beyond reliance on a single algorithm, identifying more stable thematic structures within the literature. The objective is to uncover the principal thematic cores, novel research trajectories, and uncharted gaps in AI-enabled knowledge creation, dissemination, storage, application, decision support, organizational performance, ethical governance, trust, explainability, and human–AI collaboration. This study contributes to the literature on AI-enabled Knowledge Management by providing a systematic conceptual mapping of a rapidly evolving field. It also offers practical insights for managers and organizations seeking to understand how AI and GenAI can reshape knowledge processes while generating new challenges related to data quality, algorithmic bias, privacy, accountability, organizational readiness, employee skills, and responsible implementation. In this context, AI and GenAI are interpreted as transformative infrastructures through which firms may redesign knowledge ecosystems, augment human expertise, and develop more adaptive, intelligent, and strategically oriented knowledge management capabilities. By examining AI's potential for boosting creativity, automating tasks, and improving decision-making, we also take into consideration ethical issues like fairness and inclusion. By balancing innovation with responsible practices, businesses can achieve a healthy balance. In a world that is becoming increasingly AI-driven, companies are making sure AI allows them to drive sustainable growth, give employees more power, and fit with long-term strategic goals.

Keywords: Artificial Intelligence, Knowledge Management, Generative AI, Bibliometric Analysis, Ensemble Community Detection

Paper type: Academic Research Paper

1 Introduction

In the rapidly evolving digital landscape, Knowledge Management (KM) is undergoing a fundamental paradigm shift. Previously, the field was characterized by human-centric curation and static databases, but today it is being transformed by the integration of Artificial Intelligence (AI) and Generative AI (GenAI). This transition marks a move away from viewing technology as a passive repository toward recognizing it as an active knowledge "co-constructor" capable of coexisting with human experts (see Sun and Xu 2025). This significant change requires close attention. AI is now structurally integrated into the very definition of strategic knowledge management, as illustrated by current literature (Yuan et al. 2024).

A recent industry survey reported that many organizations now use AI in at least one business function (McKinsey & Company, 2025) as GenAI becomes embedded in workflows. Organizations are improving their ability to create, store, share, and apply knowledge by leveraging Large Language Models (LLMs) and advanced natural language processing (NLP) (Nakash and Bolisani 2025). In KM, AI is perceived as highly beneficial across all processes, especially in knowledge acquisition and documentation, where it significantly reduces cognitive load and streamlines data processing (Nakash and Bolisani 2025). However, technological integration poses several challenges. As part of the implementation process, organizations must restructure their infrastructure, talent, and workflows (Singla et al. 2025). At the same time, these changes are compounded by ethical dilemmas

related to data privacy, algorithmic bias, and ownership, as well as employee resistance due to fears of job displacement and role ambiguity (see Leoni et al. 2024; Rezaei 2025; Thakuri et al. 2024). There are also significant financial and technical barriers, including integration with legacy systems, skills gaps, and resource constraints (Rezaei 2025).

Integrating Artificial Intelligence into Knowledge Management is challenging and requires a comprehensive approach that considers multiple strategies. To maximize AI's potential without compromising organizational integrity, companies should focus on three key areas: establishing robust governance frameworks, implementing ongoing upskilling programs, and executing strategic change management. Robust governance frameworks are essential for integrating AI into KM, as they ensure responsible and ethical use (see Leoni et al. 2024). Overall, these processes should not be viewed solely as a technical responsibility of IT departments.

The research question in this work explores, using bibliometric analysis, the relationship between knowledge management, artificial intelligence, and generative AI, with the aim of understanding how they can impact firms.

The work is organized as follows: in the second section, we consider the data used and the methodology adopted for the bibliometric analysis. In the third section, we discuss the results obtained. In the fourth section, we present the conclusions of the work.

2 Data and Methodology

To investigate these phenomena, we will use a bibliometric analysis approach based on co-occurrence networks and ensemble community detection (see Drago 2018, Drago & Errichiello 2026, Morelli et al. 2026 and Fortunato 2010). Community detection was applied to the relevant group of keywords identified in the literature as the core of the field. We used appropriate queries related to the literature to explore the field, and using the results from these queries in Scopus, we constructed the bibliometric dataset. In this respect, the query used was:

TITLE-ABS-KEY(
("knowledge management system" OR KMS OR "knowledge management" OR "organizational knowledge")*
AND
("artificial intelligence" OR AI OR "machine learning" OR "deep learning" OR "generative AI" OR "large language model" OR LLM* OR "natural language processing" OR NLP)*
AND
(integrat OR implement* OR adopt* OR deploy* OR "socio-technical" OR "human-in-the-loop" OR "hybrid intelligence" OR augment* OR barrier* OR challenge* OR limitation* OR risk* OR govern* OR ethic* OR bias OR fairness OR transparen* OR explainab* OR interpretab* OR accountab* OR "knowledge quality" OR valid* OR reliab* OR "knowledge verification" OR "knowledge validation" OR trust*)*
)

The query was performed on January 18, 2026. From the bibliometric dataset, we conducted the bibliometric analysis using R (see Aria & Cuccurullo 2017). The analysis focused on the co-occurrence keyword network. To improve the robustness of the results and avoid potential bias from any single algorithm (see Leskovec et al. 2010), we used a consensus approach. Consensus community detection helps synthesize the results for the different membership keywords by community (Drago & Balzanella 2015) for each method. Following the consensus clustering algorithm proposed by Drago (2018), we applied a multidimensional reduction technique, such as multiple correspondence analysis (MCA; see Greenacre & Blasius 2006), to reduce the dimensionality of this matrix. Validation was performed using different criteria to define the optimal number of clusters in the hierarchical clustering process of the keywords (Brock et al. 2008 on clustering validation). Finally, we obtained the relevant groups of keywords that represent the most significant cores (and keyword communities in the sense of Fortunato 2010) of the literature considered (see Gatto et al. 2023, Drago et al. 2023).

3 Results and Discussion

From the bibliometric analysis, we obtained the dendrogram presented in Fig. 1. The results of the final dendrogram can be analyzed cluster by cluster, or by community, considering that this is a community detection procedure, as follows:

Cluster 1, Artificial Intelligence and Knowledge Management keywords can be seen as the foundational conceptual core of recent literature bon AI-KM integration. It is not simply a collection of contributions on adopting new technologies, but rather identifies a genuine transformation of the knowledge management paradigm: from predominantly human, document-based, and repository-based systems to dynamic, predictive,

adaptive, and partly generative systems, in which artificial intelligence intervenes in the processes of identifying, acquiring, creating, archiving, sharing, and applying knowledge.

The central logic of the cluster is that AI is increasingly viewed as a cognitive and organizational infrastructure capable of extending the traditional capabilities of knowledge management. From this perspective, AI is not merely a technical tool but a socio-technical device that automates certain knowledge-intensive activities, enhances the capacity to analyze large volumes of data, facilitates the extraction of latent patterns, and supports faster and more informed decision-making. Leoni et al. (2024) emphasize that knowledge management processes involve the identification, acquisition, creation, storage, sharing, and application of knowledge, and that AI enables the knowledge spectrum to be broadened, making it accessible to all people, in every situation and at any time. In bibliometric terms, this cluster can therefore be interpreted as the foundational domain in which the AI–knowledge management relationship is conceptualized as a convergence between algorithmic capability, organizational knowledge management, and decision-making.

The keywords for the **second cluster** are: large language models, generative AI, ChatGPT, LLM, and LLMs. Cluster 2 could be defined as "Generative AI and Large Language Models for Knowledge Work." This cluster identifies the most recent and specific component of the literature on the integration of artificial intelligence and knowledge management. While the first cluster addressed the general relationship between AI and KM, this second cluster focuses on the new generation of generative language technologies, particularly Large Language Models and tools such as ChatGPT, which are considered capable of transforming everyday knowledge work. Conceptually, the cluster marks a shift from predominantly analytical, predictive, and classificatory AI to generative, conversational, and interactive AI. LLMs do not merely extract information from large databases; they produce texts, summaries, explanations, drafts, decision-making scenarios, and knowledge artifacts. Bratianu and Ioan (2025) note that Generative AI, as a subfield of AI, uses natural language processing, neural networks, and machine learning to create human-like content, and that Large Language Models process enormous datasets comprising natural languages, code, mathematical expressions, and images. ChatGPT is cited as one of the best-known applications of this technological family.

