Conceptually, the move from automation to augmentation rests on the prediction-judgment dichotomy articulated by Agrawal et al. (2018, 2025): as prediction becomes cheap, the marginal value of complementary inputs (data, judgment, action) rises. Dellermann et al. (2021) extend this insight into the framework of hybrid intelligence, in which humans provide contextual understanding, creativity, and ethical reasoning, while algorithms contribute scalable pattern recognition. Empirical work converges on the finding that hybrid teams can outperform either humans or AI alone, but only when task allocation, interface design and trust calibration are deliberately engineered (Bianchi and Brière, 2024). Three conceptual framings recur. Technological utopianism holds that AI will progressively replace human advisors. Technological scepticism emphasises algorithmic aversion (Dietvorst et al., 2015) and the irreducibility of human judgment. The third, human-machine symbiosis, is empirically supported: D'Acunto et al. (2019) show robo-optimisers improve diversification; Rossi and Utkus (2024) document that robo-advice reduces home bias and fees, lowers cash positions from 19% to 2%, and increases Sharpe ratios; Bianchi and Brière (2024) find that algorithmic alerts raise investor attention while leaving control with the investor, with only marginal additional gains from full automation.

2.3 FiDA, PSD2, and the Open Finance Trajectory

The European Union has progressively moved from sector-specific data access (PSD2 for payment accounts) toward a comprehensive Open Finance framework. PSD2 mandated free access to payment-account data via APIs but produced fragmented standards and weak incentives for data holders to invest in interfaces (European Commission, 2022). The proposed FiDA Regulation (European Commission, 2023) addresses these limitations by extending the scope of mandatory data sharing to mortgages, savings, investments, pension rights and non-life insurance, and by introducing a contractual scheme-based access model with reasonable compensation (Borowicz, 2025).

Three architectural innovations are particularly consequential for AI advisory. First, authorisation dashboards give consumers real-time control over which third parties can access which data and for which purpose (Article 8 FiDA). Second, financial data sharing schemes, industry-developed but governed under equal representation of data holders and users, define technical standards, dispute resolution and compensation models (Articles 9-10). Third, the FISP, authorised under Title V, can access customer data without per-request electronic authorisation, subject to professional indemnity insurance and supervision. From a knowledge-management

perspective, FiDA reframes siloed transactional records as structured, interoperable knowledge assets recombinable across institutional boundaries.

At the time of writing, FiDA has not yet been formally adopted: the European Parliament adopted its first-reading position on 18 April 2024, the Council its general approach on 4 December 2024, and trilogues have been ongoing since April 2025. Political agreement is plausibly achievable during the 2026 Cypriot Presidency, with operational application unlikely before 2028-2030 given the staged timelines envisaged. The European Central Bank (2024) and the European Data Protection Supervisor (2023) have issued opinions emphasising prudential clarity and strict subordination to the General Data Protection Regulation respectively (OECD, 2023).

2.4 Capital Structure Theory in Banking

Capital structure theory provides the analytical lens through which we interpret the macro-financial implications of AI advisory. Modigliani and Miller (1958, 1963) established that, under frictionless markets and absent taxes, firm value is independent of the debt-equity mix; the introduction of corporate tax deductibility of interest then generates a tax advantage of debt. Myers (1984) subsequently contrasted the static trade-off view with the pecking order theory, while Jensen and Meckling (1976) had earlier formalised the role of agency costs.

Banks are structurally distinct. Much of their debt consists of deposits performing liquidity services, and they operate under explicit capital regulation and safety nets. Gropp and Heider (2010) show that capital regulation and mispriced deposit insurance materially shape leverage choices for banks close to minimum requirements. DeAngelo and Stulz (2015) argue that high bank leverage can be socially and privately optimal once the value of producing safe, information-insensitive liquid claims is recognised. Post-crisis regulation requires a minimum 4.5% CET1 ratio, 6% Tier 1, and 2.5% capital conservation buffer, alongside a 3% leverage ratio and the Liquidity Coverage and Net Stable Funding ratios (BCBS, 2021). Alkhazali et al. (2024) find a positive association between pre-crisis regulatory capital ratios and 2020 return on assets, while accounting equity-to-assets shows no such effect, highlighting the role of high-quality capital. The implication is that any mechanism shifting bank funding from short-term deposits toward equity-like instruments tends to enhance resilience without compromising profitability.

3 Conceptual Framework

This section develops the conceptual framework that organises the paper's argument. We proceed in four steps: first, we formalise the three narratives that characterise the discourse on AI in financial advisory; second, we describe the role of FiDA as the informational and trust substrate that operationalises the symbiosis; third, we present an integrated model in which client data, algorithmic insight, and advisor expertise are jointly coordinated as knowledge assets; fourth, we derive two distinct implementation scenarios. Figure 1 summarises the resulting architecture.

3.1 Three Narratives of AI in Financial Advisory

Building on Section 2, we formalise three narratives that organise the discourse on AI in financial advisory. Technological utopianism extrapolates from the prediction-cost reduction of AI to forecast the eventual displacement of human advisors, reading partial substitution effects (Brenner and Meyll, 2020) as the leading edge of full automation. Technological scepticism, conversely, draws on algorithmic aversion (Dietvorst et al., 2015; Burton et al., 2019) and the persistence of relational capital to confine AI to an instrumental role. Both positions share a binary framing of human and machine as substitutes.

The third view, that of human-machine symbiosis, rejects this binary in favour of a complementarity logic grounded in the prediction-judgment distinction (Agrawal et al., 2018, 2025). Where prediction is cheap and accurate, machines should perform it; where judgment is scarce, contextual or value-laden, humans should retain authority. The boundary is neither fixed nor exogenous: task allocation, interface design, trust calibration and incentives jointly determine where complementarity materialises (Dellermann et al., 2021; Bianchi and Brière, 2024). Field evidence on hybrid advisory (D'Acunto et al., 2019; Rossi and Utkus, 2024) is most consistent with this configuration, which we adopt for the remainder of the paper.

3.2 The FiDA Substrate: Data, Trust, and Architecture

Symbiosis requires a substrate. Without high-quality, comprehensive and trustworthy data, machine-learning systems cannot generate insights worth a human advisor's attention; without auditable governance,

advisors cannot legitimately rely on algorithmic outputs in fiduciary contexts. FiDA supplies this substrate along three dimensions: informational, governance, and trust.

The informational dimension produces a cross-domain view of the household balance sheet by extending mandatory data sharing across mortgages, savings, investments, pensions and non-life insurance. The governance dimension is realised through financial data sharing schemes that coordinate technical standards and compensation models under explicit equality between data holders and data users, mitigating the risk that incumbents capture the access infrastructure (Borowicz, 2025).

The trust dimension is operationalised through authorisation dashboards that make consent granular, monitorable and revocable, while FISP authorisation under Title V subordinates data access to professional indemnity insurance and ongoing supervision. Collectively, these provisions translate latent transactional data into structured assets that are intangible, recombinable and governable.

3.3 An Integrated Model of Hybrid Advisory under FiDA

We propose an integrated model, illustrated in Figure 1, in which three knowledge assets are jointly coordinated: (a) client data, made interoperable and consented through FiDA mechanisms; (b) algorithmic insight, generated by machine-learning systems trained on this data and oriented toward suitability assessment, product matching and risk profiling; and (c) advisor expertise, which interprets, contextualises and where appropriate overrides algorithmic outputs in light of client-specific objectives, regulatory requirements and ethical considerations. The coordination of these assets is an ongoing organisational capability requiring governance mechanisms (audit trails, override logs), interface mechanisms (explanation layers, confidence intervals, escalation paths) and learning mechanisms (feedback loops).

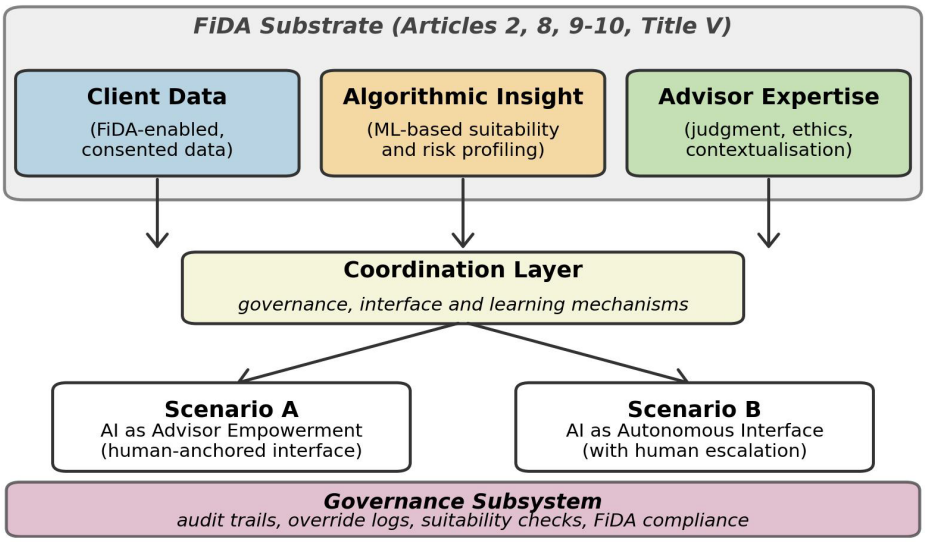

Figure 1: The integrated model of hybrid advisory under FiDA

3.4 Two Implementation Scenarios

The integrated model accommodates two distinct implementation scenarios, summarised in Table 1.

Scenario A (AI as advisor empowerment) has AI generate preliminary product recommendations, suitability scores and risk-flag alerts that are routed to human advisors. The advisor remains the primary point of contact with the client, leveraging algorithmic outputs to allocate time toward relationship building, complex planning and ethical judgment.

Scenario B (AI as autonomous interface with human escalation) has the AI system interact directly with the client for routine onboarding, risk profiling, asset allocation and rebalancing, while predefined triggers (low confidence scores, anomalous behaviour, high-stakes transactions, regulatory thresholds) escalate to human advisors. This configuration maximises scalability and lowers unit costs. Even in Scenario B, humans remain in the loop as governance actors whose oversight is structurally embedded.

Table 1: Two implementation scenarios

Dimension	Scenario A: Empowerment	Scenario B: Autonomous Interface
Primary client interface	Human advisor	AI system
AI role	Decision support	Direct interaction with escalation
Best-fit segments	Affluent, complex situations	Mass-retail, digital-first
Trust profile	Human-anchored	Algorithm-anchored, governed

The scenarios are not mutually exclusive: an institution may operate them in parallel for different segments. What unites them, distinguishing the configuration from both utopian automation and sceptical instrumentalisation, is the deliberate coordination of human and machine contributions through the FiDA-enabled knowledge architecture.

4 Methodology and Proof-of-Concept

This section presents the methodology used to translate the framework into an operational proof-of-concept. The exercise is anticipatory: FiDA is still in the legislative pipeline and authentic cross-domain data are not yet available.

4.1 Research design

We adopt a design-science research approach (Hevner et al., 2004) in which a working artefact is constructed to demonstrate how the integrated model can be operationalised. Evaluation criteria are threefold: alignment with FiDA-mandated data categories and consent mechanisms; generation of suitability-grounded recommendations that augment rather than supplant human judgment; and interpretability and auditability sufficient for advisor oversight.

4.2 Proof-of-concept architecture

The artefact comprises three layers mirroring the three knowledge assets of Section 3. The data layer ingests FiDA-aligned client data spanning the six categories enumerated in Article 2 of the proposed Regulation (credit and account products; savings and investments; occupational and individual pension rights; non-life insurance; firms' credit assessment data); it normalises continuous variables and encodes categorical variables via one-hot transformation. The reasoning layer hosts a supervised machine-learning model that takes client-product pairs as inputs and outputs a binary suitability classification with a confidence score; in an earlier thesis-level proof-of-concept (Rizzo, 2024), a gradient-boosting classifier (Friedman, 2001) was used as a tractable baseline, but the architecture treats the estimator as substitutable. The interface layer presents recommendations along with explanation artefacts and confidence intervals.

Cross-cutting all three layers is a governance subsystem recording every recommendation, override and consent change, providing the audit trail that FiDA's authorisation dashboard and supervisory architecture envisage. This subsystem differentiates the configuration from a black-box robo-advisor and renders the human-machine collaboration organisationally credible.

4.3 Data, variables, and validation approach

Because authentic FiDA data are not yet available, the proof-of-concept is trained on a synthetic dataset designed to mimic the distributional properties and structural categories that FiDA will eventually expose. Two parallel datasets are generated: a client dataset capturing demographic, financial and risk-profile attributes, and a product dataset describing representative financial products across the six FiDA categories. Client-product pairs are labelled for suitability through expert-informed rules grounded in suitability assessments analogous to those required under Article 25 of MiFID II.

The validation protocol follows standard supervised-learning practice and is reported here in methodological terms, since metrics obtained on synthetic data would not generalise to deployment. The dataset is split through stratified sampling; class imbalance is addressed via Synthetic Minority Over-sampling within a pipeline preventing information leakage; hyperparameters are selected by stratified k-fold cross-validation; performance is measured on a held-out test partition using accuracy, ROC-AUC, precision, recall and F1. Beyond predictive metrics, the artefact is assessed against the three design-science criteria of Section 4.1.

4.4 Limitations of the Proof-of-Concept

Three limitations apply. First, synthetic data cannot fully replicate the joint distribution FiDA will eventually expose. Second, expert-informed labelling embeds the labellers' heuristics. Third, the artefact instantiates a single estimator; comparative evaluation across alternative families is left to subsequent work.

5 Macro-Financial Implications

This section develops the macro-financial implications of widespread AI advisory adoption under FiDA, from the bank funding problem to a demand-side rebalancing mechanism, the behavioural conditions for it to materialise, and caveats.

5.1 The funding mix problem in banking

Banks operate at substantially higher leverage than non-financial firms because debt, especially deposits, is the funding instrument best suited to producing safe, information-insensitive liquid claims (DeAngelo and Stulz, 2015). This is privately and socially optimal in normal times, but adverse macroeconomic shocks translate disproportionately into losses for highly leveraged institutions. Post-crisis regulation has responded primarily through supply-side mechanisms (BCBS, 2021); banks with higher pre-crisis capital absorbed COVID-19 losses more effectively (Alkhazali et al., 2024). What remains under-explored is the symmetric demand-side mechanism: how households' allocation choices between deposits and risk capital instruments shape, in aggregate, the composition of bank funding.

5.2 AI Advisory as a demand-side mechanism

Field evidence on robo-advisory documents that AI-mediated advice systematically reduces idle cash positions (from 19% to 2% in one large-scale study, Rossi and Utkus, 2024), increases diversification, and modestly raises equity exposure. When scaled across the FiDA-enabled ecosystem, household wealth currently parked in deposits can be redirected, through suitable recommendations, toward risk capital instruments.

The redirection operates through three channels, summarised in Table 2. First, when AI advisory facilitates subscription of equity, AT1, or subordinated debt issued by the same banking group, deposits convert directly into Tier 1 or Tier 2 capital (Avdjiev et al., 2017; Bormann and Bräuer, 2018). Second, when recommendations steer clients toward third-party risk capital intermediated by the bank, deposits decline and fee income partially substitutes for net-interest margin. Third, even within the deposit envelope, reallocation toward longer-dated instruments improves the maturity profile and Net Stable Funding Ratio.

Table 2: Three channels of demand-side rebalancing

Channel	Mechanism	Effect
Direct conversion	Subscription of bank-issued equity/AT1/subordinated debt	Direct CET1/AT1/Tier 2 increase
Intermediated reallocation	Subscription of third-party risk capital via the bank	Deposit reduction; fee income substitutes margin
Maturity rebalancing	Reallocation toward longer-dated deposit instruments	Improved maturity profile; lower NSFR pressure

5.3 From depositors to stakeholders: behavioural mechanisms

Recommendation alone does not change behaviour; for the macro-financial channels of Section 5.2 to materialise, clients must act on algorithmic suggestions. Choice architecture (Thaler and Sunstein, 2008) is therefore central. Defaults, framing and feedback materially shift adoption: a recent field experiment with a robo-advisor found that switching the default from conventional to sustainable investing raised adoption from 23% to 42%, with 93% of investors retaining their initial setting months later (Hornuf et al., 2025). Earlier work shows that robo-advisory access mitigates the disposition effect, although specific interface choices may attenuate or reinforce it (Back et al., 2023). The same algorithmic recommendation can therefore produce very different aggregate flows depending on its presentation, defaults and rebalancing logic. Holding total assets fixed, an AI advisory system that reallocates a fraction of deposit balances into the bank's own equity-like instruments raises equity capital and lowers deposit funding, reducing the leverage ratio. Following Modigliani and Miller (1958, 1963), in frictionless markets this reallocation would not affect firm value; once frictions, distress costs and tax considerations are introduced (Myers, 1984; Jensen and Meckling, 1976), and once the

convexity of distress costs in adverse states is taken seriously, lower leverage translates into a smaller probability of losses sufficient to threaten solvency.

The transformation of depositors into stakeholders is therefore not merely a metaphor but a measurable change in claim structure. Deposit holders are short-term creditors whose claims must be honoured at par; equity holders absorb downside through reduced distributions and, in the limit, principal write-downs. After a suitability-grounded recommendation accepted under FiDA-compliant consent, a portion of the household's previous deposit balance has been converted into an equity-instrument position whose return co-moves with bank performance. In aggregate, this co-movement realigns private incentives with the institutional resilience that supply-side regulation alone cannot guarantee.

5.4 Resilience, welfare, and caveats

Four caveats temper the argument. First, redirection of deposits into risk capital is welfare-enhancing only insofar as recommendations are genuinely suitable: a system that pushes risk capital onto risk-averse or financially illiterate clients to relieve a bank's funding pressure would breach both fiduciary duty and FiDA's consent and purpose-limitation principles. The architecture of Section 3 explicitly subordinates the recommendation to a suitability test, with human oversight preserved across both implementation scenarios. Second, intra-group recommendations generate a structural conflict of interest requiring governance safeguards, transparency obligations, and reliance on independent FISPs as intermediaries. Third, retail distribution of bank capital instruments raises macro-prudential concerns. The Italian episodes of 2015-2017 (Banca Etruria, Monte dei Paschi di Siena) and the 2023 Credit Suisse AT1 write-down (Banca d'Italia, 2024) illustrate that contingent capital can be wiped out under regulatory action even when held by retail investors. The ESRB (2024) monitors household exposure to bank capital instruments as a vector of systemic vulnerability. Any framework promoting deposit-to-risk-capital transitions must therefore embed product governance, suitability assessments, and concentration limits. Fourth, macro-financial benefits are contingent on aggregation: only when AI advisory is widely deployed and FiDA scheme infrastructure is fully operational do the channels of Section 5.2 produce systemic effects. Subject to these caveats, demand-side rebalancing through AI advisory complements the supply-side capital pressures of Basel III/IV: each addresses one half of the leverage problem, and the joint effect is greater resilience to adverse shocks at lower aggregate cost than either mechanism alone.

6 Discussion

This section addresses organisational, practical, and policy implications, and acknowledges boundary conditions.

6.1 Organisational narratives and professional identities

Adopting symbiosis is not neutral. Where utopianism leads to under-investment in advisor expertise and scepticism to under-investment in algorithmic capability, the symbiotic configuration requires deliberate co-investment in both. Institutions internalising this logic redefine the advisor's role from analyst to interpreter and orchestrator, with implications for hiring, training and incentives (D'Acunto and Rossi, 2023).

6.2 Practical Implications for Financial Institutions

For institutions, the framework suggests a three-track agenda: FiDA readiness (data, consent, audit infrastructure); advisory redesign (Scenario A, B, or segmented); and capital strategy (recognising AI advisory as a potential lever in long-run funding-mix rebalancing while embedding suitability safeguards).

6.3 Policy Implications

Three policy points follow. Supervisors should treat FiDA, MiFID II suitability, and bank capital regulation as a coordinated whole. Macro-prudential authorities should monitor aggregate household exposure to bank-issued risk capital. FiDA authorisation dashboards and FISP supervision should incorporate behavioural-finance considerations (Hornuf et al., 2025).

6.4 Limitations and boundary conditions

The analysis is primarily conceptual; empirical validation requires live FiDA data. The macro-financial argument is stylised and partial-equilibrium; full assessment requires general-equilibrium modelling. The paper focuses on the EU; comparative analysis with the UK and Australia is referenced but not developed.

7 Conclusions

The convergence of AI and FiDA creates the conditions for a third narrative of AI in financial advisory, human-machine symbiosis, with macro-financial consequences that have received insufficient attention. By coordinating client data, algorithmic insight and advisor expertise as knowledge assets, financial institutions can deliver personalised advice while contributing to a structural rebalancing of their funding mix. Through suitability-grounded, FiDA-compliant recommendations, depositors can be progressively transformed into stakeholders, complementing the supply-side resilience pressures of Basel III/IV. Three avenues for future research follow: empirical validation once FiDA enters application; comparative analysis with the UK and Australia; and behavioural research on client responses to AI-mediated narratives, especially under conflict-of-interest disclosures.

8 Ethics Declaration

No ethical clearance was required. The work is conceptual and methodological, involving no human subjects, identifiable personal data, or experimental procedures requiring institutional ethical review. The proof-of-concept data are entirely synthetic.

9 AI Declaration

AI tools were used selectively in line with the IFKAD AI Tools Use Policy: (i) for literature review (Section 2), LLM-based assistants were used to identify candidate sources, subsequently verified by the authors; (ii) for language editing, AI assistants refined sentence structure. No AI-generated content was incorporated without human review and accountability. The conceptual framework, methodology, macro-financial argument and proof-of-concept are the original work of the authors.

Abstract

This article proposes an analytical framework of the Quintuple Helix for Knowledge Democracy-driven Innovation Ecosystems through Public Policies, as a theoretical-conceptual structure for analysing how innovation ecosystems may transition from functional efficiency towards socio-ecological legitimacy, inclusion, and resilience. The instrument is grounded in the integration of five theoretical fields: innovation ecosystems, helix-based innovation models, systemic public innovation policies, knowledge democracy, and sustainability-oriented governance. The framework is structured around five interdependent helices: Government, Academia, Industry, Civil Society, and the Environment. These helices are articulated through systemic public policies, understood as mechanisms of coordination, mediation, integration, and institutional orchestration. Its defining characteristic is the central position of Knowledge Democracy, conceived as the symbolic and operational core where knowledge flows, social legitimacy, participation, institutional learning, decision-making authority, and the collective appropriation of knowledge converge. The framework is operationalised through definitions, supporting theoretical references, and guiding questions organised by helix, intended to direct empirical investigations across different territorial contexts. The principal contribution of the article is to reposition innovation ecosystems as complex territorial arrangements, shaped by asymmetries, coordination processes, political choices, and knowledge governance. From a policy perspective, the instrument suggests that innovation strategies must combine directionality, participation, inter-helix articulation, socio-environmental criteria, and institutional feedback. As a theoretical-conceptual contribution, the article offers an analytical structure comprising propositions for future empirical applications across different territorial contexts.

Keywords: Quintuple Helix Innovation Systems, Knowledge Democracy, Systemic Innovation Policies, Innovation Ecosystems Governance, Socio-ecological Transition

Paper type: Academic Research Paper

1 Introduction

Innovation ecosystems help to address this complexity by framing innovation as a relational, non-linear, and territorially embedded process, involving heterogeneous actors — including government, academia, industry, civil society, and other institutional arrangements. However, when ecosystems are analysed primarily through the lens of market coordination, entrepreneurial density, or competitiveness, their democratic and socio-ecological dimensions frequently remain underdeveloped.

Helix-based innovation models offer an important pathway for overcoming this limitation. The Triple Helix accounts for innovation through the interaction between university, industry, and government (Etzkowitz and Leydesdorff, 2000). The Quadruple Helix expands this structure by incorporating civil society, culture, media, and users, connecting innovation to the knowledge society and to knowledge democracy (Carayannis and Campbell, 2009, 2014). The Quintuple Helix extends this logic further by adding the natural environment as a constitutive dimension of innovation systems, linking knowledge production to sustainability and socio-ecological transition (Carayannis and Campbell, 2010; Carayannis, Barth and Campbell, 2012).

This theoretical evolution alters the analytical significance of innovation. Within the Quintuple Helix, innovation is understood as a socially constructed, territorially embedded, and ecologically conditioned process. Knowledge Democracy is central to this discussion, as it emphasises epistemic pluralism, equitable access to knowledge, social participation, and the collective appropriation of knowledge in decision-making processes (Campbell, 2019). Accordingly, innovation ecosystems must be evaluated not solely on the basis of their technological or economic outcomes, but also in terms of their capacity to integrate diverse forms of knowledge, reduce asymmetries, and support sustainable development.

Public policies play a structuring role in this process. Traditional innovation policy frequently treats the state as a corrective actor responding to market failures, whereas more recent approaches conceive of public policy as a directional and market-shaping force, capable of mobilising resources, coordinating actors, and orienting

innovation towards collective ends (Mazzucato, 2016). Public investment in innovation may also produce persistent economic effects, stimulating research and development and broadening productive capacities (Ciaffi, Deleidi and Mazzucato, 2024). Public policies must therefore be understood as mechanisms of orchestration, coordination, and institutional learning within innovation ecosystems.

Notwithstanding these advances, the literature still lacks integrated conceptual models that connect public policies, Quintuple Helix interactions, Knowledge Democracy, and socio-ecological sustainability. This article is guided by the following research question: *How can systemic public policies structure Quintuple Helix innovation ecosystems so as to strengthen Knowledge Democracy, inclusion, and socio-ecological sustainability?* In response to this question, the article proposes and discusses an analytical framework of the Quintuple Helix for Knowledge Democracy-driven innovation ecosystems. The instrument is structured around government, academia, industry, civil society, and the environment, encompassing social legitimacy, participation, decision-making authority, and institutional learning. The article contributes to the field by shifting the analysis of innovation ecosystems from efficiency and interaction towards legitimacy, inclusion, sustainability, and institutional learning.

2 Theoretical Foundations

2.1 Innovation ecosystems and public policies

Innovation ecosystems are increasingly understood as complex, relational, and territorially rooted arrangements. They involve actors, activities, institutions, artefacts, and relationships that influence the innovative performance of a given actor or group of actors (Granstrand and Holgersson, 2020). This perspective broadens the analysis of innovation beyond isolated firms and linear technology transfer, emphasising interaction, interdependence, and collective learning.

Recent literature reinforces this systemic interpretation. Carayannis et al. (2018) argue that ecosystems may be interpreted through helix architectures, given that innovation depends upon dynamic, multi-sectoral, and multi-level interactions. Gifford et al. (2021) likewise demonstrate that knowledge-intensive innovation ecosystems evolve through the co-evolution of entrepreneurial activity and innovation policies. This indicates that ecosystems are shaped not only by bottom-up initiatives, but also by public coordination, institutional experimentation, and policy directionality.

Public policies are fundamental to this process. Traditional innovation policy frequently frames the state as a corrective actor that intervenes when markets fail. However, this view is insufficient to account for how innovation trajectories are shaped within complex ecosystems. Mazzucato (2016) argues that public policies may evolve from a focus on market correction towards a focus on market creation, actively shaping technological directions, mobilising resources, and generating new opportunities for public value. Accordingly, innovation policy is not merely an external support mechanism; it is a structuring force.

Systemic public policies coordinate actors, reduce asymmetries, develop institutional capacities, and support learning throughout the ecosystem. They may also connect innovation to broader social challenges, such as sustainability, inclusion, and territorial cohesion. Ciaffi, Deleidi and Mazzucato (2024) provide evidence that public investment in research and development can produce persistent macroeconomic effects and stimulate private research and development. This reinforces the notion that public action can influence innovation capacity beyond short-term financing.

From this standpoint, innovation ecosystems require more than entrepreneurial density or technological infrastructure. They demand governance mechanisms capable of aligning knowledge production, productive capacities, social demands, and environmental priorities. The Organisation for Economic Co-operation and Development (OECD) also emphasises that innovation policies are increasingly dependent on coordination, directionality, and systemic governance to address complex social challenges (OECD, 2023). For this reason, public policies must be understood as mechanisms of orchestration, mediation, and institutional learning within innovation ecosystems.

2.2 From the Triple Helix to the Quintuple Helix

Helix-based models provide an important theoretical foundation for analysing the institutional architecture of innovation. The Triple Helix model accounts for innovation through the interaction between university, industry, and government (Etzkowitz and Leydesdorff, 2000). In this model, universities contribute to knowledge production, firms transform knowledge into products and services, and governments furnish regulatory,

institutional, and political support. The Triple Helix was therefore instrumental in advancing the understanding of innovation in knowledge-based economies.

Nevertheless, the Triple Helix presents limitations when analysing innovation in relation to social legitimacy, participation, and democratic governance. Its focus on university–industry–government relations may under-represent users, communities, culture, media, and broader social demands. The Quadruple Helix addresses this limitation by incorporating civil society, media and cultural publics, users, and democratic contexts into innovation systems (Carayannis and Campbell, 2009; Carayannis and Campbell, 2014).

The Quadruple Helix alters the significance of participation in innovation. Civil society is no longer merely a passive recipient of technological outcomes. It becomes a source of knowledge, legitimacy, demand articulation, and social orientation. In this respect, innovation is linked to the knowledge society and to knowledge democracy, insofar as epistemic pluralism and the diversity of knowledge become conditions for more legitimate innovation systems (Carayannis and Campbell, 2014).

The Quintuple Helix extends this structure further by incorporating the natural environment as a fifth helix. Carayannis and Campbell (2010) and Carayannis, Barth and Campbell (2012) argue that the natural environment should not be treated solely as an external constraint or as a context affected by innovation. It must also be understood as a driver of knowledge production, innovation, and socio-ecological transition. The Quintuple Helix thus connects innovation to sustainability, ecological responsibility, and long-term social transformation.

This evolution from the Triple Helix to the Quintuple Helix does not represent a mere accumulation of actors. It constitutes a conceptual shift. The analytical focus moves from institutional interaction for economic innovation towards a broader architecture that integrates the knowledge society, democratic participation, and socio-ecological sustainability. Carayannis and Campbell (2021) reinforce this point by arguing that Quadruple and Quintuple Helix innovation systems are grounded in democracy and ecology. Carayannis and Campbell (2022) likewise present the Quintuple Helix as an integrative device for modern, sustainable, and democratic knowledge economies and societies.

This article adopts the Quintuple Helix as its central theoretical architecture. The Quadruple Helix is relevant as an intermediate stage, insofar as it introduces civil society and democratic participation. The analytical focus, however, is the Quintuple Helix, given that the proposed instrument integrates government, academia, industry, civil society, and the environment — a scope essential for analysing innovation ecosystems as sociotechnical and socio-ecological systems.

2.3 Knowledge, democracy, and innovation governance

Knowledge Democracy deepens the democratic dimension of innovation ecosystems. It extends democracy beyond formal political institutions, emphasising epistemic pluralism, equitable access to knowledge, social participation, co-production, and the collective appropriation of knowledge. Campbell (2019) connects democracy, knowledge, and innovation by arguing that democratic quality can enable innovation. From this perspective, innovation is shaped not only by technological capacity, but also by the conditions under which knowledge circulates and is employed in collective decision-making.

This perspective challenges technocratic visions of innovation governance. Innovation cannot be regarded as democratic merely because diverse actors are formally present within the ecosystem. Formal participation differs from substantive participation. Formal participation may entail consultation, presence, or representation without real influence. Substantive participation requires that actors be in a position to shape agendas, priorities, resource allocation, and policy learning.

Bunders et al. (2010) argue that Knowledge Democracy requires conditions under which both dominant and non-dominant actors contribute meaningfully to public policies and research agendas. This distinction is particularly significant in innovation ecosystems. Universities, firms, and governments frequently concentrate technical authority, institutional influence, and financial resources. In the absence of democratic governance mechanisms, civil society may be included symbolically, whilst actual decision-making remains concentrated within technocratic or market-oriented spheres. Seeley et al. (2019) reinforce this argument by highlighting the importance of dialogue, the recognition of diverse voices, and the challenging of dominant knowledge hierarchies.

Democratic governance of innovation is therefore distinct from technocratic coordination. Technocratic coordination may enhance efficiency, but does not necessarily broaden legitimacy, inclusion, or collective learning. Democratic governance requires institutional arrangements that enable plural forms of knowledge to influence decisions. It also requires accountability mechanisms, participatory spaces, and feedback loops through which innovation outcomes may inform future public policies.

The distinction between symbolic inclusion and real influence is equally important. Civil society and environmental concerns may appear in policy discourse without effectively shaping priorities. Within the Quintuple Helix, however, civil society and the environment must not be peripheral or merely rhetorical. They are structural dimensions of innovation. Their incorporation is substantive only when it genuinely influences the direction, legitimacy, and sustainability of innovation trajectories.

Knowledge Democracy is therefore the analytical core that connects knowledge flows, social legitimacy, participation, institutional learning, and decision-making authority within innovation ecosystems. It is the principle that transforms the Quintuple Helix from a multi-sectoral structure into a democratic governance framework.

3 Conceptual and Methodological Approach

This article is theoretical-conceptual in nature. It presents neither empirical results, nor interview data, nor comparative findings. Its objective is to construct and discuss an analytical framework that integrates theoretical fields generally addressed in isolation, offering an operational instrument for empirical investigations into the governance of innovation ecosystems in the light of Knowledge Democracy. The conceptual construction of the instrument draws upon an integrative review of the literature on innovation ecosystems, helix-based models, public innovation policies, knowledge democracy, sustainability, and innovation governance. These fields provide the theoretical foundation for understanding innovation ecosystems as complex sociotechnical and socio-ecological arrangements.

The first theoretical field concerns innovation ecosystems. This literature sustains the understanding of innovation as a relational and territorially embedded process, shaped by actors, institutions, artefacts, and knowledge flows (Granstrand and Holgersson, 2020). It also enables the article to approach ecosystems as governance spaces, rather than merely as environments for entrepreneurship or technological performance.

The second field concerns helix-based innovation models. This article traces the transition from the Triple Helix to the Quadruple and Quintuple Helix frameworks, with emphasis on the Quintuple Helix as the central architecture (Etzkowitz and Leydesdorff, 2000; Carayannis and Campbell, 2010; Carayannis, Barth and Campbell, 2012). This theoretical field enables the framework to articulate government, academia, industry, civil society, and the environment.

The third field concerns public innovation policies. This article adopts the perspective that public policies are not confined to correcting market failures, but may shape markets, define trajectories, coordinate actors, and orient innovation towards public ends (Mazzucato, 2016). This perspective grounds the role of systemic public policies as structuring mechanisms within the framework.

The fourth field concerns Knowledge Democracy and the democratic governance of innovation. This literature enables the instrument to incorporate epistemic pluralism, equitable access to knowledge, social participation, co-production, and the collective appropriation of knowledge (Campbell, 2019; Bunders et al., 2010). It also provides the basis for distinguishing formal participation from substantive participation, and knowledge diffusion from knowledge co-production.

The fifth field concerns sustainability and socio-ecological transition. The Quintuple Helix literature frames the natural environment as a structural component of innovation systems, rather than as an externality (Carayannis, Barth and Campbell, 2012). This supports the inclusion of the natural environment both as a helix and as a condition for sustainable innovation trajectories.

The methodological contribution of this article thus resides in the conceptual integration of these five fields and in the construction of a structured analytical framework. The article does not seek to conduct a systematic review in the technical sense, nor does it present empirical procedures such as interviews, coding, or comparative analysis. The empirical application of the instrument may be developed in future studies, across different territorial and institutional contexts.

4 Quintuple Helix Analytical Framework for Innovation Ecosystems

Building upon the articulation of the five theoretical fields presented above, this section proposes an analytical framework designed to guide empirical investigations into the governance of innovation ecosystems in the light of Knowledge Democracy. The framework does not constitute a normative or prescriptive model. It is an analytical instrument that enables the systematisation, operationalisation, and comparison of how different territories articulate the five helices, systemic public policies, and the democratic processes of knowledge production and appropriation.

The presence of five helices does not presuppose that such presence automatically produces democratic innovation. The quality of interaction amongst the helices depends upon whether knowledge is accessed

equitably, co-produced, and collectively appropriated. This condition is precisely what the framework's guiding questions seek to render analytically visible. In this respect, Knowledge Democracy is not an additional concept incorporated into the Quintuple Helix structure, but rather the principle that transforms a multi-sectoral architecture into a democratic governance framework.

Three complementary dimensions organise the instrument, as set out in Figure 1. The first identifies each helix, namely Government, Academia, Industry, Civil Society, and the Natural Environment, and presents its definition within the context of innovation ecosystems. These definitions delimit the analytical role of each helix and establish the criteria by which its functioning may be investigated empirically. The second presents the reference authors underpinning the role of each helix in the international literature, conferring upon the framework both theoretical anchorage and traceability for future applications. The third dimension addresses guiding questions grouped into four thematic blocks: government policies for innovation; the role of universities and society; civil society participation; and aspects of public policies and research and development investment.

The thematic blocks were deliberately organised to capture the interdependence amongst the helices. Innovation ecosystems frequently exhibit fragmentation and weak alignment amongst actors, and the mere presence of universities, firms, government agencies, and civil society organisations does not guarantee systemic integration. Coordination requires public agendas, institutional capacity, and spaces for collective learning (Edquist, 1997; Lundvall, 2010). For this reason, Block 1 investigates government policies as the institutional conditions that structure interaction amongst the remaining helices. Block 2 examines how universities operate in knowledge production, mediation, and transfer in partnership with other actors. Block 3 analyses civil society participation, distinguishing between formal presence and the capacity to influence agendas and priorities. Block 4 investigates research and development investments as mechanisms capable of generating systemic effects when combined with institutional coordination and socio-environmental criteria (Ciaffi, Deleidi and Mazzucato, 2024). This interdependence amongst the blocks reflects the relational logic of the Quintuple Helix and precludes isolated, sector-specific readings of individual helices.

The inclusion of the Natural Environment as a constitutive helix follows from the understanding that the environment is not an external variable or a passive context affected by innovation. It is a dimension of innovation systems that conditions technological trajectories and orients knowledge production towards sustainability and socio-ecological transition (Carayannis and Campbell, 2010; Carayannis, Barth and Campbell, 2012). Block 4 therefore enables investigation of the extent to which innovation policies incorporate socio-environmental criteria, and the degree to which ecosystem outcomes are evaluated beyond economic performance.

Positioned at the centre of the framework, Knowledge Democracy signals that the assessment of innovation ecosystems cannot be restricted to indicators of technological or economic performance. It must also capture the distribution of epistemic power: who defines research problems, who accesses knowledge resources, who influences public policy priorities, and who benefits from innovation outcomes. The role of the state, in this context, is not limited to financing. It involves building institutional capacities, creating inter-helix coordination mechanisms, supporting participatory spaces, and ensuring that innovation outcomes feed back into institutional learning (Mazzucato, 2016). The guiding questions were constructed to render these dimensions analytically operational, enabling the identification, within the ecosystems under investigation, of both inclusion mechanisms and the structural asymmetries that constrain substantive participation.

Helices	Definitions of the Helices	References
Government	The "Government Helix" represents the institutional and government definiition of the Stata within the Innovation Helix models. This boha highlights the oneffierxent use of the government is a regolator. Siavever, uan its duroer of his sonere and eccegmete, ecting as one of the righrires and afflore to drive innovation and sustainable development. Questions

Block 1 - Government Public Policies for Innovation

This block explores the role of public policies in encreraging innovation, challenges and orgentanities of implementation, and thatt condestation in the innovation esysteters.

- Do you know of any nxisting public policies that encosrage innovation in your regiox? What are the most relevant strangtirs?
- How do you evaluate the government coles in artiftiating policy policies aneed of innovation?
- How can yas cuaanat regulation gnoductly condicues to aducating nancratans in the neropeana?
- Do police you can neccatige the participouts of different incest in innovative activities teest in workshops, hacksftkans, and other arreas? Who are the mast participasts?
- Is your gracesm, in the technical capacity of public policy realaze sefflarves in effiericy processs innovation?
- What are the loggest challenges lailed is the mplementation of tublic renovvierx systems?
- Are there differences in smplementing public innovation policies as cartant used in the economy, education, or social arres? Can you provide strangle?
- How can government satise at different levels (level, regional, and ar nealty consatlons in arongiltening innovation exeyrement?

Block 2 - Role of Universities/Sociotechnical

This block addresses the fundessesaal role of universites in developing one valums and technologies, as well as how they colllictions with the productive etates.

- How have universities ocntributed to the development of vrzy graduate and technological processes that velataes eceouscies' evmperticensent?
- How do you evaluate asovemnent oate to strium intection and knowledge provessend in pertsanlniy with the product os assur?
- How do you are have government provessnsus ds bstared them eafflouass io hamd comsyocent?
- What are the wara challenges loved by conpacere in balancing technoscian and human asernted innovaction in the Quiztsple Helis Innovation ceuponer?
- How can universities play a more active rele in developing innovement and technologies that prossses sestainable development?
- How can proeness beass as avnlasea and selivery netrevas to pevetert ponctinl rostals in ocaas of processses? What could de improved?
- How do you are anccessary role in uvecesiesing technological anereetions into more applicable market acvocrer?
- What opprenesates can mécero has explaes to strengtoce thra relationship with the prodactive acsess within the context of the Quixtaple Helie?

Block 3 - Social Context

This block exploses how civil coniety one countions in the innovation ecesystem, strengthening collaboration between different and shalders and helping to solve social challenges.

- How can civil soniety activity participate in the Quizteple Helix innovation ecssystem by producing solations to social challenges such as digital relations and sigalt aurers in technology?
- What are the impasct of civil activity participation in innovation and in improving the quality of products and services offered by companize?
- What are massa have su lect innovation poticies cougnus iy nilamned social and pcasities mist challenge? Can you pece entergare?
- What are the nuax benefite that innovative policies provats in maaaly and the market in prorcss?
- How can collabert line between civil ercaede, ecademis, and government generete more reclinesa and socially responsible uxcent hear?
- Hev we had faet sead erremy has eeld and coffcones to shaging innovation policies that impacst acconsity irie?
- How can the participanse of NDOs and sesial eccccuneat between the impact of public innovation policies in reslernamed arces?
- Do you know how can the private ezrret moce effectively engags seall ustility in developing innovations that meel ar axicle?

Block 4 - Socioeconomic Context

This block deals with the impacts of public policies and investement in R&D on economic development and explame the socioeconomic challenges related to innovation.