The significance of this cluster is closely linked to the transformation of organizational knowledge into knowledge that can be generated, summarized, and reused through linguistic interaction. LLMs make knowledge work more accessible even to non-specialist users, as they allow repositories, documents, and information bases to be queried using natural language. Rezaei (2025) emphasizes that tools such as ChatGPT support organizations in generating personalized content, summarizing complex documents, retrieving context-specific knowledge, and personalizing interactions with users.

The keywords of the **third cluster** are: network exposure; NaaS (Network as a Service); ml driven-analytics; intent-based networking; entreprise industries; end-to-end automation; disaggregation; data lake; cognitive networks; cloud platform; cloud native; cloud; closed loop operations; autonomous networks; automation transparency; analytics; edge computing; automation; data management; operational efficiency. This third cluster can be interpreted as representing intelligent, cloud-native, and automated infrastructure for organizational knowledge management. Unlike the group focused on the linguistic production of content, such as large language models and generative AI, this cluster centers on the technical and organizational architecture that enables advanced enterprise systems to collect, process, integrate, circulate, and use knowledge. The keywords indicate an environment where knowledge is no longer treated merely as a document, repository, or encoded information, but as a continuous operational flow embedded in networks, cloud platforms, autonomous systems, data lakes, edge computing, and end-to-end automation mechanisms.

The joint presence of cloud, cloud platform, cloud-native, data lake, and data management indicates that this cluster addresses the infrastructural dimension of knowledge management systems. From this perspective, organizational knowledge is increasingly embedded in distributed, scalable, and interoperable architectures, where data from multiple sources is stored, integrated, and made available for analytical and decision-making functions. This is consistent with recent literature, which states that AI enables organizations to automate the management of large volumes of information, improve knowledge search and retrieval, classify documents, and integrate heterogeneous sources into more cohesive and usable knowledge bases. In particular, Rezaei (2025) notes that AI enhances knowledge storage by automating data organization, classification, search, and integration of diverse sources, affecting the accessibility, performance, efficiency, and security of knowledge systems.

The keywords of the **fourth cluster** are: ontology; AI; knowledge management; knowledge sharing; artificial intelligence; digital transformation; knowledge transfer; innovation; risk management; blockchain; trust; tacit knowledge; digitalization; sustainability; Industry 4.0. This cluster outlines a research trajectory focused on the semantic, socio-technical, and strategic dimensions of AI in knowledge management systems. It highlights that integrating artificial intelligence into KMSs requires not only algorithmic capabilities but also ontological

structures to represent knowledge, organizational processes to facilitate sharing and transfer, governance mechanisms to manage risks and reliability, and a persistent centrality of the human element, especially in processes involving tacit knowledge, interpretation, and managerial judgment.

In summary, the fourth cluster can be interpreted as the cluster of AI-enabled knowledge governance. It demonstrates that the digital transformation of knowledge management involves not only automating archives or generating content, but also designing intelligent, semantic, and responsible systems capable of linking human and artificial knowledge, industrial innovation, knowledge transfer, sustainability, and risk management.

The fifth cluster is centered on knowledge graph and transfer learning. This cluster identifies an emerging trend in which AI is used not only to generate or automate knowledge, but also to structure it semantically and make it transferable across different organizational domains. The co-occurrence of knowledge graphs and transfer learning suggests a shift toward knowledge management systems that represent entities, concepts, and relationships in a networked form and reuse knowledge models learned in one context to address problems in new contexts. This cluster thus serves as a bridge between knowledge representation and organizational learning, showing how AI-powered KMSs can evolve from static repositories into dynamic cognitive infrastructures that integrate, transfer, and recombine knowledge. However, this trajectory presents significant challenges, particularly regarding scalability, semantic interoperability, data quality, adaptation to heterogeneous datasets, and consistency between artificial and human organizational knowledge.

The keyword of the **sixth cluster** is based on a single keyword large language models where the **seventh cluster** is based on: machine learning; deep learning; natural language processing; big data; reinforcement learning. This data structure, with large language models as the sixth cluster, suggests that this cluster represents a recent specialization closely linked to the algorithmic core of AI, but not entirely overlapping with it. In bibliometric terms, the dendrogram appears to represent a conceptual progression: at the base is the general paradigm of machine learning; from it emerge deep and linguistic methods; finally, large language models appear as a more recent and distinct frontier, derived from the convergence of deep learning, NLP, and large databases. This seventh cluster represents the core methodological and algorithmic aspect of this literature. Unlike clusters focused on organizational systems, semantic governance, or large language models, the focus here is on the fundamental techniques that enable artificial intelligence in knowledge management: machine learning, deep learning, natural language processing, and reinforcement learning. In other words, this cluster describes the "computational" level of AI-KM – the level at which data is transformed into patterns, patterns into operational knowledge, and operational knowledge into decision support.

The seventh cluster identifies the core literature on the integration of AI and knowledge management. It highlights the role of machine learning and deep learning techniques in extracting patterns from large volumes of data, managing unstructured knowledge, and processing natural language as the primary means of accessing organizational knowledge. At the same time, it is possible to deduce that these techniques, by their nature, are primarily interpreted as supporting decision-making processes, while "reinforcement learning" suggests a trajectory toward adaptive systems capable of learning from feedback, outcomes, and subsequent interactions. Therefore, the cluster can be interpreted as the domain of the algorithmic foundations of AI-enabled knowledge decision systems, in which the value of knowledge management derives from the ability to transform heterogeneous data into actionable knowledge and more timely, accurate, and adaptive organizational decisions.

4 Conclusions

This research investigated the correlation among Artificial Intelligence (AI), Generative AI (GenAI), and Knowledge Management (KM) using a bibliometric and community-detection methodology with a Scopus-based dataset. The findings indicate that the intersection of AI and KM has developed into a significant research area, highlighting the interdependence of knowledge processes, algorithmic systems, and organizational decision-making. AI-enabled KM involves more than simply adopting new tools; it represents a relevant shift in how organizations manage knowledge, moving from human-curated models to hybrid socio-technical architectures where human expertise and AI systems collaborate.

Key findings show that the AI-KM nexus is highly important, with AI serving as an enabling infrastructure for knowledge-intensive work. The rise of GenAI and Large Language Models (LLMs) demonstrates a shift toward interactive systems that generate knowledge artifacts, underscoring the need for further research on the reliability and governance of AI-generated knowledge. The research also indicates that digital infrastructures are crucial in knowledge management, suggesting that knowledge is continuously generated through operational flows and automated analytics.

Additionally, the socio-technical and governance dimensions of AI in KM are critical, requiring both human judgment and governance mechanisms alongside automation. The methodological foundations of AI-enabled KM are rooted in machine learning and natural language processing.

The study, consistent with the objectives of bibliometric research, identifies several research gaps, including the need for rigorous indicators to measure the value of AI-enabled KM, methods for validating AI-generated knowledge, and comprehensive governance frameworks for hybrid human-AI systems. It emphasizes that organizations should approach AI-enabled KM as an organizational transformation rather than a simple technological project, integrating AI into defined knowledge processes while ensuring human involvement in critical decision-making. The findings enhance understanding of the evolving landscape of AI-enabled KM and suggest directions for future research to address current gaps and improve organizational practices.

These groups of keywords can be used to identify emerging trends and research gaps in the field. They can also assist in developing targeted literature reviews, guiding researchers toward the most impactful studies. Furthermore, they may help academics and practitioners identify potential areas for collaboration and innovation. Thus, the final expected results can be used not only to understand the existing literature on this topic but also to better identify relevant research gaps that can be addressed in future studies.

5 Acknowledgements

We would like to thank the two anonymous reviewers for their valuable comments and constructive suggestions, which have helped us improve the quality and clarity of the manuscript.

6 Ethics declaration

All data used in the analysis refer to publicly indexed scientific publications and were processed in aggregate form for bibliometric and network-analytical purposes. Therefore, no institutional ethics approval was required.

7 AI declaration

AI was used only to improve the readability and language of the work. This technology was used with control, and the results were carefully reviewed. We are ultimately responsible and accountable for the contents of the work.

Governing Adaptation: Family Councils, Dynamic Capabilities, and Company Performance in Family Firms

Attila Wieszt, Noémi Szilvia Lőrincz, Amitabh Anand
Corvinus University of Budapest, Budapest, Hungary

Abstract

Family firms often rely on resources such as long-term orientation, trust, patient capital, ownership commitment and accumulated knowledge, yet these resources may generate rigidity, risk aversion and resistance to renewal. This paper examines how this paradox is shaped by family councils, understood as governance forums operating at the boundary of family, ownership and business. While family governance, dynamic capabilities and family firm performance have each received scholarly attention, their interrelationship remains underdeveloped. In particular, little is known about how family council characteristics and functioning influence the development of dynamic capabilities and condition their translation into company performance.