- How can public policies and R&D inverse rate drive sustainable economic growth is to plans with different socioeconomic callities?
- Have the respesees allevated to research and development noovative programs, with collaborative projects between tudceses and industry, generally significant ecosurch, regnent?
- What a portogame, have the recosory and the lack of financial resources have strateries in the technological adveroement of companies? If es, in wher most?
- What is the importance of collaboration between government, academic, industry, society, and the environment in the Condogia Hulir madel in in ies usachenen?
- What can be moot challenges leved in cnccciating the different castes for the effective implementation of public innovative policiss?
- How has the government roontal invovlems in ssamficat occecsttus and ocesanric development? Are these exemples of eccures?
- Is your spantan, have public policies been different in procesting maininability and social responsibility io the current socioeconomic context?
- How have innovation policies increased mangerrtile competecemens and devecatied the economy? Can you partfly with enemyles?

6 Conclusion

The analytical framework presented in this article operationalises, through definitions, theoretical references, and guiding questions organised by helix, a structure for investigating how innovation ecosystems articulate democratic governance, public policies, and socio-ecological sustainability.

Within this framework, public policies are not interpreted as external interventions triggered by market failures. They are mechanisms that define agendas, coordinate actors, align instruments, reduce asymmetries, and create institutional conditions for collective learning. The role of the state is not to supplant the remaining helices, but to orchestrate the conditions for inter-helix cooperation, support participatory spaces, and ensure that innovation outcomes feed back into institutional learning.

Positioned at the centre of the framework, Knowledge Democracy furnishes the criterion for analysing the democratic quality of innovation governance. It renders visible the distinction between formal and substantive participation, between knowledge diffusion and knowledge co-production, and between symbolic inclusion and real influence over decision-making. Innovation may be technically advanced and economically successful whilst remaining socially exclusionary or territorially unequal. Treating knowledge as a collective resource — accessible, co-produced, and appropriated by a plurality of actors — is the condition that distinguishes ecosystems with democratic governance from those with governance that is only formally plural.

The instrument contributes to the literature on innovation ecosystems by interpreting them as complex territorial arrangements shaped by actors, institutions, power asymmetries, knowledge flows, and political choices. It contributes to Quintuple Helix theory by reinforcing civil society and the environment as structural dimensions of innovation governance. It also contributes to the public policy literature by demonstrating that innovation policies are not solely corrective or financial instruments, but may equally structure trajectories, build institutional capacities, and orient innovation towards public value.

For policymakers and practitioners, the framework indicates that innovation policy must combine strategic directionality with democratic governance. Public action should promote inter-helix coordination, support participatory spaces, reduce territorial and social asymmetries, incorporate socio-environmental criteria, and create feedback mechanisms for institutional learning. In this sense, innovation policy becomes not merely a tool for competitiveness, but also a mechanism for democratic and sustainable development.

The article has limitations. Its contribution is theoretical and conceptual, and it presents no empirical testing of the instrument. Future studies may apply the framework empirically across different territorial contexts,

comparing how innovation ecosystems vary in terms of public governance, inter-helix articulation, Knowledge Democracy, sustainability, and systemic feedback. Such applications may help to refine the instrument and evaluate its utility for analysing innovation ecosystems across diverse institutional, social, and socio-ecological contexts.

The Organizational Challenges of Digital Transformation at SMEs

Anikó Almási
Obuda University - John von Neumann Faculty, Budapest, Hungary

Abstract

Research on SME competitiveness shows that it is not the level or strength of individual competitiveness factors that determines the success of SMEs, but rather the capabilities—particularly managerial skills—that empower or limit the implementation of these factors within the organization. Digitalization became essential factor of success of enterprises. While digital transformation has become a critical driver of competitiveness, its outcomes remain uneven, particularly among SMEs, where the limited resources, fragmented information flows and resistance to change constrain the value creation. Contemporary organizations increasingly operate at the intersection of knowledge, human behaviour and digital technologies, where value creation depends not on isolated technological investments but coordinated integration of organizational capabilities, cultural norms and knowledge practices.

This study analyses the determinants of digital transformation (DT) success and failure at small and medium-sized enterprises (SMEs) through an integrated perspective that combines technological, organizational, behavioural and environmental dimensions. Building on established theoretical frameworks, including the Technology-Organization-Environment (TOE) model and GLOBE cultural dimensions model the study develops an extended analytical approach that incorporates cultural and leadership factors. The results reveal a significant gap between technological potential and organizational readiness. Although SME managers increasingly recognize the importance of digitalization and innovation as key competitiveness factors, current digital practices remain strongly control-oriented and fragmented.

The knowledge generated by digital systems often remains centralized, underutilized, or limited to small groups of managers, which restricts its contribution to organizational learning, innovation, and employee empowerment. This behaviour reflects broader cultural patterns characterized by risk aversion, hierarchical decision-making, and a preference for monitoring and cost control over experimentation and knowledge sharing. This paper argues that DT should not be understood as a purely technological process, but as an organization-wide learning and integration phenomenon in which knowledge creation, sharing and utilization are embedded in everyday practices. It is necessary to pay attention to the specific characteristics of SMEs and local cultural aspects.

Keywords: Digital Transformation, SME, success factor, organization

Paper type: Practical Paper

1 Introduction

While digital transformation (DT) becomes a strategic imperative across industries, its outcomes remain uneven – particularly in small and medium-sized enterprises (SMEs). The SME sector generally has limited resources, and this fragmented knowledge flow and behavioural resistance often constrain the realization of business value (Zang et al., 2022, Kahveci, 2025). However, in most countries, SMEs make a significant contribution to GDP and employment. Innovation and digitalization are usually a basic factor of SME competitiveness models (Chikán and Czakó, 2009, (Szerb, 2007), as well as the limitations of leadership knowledge and the management of organizational capabilities.

Organizational and environmental factors have become more significant in DT as well. Mostly the environment is analysed from a narrow perspective, focusing on direct relationships, and look at the impact of the industry, competitors, and customers. This approach often manifests at the organizational level as well, where the focus is limited to digital readiness, change management, and the corporate lifecycle. However, new research suggest that a broader scope is required to examine both organizational and external, especially the cultural factors. The analysis of internal factors is company-specific, but the external environment differs significantly depending on the country. Therefore, to ensure the validity and reliability of the results, it is appropriate to analyse cultural influences on a country-specific, homogeneous basis. This study therefore focuses on the Hungarian SMEs and aims to contribute to the literature by revealing the impact of the external environment and culture on the success of DT.

For this purpose, the research focuses on SMEs in Hungary, as external influences can be adequately analysed in the context of homogeneous external factors.

- Besides technological factors, what other elements contribute to successful DT?
- How does this relate to the specific characteristics of SMEs' resources and competencies?
- What cultural factors are characteristic of Hungary that may influence the DT process and its success?

During the research, the representative database of the “Organization of the Future” research project was used for analysis (Marciniak et al., 2022). Cultural dimensions were analysed based on the GLOBE framework (House et al., 2004). For the extended theory of DT, we used the TOE model (Baker, 2012).

2 Theoretical Background

Digital Transformation (DT) affects the entire company; it cannot be reduced simply to the implementation of a new, data-driven system. On the one hand, DT impacts the external dimension: it changes customer value propositions, contributes to the development of new products and services, and opens new marketing channels for the company (Loonam et al., 2018). The external dimension also serves as a framework: it is the social environment in which the company operates, which often culturally determines potential solutions and obstacles. On the other hand, DT also plays a strong internal role: it can lead to a more innovative company if it is integrated at the organizational level and affects the entire internal dimension of value creation at the operations and process levels (Vogelsang et al., 2018). A completely new mindset at all organizational level, new business processes, updated management knowledge, and leadership roles are essential for the success of DT (Gupta et al., 2020).

At the same time, these same SME characteristics can also be an advantage during digital transformation: processes are less complex, the flow of information and decision-making can be faster and more flexible, and managers have direct knowledge of the resource and competency gaps affecting the organization (Kim and Jin, 2024). Digital transformation often involves reviewing process milestones, optimizing information flow, restructuring the organization, etc. Therefore, digitization also plays a role in professionalization, especially among SMEs. A carefully considered digitization project often results in higher-level corporate operations, thereby raising the company to a higher level of competitiveness (Murphy, 2002).

2.1 Digital Transformation as an organizational reconfiguration

The complexity of DT has now reached a level where we are no longer discussing how tasks are allocated between IT and business, but rather how to digitize the entire organization. This requires strong connectivity and a new management approach on the part of both IT and management. Digitalization does not mean the same thing as it did in the early 2000s, so it is worth revisiting models that analyse the success of basic and widespread IT projects, such as Information Systems Success (ISS) (DeLone and McLean, 1992, Alter, 2008), Critical Success Chains (CSC), Analytic Hierarchy Process (AHP) and Fuzzy Cognitive Maps (FCM) (Rodriguez-Repiso et al., 2007), as their decision support function is underestimated. Many authors apply industry-based models and concentrate on manufacturing companies. In their opinion, manufacturing companies are particularly affected by Industry 4.0 due to the application of technology and are therefore at a different stage of digital maturity than non-manufacturing companies (König et al., 2019, Nwaiwu, 2020). business processes or whether IT serves business model development. Others emphasize the advantage of knowledge-intensive sectors (Gemmell, 2017), as connectivity and learning processes between organizations are more intense, so innovative practices spread more quickly, and the absorption and rapid application of sectoral knowledge can mean survival for SMEs in the initial phase (Krishna, 2018). Benchmarking also typically takes place within the industry, which also increases the role of sectoral customs and practices, accumulated experience, and networks (Garwin et al., 2008).

Instead of listing technological factors, the focus has shifted to complex models that can account for both environmental and organizational factors, and but also including the organizational fit of the technology in the assessment and addressing the (lack of) competence. Baker (2012) summarized and further developed Tornatzky and Fleischer's (1990) TOE framework.

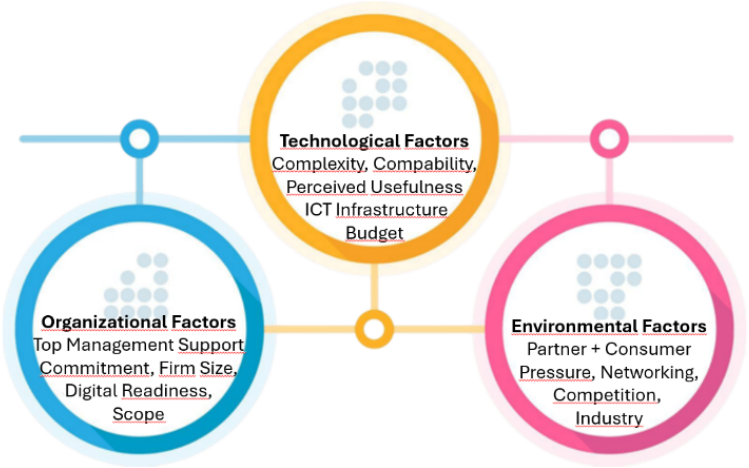

Figure 1: Types of DT / IT adoption factors (based on Baker, 2012)

While companies try to respond the constant external pressure to digitize, the environment is also subject the same trend: existing business models are becoming obsolete, and disruption demands rapid strategic responses from companies (Wirtz et al, 2022). Finding the right answers requires organizational structural changes, which are not covered by the DT project; rather, it requires leadership commitment and the expertise to manage change (Hess et al., 2016). The strength of TOE framework lies in capturing structural factors, but it underestimates micro-level dynamics as cognition, trust and leadership. This study emphasizes that behavioural and cultural dimensions can be mediating variables of explanation of DT, because leaders and culture shape how the hard elements – resources, capabilities – interact.

2.2 Cultural context

Hungary's cultural profile, as identified by the GLOBE study (House et al., 2004), provides important context to understand organizational behaviour in DT process.

Hungary has a relative high power distance: authority is typically concentrated at the top management level, and employees have limited involvement is strategic decisions. Hierarchically structured companies are typically centralized, generally the top managers have the right to make the final decisions, and the authority of middle managers has been reduced.

Strong uncertainty is also remarkable in Hungary. Risk-averse managerial practices, centralized organization structures and top-down information flow is common practice. As opportunities and possibilities increase, so does the role of internal control: managers strive to make processes and resources measurable and controllable in real time (Power, 2007).

The in-group collectivism has significant role in the business environment. Loyalty plays a key role both within the organization and in relationships between companies. Trust and the importance of relationships often outweigh the objective performance indicators. All these specialities tend to encourage group resistance to support or acceptance of change.

3 Methodology

Considering the general and exploratory nature of the research, a mixed-methods approach was adopted, combining secondary research findings with primary research data.

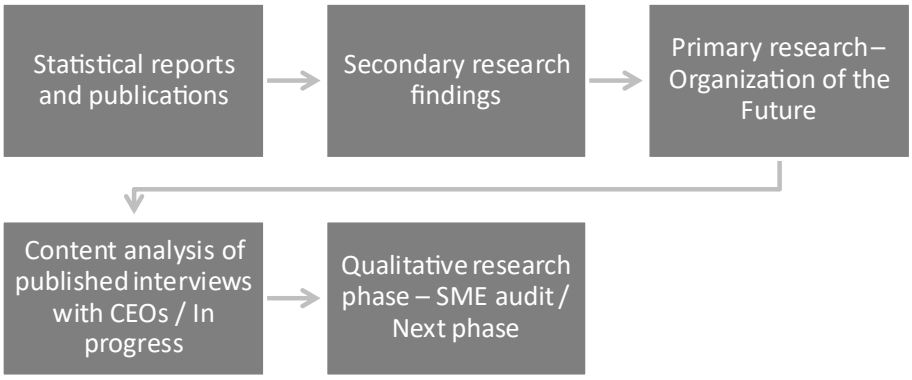

Figure 2: Data collection and analysis design

Organization of the Future research project (Marciniak et al., 2022) involved 305 companies; the survey was conducted by "Scale Research" market research company in March and April 2022. The target group was companies operating in Hungary that are larger than micro and small enterprises, employ 50 or more people. The respondents were senior managers of the companies. 53,5% of the companies are smaller medium sized with 50-99 employees, 29,37% are medium sized and 16,8% of the companies in the sample are large company with 250+ employees. The final database was constructed using stratified random sampling. The strata were defined based on company size, industry, and regional quotas.

4 Findings

4.1 Secondary data on Hungarian SMEs' digital transformation

4.1.1 Statistical reports

Based on the "Administrative burden on enterprises" research and publication of the Hungarian Central Statistical Office (HCSO) Hungarian companies spent 40 205 hours with economic statistics of divisions and 127 818 hours with Statistics of economic organizations in 2024 (HCSO, 2024). Despite this result two-thirds of Hungarian SMEs will have a website by 2023, but this figure drops to only 64% for small businesses with fewer than 50 employees. The content of the websites is also telling most of them contain product descriptions, but only 28.9% use their corporate website for sales (HCSO, 2020). A more popular solution among Hungarian SMEs is the use of social media platforms: 40.5% of businesses have both social media and a website. However, the proportion of digital services is negligible: only 16% of companies offer online customization of products and services, and only 9% had a chatbot, virtual customer service, or online communication options. The level of customer database exploitation is also low: only 13% of businesses track returning customers and tailor their online content to their needs. 93% of SMEs' online activity and 78% of their social media use was product related. Only 47% use online platforms to analyse customer feedback, 27% to collaborate with business partners, and only 12% to recruit new employees. The analysis clearly shows that the online activity of Hungarian businesses is less intense but fundamentally similar in structure to the EU average. The main difference is that SMEs in Hungary are of a single type, while in other EU countries they are more diverse and diversified.

Beyond online sales, however, there are many other areas for digitalization, and Hungary is far behind the EU average in terms of integrating digital technologies. 6.0% of local SMEs performed big data analysis, and 1.0% used external services for this purpose. The corresponding figures for the EU were 13% and 3.0%. Hungarian companies typically analyse geolocation data, and the use of data from their own systems and devices (2.6%) and data generated using social media (2.7%) is also more widespread. This means that Hungarian SMEs are lagging other countries in the region.

4.1.2 Secondary research findings

In their research, Szedmák and Szabó (2025) used semi-structured interviews to survey Hungarian experts with several years of management and digital transformation experience. Among the technological factors, the ten respondents highlighted the unreliable operation and slowness of the systems. They see the reasons for this as being that the digitized system was introduced too late, expectations within the organization were high, but often, due to budget constraints, they were unable to develop, purchase, and implement a system that would meet current needs.

At the operational level, the problem of technology and organizational alignment came to the surface. It often became apparent during the digitization project that the company did not have a deep enough understanding of its own processes. Hierarchical organizational structures encourage divisional egoism, while a digital transformation project requires the entire organization to work together. Ad hoc IT investments (often driven by currently available grant funds) are common, and the systems purchased in this way are also difficult to integrate into the company's operations.

Communication gaps and deficiencies in project management skills also proved to be critical factors in the success of digital transformation. Unprepared and unmeasurable projects are significantly more likely to end in failure, and research has also shown that negative experiences discourage digital projects in the long term. Management competencies include clearly defining the goals of the digital transformation project, as this is also the basis for measuring success.

According to the Digital Entrepreneurship Report / DEE index (Ács et al., 2025) in the case of Hungary, the period under analysis (2017–2022) showed a decline rather than stable convergence. Hungary has strong digital infrastructure, and the country also benefits from strong progress in Digital User Citizenship (DUC) factor. The society is relatively strong in digital participation, user trust, online service adoption, so Hungarian SMEs face less demand-side resistance from customers regarding digital adoption. But this individual level strength does not manifest at the institutional level: despite the strong technology foundation the entrepreneurial conversion is weak. Hungarian SMEs struggle with weak innovation and digital matchmaking and financing, ecosystem development, institutional stagnation, lack of trusted regulatory systems, lower governance coordination and inefficiencies. The authors suggest that it is essential to move from “building infrastructure” to “building entrepreneurial outcome” policy, because the high technology context cannot compensate for weak organizational and environmental conversion.

Another report of the DEE index research (Szerb and Cziegler, 2024) emphasizes the external and cultural background of these findings. The specialities of the Hungarian business environment are the patronage entrepreneurship: state-dependent entrepreneurship, the political favouritism, rent-seeking business behaviour and weakened market competition. Digital and technological infrastructure improved faster than institutions, and related knowledge has not yet reached a level that allows the technology to be effectively used and applied. That is the reason of the gap between technological readiness and entrepreneurial outcomes.

A study (Kárpáti et al., 2024) examined the digital attitudes of Hungarian and Slovak companies based on the DESI index at 210 enterprises. The most significant differences were found in the integration of ERP systems and internal processes, as well as in the goals of digitization: while Slovak companies want to improve the adaptability of their business models with digital solutions, the main motivation for Hungarian companies is cost reduction and resource allocation optimization.

4.2 Research on Organization of the Future

The structured interviews were conducted by interviewers. During the interviews, statements were presented, and respondents were asked to rate their level of agreement with the statements on a 5-point Likert scale. The resulting dataset was analysed using SPSS software. The relationship between the statements and the research questions was evaluated using ANOVA and correlation analysis. The analysis highlights the role of environmental and institutional factors in shaping managerial perceptions and digital behaviour.

The research examined the use of strategy data support, enterprise resource planning (ERP), customer relationship management (CRM), business intelligence systems and reports (BI), automation, and robotization during digitalization. The responding companies believed that the company of the future will be successful and competitive if it is technologically advanced, modern, constantly evolving, and innovative. This was followed by characteristics such as adapting to environmental expectations, being digitally mature, and being capable of renewal. At the end of the list were environmental awareness, timelessness, and a skilled workforce.

Hungarian company executives rated environmental impacts as significantly more influential (4.05 on a 5-point Likert scale) than international studies dealing with the environment. This uncertainty factor poses the greatest challenge for domestic businesses.

Companies that place a strong emphasis on the use of digital technologies reported that their leaders pay attention to errors, failures, and deviations in direct proportion to their level of digital maturity. In contrast, however, companies that consistently lead the way in strategic initiatives have focused less on errors. This also demonstrates that it is not the level of technology, but rather the attitude of leadership that determines how DT is used. When examining managers’ attitudes toward mistakes in relation to the company’s strategic initiative, the following results emerged:

Table 1: Strategic innovation compared with attitude of failure

ANOVA						
		Sum of Squares	df	Mean Square	F	Sig.
Leaders keep track of all mistakes.	Between Groups	15,076	4	3,769	2,599	,036
	Within Groups	414,763	286	1,450		
	Total	429,839	290			
Leaders direct others attention toward failures to meet standards.	Between Groups	9,617	4	2,404	3,300	,011
	Within Groups	214,175	294	,728		
	Total	223,792	298			
Leaders delay responding to urgent questions.	Between Groups	22,426	4	5,607	2,891	,023
	Within Groups	562,422	290	1,939		
	Total	584,848	294			

When examining managers' attitudes toward mistakes in relation to the company's DT level, the following results emerged:

Table 2: Priority to digital technologies compared with attitude of failure

ANOVA						
		Sum of Squares	df	Mean Square	F	Sig.
Leaders keep track of all mistakes.	Between Groups	8,454	4	2,114	1,438	,221
	Within Groups	426,281	290	1,470		
	Total	434,735	294			
Leaders direct others attention toward failures to meet standards.	Between Groups	23,346	4	5,837	8,485	,000
	Within Groups	206,371	300	,688		
	Total	229,717	304			
Leaders delay responding to urgent questions.	Between Groups	26,819	4	6,705	3,437	,009
	Within Groups	575,430	295	1,951		
	Total	602,248	299			

This highlights another important finding of the research: control is vital for Hungarian managers, and often the motivation for digitalization is to be able to monitor their company's operations more conveniently and accurately. Therefore, digitalization is often used not for forward-looking, growth-oriented functions, but to control data and processes. This, in contrast, also highlights the problem of the return on investment of DT: the control function does not increase business value. Access to data is still severely restricted for other members of the organization, and the flow of information remains closed even after digitization.

Hungarian SMEs focus primarily on the digitization of sales channels, often with under-planned, ad hoc digitization projects. In addition to company size, implementation is also a question of money: the immediate application of new technologies is the privilege of the companies with the highest turnover. However, while larger companies can afford to rapidly introduce innovative technologies, smaller companies are more experimental, one reason for which may be their limited resources. The results also show sectoral effects: both the use of new technologies (36%) and experimentation (40%) were most prevalent in the manufacturing industry, with other sectors lagging far behind.

The data analysis revealed that most managers use corporate data assets to evaluate the current situation and identify problems. Data analysis is even less common for the purpose of communicating decisions and monitoring implementation, and this seems to be the privilege of larger SMEs. The low level of integration is also revealed: companies use automation mostly for isolated activities, and only 13% use it comprehensively, with a process-oriented approach.

Data-driven corporate operations can provide opportunities for both centralization and decentralization of decision-making. Quantitative analyses are typically (72.5%) only available to a narrower management layer, and 23.6% of managers completely reject the possibility that data analyses made available through digitalization will become accessible to a wider audience in the coming years. Only 9.2% of companies plan to expand data access within their organization and decentralize their decision-making processes in the next three years. The sample clearly showed the impact of leadership style on the centralization of decision-making processes, but this topic goes beyond the scope of the present study.

5 Discussion

The findings confirms that the success of DT in Hungarian SMEs is determined less by the availability of technology and more by the interaction between organizational capabilities, leadership behaviour and institutional environment. The secondary data show that Hungarian SMEs possess relatively strong basic digital infrastructure. However, the low level of ERP integration, big data analytics reveals that digital maturity remains shallow and functionally isolated. Also the Organization of the future research phase shows many digital projects fail because firms do not completely understand their own processes before attempting digitalization.

The empirical results also highlight the dominance of centralized managerial behaviour. This control-oriented managerial behaviour significantly reduces the knowledge-creation potential of DT. Managers are not necessarily passive but rather controlling reactive. It means that they do not develop proactively and focus on errors, deviations and risk. DT thus serves monitoring and risk reduction rather than decentralization or organization growth.

These findings are strongly connected to the Hungarian cultural context described by the GLOBE dimensions. High power distance supports centralised decision-making and restricted participation, while strong uncertainty avoidance encourages defensive strategies, preference for proven technologies, and low tolerance for experimentation. In-group collectivism strengthens loyalty-based organizational processes and resistance to externally initiated change. Environmental factors further intensify these challenges. This reinforces short-term thinking and risk-averse investment behaviour. DT projects fail not because technology is unavailable, but because organizations lack shared understanding, strategic alignment and cultural readiness for knowledge sharing. This study therefor suggest that successful DT requires a shift from technology-oriented implementation toward organization-wide knowledge integration.

6 Conclusion

The study demonstrates that DT in SME sector cannot be understood as a purely technological project. Because of the rapidly changing innovation and digitalization solutions nowadays the IT knowledge is not enough to manage the corporate digitalization projects. The complexity of contemporary DT requires an organization-wide approach: strong connectivity between the top management and other departments of the companies. Therefore, the success and failure factors of DT have also changed. Alignment between business and functional level IT strategy, organization support, resistant to change and resilience became the important bottleneck of DT. Culture and environmental conditions are closely interconnected to DT. Organizational integration, strategic coordination and the ability to transform digital information into shared organizational knowledge and renewed processes.

However, the cultural characteristics helps to explain why DT often serves managerial supervision. Overestimation of environmental uncertainty and the persistence of centralized managerial attitudes create significant barriers to organizational integration and long-term digital value creation.

For successful DT project Hungarian SME leaders must move beyond isolated IT projects and adopt systematic organizational perspective. This includes stronger process orientation, broader access to data, leadership development, employee involvement and redesign of decision-making practice. DT should be treated not as an IT investment but as a strategic capability-building process.

The practical implication of this study is that future competitiveness depends not only on the quantity of digital tools, but on how effectively firms integrate technology into organizational routines, collaborative processes and strategic renewal. Without decentralization, organization restructure, and managerial support for change even advanced digital technologies will remain underutilized and unable to generate sustainable business value.

Microfoundations of Dynamic Capabilities: Intelligent Knowledge for Sustainable Internationalisation in Higher Education

Judit Fortvingler
Eotvos Lorand University, Budapest, Hungary

Abstract

As global competition intensifies, international higher education institutions must develop strong organisational agility to remain competitive. However, the sector's traditional emphasis on volume-driven massification frequently generates bureaucratic rigidities that constrain adaptation within international operations. While dynamic capabilities theory addresses such environmental volatility, its predominantly macro-level focus offers limited insight into how universities adapt internally.

To address this gap, this paper examines the cognitive microfoundations of dynamic capabilities, within the context of internationalisation, focusing on how the intelligent knowledge of international academic leaders facilitates strategic renewal and sustainable internationalisation. Building on this perspective, the paper proposes a conceptual framework that links individual-level cognition to organisational-level adaptation.

The research adopts a qualitative, comparative methodology, examining three structurally distinct Hungarian universities governed by different operational models: a traditional state university, a centralised public institution, and a market-oriented private university. Data were collected via in-depth interviews with senior leaders responsible for international affairs. Using the proposed framework, the analysis maps leaders' cognitive capabilities onto the key stages of dynamic capabilities: sensing, seizing, and transforming.

The findings suggest that managerial cognition plays a critical role in enabling agility in international higher education. Process-oriented expertise allows executives to detect emerging global shifts, while experience-based judgement helps reconcile financial pressures with academic values under conditions of uncertainty. In addition, contextual awareness allows leaders to interpret external demands in ways that reduce internal resistance during organisational change. The results also indicate that governance structures significantly shape these processes: while market-oriented institutions rely on rapid structural adjustments, state-funded universities depend more heavily on individual leadership to overcome institutional inertia and build organisational resilience.

From a practical perspective, the study highlights the importance of developing multidimensional cognitive competencies among international academic leaders, rather than relying solely on formal administrative procedures. To ensure continuity in internationalisation strategies, individual expertise should be embedded within institutional processes and practices.

By introducing a micro-level perspective on dynamic capabilities, the paper shows how managerial cognition can support sustainable internationalisation in institutions outside the global elite tier. The study contributes to a more context-sensitive understanding of academic agility, demonstrating that institutional resilience in international operations can be built without uncritically importing corporate management models.

Keywords: dynamic capabilities, microfoundations, intelligent knowledge, higher education internationalisation, organisational resilience.

Paper type: Academic Research Paper

1 Introduction

Internationalisation has evolved from a peripheral activity into a central strategic priority, driven by global complexity and the need for sustainable growth (de Wit, 2020; Knight, 2004). As knowledge-intensive organisations, universities must adapt to shifting demographics, funding, and regulations (Seeber et al., 2016). Ensuring strategic sustainability requires more than traditional administrative management: it demands profound organisational agility and adaptive resilience.

While dynamic capabilities (DCs) theory explains organisational adaptation (Teece, Pisano and Shuen, 1997; Teece, 2007), its application to higher education is problematic. Universities face a unique tension: the systemic drive to build volume through massification (Marginson, 2016) creates bureaucratic rigidities that conflict with the agility required for DCs. Since macro-level models fail to explain how this tension is navigated daily, a shift toward the microfoundations of DCs (Helfat and Peteraf, 2015) is required, focusing on the role of individual academic leadership in driving internationalisation.

To understand how this tension is resolved at the micro-level, this study introduces intelligent knowledge as a theoretical bridge, building on Schiuma's (2011) knowledge assets framework and Davenport and Prusak's (1998) domains of human expertise. By examining the cognitive and practical tools of boundary-spanning

international leaders, the paper addresses three research questions: (RQ1) How do international academic leaders apply intelligent knowledge within institutional sensing, seizing, and transforming processes? (RQ2) How does institutional context shape these dynamic capabilities? (RQ3) How does leader-level knowledge contribute to embedding sustainable internationalisation?

Consequently, this paper investigates international leadership as a strategic microfoundation for DCs, operationalised through experiential, judgement-based, and contextual intelligent knowledge. The study contributes to the literature by demonstrating why corporate models cannot be adopted verbatim in academia without accounting for the specific, multidimensional intelligent knowledge of its academic leaders managing international operations.

2 Literature Review

This section establishes the theoretical foundations of the study. It first explores the macro-level DCs framework and its microfoundations within higher education. It then examines the boundary-spanning role of international academic leaders and the cognitive mechanisms underlying their intelligent knowledge. In addition, the section discusses how institutional context shapes organisational resilience, ultimately integrating these perspectives into a conceptual framework that links individual-level cognition to organisational adaptation.

2.1 Dynamic capabilities and their microfoundations in higher education

The DC framework explains how organisations achieve competitive advantage (Teece, Pisano and Shuen, 1997) through three processes: *sensing*, *seizing and transforming* (Teece, Peteraf and Leih, 2016). Recent literature recognises that DCs are rooted in human action, specifically managerial cognition (Helfat and Peteraf, 2015). However, this individual-level expertise must be systematically embedded into collective organisational structures and routines to generate lasting DCs (Felin et al., 2012). This embedding process fundamentally relies on the continuous conversion of individual, tacit expertise into explicit organisational assets (Nonaka and Takeuchi, 1995).

While this theoretical model originated and has been empirically investigated predominantly in the profit-oriented corporate sector (Teece, Peteraf and Leih, 2016), its application to higher education institutions (HEIs) requires significant contextual adaptation. Universities operate under unique governance structures, strict state or foundation regulations, and deeply entrenched organisational histories. In higher education, recent research suggests that dynamic-capability-consistent governance and resource allocation can help institutions respond to policy shifts and financial pressures (Heaton, Teece and Agronin, 2023), while evidence from the COVID-19 context indicates that DCs can also support HEIs in coping with external shocks (Salam et al., 2023). However, applying corporate DC logic encounters a sector-specific tension: massification and economies of scale (Marginson, 2016) create rigidities that conflict with academic quality and institutional values (Noui, 2020). Addressing this tension between scale and agility requires context-sensitive leadership.

2.2 International academic leadership and intelligent knowledge

International academic leaders occupy critical boundary-spanning positions (Whitchurch, 2008), requiring continuous navigation across cultural and organisational domains. The synergy between entrepreneurial and enabling leadership acts as a catalyst for innovation (Beresford-Dey, Howden and Martindale, 2024), which, in the context of HEIs, allows leaders to sense global signals, seize strategic actions, and transform them into internal routines.

Despite leadership's recognised importance, the mechanisms connecting managerial cognition to organisational outcomes remain under-researched (Altintas, 2023). While knowledge management is linked to academic performance (Paudel, Bhattarai and Chalise, 2023), exactly how managerial cognition translates into organisational action and agility requires further exploration. This study builds on Schiuma's (2011) knowledge assets dynamics framework, which emphasises three fundamental management processes: the identification and measurement of knowledge assets, the mapping of their relationships, and the management of knowledge asset flows. While intelligent knowledge is often discussed in relation to technological and AI-driven systems, this study focuses on its human cognitive microfoundations. To conceptualise the micro-level of international academic leadership, the paper integrates Schiuma's (2011) process-oriented logic with Davenport and Prusak's (1998) foundational dimensions of knowledge. In this context, *intelligent knowledge* refers to the experiential, judgement-based, and contextual assets through which leaders interpret signals, make strategic judgements,

and translate external demands into change. How these specific knowledge domains act as the micro-level drivers of institutional agility will be further conceptualised in Section 2.4.

2.3. Institutional context and sustainable internationalisation through organisational resilience

The capacity to operationalise DCs is constrained by the macro-level institutional context. State-funded HEIs face bureaucratic complexity, while private institutions often exhibit greater market-driven flexibility (Levy, 2006). In the context of this study, sustainable internationalisation is conceptualised not merely in terms of maintaining international metrics, but as the institution's ongoing adaptive capacity. From a DCs perspective, sustainable advantage in highly volatile environments depends on organisational resilience (Leih and Teece, 2016; Teece, 2018). Accordingly, sustainable internationalisation represents a university's ability to reconfigure resources and operating models (transforming) in response to exogenous shocks. In this sense, the microfoundation of this resilience lies in the intelligent knowledge of boundary-spanning leaders, through which temporary internationalisation efforts become embedded in formal institutional routines.

2.4 Conceptual framework

This study proposes a conceptual framework (Figure 1) to illustrate how boundary-spanning leaders drive sustainable internationalisation. It synthesises the DCs framework (Teece, 2007; Teece, Peteraf and Leih, 2016) with the microfoundations of knowledge assets (Schiuma, 2011) and the domains of human expertise (Davenport and Prusak, 1998) within the specific institutional context of higher education through a five-step sequence: 1) international academic leadership serves as starting point, (2) the macro-level institutional context defines the boundary conditions, (3) the leader's intelligent knowledge operates as the mediating mechanism, (4) DCs provide the process through which adaptation occurs, and (5) sustainable internationalisation emerges as the organisational outcome.

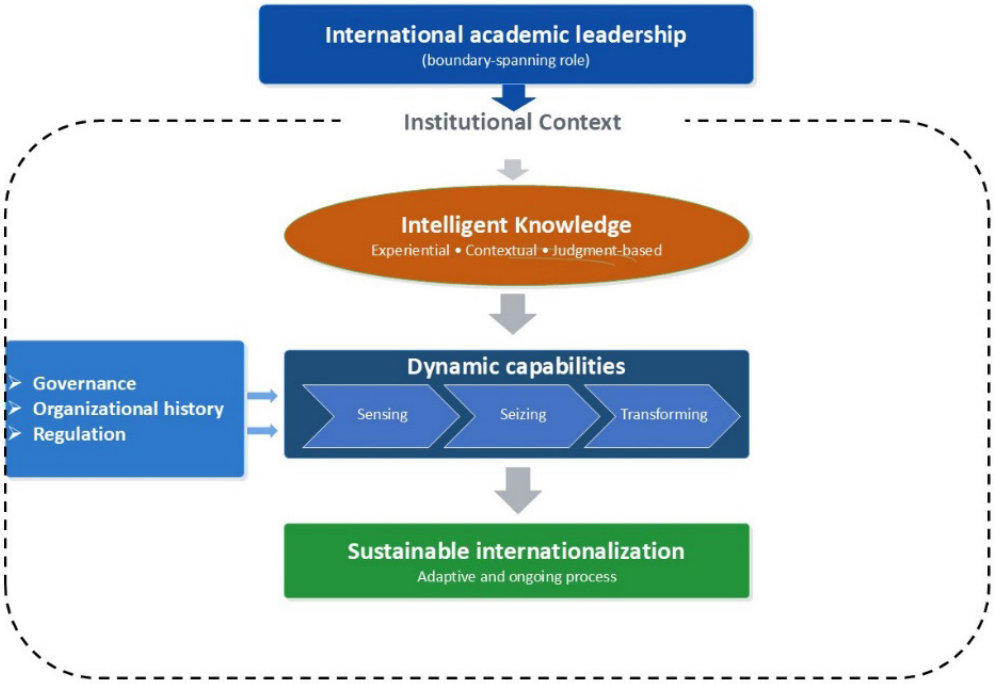

Figure 1: The proposed conceptual framework
Source: Author's own elaboration based on Teece, Peteraf and Leih (2016), Schiuma (2011), and Davenport and Prusak (1998)

To operationalise this theoretical bridge, the present study conceptually adapts Davenport and Prusak's (1998) knowledge dimensions to the specific context of international academic leadership, positioning them as the primary micro-level drivers of institutional agility. Consequently, these domains predominantly inform the sequential phases of DCs (Teece, Peteraf and Leih, 2016) as follows:

- *Experiential knowledge* provides process-based expertise for sensing early signals and scaling operations.

- *Judgement-based* knowledge enables strategic decision-making and tension-resolution (e.g., revenue vs. quality) during the seizing phase.
- *Contextual knowledge* enables boundary-spanning leaders to translate global trends into specific institutional settings, reducing resistance during the transforming phase.

As illustrated in Figure 1, these mapped theoretical intersections do not operate in isolation. The model captures how distinct knowledge domains underpin the sequential organisational phases of sensing, seizing, and transforming. At the same time, it shows that this entire micro-level mechanism is embedded within a broader macro-level institutional context (e.g., state vs. private governance), which determines the conditions under which organisational resilience and sustainable internationalisation can emerge. While these knowledge domains interact fluidly in practice, the framework highlights their primary theoretical intersections with the DC phases.

3 Methodology

3.1 Research design and case selection

This exploratory study uses a comparative multiple-case design for theory elaboration (Yin, 2018). Cases enable *theoretical replication* to examine the conceptual framework from different contextual angles (Eisenhardt, 1989; Eisenhardt and Graebner, 2007; Yin, 2018). Using purposeful sampling for maximum variation (Patton, 2015), three distinct Hungarian HEIs were selected (Table 1). This variation allows for a nuanced exploration of how institutional legacy and governance influence DCs. *Elite interviews* (Harvey, 2011) with boundary-spanning senior international leaders provided the strategic oversight necessary to navigate global trends and internal constraints.

Table 1**:** Profiles of the selected HEIs and interviewees

Case code	Institutional governance	Institutional history	Size	Interviewee role
TS (traditional state)	state-funded, decentralised, research focus	>100 years	20,000+ students	Vice-Rector for International Affairs
CS (centralised state)	state-funded, centralised	10+ years	6,000+ students	Vice-Rector for International Affairs
PM (private market)	British-accredited private institution	30+ years	1,000+ students	Rector

Note: In the PM case, the Rector fulfils the boundary-spanning role due to a flatter hierarchy.

3.2 Data collection and analysis

Data were gathered through semi-structured elite interviews. An eight-question guide, mapped to the sensing, seizing, and transforming phases, used probing questions to elicit concrete strategic episodes (Kvale and Brinkmann, 2009). Interviews were conducted in Hungarian to preserve deep contextual nuance (van Nes et al., 2010), then transcribed and selected representative quotes were translated into English.

Deductive thematic analysis (Braun and Clarke, 2006) categorised data into an Excel matrix based on the conceptual framework (context, knowledge dimensions, DC phases). Analysis followed a two-step logic (Miles, Huberman and Saldaña, 2014): a within-case analysis of each HEI, followed by a cross-case comparison to identify patterns and variances across governance models.

4 Findings

Analysis reveals that while all three institutions employ DCs to navigate internationalisation, micro-level leadership knowledge and macro-level context produce distinct trajectories. The synthesis follows the conceptual model's logic (Figure 1). The analysis first explores how institutional context creates inertia or fosters agility, before examining the activation of leaders' intelligent knowledge and the resulting tensions between massification and quality. This leads to an operational overview of the sensing, seizing, and transforming phases, ultimately identifying distinct pathways to organisational resilience.

4.1. The role of institutional context: inertia versus agility

The institutional environment fundamentally impacts internationalisation's speed and governance. For the TS university, historical legacy provides reputational capital but immense organisational inertia. As the TS leader

noted, faculties are "highly sceptical of centralisation goals," which transforms any strategic shift into a "pull-back force" requiring extensive internal negotiations.

Conversely, the CS university's hierarchical framework necessitates "highly central management," which allows the institution to "react faster to exogenous shocks because it is more centralised." However, the most extreme agility was observed in the PM institution, where being unencumbered by bureaucracy enabled rapid decision-making. The PM rector explained this operational freedom through stark financial realities: in its early stages, the institution was "on the verge of bankruptcy", necessitating radical, immediate market pivots over prolonged academic consensus-building.

4.2. The microfoundations: activating intelligent knowledge

The microfoundations driving the internationalization process, conceptualised as leaders' intelligent knowledge of boundary-spanning leaders, varied by institutional type. The TS leader utilised deep contextual knowledge to overcome internal resistance. Having previously served at the faculty level, the leader gained legitimacy because the apparatus "knew that I had suffered with the central administration just as they did". Similarly, the CS leader mobilised experiential knowledge. Despite serving as a vice-dean, like their TS counterpart, the CS leader emphasised a bottom-up trajectory, having started as an international coordinator. This meant they already "knew the international processes well" from the ground up, allowing them to scale this practical, operational expertise directly to the rectorate level as a "huge resource".

Conversely, PM microfoundations were rooted in business judgement over traditional academic socialisation. The PM leader emphasised that survival required "looking for business solutions, not academic ones." Lacking a regional blueprint, the PM's international strategy became a "trial-and-error game," relying heavily on the leader's entrepreneurial risk-taking rather than established institutional data.

4.3. Navigating the core tension: massification versus quality

Leaders navigated the tension between revenue-driven massification and academic quality through distinct strategies. TS employed a structural compromise: fee-paying bachelor's students generate revenue, while doctoral students "bring the necessary energy from a scientific output perspective" to sustain quality.

The CS leader criticised ranking pressures, noting that pursuing quotas ("let international students come, because it pushes up the ranking") can result in admitting candidates who "hinder the academic progression of domestic students." The PM rector articulated a private paradox: "Until you have an established brand name, you sacrifice quality... because you must generate a return for the owners." To mitigate this aggressive massification, the PM institution strategically utilised its British accreditation as a strict quality assurance shield to legitimise degrees on the global market. However, the PM leader noted that having finally achieved stability, the institution is now positioned to initiate a very gradual, deliberate shift toward enhancing student quality.

4.4. Operationalising dynamic capabilities

All institutions showed strong sensing: TS utilised embassy networks, CS monitored conferences, and PM recognised the marketing value of European visas. However, seizing and transforming diverged significantly.

During seizing, TS university relied on incremental experimentation, testing "small variations" to preserve "fragile faculty consensus". Conversely, the CS leader utilised top-down authority for strategic commitments, acknowledging that seizing international markets "requires financial sacrifices from the universities." The PM leader, driven by financial pressure, engaged in high-stakes risk-taking, describing seizing as a forced "trial-and-error game."

The most drastic differences emerged in the transforming phase. At TS, administrative complexity delays change: "you have to get 100 or 200 people to change their mindset, and obviously, that is much slower." The CS institution managed to embed certain processes through formalisation (e.g., "written rector's directives remained"), yet informal initiatives collapsed post-leadership. In contrast, the PM university exhibited radical transformation capabilities. During the pandemic, it executed a "25% staff layoff" and, in a previous instance, rapidly phased out unprofitable language programmes: drastic, immediate reconfigurations that, as the leader noted, "would never work in a state institution".

4.5. Pathways to resilience

As conceptualised (see Section 2.4), this study operationalises sustainable internationalisation through organisational resilience. The empirical data reveal that HEIs achieve this resilient state through entirely different pathways.

For the TS university, resilience stems from its massive size and structural heterogeneity: its faculties function as “small laboratories where you can test mini worlds” and cross-pollinate best practices. For the CS university, resilience is secured through strategic international embeddedness. The leader identified prestigious European grants as the ultimate safety net, as these 5-to-10-year commitments “strongly anchor the institution into the European Higher Education Area”, providing a buffer against domestic financial shocks. Finally, the private PM university’s resilience is derived from two distinct factors. First, its predominantly non-academic leadership mindset allows the institution to immediately reframe and resolve external shocks as pragmatic business problems. Second, resilience is rooted in a highly autonomous, “live and let live” organisational culture. This emphasis on personal freedom generates remarkable personnel stability and low staff turnover, acting as the institution’s primary shield during turbulent times.

Collectively, these divergent micro-level solutions suggest that there is no universal template: the sustainability of internationalisation depends entirely on the intelligent alignment of leadership knowledge with the specific institutional context.

5 Discussion

This study unpacks the black box of DCs in higher education by examining the microfoundations of international academic leadership. This section addresses the three research questions by integrating empirical findings with the theoretical frameworks of dynamic capabilities (Teece, 2007; Teece, Peteraf and Leih, 2016) and synthesising Schiuma’s (2011) knowledge asset logic with Davenport and Prusak’s (1998) dimensions. By operationalising intelligent knowledge as a multidimensional cognitive asset, the following analysis demonstrates how individual-level leadership drives institutional adaptation within the international higher education landscape.

5.1. The micro-macro linkage: activating dynamic capabilities

In response to RQ1 (how leaders apply intelligent knowledge across DC phases) and RQ2 (how institutional context shapes this operationalisation), the cross-case analysis suggests that corporate DC models require significant contextual adaptation for HEIs. The findings corroborate Helfat and Peteraf’s (2015) argument that managerial cognition constitutes a key microfoundation of DCs and extend Altintas’s (2023) framework by illustrating how individual-level cognitive processes drive organisational knowledge management. This transformation aligns with the knowledge-creation logic proposed by Nonaka and Takeuchi (1995), suggesting that international leaders’ intelligent knowledge is systematically converted from individual tacit insights into explicit institutional routines.

During sensing, all leaders relied heavily on experiential knowledge (Davenport and Prusak, 1998) to identify global weak signals. However, the institutional context (RQ2) dictated the focus of this sensing. In the PM case, operating with greater autonomy from state bureaucracy, consistent with established observations on private institutional agility and market-driven adaptation (Levy, 2006), experiential knowledge facilitated the rapid identification of revenue-generating market niches. Conversely, in the TS and CS cases, sensing was shaped by state expectations, requiring leaders to scan for signals that corresponded to national regulations and traditional academic prestige.

The critical divergence emerged during seizing, where judgement-based knowledge (Davenport and Prusak, 1998) assumed particular importance. While PM seizing mirrored corporate logic via rapid resource mobilisation (Teece, Peteraf and Leih, 2016), leaders at TS and CS institutions faced considerable organisational inertia. For these boundary-spanning executives (Whitchurch, 2008), seizing required careful balancing, utilizing intuitive judgement to reconcile systemic pressure for revenue growth with entrenched academic values. In these state environments, judgement-based knowledge acted as the crucial mechanism for navigating institutional hesitancy and mitigating deeply rooted faculty resistance.

Finally, the transforming phase highlighted the importance of contextual knowledge (Davenport and Prusak, 1998) in addressing internal resistance. The PM institution exhibited high organisational agility, allowing leadership to implement structural changes rapidly. However, in TS and CS environments, the legacy of academic silos presented significant barriers. Leaders achieved strategic transformation by reconfiguring resources and operating models (Teece, 2018). To accomplish this, they actively managed knowledge asset flows (Schiuma, 2011) and embedded individual decisions into collective routines (Felin et al., 2012), translating market demands into acceptable academic discourse to mitigate faculty pushback.

5.2. Resolving the massification tension and building resilience

RQ3 explored how leader-level intelligent knowledge contributes to the long-term embedding of sustainable internationalisation. Given the profound tension between volume-based massification and academic quality (Marginson, 2016; Noui, 2020), findings show that boundary-spanning leaders use this cognitive asset to navigate this conflict, achieving a form of organisational ambidexterity and thereby generating organisational resilience.

Sustainable internationalisation manifests as organisational resilience, the continuous adaptive capacity to survive exogenous shocks (Salam et al., 2023). The pathways to this resilience differ fundamentally based on macro-level governance (Heaton, Teece and Agronin, 2023). The TS university achieves resilience through its massive scale and decentralised faculty networks, which act as "mini laboratories" for international practices. The CS university builds resilience through deep structural embeddedness in European grant networks. Meanwhile, the PM institution achieves resilience through raw organisational agility (Teece, Peteraf and Leih, 2016) and a highly cohesive organisational culture that values rapid adaptation over academic traditions. In all three scenarios, it is the international leader's specific intelligent knowledge that helps institutions manage the pressures generated by massification, enhancing their evolutionary fitness and transforming temporary crisis management into embedded institutional resilience (Leih and Teece, 2016).

5.3. Theoretical contributions

This study makes two primary theoretical contributions. First, it extends the DCs framework (Teece, 2007) in the higher education context by integrating Schiuma's (2011) process-oriented logic with Davenport and Prusak's (1998) knowledge dimensions, conceptualised here as intelligent knowledge, as a necessary microfoundation. It demonstrates that the sequence of sensing, seizing, and transforming (Teece, Peteraf and Leih, 2016) in academia is not a uniform, macro-level routine, but an individual-level process driven by the cognitive domains of boundary-spanning international academic leaders. Second, the study contributes to the internationalisation literature by demonstrating that corporate agility models are inherently constrained by the macro-level governance structures of HEIs (state-funded versus private).

6 Conclusions

As this study has demonstrated, achieving sustainable internationalisation in today's turbulent higher education sector goes beyond mere strategic intent: it fundamentally depends on the dynamic capabilities embedded within institutional leadership. This paper argues that navigating the inherent tension between volume-driven massification and academic quality requires well-developed dynamic capabilities (DCs). Through a comparative analysis of three Hungarian HEIs, the study concludes that sustainable internationalisation is not achieved through rigid, macro-level corporate models, but through the micro-level intelligent knowledge of boundary-spanning leaders responsible for internationalisation. It is the leader's ability to align experiential, judgement-based, and contextual knowledge with the specific governance structure of the institution that drives sensing, seizing, and transforming activities, effectively generating organisational resilience.

From a practical and managerial perspective, the findings offer critical implications for university leadership, revealing that structural and administrative changes alone are insufficient without the right cognitive microfoundations. Vice-rectors must actively cultivate all three domains of intelligent knowledge: experiential knowledge to sense global signals and scale operations, judgement-based knowledge to make bold decisions under high uncertainty during the seizing phase, and contextual knowledge to overcome institutional inertia during transformation. In addition, to prevent informal initiatives from collapsing during leadership succession, universities must systematically embed this individual expertise into formal institutional routines, ensuring long-term knowledge retention and organisational resilience.

While drawn from the Hungarian higher education context, the implications extend far beyond this geographical boundary. The findings are highly relevant for a broad segment of HEIs globally that operate outside the elite tier. For such institutions, leadership's cognitive agility remains a key source of adaptive capacity. Future research should quantitatively test the proposed conceptual framework across diverse national contexts and explore how mid-level academic managers, such as faculty deans, interact with top leadership to execute DCs and drive institutional transformation in the field of internationalisation.

Human–LLM Collaboration in Tactical Production Decision-Making: A Literature Review

Ines Ben Atitallah, Remsei Sándor, Heba F. Zaher
Széchenyi István Egyetem, Győr, Hungry

Abstract

This research seeks to investigate how large language models contribute to decision-making in manufacturing settings, with special emphasis on how LLM use influences decision effectiveness and the creation of a collaborative decision-making process between humans and LLMs.

The study adopts a literature review following PRISMA 2020 guidelines. A total of 145 papers were sourced from the Scopus and Web of Science databases (2020–2026). After duplicate removal and title and abstract analysis, 53 papers remained for detailed review. Out of these, 38 papers were included in the study. An additional 9 sources were selected through manual searches, bringing the total to 47. The studies were analysed across four dimensions: decision context, LLM involvement, human–LLM collaboration, and decision outcomes.

The results reveal that LLMs are primarily utilised for decision support purposes at the tactical level in production environments, such as planning, scheduling, diagnostics, and coordination. Despite demonstrating significant abilities in data processing and reasoning, the effect of LLMs on decision quality remains uncertain. Current literature mainly emphasises the technical aspects of LLMs rather than the human-machine interaction process, trust-building mechanism, and integration with organisational practices. Studies usually employ a human-in-the-loop framework, where decision-making remains in human hands.

This study focuses on peer-reviewed journal articles published in English and indexed in Scopus and Web of Science. As a result, some relevant research from other sources or languages may not be included. The study offers insights for organisations adopting LLM-based decision-support systems, emphasising the need for transparency, human intervention, and alignment with decision-making contexts and processes. This study provides a clear picture of how current research on LLMs in manufacturing decision-making is structured and highlights the main gaps that still exist. It shows that future research should go beyond focusing solely on technical capabilities and pay more attention to how humans actually interact with LLMs, as well as to how these systems influence decision quality in real-world situations.

The paper makes an original contribution by integrating scattered literature and highlighting significant knowledge gaps in decision-quality evaluation and human-LLM cooperation in tactical production decision-making.

Keywords – Large Language Models; Tactical Decision-Making; Manufacturing; Human–AI Collaboration; Decision Support Systems

Paper type – Literature review

1 Introduction

The rapid development of AI, particularly large language models (LLMs), has significantly expanded decision support capabilities. LLMs can significantly enhance decision-making in manufacturing and production. Specifically, because tactical decisions in manufacturing are complex and require substantial information, LLMs can provide decision-makers with valuable insights. At the same time, the current scholarly literature is fragmented in its discussion of the application of LLMs in decision-making. In other words, most studies focus on the technical capabilities of LLMs (optimisation, reasoning, and system integration). However, few articles discuss how LLMs interact with humans, what role they play in decision-making, and how they can be successfully implemented in production processes.

Considering the above gap, it is necessary to understand the influence large language models have on decisions made in manufacturing companies. The objective of the present paper is to examine the influence of artificial intelligence technologies on tactical decision-making and design processes with the aim of integrating human and artificial intelligence decisions. An analysis of prior research on this issue will be conducted to assess the current situation and identify knowledge gaps.

2 Review Protocol

A structured review protocol was developed to define the scope, research questions, and procedures guiding the literature review. While this study does not follow a fully systematic literature review (SLR) approach,

it draws on selected principles from established guidelines, such as PRISMA, to enhance transparency, consistency, and methodological rigor in the review process.

The review is guided by the following research questions:

- ***RQ1:*** *How can organisations design processes and systems to effectively integrate human judgment with LLM-based decision support?*
- ***RQ2:*** *How does LLM-supported decision-making influence the quality of tactical production decisions?*

The above queries guided the entire review process, from searching to the selection of studies. In this regard, this review adhered to the PRISMA 2020 guidelines (Page et al., 2021) in the presentation of the search and selection process and was done in adherence to the systematic review methods provided by Kitchenham and Charters (2007).

Figure 1 provides a flow diagram showing the process through which the studies were selected. The Rayyan tool was used in the handling of records and decisions during the screening process.

2.1 Search strategy

A comprehensive, automated search was conducted in Scopus and Web of Science to capture peer-reviewed studies (2020–2026) on LLMs and manufacturing decision-making. The core Boolean query was:

("decision making" OR "decision-making") AND ("large language model" OR "LLM" OR "LLMs") AND ("manufactur*" OR "production")*

This query was applied identically in both databases. Filters were applied to limit results to English-language journal articles from 2020 to 2026, focusing on subject categories relevant to business, management, decision sciences, engineering, and operations research. The searches were last run on 30-03-2026. Initial results totalled 145 records: 74 from Scopus and 71 from Web of Science (Table 1). All retrieved citations were exported (RIS format) and imported into Rayyan for management and screening.

Table 1. Search log detailing databases, queries, filters, and the initial number of articles (2020–2026).

Database	Search String	Filters	Number of articles
Scopus	("decision making" OR "decision-making") AND ("large language model*" OR "LLM" OR "LLMs") AND ("manufactur*" OR "production")	2020–2026; Decision Sciences; Business & Management; Social Sciences; Multidisciplinary	74
Web of Science		2020–2026; Business; Management; Economics; Engineering Manufacturing; Operations Research; Industrial Engineering	71
Total			145

2.2 Study selection process (PRISMA)

The screen adopted the PRISMA 2020 protocol (Matthew J. Page et al., 2021) in four distinct phases: identification, screening, eligibility, and inclusion. Articles were eligible for inclusion if they were published during the years 2020–2026, written in English, and dealt specifically with LLMs or other AI technologies used in decision-making processes in manufacturing/production environments, focusing primarily on human-AI decision interactions and their decision quality effects. Exclusion criteria comprised studies outside the manufacturing domain (e.g., healthcare or finance), papers not involving decision support, non-academic sources (e.g., white papers), and articles lacking sufficient methodological or contextual detail. These criteria were consistently applied across all screening stages to ensure alignment with the research questions.

After importing 145 articles in the Rayyan database, 24 duplicates were filtered out, leaving 121 unique articles. Screening was then performed based on titles and abstracts, and 68 articles were excluded since they were not relevant. Thus, a total of 53 papers underwent full-text screening. Out of the 53 articles, 15 were excluded for being less relevant or having inadequate methodology. To further increase the scope of the study, an additional nine papers that were found during the early stages of background research before keyword search were included in the review. Thereby, the final number of articles in the review is 47. Table 2 summarises these results, and Figure 1 illustrates the selection process.

Table 2. PRISMA study selection summary (2020–2026).

PRISMA Stage	Number of Records
Records identified (databases)	145
Duplicates removed	24
Records screened	121
Records excluded (title/abstract)	68
Full-text articles assessed	53
Full-text articles excluded	15
Additional records (manual search)	9
Final included studies	47

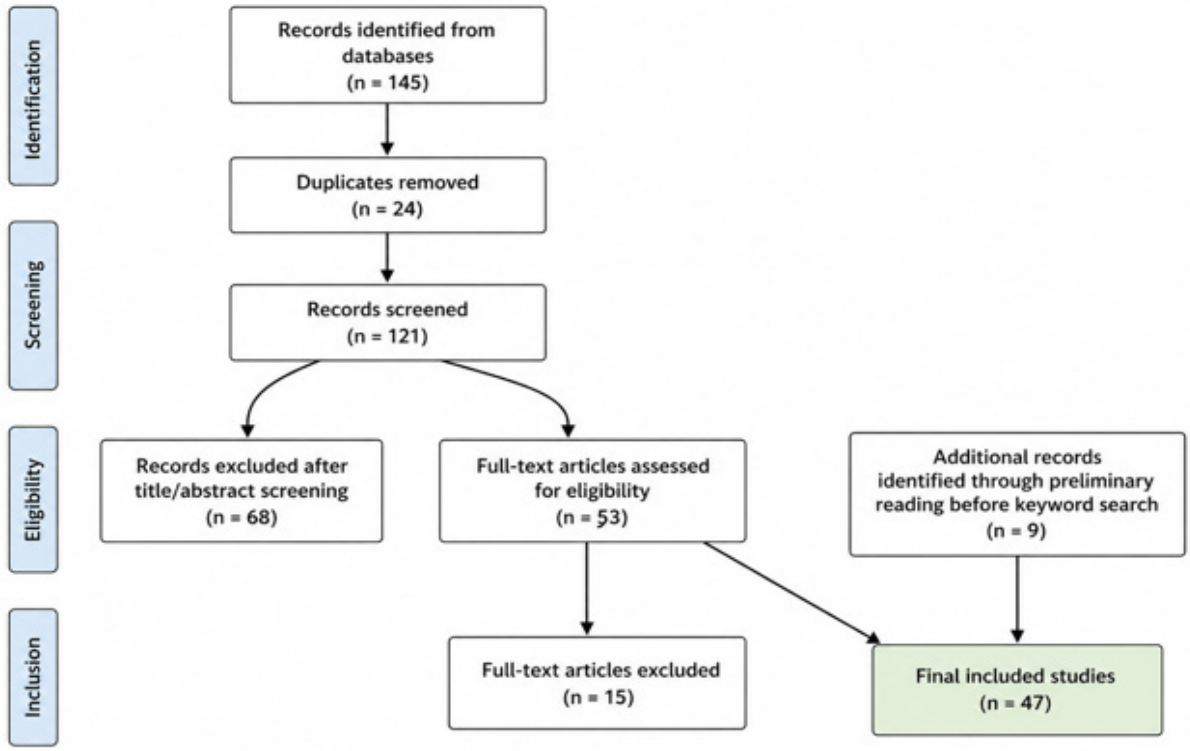

Figure 1. PRISMA 2020 flow diagram of study selection

2.3 Data extraction

Data were extracted from each study into a standardised form. Key fields included: author(s) and year; publication source; type of LLM or AI tool evaluated; decision context (e.g., scheduling, resource allocation, maintenance); decision level (tactical, operational); nature of human–AI interaction (e.g., advisory, collaborative, or autonomous); evaluation methodology (e.g., case study, experiment, simulation); and reported performance outcomes (e.g., efficiency, accuracy, timeliness). Further, data on how the human factor was defined in each study, the level of interaction between the human and the LLM, and any discussion of decision-making were collected. When available, the effects on decision-quality outcomes were noted; however, since very few studies measured decision quality, proxies for decision quality (such as improved performance or decreased errors) were also included. Any process or system design suggestions for integrating the human and the LLM were also collected. The selection of the fields was guided by RQ1 (decision-quality outcomes) and RQ2 (process and system design factors).

3 Overview of the Reviewed Studies

To provide a comprehensive understanding of the literature, this section will present a discussion of all 47 reviewed articles from two perspectives: concept classification and factor analysis of decision-making processes.

In the first case, a concept matrix (Webster & Watson, 2002) will be used in order to examine the current state of the literature. In the second one, a factor analysis will be applied to examine the collaborative process between humans and LLMs during production decisions.

3.1 Concept matrix of LLM applications in manufacturing

Table 3 shows the classification of reviewed studies using a concept matrix approach. The literature shows a strong concentration on LLM decision support, indicating that most research focuses on improving technological performance in terms of efficiency, optimisation, and automation in production decision-making.

Table 3. Classification of reviewed studies using a concept matrix approach.

Concept	Description (Focus)	Representative Studies
LLM decision support	General use of LLMs as decision-support tools in production and manufacturing systems, focusing on efficiency, optimisation, monitoring, and assistance	Vafeiadis et al. (2025); Gholami (2024); Fan et al. (2026); Cimino et al. (2026); Li et al. (2025, 2026); Lin et al. (2025); Tong et al. (2026); Liu et al. (2026); Wu et al. (2026); Sadeghi et al. (2026); Garcia et al. (2024); Colabianchi et al. (2024)
Decision support in scheduling	Application of LLMs in tasks such as sequencing, production scheduling, coordination, and real-time adjustment of activities under constraints	Genetti et al. (2026); Wu et al. (2025); Yang et al. (2026)
LLM-assisted diagnosis	Use of LLMs for fault detection, maintenance, troubleshooting, and diagnostic reasoning in industrial systems	Marandi et al. (2025); Nie et al. (2026); Wu et al. (2025); Jadhav et al. (2025)
Knowledge-driven decisions	Use of LLMs to extract, structure, and apply domain knowledge (e.g., tacit knowledge, ontologies, knowledge graphs) in decision processes	Rank et al. (2025); Ioshchikhes et al. (2026); Skrzek et al. (2026); Yan et al. (2026)
Planning decision support	Use of LLMs in production planning, system design, and resource allocation across multiple stages, often involving forecasting and optimisation	Werheid et al. (2025); Huang et al. (2026); Tan et al. (2026); Teng et al. (2025); Cimino et al. (2026)
Human–LLM collaboration	Studies focusing on interaction, co-pilot systems, trust, explainability, and human-in-the-loop decision-making	Colabianchi et al. (2024); Sridhar et al. (2026); Favier et al. (2025); Wang et al. (2026); Cai et al. (2026); Sabbah & Li (2025); Elgeddawy (2026); Passerini et al. (2025)
Human–robot–LLM interaction	Integration of LLMs into robotic or embodied systems where humans provide guidance, perception, or commands	Liu et al. (2026 – AR-assisted motion planning); Ding et al. (2026); Dong et al. (2025)
AI autonomy in decisions	Fully or highly autonomous LLM-driven decision-making systems with minimal or no human involvement	Wu et al. (2025); Yang et al. (2026); Ajraou et al. (2026)

More specific applications, such as scheduling, diagnosis, and planning, are present but less common, suggesting that research is fragmented across individual production functions rather than addressing decision-making as an integrated process. Although some studies explore human–LLM interaction, this remains one of the least developed areas. While interest is increasing, few studies examine interaction processes, trust-building, or decision quality in depth. At the same time, another trend is evident toward increasing automation, with several studies focusing on autonomous systems (e.g., robot-based manufacturing), where human involvement becomes limited.

3.2 Key factors influencing human–LLM collaboration

In the previous section, the concept matrix illustrates the research that has been conducted. However, this section further investigates the literature on human–LLM interaction to identify the factors influencing LLM-based decision-making in production environments.

The findings demonstrate that decision-making effectiveness is influenced by several dimensions, including decision attributes, LLM features, human factors, organisational settings, and the production context.

Table 4. Factors shaping LLM-supported decision-making.

Category	Key Factor	Short Explanation	Supporting Studies
Decision Characteristics	Decision complexity and uncertainty	LLMs are more useful in complex and uncertain decisions but also increase the risks of misinterpretation.	Cai et al. (2026); Wu et al. (2026); Tong et al. (2026); Sadeghi et al. (2026); Yang et al. (2026); Garcia et al. (2024)
	Time constraints (real-time vs planned)	Real-time decisions require speed, while planned decisions allow validation, affecting decision reliability.	Yang et al. (2026); Cai et al. (2026); Jadhav et al. (2025); Werheid et al. (2025); Fan et al. (2026)
	Decision structure	LLMs are commonly applied in semi-structured or unstructured tasks, where human interpretation remains important.	Sadeghi et al. (2026); Sabbah & Li (2025); Passerini et al. (2025); Favier et al. (2025)
LLM Characteristics	Explainability of outputs	Clear explanations improve trust and support better decision validation.	Passerini et al. (2025); Sridhar et al. (2026); Elgeddawy (2026); Cai et al. (2026); Genetti et al. (2026)
	Reasoning capability	Strong reasoning improves adaptability, but its effectiveness may vary depending on context.	Liu et al. (2026); Jadhav et al. (2025); Fan et al. (2026); Favier et al. (2025)
	Reliability	Inconsistent or hallucinated outputs can reduce decision quality.	Wang et al. (2026); Cai et al. (2026); Passerini et al. (2025); Cariaga (2025); Garcia et al. (2024)
	System integration	Integration with systems (KG, DT, agents) improves accuracy and usefulness.	Wu et al. (2024); Wu et al. (2026); Teng et al. (2025); Yang et al. (2026); Garcia et al. (2024)
Human Factors	Trust and reliance	Trust affects how much users depend on LLM outputs.	Elgeddawy (2026); Sabbah & Li (2025); Wang et al. (2026); Cariaga (2025); Genetti et al. (2026)
	Expertise	Skilled users better interpret and validate LLM outputs.	Liu et al. (2026); Passerini et al. (2025); Rank et al. (2025)
	Cognitive load and usability	LLMs can reduce effort, but poor design may increase confusion.	Colabianchi et al. (2024); Werheid et al. (2025)
	Decision authority	Humans usually retain final control in decision-making.	Cai et al. (2026); Elgeddawy (2026); Sridhar et al. (2026); Werheid et al. (2025)
Organisational Factors	Workflow integration	Effective integration into workflows improves decision support.	Colabianchi et al. (2024); Garcia et al. (2024); Werheid et al. (2025)
	Adoption culture and governance	Organizational readiness and policies influence adoption.	Elgeddawy (2026); Cariaga (2025); Wulf et al. (2024)
	Training and change management	Training is needed to ensure effective use of LLMs.	Passerini et al. (2025); Wang et al. (2026); Cariaga (2025)
Production Context	Industry/domain	LLM effectiveness varies across industries and applications.	Wu et al. (2026); Sadeghi et al. (2026); Tong et al. (2026); Garcia et al. (2024)
	Environment dynamics	Dynamic environments require higher adaptability from LLMs.	Wu et al. (2026); Yang et al. (2026); Cai et al. (2026); Liu et al. (2026)
	Data availability and quality	High-quality data is essential for reliable LLM outputs.	Wu et al. (2024); Garcia et al. (2024); Wu et al. (2024 – ProcessCarbonAgent)
	Task type	LLM performance varies depending on the type of decision task.	Colabianchi et al. (2024); Jadhav et al. (2025); Liu et al. (2026)

From the analysis in Table 4 above, it becomes clear that apart from being influenced by the technology itself, decision making supported by LLM technology is affected by many interrelated factors. Even though certain features of the technology, such as reasoning capability, explainability, and system integration, are significant, their impact on overall efficiency depends heavily on how they relate to human decision-makers and the context. Specifically, human variables such as expertise and decision-making ability significantly influence how outputs from an LLM are understood and utilised. At the same time, organisational factors such as

integration into workflow, governance and training play an important role in determining the success of implementation. Moreover, production variables contribute, including task types, data quality, and a dynamic environment.

4 Human–LLM Collaboration in Tactical Production Decision-Making: Roles, Patterns, and Challenges

This section analyses how LLMs are applied in tactical production decision-making, by analysing their functions, relations with human decision makers, and major obstacles to their application.

4.1. Decision types and context

Most of the decision-making processes aided by LLMs fall into the category of semi-structured decisions, where models suggest recommendations and humans make the final decisions. This can be seen in fields such as scheduling and planning, where the outputs need to reviewed and adjusted. These contexts are typically complex, involving multiple constraints and dependencies, and often require real-time or short-term responses.

Overall, LLM-supported decisions are primarily semi-structured, complex, and time-sensitive, reflecting the nature of tactical production decision-making. However, limited attention has been given to understanding human–LLM interaction in these settings (Genetti et al., 2026; Wu et al., 2025; Yang et al., 2026; Tan et al., 2026).

4.2 LLM in tactical production decision-making

LLMs are primarily used for tactical production tasks, such as scheduling and coordination, production planning, and maintenance or diagnostics (Genetti et al., 2026; Wu et al., 2025; Tan et al., 2026; Marandi et al., 2025). Additional uses include monitoring, robotic coordination, and sustainability-related decisions (Ajraou et al., 2026; Liu et al., 2026).

These applications span shop-floor activities (e.g., assembly, machining) and system-level contexts (e.g., supply chains, energy systems). Overall, LLMs are most often used in information-rich, dynamic, and semi-structured environments requiring timely decisionsHuang et al., 2026; Werheid et al., 2025; Wu et al., 2026).

4.3 Human–LLM collaboration patterns

Three main types of collaboration between humans and LLMs can be identified. First, fully autonomous decision-making by LLMs without human involvement is rare, though it occurs in some highly automated systems, such as multi-agent production scheduling or robotic control (e.g., Wu et al., 2024). Second, a common approach is human validation, where LLMs generate suggestions that are then reviewed and confirmed by human decision-makers, for example, in fault diagnosis or maintenance support systems (e.g., Nie et al., 2026; Sridhar et al., 2026). Third, some studies describe a more interactive form of collaboration, where humans and LLMs work together through continuous communication and joint decision-making, such as in co-pilot systems or human–robot collaboration environments (e.g., Ding et al., 2026; Sabbah & Li, 2025; Colabianchi et al., 2024). Overall, most research focuses on the last two approaches, where human involvement remains essential.

4.4 LLM Capabilities and limitations

The literature highlights that LLMs are effective in processing large volumes of data and supporting reasoning tasks such as planning and diagnosis (e.g., Nie et al., 2026; Liu et al., 2026). They can also generate context-aware explanations, improving accessibility for users (Genetti et al., 2026). Nevertheless, this technique has important constraints. Explainability is low, which complicates model reasoning, and reliability problems, such as hallucinations and inconsistency, undermine trust in LLM recommendations. (Wang et al., 2026; Passerini et al., 2025).

4.5 Challenges in real production contexts

Using LLMs in real production environments comes with several practical challenges. One of the main issues is trust, as users are often cautious when relying on model outputs that may not always be fully transparent or consistent (Dong et al., 2025; Wang et al., 2026). Usability is another important factor, since these systems need to be easy to understand and interact with in order to support decision-making effectively. At the same time, integrating LLMs into existing industrial environments is not straightforward. It requires aligning them with

current systems, workflows, and organisational processes, which can be complex and time-consuming (Fan et al., 2024; Elgeddawy, 2026).

5 Discussion

In examining the selected articles, the following consistent trends in the use of LLMs in production decision-making can be highlighted. First, LLMs are primarily used to support decision-making and are not intended to be fully autonomous decision-makers. Most existing examples of the use of LLMs relate to tactical data-driven decisions involving scheduling, planning, maintenance, coordination, and other tasks in which LLMs assist in dealing with substantial amounts of data and making relevant decisions. At the same time, the growing role of human–LLM interaction is evident in many studies that use human-in-the-loop frameworks to integrate AI-generated results with human evaluation.

Despite these developments, several important tensions emerge in the literature. Although LLMs are frequently characterized as able to perform complex reasoning tasks, their low level of reliability and explainability reduce user trust and restrict their practical use. This creates a clear gap between the potential for autonomous decision-making and the ongoing need for human oversight. In addition, the use of general-purpose LLMs does not always align with the highly specific requirements of production environments, highlighting the need for better integration with domain knowledge and context-specific data. Furthermore, while many studies recognise the importance of human–AI interaction, only a few examine in detail how factors such as trust, usability, and cognitive load influence the effective use of LLMs in decision-making.

To conclude, the field still seems fragmented and at its early development stages, with most studies being conducted based on simulation or experimentation with no practical testing verification. Most research has concentrated on the technical aspects rather than the decision process and interaction mechanisms. This indicates that while there is great promise in using LLMs to facilitate production decisions, there is still much to learn about their functioning in practical decision-making scenarios.

6 Research Gap and Future Research Directions

Despite the growing interest in LLM-supported decision-making, several critical gaps remain in the literature. First, there is a lack of formalised models for human–LLM interaction. While human-in-the-loop methods are widely used, defining roles and interaction processes is difficult, hindering the development of decision support systems that can be designed, compared, and evaluated systematically (RQ1).

Secondly, the quality of decision-making and the performance of LLM-based decision-making are underexplored. Many studies focus on technical aspects, such as a machine's ability to provide decision support, but fail to present evidence of its contribution to improved decision outcomes. Consequently, essential characteristics, including accuracy and robustness, are not properly analysed, making it impossible to assess the true value of decision support provided by LLMs (RQ2).

Furthermore, there appears to be little research into domain-related adaptation and integration into production systems. A number of researchers employ LLMs that are general in nature without adequately considering the importance of domain knowledge, structured data integration, and interoperability with existing industrial systems. This limits the practicality of the current techniques in actual implementation scenarios.

In addition, the current body of literature remains relatively fragmented, with many studies focusing on specific applications or technical solutions rather than offering a comprehensive understanding of decision-making processes. A significant number of studies also lack real-world validation, which limits the ability to evaluate how LLM-supported decision-making performs in practical industrial environments. Moreover, the influence of human–LLM interaction and organisational factors on decision outcomes is still insufficiently explored.

Therefore, future studies should focus on ways to develop an appropriate structure for collaboration, define standardized approaches to assessing decision quality, and carry out empirical research on how these types of systems can be applied in industry settings. Greater emphasis is also needed on human-centred design and system integration, ensuring that LLM-based decision systems are not only technically effective but also usable, trustworthy, and aligned with organisational processes

7 Research Limitations

There are some limitations associated with the study. First, the review of literature was performed using scientific articles available only in English, indexed in Scopus and WoS databases. This means that relevant

studies published in different databases or conferences, or written in languages other than English, might be excluded from the analysis.

8 Conclusion

This study provides a structured literature review of emerging applications of large language models (LLMs) in decision-support systems in manufacturing contexts. The findings show that LLMs are widely used to support tactical decision-making tasks such as scheduling, planning, diagnostics, and coordination, offering clear advantages in data processing, efficiency, and reasoning capabilities. However, their actual influence on decision-making processes and outcomes remains insufficiently explored. Existing research tends to focus primarily on technological performance, with limited attention to how LLMs can be effectively integrated into decision-making processes, particularly to improve collaboration and acceptance of AI-generated outcomes.

The present study adds to existing knowledge by highlighting certain significant gaps. To start with, there is a lack of well-defined frameworks that explain how humans and LLMs should collaborate in decision-making contexts. Second, there is an absence of sufficient empirical information from actual production settings, thus constraining our understanding of how the system functions in practice. Third, there is a lack of studies examining the factors that influence human–LLM collaboration, including aspects such as trust, usability, and decision authority.

The results also indicate that the success of the integration of LLMs into decision support systems depends on the alignment between technological capabilities, decision-making requirements, and organisational processes. Without such alignment, the potential benefits of LLMs may not be fully realised.

Like any research, there are certain limitations to the current study. The review is based on academic articles published in English and indexed in the Scopus and Web of Science databases. As a result, relevant studies from other databases or non-English sources may not have been included, which may limit the completeness of the analysis and the generalisability of the findings.

Future research should therefore focus on developing structured frameworks for human–LLM collaboration, establishing clear criteria for evaluating decision quality, and conducting empirical studies in real industrial settings. These directions are essential for advancing the practical use of LLMs and ensuring their effective contribution to decision-making in manufacturing.

9 Ethic Declaration

The study is solely based on existing literature without engaging human participants or experimenting. Therefore, ethical approval is not necessary for the study.

10 AI Declaration

The tool Rayyan was used to assist in identifying and removing duplicate records during the study selection process. Additionally, Google Gemini was used to generate a PRISMA 2020 flow diagram illustrating the study selection process.

Co-Creation of Knowledge in Marketing: Human-AI Collaboration in the Construction of Proto-Personas

Eduardo Trauer
State University of Santa Catarina – ESAG/Udesc, Florianópolis, Brazil

Abstract

This study investigates, through the lens of the Knowledge Management 5.0 (KM 5.0) paradigm, the role of Generative Artificial Intelligence (GAI) as a partner in the co-creation of knowledge for the development of proto-personas within the context of data-driven marketing. The research addresses the challenge of understanding consumer behaviour in niche markets – in this study, the bonsai market – which are characterised by a scarcity of structured data and a predominance of tacit context.

An applied qualitative approach was adopted, with an exploratory-descriptive design. The study was conducted with 71 undergraduate students (67 valid responses; response rate of 94.4%) enrolled in Marketing courses at ESAG/Udesc. Participants interacted with a Generative Artificial Intelligence Agent (GAIA) named John Jobs Naka (J. J. Naka), configured using a specialised corpus derived from in-depth qualitative interviews with recognised sector experts, together with technical publications and secondary data. The methodological framework was structured on the SECI model (Socialisation, Externalisation, Combination and Internalisation) to enable the analysis of knowledge conversion processes in human-AI interaction.

The findings demonstrate that GAIA can function as a cognitive mediator, facilitating the externalisation and integration of knowledge while supporting the development of proto-personas as strategic marketing artefacts. The quantitative results indicate high levels of acceptance and perceived utility – 98.5% of participants recognised the agent as an effective partner; the clarity score was 4.19/5; and recommendability 8.57/10. Qualitative analysis highlights three key aspects: cognitive mediation, empathy and humanisation (aligned with H2H marketing), and epistemological integration of tacit and explicit knowledge.

This cutting-edge study represents an advancement of KM 5.0 by demonstrating the capacity of GAIA to enhance learning processes, support agile knowledge development and enable the generation of sophisticated consumer insights in niche markets. The findings also have relevant implications for the fields of marketing and higher education, positioning GAIA as scalable tools for the co-creation of knowledge while preserving human centrality in decision-making processes.

Keywords: Generative Artificial Intelligence Agent; Knowledge Co-creation; Proto-personas; Data-driven marketing; KM 5.0.

Paper type: Academic Research Paper

1 Introduction

The development of proto-personas in the context of data-driven marketing has emerged as a relevant exploratory practice for understanding consumers and markets, particularly in niche contexts characterised by a high degree of specialisation, tacit knowledge, and a lack of structured data. The bonsai segment is a typical example of such a niche.

In educational and organisational settings, efficient consolidation of quantitative and qualitative information, frequently drawn from specialised and difficult-to-access sources, is essential. GAI, when informed by a refined knowledge base, may assume the role of a supporting agent for the co-creation of market knowledge. In this study, the findings from in-depth qualitative interviews with recognised bonsai experts constituted the knowledge base. The generation of proto-personas by undergraduate Business Administration students, using a GAIA, illustrates a dynamic of human AI collaboration. Thus, interpretation, synthesis and contextualisation are not entirely delegated to technology, but rather constructed jointly, combining human expertise, empirical data and generative capacity of the system.

The aim of this article is to analyse how collaboration between ESAG/Udesc students and GAIA – configures on the basis of specialised knowledge co-creation in marketing through the construction of proto-personas that represent the ideal customer profile in the target market. The research is guided by the following question: how can human-AI collaboration mediated by GAIA grounded in specialised knowledge support the agile generation of proto-personas within the context of data-driven marketing?

2 Literature Review

The use of buyer personas and proto-personas in marketing has been discussed as a practice aimed at understanding consumers and achieving strategic alignment of teams, products and markets. While buyer personas require consolidated databases, proto-personas emerge as preliminary representations constructed from the empirical knowledge of specialist – i.e., the externalisation of their tacit knowledge (Cooper, 2004; Nonaka and Toyama, 2021; Pinheiro et al., 2018; Trauer and Valdati, 2023; Trauer and Valdati, 2024; Trauer and Valdati, 2025). This approach proves particularly relevant in niche markets where structured data are scarce, and knowledge resides predominantly in the accumulated experience of actors in the sector. In these contexts , the construction of proto-personas assumes an exploratory and iterative character, enabling the externalisation of implicit knowledge and the initial formulation of patterns of consumer behaviour, motivations and needs, as reported in previous research on knowledge-creation and use in organisations (Davenport and Prusak, 1998).

Advances in the field of GAI and Large Language Models (LLMs) have broadened the debate on the role of these technologies as mediators in complex cognitive processes. Unlike traditional decision-support systems, GAIAs are capable of synthesising information from multiple sources, structuring narratives and supporting interpretive processes in direct interaction with human users. Indeed, AI agents and generative AI have been shown to be at the peak of the hype cycle, exhibiting strong momentum in the current market (den Hamer et al., 2025; Gartner, 2024; Mora-López et al., 2026). These systems may function as cognitive partners, particularly when supplied with specialised and contextualised knowledge bases (Trauer and Valdati, 2024; Trauer and Valdati, 2025). In the field of marketing, this human-AI collaboration has been associated with the expansion of analytical capacity, the acceleration of exploratory processes, and the strengthening of empathy in the understanding of specialist markets, reinforcing human-centred relational approaches as presented by H2H paradigm (Kotler et al., 2024).

In the context of education and data-driven marketing, agile methodologies have gained prominence as particularly well-suited to addressing problems, characterised by uncertainty, complexity, and constraints of time and resources. The literature suggests that short cycles of experimentation, incremental learning and continuous validation are especially effective in the construction of exploratory artefacts such as proto-personas (Cooper, 2004; Trauer and Valdati, 2024). The integration of agile methodologies with GAIA enhances this process by enabling the rapid incorporation of specialised knowledge, the interative reformulation of hypotheses, and the reduction of costs associated with traditional qualitative data collection. Asa such, collaboration between humans and GAIA, underpinned by knowledge bases derived from human experts, constitutes a promising approach to the co-creation of market knowledge in niche markets, thereby contributing to consistent, efficient and contextualised decision-making.

The transition from conventional GAI to agent-based architecture represents a fundamental evolution, moving from systems that merely respond to commands towards proactive computational entities. The following section develops this theoretical framework with a focus on the integration of RAG-type (Retrieval-Augmented Generation) agents.

2.1 The nature of generative AI agents

GAI differs from traditional algorithms in that operates in a probabilistic and non-deterministic manner. Whereas an algorithm follows rigid coding steps to transform an input into an output, GAI employs neural networks trained on vast datasets to identify patterns and generate new content(Dar and Gul, 2025).

When this generative capacity is encapsulated in the form of an AI agent, the system acquires autonomy. Historically, AI research has focused on the development of rational agents that act to achieve the best expected outcome in the face of uncertainty (Russell et al., 2021). Currently, an AI agent is defined as an autonomous or semi-autonomous software entity that employs AI techniques to perceive its environment, make decisions, execute actions and attain goals.

These authors differentiate the terminology along a spectrum of autonomy as follows:

- AI assistants: modules that assist with tasks under the direct request and guidance of a human user;
- AI agents: entities that operate independently, extending beyond simple responses to prompts by assuming control of planning and execution to achieve objectives; and
- Agentic AI: a broader approach to building solutions based on one or more collaborative AI agents.

2.1.1 Core architecture and agentic capabilities

Unlike a standalone LLM, and agent combines the LLM with peripheral components in order to act (Taurion, 2026). The anatomy of an AI agent is structured around six core capabilities: perception, decision-making, actioning, agency, adaptability and knowledge (den Hamer et al., 2025).

LLMs function as the central cognitive engine for interpretation and decision-making, and their architecture comprises:

- Memory: essential for maintaining the context of ongoing tasks and retaining the history of interactions (Taurion, 2026);
- Orchestration layer (planning): controls the execution flow, frequently operating in continuous loops (primary execution loops, secondary adaptation loops, and tertiary control/planning loops) (den Hamer et al., 2025); and
- Tools and connectors: interfaces that enable the agent to interact with the real world, query APIs, analyse documents and retrieve information from external databases (Taurion, 2026).