The paper develops a review-based conceptual model through a structured integrative literature synthesis. It connects three literature streams: family council and family governance research, dynamic capabilities research in family firms, and studies on family firm performance. Rather than presenting a systematic review, the study uses these streams to build a causal conceptual model of the family council–dynamic capabilities–company performance relationship.

The model proposes that family council characteristics and functioning influence the development of sensing, seizing and transforming capabilities. This relationship may be mediated or moderated by variables such as socioemotional wealth balancing, family social capital, intergenerational knowledge transfer, legitimacy creation, conflict processing and ambidextrous governance. Second, the model argues that family councils moderate the relationship between dynamic capabilities and company performance by shaping whether adaptive capabilities receive family support, ownership legitimacy and resource commitment. Third, the model includes recursive feedback loops: dynamic capabilities and performance outcomes may reshape the characteristics, legitimacy and functioning of the family council over time.

The paper contributes by positioning the family council not merely as a communication body, but as a governance infrastructure for firm-level adaptation. It also identifies future research directions on the family council–dynamic capabilities link, the dynamic capabilities–performance black box, contextual conditions and feedback processes.

Keywords: family council; dynamic capabilities; family governance; company performance; family firms

Paper type: Academic Research Paper

1 Introduction

Family firms often show the same duality. On the one hand, these firms can build on resources that are difficult for many non-family firms to access: long-term orientation, trust, patient capital, strong ownership commitment, accumulated industry knowledge, and stable relationship networks. On the other hand, these same resources can easily become rigidity. The protection of tradition may hinder renewal, the preservation of family control may slow down decisions, conflict avoidance may postpone necessary changes, and past successes may reinforce those routines that no longer work in a new market situation. The strategic question for family firms is therefore not simply whether they possess specific family resources, but whether they are able to transform these into firm-level capabilities that support adaptation and renewal.

This duality makes the question of how family firms are able to adapt particularly important. The theory of dynamic capabilities offers a strategic management explanation for this. Dynamic capabilities describe how the firm senses the opportunities and threats appearing in its environment, how it mobilizes resources to seize them, and how it transforms its resources, routines, and operations under changing circumstances (Teece, Pisano and Shuen, 1997; Teece, 2007). In the case of family firms, however, these capabilities cannot be interpreted merely as management routines. The family's goals, values, ownership logic, conflicts, and long-term intentions directly shape what the firm perceives, what it is willing to allocate resources to, and what kind of change it considers acceptable. Thus, dynamic capabilities in family firms appear as adaptation processes saturated with family meanings and ownership preferences.

This is where the family council comes in. The family council is one of the central institutions of family governance: a forum that operates at the boundary of the family, ownership, and the firm, and in which family members discuss and work through shared issues, ownership intentions, values, conflicts, and strategic questions (Gersick et al., 1997; Suess, 2014; Chrisman et al., 2018). The family council is therefore not simply a "communication space." It becomes strategically significant when it is able to organize family intentions, values,

and tensions in a way that also influences the firm's adaptive capacity. In this sense, the family council may operate as a translating and legitimizing mechanism between the family system and corporate strategic action.

In the literature, however, this relationship has not yet been sufficiently clarified. Research on family governance says much about how the family organizes its own involvement in the firm. The literature on dynamic capabilities says much about how the firm adapts in a changing environment. Research on family firm performance has long debated what performance exactly means in the case of firms that do not pursue exclusively financial goals. These research areas, however, often run alongside each other. We know little about how the characteristics and functioning of the family council contribute to the development of dynamic capabilities, and even less about how the family council influences the transformation of dynamic capabilities into company performance. The gap is therefore twofold: it is not clear how the family council becomes an antecedent of dynamic capabilities, nor under what conditions it strengthens or weakens the performance effect of dynamic capabilities.

This study aims to address this gap. We do not argue that the family council is the only factor that shapes the adaptation of family firms. Ownership structure, generational stage, family culture, firm size, the industry environment, and the intensity of competition are also important. The focus of the study is narrower: we examine how the characteristics and functioning of the family council may be connected to dynamic capabilities, and through them to company performance. Therefore, we interpret the effect of the family council not as an automatically positive direct effect, but through mechanisms, conditions, and feedback loops.

Accordingly, our research question is the following: How and under what conditions do the characteristics and functioning of the family council influence the development of dynamic capabilities, as well as their transformation into company performance in family firms?

The study is based on a structured integrative literature synthesis. We connect the results of three streams of literature: research on the relationship between the family council and dynamic capabilities, the family firm literature examining the relationship between dynamic capabilities and company performance, and works on the interpretation of family firm performance. The aim is not to present a comprehensive systematic literature review, but to develop a causal conceptual model that arranges the lessons of the three areas into a single explanatory framework.

According to the proposed model, the characteristics and functioning of the family council first influence the development of dynamic capabilities. This relationship may operate through mediating and moderating variables, for example through the balancing of socioemotional wealth-related considerations, family social capital, intergenerational knowledge transfer, legitimacy creation, conflict processing, or the support of ambidexterity. Second, the family council does not only shape the development of dynamic capabilities, but also whether these capabilities are able to become actual company performance. Here, the family council appears as a moderator: it influences whether the sensing, seizing, and transforming processes receive family support, ownership legitimacy, and sustained resource commitment. Third, the model also assumes feedback loops: the emerging dynamic capabilities and the results of company performance feed back over time into the characteristics, legitimacy, and functioning of the family council. In this way, the study proposes not a linear, but a recursive governance–capability–performance logic.

The main contribution of the study is therefore that it interprets the family council not merely as a family governance forum, but as one possible governance infrastructure of firm-level adaptive capacity. In this way, it provides a more precise picture of how, in family firms, family-level intentions and relational patterns may become firm-level capabilities — or, conversely, how they may hinder their development and transformation into performance. Overall, the strategic significance of the family council therefore does not lie in its existence in itself, but in whether it is able to place the energies, tensions, and long-term preferences of the family system in the service of firm-level renewal.

2 Methodology

This study is not a comprehensive systematic literature review in the traditional sense. The reason for this is not technical, but rather substantive. The relationship under examination—family council, dynamic capabilities, and corporate performance—is a research intersection on which few direct studies are based. If we were to consider only those articles that simultaneously use the concepts of family council, dynamic capabilities, and performance, we would not obtain a sufficient empirical and theoretical foundation for constructing a meaningful model. The relevant knowledge is therefore not found in a single, well-defined body of literature, but rather across multiple, partially overlapping research areas.

For this reason, the study employs a structured integrative literature synthesis. The aim of integrative literature synthesis is not merely to compile existing findings, but to reorganize them within a theoretically

meaningful explanatory framework (Webster and Watson, 2002; Snyder, 2019). In the case of this study, this is particularly warranted because the three central concepts are linked to different scholarly traditions. The family council appears primarily in the literature on family governance. Dynamic capabilities originate from strategic management and are subsequently applied in the context of family businesses. Performance, meanwhile, poses a distinct challenge in family business research, as family, ownership, and non-financial goals come into play alongside financial performance.

The synthesis is based on three strands of literature. The first comprises research examining the relationship between the family council and dynamic capabilities, as well as studies from which such a relationship can be indirectly inferred. In this area, the number of direct findings was low, so the search was expanded to include the relationship between family business characteristics and dynamic capabilities. This literature helps identify the family, ownership, and governance factors that may influence the development of sensing, seizing, and transforming capabilities. The second line of literature addresses the relationship between dynamic capabilities and firm performance in family businesses. We use this literature with caution because several identified mediating variables—such as innovation, knowledge integration, strategic flexibility, or entrepreneurial orientation—partially overlap with the concept of dynamic capabilities. Therefore, we do not view these as independent, clear-cut mediators, but rather as conceptually mixed constructs that nuance the interpretation of the DC–performance relationship. The third strand addresses the concept of family business performance. Its primary role is not to incorporate every possible dimension of family performance into the model, but rather to clarify that the focus of this study is on business performance, particularly performance related to adaptability, operational efficiency, market responsiveness, financial performance, and resilience.

The methodological logic of the study therefore consists of three steps. First, we identify which family council characteristics and operational features in the literature are directly or indirectly linked to dynamic capabilities. Second, we identify the variables that may mediate or moderate the relationship between the family council and dynamic capabilities. Third, we incorporate the relationship between dynamic capabilities and organizational performance into the model in a way that avoids conceptual circularity: we do not automatically treat as separate mediators those phenomena that may themselves be part of or direct manifestations of dynamic capabilities.