2.1.2 RAG-Based agents (Retrieval-Augmented Generation)

Among the greatest challenges for the adoption of LLMs in corporate and business environments are the phenomenon of hallucination (the fabrication of data) (Kalai et al., 2025; OpenAi, 2025; Swain, 2025; Xing, 2025), and the lack of transparency (the so-called *black box* problem) in the decision-making process of models. To mitigate these risks and ensure that the agent's knowledge is factual, up to date and domain-specific risks and ensure that the agent's knowledge is factual, up to date and domain-specific, RAG-type agent architecture may be employed (Acatrinei, 2025; Wang et al., 2026).

RAG architecture functions by anchoring the agent's responses in domain-specific knowledge bases, rather than relying solely on the model's parametric (trained) knowledge, thereby mitigating hallucinations and improving reliability in decision-making workflows (Wang et al., 2026). According to Wang et al. (2026), the structure of a knowledge management focused agent employing RAG functions as presented in Figure 1:

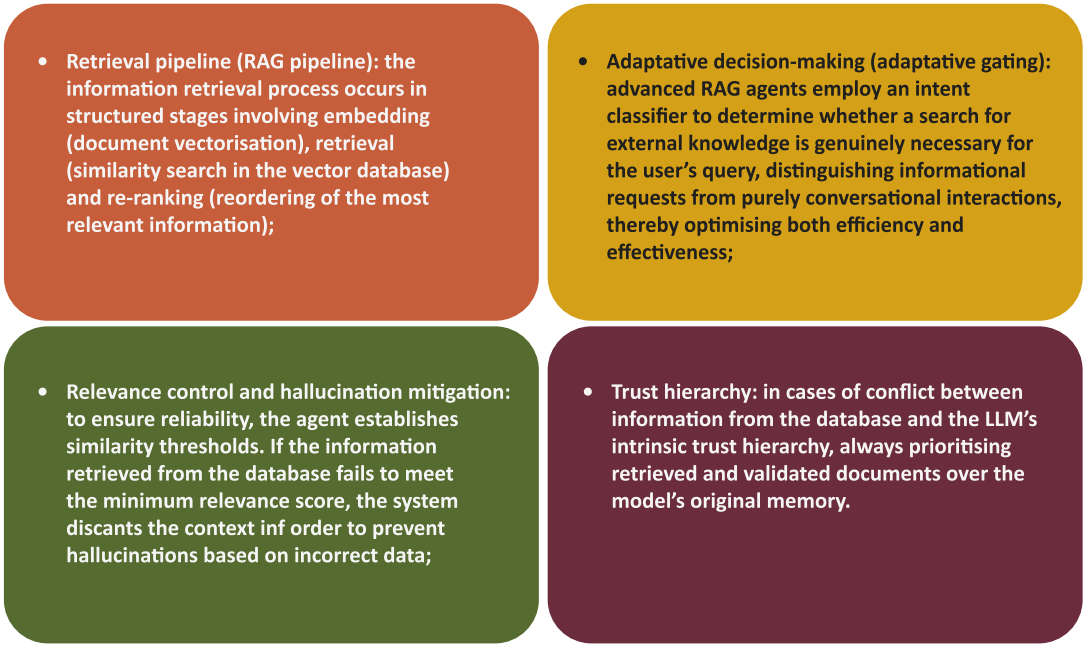

Figure 1- RAG-Based agents (Retrieval-Augmented Generation) (Wang et al., 2026)

In the context of marketing and proto-persona ideation, the RAG agent does not operate by generating creative text from nothing but instead retrieves factual data on consumer behaviour, guidelines provided, and reports from the database supplied to it, and subsequently employs the LLM to analyse and synthesise this information. This ensures that human-AI co-creation is simultaneously innovative and grounded in the empirical reality of the market, drawing on the interviews conducted and provided to GAIA (Acatrinei, 2025; Wang et al., 2026).

2.2 Human-AI collaboration in the construction of proto-personas

Proto-personas are semi-fictional representations of ideal customers, conceived on the basis of tacit knowledge and the insights shared by specialists (Trauer and Valdati, 2023; Trauer and Valdati, 2024; Trauer and Valdati, 2025). They offer an agile ana low-cost approach to strategic alignment, hypothesis formulation, and

consumer-centred decision-making, enabling rapid actions while more robust market data are collected and validated.

The incorporation of GAIA into this process acts as a cognitive catalyst. Rather than functioning as a passive tool, the AI operates as a cognitive mediator and empathic interlocutor, facilitating the externalisation of practitioners' knowledge and its internalisation by undergraduate students. The successful construction of these proto-personas occurs through the advantageous integration of the stages of the knowledge creation model proposed by (Nonaka and Takeuchi, 1995; Nonaka and Toyama, 2021): Externalisation – produced during the researcher's interviews with sector specialists; Internalisation – during the students interviews process with J. J. Naka; Socialisation once again – arising from reports produced by students. Socialisation also occurs when students present their findings orally in seminars.

This collaborative dynamic reflects the principles of H2H marketing (Kotler et al., 2024), ensuring that, despite algorithmic mediation, the process retains authenticity and remains centred on the real and psychological needs of individuals. The interative interaction with AI provides a safe environment, available around the clock, for testing, simulating real market conditions, and deepening target audience segmentation.

2.3 Challenges, ethics and corporate governance

Agent-mediated co-creation shows considerable promise. However, it presents significant practical and ethical challenges. The increasing autonomy of AI calls for careful attention to reliability and security (Taurion, 2026). Language models may make interpretive errors of fabricate plausible yet incorrect facts, giving rise to a phenomenon known as hallucination (Dar and Gul, 2025; Kalai et al., 2025; OpenAi, 2025; Swain, 2025; Taurion, 2026; Xing, 2025). Furthermore, because of their inherent complexity, deep learning algorithms frequently operate as a black box and therefore undermine transparency in decision-making (Dar and Gul, 2025).

Excessive delegation of critical thinking and creativity to AI may lead to dependence on technology, compromising the problem-solving abilities of the humans involved. The security of corporate data is equally critical, as agents that interact with and retrieve information from real databases and APIs are vulnerable to attacks such as *prompt injection*, which may force them to leak sensitive data or make unintended decisions (Dar and Gul, 2025; Taurion, 2026).

Implementing these corporate architectures requires more than mere technological adoption – it requires rigorous governance. It is essential to establish clear boundaries for AI operation, to maintain human supervision and validation at critical stages, to ensure continuous monitoring and to enforce stringent data protection policies. With appropriate regulation and oversight, GAIAs may serve as secure and scalable partners in the generation of insights and market intelligence.

3 Methodology

This study adopts an applied qualitative approach with an exploratory-descriptive design, grounded in the KM 5.0 paradigm. This emphasises the integration of advanced technologies with human-centred knowledge processes (Keidanren, 2018; Nonaka and Takeuchi, 1995; Nonaka and Toyama, 2021). The research was conducted within the Digital Marketing Environments and Data-Driven Marketing modules at ESAG/Udesc during the 2025-2 semester, incorporating a GAIA developed via ChatGPT. The agent named J. J. Naka, was designed to function as a cognitive mediator in knowledge co-creation processes, supporting the development of proto-personas in an educational context.

The target population that has participated in the final evaluation survey comprised 71 students enrolled in the 2025-2 semester, of whom 67 participated effectively, yielding a response rate of 94.4%. Participants included both Brazilian students and European exchange students, representing a heterogenous learning environment. Students conducted individual interviews with GAIA in either Portuguese and English and recorded the responses for subsequent systematisation. Employing a methodological framework previously introduced in the classroom, students organised themselves into groups to develop proto-personas representative of consumer segments within the Brazilian bonsai market. These proto-personas were constructed through the integration of tacit knowledge from real market specialists – externalised to form J. J. Naka knowledge base – together with secondary data, following the conceptualisation proposed by (Trauer and Valdati, 2024). Variables such as demographic profile, motivations, objectives, challenges and information sources were considered.

The methodological approach was based on the SECI model of knowledge creation – Socialisation, Externalisation, Combination and Internalisation – originally proposed by (Nonaka and Takeuchi, 1995).

Data collection was carried out by means of a structured questionnaire comprising both closed-ended items (Likert scale) and open-ended questions. This enabled the assessment of variables such as the clarity of the agent's responses, its contribution to understanding consumer behaviour, the perception of the agent as a

cognitive partner, and the intention of use AI in the future. The findings indicate that integration of generative AI with active pedagogical strategies enhances the development of proto-personas as both a learning tool and strategic marketing resource in niche markets. Furthermore, the results reinforce the relevance of KM 5.0 principles and H2H marketing (Kotler et al., 2024), emphasising the rote of AI as a facilitator in the co-creation of knowledge without compromising human centrality in the learning process.

4 Results

The response adhesion rate in this survey was 94.4%, derived from 67 valid responses. This figure approaches census-level coverage. Amongst the principal findings, the following merit particular attention:

- Quantitative efficacy and technological acceptance: data measured by Likert scale attest to a high level of acceptance and perceived pedagogical utility of the technology. Notably, 98.5% of participants recognised J. J. Naka as an effective mediator, perceiving the system not as a mere search engine but as an active partner in knowledge construction and a facilitator for the generation of detailed consumer insights. In addition, the agent's communicative capacity received a score of 4.19 out of 5 on the response clarity criterion. Satisfaction levels culminated in a strong behavioural intention, with the agent achieving a recommendability score of 8.57 out of 10.
- Qualitative foundations of successful co-creation: analysis of the open-ended questions and students' perceptions revealed that the efficacy of proto-persona construction rested upon three analytical pillars:
    - Cognitive mediation: J. J. Naka as a cognitive catalyst, facilitating the process of knowledge externalisation by students. This mediation promoted higher level strategic reflection on consumer behaviour within the Brazilian bonsai niche market, and resulted in more sophisticated and segmented market analyses;
    - Empathy and humanisation (H2H marketing): corroborating the theoretical framework of human-centred relational marketing, participants attributed markedly anthropomorphic characteristics to the system. The agent was described as practical and direct, instructive and attentive as well as empathic and trustworthy. This personification of technology proved fundamental in establishing trust and enabling authentic dialogue, both essential to the co-creation dynamic;
    - Epistemological integration: the collaboration enabled the advantageous integration of a technical and informational knowledge (supplied and structured by the AI) with tacit knowledge (inferred and produced by the student). This ensured the generation of proto-personas that were both market coherent and contextually aligned.
- Educational impact and practical skills development: in the context of the teaching and learning process, AI mediation strengthened active methodologies by creating a safe readily available environment for experimentation. Students were able to iterate, test hypotheses and refine their interpretations of proto-personas through continuous feedback cycles. Consequently, the development of practical skills for transforming abstract theories into actionable insights was observed simulation real market conditions and enhancing data-driven analytical capabilities. The motivational impact was also considerable, with multiple students reporting their intention to incorporate such agents as strategic allies both in their professional lives and in future projects.

These experiment findings reinforce the premise that GAIAs can function effectively as empathic interlocutors and co-creators of value, enabling pedagogical innovation and knowledge management practices in specialised niche markets.

4.1 Contributions to academia

In the academic and educational context, the construction of proto-personas supported by GAIA represents a significant technological and pedagogical innovation. This integration contributes to learning in several noteworthy ways:

- Fostering active methodologies and safe experimentation: GAIA-mediated interaction provides a safe environment for experimentation where students may test hypotheses about consumer profiles and iteratively refine their interpretations on a continuous basis;
- Development of practical skills and critical thinking: the use of these technologies helps students to transform abstract theory into actionable insights. By simulating real market conditions in the creation of proto-personas, students develop data-driven analytical capabilities and sharpen their critical thinking skills;

- Experiential and applied learning: for higher educational institutions, the systematic adoption of AI agents as pedagogical mediators in field work activities, interdisciplinary projects or market simulations directly promotes high-impact experiential applied learning;
- Cognitive partnership in knowledge co-creation: AI agents function as cognitive partners and empathic interlocutors, actively assisting in the construction and structuring of the knowledge required to design proto-personas;
- Increased motivation and professional development: the use of AI in the classroom tends to significantly increase student engagement and motivation in future projects. The practice actively prepares future professionals, particularly in marketing, by cultivating a culture of co-creation and innovation while maintaining human centrality and autonomy in the learning process.

4.2 Contributions to the market

Beyond the educational environment, proto-personas are employed as provisional, semi-fictional representations of ideal customers. They are constructed from the tacit knowledge and shared insights of specialist teams. Originally conceived in the software industry as a low-cost, rapid-implementation alternative (Pinheiro et al., 2018), they are being adapted to the marketing environment as a means of generating tactical and strategic marketing actions (Trauer and Valdati, 2023).

Their practical application in the corporate and business world is most prominent in the following areas:

- Strategic alignment and decision-making: proto-personas provide an agile approach to aligning teams, jointly formulating hypotheses about customers and guiding strategic decisions. They offer an immediate, consumer-centred perspective whilst more robust and detailed market data are collected for future validation;
- Competitive advantage in marketing: for marketing professionals, the construction of proto-personas, particularly when optimised through GAIA, serves as tactical tool for cost reduction and increased strategic response speed. They are especially useful in the initial exploration of as yet unstructured market segments and consumption niches that demand a high degree of customisation, and
- Multidisciplinary adoption: the logic of proto-personas of the detailed understanding of users' needs may be extended beyond technology and marketing, to sectors such as design, business administration, humane-centred smart cities, and healthcare.

Figure 2 presents an adaptation of the SECI model of knowledge creation proposed by Nonaka and Takeuchi (1995) and Nonaka and Toyama (2021), applied to the context of proto-persona development supported by GAIA – here referred to as J. J. Naka. The model retains the classical structure of the four knowledge conversion modes – Socialisation, Externalisation, Combination and Internalisation. It incorporates empirical elements from this research process, highlighting technological mediation as an integral component of the knowledge creation dynamic. At the centre of Figure 2, agent Naka functions as an articulating element, connecting the different phases of the process and enhancing the transformation and circulation of knowledge amongst participants.

In the Socialisation quadrant, the origin of tacit knowledge is identified through in-depth interviews with bonsai market specialists, as well as the continuation of this process in student interactions and group discussions. The inclusion of seminar presentations within this quadrant reinforces the notion that the exchange of experiences, perceptions and interpretations between students and the lecturer constitutes a moment of shared tacit knowledge generation.

In the Externalisation quadrant, this knowledge becomes explicit through the recording and transcription of interviews, and the incorporation of secondary sources such as books and technical reports that feed into the GAIA's knowledge base. This process illustrates the structured transformation of tacit knowledge into communicable and reusable artefacts.

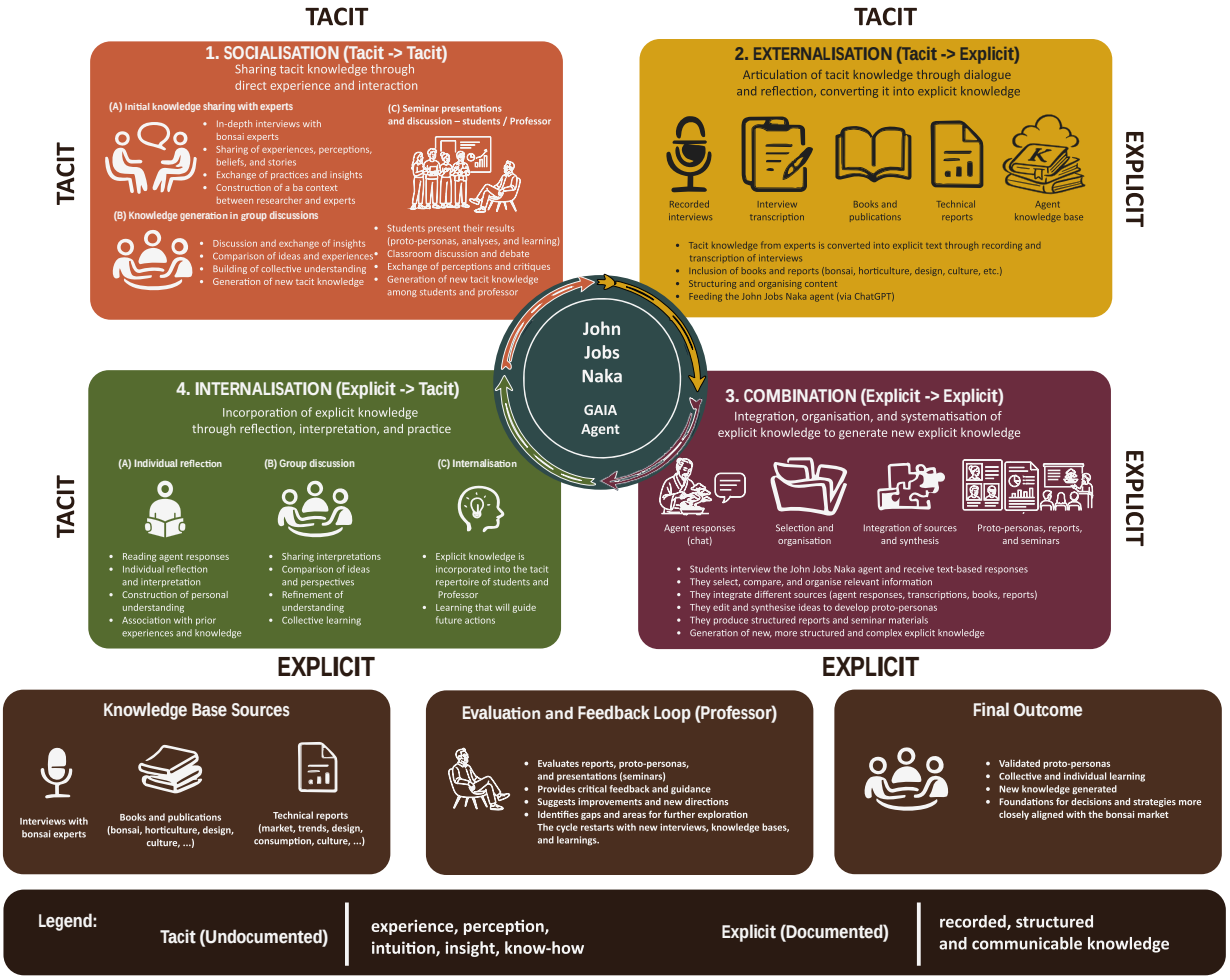

Figure 2 - Knowledge Creation Model - Proto-Personas with GAIA adapted by Nonaka and Toyama (2021)

In the lower quadrants, Figure 2 makes explicit an analytical distinction between Combination and Internalisation. Combination is represented by the activities of organising, selecting, integrating and synthesising explicit content. These are carried out by students on the basis of the agent's responses and other sources, and generate proto-personas, reports and presentation materials. Internalisation occurs when students individually read, reflect upon and interpret this information, incorporating it into their tacit repertoire - a process that extends to group discussions and the learning arising from participating in seminars. Finally, the assessment conducted by the lecturer serves as a feedback mechanism for the system, which contributes to the continuous refinement of knowledge and reinforces the spiral nature of the model, consistent with the dynamic perspective of organisational knowledge creation.

4 Limitations

The configuration of the John Jobs Naka agent via ChatGPT presented specific structural characteristics and limitations during its application.

- Closed knowledge base: the agent was configured with a restricted corpus (knowledge base), which may limit the exploration of content extending beyond the specific scope of bonsai;
- Absence of cross-session memory: the system employed does not retain memory of interactions across different sessions, which restricts the capacity for medium- and long-term longitudinal knowledge construction;
- Lack of external validation: the project did not include external validation by bonsai segment specialists to confirm the accuracy and level of expertise of the domain information; and
- Refinement limitations: time constraints during the academic semester means there were limited opportunities to refine configuration prompts, test new iterations or incorporate student feedback with a view to improving the agent's responses.

5 Conclusion

This study demonstrates that human-AI collaboration mediated by GAIA and underpinned by specialist expertise may function as an efficient and effective mechanism of co-creation within a data-driven marketing context. It may enable the agile generation of proto-personas in niche markets characterised by a scarcity of structured and secondary data. From the perspective of the SECI model, the findings indicate that the GAI agent may operate as a cognitive mediator, enhancing the processes of externalisation, combination, and internalisation of knowledge, without displacing the centrality of human interpretation.

Empirically, the interaction between students and the agent J. J. Naka facilitated the development of coherent and contextually-grounded artefacts without the need for physical travel or scheduling consultations with human experts. The process enabled the integration of specialised tacit knowledge and explicit information through continuous cycles of refinement. This dynamic supports the notion that GAI agents, when anchored in refined knowledge bases, can expand analytical capacity and reduce divergences in the exploration of niche markets.

As a contribution, the study integrates KM 5.0 with agent-based generative AI architectures, highlighting their applicability in the construction of marketing knowledge - particularly proto-personas - and in supporting active learning methodologies. From a methodological standpoint, it demonstrates the feasibility of employing a GAIA as a structuring instrument for the generation of exploratory artefacts. In practical terms, the findings point to the potential for accelerating analytical and decision-making processes in contexts characterised by high complexity and limited data availability.

The limitations identified indicate the need for external validation, expansion of the knowledge corpus, and application across different contexts, thereby opening avenues for future research into the robustness and scalability of human-AI co-creation.

6 Ethic declaration

The author declares that the research described in this study involved human participants in an educational context, characterising it as a low-risk activity. Student participation was voluntary, and the data collected were treated anonymously and confidentially, with no identification of participants at any stage.

In accordance with institutional guidelines and the nature of the study, submission to a Research Ethics Committee was not required. The study upheld the ethical principles applicable to research involving human participants, including confidentiality, voluntariness and the responsible use of data.

7 AI declaration

The author declares that GAI tools were employed in a limited and controlled manner during the development of this study. Specifically, AI was used to support the initial development of Figure 1, inspired by the SECI model proposed by Nonaka and Takeuchi (1995) and Nonaka and Toyama (2021).

The AI tool was employed in the visual structuring and preliminary layout of this figure, including suggestions regarding spatial organisation, graphic elements and visual hierarchy. The material generated was used exclusively as a draft for conceptual visualisation. Figure 1 was subsequently refined by the author using Adobe Illustrator software.

All subsequent stages - including the refinement of the model, theoretical alignment, adaptation to the empirical context, and the final version of Figure 1 - were developed, critically evaluated and validated in their entirety by the author, thereby reflecting the author's intellectual contribution and theoretical interpretation.

Beyond Prediction: Building Sustainable Human-AI Knowledge Ecosystems in Healthcare Organizations

Sara El Matouk, Daniele Allega
Universitas Mercatorum, Rome, Italy

Abstract

Healthcare organizations increasingly rely on unstructured narrative material - such as clinical notes, referral letters, discharge summaries, and other health-related texts - to understand patient trajectories, treatment responses, and emerging vulnerabilities. Yet the sustainable use of these resources cannot be reduced to predictive performance. This paper argues that the long-term viability of AI in healthcare depends on the socio-technical and governance conditions under which narrative data, model outputs, and human oversight are organized. It addresses the following question: what socio-technical and governance conditions are required for the sustainable development of human-in-the-loop AI systems based on health-related narrative data?

The argument is developed through PRAXIS, an early-stage doctoral research protocol that should be understood here as an illustrative governance case rather than as a validated clinical deployment. PRAXIS is designed to support signal extraction and interpretive structuring from Italian health-related narratives while keeping annotation and classification decisions under expert human supervision. In its current phase, the protocol relies on a corpus of participant-generated narratives from university students aged 19-24 and does not report final empirical results or clinician-facing deployment. This bounded setting is methodologically useful because it allows annotation procedures, interpretive standards, and governance mechanisms to be developed before extension to more sensitive populations and institutional settings.

The paper proposes a governance-first framework organized around three interdependent layers: an AI layer responsible for signal extraction and candidate annotation generation; a human layer responsible for review, disagreement management, calibrated reliance, and interpretive accountability; and an organizational knowledge governance layer responsible for provenance, access, lifecycle management, and controlled transfer across populations. Within this framework, label fitting - the embedding of population-specific assumptions in annotation schemes - is introduced as a distinct governance risk that differs from technical distribution shift and therefore requires lifecycle governance and cross-population review.

The contribution of the paper is threefold. First, it reframes sustainable healthcare AI as a knowledge-ecosystem problem rather than a narrow prediction problem. Second, it specifies governance requirements that make human-in-the-loop oversight meaningful rather than symbolic. Third, it offers a tractable blueprint for future institutional deployment in which governance precedes deployment, AI augments rather than displaces expert judgment, and sustainability is evaluated through interpretability, calibrated trust, workload, reproducibility, and organizational robustness as well as accuracy.

Paper type: Academic Research Paper

1 Introduction

Narrative data occupy a structurally difficult but increasingly important position in healthcare organizations. Clinical notes, referral letters, discharge summaries, intake descriptions, and patient-written accounts contain knowledge that rarely fits neatly into structured fields. They capture sequencing, ambiguity, experiential nuance, and the language through which conditions are interpreted in practice. For this reason, they are often indispensable to professional judgment. At the same time, these same properties make narrative data hard to search, annotate, compare, and govern at scale.

This tension helps explain the appeal of AI and natural language processing in healthcare. If large volumes of free text can be transformed into usable signals, healthcare organizations may be better able to identify emerging risks, monitor trajectories, and support decision-making. Yet the dominant evaluative lens remains heavily accuracy-centered. Systems are commonly assessed in terms of benchmark performance, while the conditions that make them trustworthy in use remain under-specified. A model can be statistically impressive and still be opaque, context-bound, difficult to contest, or institutionally ungovernable (Topol, 2019; Obermeyer and Emanuel, 2016; Shortliffe and Sepulveda, 2018).

This paper addresses the following research question: what socio-technical and governance conditions are required for the sustainable development of human-in-the-loop AI systems based on health-related narrative data? It does so through PRAXIS, an early-stage doctoral research protocol designed from inception as human-in-the-loop. PRAXIS is presented here as an illustrative analytical case for deriving governance requirements, not

as a completed empirical study. Data collection is ongoing, no final results are reported, and the current phase does not constitute clinician-facing deployment.

The paper makes three contributions. First, it reframes sustainable healthcare AI as a knowledge-ecosystem problem rather than a narrow prediction problem. Second, it identifies design requirements that make human oversight meaningful rather than symbolic. Third, it introduces label fitting as a governance risk that arises when annotation schemes built on one population are transferred to others without explicit scope review. The argument proceeds by situating PRAXIS in the literature on healthcare AI, socio-technical systems, and knowledge management, then developing a governance-first framework organized around AI, human, and organizational knowledge-governance layers.

2 Background: From Accuracy to Sustainable Knowledge Ecosystems

2.1 AI in healthcare beyond accuracy

Early discussion of AI in healthcare often emphasized the possibility that machine-learning systems could match or exceed human performance on bounded tasks. That prospect remains important, but real-world implementation has exposed a persistent gap between benchmark results and practical reliability. Clinical impact depends not only on whether a system can classify, rank, or predict within a curated dataset, but also on whether its outputs are interpretable, whether the underlying data are fit for purpose, and whether the surrounding organization can absorb and govern the tool over time (Kelly et al., 2019; Cresswell et al., 2020).

This broader understanding has become central to trustworthy AI frameworks. Robustness, fairness, accountability, and interpretability matter because healthcare decisions are embedded in institutional settings where errors are costly and responsibilities cannot be externalized to the model (European Commission, 2019). The distinction between technical validity and practical usefulness is therefore crucial. A system may perform well under training conditions and still fail when users cannot understand what it is flagging, when the training population is too narrow, or when institutional routines do not support effective review (Obermeyer and Emanuel, 2016; Shortliffe and Sepulveda, 2018).

Natural language processing intensifies these concerns. When AI systems operate on narrative material rather than on structured variables, the link between outputs and source meaning is less transparent. Statistical regularities can easily be mistaken for validated clinical signals. In high-stakes contexts, this produces a recurring risk of overclaiming: the treatment of machine-generated associations as settled findings rather than as candidate signals requiring expert appraisal. Sustainable deployment therefore requires evaluative criteria that extend beyond accuracy to include interpretability, scope control, auditability, and equity across different populations.

2.2 Human-AI interaction as a socio-technical problem

Healthcare AI does not operate in a vacuum. It is embedded in socio-technical systems composed of professionals, routines, interfaces, institutional cultures, and accountability structures. Socio-technical research has long shown that technical outcomes depend on the arrangement of social practices around the tool and that social and technical elements are mutually constitutive (Carayon, 2006; Baxter and Sommerville, 2011). For narrative AI, this means that the usefulness of a model depends on who reviews outputs, what they are expected to do with them, and how disagreement or override is handled.

A well-documented danger in human-AI interaction is automation bias: the tendency to defer to automated outputs even when independent judgment would justify correction (Parasuraman and Manzey, 2010). In healthcare settings, this can erode the very quality of oversight that human-in-the-loop design is meant to protect. Equally problematic is the opposite condition, where system outputs are so poorly explained or so poorly integrated into work routines that they are ignored, distrusted, or treated as noise. In both cases, the challenge is organizational as much as technical.

For this reason, human-in-the-loop cannot be treated as a governance solution in itself. A human positioned at a decision point contributes meaningful oversight only when the work of interpretation has been explicitly designed. This requires clear review standards, documented reasons for accepting or rejecting suggestions, and protocols for handling uncertainty and disagreement (Amershi et al., 2019). In future clinician-facing applications, it also requires attention to workload, training, and role redesign so that AI augments rather than distorts professional judgment.

2.3 Knowledge governance, semantic entropy, and label fitting

A complementary perspective comes from knowledge management. From this viewpoint, corpora, annotation schemes, candidate labels, model outputs, and procedural documents are not merely technical artifacts. They are organizational knowledge assets whose value depends on the conditions under which they are created, validated, revised, and transferred (Davenport and Prusak, 1998; Nonaka and Takeuchi, 1995). If such assets are moved across settings without documented provenance or explicit scope control, the organization is not simply scaling knowledge. It is also scaling the hidden assumptions sedimented in those assets.

Recent work on the knowledge commoditization paradox sharpens this problem by arguing that the transformation of context-rich professional knowledge into AI-accessible representations can generate semantic entropy: a progressive loss of contextual information through computational abstraction. The issue is not that abstraction is always undesirable, but that it can strip away precisely the relational and situational cues that experts need in order to judge meaning appropriately. In this sense, AI-mediated representation is never a neutral translation process (Allega, Puzio and Rizzo, 2026b).

Companion work in other high-stakes domains suggests that trustworthy AI architectures should preserve provenance, explicit scope boundaries, and structured forms of contestability instead of collapsing all judgment into opaque outputs. Layered governance, auditable reasoning, and explicit management of disagreement have been proposed as ways to make hybrid systems more accountable over time (Allega, Puzio and Rizzo, 2026a; Allega, Puzio and Rizzo, 2026c; Allega, Puzio and Rizzo, 2026d). The present paper does not transfer legal AI content into healthcare. Rather, it adapts a governance logic from adjacent high-stakes domains to the analysis of health-related narratives.

Within this context, the paper introduces label fitting as a governance problem. Label fitting occurs when annotation schemes developed on a specific and narrow population encode interpretive assumptions that are locally reasonable but misleading when transferred elsewhere. It differs from technical distribution shift because the instability lies at the annotation and interpretation layer rather than only in feature distributions. Addressing label fitting therefore requires lifecycle governance, cross-population review, and explicit documentation of where an annotation scheme is valid and where it is not.

3 The PRAXIS Protocol as an Early-Stage Illustrative Case

PRAXIS is an early-stage doctoral research project aimed at developing governance-robust procedures for extracting structured signals from health-related narrative data produced in Italian. Its long-term horizon is translational: to support the systematic organizational use of narrative material in institutional and, potentially, clinical settings. In the present paper, however, PRAXIS functions as an early-stage case through which governance requirements can be made explicit before any strong claims about performance or clinical use are advanced.

The current phase involves a corpus of participant-generated Italian narratives collected from university students aged 19-24 through a standardized protocol. Participants produce free-text written responses designed to elicit personally relevant health-related accounts. This bounded setting is methodologically useful because it is ethically accessible and allows annotation procedures to be refined before extension to more sensitive populations. Data collection is ongoing and no final empirical results are available at this stage.

From inception, PRAXIS is human-in-the-loop. NLP and text-analysis components support signal extraction, linguistic structuring, and candidate annotation generation, but all interpretive judgments and final classification choices remain under expert human supervision. The annotation scheme is treated not as a finished technical product but as an evolving knowledge asset subject to revision, discrepancy review, and explicit documentation. The protocol is designed to extend to additional sub-populations, including clinical populations, in later phases. Clinician-facing deployment therefore remains a long-term translational objective rather than an empirical feature of the current phase.

4 A Governance-First Framework for Human-in-the-Loop AI

The framework proposed here organizes sustainable human-in-the-loop AI development around three interdependent layers: the AI layer, the human layer, and the organizational knowledge-governance layer. Each layer has a primary function, a characteristic set of risks, and a set of governance requirements. The key assumption is that sustainability cannot be achieved by strengthening only one layer. Risk in any layer propagates to the others, while governance at each layer presupposes adequate governance in the adjacent ones.

4.1 The AI layer

Within PRAXIS, the AI layer is responsible for signal extraction, linguistic structuring, and candidate annotation generation. It processes volumes of narrative material that would be analytically difficult to handle through unaided manual review alone and presents provisional outputs that expert reviewers can evaluate, modify, or reject. The value of this layer lies in amplification and ordering, not in autonomous decision-making. In the current phase, its role is therefore explicitly supportive and bounded.

The principal governance risks at this layer are overclaiming, opacity, overfitting, and boundary violation. Overclaiming occurs when machine-generated patterns are treated as established findings rather than as candidate signals. Opacity makes it difficult for reviewers to understand why a suggestion has been produced. Overfitting arises when models or procedures reflect a narrow construction context too closely. Boundary violation occurs when outputs are applied outside the population, domain, or task conditions for which they were developed. These are not marginal defects; they determine whether later human review can be meaningful at all.

Effective governance of the AI layer therefore requires interpretability standards, error-analysis routines, versioned change control, and explicit scope documentation. In more mature institutional settings, such standards may be operationalized through evidence spans, uncertainty cues, model cards, or privacy-preserving data architectures. Yet the governance point is prior to any specific method: AI outputs must remain inspectable, documented, and contestable, and any change to model components or annotation suggestions must be traceable over time (Mitchell et al., 2019; European Commission, 2019).

4.2 The human layer

In the current PRAXIS phase, the human layer is occupied by expert reviewers rather than clinicians. In later translational phases, the same governance logic would extend to clinician-facing use. The substantive point is that human involvement is not a symbolic checkpoint. It is a knowledge practice through which candidate signals are interpreted, contextual meaning is restored, ambiguous cases are adjudicated, and the limits of the category system are made visible. Final responsibility therefore remains human even when AI contributes to the organization of the evidence.

This layer is vulnerable to automation bias, interpretive inconsistency, reasoning-traceability loss, and excessive reliance on already stabilized categories. Reviewers may defer too quickly to machine suggestions, disagree without documented rationale, or overlook cases that do not fit the current annotation vocabulary. In a healthcare context, these failures are serious because they affect not only immediate classification quality but also the long-term calibration of the system and the organization's confidence in it (Parasuraman and Manzey, 2010; Amershi et al., 2019).

Governance of the human layer requires explicit annotation guidelines, co-annotation and discrepancy-review practices, protocols for calibrated reliance, and documentation of interpretive rationale. Disagreement is especially important. Rather than being treated only as noise to be minimized, it should also be treated as information about the adequacy of the scheme and the uncertainty of the underlying case. This makes the human layer both a review mechanism and a learning mechanism for the broader knowledge ecosystem (Artstein and Poesio, 2008; Allega, Puzio and Rizzo, 2026d).

4.3 The organizational knowledge-governance layer

The organizational layer treats the corpus, annotation schemes, output histories, and procedural documents as maintained knowledge assets rather than as disposable project by-products. It is here that provenance, access, revision, and transferability are governed. This layer matters because even well-designed AI tools and well-trained reviewers can produce fragile systems if the surrounding organization does not record how assets were built, under what conditions they can be reused, and how they should be revised over time (Davenport and Prusak, 1998; Nonaka and Takeuchi, 1995).

The central risk foregrounded in this paper - label fitting - sits at this layer. When labels built on one population are reused in another without structured review, the organization can mistake local adequacy for general validity. The result is not simply lower performance. It is a loss of semantic integrity. In effect, the organization begins to treat historically contingent annotation choices as if they were stable knowledge. This risk is amplified when documentation is fragmented, when provenance is weak, or when asset reuse is driven by convenience rather than governed scope control (Allega, Puzio and Rizzo, 2026b).

Governance at the organizational layer therefore requires four minimum capabilities: provenance documentation for corpus elements and protocol versions; access governance defining who can use, modify, or

redistribute assets; lifecycle governance specifying how assets are reviewed, revised, and retired; and cross-population review procedures that test transferability before extension to new groups. In later institutional settings, these routines can also support organizational learning loops in which frontline review feeds back into training, threshold setting, and documentation updates. Table 1 summarizes the framework.

Table 1: Governance-first framework for sustainable human-AI narrative analysis

Layer	Key risks	Governance requirements
AI	Overclaiming Opacity Overfitting Boundary violation	Interpretability standards Error analysis Versioning Scope documentation
Human	Automation bias Interpretive inconsistency Reasoning-traceability loss Category lock-in	Annotation guidelines Co-annotation and discrepancy review Calibrated reliance protocols Documentation of interpretive rationale
Organizational knowledge governance	Fragmentation Weak reproducibility Label fitting Misapplication	Provenance documentation Access governance Lifecycle governance Cross-population review protocols

Taken together, the three layers show why sustainable healthcare AI cannot be reduced to a question of model quality. The AI layer must be interpretable and scoped; the human layer must be structured and traceable; and the organizational layer must preserve provenance and manage transferability. Sustainability is achieved only when these layers are aligned and jointly maintained.

5 Discussion

5.1 Sustainability as a property of the whole configuration

The main implication of the framework is that sustainable AI in healthcare is a property of the socio-technical configuration as a whole, not of the AI component in isolation. This has two consequences. First, evaluation must move beyond predictive metrics toward a broader assessment of interpretability, calibrated trust, workload, reproducibility, workflow compatibility, governance compliance, and equity. Second, the relevant organizational question is not simply whether a model is accurate, but whether the organization has built the human and governance capacities required to use its outputs responsibly (Baxter and Sommerville, 2011; European Commission, 2019).

This shift also reframes human capability. In a governance-first ecosystem, valuable human capabilities include not only domain expertise but also the ability to contest outputs, document rationale, calibrate reliance, manage disagreement, and steward evolving knowledge assets. These are organizational capabilities as much as individual ones. They require training, documented routines, and role clarity. In future clinician-facing settings, the clinician is not displaced by AI; rather, the clinician becomes more explicitly an accountable interpreter of machine-assisted signals embedded in governed workflows.

The framework likewise suggests that the most useful contribution of AI to healthcare organizations may be organizational rather than purely predictive. By making narrative material more tractable for review, AI can help convert diffuse textual material into maintained knowledge resources. But that conversion is sustainable only if semantic indicators remain linked to provenance, uncertainty, and revision histories. Otherwise, organizations risk institutionalizing decontextualized proxies that are easier to process but less meaningful in practice.

5.2 Practical implications and limitations

Practically, the framework encourages organizations to invest early in governance before attempting broad deployment. In the PRAXIS case, this means treating annotation design, discrepancy logging, and scope documentation as core development tasks rather than as administrative add-ons. The same logic can guide future institutional work: governance should begin at the moment data are collected and categories are created, not after a model has already been optimized. In this sense, the framework offers a blueprint for organizations that want AI to augment professional knowledge without eroding accountability.

The paper also clarifies why an early-stage non-clinical protocol can be analytically valuable. Working first with an ethically accessible student corpus does not solve the challenges of clinical deployment, but it does make

visible the conditions under which interpretive schemes are built, revised, and stabilized. This is precisely where hidden assumptions can become sedimented and later misapplied. The current phase therefore provides a controlled environment for identifying governance requirements before institutional use expands.

At the same time, the paper has clear limitations. The framework is conceptual and analytically derived rather than empirically validated. It has not yet been tested against completed performance results, multi-site deployment, or practitioner workflow studies. The student corpus is useful for protocol development but cannot substitute for work with clinical populations. Future research should therefore complete the current data-collection phase, examine how label fitting appears across additional sub-populations, and test the framework with institutional actors, clinician users, and longitudinal governance measures

6 Conclusions

This paper has argued that sustainable AI development in healthcare begins before deployment, in the governed construction of data, labels, review practices, and organizational conditions. Using PRAXIS as an early-stage illustrative case, it has proposed a governance-first framework organized around AI, human, and organizational knowledge-governance layers. The framework treats narrative AI not as a stand-alone predictive technology but as part of a broader human-AI knowledge ecosystem whose sustainability depends on provenance, interpretability, calibrated reliance, and controlled transfer across contexts.

The central governance problem emphasized here is label fitting: the embedding of population-specific interpretive assumptions in annotation schemes that are later transferred without adequate scope review. Framed this way, sustainable healthcare AI is not achieved by accuracy alone. It requires institutions that can preserve semantic integrity, document uncertainty, and keep human accountability active as systems evolve. PRAXIS remains early-stage, and the framework now awaits empirical testing. Its contribution is to specify, in operational terms, what governance-first AI development requires and why that requirement is foundational rather than optional.

7 Ethics Declaration

This paper discusses an ongoing research protocol (PRAXIS) involving participant-generated written narratives from consenting adults aged 19-24. The manuscript does not report completed clinical research results and does not involve personal health data from clinical populations in the current phase. The protocol is conducted in accordance with applicable ethical principles for research involving human participants, including informed consent, data anonymization, confidentiality, and relevant data-protection requirements. Any future extension to clinical populations or institutional deployment will require review and authorization under the relevant procedures before implementation.

8 AI Declaration

AI-assisted writing tools were used for outlining, language refinement, and editorial revision during the preparation of this manuscript. They were not used to generate empirical data, statistical findings, or unverified references. All arguments, factual claims, citationsand bibliographic details were reviewed and approved by the authors, who retain full responsibility for the content of the paper.

From Paradoxes and Entropies to Sustainable Knowledge Ecosystems: Architectural and Governance Principles

Daniele Allega[1], Gabriele Rizzo[2]
[1] Universitas Mercatorum, Rome, Italy
[2] LUISS Guido Carli University, Rome, Italy

Abstract

Artificial Intelligence is often presented as a shortcut to organizational sustainability, yet many AI initiatives underperform because firms attempt to automate before they have structured, governed, and shared their knowledge assets. This paper addresses that gap by asking how organizations can move from fragmented, tool-centred AI adoption to sustainable knowledge ecosystems. We build a design-oriented conceptual framework through analytical generalization from four design artifacts previously developed in the legal-AI domain: the knowledge commoditization paradox (Allega, Puzio and Rizzo, 2026b), the MERL-T multi-expert architecture (Allega, Puzio and Rizzo, 2026c), the RLCF governance model (Allega, Puzio and Rizzo, 2026d), and the ALIS platform framework (Allega, Puzio and Rizzo, 2026a). The legal domain is treated as a revelatory setting because it concentrates stringent requirements for traceability, pluralism, accountability, and knowledge integrity that are increasingly relevant across knowledge-intensive organizations. The paper makes two main contributions. First, it extends the earlier notion of semantic entropy by identifying three entropic pressures that undermine the Knowledge Journey: coordination entropy, generated by fragmented repositories and inconsistent taxonomies; semantic entropy, generated by the decontextualization of knowledge during computational representation; and governance entropy, generated by opaque AI-mediated workflows that dilute authority and responsibility. Second, it translates these pressures into five design principles for sustainable knowledge ecosystems: commons-first knowledge architecture, provenance-preserving services, epistemically differentiated human-AI collaboration, community-anchored governance, and sustainability-by-measurement. These principles are then mapped onto the three phases of Planning, Acquisition, and Impact to show how organizations can reduce hidden costs such as search time, duplication of effort, hallucinated outputs, accountability gaps, and knowledge lock-in. Rather than treating AI as a stand-alone capability, the paper argues that sustainable value emerges when architectural choices and governance mechanisms are designed together. The result is a practical and theoretically grounded model for organizations seeking to transform knowledge management from a hidden cost centre into a resilient, auditable, and sustainability-oriented ecosystem.

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence has become a strategic horizon for organizations seeking resilience, efficiency, and sustainability. Yet, in practice, many AI programs begin at the wrong point. They start from models, copilots, or chat interfaces, while the knowledge infrastructure on which those tools depend remains fragmented, weakly governed, and poorly documented. As a result, organizations often accelerate access to inconsistent content rather than improving the quality of organizational knowing. The hidden costs are familiar: time lost searching for information, duplicated work, obsolete versions of documents, repeated reinvention of solutions, and growing dependence on opaque external platforms.

This mismatch reveals a broader conceptual problem. In many organizational debates, technological capability is treated as if it were equivalent to strategic readiness. However, knowledge-intensive work depends not only on access to information, but also on the ability to preserve context, identify provenance, recognize expertise, and govern the interaction between human judgement and machine outputs. Classical knowledge management already emphasized that valuable knowledge is not exhausted by codified information (Polanyi, 1966; Nonaka and Takeuchi, 1995). More recent research shows that AI can also reconfigure professional practice, redistribute authority, and create new forms of opacity and dependence (Pasquale, 2015; Pachidi et al., 2021; Susskind and Susskind, 2015).

The present paper addresses this gap through a design-oriented perspective. We draw on a research program originally developed in the legal-AI domain, where requirements for traceability, accountability, and interpretive plurality are particularly demanding. That work produced four complementary artifacts: a theoretical account of the knowledge commoditization paradox (Allega, Puzio and Rizzo, 2026b), a multi-expert architecture for trustworthy reasoning (Allega, Puzio and Rizzo, 2026c), a governance model for community-based validation

(Allega, Puzio and Rizzo, 2026d), and a platform framework that combines commons and differentiated services (Allega, Puzio and Rizzo, 2026a). Although domain-specific in origin, these artifacts expose more general organizational problems that are increasingly visible across industries.

The paper therefore asks two questions. First, how can the paradoxes created by AI-mediated knowledge management be reorganized into actionable design problems? Second, which architectural and governance principles can guide the Knowledge Journey toward sustainable value creation? To answer them, we extend the earlier notion of semantic entropy into a broader framework of organizational entropies and derive five principles for sustainable knowledge ecosystems.

The contribution is threefold. Theoretically, the paper reframes AI-enabled knowledge management as an ecosystem design problem rather than a tool-adoption problem. Conceptually, it introduces coordination entropy and governance entropy alongside semantic entropy. Practically, it offers an operational model aligned with the three phases of Planning, Acquisition, and Impact showing how firms can turn hidden costs into sustainable competitive advantage.

2 Theoretical Background

2.1 The knowledge commoditization paradox

The starting point of our argument is the knowledge commoditization paradox: the simultaneous necessity and impossibility of reducing complex organizational knowledge to computationally accessible and tradable representations (Allega, Puzio and Rizzo, 2026b). AI systems require knowledge to be structured, indexed, embedded, linked, or otherwise made processable. Yet the very operations that increase computational accessibility tend to strip away the contextual richness that makes knowledge valuable in organizational settings. This tension is visible in the movement from documents and practices to vectors, metadata, and machine-readable schemas.

This problem has both economic and epistemic roots. Arrow (1962) showed that information markets are marked by deep asymmetries: value is difficult to assess before use, yet once revealed it becomes difficult to appropriate. In organizational settings, the challenge is amplified because knowledge is not a neutral object. It is embedded in routines, interpretive communities, hierarchies of authority, and situated practices. When organizations try to externalize that knowledge for AI systems, they face a difficult choice between oversimplified codification and increasingly expensive representational complexity.

Earlier work in our research stream described this process through the concept of semantic entropy: the progressive loss of contextual information through computational abstraction (Allega, Puzio and Rizzo, 2026b). This diagnosis is consistent with broader critiques of statistical language systems that capture form and correlation more easily than grounded meaning and pragmatic context (Bender and Koller, 2020). It is also reinforced by recent research on retrieval architectures. Weller et al. (2025) show that single-vector embedding systems face structural limits in representing all possible relevance combinations, suggesting that some knowledge access failures are not merely training-data problems but architectural bottlenecks.

The implication is significant for knowledge management. If computational representations are intrinsically selective, then organizations cannot assume that more AI automatically means better knowledge. They must instead decide what kind of knowledge losses are acceptable, what forms of human intervention remain necessary, and what architectural choices can reduce avoidable distortions.

2.2 From semantic entropy to coordination and governance entropy

We extend the previous concept of semantic entropy by proposing two additional entropic pressures that affect the organizational Knowledge Journey. We use entropy analogically but operationally, following the intuition that systems lose coherence when structure, signal, and accountability dissipate across transformations (Shannon, 1948).

Coordination entropy refers to the dissipation generated by fragmented repositories, inconsistent taxonomies, poorly maintained metadata, and misaligned workflows. Here the problem is not only that knowledge is reduced during computational processing, but that organizations cannot even coordinate what counts as relevant knowledge, where it resides, who owns it, or how it should circulate. Coordination entropy manifests in duplicated work, search costs, onboarding delays, and recurrent reconstruction of prior knowledge.

Governance entropy refers to the dilution of authority, responsibility, and legitimacy across opaque AI-mediated processes. As knowledge moves through retrieval tools, automated classifications, external APIs, and generative interfaces, the chain of accountability becomes harder to reconstruct. Who validated the source?

Who designed the ranking logic? Who is responsible for errors, omissions, bias, or overconfident outputs? In this sense, governance entropy is not merely a legal or ethical issue; it is an organizational knowledge problem because it affects whether outputs can be trusted, contested, and improved.

These three entropies are recursively related. Poor coordination amplifies semantic loss because inconsistent architectures increase the risk that models retrieve the wrong representations. Semantic loss amplifies governance problems because opaque outputs are harder to audit when context has already been stripped away. Governance failures, in turn, worsen coordination because actors lose incentives to share, curate, and maintain common knowledge resources. The Knowledge Journey is therefore destabilized not by a single defect, but by an entropic cascade.

2.3 Knowledge ecosystems as hybrid and governed infrastructures

If AI-mediated knowledge management is shaped by entropic pressures, then sustainable response requires more than better interfaces or larger models. It requires organizations to think in terms of knowledge ecosystems: layered socio-technical arrangements in which human expertise, codified resources, computational services, and governance mechanisms are designed together.

This ecosystem view shifts the focus from isolated tools to infrastructural choices. Platform research has long shown that control over standards, access points, and boundary resources structures who can participate in value creation and on what terms (Parker, Van Alstyne and Choudary, 2016). In knowledge-intensive settings, the same logic applies to ontologies, APIs, retrieval services, and validation rules. Without explicit governance, firms risk reproducing new asymmetries of dependency and opacity (Pasquale, 2015; Varoufakis, 2023).

Our prior work responds to this challenge by combining a commons layer, provenance-aware services, community-based governance, and differentiated applications (Allega, Puzio and Rizzo, 2026a). The broader organizational lesson is that sustainable knowledge ecosystems are hybrid by design. They do not eliminate human judgement, nor do they reject automation. Rather, they distribute roles between humans and machines in ways that preserve knowledge integrity while enabling scale, reuse, and continuous improvement.

3 Research Design

This paper is an academic conceptual study informed by design-science research (Hevner et al., 2004). Its purpose is not to test a single causal hypothesis, but to derive prescriptive design knowledge from a coherent set of previously developed artifacts. The analytical strategy is one of conceptual synthesis and analytical generalization from a revelatory domain: legal AI.

The legal domain is particularly suitable for this role because it concentrates requirements that are increasingly relevant across knowledge-intensive organizations: traceability of sources, explicit reasoning paths, interpretive plurality, temporal versioning, and high accountability for error. In other words, it exposes at high intensity the same tensions that other organizations face when deploying AI over strategic knowledge assets.

The empirical and conceptual inputs used for the synthesis are four artifacts reported in the CIDE 2025 proceedings. The first identified the knowledge commoditization paradox and formalized semantic entropy as a degradation function (Allega, Puzio and Rizzo, 2026b). The second developed MERL-T, a multi-expert architecture that combines explicit knowledge representation, differentiated reasoning, and provenance-preserving retrieval (Allega, Puzio and Rizzo, 2026c). The third introduced RLCF, a governance framework based on dynamic authority, uncertainty-preserving aggregation, and bias-aware community validation (Allega, Puzio and Rizzo, 2026d). The fourth integrated these ideas into a platform architecture structured around commons, services, governance, and applications (Allega, Puzio and Rizzo, 2026a).

The synthesis proceeded in four steps. First, we identified recurring problems across the four artifacts. Second, we clustered these problems into three higher-order entropic pressures: coordination, semantic, and governance entropy. Third, we mapped the design responses developed in the legal domain to those pressures. Fourth, we generalized them into organizational principles that can guide the Knowledge Journey across the phases of Planning, Acquisition, and Impact.

The resulting framework should therefore be read as design knowledge with both theoretical and managerial intent: it does not claim universal optimality, but it specifies a coherent set of architectural and governance principles that organizations can adapt to their own sectoral and strategic contexts.

Table 1: Entropic pressures, organizational manifestations, and design responses

Entropic pressure	Typical hidden cost	Primary design response	Indicative metrics
Coordination entropy	Search time, duplication, obsolete versions, siloed know-how	Commons-first knowledge architecture	Search time, reuse rate, onboarding time
Semantic entropy	Context loss, brittle retrieval, hallucinated outputs, weak explainability	Provenance-preserving services and differentiated human-AI collaboration	Provenance coverage, expert override rate, retrieval quality
Governance entropy	Accountability gaps, bias, opaque decisions, platform lock-in	Community-anchored governance and sustainability-by-measurement	Auditability, participation diversity, incident rate

4 Architectural and Governance Principles for Sustainable Knowledge Ecosystems

4.1 Planning phase: commons-first knowledge architecture

The first principle is that organizations should design a knowledge commons before they scale AI applications. In practice, this means investing in explicit taxonomies, metadata conventions, document ownership rules, versioning logic, and shared schemas for critical knowledge domains. The purpose is not bureaucratic neatness. It is to reduce coordination entropy by creating a stable layer of organizational meaning on top of which computational services can operate.

Our prior legal-domain implementations illustrate why this matters. Knowledge graphs, argument structures, and typed entities were not introduced as academic embellishments, but as mechanisms for making relations explicit, queryable, and governable (Allega, Puzio and Rizzo, 2026a; 2026c). The same logic generalizes to other sectors. A company cannot expect an intelligent intranet, an AI copilot, or a semantic search system to produce robust results if basic categories, ownership responsibilities, and update rules remain unstable.

A commons-first architecture also has sustainability implications. It reduces redundant local solutions, limits dependence on proprietary vendor logic, and creates reusable assets that can support multiple applications over time. From a knowledge-based view of the firm, such shared and governable knowledge resources are not peripheral infrastructure but a basis for sustained advantage because they improve the integration and application of specialized knowledge (Grant, 1996). This is particularly important in organizations where knowledge turnover, mergers, and distributed work routinely degrade continuity. Leadership therefore matters not only as sponsorship, but as stewardship: someone must be responsible for maintaining the architecture of organizational knowledge, not merely for purchasing the next AI tool.

4.2 Acquisition phase: provenance-preserving human-AI integration

The second and third principles address the Acquisition phase. First, knowledge services should preserve provenance. Retrieval, summarization, recommendation, and reasoning systems should expose their sources, timestamps, confidence signals, and evidentiary paths rather than producing answer-only outputs. Provenance is the organizational antidote to semantic entropy because it reconnects machine-readable representations to the contexts from which they were derived.

Second, organizations should design human-AI collaboration in an epistemically differentiated way. Tacit knowledge cannot be captured by indiscriminate ingestion alone. It emerges through interviews, process documentation, exception handling, narratives of practice, and expert interpretation. For this reason, AI should not be configured as a monolithic substitute for expertise. It should be embedded in workflows that distinguish between types of knowledge and types of reasoning.

The MERL-T artifact is instructive here. Its contribution was not simply better performance, but the separation of interpretive roles into differentiated expert modules combined through explicit synthesis logic (Allega, Puzio and Rizzo, 2026c). The broader organizational lesson is that sustainable knowledge acquisition requires role clarity. Rule-based content, conceptual definitions, experiential judgement, and precedent-like cases often demand different treatment. When everything is collapsed into a single black-box interaction, organizations gain superficial fluency but lose the ability to understand where knowledge came from, why it was selected, and when a human expert should intervene.

This point also resonates with the external literature on retrieval limits. If certain failures of knowledge access are architectural rather than purely statistical, then organizations should resist the temptation to treat larger

embeddings or more data as universal remedies (Weller et al., 2025). Hybrid approaches - combining structured repositories, explicit links, retrieval services, and human validation - are better suited to preserving the contextual integrity of strategic knowledge.

In practical terms, the Acquisition phase should therefore include structured elicitation routines, provenance-aware APIs, and expert review checkpoints. AI can accelerate extraction and integration, but it should do so in ways that preserve human experience and intuition as first-class organizational resources rather than residual corrections.

4.3 Impact phase: contestable governance and sustainability-by-measurement

The fourth principle is that sustainable knowledge ecosystems require contestable governance. Once knowledge is collected and distributed through AI-mediated services, organizations need mechanisms that specify who can contribute, who can validate, how disagreement is handled, and how risk is escalated. Governance cannot be postponed to compliance departments after deployment; it must be embedded into the ecosystem itself.

The RLCF and ALIS artifacts point to four useful mechanisms in this regard: dynamic authority, uncertainty-preserving aggregation, explicit transparency rules, and structured challenge functions such as Devil's Advocate roles (Allega, Puzio and Rizzo, 2026a; 2026d). These mechanisms matter because not all knowledge domains converge on a single correct answer, and organizations often damage learning when they force premature consensus. In high-stakes environments, responsible AI should sometimes present bounded disagreement rather than spurious certainty. This is consistent with recent alignment research arguing that pluralistic AI should preserve heterogeneous perspectives rather than collapse them into a single dominant reward signal (Sorensen et al., 2024; Chakraborty et al., 2024).

The fifth principle follows directly: sustainability must be measured through feedback loops, not assumed as a by-product of adoption. Many organizations evaluate AI systems through local efficiency metrics only, such as faster response times or reduced service tickets. Those indicators matter, but they do not reveal whether the knowledge ecosystem is becoming more robust. A sustainability-oriented measurement system should therefore include both operational and epistemic indicators: search time, reuse rate, provenance coverage, expert override rate, auditability of outputs, participation diversity in validation, decision latency for ESG-related issues, and the persistence of organizational knowledge despite turnover.

This broader view of impact also aligns with emerging expectations around trustworthy and accountable AI, including requirements for transparency, human oversight, and traceability in high-risk contexts (European Union, 2024). More importantly, it recognizes that organizational sustainability is not only environmental. It is also cognitive and institutional. A sustainable knowledge ecosystem is one that preserves continuity, supports informed decisions, and can be corrected when its classifications, recommendations, or summaries are found wanting.

5 Discussion

The framework developed in this paper contributes to knowledge management research by shifting the unit of analysis from isolated AI tools to sustainable knowledge ecosystems. Much current debate still assumes that the core managerial challenge is adoption: whether firms can introduce copilots, retrieval tools, or generative systems into existing processes. Our findings suggest that this view is too narrow. The decisive issue is architectural and governance readiness. Organizations do not fail only because models are inaccurate; they fail because the ecosystems into which those models are inserted are entropically fragile.

A first theoretical contribution is therefore the extension of semantic entropy into a wider three-part model. Semantic entropy captures loss of context during computational representation, but organizations also suffer from coordination entropy and governance entropy. This broader framework helps explain why AI programs can disappoint even when the underlying model appears technically strong. In this sense, the problem is not simply one of information processing, but of preserving and organizing multiple forms of knowledge under conditions of pluralism, which recent alignment research has likewise identified as a central challenge for AI systems intended to serve heterogeneous communities (Sorensen et al., 2024; Chakraborty et al., 2024). Poor taxonomy design, missing ownership, fragmented repositories, and opaque decision chains can neutralize or distort otherwise useful systems.

A second contribution is methodological and design-oriented. By analytically generalizing from a high-accountability domain, the paper shows how artifact-based research can inform broader KM theory. The legal field is not identical to manufacturing, healthcare, consulting, or the public sector, but it makes visible a set of

design demands - provenance, contestability, explicit reasoning, pluralism - that are becoming increasingly relevant across knowledge-intensive organizations.

A third contribution concerns sustainability. In many organizational discussions, sustainability enters the AI agenda late, often as a reporting or compliance category. The present framework suggests that sustainability begins much earlier, in how knowledge is structured, governed, and renewed. Reducing search waste, limiting duplication, preserving institutional memory, avoiding hallucinated outputs, and making decisions auditable are not secondary efficiency gains. They are part of building organizations that can endure change without losing the quality of their knowing.

For managers, the paper implies a sequence of intervention. First, map where coordination entropy is highest: fragmented repositories, inconsistent tags, undocumented expert routines. Second, build a commons layer with explicit ownership and versioning rules. Third, ensure that AI services expose provenance and that human expertise is segmented rather than flattened. Fourth, embed governance mechanisms that preserve contestability and learning. Fifth, measure the ecosystem through both efficiency and epistemic integrity indicators.

The framework also has clear limits. It is conceptual and design-oriented, not a large-sample empirical validation. The proposed principles emerged from one revelatory domain and should now be tested across sectors such as manufacturing, healthcare, and public administration. In addition, organizations differ in scale and maturity; not all need full knowledge graphs or elaborate governance boards. The relevant claim is therefore not that one architecture fits all, but that sustainable AI requires some explicit combination of commons, provenance, differentiated collaboration, governance, and feedback.

6 Conclusion

This paper argued that the path from AI adoption to organizational sustainability passes through the deliberate design of knowledge ecosystems. Starting from the knowledge commoditization paradox, we identified an entropic cascade - coordination, semantic, and governance entropy - that helps explain why many AI initiatives struggle to create durable value. We then derived five principles to counter those pressures: commons-first knowledge architecture, provenance-preserving services, epistemically differentiated human-AI collaboration, community-anchored governance, and sustainability-by-measurement.

The central implication is straightforward. Organizations should stop treating AI as an isolated capability and start treating it as a knowledge-infrastructure challenge. Sustainable value does not emerge when a model is merely added to existing processes. It emerges when knowledge assets, human expertise, and governance mechanisms are intentionally configured as a resilient ecosystem. Under these conditions, the hidden costs of fragmented knowledge can be transformed into a durable source of organizational learning, accountability, and sustainable advantage.

7 Ethics Declaration

This paper is conceptual and relies on published sources and previously reported design artifacts. It does not involve human participants, personal data collection, or experimental intervention. Consequently, formal ethical clearance was not required.

8 AI Declaration

An AI language tool was used to support drafting, language refinement, and formatting under full human supervision. The tool was not used to fabricate evidence or citations. All arguments, source selection, and final editorial decisions were reviewed and validated by the authors.

Organisational AI Literacy and Readiness: Enabling Factors and Barriers

Riccardo Michele Colangelo, Eleonora Petrazzuoli, Maria Menshikova
Universitas Mercatorum, Rome, Italy

Abstract

The spread of artificial intelligence (AI) within organisations is reshaping how they operate, leading to deep and systemic transformations across processes, structures and decision-making practices.
In this context, the distinct concepts of AI literacy and AI readiness are increasingly central to understanding organisational AI-driven transformation.
This study investigates the relationship between AI literacy and AI readiness within organisations, also examining which enabling factors and barriers influence these constructs across multiple organisational levels.
By adopting an integrated bibliometric and systematic approach, this study aims to provide an overview of how these constructs are addressed in the literature, followed by a systematic analysis of enabling factors and barriers to AI literacy and AI readiness, with specific regard to 61 Q1 journal articles in the business, management, and accounting domain.
The bibliometric analysis, conducted using Biblioshiny, maps publication trends, geographical distribution and keyword co-occurrence networks.
The systematic analysis further explores enabling factors and barriers to AI literacy and AI readiness on a targeted selection of relevant peer-reviewed publications, using a specific purpose-built analytical framework, across micro (individual), meso (team), and macro (organisational) levels.
The key findings indicate that AI literacy is primarily associated with individual-level capabilities, including AI knowledge, self-efficacy and critical thinking skills, while AI readiness is predominantly linked to organisational dimensions such as technological infrastructure, data availability, leadership support and strategic alignment. Key barriers include skill gaps, cognitive biases, resource constraints, legacy systems, organisational rigidity, and regulatory uncertainty.
The study also identifies cross-cutting factors, such as trust in AI systems, ethical considerations and algorithmic bias, which influence both constructs and reflect the socio-technical nature of AI adoption.
Overall, the findings suggest that AI literacy and AI readiness are strongly interdependent constructs: they are closely interconnected and often mutually reinforcing in shaping how organisations engage with artificial intelligence, although they remain distinct constructs.

Keywords: AI literacy, AI readiness, Organisations, Enabling factors, Barriers

Paper type: Academic Research Paper

1 Introduction

The rapid diffusion of artificial intelligence (AI) across organisations is driving a profound AI-driven transformation that affects skills, competencies, decision-making processes, governance structures, and regulatory compliance. In this evolving landscape, AI literacy is increasingly framed not merely as an individual technical skill, but as a strategic organisational capability, not limited to decision-makers.

AI literacy, while remaining central to the research agenda (Jiang et al., 2024), lends itself to multiple definitions. The current state of the literature reveals a lack of a widely applicable definition of AI literacy (Liu et al., 2025), as highlighted by several systematic literature reviews documented in the scholarly literature (Lintner, 2024).

Indeed, AI literacy has been defined as “comprehensive proficiency” related to the “understanding, using, and working with AI” (Steinhauser and Heid, 2026), which “enables individuals to develop effective solutions” (Yordudom et. al, 2026) and “encompasses a crucial set of skills” (Roozen et al., 2025). Recent studies highlight that “AI literacy transcends fundamental digital literacy” (Lee et al., 2026), enabling “individuals to understand, critically assess, and purposefully engage with AI” (Testa et al., 2026).

The literature often combines or overlaps AI literacy with related constructs such as AI readiness (Jiang et al., 2024), which has also been examined in specific studies within the academic literature (Kaewsawad et al., 2025).

While, in the literature, readiness is conceptualized as “conditions that enable organizations to acquire, assimilate, and apply new knowledge” (Steinhauser and Heid, 2026), AI readiness concerns measures aimed to the preparation “for the changes involved in technology, infrastructure” (Sharma et al., 2022)” and it “can be understood as the extent to which individuals are prepared to engage with AI technologies in applied contexts”

(Testa et al., 2026). It should be acknowledged that "AI readiness is multidimensional" (Holmström, 2022) and that the readiness itself "may be either organizational or individual readiness" (Issa et al., 2022).

This study examines the relationship between AI literacy and AI readiness, while also identifying enabling factors and barriers emerging from the most relevant literature in business, management and accounting.

It contributes to the ongoing academic debate on these constructs by advancing the state of the art beyond the boundaries of a conventional systematic literature review.

The paper addresses the following research questions:

- *RQ1: There are boundaries and intersections between AI literacy and AI readiness? Do these notions represent distinct analytical dimensions or complementary facets?*
- *RQ2: What factors enable or hinder the development of AI literacy and AI readiness within organisations?*

The structure of the paper is as follows. Section 2 outlines the research methodology. Section 3 presents bibliometric evidence, both at a general level and within the specific thematic domain investigated. Section 4 provides a systematic content analysis of selected articles, based on a purposefully designed analytical framework aimed at identifying multi-level enabling factors and barriers associated with the two focal constructs. Section 5 discusses the findings, with particular emphasis on insights derived from the bibliometric analysis. Finally, Section 6 concludes the paper by summarising the main contributions and outlining avenues for future research.

2 Methodology

This paper aims to address the research questions through a combination of bibliometric and systematic analysis of selected documents within the business, management and accounting domain.

The present study draws on documents indexed in the Scopus database. The dataset was selected following the PRISMA framework, as illustrated in Figure 1.

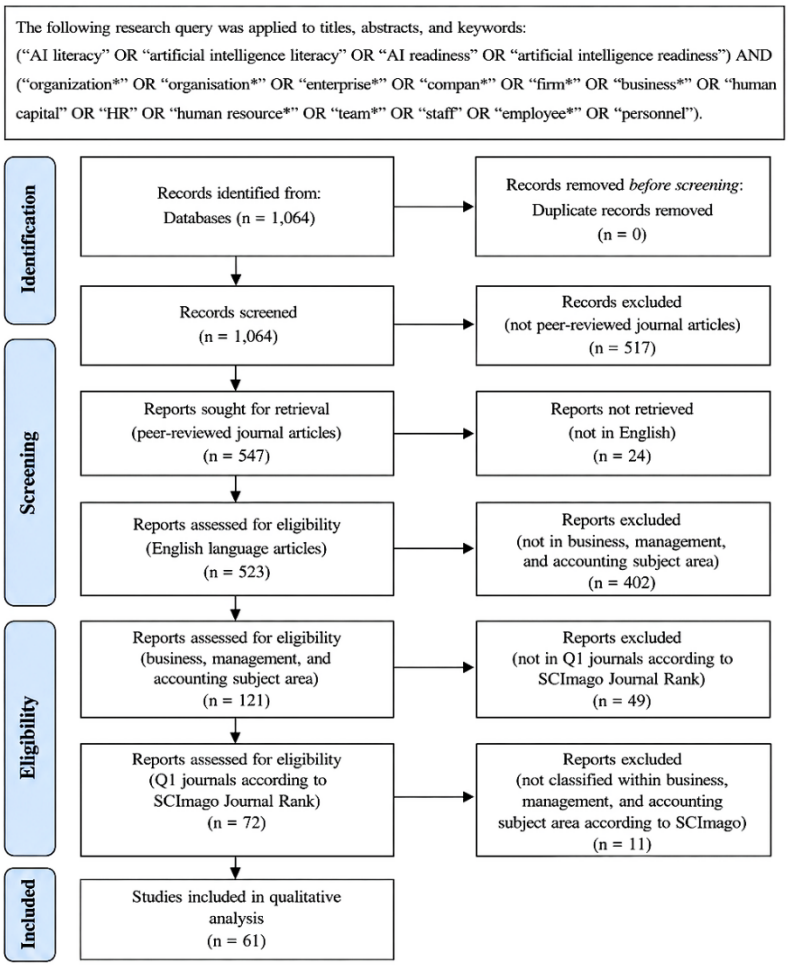

Figure 1: PRISMA framework applied to the reference dataset

The following research query was applied to titles, abstracts, and keywords:

("AI literacy" OR "artificial intelligence literacy" OR "AI readiness" OR "artificial intelligence readiness") AND ("organization" OR "organisation*" OR "enterprise*" OR "compan*" OR "firm*" OR "business*" OR "human capital" OR "HR" OR "human resource*" OR "team*" OR "staff" OR "employee*" OR "personnel").*

The initial search yielded 1,064 documents. The same number of contributions was obtained when considering the time span from 2020 to 2026. Restricting the sample to peer reviewed journal articles resulted in 547 documents, of which 523 were in English. This subset was used for the preliminary bibliometric analysis.

After further filtering, aimed to ensure domain specificity, the analysis focused on the business, management and accounting subject area, resulting in a final subset of 121 documents. This subset was used for a second, domain-specific bibliometric analysis.

In order to ensure the inclusion of relevant contributions, within the specific CSV subset, only articles published in Q1-ranked journals were selected using the SCImago Journal Rank, resulting in 72 documents. After excluding 11 articles published in Q1 journals that were not classified within the business, management, and accounting subject area according to SCImago, the final sample was reduced to 61 contributions. This final set of documents was subsequently used for the systematic analysis.

For the bibliometric analysis, Biblioshiny is employed in order to identify publication trends over time, country-level scientific production and the co-occurrence network of authors' keywords. This approach enables both a general overview of the intellectual and conceptual development and a specific insight regarding the abovementioned field.

The systematic analysis, in contrast, focuses on identifying the enabling factors and barriers related to both AI literacy and AI readiness within the specific context of business, management, and accounting. In particular, this analysis examines these factors across three levels: micro (individual), meso (team), and macro (organizational). This multi-level perspective is adopted to highlight similarities and differences in enabling conditions and barriers across the two theoretical constructs.

3 Bibliometric Analysis

Prior to the systematic analysis related to enabling factors and barriers to AI literacy and AI readiness, the bibliometric approach provides a broad-level overview and subsequently enables a more fine-grained focus on the business, management and accounting domain.

In particular, it allows for the identification of the evolution of scientific production over time, the mapping of its geographical distribution through the identification of the most productive countries and the generation of meaningful insights.

Moreover, co-occurrence mapping based on authors' keywords helps to uncover the intellectual structure of the field and the main thematic connections within the literature.

3.1 General bibliometric analysis

Prior to analysing articles specifically related to the field of business management and accounting, it is appropriate to carry out a preliminary and broader bibliometric analysis.

This analysis is based on a dataset of 523 articles retrieved from Scopus , covering the most recent decade (2016–2026). More specifically, these contributions represent a subset of the initial dataset and, without considering specific subject areas, meet the following inclusion criteria: only journal articles (547) and, subsequently, only publications in English (523).

The results of the analysis are as follows.

The bibliometric analysis shows a growing annual distribution of research articles on AI literacy and AI readiness in organisations, as illustrated in Figure 2.

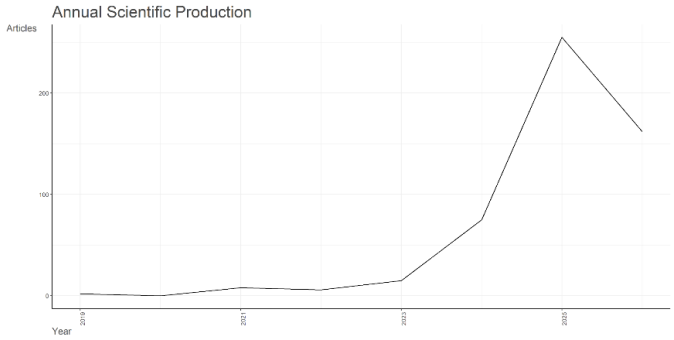

Figure 2: Trend of publication

Table 1 reports the yearly publication output on AI literacy and AI readiness in organisations over the analysed period (2016–2026). The data show no publications between 2016 and 2018, followed by the first emerging contributions in 2019 (2 articles). After a brief interruption in 2020 (0 articles), an increase can be observed in 2021 with 8 publications, followed by a slight decline in 2022 (6 articles). From 2023 onwards, the field experiences a clear acceleration, with 15 articles published in 2023 and a substantial jump in 2024 (75 articles). This growth culminates in 2025, with 255 publications. Although 2026 data are still partial, the 162 articles already recorded confirm the continuation of this strong upward trajectory, suggesting intensifying academic attention in this domain.

Table 1: Number of articles per year

Year	Articles
2016	0
2017	0
2018	0
2019	2
2020	0
2021	8
2022	6
2023	15
2024	75
2025	255
2026	162

Figure 3 illustrates a Country-wise production map, in which colour intensity reflects the number of articles, with darker tones representing higher publication volumes at the national level.

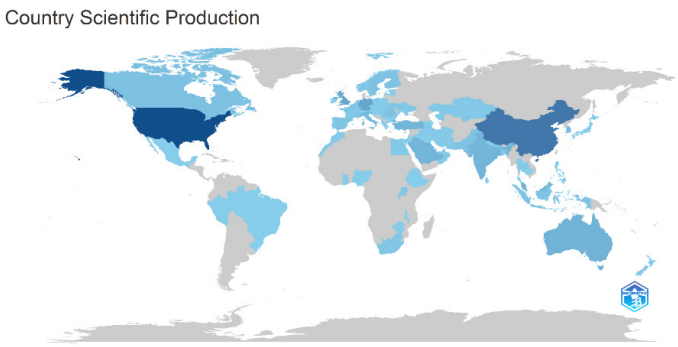

Figure 3: Country-wise production map

Table 2 highlights the top 10 countries that have made the most significant contributions to the topic. The data reveal a strong concentration of scientific production in the United States (357 articles) and China (235 articles), followed by the United Kingdom (108) and Germany (105). Other relevant contributors include Australia (72), Saudi Arabia (67), Turkey (67), India (66), Malaysia (64), and Italy (50).

Table 2: Top 10 countries contributing maximum number of articles

Country	Number of articles
USA	357
CHINA	235
UK	108
GERMANY	105
AUSTRALIA	72

ITALY	50

Bibliometric analysis also includes co-occurrence analysis of authors' keywords, enabling the identification of dominant thematic clusters and the relationships among emerging research topics (Agbo et al., 2021) as illustrated in Figure 4.

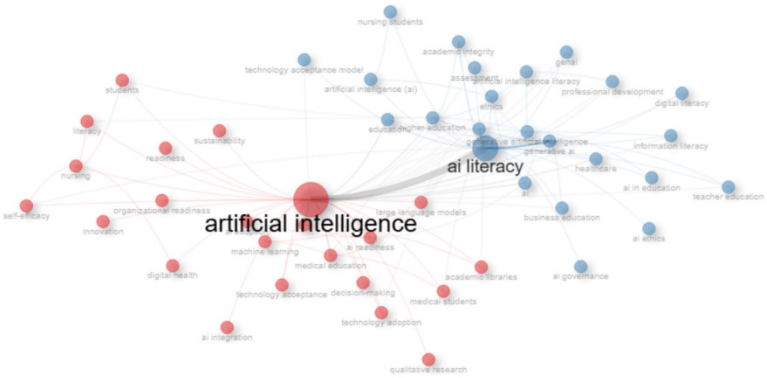

Figure 4: Keywords network (authors' keywords)

The co-occurrence network of authors' keywords reveals a structured thematic landscape organized around two main clusters

The red cluster is centered on artificial intelligence, which emerges as the dominant and most connected node in the network. This cluster primarily reflects a perspective centered on AI adoption and application, also in specific fields (e.g. healthcare). This cluster contains terms such as technology adoption, organizational readiness, AI readiness, and self-efficacy.

In contrast, the blue cluster is organized around AI literacy, which appears as a highly prominent concept. This cluster reflects a focus on the skills and knowledge required to effectively and responsibly engage with AI technologies and contains key terms such as artificial intelligence literacy and generative AI. At the same time, the inclusion of AI ethics and AI governance highlights increasing attention to the societal and normative implications of AI use. The educational dimension is further emphasized by keywords such as higher education, teacher education and professional development.

There are bridging keywords connecting the two clusters and indicating a progressive convergence between AI application and AI literacy discourses. Notably, the term literacy also appears in the red cluster, suggesting that competence-related dimensions are linked with AI readiness and adoption.

Overall, the increasing prominence of AI literacy suggests a shift from operational use toward critical engagement, competency development and responsible use and governance of AI.

3.2 Bibliometric analysis in the field of business, management and accounting

After this preliminary bibliometric analysis, it is appropriate to further examine the same bibliometric dimensions on a more restricted sample, comprising only articles related to the field of business, management and accounting. This inclusion criterion was specified in order to export a more focused and domain-specific database through Scopus.

This subset consists of 121 articles and enables the identification of specific bibliometric trends within the field of analysis.

The annual distribution of research articles on AI literacy and AI readiness in organisations is illustrated in Figure 3 and it is highly consistent with patterns observed in Figure 2, regardless of the specific field.

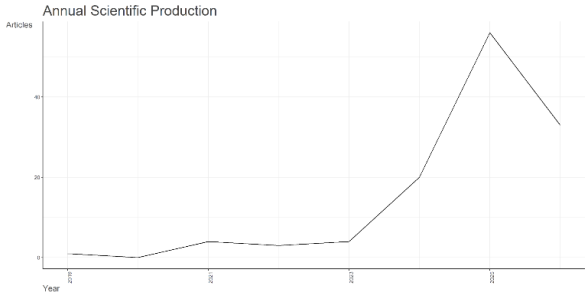

Figure 5: Trend of publication

Table 3 reports the corresponding yearly publication output within the specific field over the period analysed. The results indicate a gradual increase starting in 2021. A marked growth is observed from 2024 onwards, with a substantial peak in 2025, suggesting a rapidly accelerating research interest in the topic. Although 2026 data are partial, they already confirm the continuation of this upward trend.

Table 3: Number of articles per year

Year	Articles
2016	0
2017	0
2018	0
2019	1
2020	0
2021	4
2022	3
2023	4
2024	20
2025	56
2026	33

Figure 6 provides a visual representation of the most productive countries.

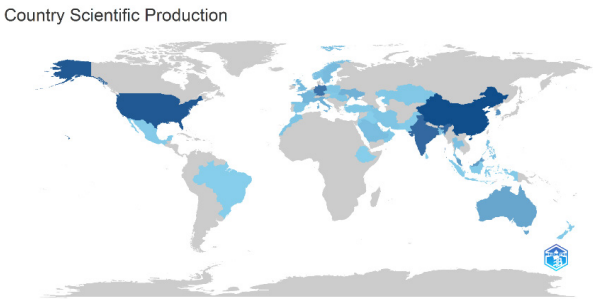

Figure 6: Country-wise production map

Table 4 highlights the top 10 countries that have made the most significant contributions to the topic within the specific field. The analysis reveals that China holds the leading position, contributing a total of 45 articles, followed closely by the United States with 41 publications and India with 35. Germany ranks fourth with 31 articles, while South Korea contributes 21 publications. Malaysia accounts for 17 articles, followed by Australia with 14 and Italy with 11. Ukraine and France complete the top ten, with 10 and 9 publications respectively. Overall, the results indicate a strong geographical concentration of research activity in Asia, North America, and selected European countries.

Table 4: Top 10 countries contributing maximum number of articles

Country	Number of articles
CHINA	45
USA	41
INDIA	35
GERMANY	31
SOUTH KOREA	21
MALAYSIA	17
AUSTRALIA	14
ITALY	11
UKRAINE	10
FRANCE	9

The bibliometric analysis is complemented by a co-occurrence analysis of authors' keywords, shown in Figure7.

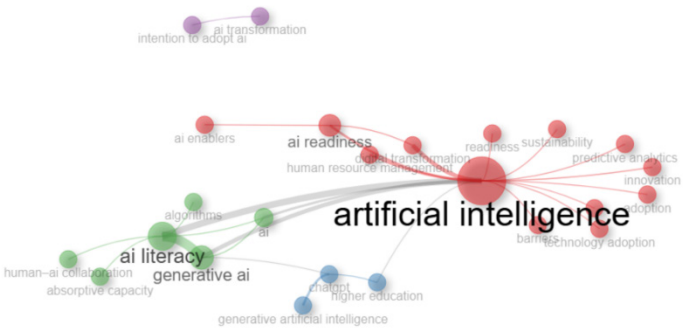

Figure 7: Keywords network (authors' keywords)

This keyword co-occurrence map reveals 4 distinct clusters, each reflecting a thematic area.

The red cluster is dominant and centered on artificial intelligence. It captures strategic and organisational dimensions of AI implementation. Key themes include, for example, AI readiness, digital transformation, technology adoption, innovation, predictive analytics and sustainability. It also reflects barriers and enablers at the organisational level.

The green cluster revolves around AI literacy and generative AI, including topics like algorithms, human–AI collaboration, and absorptive capacity, suggesting a focus on knowledge acquisition and user competences.

The blue cluster is smaller and more application-oriented, suggesting a link between higher education and AI literacy.

The purple cluster focuses on the early-stage perspective of AI integration, highlighting intention to adopt AI.

Overall, the network suggests a thematic progression: from intent and transformation (purple), organisational AI readiness and adoption (red), AI literacy development (green) and practical applications, especially in education (blue).

4 Systematic Analysis

As outlined in the methodology section, following the bibliometric analysis, the subset of 121 articles related to the field of business, management and accounting was identified in order to conduct a more in-depth systematic analysis.

For this purpose, journal quality was assessed using the SCImago Journal Rank, retaining only Q1-ranked journals from the specific CSV subset (121), which resulted in 72 articles. After excluding 11 articles published in Q1 journals not classified within the business, management and accounting subject area according to SCImago, the final sample was reduced to 61 contributions.

The systematic analysis was ultimately conducted on 61 articles.

These articles were analysed through a specifically purpose-built analytical framework designed to identify enabling factors and barriers at the micro (e.g. employees), meso (e.g. teams), and macro (e.g. organisation) levels, with reference to AI literacy or AI readiness within the specific context outlined above.

In particular, studies related to AI literacy are predominantly concentrated at the micro level, focusing on individual competencies, cognitive capabilities, and human–AI interaction. In this domain, the most recurrent enabling factors include self-efficacy (Duong, 2026), AI knowledge, critical evaluation skills (Kulkarni at al, 2024), and usage capabilities, while the main barriers concern low levels of competence, difficulties in understanding AI systems, cognitive biases, and over-reliance on automated outputs (Jeremiah, 2025).

In contrast, AI readiness primarily emerges at the meso and macro levels, with a focus on the organisational and systemic capabilities required for the adoption and implementation of AI. In these studies, enabling factors include technological infrastructure (Nguyen at al., 2024), data availability and quality, top management support, strategic alignment, and organizational capabilities, whereas the most relevant barriers are represented by resource constraints, high costs, legacy systems, lack of specialized skills, organizational rigidity, and regulatory uncertainty (Kumar at al., 2021).

Two tables presenting the main enabling factors and barriers related to AI literacy and AI readiness are provided in the paper's appendix.

5 Discussion

The analysis also highlights that some contributions adopt a multi-level perspective, integrating both individual and organizational dimensions. In such cases, AI literacy is frequently identified as an enabling factor for AI readiness, suggesting a hierarchical or sequential relationship between the two constructs (Baabdullah at al., 2021). In particular, individual competencies contribute to strengthening the organizational capacity to effectively adopt and leverage AI technologies.