This approach, of course, does not replace subsequent empirical testing. The aim of the study is not to prove causal relationships, but to propose a conceptual model that more accurately maps out the possible relationships between family council, dynamic capabilities, and corporate performance. Accordingly, the results are presented not as definitive empirical statements, but as theoretically grounded relationships that can be examined in future research.

3 Findings - The Integrated FC–DC–Corporate Performance Model

Based on the literature review, the relationship between the family council, dynamic capabilities, and corporate performance cannot be described as a simple linear causal chain. The family council is not merely a precursor to dynamic capabilities, nor is it a simple mediator between dynamic capabilities and performance. In the model (see Figure 1), the family council plays a dual role. On the one hand, the characteristics and functioning of the family council shape the development of dynamic capabilities. On the other hand, these same characteristics and operational features also influence whether the dynamic capabilities that are already developing can translate into corporate performance. The model therefore focuses not on the mere existence of the family council, but on its quality, functioning, and context.

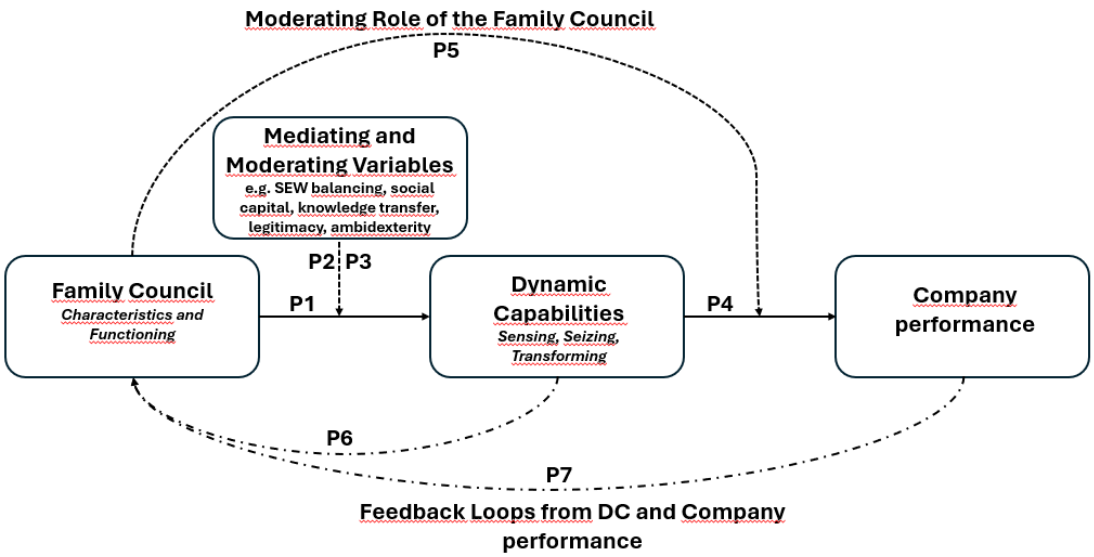

Figure 1 – The Conceptual Model (Family Council, Dynamic Capabilities and Company Performance) and our propositions

3.1 The characteristics and functioning of the family council as precursors to dynamic capabilities

The first major relationship exists between the family council and dynamic capabilities. By characteristics of the family council, we mean the relatively stable structural and formal factors that determine the council's composition, mandate, and connections. These include, for example, generational composition, representation of family branches, formal regulation, authority, decision-making or advisory roles, the regularity of meetings, and how the council relates to shareholder forums, the board of directors, or company management.

The functioning of the family council, on the other hand, refers to how the council operates in practice. Here, the quality of dialogue, trust, the ability to resolve conflicts, strategic alignment, decision-making discipline, openness, and the handling of differing opinions become important. This distinction is important because a family council can be well-designed in formal terms but function poorly. Similarly, a less formalized family council can be strong if it is actually capable of building trust, shared understanding, and a strategic direction.

The three core elements of dynamic capabilities—sensing, seizing, and transforming—can relate to the family council in different ways. Sensing, or the perception of opportunities and threats, is particularly sensitive to who participates in the family council and what information enters the family decision-making process. Generational diversity, the involvement of external advisors, the participation of younger family members, or the emergence of different corporate roles can broaden what the family perceives from its environment. If the family council is closed, homogeneous, or merely echoes the opinions of dominant family members, then sensing may narrow. In such cases, the family does not perceive environmental changes more accurately, but rather reinforces its own previous interpretations.

Seizing, or seizing opportunities, requires different types of family council conditions. Here, the legitimacy of decisions, commitment of resources, owner consensus, and the interpretation of risks from a family perspective become important. A well-functioning family council can help ensure that the family not only recognizes a strategic opportunity but is also willing to allocate resources to it. This is particularly important in family businesses, where investment decisions are not merely financial calculations but often involve identity, control, legacy, and family reputation. In this sense, the family council does not replace corporate management, but it can influence whether lasting owner support is established behind corporate management.

Transformation—that is, the restructuring of corporate resources, routines, and operating patterns—is perhaps the most sensitive to the functioning of the family system. Change in family businesses is often not just an organizational or strategic issue, but also a reinterpretation of family identity. A new business model, a leadership transition, a shift toward digitalization, or internationalization can easily raise the question of what will remain of the family legacy. The family council can support the capacity for transformation if it interprets change not as a rejection of the past, but as a means of ensuring the family business's continuity. If, however, the council equates the protection of tradition with the rejection of change, then the capacity for transformation may weaken.

3.2 Mediating and moderating variables in the FC–DC relationship

The relationship between family council and dynamic capabilities does not operate directly, automatically, or in the same way in every family business. Based on a comparison of the literature, several variables can be identified that may mediate or moderate this relationship. These are not elements of the same nature. Some function more as processes, others as relational resources, and still others as contextual conditions. Therefore, it is not appropriate to uniformly refer to all of them as "mechanisms." In the model, we treat them as mediating and moderating variables.

Balancing the aspects related to social-emotional capital is one of the most important mediating processes. In family businesses, strategic decisions often have not only economic but also social-emotional consequences. Fear of losing control, protecting the family name, attachment to the founder's legacy, or the intention to pass the business on to the next generation can all influence what kind of adaptation the family considers acceptable. The family council can support dynamic capabilities if it does not suppress these considerations but also does not allow them to completely dominate strategic decisions. The challenge is to strike a balance between family dynamics and the company's adaptation needs.

Family social capital is also important. Trust, a shared language, the density of relationships, and the willingness of family members to cooperate can reduce the cost of decision-making and accelerate the mobilization of resources. At the same time, overly closed social capital can restrict the flow of information and reinforce the echo chamber effect. Therefore, family social capital is not a positive factor in and of itself. The question is whether it supports the acceptance of differing information, constructive debate, and strategic change.

Intergenerational knowledge transfer is particularly important from the perspectives of sensing and transforming. In family businesses, significant knowledge can accumulate in tacit form: in relationships, stories, decision-making patterns, corporate memory, and industry experience. The family council can help make this knowledge visible and transferable. At the same time, intergenerational knowledge transfer cannot simply mean adopting the older generation's way of thinking. In terms of dynamic capabilities, it becomes valuable only if old knowledge can be reinterpreted in new situations.

Legitimacy-building and conflict resolution also influence the FC–DC relationship. Strategic adaptation often involves losses, uncertainty, and role changes. If the family council is able to legitimize the change, the company can more easily move from recognition to action. If conflicts are avoided or suppressed, decision-making paralysis may persist behind the facade of apparent agreement.

Several moderating factors can shape this relationship. The generational stage, family complexity, concentration or dispersion of ownership, the maturity of the family council, the size of the company, industry dynamics, and the cultural context can all influence the extent to which the family council's characteristics and functioning impact dynamic capabilities. In a first-generation, founder-led company, the role of the family council may differ from that in a multi-branch, multi-generational family of owners. In a stable, slowly changing industry, a different type of council operation may suffice than in the face of strong technological or market turbulence.

3.3 Dynamic capabilities and firm Performance

The third element of the model is the relationship between dynamic capabilities and firm performance. According to the theory of dynamic capabilities, the ultimate significance of sensing, seizing, and transforming lies in the firm's ability to adapt, renew itself, and maintain its competitiveness in a changing environment (Teece, 2007). However, the impact on performance is not self-evident. Not every instance of sensing leads to action, not every strategic decision leads to successful implementation, and not every transformation improves the company's performance.

Particular caution is required when interpreting the DC–performance relationship. The literature often identifies mediating variables that are conceptually close to dynamic capabilities themselves. Innovation, for example, can be an output of dynamic capabilities, but in many studies it appears partly as a component of seizing or transforming. In many cases, knowledge integration is more of a micro-condition of dynamic capabilities rather than a clear mediating variable between them and performance. Strategic flexibility is also difficult to separate from the functions of sensing and transforming. Therefore, the present model does not base its explanation of the DC–performance relationship on these.

In the model, dynamic capabilities contribute to corporate performance when sensing, resource mobilization, and transformation are transformed into coordinated, timely, and resource-efficient corporate action. Here, corporate performance primarily refers to operational efficiency, market responsiveness, financial performance, speed of adaptation, and resilience. The emphasis, therefore, is not on the fact that dynamic

capabilities are generally “good” for performance, but rather on the conditions under which they can actually be translated into performance.

3.4 The family council as a moderator of the DC–corporate performance relationship

A central tenet of the model is that the family council influences not only the development of dynamic capabilities but also their impact on performance. Therefore, the characteristics and functioning of the family council can also be interpreted as a moderator of the DC–corporate performance relationship. This does not mean that the family council mediates between dynamic capabilities and performance. The family council does not follow dynamic capabilities in the causal chain. Rather, it influences whether the established sensing, seizing, and transforming processes receive family support, owner legitimacy, and sustained resource commitment.

This moderating role is particularly important in the case of seizing and transforming. A company may perceive a market opportunity, but if the family council is unable to build owner consensus, seizing the opportunity may stall. The company may be capable of organizational restructuring, but if the family interprets the change as a threat to family identity, the restructuring may provoke resistance. The reverse is also true: a well-functioning family council can lend legitimacy to change, help the family interpret risks, and provide long-term support for decisions that are uncertain in the short term but strategically necessary.

The family council thus influences the DC–performance relationship by reducing or increasing organizational friction regarding dynamic capabilities. If the council functions well, adaptive capabilities can be more easily translated into coordinated corporate action. If it functions poorly, those same capabilities may remain partially untapped or be lost amid family conflicts, decision-making delays, and a lack of legitimacy.

3.5 Recursive feedback loops

The model does not stop at the relationship between the DC and corporate performance. It also assumes two feedback loops. The first feeds back to the family council from the dynamic capabilities. As the company develops its sensing, seizing, and transforming capabilities, new types of governance needs may emerge. The family council must manage different information, involve new stakeholders, legitimize more complex decisions, and, over time, adapt its own operations as well. The development of dynamic capabilities therefore requires not only corporate but also family governance learning.

The second feedback loop comes from corporate performance. Successful performance can strengthen the family council’s legitimacy, increase the family’s confidence in joint decision-making processes, and reinforce the council’s strategic role. Poor performance, on the other hand, can trigger conflicts, blame, loss of trust, or demands for governance reform. Performance is thus not merely the endpoint of the model but also a form of feedback that shapes the characteristics and functioning of the family council.

For this reason, the model is fundamentally recursive. The family council shapes dynamic capabilities; dynamic capabilities influence corporate performance; and the family council moderates this relationship. Meanwhile, dynamic capabilities and corporate performance feed back into the family council. Thus, the adaptation of a family business is not a one-time causal chain, but a continuous governance–capability–performance cycle.

3.6 Propositions

P1. The characteristics and functioning of the family council influence the development of dynamic capabilities in family businesses by shaping the quality of the sensing, seizing, and transforming processes.

P2. The relationship between the characteristics and functioning of the family council and dynamic capabilities may be mediated by family and governance variables such as the balancing of social-emotional aspects, family social capital, intergenerational knowledge transfer, legitimacy building, conflict resolution, and the promotion of ambidexterity.

P3. The strength and direction of the relationship between the characteristics and functioning of the family council and dynamic capabilities are moderated by family, ownership, governance, and external contextual conditions, such as generational stage, family complexity, ownership structure, council maturity, industry dynamism, and cultural context.

P4. Dynamic capabilities contribute to corporate performance when the sensing, seizing, and transforming processes are translated into timely, coordinated, and resource-efficient corporate action.

P5. The characteristics and functioning of the family council moderate the relationship between dynamic capabilities and corporate performance by influencing family support for dynamic capabilities, their ownership legitimacy, resource availability, and organizational acceptance.

P6. The development of dynamic capabilities has an impact on the family council because it creates new governance demands, learning tasks, coordination needs, and operational expectations.

P7. Corporate performance affects the family council by shaping its legitimacy, perceived usefulness, level of conflict, strategic priorities, and willingness to undergo management renewal.

4 Discussion

The most important theoretical claim of the proposed model is that the family council should not be viewed merely as a forum for family communication or conflict resolution. The family council is one possible governance infrastructure for the adaptation of the family business. Its impact does not stem from its formal existence, but rather from its characteristics, how it operates, and its ability to organize family intentions, tensions, and preferences into a form that can be processed for corporate adaptation. In doing so, the model clarifies the relationship between the literature on family governance and that on dynamic capabilities. The family council is not simply a "family background factor," but a governance space that can influence what the company perceives, what opportunities it seizes, and what transformations it considers legitimate.

The model's second contribution is the clarification of the family council's dual role. On the one hand, the family council is a precursor to dynamic capabilities: its characteristics and functioning influence the development of sensing, seizing, and transforming processes. On the other hand, the family council also acts as a moderator of the relationship between dynamic capabilities and firm performance. This means that the performance impact of dynamic capabilities may depend on whether the family is able to provide support, ownership legitimacy, resource commitment, and acceptance for adaptive action. The model therefore does not position the family council as a mediator between dynamic capabilities and performance. Instead, it posits that the council is simultaneously involved in the development of capabilities and in the conditions for translating them into performance.

From a practical perspective, this means that when evaluating family counseling, it is not sufficient to examine whether it improves family communication or reduces conflicts. These are important outcomes, but they do not capture the strategic significance of counseling. It must also be examined whether the council contributes to the perception of environmental changes, the seizing of strategic opportunities, the reallocation of resources, and the family's legitimization of changes. A family council truly becomes a strategic forum when it not only maintains family unity but also helps the company adapt more effectively.

The model also identifies several directions for future research. First, the FC–DC relationship must be examined more closely: which family council characteristics and operational features have the strongest impact on the sensing, seizing, and transforming dimensions. Second, it must be clarified when the identified variables—such as the balancing of socio-emotional aspects, family social capital, intergenerational knowledge transfer, legitimacy, and conflict resolution—function as mediators, moderators, or contextual conditions. Third, it remains unclear exactly through which processes dynamic capabilities translate into firm performance; this requires particularly careful examination, as several previously used mediators conceptually overlap with the dynamic capabilities themselves. Fourth, it must be empirically tested whether the characteristics and functioning of the family council truly moderate the DC–performance relationship. Finally, the external context requires more attention: we do not know exactly how market dynamism, the intensity of competition, technological turbulence, or industry maturity interact with the functioning of the family council. Longitudinal studies are also needed to understand how dynamic capabilities and corporate performance influence the legitimacy, composition, and functioning of the family council.

5 Conclusion

This study suggests that the strategic significance of the family council should not be understood merely in terms of its existence, but rather in relation to its dynamic capabilities and corporate performance. The family council can become an important institution for the family business's adaptation, but only if it can channel the family system's values, tensions, and long-term preferences to support the processes of sensing, seizing, and transforming. The proposed model is therefore not a normative statement about the usefulness of the family council, but rather a framework for future empirical research to better understand the relationship between family governance, dynamic capabilities, and corporate performance.

6 Ethics Declaration

This paper is based on a structured integrative literature synthesis and does not involve human participants, personal data, interviews, experiments, or fieldwork. Therefore, ethical clearance was not required.

Analytics Maturity and AI Governance for Organizational Trust: A Swiss Capability Perspective

Viktoriia Apalkova
University of Applied Sciences and Arts Western Switzerland, Fribourg, Switzerland

Abstract

This study examines how analytics maturity and AI governance are articulated as organizational capabilities that support trust in AI-driven and data-based decision-making. As organizations increasingly rely on artificial intelligence (AI) and advanced analytics, trust has become a critical concern, extending beyond technical performance to include reliability, responsibility, and institutional alignment. While existing research often treats analytics maturity as a linear progression and AI governance as a set of external constraints, this study adopts a configurational and capability-based perspective grounded in the Resource-Based View (RBV) and Dynamic Capabilities Theory (DCT).

Drawing on qualitative analysis of corporate website discourse from ten Swiss organizations across multiple industries, the study explores how AI applications, data infrastructures, governance mechanisms, and trust-related narratives are publicly communicated. The findings demonstrate that analytics maturity is not represented as a linear developmental path but as distinct configurations of interdependent resources, combining technical, organizational, and governance capabilities. AI governance emerges as an embedded organizational capability that supports trust by enabling reliability, accountability, and alignment with institutional expectations, rather than functioning solely as a compliance mechanism.