Finally, increasing attention is devoted to cross-cutting factors, such as trust in AI systems, ethical considerations, algorithmic bias, and transformations in decision-making processes, which influence both literacy and readiness, highlighting the socio-technical nature of artificial intelligence adoption. Trust, for instance, is frequently identified as a key mediator at the individual level, shaping users' willingness to engage with AI systems, while at the organizational level it becomes intertwined with governance, transparency, and accountability mechanisms (Vafaei-Zadeh at al., 2025). Similarly, ethical concerns, ranging from bias and fairness to data privacy, are increasingly framed not only as risks or barriers, but also as conditions for sustainable and responsible AI deployment.

Finally, the literature underscores that the adoption of AI entails a reconfiguration of decision-making processes, where human judgment and algorithmic outputs become progressively intertwined. This transformation is particularly evident in studies on organizational AI readiness and digital transformation, which show how AI reshapes organizational activities, structures, and strategic goals (Holmström, 2022). At the same time, research on human-AI interaction highlights the emergence of hybrid forms of decision-making, in which AI systems actively collaborate with human actors, challenging traditional notions of autonomy, expertise, and control.

These findings suggest that AI adoption cannot be fully understood through a purely technological lens, but should instead be interpreted as a complex socio-technical phenomenon, in which individual competencies and organizational capabilities co-evolve. In particular, studies explicitly linking AI literacy and AI readiness highlight how individual-level capabilities, such as AI knowledge, self-efficacy, and critical understanding, contribute to shaping organizational readiness and implementation capacity (Issa at al., 2022).

6 Conclusion

This study explored the relationships between AI literacy and AI readiness, with particular attention to their respective enabling factors and barriers. It also employed a bibliometric approach alongside a more in-depth systematic analysis of Q1 journal articles in the fields of business management and accounting.

The analysis focused on enabling factors and barriers related to three different levels within organizations and led to several key findings in response to the research questions posed.

RQ1: AI literacy and AI readiness are distinct yet strongly interdependent constructs, operating across different levels of analysis but converging within a common socio-technical framework. While AI literacy primarily concerns individual-level capabilities related to understanding and interacting with AI, AI readiness reflects the organizational capacity to adopt and implement these technologies.

RQ2: The development of AI literacy and AI readiness is influenced by a multi-level set of enabling factors and barriers, reflecting the socio-technical nature of AI adoption. At the individual level, capabilities such as AI knowledge, self-efficacy, and critical evaluation skills emerge as key enablers, while skill gaps, cognitive biases, and limited understanding represent major obstacles. At the organizational level, factors such as technological infrastructure, data availability, leadership support, and strategic alignment are critical in enabling AI readiness,

whereas resource constraints, legacy systems, organizational rigidity, and regulatory uncertainty act as significant barriers. Additionally, cross-cutting elements, such as trust, ethical considerations, and algorithmic bias, play a pivotal role across both dimensions. Overall, the findings suggest that successful AI adoption depends on the alignment of individual competencies and organizational capabilities, supported by appropriate governance and ethical frameworks.

This study is characterised by several limitations. In particular, the present analysis is exclusively based on the Scopus database, which, despite its broad coverage and scholarly reliability, may nevertheless impose certain constraints on a more comprehensive systematic exploration of the investigated themes. Indeed, relevant studies and contributions might exist outside the Scopus-indexed corpus and therefore remain unconsidered in this review.

The analyses conducted in this article aim to provide research insights that may contribute to enriching the scientific debate on AI literacy and AI readiness, conceptualized as two distinct yet interrelated constructs.

The identification of shared enabling factors and barriers offers a basis for future research, which should further explore the reciprocal relationships between these constructs, moving beyond the boundaries of each individual domain. Future research may also address the inherent limitations of this study by expanding the analytical dataset.

Furthermore, the exclusion of book chapters and other document types, as well as contributions published in non-Q1 journals and not related to the fields of business management and accounting, may have resulted in the omission of potentially significant contributions to the topic under investigation.

Furthermore, future research could extend both the scope of the search strategy and the breadth of the research area by incorporating additional relevant keywords. It may also be beneficial to include other kinds of contributions, which could offer valuable and complementary insights to the existing body of literature.

Annex 1: Enabling factors and barriers to AI literacy

AI Literacy		
Level	**Enabling actors**	**Barriers**
Micro	Fintech literacy dimensions, technical capacity; critical thinking; professional experience; AI-driven technologies; communication and collaboration; safety and ethics; problem-solving; AI self-efficacy; AI competency; AI knowledge; perceived desirability; Perceived feasibility; attitude towards entrepreneurship; global mindset; AI understanding; human–AI communication capability and interaction; human-AI collaboration; data-driven insights; individual competencies; cognitive capabilities.	Lower tech infrastructure and culture; data privacy; lack of transparency; information asymmetry; strong dependence on AI; tariff policy uncertainty; environmental uncertainty; perceived risk; cognitive dissonance (desirability–feasibility mismatch); ethical concerns; algorithmic bias; identity tension; feedback loop bias.
Meso	Algorithmic literacy; decentralization of algorithmic skills; workforce training/reskilling; AI infrastructure; Generative AI e LLM; AI competencies; ethical AI frameworks; AI value identification; AI implementation ability; HR-related AI capability; executive expertise; decision scrutiny; managerial attention; resource allocation; executive power; technological readiness; cross-functional collaboration; leadership support; data integration.	Digital gap; bias; over-dependency AI; lack of AI orientation; limited AI implementation ability; minimal AI business impact; skill gap; rigid business models; resistance to change; lack of integration; low knowledge; AI complexity.
Macro		

Annex 2: Enabling factors and barriers to AI readiness

AI Readiness		
Level	**Enabling actors**	**Barriers**
Micro	Social Influence; emotional trust; task-technology Fit.	Psychological and motivational resources; generational gap.
Meso	Technological and organizational capability; critically interpret algorithmic outputs; value-oriented capabilities; governance; understanding AI limitations; Interactivity; autonomy; mobility; human-AI collaboration; data capabilities; technology roadmapping; infrastructure; attitude; awareness; professional expertise.	Gap between technological adoption and value realization; rely uncritically on algorithmic outputs; multiple stakeholders; lack complete human-level language abilities; organizational barriers; strategic and economic barriers; AI phobia; AI fever; black box AI; governance; high cost; legacy systems; need for appropriate skill; social order
Macro	Scientific research output; internet infrastructure; public consumption expense; education; governance; gender equality; organizational readiness; structural readiness; cultural readiness; digital infrastructure; internet connection; sensor networks; institutional coordination; public-private partnerships; machine learning and analytics; digital capability.	Technical barriers; limitations in using generative AI tools; political issues; lack of economic policy and regulations; lack of IT infrastructure; limited digital infrastructure; connectivity barriers; low levels of digital literacy.

New Frontiers in Organizational Aesthetics

Giovanna Afeltra[1], Maria Menshikova[2], Maria Pia Ciano[3]
[1] University San Raffaele, Rome, Italy
[2] Mercatorum University, Rome, Italy
[3] Notthingham University, UK

Abstract

Over the past decades, Organizational Aesthetics (OA) has evolved from a marginal research stream into a vibrant interdisciplinary field addressing the sensory, effective, and material dimensions of organizing. Despite this growing interest, the literature remains fragmented across disciplines, methodologies, and levels of analysis, leaving key theoretical and empirical questions unresolved. This study responds to these challenges by offering a comprehensive Bibliometric-Systematic Literature Review (B-SLR) of OA research to map its intellectual structure, methodological trends, and emerging frontiers.

Drawing on a dataset of 82 peer-reviewed journal articles indexed in Scopus, the study combines bibliometric techniques (using Bibliometrix) with an in-depth qualitative analysis of selected contributions from leading journals. The findings show a steady growth of OA research since the mid-1990s, with strong contributions from the United Kingdom and the United States, alongside increasing global diversification. Thematic analysis highlights core areas such as embodiment, emotions, and aesthetic labour, while identifying emerging domains including workplace aesthetics, employee well-being, and environmental design.

The review reveals that OA has shifted from a focus on beauty and artefacts toward a broader understanding of aesthetics as a constitutive, embodied, and political dimension of organizational life. Methodologically, the field remains dominated by qualitative and interpretive approaches, though recent studies signal a move toward quantitative and mixed-methods approaches. Importantly, the analysis uncovers a growing "aesthetic turn" in digital and hybrid work environments, where aesthetic experience extends beyond physical spaces into virtual and platform-mediated contexts.

Building on these insights, the paper proposes a future research agenda centered on theoretical integration, ethical and responsible organizing, methodological advancement, digital aesthetics, and cross-cultural perspectives. Overall, the study positions OA as a critical lens for understanding contemporary organisations and highlights its relevance for both scholars and practitioners seeking to design more human-centred, inclusive, and sustainable work environments.

Keywords: Organizational Aesthetics, Workplace Aesthetics, Work Environment Aesthetics, Office Aesthetics

Paper Type: Academic Research Paper

1 Introduction

Over the last decades, research on Organizational Aesthetics (OA) has moved from a niche concern to a interdisciplinary conversation about the sensory, affective, and material dimensions of organising shape strategy, coordination, identity, and power. Early studies showed that aesthetic cues - sounds, images, spatial design, dress and bodies, artefacts, and atmospheres - are not epiphenomena but constitutive of how organisations work in practice (Witz et al. 2003; Barry & Rerup, 2006; Bathurst, 2009). Subsequent contributions deepened this insight by foregrounding paradox, politics, and embodiment: aesthetics can humanise and enliven organising, but it also frames and disciplines conduct through tastes, styles, and senses (Linstead, 2018; Strati, 2019; Strati, 2025).

In parallel, scholars have examined aesthetic labour and gendered embodiment in service and cultural industries (Witz et al., 2003; Warren, 2008), cinematic and visual framings of organising (Barry & Rerup, 2006), music and emotion in work (Richard & Reveley, 2007), and the role of office quality, ambience, and atmospheres for performance and well-being (Teven & Comadena, 1996). More recently, OA has intersected with information systems, urban and spatial studies, and contemporary workplace transformations, remote/hybrid arrangements, co-working infrastructures, and the aesthetic governance of digital platforms (Du et al. 2024; Ricciardelli et al. 2024; Tuzcuoğlu et al. 2025). These developments signal a field that is simultaneously consolidating core constructs and pushing into new terrains related to temporary projects, power and political aesthetics, as well as the moral ambivalence of taste and style (Raadik & Kuura, 2025; Strati, 2025; Chang et al., 2023).

Despite this expansion, literature remains fragmented across disciplines (organisation studies, sociology, philosophy of management, information systems, communication, urban studies), approaches (ethnography, visual analysis, discourse analysis, experiments, surveys), and levels of analysis (micro-embodiment, meso-

spaces and artefacts, macro-cultural fields. Fundamental debates persist around: (1) whether aesthetics is primarily epistemic, an alternative way of knowing organizations, or ontological, constitutive of organizations themselves (Warren, 2008; Linstead, 2018); (2) how to reconcile the edifying and attractive promise of aesthetics with its more disciplinary and political functions (Strati, 2019, 2025); and (3) which methods best capture fleeting, atmospheric, and multisensory phenomena without reducing their essence (Warren, 2008; Barry & Rerup, 2006). New empirical sites, hybrid workscapes, digitally mediated collaboration, and the aestheticisation of everyday organisational life, have intensified these questions (Du et al., 2024; Tuzcuoğlu et al., 2025), while adjacent conversations on "aesthetic intelligence" in management, brand atmospherics, and religious or moralised forms of aesthetic labour widen the scope (Bjerke et al. 2010; Lewis & Aune, 2023).

This paper responds to these dynamics by offering a Bibliometric-Systematic Literature analysis of the OA corpus to map its evolution, intellectual structure, and emergent frontiers.

2 Methodology

This study adopts the Bibliometric-Systematic Literature Review (B-SLR) approach by Marzi et al. (2025), integrating the quantitative rigour of bibliometric analysis with the qualitative depth of systematic review. Combining analytical, synthetic, and theory-building phases, the process follows Marzi et al.'s 10-step framework to ensure rigour, transparency, and replicability.

Step 1: Definition of Research Question and Boundaries of the Study

Despite growing interest across disciplines, the concept of OA remains theoretically fragmented and empirically limited. This exploration informed the formulation of the central research question:

How has the concept of organizational aesthetics been conceptualized and investigated within management and organization studies?

Which countries have most influenced the development of organizational aesthetics as a field of study?

What research methodologies have been used to study aesthetics in organizations?

How is organizational aesthetics evolving in digital and hybrid work environments?

What are the possible future research directions in the field of organizational aesthetics?

Step 2: Search Query Definition

Drawing on existing terminology and alternative expressions found in previous works, the final query was formulated as: *"organizational aesthetics" OR "work environment aesthetics" OR "workplace aesthetics" OR "office aesthetics".* The search was tested and refined through trial queries to balance recall and relevance.

Step 3: Database Selection

Scopus was selected as the primary data source (Marzi et al., 2025). The search was executed in April 2026, retrieving an initial dataset of 136 documents.

Step 4: Data Screening

Applying the inclusion criteria (peer-reviewed, English-language journal articles) led to a refined dataset of 89 documents. Only peer-reviewed journal articles written in English were considered. Moreover, in accordance with PRISMA and AMSTAR 2 protocols, the dataset was screened to remove duplicates and ineligible records.

Step 5: Data Cleaning and Export

All retained records were manually reviewed to verify alignment with the research focus on OA. The final set of 82 articles was exported from Scopus in CSV format for bibliometric processing.

Step 6: Bibliometric Approach

The bibliometric analysis was performed using Bibliometrix to enable descriptive and network-based analyses, including co-occurrence of keywords.

Step 7: Cluster Identification and Thematic Mapping

The co-occurrence network generated by Bibliometrix was used to identify thematic clusters. The clusters were visually examined through network, density, and overlay visualizations to capture both established and emerging topics.

Step 8: Sample Ordering and Selection for Systematic Review

To deepen the analysis, the review focused on contributions published in the three top-ranked journals (according to SCImago) that most frequently addressed organizational aesthetics: Organization Studies, Organization, and Management Learning. From these journals, 17 articles were selected.

Step 9: Systematic Literature Review

A qualitative content analysis was conducted on the selected papers, examining their objectives, theories, methods, and findings.

Step 10: Theory Development and Future Research Agenda

In the final stage, the insights from both bibliometric and systematic analyses were synthesized to formulate a Future Research Agenda.

3 Results

3.1 Bibliometric analysis

The analysis shows a steady rise in OA research from 1996 to 2025. After an exploratory phase until the mid-2000s, publications grew rapidly between 2005 and 2011, with peaks in 2013, 2022 and 2025 (Fig.1). This trend confirms the field's progressive maturation as a recognised area within management and organisation studies.

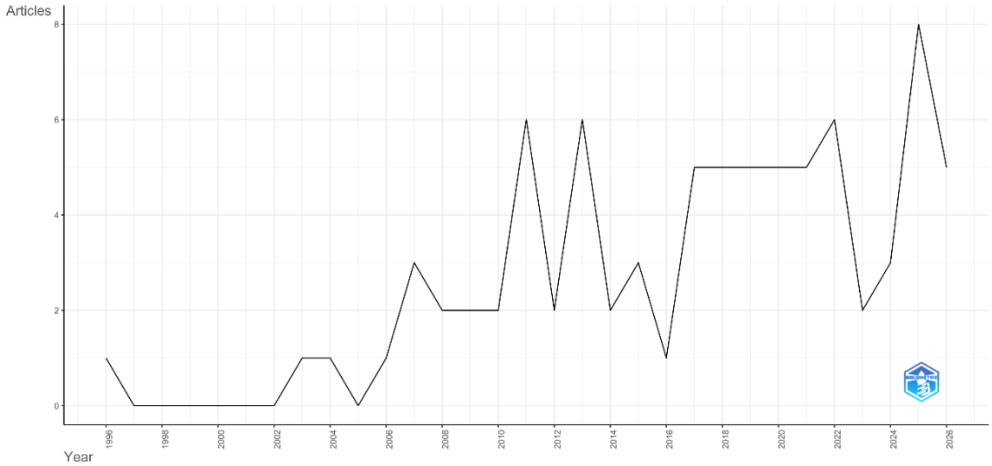

Figure 1. Annual Scientific Production
(Source: Authors' elaboration through Bibliometrix)

Regarding the geographical distribution of scientific production, the analysis identifies key contributors to OA research: the United Kingdom (21), United States (21), France (15), Brazil (10), and China (10), Israel (9), Netherland (9), Italy (8), Australia (7), Denmark (7). It is interesting to note that the studies in this field are present globally in European, Asiatic and American countries, enriching this domain with different cultural perseverance (Fig. 2).

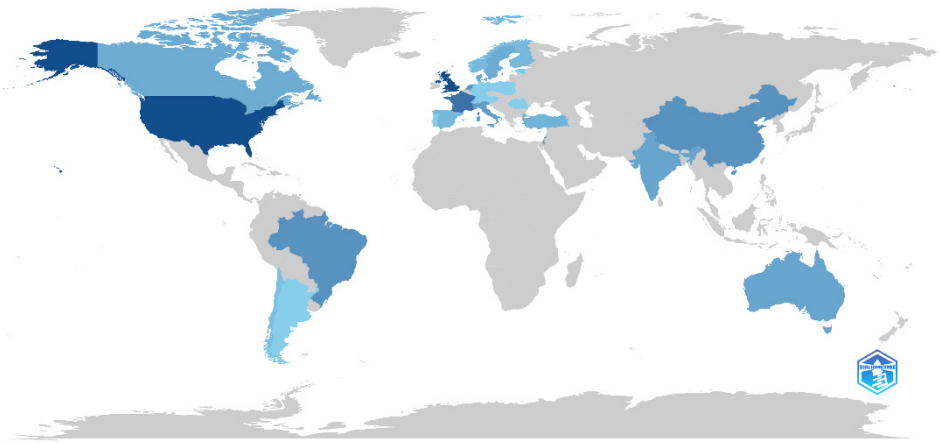

Figure 2. Country Scientific Production

Figure 3 highlights the main academic journals contributing to the literature on OA, showing a relatively concentrated distribution across a limited number of sources. In particular, "Organization Studies" emerges as the leading outlet, with the highest number of contributions (12 articles), confirming its central role for this research field. It is followed by "International Journal of Work Organisation" and "Emotion and Organization", each with three contributions. A second group of journals, including "Culture and Organization", "Journal of Management Inquiry", "Journal of Organizational Change Management", "Management Learning",

“Organization Science”, and “Studi di Estetica” each contributes two articles. “Academy of Management Annals” appears with a single contribution.

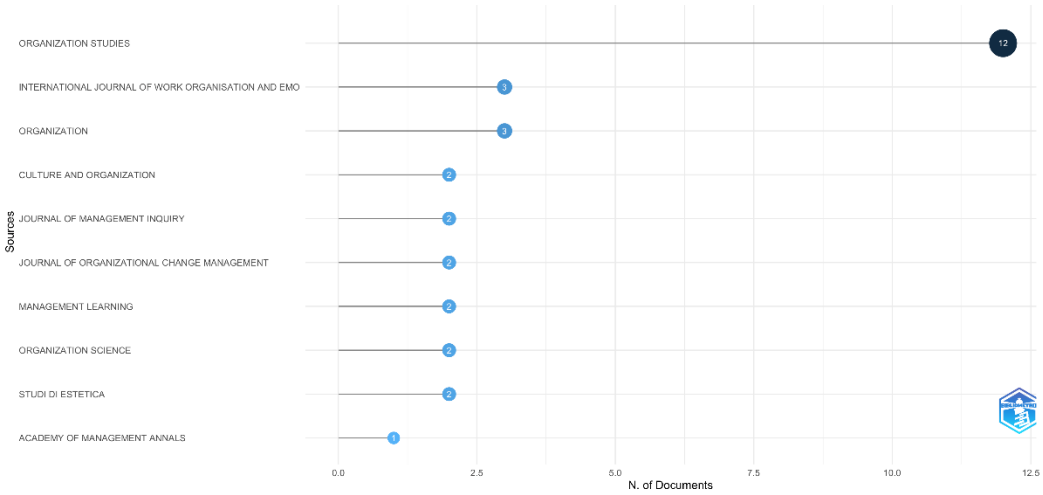

Figure 3. Most Relevant Sources
(Source: Authors’ elaboration through Bibliometrix)

Figure 4 presents a thematic map of literature, organizing key topics (authors’ keywords) according to their centrality (relevance within the field) and density (level of development). In the motor themes quadrant (high centrality and high density), topics such as organizational aesthetics, embodiment, and emotions emerge as well-developed and highly influential. These themes appear to play a pivotal role in shaping the intellectual structure of the field, suggesting a strong integration between aesthetic experience and embodied organizational processes. Closely related, the cluster including aesthetics, art, and aesthetic labour also occupies a central position, reinforcing the importance of artistic and expressive dimensions of organizational practices. The basic themes quadrant (high centrality but lower density) includes organizational aesthetics, creativity, and arts. These topics are foundational to the field and widely connected to other themes, yet they appear less internally developed, indicating opportunities for further theoretical consolidation. The niche themes quadrant (high density but lower centrality) is represented by topics such as employee well-being and office aesthetics. These areas are well developed but more specialized, suggesting focused streams of research that are not yet fully integrated into the broader discourse. The emerging or declining themes quadrant (low centrality and low density) includes environmental aesthetics, cultural and creative industries, and organizational design. These topics could represent both new research directions to be developed in the future and areas that are losing importance within the field.

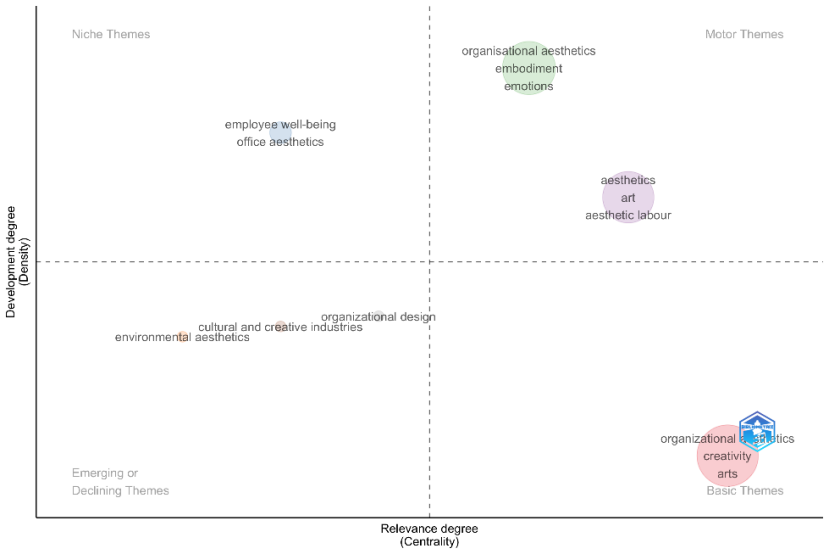

Figure 4. Thematic Map
(Source: Authors’ elaboration through Bibliometrix)

3.2 Systematic Analysis

3.2.1. Conceptualization and investigation of OA

Across the period covered by the dataset, OA has moved from a niche metaphor to a substantive analytic lens. Early and continuing contributions of Strati conceptualize aesthetics as embodied, sensory and experiential knowing in organizations, linking artefacts, spaces and everyday practices to how organizational members feel, judge and act (e.g., Strati 2019; Strati 2025). Building on this, research has treated aesthetics not simply as "beauty" but as a material–symbolic infrastructure through which organizations produce meaning.

A strong critical stream shows how aesthetics organizes identities and power. Several studies examine how spatial and visual regimes regulate inclusion/exclusion, identity work, and gendered displays (Wasserman & Frenkel 2011; 2015; Wasserman 2012; Sapir et al. 2025; Kachtan & Wasserman 2015). In parallel, classic work on aesthetic labour demonstrates how organizations script employees' looks and performances as part of value creation (Witz et al. 2003). Other authors connect OA to leadership, creativity and design logics (Barry & Rerup 2006; Bathurst 2009), or develop reflexive agendas for studying interactional and performative aesthetics (Warren 2008). Sustainability-oriented contributions argue for the value of beauty in responsible organizing (Ivanaj et al. 2018) and link urban/organizational design to social innovation (Ricciardelli et al. 2025).

3.2.2. Research methodologies used

Methodologically, the field is predominantly qualitative and interpretive. The dataset includes ethnography, interviews, visual/arts-based methods, and practice-based inquiry (e.g., Warren 2008; Strati 2019, Strati 2025). Critical-spatial analyses interrogate open-plan offices, transparency, and visibility as aesthetic–power mechanisms (Wasserman 2012; Wasserman & Frenkel 2015).

In recent years mixed and quantitative operationalizations have begun to appear, e.g. measurement of workplace aesthetic appreciation and links to strain/well-being (Nair et al. 2026). Field and quasi-experimental designs examine aesthetic cues in employment and HR contexts (Ronda & de Gracia 2022; Merriman et al. 2025). Built-environment/space studies use comparative workplace evaluations (Kirillova et al. 2020) and home-vs-office assessments (Tuzcuoğlu et al 2025).

3.2.3. OA in digital and hybrid work environments

Post-2020 documents in the dataset point to an aesthetic turn in hybrid and digital work. Some studies compare home and office aesthetics and their effects on satisfaction and productivity, highlighting how comfort, biophilic elements, and sensory cues travel (or not) across settings (Tuzcuoğlu et al. 2025; Kirillova et al. 2020). HR-facing work shows that aesthetic signaling in online job posts (e.g., biophilic imagery, visual tone) shapes applicant arousal and interest (Merriman et al. 2025), while office aesthetics influences job choice in competitive markets (Ronda & de Gracia 2022).

At the same time, some research underscores how visibility, exposure, and aesthetic control mutate in open/transparent workplaces, now also digital, with implications for identity regulation and gendered performances (Wasserman 2012; Wasserman & Frenkel 2011; Sapir et al. 2025; Vonk 2024). OA is currently being reconfigured through processes of digital mediation, in which aesthetic experience transcends material architecture and manifests in virtual interfaces, online platforms, and technologically framed embodiments.

3.2.4. Future research directions

Analysis of the documents in the dataset has identified several priorities for future research.

The first direction concerns theoretical integration and ethics. Scholars are encouraged to bridge OA with established frameworks such as sensemaking, institutional theory, and identity regulation to understand how aesthetic regimes contribute to the stabilization or disruption of organizational norms. Building on the work of Wasserman & Frenkel (2015), future research should also explore the intersection between aesthetics, ethics, and inclusion, examining how aesthetic arrangements influence issues of sustainability, fairness, and diversity within organizations (Ivanaj et al., 2018; Ricciardelli et al., 2025).

A second direction involves developing measurement tools and conducting causal analysis. While recent studies have begun to operationalize aesthetic experiences (e.g., Nair et al., 2026), further research is needed to design validated, multi-dimensional instruments that can capture environmental, interactional, and digital aesthetics. The use of field experiments and longitudinal designs could help identify the causal impact of aesthetic variables on creativity, learning, employee retention, and well-being.

A third emerging area relates to aesthetics in hybrid and digital environments. As organizations increasingly rely on virtual collaboration and hybrid work models, it becomes essential to investigate how digital platforms,

algorithmic interfaces, and camera-mediated interactions shape aesthetic experience and organizational sensemaking. Studies such as Tuzcuoğlu et al. (2025) and Merriman et al. (2025) highlight the need to explore how employees craft personal aesthetic ecologies that span across home, office, and virtual spaces.

Future research should also revisit questions of power, gender, and aesthetic labour in contemporary contexts. Classic insights on aesthetic labour (Witz et al. 2003) can be updated to address new organizational forms characterized by social media visibility, employer branding, and influencer-style communication.

Another promising avenue concerns cross-cultural and Global South perspectives. Research on OA is expanding geographically, comparative studies could uncover diverse cultural repertoires of taste, embodiment, and spatial sensibility, highlighting how these differences shape aesthetic practices and their organizational implications.

Finally, scholars should advance research on aesthetics for responsible and regenerative organising, linking aesthetics with sustainability and well-being. Building on Ivanaj et al. (2018) and Ricciardelli et al. (2024), future studies could explore how aesthetic design fosters restorative, biophilic, and ethical work environments, aligning beauty with ecological and social value creation.

6 Conclusions

This study provided a comprehensive overview of the intellectual evolution, thematic configuration, and methodological orientations of research on organisational aesthetics, offering both theoretical contributions and practical implications for management and organisational practice. By applying the Bibliometric-Systematic Literature Review (B-SLR) methodology (Marzi et al., 2025), the analysis combined quantitative mapping with qualitative synthesis to identify the main conceptual, methodological, and geographical trends that define the field.

The results show that the concept of organisational aesthetics has evolved from early interpretations centred on beauty, design, and artefacts toward a broader and more complex understanding of aesthetics as an embodied, affective, and political dimension of organising. In management and organisation studies, aesthetics is now conceptualised as a constitutive mechanism through which meaning, identity, and power are produced and experienced in organisations, rather than as a secondary or decorative element (Strati, 2019; Linstead, 2018; Warren, 2008).

From a geographical perspective, the field has been primarily shaped by scholarship from the United Kingdom and the United States, reflecting their strong traditions in critical and interpretive organisation theory. In recent years, significant contributions have also emerged from other European (e.g. Netherland, Italy) and non-European countries (Brazil, China, Israele) signalling a growing internationalisation and cultural diversification of the research landscape.

Regarding the methodologic approach, the analysis confirms the dominance of qualitative and interpretive approaches, including ethnography, visual and arts-based methods, and discourse analysis, used to explore the sensory, spatial, and emotional dimensions of organising. However, more recent studies have begun to employ quantitative and mixed-method designs, including experimental and survey-based approaches (e.g., Ronda & De Gràcia, 2022), indicating an increasing methodological pluralism and a willingness to operationalise aesthetic constructs empirically.

Regarding its evolution, organisational aesthetics is undergoing a digital and hybrid transformation. Post-2020 studies reveal that aesthetic experience increasingly extends beyond physical environments into digital platforms and hybrid workspaces (Tuzcuoğlu et al., 2025; Merriman et al., 2025). Aesthetics now encompasses virtual atmospheres, algorithmic visibility, and camera-mediated performances, reshaping how employees experience embodiment, organizational identity and belonging in hybrid organisations.

As for future research directions, the findings point to five main avenues for development: i) theoretical integration, linking aesthetics to sensemaking, institutional theory, and identity regulation to explain how aesthetic regimes stabilise or challenge organisational norms; ii) ethical and responsible organising aimed at exploring how aesthetic design can support inclusion, diversity, and sustainability (Ivanaj et al., 2018; Ricciardelli et al., 2024); iii) measurement and operationalisation aimed to developing reliable instruments to capture the multidimensional nature of aesthetic organizational experience; iv) digital and hybrid work aesthetics aimed at analysing how technology mediates sensory experience and power relations; v) cross-cultural perspectives aimed at comparing aesthetic sensibilities and practices across cultural contexts to enrich theoretical and practical understanding.

This research shows that organisational aesthetics has matured into a distinct, interdisciplinary, and methodologically diverse field, with expanding theoretical depth and global reach. It highlights that aesthetics is not only about beauty or design but about how organisations feel, look, and make sense of themselves through

sensory and material experiences. For practitioners, this perspective offers valuable insights into how aesthetic awareness can enhance leadership, engagement, and well-being, particularly in digitally mediated work contexts. For scholars, it sets the stage for a new generation of studies that treat aesthetics as a core organisational capability and ethical responsibility, essential for reimagining organisations as human-centred, creative, and regenerative spaces.

7 Ethics Declaration

The research was conducted in accordance with relevant ethical guidelines and principles and official approval was not required.

8 AI Declaration

Artificial Intelligence assistance was used for linguistic proofreading and improvement of English readability. No AI-generated content, ideas, or analysis were included in the scientific development of the paper.

AI-Mediated Knowledge Curation in Platform-Based E-Commerce

Stefano Allega, Daniele Allega, Sara El Matouk, Giovanni Spatola
Universitas Mercatorum, Rome, Italy

Abstract

Digital platforms have become entrepreneurial infrastructures rather than simple marketing channels. For start-ups and small and medium-sized enterprises operating in platform-based e-commerce, social media content, online product reviews and customer-service chat transcripts form a distributed textual environment through which opportunities, risks and customer expectations are continuously signalled. This paper develops a conceptual and methodological framework for understanding how artificial intelligence mediates the curation of these multi-source textual assets. The study examines how digital transformation, new technologies and platform dependency reshape entrepreneurial behaviours and knowledge work. Drawing on digital entrepreneurship, the knowledge-based view, platform ecosystem research, the attention economy and emerging literature on AI-mediated knowledge work, the paper argues that AI-enabled analytics operate as a curation layer that extracts, ranks, synthesises and repurposes textual signals. This layer can improve opportunity recognition, experimentation and customer responsiveness, but it also generates a knowledge commoditisation paradox: the same processes that make entrepreneurial knowledge scalable and operationally useful may reduce contextual richness, increase dependency on platform intermediaries and deepen information asymmetries. The paper proposes a mixed-method research design combining semi-structured interviews, digital ethnography, topic modelling, sentiment analysis and intent classification. This design enables researchers to connect entrepreneurs' interpretive practices with the computational patterns found across social, review and support texts. The paper contributes to digital entrepreneurship by conceptualising multi-source text as entrepreneurial knowledge infrastructure; to organisational learning by clarifying how AI-mediated curation converts feedback into routines; to platform economy scholarship by linking visibility, reputation and data access to knowledge governance; and to AI governance by identifying validation routines for trustworthy curation. Managerially, the framework supports SMEs, consultants and platform managers in developing auditable, cross-source and human-accountable knowledge routines. It also suggests policy directions concerning fake reviews, sustainability claims, data portability and platform transparency.

Keywords: Entrepreneurship; Digital Transformation; Entrepreneurial Behaviours; Knowledge Curation; Digital Platforms

Paper type: Academic Research Paper

1 Introduction

Entrepreneurship increasingly occurs inside digital environments in which platforms organise attention, transaction, reputation and learning. E-commerce marketplaces, social media applications and customer-service tools do not merely help firms sell products. They structure what potential customers see, what entrepreneurs can measure, how trust is produced and how quickly a young venture can learn from the market. For start-ups and small and medium-sized enterprises (SMEs), this shift is both enabling and constraining. Platforms reduce entry barriers by providing ready-made infrastructures for discovery, payments, fulfilment and communication. At the same time, they create dependence on algorithmic visibility, platform rules and data-access conditions that entrepreneurs often cannot control.

This paper examines one specific but central dimension of that transformation: AI-mediated knowledge curation in platform-based e-commerce. The empirical phenomenon motivating the paper is simple. Entrepreneurs now face a continuous flow of textual signals distributed across social media comments, influencer posts, online reviews, marketplace questions, chatbot transcripts, complaint messages and product-return explanations. These signals contain knowledge about customer preferences, unmet needs, perceived quality, delivery problems, sustainability expectations, pricing sensitivity and competitor positioning. However, they are noisy, fragmented and unevenly accessible. Artificial intelligence (AI) tools are therefore increasingly used to classify, summarise, rank and transform these texts into actionable insights.

The paper argues that AI-mediated curation should not be understood as a purely technical support activity. It is a knowledge process that shapes entrepreneurial behaviour. When AI systems decide which complaints are urgent, which review themes matter, which social posts indicate emerging demand and which customer-service conversations should be escalated, they influence opportunity recognition, experimentation and resource allocation. They also influence the language through which entrepreneurs describe their markets. Knowledge becomes scalable, but it may also become standardised and detached from the context in which it was produced.

The study therefore asks: how does AI-mediated curation of platform-based textual data reshape entrepreneurial knowledge practices in e-commerce start-ups and SMEs? The paper answers this question conceptually and methodologically. It develops a framework that connects digital entrepreneurship, knowledge-based theory, platform ecosystem research and AI governance. It also proposes a mixed-method research design suitable for future empirical application.

2 Theoretical Background

Digital entrepreneurship refers to entrepreneurial action enabled, constrained or transformed by digital technologies (Nambisan, 2017; von Briel et al., 2018). Unlike traditional venture creation, digital entrepreneurship unfolds in environments where products, processes and market interactions are partly dematerialised. Boundaries between innovation, communication and distribution are blurred. Entrepreneurs can test a product story through a social media post before manufacturing at scale, use marketplace reviews as product-development input and adapt advertising messages through automated analytics. Digital transformation therefore changes not only the tools available to entrepreneurs but also the temporal rhythm and evidentiary basis of entrepreneurial decision-making (Vial, 2019).

Within this environment, knowledge becomes a strategic asset. The knowledge-based view sees firms as institutions for integrating and applying knowledge (Grant, 1996; Kogut and Zander, 1992). Entrepreneurial firms are especially dependent on knowledge because they operate under uncertainty and limited resources. They must interpret weak signals faster than larger competitors while avoiding premature conclusions based on incomplete data. Organisational learning literature further shows that firms transform experience into routines, but those routines can either enable adaptation or lock organisations into narrow interpretations (Cohen and Levinthal, 1990; Nonaka, 1994).

Platform-based e-commerce intensifies this challenge. Platforms act as multi-sided markets that coordinate interactions between sellers, buyers, advertisers, reviewers, logistics providers and service partners (Parker et al., 2016; Gawer, 2021). They also control important conditions of visibility and data access. Entrepreneurial knowledge is therefore not produced in a neutral environment. It is mediated by ranking systems, review architectures, recommendation algorithms, moderation rules and dashboard metrics. A complaint that becomes visible in a review section may shape reputation more strongly than an equivalent complaint expressed privately. A trend detected by a social media algorithm may be amplified because the platform itself rewards certain forms of engagement.

Recent work on AI and knowledge work suggests that machine learning systems increasingly perform tasks that were previously reserved for human analysts, including classification, summarisation, prediction and recommendation (Davenport and Ronanki, 2018; Raisch and Krakowski, 2021). These systems can increase analytical capacity, especially for SMEs that lack large research departments. Yet AI also creates problems of opacity, bias, explainability and accountability (Pasquale, 2015; Floridi and Cowls, 2019). In entrepreneurial contexts, these risks are amplified because decisions are fast, resources are scarce and validation routines may be informal.

The concept of the knowledge commoditisation paradox is useful here. Prior work by Allega and Puzio (2025a) argues that AI-driven value extraction can make knowledge more operationally useful while simultaneously reducing its contextual richness and concentrating power in those who control infrastructures for extraction. This paper transfers that insight from information-intensive organisations to platform-based e-commerce. The same AI routines that help entrepreneurs convert dispersed feedback into decisions may also flatten ambiguity, privilege measurable signals and deepen dependence on platforms and software providers.

3 Conceptual Framework

The proposed framework treats platform-based textual data as entrepreneurial knowledge infrastructure. Infrastructure is not visible only when it fails; it is the background system that enables action. In e-commerce, customer reviews, social media conversations and support transcripts are part of the knowledge infrastructure because they provide recurring evidence about market needs and venture performance. They are not raw truth. They are situated expressions shaped by platform design, customer expectations, cultural norms and strategic behaviour by competitors or influencers.

AI-mediated curation is defined here as the use of computational systems to select, classify, rank, summarise and repurpose textual signals for entrepreneurial decision-making. The definition emphasises mediation because AI does not simply reveal knowledge that already exists. It organises signals according to categories, thresholds and optimisation objectives. For example, an intent-classification model may divide customer messages into delivery, defect, refund and product-use categories. A topic model may group reviews into

themes such as sizing, packaging, durability or sustainability. A generative system may summarise hundreds of comments into a short report. In each case, the system changes the form in which knowledge becomes available.

The framework contains four interacting layers. The first layer is the platform signal layer, which includes social media posts, comments, marketplace reviews, ratings, questions and customer-service conversations. The second layer is the AI curation layer, which performs filtering, classification, sentiment analysis, clustering, summarisation and anomaly detection. The third layer is the entrepreneurial interpretation layer, where founders, managers and employees evaluate AI outputs in relation to strategy, identity, resources and tacit knowledge. The fourth layer is the action and learning layer, where curated insights are converted into product changes, communication choices, pricing experiments, service routines and governance practices.

The key claim is that entrepreneurial value emerges when these layers are connected through validation routines. AI curation without interpretation risks becoming automated noise reduction. Human interpretation without computational support risks being overwhelmed by volume and fragmentation. Learning occurs when entrepreneurs compare AI outputs with lived experience, inspect contradictory evidence, revisit categories and document the decisions that follow. This means that the quality of AI-mediated curation should be assessed not only by technical accuracy but also by its contribution to reflexive entrepreneurial learning.

Three propositions follow. First, AI-mediated curation improves opportunity recognition when it integrates multiple textual sources rather than relying on a single platform metric. Second, AI-mediated curation strengthens entrepreneurial experimentation when outputs are connected to explicit learning routines, such as hypothesis logs or post-experiment reviews. Third, AI-mediated curation increases the risk of knowledge commoditisation when categories, data access and model outputs are controlled by external platforms without transparency or portability.

4 Research Design

The paper proposes a mixed-method design that can be applied to start-ups and SMEs operating in platform-based e-commerce. The design combines qualitative interpretation with computational text analysis. This combination is appropriate because the research object is both social and technical. Entrepreneurial behaviour cannot be inferred from text-mining outputs alone, while interviews alone cannot capture the scale and patterning of digital textual environments.

The qualitative component would include semi-structured interviews with founders, marketing managers, customer-service employees and external consultants. Interviews would explore how firms collect textual data, which AI tools they use, how they validate outputs, how decisions are documented and how platform dependency is perceived. Digital ethnography would complement interviews by observing dashboards, workflows, review-management practices and communication routines. This element is important because entrepreneurs may describe their practices differently from how work is actually organised under time pressure.

The computational component would analyse three families of text: social media content, online reviews and support conversations. Topic modelling can identify recurrent themes across large volumes of text. Sentiment analysis can estimate the emotional direction of customer evaluations, while recognising that sentiment should be treated as an imperfect indicator rather than as an objective measure. Intent classification can distinguish between requests for information, complaints, praise, suggestions and purchase hesitation. Where possible, computational outputs should be compared across platforms to identify whether a theme is platform-specific or genuinely cross-source.

The two components are integrated through iterative comparison. Interview findings inform the categories used in text analysis, and computational results generate questions for follow-up interviews. For example, if topic modelling shows that packaging is a recurrent issue in reviews but entrepreneurs do not mention it as a strategic concern, researchers can investigate whether the signal is ignored, already solved or considered irrelevant. If support transcripts show repeated confusion about product use, but social media content is positive, researchers can examine whether public reputation hides private friction.

Sampling should focus on SMEs and start-ups that sell through at least one digital platform and use at least one AI-enabled tool for analytics, customer support or content management. Cases should vary by sector, firm age, platform dependency and internal analytical capacity. This variation would allow researchers to compare firms that rely almost entirely on external dashboards with firms that build their own cross-source knowledge routines. Ethical safeguards are necessary because customer texts may include personal data, complaints or commercially sensitive information. Anonymisation, access control and clear consent procedures should be incorporated from the beginning of the study.

Table 1: Proposed research design and analytical purpose

Research element	Main data or activity	Analytical purpose
Semi-structured interviews	Founders, managers, customer-service staff and consultants	Understand decision routines, validation practices and perceived platform dependency
Digital ethnography	Dashboards, review workflows and AI-enabled support tools	Observe how curated outputs are embedded in everyday entrepreneurial work
Text analysis	Social media comments, online reviews and support transcripts	Identify topics, sentiment, intent and cross-source patterns
Iterative integration	Comparison between interview themes and computational outputs	Connect human interpretation with machine-readable patterns and contradictions

The table summarises the research design. It is intended to remain editable in the submitted document and to support comparison between human interpretation and computational analysis.

5 Analytical Dimensions and Expected Findings

The framework suggests five analytical dimensions for studying AI-mediated knowledge curation.

The first is source diversity. Entrepreneurial knowledge is stronger when firms compare multiple sources rather than privileging the most visible metric. A high rating on a marketplace may coexist with repeated support complaints. Social media enthusiasm may not translate into repeat purchase. Cross-source comparison protects entrepreneurs from over-learning from a single platform environment.

The second dimension is interpretive ownership. AI systems can generate summaries, but entrepreneurs must decide what those summaries mean for the venture. Interpretive ownership exists when teams understand the categories used by their tools, can challenge outputs and can connect findings to strategic choices. Without this ownership, AI becomes an external authority rather than a learning aid. This risk is especially relevant for SMEs that purchase packaged analytics tools but lack the expertise to inspect their assumptions.

The third dimension is temporal responsiveness. Digital platforms accelerate feedback cycles. Entrepreneurs can detect reactions soon after a campaign, product launch or service failure. AI can increase responsiveness by highlighting anomalies and emerging themes. However, speed can also encourage reactive behaviour. A sudden increase in negative comments may reflect a genuine quality problem, a logistics delay, a viral misunderstanding or coordinated manipulation. Responsiveness must therefore be balanced by verification.

The fourth dimension is platform dependency. Many AI-curated insights are produced from data that entrepreneurs access through platform interfaces. If platforms change their ranking rules, restrict data exports or alter review visibility, firms may lose part of their knowledge base. Dependency is not only commercial; it is epistemic. Entrepreneurs may come to understand their customers through the categories made available by platforms. This can narrow strategic imagination and reinforce short-term optimisation.

The fifth dimension is accountability. AI-mediated curation can influence product design, advertising claims, customer treatment and resource allocation. Firms therefore need routines for documenting how outputs are used. Accountability does not require every entrepreneur to become a data scientist. It requires clear responsibility for data quality, model limitations, human review and decision traceability. Prior research on community feedback and trustworthy AI systems (Allega and Puzio, 2025b; Allega and Puzio, 2025c) is relevant because it shows the importance of preserving disagreement and uncertainty rather than converting all feedback into a single authoritative score.

6 Practical implications

For entrepreneurs and SME managers, the paper suggests that AI-mediated curation should be designed as a learning routine rather than as a dashboard feature. A practical routine may begin with mapping all available textual sources, including public reviews, private support messages, social comments and return explanations. Firms can then define a limited set of decision categories, such as product improvement, service failure, communication clarity, pricing concern and opportunity signal. The aim is not to automate all interpretation, but to make interpretation more systematic.

Second, SMEs should use cross-source validation. A theme should be treated as strategically important when it appears across several sources or when it is strongly connected to a critical business objective. For example, a sustainability claim that generates positive social engagement but sceptical reviews may require evidence-based clarification before being amplified. A packaging complaint that appears in support transcripts and reviews may deserve operational attention even if average ratings remain high.

Third, entrepreneurs should maintain human accountability for AI outputs. Teams can create short decision logs indicating what the AI system suggested, what evidence was inspected, what action was taken and what result followed. This practice is simple but powerful. It transforms AI from a black-box recommendation engine into part of an organisational memory. It also supports future auditing if decisions are challenged by customers, partners or regulators.

Fourth, consultants, accountants and digital advisors serving SMEs can play an important role. Many small firms do not have internal data governance expertise. Advisors can help entrepreneurs choose tools, define categories, document processes and avoid over-reliance on platform dashboards. This is consistent with the broader role of knowledge professionals in supporting digital transformation among SMEs.

Finally, platform managers and policymakers should recognise that data access and transparency affect entrepreneurial knowledge. Review authenticity, data portability, explainable ranking changes and access to historical performance data are not only technical issues. They shape the ability of SMEs to learn, compete and innovate. Policies that support fair access to platform-generated knowledge can therefore contribute to a healthier entrepreneurial ecosystem.

7 Discussion

The central insight of the paper is that AI-mediated knowledge curation is an entrepreneurial capability. It combines technological tools, interpretive judgement and governance routines. This perspective moves beyond two common simplifications. The first simplification is technological optimism, which treats AI analytics as a straightforward solution to information overload. The second is technological pessimism, which treats AI as necessarily alienating or manipulative. The more useful position is relational: AI becomes valuable or harmful depending on how it is embedded in entrepreneurial practice.

The framework also clarifies how the knowledge commoditisation paradox operates in platform-based e-commerce. AI systems make knowledge more mobile, comparable and operational. A founder can receive a summary of thousands of comments in minutes. A marketing manager can compare sentiment across channels. A customer-service team can identify recurring problems. These are real benefits. Yet the same processes may detach signals from context. Sarcasm, cultural references, platform-specific norms and minority concerns can disappear in aggregated summaries. What is easy to count may dominate what is strategically important.

For theory, the paper contributes to digital entrepreneurship by showing that entrepreneurial opportunity is increasingly mediated by textual infrastructures and AI categorisation. It contributes to the knowledge-based view by identifying curation as a mechanism through which dispersed external knowledge is transformed into internal routines. It contributes to platform ecosystem research by emphasising epistemic dependency: platforms do not only mediate transactions but also mediate what entrepreneurs can know. It contributes to AI governance by bringing accountability and validation into the everyday practices of SMEs, rather than treating governance as a concern only for large technology firms.

The paper has limitations. It is conceptual and methodological rather than empirical. Its propositions require testing across sectors and countries. E-commerce SMEs differ in their analytical maturity, customer base, regulation and dependence on platforms. Future research should examine longitudinal cases to understand how curation routines evolve as firms grow. Comparative studies could also examine whether platform-native ventures behave differently from traditional SMEs undergoing digital transformation.

8 Conclusions

This paper developed a framework for understanding AI-mediated knowledge curation in platform-based e-commerce. It argued that social media content, online reviews and customer-service conversations form a distributed knowledge infrastructure for start-ups and SMEs. AI tools can help entrepreneurs extract and organise signals from this infrastructure, supporting opportunity recognition, experimentation and responsiveness. However, these tools also create risks of standardisation, opacity and platform dependency.

The proposed framework connects platform signals, AI curation, entrepreneurial interpretation and organisational learning. Its main practical message is that entrepreneurs should not delegate knowledge work to AI systems. They should build accountable routines that combine computational scale with human judgement. The main theoretical message is that digital entrepreneurship increasingly depends on the governance of knowledge flows, not only on access to technologies. New technologies matter most when they change what entrepreneurs notice, how they learn and how they act under uncertainty.

8 Acknowledgements

The authors acknowledge the intellectual continuity between this paper and prior research on AI-driven knowledge commoditisation, trustworthy artificial intelligence architectures and community feedback mechanisms. No external funding was received for the preparation of this paper.

9 Ethics Declaration

This paper is a conceptual and methodological academic research paper based on secondary literature and a proposed future research design. No primary data from human participants, customers or firms were collected for the preparation of this manuscript. Ethical clearance was therefore not required at this stage. Any future empirical implementation involving interviews, customer-service transcripts, social media data or online reviews should obtain appropriate institutional approval, informed consent where applicable, anonymise personal data and comply with relevant data-protection rules.

10 AI Declaration

AI tools were used to support language drafting, structural editing and formatting of this manuscript. The authors reviewed, selected, revised and verified the resulting material, remain fully responsible for the scholarly content, and confirm that AI-generated text was not used as a substitute for authorial judgement, source evaluation or ethical accountability.

Smart Healthy Cities Advancing

Mauro Romanelli
University of Naples Parthenope, Napoli, Italy

Abstract

Cities are adopting a smart city strategy in order to support and improve smart urban health to achieve better quality of life within smart healthy urban communities. Cities are rediscovering the smart urban health as a driver of urban growth and innovation. Cities are going into the future, encouraging urban stakeholders' engagement and collaboration, and embracing a smart city mind set and urban health view to urban value creation. The study aims to elucidate how the European cities are rethinking on the future of urban communities, adopting a smart view and focusing on urban health to improve the wealth of urban communities. The study relies on qualitative research analysis. The research analyzes two case studies drawn from policy documents related to European cities that are rethinking on future design of the city, and planning a smart view to urban growth, leading to smart health as a driver of urban innovation. Brussels and Wien have designed a smart healthy city strategy, promoting urban health, and driving smart urban innovation. Smart urban health planning helps shape sustainable and wealthy cities, leading to responsible urban innovation and sustainable growth, supporting multi-actor collaborative innovation, and focusing on community development. Smart urban health and innovation support collaborative spaces in order to drive smart and responsible urban innovation. Introducing the smart urban health view within urban planning is enriching the approach to smart city vision, enabling the smart mind set as a way to design and implement organizational and collaborative spaces for innovation. Driving smart urban health refers to collaborative frameworks that involve a variety of urban stakeholders and actors that contribute to shaping the city a smart innovative community which is able to contribute to sustainable growth and social innovation. The smart city vision supports a collaborative platform that enhances smart health, leading to social innovation within urban communities.

Keywords: smart city, smart health, healthy city, urban innovation.

Paper type: Academic Research Paper

1 Introduction

Today, cities are designing smart city plans to drive responsible urban innovation, leading to *more than human* and post-anthropocentric healthy cities (Kocak and Sancaktutan, 2025), generating desired outcomes for humans and nonhumans (Yigitcanlar, 2018; Yigitcanlar *et al.*, 2021), meeting urban healthcare as a grand societal challenge (Voegtlin, Scherer, Stahl and Hawn, 2022; Agarwal *et al.*, 2025), and empowering healthcare innovation, leading to high wellbeing of citizens (Alves *et al.*, 2025), and supporting collaborative frameworks for quality of life improvement (Mora *et al.*, 2023; Yigitcanlar *et al.*, 2021).

Smart cities contribute to supporting community wellbeing (Thompson *et al.*, 2023), empowering the e-health in order to improve public health, bridging digital technologies and business (Eysenbach, 2001).

A healthy city improves its environments and expands its resources, supporting people empowerment and engagement, achieving their highest potential (WHO, 2022). With more than 50 percent of people living in cities, providing services-solutions to make the city wealthy and innovative, healthy and sustainable relies on smart city development to improve urban health innovation, wellbeing and quality of life, leading to collaborative approaches (Thompson *et al.*, 2023; Meijer and Bolivar, 2016).

As organizational spaces (Knox, 2010), net action (Czarniawska, 2002), cities are rethinking on smart city urban planning towards truly smart urban healthy system of systems, doing good, leading to responsible urban innovation, towards an organised maturity through open health services and platforms that enable positive freedoms (Lee *et al.*, 2014; Yigitcanlar, 2018; Scherer, Neesham, Schoeneborn and Scholz, 2023).

Urban health matters critically, whereas smart mind set helps improve urban health innovation and ubiquitous services for citizen wellbeing, quality of life, safety, and nature friendliness, following a collaborative model (Sapienza *et al.*, 2022; Ji *et al.*, 2021; Meijer and Bolivar, 2016).

Smart and healthy cities rely on using technology, community and policy as key drivers for responsible urban health management, design and deployment, city operational design and innovation, leading to equitable and living cities, focusing on wellbeing and healthcare issues and benefits (Trencher and Karvonen, 2019; Yigitcanlar *et al.*, 2021; Jahroh *et al.*, 2025).

Still few studies focus on smart urban health planning and responsible innovation (Solanas *et al.*, 2014). How do cities aim at planning smart and healthy cities? How smart city view helps support smart healthy city and responsible urban innovation? This study aims to elucidate how cities and municipalities of Brussels and Wien

are dealing with urban health management and innovation, adopting a smart city plan. After the introduction, the theoretical background relates to smart and healthy cities that contribute to responsible urban innovation. Methodological section follows in the third section. Findings are presented in the fourth section. Finally, discussion and conclusions are outlined.

2 Smart and Healthy Cities for Responsible Urban Innovation

Smart healthy cities contribute to digital urban ecosystems for wealth and wellbeing, empowering open and collaborative ways for health services innovation to improve healthy human and urban life (Paskaleva, Evans and Watson, 2021), leading to sustainable healthy development through technology- community-policy drivers (Yigitcanlar and Cugurullo, 2020).

Smart city is a healthy system of systems which is able to generate desired outcomes and futures for all humans-and-non-humans (Yigitcanlar, 2018). Smart city development leads to quality of life, supporting community integration, relying on environmental and healthy wellbeing (Macke *et al.*, 2018), fostering collaboration among technology developers, healthcare providers and policymakers to create an inclusive healthcare system (Agarwal *et al.*, 2025). Smart city improves healthcare as a critical infrastructure (Washburn *et al.*, 2010).

Smart health aims to promote high position of health within society, augmenting mobile health with sensing capabilities of smart city, leading to a convergent ubiquitous health paradigm (Solanas *et al.*, 2014). Healthy smart cities provide an urban healthy place for citizen engagement and cooperation (Kocak and Sancaktutan, 2025) in order to reduce the impact of pollution, carbon emission, waste and heat, improving human health. Healthy city is a system of health sectors (Ziafati, Bafarasati and Sharifi, 2024), improving health equity and well-being, and meeting urban health as grand societal challenge and driver (Vardoulakis and Kinney, 2019).

Smart city vision and implementation should develop as responsible urban innovation, leading to trustworthy healthcare innovation and technology for users' care acceptance, aligning technology with societal and human values within urban communities (Li *et al.*, 2023).

Cities aim at planning smart city progressive cities, dealing with social challenges, and shaping urban collaborative ecosystems for responsible innovation (Mora *et al.*, 2023), leading to a smart community that enables a *continuum* of public-private actors which combine technology and policy, and shape the urban community, improving social and healthcare services, and leading to responsible urban health innovation (Gil-Garcia, Pardo and Nam, 2015; Meijer and Bolivar, 2016; Voegtlin, Scherer, Stahl and Hawn, 2022).

A smart healthy city aims at combining technology, policy and community-driven sources to provide innovative as well as collaborative initiatives that contribute to engendering and improving health care services that benefit urban ecosystems.

Rethinking on the urban planning following a smart city view helps shape smart responsible, healthy and sustainable cities (Yigitcanlar, 2018), following a socio-technical and collaborative view (Meijer and Thaens, 2018), meeting the health needs of urban communities, tackling social challenges, focusing on collaborative frameworks and community engagement for urban health innovation and wellbeing (Trencher and Karvonen, 2019).

Smart healthy cities rely on collaborative and community-driven platforms that support urban stakeholder communication, providing digital solutions for quality of life, health and wellbeing improvement, embedding health smart city model for smart healthy and wealthy communities (Mora, Deakin and Reid, 2019; Mouton *et al.*, 2019).

3 Methodological Section

The study has employed a qualitative and descriptive methodology. Brussels and Wien have clearly identified a smart city planning to make a smart healthy city. Rethinking smart healthy responsible urban innovation leads to *smart and healthy more than human* cities, and relies on information sources collection drawn by city planning to track the pathway towards a smart innovative responsible city (Yigitcanlar, 2018; Cristiano and Zilio, 2021; Thompson *et al.*, 2023; Sancino and Hudson, 2020). The study focuses on two illustrative and comparative case studies to explore a comprehensive understanding of a phenomenon still in progress, emerging in contemporary times, whereas the boundaries between the phenomenon and the context are not clearly evident following a case study methodology through an empirical inquiry without the rigidity of a predefined structure for observations and analysis (Yin, 2009). The research methods involved case selection and data collection from policy documents (*Smart Climate City Strategy Vienna; Smart City Strategy of the City of Brussels*).

4 Findings

The *Smart City Strategy of the City of Brussels* frames urban development around the integration of digital innovation, sustainability, and citizen well-being, positioning smart urban health as a central pillar of its broader vision. The strategy adopts a holistic understanding of health that extends beyond healthcare services to encompass environmental quality, social inclusion, mobility, and digital accessibility. In this sense, Brussels aligns with the principles of the *Healthy City* approach, which emphasizes the social determinants of health, equitable access to resources, and the creation of environments that support physical, mental, and social well-being.

Within the strategy, smart urban health is conceptualized as the use of data, digital tools, and intelligent infrastructures to monitor, understand, and improve the health of the urban population. This includes the deployment of sensors to track air quality, noise levels, and urban heat; the use of open data platforms to support evidence-based policymaking; and the promotion of digital health services that enhance accessibility and efficiency. The city also prioritizes active mobility, green spaces, and sustainable transport systems, recognizing their direct impact on public health and quality of life. The Healthy City dimension is reflected in Brussels' commitment to equity, participation, and social cohesion. The strategy highlights the need to reduce health disparities by ensuring that technological innovation benefits all residents, including vulnerable groups. Citizen participation is encouraged through co-creation platforms, digital engagement tools, and community-based initiatives that allow residents to contribute to decision-making processes. This participatory governance model reinforces the idea that health is a shared responsibility shaped by collective action. By integrating the Healthy City framework with smart technologies, Brussels advances toward a *Smart Healthy City* model. This hybrid approach leverages digital innovation not as an end in itself but as a means to enhance well-being, sustainability, and inclusiveness. The strategy positions Brussels as a city where technology supports healthier lifestyles, more resilient environments, and a governance system that is transparent, collaborative, and oriented toward long-term public value.

A healthy city adopts the ambitions of the 2030 Energy-Climate Plan and reduces its total energy consumption and its greenhouse gas emissions, in particular by focusing on the production of renewable energy, and puts the health of its inhabitants first, by improving the quality of the air in the city and by combatting noise pollution in public spaces and residential areas. The Smart City strategy contributes to improving waste management and the cleanliness of public spaces through digital technologies and data analysis; managing exemplary buildings by exploiting new technologies for the recovery of primary energy resources, by providing monitoring tools to objectify and improve the reduction of energy and water consumption in the territory, and by promoting the energy management of municipal buildings, integrating sustainable development into the city's processes by developing the capacity to continuously monitor the territory, using technologies to make urban spaces greener and friendly for biodiversity.

The *Smart Climate City Strategy of Vienna* positions health, well-being, and climate resilience as central pillars of the city's long-term urban transformation, integrating the principles of *smart urban health* and the *Healthy City* approach into a comprehensive framework that links climate action, digital innovation, and social equity. Vienna's vision recognizes that urban health is shaped by both healthcare systems and environmental quality, mobility patterns, housing conditions, and social cohesion. *Smart urban health* relies on using data, digital tools, and intelligent infrastructures to monitor and improve environmental and health-related indicators, deploying sensor networks to track air quality, noise pollution, heat stress, and mobility flows, enabling evidence-based interventions that enhance public health. Digital platforms and open data systems support transparency and allow policymakers, researchers, and citizens to access real-time information. Vienna also promotes digital health services, telemedicine, and smart care solutions to improve accessibility and efficiency, particularly for vulnerable populations. The ambition and aims of a smart city plan is to safeguard health's interests and wellbeing of people, helping shape safe and clean urban environments that minimize waste and reduce water and soil pollution, noise and heat pollution as far as possible. Smart city framework relies on promoting health and social inclusion by supporting policies that contribute to improving the health of urban community and residents, so achieving and meeting social and health goals, and helping Vienna's healthcare sector to contribute significantly to decarbonisation, focusing strongly on sustainable urban development issues, improving urban health as social innovation, and digital and social inclusion, whereas urban health system improvement is leading to local economic development too. Vienna advances toward a *Smart Healthy City* model merging climate action, digital innovation, and health-oriented urban planning, reducing emissions, expanding green infrastructure, and improving energy efficiency directly enhance public well-being. Technology is as a means to create a resilient, inclusive, and health-promoting urban environment. *Smart Climate City Strategy* demonstrates how cities can integrate smart technologies with social and environmental policies to support healthier, more sustainable, and more equitable urban futures.

5 Discussion and Conclusions

The European cities are planning smart urban health for quality of life improvement, leading to smart responsible and healthy urban communities, engines of innovation and collaborative open spaces. Smart city vision develops the city of the future and supports responsible innovation to achieve sustainable urban, leading to healthy and safe urban environments. Smart urban health planning helps to shape sustainable and wealthy cities. Advancing smart urban health helps drive responsible urban innovation and sustainable urban growth, leading to multi-actor collaborative innovation, focusing on community development, leading to smart city as a platform for responsible collaborative innovation. The Wien smart vision relies on the role of technology to support inclusive healthy and wealthy smart urban ecosystems by enhancing co-participation, and strengthening co-decision-making for urban responsible innovation and sustainable growth, meeting grand urban challenges, dealing with climate change and pollution issues. The city and the municipality of Brussels aims at embedding both health and smart vision in the urban planning, looking at the goal of sustainable and more than human city, fostering a collaborative and inclusive approach in order to shape urban meeting places for urban health and value creation. Cities are planning a smart city design to improve urban health and wellbeing of citizens, providing a community-led digital platform that helps shape wealthy urban communities, making a healthy responsible urban community, an engine of innovative services and approaches through healthcare, citizens and urban stakeholders. Smart city development relies on promoting responsible innovation by developing socially inclusive and open health urban ecosystems that enhance the interaction that concerns humans, technologies and community, leading to healthier cities on becoming intelligent cities. Cities are adopting a smart city vision in order to improve urban health competences and issues. The future and maturity of smart city development relies on embedding health care services and innovation within the smart city ecosystem, leading to a smart and healthy more-than-human community, and meeting urban health, a grand societal opportunity, and combining technology, smart city policy and community to make smart urban health a responsible innovation, and develop both a mind set and way leading to wealthy urban ecosystems.

Cultural Organizations and Young Audiences: A Collaborative View through Artificial Intelligence

Mauro Romanelli[1], Alexandra Zbuchea[2], Monica Bira[2]
[1] University of Naples Parthenope, Napoli, Italy
[2] National School of Political and Administrative Studies, Romania, Bucharest

Abstract

Cultural organizations are developing and implementing Artificial Intelligence (AI) and digital interactive technologies in order to improve cultural and social value production, meeting and engaging the young audiences in cultural heritage landscape. AI is increasingly shaping the strategies and operations of cultural organizations such as museums, galleries, libraries, and arts institutions. AI helps cultural organizations to improve the interaction with young people who act as agents of cultural heritage. AI helps enable cultural and heritage institutions and organizations as collaborative spaces that function as socio technical environments where communities, professionals, and technologies interact to co-create cultural value. AI supports cultural organizations to shape cultural heritage environments as collaborative spaces and meeting places for social innovation development. AI aims to facilitate collaborative interpretation and contribute to cultural knowledge. The study aims at investigating the relationships between cultural organizations, artificial intelligence and young audiences. AI supports cultural heritage sites as collaborative spaces for social innovation. AI helps drive cultural organizations to play a significant role in cultural value and knowledge creation, acting as agents of social change and value. Engaging young audiences in becoming proactive actors who contribute to social value creation within cultural heritage ecosystems supports social and technological innovation within cultural organizations that are rediscovering new sources and energies in order to behave as social value-driven and knowledge-led intelligent organizations that contribute to public value and better quality of life, driving social change within communities. The challenge of cultural organizations is to use AI to engage young people and make them proactive actors and responsible co-producers of social and cultural value. Cultural organizations enable youth to shape narratives and contribute to increasing the youth engagement, positioning themselves as platforms of social exchange and dialogue, enabling cultural heritage sites as digital and onsite meeting collaborative places that contribute to supporting cultural value creation.

Keywords: artificial intelligence, cultural organizations, collaborative spaces.

Paper type: Academic Research Paper

1 Introduction

Digital interactive technologies and Artificial Intelligence (AI) are leading museums and cultural organizations into the future. Cultural organizations are providing new services and facilities that contribute to meeting young audiences, enriching the experiences of visitors, and restructuring processes within the cultural organizations' landscape, by developing, using and implementing AI within cultural heritage.

AI is providing significant opportunities for cultural organizations which aim to innovate and expand their reach. AI-driven tools are expanding how cultural organizations interact with audiences. The growing integration of AI within processes and strategies of cultural organizations and museums is reshaping how institutions curate, interpret, and communicate heritage, with particular implications for younger audiences, who increasingly expect digital interactivity, personalization, and participatory experiences. Cultural organizations are using AI to increasingly engage young audience. In particular, AI technologies exert influence on behaviors and lifestyles, trust and perceived authenticity of young persons (Lata and Rana, 2025; Bachnik et al., 2025; Chen et al., 2026). Engaging youth in the cultural heritage management processes helps preserve the transmission of heritage values, and supports the diversification of knowledge systems, leading to inclusive approaches in heritage management (Zhang, 2025). AI generative systems facilitate collaborative annotation, storytelling, and interpretation, enabling users with diverse backgrounds to contribute meaningfully to cultural knowledge.

AI refers to a broad set of digital technologies. AI facilitates the automation of existing processes hitherto carried out by other means (human labour, and other forms of calculation) (Caramiaux, 2023). On the other side, youth, aged between 15-24 are the decision-makers of the future and agents of cultural heritage (Zhang, 2025).

AI is transforming cultural organizations into responsive, data-driven, socially innovative and participatory ecosystems, particularly attractive to younger audiences who seek personalization, interactivity, and hybrid experiences. AI helps cultural organizations and audiences to experiment cultural heritage landscape as a meeting as well as collaborative and participatory space for innovation (Montanari, Mattarelli, and Scapolan, 2020; Capdevila, 2019; Zhang, 2025).

Few studies investigate the relationships between cultural organizations that introducing and implementing AI technologies and applications, and the young visitors and audiences. Few studies investigate how the interaction between AI and cultural organizations is opening to new opportunities of engendering collaborative spaces for innovation within the cultural heritage landscape.

The study is exploratory and qualitative. The aim of the study is to elucidate how cultural organizations are managing AI technologies and engaging new audiences, involving young visitors, rediscovering new sources, energies and capabilities, leading to collaborative spaces and innovation within cultural heritage environments.

The adoption of AI is driving broader organizational and social change and innovation. Cultural institutions are increasingly required to develop new skills and infrastructures, leading to the importance of interdisciplinary collaboration between technologists, curators, and policymakers, and overcoming the resistance to change and the lack of technical expertise as barriers that especially influence social performances of cultural organizations.

The study is organized as follows. After the introduction the theoretical background on the relationships between cultural organizations and AI with regards to collaborative spaces is presented. In the third paragraph the methodological section follows. The fourth section presents the relationship between AI, cultural organizations and the young audiences. Finally, discussion and conclusions are outlined.

2 Towards Collaborative Spaces through Cultural Organizations Managing Artificial Intelligence

Collaborative and open spaces provide meeting places for social interaction, enabling several actors to construct a pathway for social innovation and value creation (Montanari, Mattarelli, and Scapolan, 2020). Collaborative spaces support multi-actor and co-initiation of collaborative innovation processes (Sørensen and Torfing, 2018, and provide opportunities for the development of creative solutions through the collective knowledge and experience of actors that contribute to innovation genesis (Hartley, Sørensen and Torfing, 2013), leading to collaborative working practices and spaces (Yacoub and Hefliger, 2024), that enhance creative platforms (Capdevila, 2019), and foster openness, collaboration and knowledge sharing and skills (Boutillier *et al.*, 2020).

Participatory and collaborative spaces in cultural organizations are increasingly recognized as key infrastructures for enabling participatory innovation, collective knowledge production, and digitally augmented cultural engagement of youth, and supporting participatory approaches (Zhang, 2025). AI may play a significant role in augmenting the potential of cultural heritage environments as collaborative as well as meeting places for social exchange and new knowledge construction. In particular, the practices of cultural heritage practitioners, archivists, and librarians rely on collaboration and cooperative practices. They jointly contribute to generating an intelligence which is artificial by sense making what they interpret in their collections (Caramiaux, 2023).

Technology enables collaboration between users and cultural context (Giugliano and Laudante, 2020). Recent scholarship emphasizes the relationship between co-creation and participatory initiatives as improved by the use of AI with regards to young visitors' experiences. Engaging and involving the young visitors through AI within cultural heritage value creation is opening new ways to make cultural heritage ecosystems as collaborative as well as participatory meeting places for innovation. AI helps explore collaborative design methods to achieve human-computer interaction and improve cultural landscape design (Tang, Zheng, Chen, Yan and Chen, 2024). Emerging AI digital technologies contribute to promoting the development of participation, and creating new opportunities for young people who engage in various digitally mediated activities, offering new spaces for empowering the voices of young people, and providing new spaces of dialogue, sense making, knowledge and information exchange, and social value. AI supports current heritage management practices, driving the young people to act as proactive co-producers and intelligent and aware agents of meaning construction, abandoning the actual position of merely users and passive recipients of heritage values (Zhang, 2025). AI helps enable cultural and heritage institutions and organizations to shape collaborative spaces that function as socio technical environments where communities, professionals, and technologies interact to co create cultural value (Simon, 2010). AI can facilitate such participation by analyzing user-generated content, clustering themes, or generating adaptive displays that reflect collective contributions. Moreover, AI supports institutional decision-making by analyzing visitor flows, sentiment, and engagement patterns, enabling museums to design youth-centered strategies grounded in empirical evidence (Bonacini and Giaccone, 2022).

3 Methodological Section

The study employed a qualitative, descriptive and exploratory methodology to analyse how the interplay between the AI technologies, cultural organization, and the audience, in particular, the young audiences and visitors enable the rise of collaborative as well as organisational spaces that contribute to improving the quality of visitors' experiences, and engendering new ways and practices of providing cultural heritage services, and

driving value creation through participatory as well as cooperative ways, leading to culture-led and creative-driven itineraries for value creation. The study is conceptual, exploratory and theoretical because the boundaries between cultural organizations, AI and the collaborative ways to organisational innovation within cultural heritage ecosystems are not yet defined in a satisfying way. Conceptual papers aim to propose new frameworks with regards to untested relationships among constructs, focusing on integration and association of logical arguments, without providing data (Gilson and Goldberg, 2015). The study refers to the analysis of articles related to the relationship between cultural organizations, AI and young audiences. The selected contributions are interpreted in a narrative synthesis to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods *et al.*, 2004).

4 Artificial Intelligence, Cultural Organizations and Young Audiences

The academic literature is increasingly concerned with how cultural organizations use digital technologies to improve their offerings and attract more customers. In parallel, the same technologies, including AI, are shaping new ways of cultural engagement, especially in the case of young persons, the digital-native ones. In the context of a relatively low interest in cultural consumption, the use of digital and AI technologies could make cultural organizations more appealing, including by offering new experiences.

Technology is credited as a factor of resilience in cultural sector (Wang and Huang, 2024). It contributes to diversification of the offer and even with systemic changes in the way culture is produced, distributed and consumed (Yordanova and Todorova, 2025). Adoption of digital and AI technologies is not simple, especially for cultural organizations due to various types of limits – budgetary, lack of expertise, willingness for change etc. Additionally, these changes are not always seen as positive considering various stakeholders.

Technological innovation takes many forms. Yordanova and Todorova (2025) identified nine main ones: Artificial Intelligence (AI), Robotics, Big Data, Virtual Reality (VR), Augmented Reality (AR), Digitalization, 3D Printing, Data Analytics, and the Internet of Things (IoT). Their analysis identified the most used ones as AI, digitalization and VR. These might be more common considering their direct positive impact both on cultural organizations and cultural consumption.

Especially the AI integration offers not only a technological improvement, but also a shift in how culture is created, mediated and experienced. Young audience, already more literate in terms of digital and AI technologies, are the primary beneficiaries and users of AI integrated into cultural organizations and cultural consumption. Even several years ago, AI – e.g. the chat bot – was credited with mediating heritage and engaging audiences (Gaia, Boiano and Borda, 2019). The developments in the field of generative AI have led to new ways of personalized and meaningful experience of heritage and culture (Trichopoulos, Ordoumpozanis and Caridakis, 2026).

AI is credited with significantly influencing both the consumption behaviour and the lifestyle of young persons, especially (Lata and Rana, 2025). For instance, the interest and support towards more sustainable behaviour among young people is related to increased use of AI. Young people tend to have a complex relationship with AI in terms of trust and perceived authenticity (Bachnik et al., 2025; Chen et al., 2026). Studies show that young people make a critical but imperfect effort to discern what is “real” and “authentic” when AI is involved. This means that cultural organizations have to be aware that young audiences are influenced by AI and open to it, but in the same time they can approach it with some caution and display selective trust. This means cultural organizations need to be transparent about AI use and intentional in framing authenticity related to it.

The perceived authenticity also influences emotional engagement (Tang, Dong and Cheng, 2025). Studies show that authenticity in AI-driven experiences is critical for memory retention and identity formation among young persons. Still, cultural characteristics and values influence the way humans related to AI-experiences and contribute to contextualizing the social and cultural impact (Shin, Al-Imamy and Hwang, 2022).

Cultural organizations could use AI in many ways to engage meaningfully the audience, especially the young one. Chat bots and conversational agents could contribute to personalized assistance and gamification (Iodice, Clemente and Bifulco, 2024). AI, in general, contributes to compelling storytelling, contributing to cultural inclusiveness, engagement, enhancing cultural inclusivenes, sensitivity and understanding (European Parliament, 2023; Lau, 2025; UNESCO, 2022; Wang and Zhang, 2026). AI can also be used to curate more appealing and relevant exhibitions, considering specific young audiences (Trichopoulos, Ordoumpozanis and Caridakis, 2026). AR and VR technologies enable immersive and multisensory experienced, enhance emotional perception as well as learning (Tsoukala et al., 2024; Xu et al., 2025).

AI has numerous implications in other aspects of cultural and heritage management, such as preservation of heritage, featuring both positive and negative aspects (Ghaith and Hutson, 2024). Considering its many advantages, for many cultural organizations, AI becomes a must in order to attract younger audiences (Vidu,

Zbuchea and Pinzaru, 2021), but also to contribute to more effective heritage and cultural management. Critical to its sustainable impact is, still, the establishment of ethical practices in this field.

5 Discussion and Conclusions

There is an increasing interest within cultural organization which are using AI and intelligent technologies to improve cultural services and engage the young audiences, and focus actions and policies to involve the young generations. Intelligent technologies are reshaping the relationships between cultural organizations and its social and cultural ecosystems, providing opportunities for cultural value creation, audience engagement, and organizational innovation. Cultural organizations take the opportunity of developing and implementing AI technologies in order to assume the responsibility to promote inclusivity and support the participation and the engagement of the audience in cultural value production. In particular, AI helps cultural organizations to engage more actively young visitors, enabling them to gather information and reflect on cultural heritage meaning and importance in order to support organizations and people to advance dealing with complexity, and promoting social issues.

Increasingly, advanced, digital and interactive information and communication technologies exert influence on social and organizational change within cultural organizations that aim at dealing with technology to drive organizational as well as strategic innovation. Moreover, unexplored territories for knowledge augmentation and learning are emerging whereas the intelligent technologies support processes of knowledge creation and sharing, and contribute to fostering the interaction and communication between audiences and the professionals at work within cultural organizations. AI technologies are entering into the cultural heritage field, opening new opportunities for building cultural collaborative spaces and engendering new authentic cultural value. Cultural organizations are becoming meeting places that empower cooperative efforts and energies, involving a variety of actors (human, collective, technological) that contribute to improving the visitors' experiences, and producing social and cultural value, leading to social innovation and inclusion issues.

There are social, managerial and organizational implications emerging from this preliminary investigation. Cultural organizations contribute to enhancing social value, and shaping proactive young visitors who rediscover the potential of bridging human capabilities and technological infrastructure. Introducing and implementing AI within cultural organizations' landscape enables management processes, redesigning organizational and human resources management policies. Making cultural heritage sites as collaborative meeting places for interaction between the audience and cultural organizations is opening new perspectives, and searching for management and organizational solutions.

The sustainable adoption of AI relies on balancing innovation with ethical responsibility, ensuring that AI enhances cultural understanding without compromising authenticity, inclusivity, or human agency. As cultural organizations continue to evolve, AI will likely play an increasingly central role in shaping how young people encounter, interpret, and co-create cultural heritage.

Cultural organizations are dealing with AI design and implementation in order to engage new audiences and restore the relationship with young visitors, leading to intelligent organizations which rely on knowledge-led sources and capabilities.

Future research perspective imply to explore long term AI impact, with regards to enhancing cultural diversity, and understanding the potential and the evolving role of human expertise in AI-supported environments. Research agenda relies on testing the perceptions of young visitors in using AI applications to manage the cultural heritage sources, and appreciate how cultural organizations are engaging them, meeting their needs and preferences.

Further research also aims to identify the trajectories of change and innovation provided by the impact of AI technologies within the organization of cultural institutions, leading to a variety of potential organizational solutions that contribute to value creation, and bridging social, organizational and technological infrastructures.

6 Ethics Declaration

I declare that any ethical clearance was required for the research.

7 AI Declaration

I declare that AI tools were not used to create this paper.

The Digital Platform as Cognitive Infrastructure: Investigating Human-AI Synergy and Algorithmic Governance in Investment Management

Paola Demartini, Alessandro Salvatori
Roma Tre University, Rome, Italy

Abstract

Over the past two decades, the financial sector has undergone a profound transformation, firmly positioning information as its primary competitive asset and placing Artificial Intelligence (AI) at the core of this shift. By interpreting diverse data volumes at speeds beyond human capacity, AI serves as a critical supportive technology. Within this landscape, digital platforms like BlackRock's Aladdin have emerged as essential cognitive infrastructures functioning as comprehensive operating systems for modern finance. These platforms seamlessly integrate the entire investment lifecycle into a unified data layer, reshaping organizational roles and business models by facilitating a vital interaction between human insight and algorithmic intelligence.

Despite AI's well-documented technical capabilities, a critical gap remains in understanding the socio-technical dynamics of this human-AI synergy within institutional settings. Current literature predominantly focuses on the predictive accuracy of "black box" models or macro-level regulatory frameworks, overlooking how professionals navigate daily trade-offs between algorithmic performance and explainability. Furthermore, there is limited empirical exploration of the modern financial analyst's "hybrid profile," which requires combining computational literacy with ethical sensitivity within established platform constraints.

To address this gap, this study investigates how digital investment platforms facilitate human-AI synergy while managing structural risks of algorithmic opacity and bias. Employing a qualitative, exploratory approach, the research utilizes semi-structured interviews with senior European Union professionals involved in investment products, digital financial advisory, platform delivery, and risk-related decision-making. The investigation focuses on integrating AI-driven insights into fundamental analysis, perceptions of algorithmic opacity, the EU AI Act's impact on governance, and platforms' role in standardizing information.

Preliminary findings indicate that rather than replacing human experience, AI fundamentally reconfigures it, shifting professional judgment toward problem definition, exception management, and robustness testing. Integrated platforms provide a "common data language" that aligns internal functions, significantly reducing manual errors and operational risk. However, a persistent tension exists between maximizing predictive power and maintaining the transparency demanded by the EU AI Act, which frames AI as a corporate governance issue rather than mere efficiency. Ultimately, the study highlights a "new responsibility pact" requiring auditable decision-making, while warning that "algorithmic convergence" through dominant platforms could dangerously amplify market volatility. Sustainable innovation requires these cognitive infrastructures to be supported by robust data governance.

Keywords: Digital Platform, investment decision, financial sector, BlackRock's Aladdin

Paper type: Academic Research

1 Introduction

Over the past two decades, the global financial sector has undergone a profound structural and epistemological transformation, firmly positioning information processing as its primary competitive asset (Varshney & Varshney, 2026). Within this highly complex and historically intermediated environment, Artificial Intelligence (AI) has emerged not merely as a supplementary tool for operational efficiency, but as a foundational "cognitive infrastructure" (Davenport et al., 2020). AI architectures are now capable of collecting, cleaning, connecting, and interpreting increasingly diverse volumes of both structured and unstructured data, offering insights and executing decisions at speeds that vastly exceed human cognitive capacity (Chen, Härdle, & Ong, 2021; Cao, 2024). This evolution marks a transition from simple digitalization—where physical infrastructure and paper-based systems were translated into digital formats—to an era of intelligent finance, where advanced algorithms dynamically estimate conditional probabilities and integrate textual, visual, and behavioral data into unified analytical pipelines (Arner, Barberis, & Buckley, 2016; Brynjolfsson & McAfee, 2017).

In this landscape, digital investment platforms have emerged as essential mechanisms that facilitate the critical interaction between human insight and algorithmic intelligence (FT, 2020). A preeminent manifestation of this shift is BlackRock's Aladdin platform, which functions as a comprehensive "operating system" for modern finance (BlackRock, 2024). Aladdin and similar platforms seamlessly integrate the entire investment lifecycle—

encompassing portfolio construction, trade execution, risk control, accounting, and regulatory reporting—into a unified, standardized data layer (Buehlmaier & Whited, 2023). As organizations strive for long-term sustainability and resilience in globalized capital markets, these technological platforms represent a new "operational language" that fundamentally reshapes professional roles, required skill sets, and institutional business models (FT, 2020).

Despite the extensive and well-documented technical capabilities of Artificial Intelligence in finance—such as its capacity for high-dimensional pattern recognition, non-linear forecasting, and anomaly detection (Ruff et al., 2021)—a critical gap persists in the academic literature regarding the socio-technical dynamics of this transformation. Current scholarship predominantly bifurcates into two distinct domains: technical evaluations focused on the predictive accuracy of specific "black box" machine learning models (Goodfellow, Bengio, & Courville, 2016), and macro-level legal analyses concentrated on regulatory frameworks, such as the European Union's Artificial Intelligence Act (European Commission, 2023). Consequently, there is a pronounced lack of empirical investigation into the daily realities of "human-AI synergy" within institutional investment settings. The literature often overlooks how financial professionals navigate the continuous, complex trade-offs between maximizing algorithmic predictive performance and satisfying the institutional mandates for explainability and transparency (Barredo Arrieta et al., 2020; Quinn, 2023). Furthermore, there remains limited exploration of the modern financial analyst's "hybrid profile," which necessitates a delicate balance of computational literacy, economic intuition, and ethical sensitivity, all functioning within the rigid constraints of established platform architectures.