Trust is constructed differently across sectors, reflecting industry-specific logics such as clinical validation in healthcare, risk control in finance, data sovereignty in telecommunications, and operational safety in industrial and energy contexts. These findings highlight that trust in AI is not universal but context-dependent and institutionally embedded.

The study contributes by reconceptualizing analytics maturity as a configurational phenomenon, repositioning AI governance as an enabling capability, and demonstrating how trust is co-constructed through the alignment of organizational resources and institutional expectations. The results underline the importance for organizations to align technical capabilities with governance structures and communication practices to sustain trust in AI-enabled environments..

Keywords: Analytics maturity, AI governance, Organizational trust, Dynamic capabilities, Switzerland.

Paper type: Academic Research Paper

1 Introduction

The increasing reliance on artificial intelligence (AI) and advanced analytics in organizational decision-making has brought ***organizational trust*** to the forefront of both academic and managerial debates. As AI systems increasingly influence critical decisions, questions arise not only about their technical performance, but also about whether organizations can be trusted to design, govern, and use AI responsibly. Recent research suggests that trust in AI-enabled decision-making depends less on algorithmic sophistication and more on organizational capabilities related to analytics maturity and AI governance (Bakonyi, Z., 2024 ; Smit, D. et al., 2021 ; Lahusen, C. et al., 2024).

Organizational analytics maturity refers to the extent to which data and analytics are systematically embedded in organizational structures, routines, and decision-making processes (Grossman, R. L., 2018; Lismont, J. et al., 2017). High levels of analytics maturity are associated with coordinated data practices, shared analytical understanding, and the ability to integrate analytics into strategic and operational decisions (Król, K. et al., 2020). However, much of the existing analytics maturity literature remains technocentric, emphasizing data infrastructure and analytical tools while paying limited attention to how maturity contributes to trust in ***data-driven decisions***, both internally and externally (Ariyarathna, K. et al., 2019; Langer, B., 2025; Steinmetz, S. et al., 2025).

In parallel, the literature on ***AI governance*** has expanded rapidly, focusing on ethical principles, regulatory compliance, and technical safeguards such as transparency, explainability, and fairness (Bahangulu, J. K. et al., 2025; Birkstedt, T. et al. 2023; Choung, H. et al., 2024). While these studies provide essential normative guidance, AI governance is often conceptualized as a set of constraints imposed on organizations (Batool, A. et al., 2025), rather than as an enabling organizational capability that supports trust in AI systems and analytics-based decision-making.

From a ***Resource-Based View*** (RBV), analytics maturity and AI governance can be understood as intangible, knowledge-based organizational resources embedded in routines, governance structures, and shared interpretations of data and AI use (Moderno, O. B. D. S. et al. , 2024). These resources are socially complex and

difficult to imitate, making them central to the development of organizational trust. From a ***Dynamic Capabilities Theory*** (DCT) perspective, analytics maturity and AI governance enable organizations to continuously align AI practices with evolving technological, regulatory, and societal expectations, thereby sustaining trust over time rather than achieving short-term performance gains (Lahusen, C. et al., 2024; Herrera-Poyatos, A. et al., 2025).

The ***Swiss organizational context*** offers a particularly relevant setting for examining these dynamics. Switzerland is characterized by high institutional trust, strong regulatory frameworks, and a knowledge-intensive economy in which reliability, accountability (Albu, O. B. et al., 2019), and transparency are central organizational values. In such an environment, trust in AI and data-driven decision-making is not assumed but must be actively constructed and maintained through visible governance practices and mature analytics capabilities.

Despite the growing relevance of trust in AI, existing research rarely examines how analytics maturity and AI governance jointly function as organizational capabilities that support trust, nor how organizations publicly articulate these capabilities. Moreover, empirical studies often rely on surveys or interviews, providing limited insight into how trust is built and communicated through organizational digital discourse. This study addresses this gap by adopting a capability-based perspective on analytics maturity and AI governance and by examining how Swiss organizations articulate trust-building practices in relation to AI and analytics.

Grounded in RBV and DCT, the study is guided by the following research questions focused on organizational trust in AI and data-driven decision-making:

- ***RQ1:*** *How do Swiss organizations publicly articulate analytics maturity and AI governance as foundations for organizational trust in AI and data-driven decision-making?*
- ***RQ2:*** *What governance-related knowledge resources and organizational structures are emphasized to support trust in the use of AI and analytics?*
- ***RQ3:*** *How do different configurations of analytics maturity and AI governance reflect distinct approaches to building and maintaining organizational trust in the Swiss context?*

2 Methodology

This study adopts a qualitative, multiple-case research design to examine how organizations articulate analytics maturity, AI governance, and organizational trust through publicly available corporate communication. The objective is not to assess internal technological performance, but to analyze how AI application is constructed, described, and legitimized in organizational discourse, with a particular focus on the relationship between analytics maturity and trust. A qualitative approach is appropriate given the exploratory nature of the research and its emphasis on meaning-making processes and semantic interpretation.

The study is based on data collected from official corporate websites, including innovation and AI-related pages, governance and sustainability sections, media releases, and career-related materials. Corporate websites are treated as institutional communication artifacts, reflecting both organizational practices and deliberate efforts to present capabilities, responsibility, and strategic direction to external stakeholders. Website content represents a form of unstructured textual data, which can be systematically analyzed to extract insights about organizational behavior and positioning. This approach aligns with recent methodological developments that emphasize the analytical value of unstructured web data and its interpretation through qualitative and natural language-based techniques (Pichiyan et al., 2023).

A purposive sampling strategy was used to select ten organizations operating in Switzerland, ensuring diversity across industries, regulatory environments, and AI application contexts. The sample includes companies from healthcare, finance, insurance, telecommunications, energy, industrial technology, consumer goods, and mining. This diversity allows capturing variation in how AI is applied, governed, and communicated, supporting a configurational perspective on analytics maturity and trust.

Table 1: Sample of analyzed companies

Company	Industry	Key characteristic*
Nestlé	Food & Beverage	AI across value chain and consumer services
ABB	Industrial Technology	Industrial AI platforms and analytics
Novartis	Pharmaceuticals	AI-driven R&D and innovation ecosystem
Roche	Healthcare	AI in diagnostics and clinical processes
UBS	Banking	AI for risk management and financial services
Zurich Insurance Group	Insurance	AI in underwriting and claims
Swiss Re	Reinsurance	AI for risk modelling and analytics
Swisscom	Telecommunications	AI platforms and data sovereignty
Axpo Group	Energy	AI in critical infrastructure operations

Company	Industry	Key characteristic*
Glencore	Mining	Automation and safety-driven AI applications

The analysis follows a qualitative coding approach focused on the semantic interpretation of AI application discourse. Rather than identifying only the presence of AI technologies, the study examines how organizations describe AI, what meanings are attached to it, and how it is linked to broader constructs such as strategy, governance, and trust. This approach is grounded in interpretive analysis of textual data, where language is understood as a mechanism through which organizations construct and communicate their capabilities and intentions.

The coding framework was developed using a hybrid approach, combining concept-driven categories from existing literature with iterative refinement during analysis. In particular, the study conceptualizes trust as a latent construct that is not directly measurable in website data but can be inferred from organizational discourse on reliability, responsibility, and stakeholder impact (Patent & Searle, 2019). Based on this perspective, the following coding categories were applied: AI_USE (descriptions of AI applications), DATA_MATURITY (data and analytics capabilities), STRATEGY (strategic positioning of AI), GOVERNANCE (rules, controls, and compliance mechanisms), ETHICS (fairness, transparency, responsibility), TRUST (explicit or implicit trust-related narratives), and CAPABILITY (organizational skills, structures, and learning processes).

Coding used short textual segments to capture precise semantic expressions and ensure consistency. The analysis was iterative, combining within-case interpretation with cross-case comparison to identify patterns in how AI application is constructed and related to governance and trust across institutional contexts.

An institutional perspective informs the interpretation, recognizing that corporate communication is shaped by regulation, industry norms, and legitimacy pressures. AI discourse is therefore understood not only as reflecting technological capability but also as a strategic communication practice through which organizations signal alignment with societal expectations and build trust. Differences across companies are interpreted as reflecting institutional variation rather than purely technological differences.

Analytical rigor is ensured through systematic coding, multiple-case comparison, and the use of official sources. The reliance on publicly available data may emphasize strategic representation over internal practices, but it provides valuable insights into how organizations construct and communicate AI capabilities, governance, and trust.

3 Results

The analysis reveals that the articulation of AI application across Swiss organizations cannot be reduced to a single dimension of technological adoption or analytics maturity. Rather than conceptualizing analytics maturity as a linear progression, this study interprets it through distinct organizational configurations, where technical capabilities, organizational structures, governance arrangements, and trust-oriented narratives are combined in different ways. This finding challenges traditional maturity models and supports a configurational understanding of AI as a bundle of interdependent organizational resources embedded in institutional contexts.

At the same time, trust emerges as a central organizing concept across all cases. Trust is interpreted as a context-dependent construct encompassing perceptions of reliability, responsibility, and institutional alignment. This interpretation allows capturing the diverse ways in which organizations construct trust in relation to AI and analytics, reflecting differences in industry requirements, regulatory pressures, and stakeholder expectations.

At the most immediate level, AI is consistently presented as an operational and technological resource, embedded in core processes such as drug discovery, financial risk management, claims processing, industrial optimization, and infrastructure management. Organizations describe AI through concrete applications, such as “AI… identify molecules” (Novartis), “detect fraud and anticipate market trends” (UBS), or “automate claims handling” (Swiss Re). Across cases, these applications are closely linked to data infrastructures, with repeated emphasis on “large volumes of unstructured data” (Swiss Re), “predictive analytics” (Nestlé), and “data-driven

business" (Swisscom). This indicates that AI is not conceptualized as a standalone technology but as a data-dependent analytical resource, forming the technical foundation of analytics maturity.

This technical resource base is embedded within an organizational layer, where AI is framed as a strategic and capability-building resource. Companies explicitly position AI as central to their long-term development, as reflected in formulations such as "AI360 strategy" (Zurich), "AI-enabled institution" (UBS), and "transform patient care" (Roche). In parallel, organizations emphasize capability development through AI labs, training programs, interdisciplinary expertise, and partnerships. These elements indicate that analytics maturity is constructed as an organizational capability, reflecting the ability to integrate, deploy, and scale AI-related resources across the firm.

Beyond these dimensions, the findings highlight a governance layer, where AI governance is articulated as a complementary resource ensuring the responsible and controlled use of AI. In highly regulated sectors such as healthcare, finance, and insurance, governance is explicitly formalized through compliance frameworks, validation procedures, and ethical principles. For example, Novartis refers to an "AI Risk & Compliance Management Framework," while Roche emphasizes that AI "must undergo rigorous clinical validation." Similarly, financial institutions highlight "strong oversight" (UBS) and regulatory alignment (Swiss Re). In contrast, organizations in less regulated sectors, such as consumer goods (Nestlé) and industrial technology (ABB), provide only limited or implicit references to AI governance. In the case of Glencore, governance is present but framed through safety systems rather than AI-specific mechanisms. These differences indicate that governance resources are selectively developed and communicated, depending on institutional context and stakeholder expectations.

At a higher level, the analysis reveals an institutional layer, where AI-related resources are linked to trust, legitimacy, and societal alignment. Across all cases, AI is associated with trust-related outcomes, yet the mechanisms through which trust is constructed differ significantly. In healthcare, trust is grounded in clinical validation and patient outcomes ("safe and reliable healthcare-grade AI" – Roche), emphasizing reliability and responsibility. In finance, trust is associated with risk control and responsible decision-making ("responsible and sustainable AI" – UBS), reflecting institutional expectations of accountability. In telecommunications, trust is framed through data sovereignty and security ("secure, trustworthy AI solutions made in Switzerland" – Swisscom), highlighting institutional alignment with national data standards. In energy and mining, trust is linked to safety and operational reliability ("reliable operation of plants" – Axpo; "everyone should return home unharmed" – Glencore), emphasizing responsibility toward infrastructure and workforce. These findings demonstrate that trust is not a universal outcome of AI adoption, but an institutionally embedded construct shaped by industry-specific logics.

Table 2: Cross-case comparison of AI application and governance articulation

Company	AI application focus	Governance articulation	Trust construction
Novartis	R&D, innovation	Strong (formal frameworks)	Patient outcomes
Roche	Clinical AI, diagnostics	Very strong (validation)	Safety & reliability
UBS	Risk, advisory	Strong (oversight)	Risk control
Zurich	Claims, underwriting	Strong (training-based)	Customer resilience
Swiss Re	Risk modelling	Strong (compliance)	Data transparency
Swisscom	AI platforms	Strong (data security)	Data sovereignty
Axpo	Infrastructure operations	Strong (regulatory)	Safety & reliability
ABB	Industrial analytics	Limited (implicit)	Performance
Nestlé	Consumer AI	Limited (implicit)	Product/service trust
Glencore	Automation & safety	Strong (non-AI governance)	Worker safety

The comparative analysis further reveals that organizations cluster into distinct configurations of AI-related resources, reflecting different approaches to building and maintaining trust.

Table 3: Configurations of AI-related resources and trust

Configuration	Companies	Resource characteristics	Trust logic
Integrated resource configuration	Nestlé, ABB	Strong AI and data resources, weak governance articulation	Implicit (performance-based reliability)
Trust-oriented resource configuration	Novartis, Roche, UBS, Zurich, Swiss Re, Swisscom, Axpo	Strong alignment of AI, governance, and ethical resources	Explicit (regulated and institutional trust)
Operational–safety resource configuration	Glencore	AI embedded in safety and operational control systems	Operational trust (safety and responsibility)

These configurations demonstrate that organizations do not converge toward a single model of analytics maturity. Instead, they exhibit qualitatively distinct combinations of AI capability, governance, and institutional alignment. Figure 1 summarizes the multi-layered configuration of AI-related resources identified across cases.

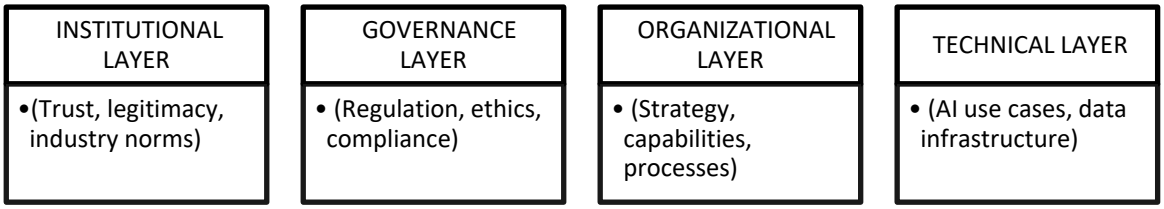

Figure 1: T. Conceptual framework: AI application as a multi-layered construct

The empirical findings provide clear answers to the research questions. First, Swiss organizations articulate analytics maturity as the development and integration of AI-related technical and organizational resources, while governance is positioned as a complementary resource ensuring responsible and controlled use. Trust, understood as a context-dependent construct encompassing reliability, responsibility, and institutional alignment, is constructed as the outcome of this resource configuration rather than as an independent objective. Second, governance-related knowledge resources include formal frameworks, validation mechanisms, compliance structures, and organizational capabilities such as training and interdisciplinary expertise, all of which contribute to the credibility and reliability of AI systems. Third, different configurations of analytics maturity and AI governance reflect distinct, institutionally shaped approaches to trust construction, depending on industry context and regulatory environment.

4 Discussion

The findings challenge dominant assumptions in the analytics maturity literature by demonstrating that maturity is not best understood as a linear progression of technological sophistication. Instead, it is more accurately conceptualized as a configuration of interdependent organizational resources, where value emerges from alignment rather than accumulation. This shifts attention away from staged development models toward the structural integration of capabilities, highlighting that similar levels of technological advancement can produce different outcomes depending on how resources are combined.

AI governance, typically framed as a set of external constraints or normative requirements, appears here as an organizationally embedded resource with both operational and symbolic functions. Governance mechanisms do not merely regulate AI use but actively contribute to the construction of reliability and responsibility. Their role extends beyond compliance toward enabling organizations to demonstrate alignment with institutional expectations, thereby reinforcing trust. This dual function suggests that governance should be understood as part of the organization's capability architecture, rather than as an external overlay.

Trust itself does not emerge from technological performance alone but from the coherence between resources and institutional context. The variation in trust logics across industries indicates that trust is constructed through different mechanisms—validation in healthcare, risk control in finance, data sovereignty in telecommunications, and safety in industrial environments. These differences reinforce the interpretation of trust as context-dependent, shaped by sectoral norms and expectations rather than universally defined criteria.

From a Resource-Based View perspective, analytics maturity and AI governance function as intangible, socially complex resources that extend beyond efficiency gains. Their strategic relevance lies in their contribution to organizational legitimacy and trustworthiness, particularly in environments characterized by regulatory intensity and societal scrutiny. This expands the RBV by emphasizing non-economic value creation, where trust becomes a critical outcome of resource configuration.

Dynamic Capabilities Theory further clarifies these differences. The observed configurations reflect varying abilities to align and reconfigure resources over time, particularly in response to evolving institutional demands. Configurations characterized by strong alignment between AI capabilities and governance structures indicate more advanced dynamic capabilities, where organizations continuously adapt not only their technologies but also their governance practices and communication strategies. Trust, in this sense, becomes a dynamic outcome, sustained through ongoing capability development rather than achieved through static implementation.

The Swiss context reinforces these dynamics. The prominence of governance and trust-oriented configurations reflects broader institutional conditions in which reliability, accountability, and transparency are central expectations. Organizational practices and their articulation are therefore shaped not only by internal

capabilities but also by institutional pressures that define what constitutes trustworthy AI. This highlights the importance of considering national and sectoral contexts when analyzing AI governance and trust.

5 Conclusions

A configurational perspective offers a more appropriate lens for understanding analytics maturity and AI governance. Rather than progressing through predefined stages, organizations develop distinct capability combinations shaped by internal resource alignment and external institutional expectations. Within these configurations, trust does not result directly from technological advancement but from how capabilities are structured, governed, and communicated.

Analytics maturity and AI governance function as complementary capabilities that jointly shape perceptions of reliability and responsibility. Their interdependence suggests that technical improvements alone are insufficient for sustaining trust, particularly where accountability and transparency are critical.

Three contributions follow. First, analytics maturity is reconceptualized as a configurational phenomenon, shifting the focus from progression to alignment. Second, AI governance is repositioned as an enabling capability integral to trust construction. Third, trust in AI is shown to be institutionally embedded, varying across sectors and shaped by context-specific expectations.

Practically, organizations should prioritize alignment of technical, organizational, and governance capabilities rather than treating them as separate initiatives. Trust emerges from coherence, implying that AI investments must be accompanied by parallel developments in governance, capabilities, and communication.

The reliance on website data limits insight into internal practices, suggesting future research should combine discourse analysis with in-depth studies. Extending analysis across national contexts would further clarify institutional influences. Sustaining trust in AI ultimately depends less on technological advancement alone than on continuous alignment with evolving expectations.

6 Ethics Declaration

This study is based exclusively on publicly available data collected from official corporate websites. No human participants were involved, and no personal or sensitive data were collected or processed. The research complies with applicable ethical standards for academic research and does not require formal ethical approval.

7 AI Declaration

The author declares that artificial intelligence tools were used solely for language refinement and editing support. All conceptual development, data collection, analysis, and interpretation were conducted independently by the author. The author takes full responsibility for the content and integrity of the work.

Redefining Financial Advisory: Human-Machine Collaboration and Organisational Transformation Under the EU Financial Data Access Regulation

Gabriele Rizzo[1], Daniele Allega[12]
[1] LUISS Guido Carli University, Rome, Italy
[2] Mercatorum University, Rome, Italy

Abstract

The convergence of artificial intelligence and the proposed European Financial Data Access Regulation (FiDA) is reshaping financial advisory in ways that affect both client relationships and the structural composition of financial institutions. The dominant discourse has long oscillated between two extreme narratives: technological utopianism, which forecasts the displacement of human advisors, and technological scepticism, which confines algorithms to instrumental roles. This paper articulates a third narrative, that of human-machine symbiosis, in which AI capabilities and human expertise are deliberately coordinated as complementary contributors to advisory decision-making, and shows that this view carries macro-financial consequences that have received insufficient attention. The argument unfolds in four steps. We first review four interconnected literatures: AI in financial advisory, human-machine collaboration, FiDA and Open Finance, and capital structure theory in banking. We then develop a conceptual framework in which client data, algorithmic insight, and advisor expertise are coordinated as knowledge assets, deriving two implementation scenarios that distinguish AI-as-empowerment from AI-as-autonomous-interface configurations. A design-science proof-of-concept operationalises the framework on FiDA-aligned synthetic data, evaluated against alignment, suitability-augmentation, and interpretability criteria. Finally, we develop the macro-financial implications. AI-mediated advisory under FiDA can serve as a demand-side mechanism that complements the supply-side capital pressures of Basel III/IV. Through three transmission channels, ranging from direct conversion of deposits into Tier 1 or Tier 2 capital to maturity-profile improvements, depositors are progressively transformed into stakeholders, lowering institutional leverage and enhancing resilience to adverse macroeconomic shocks. The contribution is fourfold: a theoretically grounded alternative to dominant narratives; a mapping of FiDA provisions onto AI-advisory operational requirements; a development of macro-financial implications linking micro-personalisation to capital structure dynamics; and an algorithm-agnostic proof-of-concept.

Keywords: Human-Machine Collaboration, FiDA, Artificial Intelligence, Financial Advisory, Capital Structure

Paper type: Academic Research Paper

1 Introduction

The financial services industry is undergoing a profound transformation driven by artificial intelligence (AI), with implications extending far beyond operational efficiency to the structural composition of financial institutions (Agrawal et al., 2018; D'Acunto and Rossi, 2023). Yet the dominant discourse has long oscillated between two extremes. Technological utopianism envisions AI as a superior replacement for human judgment. Technological scepticism, conversely, relegates algorithms to mere computational tools, subordinate to human expertise and incapable of capturing the relational dimensions of advice. Both framings prove inadequate for the hybrid reality of contemporary financial organisations. Recent empirical evidence points to a third path: a symbiotic configuration in which AI capabilities and human expertise coalesce into collaborative decision-making systems that, when appropriately designed, can outperform either component operating alone (Dellermann et al., 2021; Bianchi and Brière, 2024). Hybrid advisory arrangements are rapidly emerging as the prevailing configuration in wealth management (Cardillo and Chiappini, 2024). However, this paradigm shift demands a robust regulatory and informational substrate. The proposed European Financial Data Access (FiDA) Regulation (European Commission, 2023) constitutes such a substrate. Building on PSD2, FiDA extends mandatory data sharing to mortgages, savings, investments, pension rights and non-life insurance. It introduces authorisation dashboards, financial data sharing schemes with multi-stakeholder governance, and a new entity, the Financial Information Service Provider (FISP). Drawing on capital structure theory (Modigliani and Miller, 1958, 1963; Myers, 1984; Jensen and Meckling, 1976) and post-crisis banking literature (DeAngelo and Stulz, 2015; Gropp and Heider, 2010), we contend that AI-powered advisory deployed within the FiDA framework can act as a mechanism for rebalancing the funding mix of financial institutions, transforming clients from creditors into stakeholders and thereby enhancing institutional resilience. Two research questions guide our analysis. First, how does FiDA enable a third narrative of human-machine collaboration distinct from automation and

scepticism? Second, how can AI-augmented advisory contribute to a structural rebalancing of bank funding? Each is addressed in turn below.

2 Theoretical Framework and Literature Review

This section reviews four interconnected literatures: AI in financial advisory; human-machine collaboration; FiDA and Open Finance; and capital structure theory in banking. Their intersection grounds our thesis that AI-mediated advisory under FiDA can reshape bank funding mixes.

2.1 Artificial Intelligence in Financial Advisory Services

Artificial intelligence has been described as a prediction technology whose principal economic effect is to drastically reduce the cost of forecasting outcomes from data (Agrawal et al., 2018). In financial advisory, this translates into machine-learning systems capable of inferring investor risk tolerance, allocating assets, and detecting behavioural anomalies at scale (Duan et al., 2019; Judijanto et al., 2022). Recent reviews document a sharp acceleration of AI adoption in financial services since 2020, with robo-advisors emerging among the fastest-growing applications (Cardillo and Chiappini, 2024).

Empirical work has examined whether algorithmic platforms substitute for or complement human advice. Brenner and Meyll (2020) show that robo-advisor use is associated with a 15-16 percentage point reduction in the likelihood of consulting a human advisor, particularly among investors concerned about fraud or conflicts of interest. Aristei and Gallo (2026) refine this picture using Italian household data: robo-advice substitutes for commission-based human advisors but complements independent fee-only advisors, suggesting that the substitution effect is conditional on the incentive structure of the human counterpart. A parallel literature on AI-based recommendation systems shows that hybrid architectures combining content-based and collaborative filtering, often built on gradient boosting (Friedman, 2001), outperform either method alone on banking datasets.

2.2 Human-Machine Collaboration: Narratives, Complementarity, and Trust