To address these theoretical and empirical gaps, this research investigates the socio-technical integration of advanced algorithms in investment banking. The primary research question guiding this study is: *How do digital investment platforms facilitate human-AI synergy while managing the structural risks of algorithmic opacity and bias?* By analyzing AI not merely as an isolated technological deployment but as a systemic architectural shift, this paper seeks to elucidate how financial judgment is being transformed from a purely human cognitive exercise into a technologically mediated, probabilistic discipline (Lopez de Prado, 2020).

2 Research Design and Methodology

To examine Artificial Intelligence as a structural reconfiguration of financial intermediation rather than a mere technical enhancement, this study adopts a qualitative, exploratory, and interpretative methodological framework. The epistemological positioning of this research is intentionally systemic; rather than testing a narrow econometric hypothesis regarding algorithmic generation, the objective is to investigate how AI operates as a cognitive infrastructure that reshapes decision-making processes, governance structures, and competitive dynamics.

The research employs a multi-layered methodological strategy that integrates conceptual-theoretical literature, institutional-regulatory analyses, and empirical-operational investigations. The foundational layer consists of a critical literature review encompassing peer-reviewed academic articles, regulatory frameworks (e.g., the EU AI Act, EBA guidelines), and institutional reports (BIS, OECD, FSB) published predominantly between 2016 and 2025. This documentary analysis serves to construct a theoretical baseline regarding the promises and limitations of financial AI (FSB, 2024; OECD, 2023).

The core empirical investigation utilizes a qualitative case study design centered on BlackRock's Aladdin platform, supplemented by comparative evaluations of platforms such as VantagePoint AI, Tickeron, Danelfin and the Numerai ecosystem. Aladdin was selected as a paradigmatic case due to its systemic relevance, overseeing tens of trillions of dollars in global assets, its hybrid architecture combining deterministic quantitative models with generative AI interfaces, and its widespread cross-institutional adoption (BlackRock, 2024; Financial Times, 2020). To bridge the theoretical framework with operational reality, the study incorporates semi-structured interviews with senior financial professionals operating within the European Union. Participants include senior professionals involved in investment products and services, digital financial advisory, platform delivery, and risk-related decision-making processes (see table 1).

Table 1**:** Research data source Synopsis

Source Category	Number	Selection Criteria	Role in Analysis
Peer-reviewed academic articles	24	Relevance to AI, ML, finance (2016–2025)	Theoretical framework
Institutional reports (BIS, FSB, OECD, EU, ECB)	13	Regulatory authority and policy relevance	Governance & systemic risk analysis
Industry reports (McKinsey, Deloitte, PwC, BlackRock)	17	Practical implementation insight	Operational & strategic assessment

Source Category	Number	Selection Criteria	Role in Analysis
Legal and regulatory documents (AI Act, GDPR, EBA Guidelines)	6	Normative binding frameworks	Compliance dimension
Web-based supplementary sources (Sitography)	36	Definitional clarification or descriptive background	Supporting descriptive context
Case study platforms analysed	6 (Aladdin VantagePoint AI, Tickeron, Danelfin and the Numerai ecosystem)	Systemic significance	Infrastructure evaluation
Semi-structured interviews	3	Direct institutional AI involvement	Empirical validation
Total documentary sources	100	Multi-layer screening	Integrated synthesis

A critical empirical focal point is the implementation of the Aladdin platform within "Omega Bank," a major European banking group. The semi-structured interviews with Omega Bank's head of investment products and the head of the Digital Financial Advisor office were designed to uncover the strategic rationale for adoption, the practical configuration of the platform, and its daily utilization in managing hundreds of thousands of financial instruments (see the questionnaire in annex 1). The interview transcripts were analyzed using a thematic coding methodology to identify recurring operational patterns, discrepancies between academic theory and institutional practice, and the practical challenges of algorithmic governance. While the geographical concentration on the European context and the reliance on a specific institutional case study pose inherent limitations to generalizability, this qualitative approach provides unparalleled depth in interpreting the socio-technical realities of AI integration.

3 Findings

The empirical investigation yields multi-dimensional findings regarding how AI operates beyond current standard implementations, fundamentally restructuring the epistemological basis of investment banking. The findings are organized according to the core thematic branches identified in the conceptual mind map structuring the advanced applications of AI in finance.

3.1 Cognitive infrastructures and the "Common Data Language"

A foundational finding is that the true transformational power of platforms like Aladdin does not stem from autonomous "artificial intelligence" making unilateral decisions, but rather from the establishment of a "common data language" (BlackRock, 2024). Within Omega Bank, Aladdin normalizes disparate data streams related to positions, transactions, market volatility, and macroeconomics into a unified, centralized data layer. This architectural unification ensures that front-office portfolio managers, middle-office risk officers, and back-office compliance teams operate from an identical informational base (Figure 1).

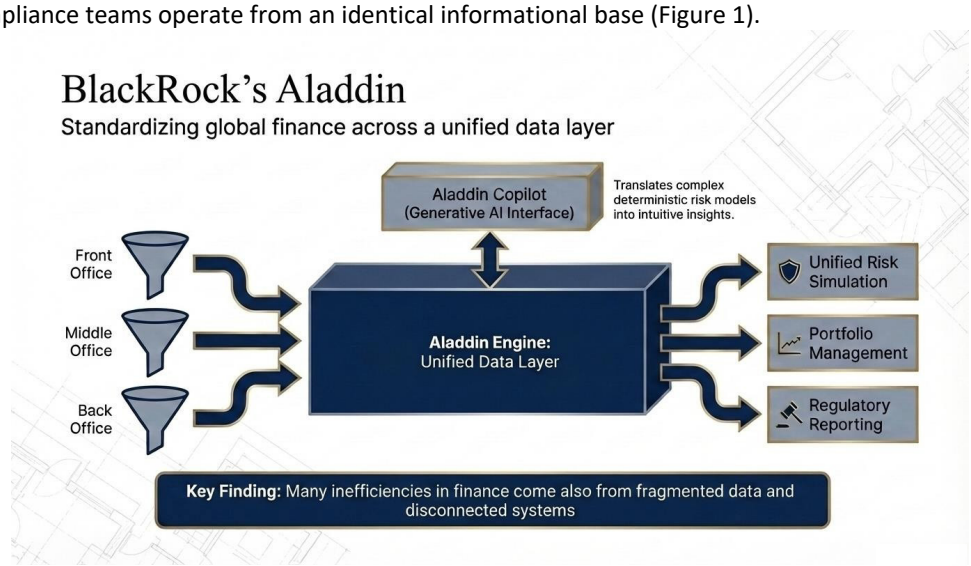

Figure 1: Aladdin engine

By centralizing data on approximately 70,000 financial instruments from client portfolios, within a broader universe of hundreds of thousands of mapped instruments, the platform drastically reduces operational risks historically caused by manual reconciliations, data silos, and informational asymmetries. Consequently, complex analytical tasks—such as simulating the impact of a 200-basis-point interest rate hike or conducting multi-factor stress tests—become almost instantaneous. The platform acts as an enabling infrastructure for organizational standardization, aligning individual discretionary advisory proposals with institutionally mandated model portfolios (Figure 2).

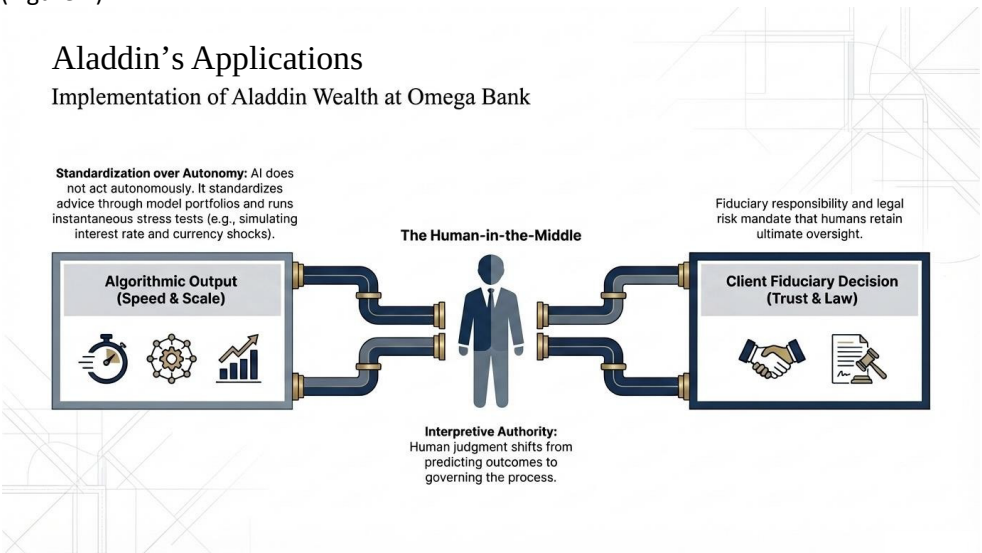

Figure 2: Implementation of Aladdin wealth at Omega bank

3.2 Predicting asset returns: A methodological shift

Moving beyond operational efficiency, the analysis of AI's advanced capabilities reveals a profound methodological shift in the attempt to predict asset returns. For decades, traditional econometric forecasting relied on linear models that imposed restrictive assumptions regarding market stationarity, variable independence, and distributional normality. The findings indicate that AI initiates a paradigm shift from linear modelling to non-linear machine learning, embracing high-dimensional function approximation (Feng, He, & Polson, 2018). AI systems do not approach prediction as the deterministic forecasting of a single future price point; instead, they operate on the principle of *probabilistic inference under uncertainty* (Lopez de Prado, 2020). Modern algorithms process massive datasets to approximate complex conditional probability distributions—estimating the likelihood of specific market regimes, the probability of excess returns, or the trajectory of expected volatility. This shift aligns with the realization that uncertainty in financial markets cannot be eliminated, but it can be mathematically modelled and probabilistically managed.

3.3 Key AI architectures in predictive analytics

The research identifies four key AI architectures driving this methodological shift. First, Deep Learning and Long Short-Term Memory (LSTM) networks are increasingly utilized to capture sequential, long-term dependencies in time-series data (Heaton, Polson, & Witte, 2016). LSTMs are particularly effective at identifying momentum effects and delayed macroeconomic transmission mechanisms across varying market regimes. Second, Classical Machine Learning models, such as Support Vector Machines (SVMs), Random Forests, and gradient-boosting algorithms (e.g., XGBoost), remain vital for cross-sectional stock selection due to their robustness in handling noisy datasets and their relative interpretability compared to deep neural networks (Nakamura, 2022). Third, Natural Language Processing (NLP) and sentiment analysis represent a breakthrough in converting qualitative information—such as central bank press releases, corporate earnings calls, and social media dynamics—into quantifiable metrics that capture behavioral market distortions (Tetlock, 2007; Malo et al., 2014). Finally, the deployment of Hybrid Systems allows institutions to merge traditional financial data with alternative data streams, such as satellite imagery of retail parking lots or mobile geolocation data, expanding the informational surface available for algorithmic analysis (McKinsey & Company, 2023).

3.4 Real-World forecasting platforms

The democratization of AI technologies has led to the proliferation of Real-World Forecasting Platforms, which operationalize these complex architectures into accessible, commercial interfaces. The study examined

several dominant paradigms. *VantagePoint AI* utilizes neural networks grounded in intermarket analysis, processing dozens of correlated variables across commodities, currencies, and equities to generate short-term directional forecasts (VantagePoint, 2025). *Tickeron* aggregates pattern recognition algorithms and probabilistic trend classifiers into a unified terminal, offering users dynamic probabilities of trend continuation or breakout events (Tickeron, 2025). *Danelfin* introduces an innovative cross-sectional prediction model, synthesizing thousands of fundamental and technical indicators through ensemble learning to assign an "AI Score" (from 1 to 10) representing a stock's probability of outperforming a benchmark (Danelfin, 2025). While these platforms compress immense informational complexity into actionable insights, they also risk fostering behavioral overconfidence if users misinterpret high probabilistic scores as deterministic guarantees, particularly given inherent cognitive biases (Kahneman & Tversky, 1979).

3.5 AI-Native organizations: The Numerai paradigm

Beyond retail platforms, the findings highlight the emergence of AI-Native Organizations, which completely restructure the investment production function around algorithmic prediction. *Numerai* represents a radical paradigm shift: it operates as a crowdsourced hedge fund utilizing tournament logic (Numerai, 2026). Numerai provides global data scientists with highly engineered, *obfuscated data*—intentionally stripping the economic semantics from the variables to prevent narrative-driven overfitting. Participants train diverse machine learning models and submit their predictions, which the platform aggregates. Crucially, Numerai introduces an economic incentive design via *staking and burn mechanisms* utilizing its proprietary cryptocurrency (figure 3). If models fail out-of-sample, the participant's staked capital is burned; if successful, they are rewarded (Numerai Docs, 2025). This architecture resolves the issue of accountability in crowdsourcing, acting as an endogenous filter for trust and robustness. Similarly, *WorldQuant BRAIN* operates as a simulation platform that institutionalizes external quant research, further proving that algorithmic prediction is evolving into a distributed, competitive ecosystem rather than a localized institutional secret (WorldQuant, 2025).

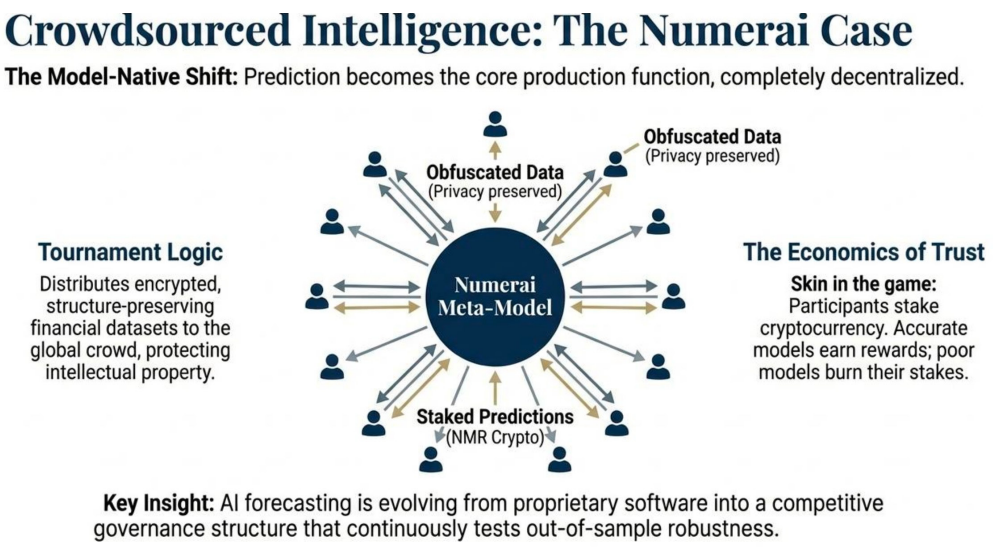

Figure 3: Crowdsourced Intelligence

3.6 Reconfiguring human expertise: The hybrid profile

Ultimately, the empirical evidence from both platform implementation and AI-native models demonstrates that AI does not replace human experience; it reconfigures it. The traditional investment banker is evolving into a "hybrid profile". Analysts who delegate computational forecasting to models do not abdicate professional judgment. Instead, their cognitive efforts shift *upstream*—to problem definition, feature engineering, and rigorous data governance—and *downstream*—to robustness testing, exception management, and controlling for algorithmic drift (Lopez de Prado, 2020). The integration of conversational modules, such as Aladdin-Copilot, further supports this by translating complex risk scenarios into natural language, assisting the "human in the middle" in preparing client narratives and ensuring fiduciary suitability before executing trades (BlackRock, 2024).

4 Discussion

The findings of this study necessitate a critical discussion regarding the socio-technical limitations, systemic risks, and governance imperatives surrounding the integration of AI in investment management. The analysis is structured around the conceptual framework of structural limits and strategic synthesis.

4.1 Structural limits and technical failures associated with financial AI

While the methodological shift toward non-linear machine learning expands predictive boundaries, the discussion must emphasize the inherent technical failures associated with financial AI. Financial markets are characterized by non-stationarity and reflexivity; the statistical properties of asset returns shift continuously due to changing macroeconomic policies, participant behaviors, and structural breaks (Lo, 2004; Potters, Cont, & Bouchaud, 1998). Consequently, predictive models are highly susceptible to *overfitting*—the tendency of an algorithm to capture historical noise rather than economically meaningful signals, resulting in predictive fragility when applied to out-of-sample, real-world data. This fragility was starkly evident during the COVID-19 pandemic shock of March 2020, where models trained exclusively in low-volatility regimes failed dramatically. Furthermore, the pervasive risk of *data leakage*—where future information inadvertently contaminates training datasets—can create a dangerous illusion of algorithmic precision, misleading risk management committees (Lopez de Prado, 2020). The inherent limits of AI dictate that while computational power has scaled exponentially, the signal-to-noise ratio in financial forecasting remains stubbornly low.

4.2 Market dynamics and systemic risks

From a macro-institutional perspective, the widespread adoption of AI introduces severe systemic risks tied to market dynamics. Financial markets are adaptive ecosystems. When multiple institutions deploy similar AI architectures, consume the same alternative data feeds, and utilize homogenized platforms like Aladdin, the sector faces a high risk of algorithmic convergence (Financial Times, 2020). This convergence implies that market participants may react uniformly and simultaneously to specific algorithmic stimuli, potentially causing "herd behavior" that exacerbates market selloffs and amplifies systemic volatility, reminiscent of the 2010 Flash Crash (BIS, 2024; FSB, 2024). The democratization of platforms like VantagePoint and Tickeron across retail spaces further compound this issue; if a collective mass of retail algorithms executes simultaneous breakout strategies, they can create self-reinforcing price shocks. Furthermore, technological dependence on a concentrated group of dominant cloud and AI providers exposes the global financial system to amplified operational and cyber risks (Zetzsche, Buckley, & Arner, 2020).

4.3 Institutional concerns and algorithmic governance

The tension between maximizing predictive accuracy (often via complex deep learning networks) and maintaining interpretability creates profound institutional concerns. In the heavily regulated domain of investment banking, relying on "black box" algorithms poses severe fiduciary and legal risks (Goodfellow, Bengio, & Courville, 2016). If an AI system systematically denies credit, misallocates capital, or executes a highly detrimental trade, institutions struggle to map the precise algorithmic logic to assign legal accountability (Goodman & Flaxman, 2017). Data bias poses an additional threat; algorithms trained on historically prejudiced datasets can systematically discriminate, as observed in consumer lending anomalies (Bartlett et al., 2019; O'Neil, 2016; Mehrabi et al., 2021). While post hoc Explainable AI (XAI) techniques offer partial transparency by highlighting feature importance, they do not resolve the fundamental opacity of deep neural networks (Barredo Arrieta et al., 2020; Quinn, 2023).

This opacity is directly confronted by the regulatory landscape, most notably the European Union's AI Act (European Commission, 2021; European Commission, 2023). The AI Act acts as a catalyst for algorithmic governance by introducing a risk-based framework in which certain financial AI applications—particularly those affecting credit scoring, risk assessment, or other high-impact decision-making processes—may fall within the high-risk category. For such systems, the regulation imposes stringent requirements for data quality, human oversight, traceability, and rigorous conformity assessments. Consequently, the discourse surrounding AI is forced to transition from a narrative of pure operational efficiency to an imperative of corporate ethics and governance. The deployment of AI necessitates a "new responsibility pact," meaning that the promise of rapid, highly personalized, data-driven financial advice must be inexorably linked to guarantees of fair, defensible, non-discriminatory, and highly verifiable decision-making structures.

4.4 Strategic synthesis: human-in-the-loop and financial Judgment

Synthesizing these technical capacities and structural risks reveals a new strategic reality for investment banking. AI cannot eliminate the ontological uncertainty of markets; instead, it serves to provide *probabilistic*

decision support. The competitive edge for modern institutions is no longer derived from discovering a flawless, deterministic oracle, but rather from securing *marginal accuracy*—a slight probabilistic tilt toward outperformance that, when applied across multi-trillion-dollar portfolios under strict risk constraints, yields massive economic value.

Achieving this requires a fundamental *transformation of financial judgment*. Judgment is no longer the sole purview of the isolated star analyst; it is the product of an ensemble of models governed by strict institutional protocols. The most resilient organizational architecture is one grounded in *human-in-the-loop governance*. Human professionals are not rendered obsolete; they are elevated to the role of systemic overseers. While AI handles high-dimensional signal extraction and pattern recognition, human actors provide the critical contextual interpretation of novel geopolitical events, manage ethical compliance, and bear the ultimate fiduciary responsibility that algorithms cannot legally assume.

5 Conclusions, Limitations, and Future Research

This study concludes that Artificial Intelligence in investment banking constitutes a structural reconfiguration of the financial architecture rather than a mere technological optimization. AI does not act as a deterministic oracle capable of guaranteeing return forecasts; its foundational value lies in providing disciplined, probabilistic advantages under conditions of deep uncertainty. Digital investment platforms, functioning as cognitive infrastructures, successfully facilitate human-AI synergy by synthesizing vast data layers, enabling complex non-linear machine learning, and standardizing operational processes. However, this synergy is inherently precarious. Sustainable innovation within the financial sector requires these cognitive infrastructures to be firmly embedded within robust algorithmic governance frameworks, particularly in light of stringent mandates such as the EU AI Act (European Commission, 2023; OECD, 2023). Intelligent finance is only viable if the algorithmic systems driving it are transparent, auditable, and ethically grounded by human professionals who maintain ultimate fiduciary authority.

The research acknowledges several methodological limitations. The qualitative nature of the empirical investigation, based on semi-structured interviews concentrated within the European Union banking sector, restricts the broader global generalizability of the findings. The analysis lacks access to proprietary quantitative datasets and the underlying source code of the platforms examined, relying instead on user perspectives, public documentation, and literature. Furthermore, the study observes the regulatory environment during the early, highly dynamic implementation phase of the EU AI Act, meaning that long-term compliance impacts are yet to be fully realized.

Future research must expand upon these findings by investigating the longitudinal effectiveness of Explainable AI (XAI) in meeting evolving regulatory compliance standards across divergent global jurisdictions (e.g., comparing EU, US, and Asian regulatory environments). Subsequent studies should critically evaluate the political economy of platform-based financial infrastructures, specifically quantifying the systemic implications of technological dependence and the concentration risks posed by algorithmic convergence (Zetzsche, Buckley, & Arner, 2020). Finally, empirical research is needed to track the long-term economic performance and behavioral stability of retail AI forecasting tools and crowdsourced AI-native ecosystems during periods of extreme macroeconomic shock.

Annex 1 Questionnaire

Introductory / Context-setting

- What's your name and which role do you play within your organisation?
- Could you tell me about your current role and how long you've been using the Aladdin platform?
- How was Aladdin introduced within your organisation? What were the needs?
- Before adopting Aladdin, what kind of tools or processes were you using for portfolio and risk management?

Operational Use and Integration

- In which phases of your work do you mainly use Aladdin — portfolio construction, risk monitoring, reporting, or client advisory?
- How are you training or updating to make the best use of the platform and fully exploit its operational potential?
- How does Aladdin interact with other internal systems (CRM, accounting, ESG databases, etc.)?
- From your experience, what are the main benefits in terms of speed, efficiency, or data consistency compared with legacy tools?
- To what extent do you rely on Aladdin's outputs versus your own professional judgment when taking investment decisions?

Artificial Intelligence and Analytics Capabilities

- Which AI- or machine-learning-based functions within Aladdin are most relevant for your activity?
- Do you perceive these tools as decision-support instruments or as autonomous decision-makers?
- How transparent are the algorithms' results to you — do you understand why a certain recommendation or risk alert is generated?
- How does your team validate or challenge model outputs before acting on them?

Data Quality and Governance

- How is data quality managed within the platform? Do you encounter issues of completeness, timeliness, or bias in the datasets used?
- Are there internal procedures or controls to ensure that Aladdin's data inputs are consistent with your bank's risk-governance standards?
- In your opinion, how critical is data governance for achieving reliable AI-driven insights?

Human Factor and Professional Culture

- Has the adoption of Aladdin changed the required skill-set for professionals in your division?
- How do you balance quantitative model outputs with qualitative considerations, such as client expectations or market intuition?
- Do you think younger generations of analysts relate differently to Aladdin compared with senior portfolio managers?

Client Relationship and Transparency

- How do you explain to clients that part of the investment process is supported by AI-driven analytics?
- Have clients ever expressed concerns about automation, opacity, or loss of human oversight?
- Does Aladdin help you enhance the personalisation of advisory services (e.g., ESG preferences, behavioural analysis)?

Risk Management and Regulatory Compliance

- How does Aladdin assist you in identifying and monitoring portfolio risks such as VaR, stress testing, or concentration risk?
- In what ways does the platform help fulfil regulatory requirements (e.g., MiFID II, ESG disclosures, internal audits)?
- How is accountability managed if an AI-driven recommendation leads to a loss — who bears responsibility?

Strategic Vision and Future Outlook

- In your view, what is the next evolutionary step for platforms like Aladdin — more automation or more human interpretability?
- How do you imagine the ideal interaction between human advisors and AI systems five years from now?
- What advice would you give to a financial institution that is about to implement Aladdin for the first time?

Digital Innovations in Sustainable Supply Chain Business Models

Maria Rosaria Marcone
Marche Polytechnic University, Ancona, Italy

Abstract

The aim of this work is to identify the new innovative phenomena affecting Supply Chain Business Model Systems (SCBMSs), with reference to supply chain relationships that become digital. The focus is on upstream supply chain operators and leading supply chain firms.

We hypothesize that leading firms (almost always small and medium-sized) providing these technologies need to search for external knowledge, improve cooperation, develop servitized offers and connectivity along the value chain. These approaches allow wider customer contact, easier communication, and automated value-capturing and value co-creation processes. Supply chain platform development, and servitization are important in providing advanced digital technologies solutions. We focus on the notion of knowledge complexity, which reflects both the variety and newly-rarity of the knowledge stock available in a given supply cain ecosystem. Existing research on the relationship between strategic renewal and corporate purpose appears fragmented and provides mixed insights. Some evidence points to purpose-driven firms as being more flexible in navigating change better able to radically reinvent themselves. Regarding the methodology, this research used theoretical sampling for case selection since the objective is to build concepts and theory regarding the mechanisms involved in supply chain business model (SCBM) when digital technologies challenge factors are present. Therefore, the main criterion for sample definition was to search for cases representative of I4.0 technology provision regarding key technologies offered with leading representativeness of the technologies and companies analysed in the manufacturing supply chain (SC). Our results show that the I4.0 technologies and solutions impact the whole SCBMSs. This paper can contribute to both theory building and provide important practical implications by: (a) enriching the conceptual understanding of the unintended consequences of digital transformation; (b) providing managers important insights and practical advice for riding on the digitalisation to enhance operations-supply side relationships and supply chain value offered.

Keywords: digital supply chain, business model innovation, ecosystems, digital supply chain platforms.

Paper type: Academic Research Paper

1 Introduction

The aim of this work is to identify the new innovative phenomena affecting Supply Chain Business Model Systems (SCBMSs), with reference to supply chain relationships that become digital (Müller et al., 2021; Marcon et al., 2022). The focus is on upstream supply chain operators and leading firms (sometimes their business-industrial clients); the supply chains studied are truly innovative ones such as the machinery, biomedical, agri-tech food, chemical, medtech supply chains.

We hypothesize that SC leading firms (almost always small and medium-sized) providing these technologies need to search for external knowledge, improve cooperation, develop servitized offers and connectivity along the value chain (Frank et al., 2022; Besiroglu et al., 2024; Grimm et al., 20242). These approaches allow wider customer contact, easier communication, and automated value-capturing and value co-creation processes.

Existing research on the relationship between strategic renewal and corporate purpose appears fragmented and provides mixed insights. Some evidence points to purpose-driven firms as being more flexible in navigating change better able to radically reinvent themselves.

The field of this study is digital transformation both in firm's sustainable strategies and in SC restructuring or redesign. Digital transformation is a process of integrating digital technologies into all firms and SC business activities: a mega-process that involves substantial changes in technology, business management culture, design and engineering operations in production systems, and supply chain value generation (macro-level changes) (Thomas and Ritala, 2022; Teoh et al., 2023; Laamanen et al., 2025). The research perspective is the most recent one of innovation that considers the prerogative of digital servitization which favours the creation of a new serviced business model by implementing digital resources for the creation of new sustainable – at firm level and for the complete SC - value. The comprehensive development of digitalising sustainability information for communication across supply chain actors has become increasingly important.

The research's focuses are as follows. The first is about the SC digital innovative sustainability evolution. Supply chain's firms that attach strategic importance to environmental issues are those that recognize a new opportunity to compete. They are inclined to make large investments intended for the adoption of non-polluting

technological solutions in production systems, as well as to initiate internal training activities to increase human resources' environmental skills and also to design specific and well-detailed internal managerial procedures. Sustainability is a potential competitive advantage. Sustainable development is currently a pivotal element in the processes of formulating the competitive strategies of many enterprises (we will deal with manufacturing ones) and presupposes that additional objectives compared to traditional ones (economic-financial objectives) are considered both in the formulation of growth strategies and in the design of modern internal governance procedures.

The second is the renovation or even design of new Supply Chain Business Model Systems (SCBMSs).

The business model of modern supply chains must necessarily be restructured by the companies operating there, by new entrants, and more generally by economic innovation actors, including those external to the SC, who, together with SC companies, are included in new open innovation or open innovation (OI) systems. All these economic innovation actors are oriented towards capturing early signs of change coming from outside (digital technologies, new firms as the start-up, institutional incentives and regulatory laws, etc.) or even acting proactively on the external context (supply relationships, the relevant social environment, new and more advanced digital strategies than in the past.

Business model modification is concretely and profitably possible in the production structures and governance structures of the SCs to which they belong, which with agility (operational agility) adapt to new and disruptive technologies and new strategic drives through which to compete (green innovation, sustainability, digital SC relationships up stream and down stream).

This research explores DT technology integration into global manufacturing firms from an operational capability perspective. The research followed the single case study guidelines and took additional inspiration from longitudinal case study guidelines and process study guidelines. Several sources for data analysis are available for case study research. This helped highlight overlapping or emerging concepts, themes, and dimensions as a contribution of new theoretical insights.

2 Theoretical Framework

The modification of the SCBM and the new value creation resulting from it are sources of a competitive advantage that has also been modified, as it differs, sometimes significantly, from the past. Moreover, in strategic management studies, traditionally focused on decision formulation, increasing importance is recognized in the analysis of how changes are generated and in the evaluation of the effects they generate (Frankenberger and Sauer, 2019).

The production of scientific contributions on the topic of business models is more active and livelier than ever. However, there is a lack of references and above all field explorations on the birth of new SCBMs. Some useful insights can start from the reflections that some authors have started on topics, reported below: Brucherer (2012) recognizes two important causes of modification of business models 'macro-dimensions', the market and industry; Teece (2010) argues that the criticality of the operational meaning of the business model lies in the connection it makes possible between the 'micro-foundations' or 'micro-elements' constituting the business strategy and the competitive performance actually achieved by it; other authors (Blackburne and Buckley, 2019) are among the most convinced supporters of the business model as an operational process in continuous evolution; others state that supply chain business model innovation (SCBMI) mediates the link between technological innovation and supply chain performance (Tate et al., 2010; Karimi-Walter, 2016; Gölgeci et al., 2018). These authors define the SCBM is defined as new, when it is the result of the design, by managers and entrepreneurs, of a radically new system of activities for objectives, structure and forms of governance (architectural novelty of the business) or a system, in which activities with elements of novelty (objectives, structure, governance) integrate with unmodified activities (complementary novelty of the business).

Knowledge management (KM), its growth or disruptive development is an important research field and the basis for the performance of effective managerial procedures and more than ever open to new digital technologies.

The knowledge management in innovative and sustainability-oriented supply chain management procedures includes key firm's areas of enterprise and business partner's areas with which it interacts.

KM in SCM that includes many kinds of business partner interaction, joint knowledge creation and knowledge dissemination at both inter- and intra-organizational levels to enhance the efficiency of supply chain activities (Pahm et al., 2024). KM in SCM uses a range of advanced technologies for capturing and processing supply chain-related information. This acquired and refined information (i.e. knowledge) is circulated within firms and their externalities to make timely decisions and thereby sustain competitiveness (Massa et al., 2023; Gustafsson et al., 2024).

RQ 1. KM strategies generate (this binominial) structural managerial procedure changes of SCs.

Medium sized firms (MSFs) employ OI practices (Livieratos et al. 2024) to overcome the challenges associated with successfully utilizing digital innovative technologies (Hongyun et al. 2023; Meng et al. 2021). This research gap raises an important research question about what the challenges in SMEs are leveraging business model and related digital innovations and what particular OI practices through collaborations and partnerships with external innovators SMEs employ to overcome the challenges.

Indeed, MSFs with resource constraints may trigger different OI practices based on their situational experience (Spithoven et al. 2013; Brunswicker and Vanhaverbeke 2015; Massa et al. 2023). Our study explores (1) the challenges in MSFs leveraging business model and related digital innovations for service delivery; (2) the specific OI practices through collaborations and partnerships with external organizations employed by SMEs; and (3) proposes a framework that connects OI collaborations and partnerships to the specific challenges faced by SMEs leveraging business model and related digital innovations. In modern digitalized and sustainability-oriented SCs, innovations are inspired by principles never experienced in the past. Attention to open innovation may appear as a strategy for firms to respond to technological adoption, there is limited research on. We investigate as follows.

RQ 2. OI is a great opportunity for improve firm's knowledge management.

Digital supply chain platforms are emerging as critical infrastructures that empower the digital transformation of manufacturing, attracting growing academic and practical interest. By leveraging modular digital architectures, IDPs enable extensive interconnectivity among humans, machines, physical objects, and systems, thereby facilitating the integration and sharing of heterogeneous resources (Pauli et al., 2025; Bai et al., 2026).

Also, the platform-native firms, as cross-boundary entrants, orchestrate value co-creation strategies—resource integration, service exchange and institutional arrangements—to develop digital platforms in new and modern SC. We believe, welcoming the analyses of Qin and Li Sun (2026) that the ability to combine knowledge is an important mediator. Additionally, we introduce the moderating role of the ease of knowledge combination, investigating how it interacts with knowledge dependence to influence innovation outcomes. Specifically, how it facilitates the adoption of sustainable technologies in increasing opportunities to continuously improve capacities to successfully introduce digital technologies. We adopt the concept of knowledge dependence to explain how suppliers drive innovation and capture value within value chains. Knowledge dependence among SC's levels is central to this process, as the need to obtain external and complementary knowledge promotes interconnections and interdependence among firms (Kristiansen, 2026)

RQ 3a. The platform generates supply chains restructuring.

Regarding the s it has been studied how the digital technologies facilitate diverse functions within digital servitization, including monitoring, controlling, automating processes, and creating fully autonomous solutions (Kohtamäki *et al.*, 2019; Kristiansen, and Aas 2026). Other studies have highlighted that successful digital servitization relies on technical capabilities and the willingness of ecosystem actors to cooperate, particularly concerning data exchange (Kolagar et al., 2022). In addition to technical factors, social elements must be considered when assessing the feasibility digital servitization outcomes (Dalenogare et al., 2023). Non-large enterprises can also be leading players (Khan et al., 2026). the digital platform generates the servitization of the supply chain (Orgink et al., 2023).

Supply chain platform development, and servitization are important in providing advanced digital technologies solutions. We focus on the notion of knowledge complexity, which reflects both the variety and newly-rarity of the knowledge stock available in a given supply cain ecosystem (Hillebrand et al., 2025). Variety as increasing complexity that has positive impact on recombinant knowledge dynamics as it supports the scope for the recombinant generation of new knowledge and eventually leads to augmented rates of introduction of innovations.

This paper also sheds light on how innovative resources interact with other resources to drive servitization, bridging the gap in research between servitization and innovation (Coreynen et al., 2017; Kohtamäki et al., 2019).

RQ 3b. Digital SC platform as digital SC servitization.

3 Methodology

This research uses theoretical sampling for case selection since the objective is to build concepts and theory regarding the mechanisms involved in supply chain business model (SCBM) when digital technologies challenge factors are present (Thomas and Ritala, 2022). Therefore, the main criterion for sample definition was to search for cases representative of I4.0 technology provision regarding key technologies offered with leading representativeness of the technologies and companies analyzed in the manufacturing industry.

In the second step, we analyzed the technologies offered by these companies to consider a diversity of technologies related to I4.0 solutions and the profile of the companies' business models, i.e., whether the business models were strongly oriented to I4.0 solutions and not only the provision of single technologies. In this sense, although some companies focus on specific technologies, all selected provide integrative solutions to manufacturers based on the leading technology.

Qualitative research has been chosen. The research framework design emerges through an inductive analysis method with the intention of having a positive-interpretative position, in order to highlight emerging innovative phenomena (Figure 1).

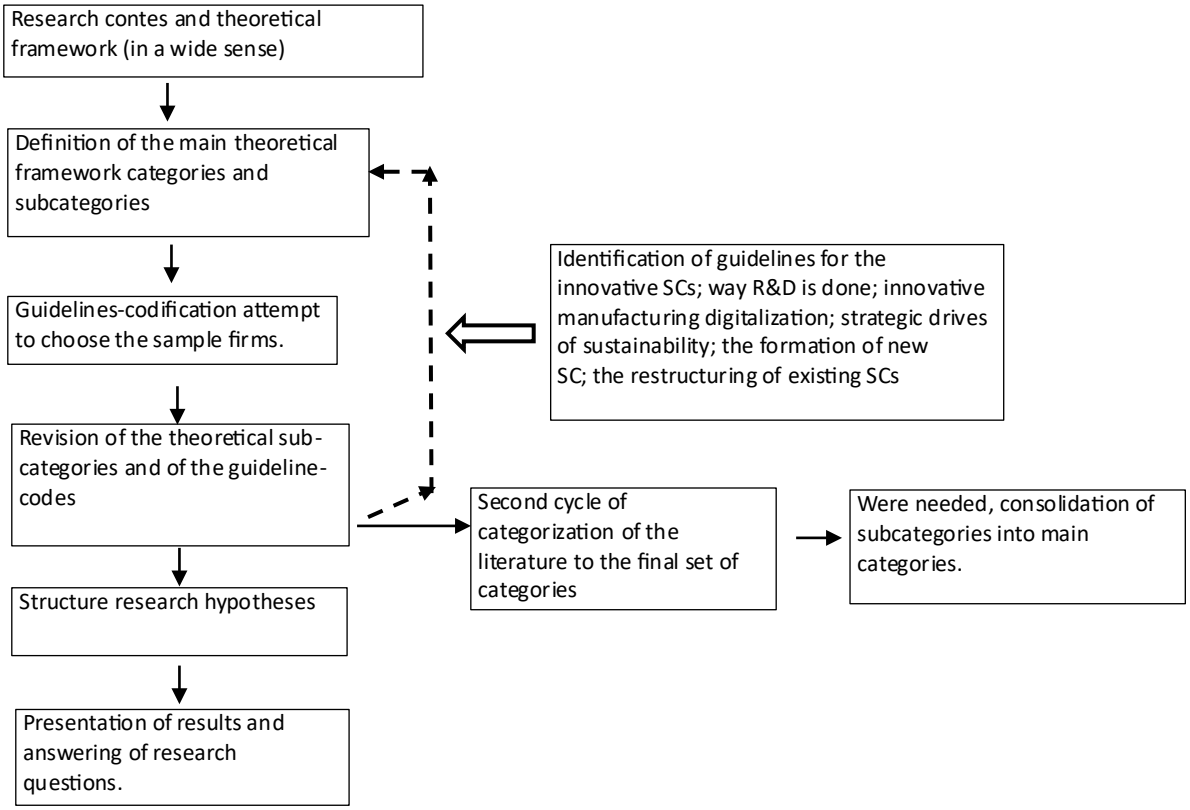

Figure 1: Steps of research process
Source: our elaboration

An interpretative, qualitative approach utilizing selected multi-case study analysis is chosen: drawing on qualitative analysis, it was first investigated how companies belonging to their supply chain design their research activities, to generate sustainable innovative processes (sheet 1), and then the reconfiguration of sustainable innovative supply chain, sustainable strategic choices of supply chain companies, strategies and structural choices (way of doing research, redesign of supply side relations, digitization of the supply chain relationships, foreign development). Several sources for data collection are available for case study research.

We used an explorative approach, conducting semi-structured interviews with firms' managers, sustainability experts, researchers, etc. Analysis of sector and sub-sectors data based has been conducted on the re-elaboration of industry associations reports (both national and European reference) (see sheet 1). Data were collected from 2024 to these first months 2026 through face-to-face interviews conducted at participants' offices or neutral meeting locations in Italy. Conducting interviews in person allowed for richer interactions, capturing non-verbal cues and fostering a deeper rapport with participants. The focus on a single country ensures consistency in cultural, regulatory, and economic contexts, which are critical factors influencing the adoption of AI technologies.

The aim of the work is to follow the strategic development of the cases over time (evolution, growth, etc.). The iterative analysis which perhaps better than other approaches, it is believed, may prelude a longitudinal analysis. Instead of testing a predefined hypothesis, this study aims to generate insights through an open-ended, iterative process for explorative data collection from cases. This study approach is technically possible for the supply chain leading firms; not applicable for startups, spin-offs, institutional stakeholders, because the first two are too young and are continuously subject to change, with regard to content, institutional interventions.

Sheet 1: Methodology choices

A) Strategic drives

The emphasis on the SCBMI has led to the direction of field experimentation, privileging, in this step of empirical research which is still being completed, the investigation of the development strategic drives which are expressed in the table that follows (see table 1).

Table 1: Strategic drives

Strategic drives	SC micro-foundation practices
(1) SC value co-creation	- attitudine e l'impegno ai progetti collaborativi di miglioramento - estensione delle interdipendenze fra le imprese all'interno della SC (relativa importanza di un cliente per il business del fornitore e criticità delle forniture) - problem solving
(2) Ways of doing innovation	- OI - innovation community - other external drive
(3) Relationship efficiency	- the duration of the relationship and the types of past experiences; - technological or procedural links between firms and among diversified SCs;
(4) Digital relationships	platformization (digital relationships and role of the leading firms)
(5) Governance	the length and complexity of the Supply Chain

B) Source data collection

Primary data were collected as shown in the following: (a) Semi-structured interviews in trade fair forums; (b) Industry conferences; (c) Semi-structured Interviews in meeting-round table; (d) Semi-structured Interviews in visiting (CPO, CFO); (e) Semi-structured Interviews in scientific Italian managerial conference (CEO, CPO, CFO); (f) Direct observations.

Secondary data were collected as shown in the following: (1) Press coverage, company blogs, analyst reports; (2) Interviews given by the area manager and published in European media outlets; (3) Reports of sector research centres and consultancies; (4) Company blogs, analyst reports (Make Up the future)-2026. Champions-Italy Post Ranking.

C) R&D activities

Strategic choices were analysed, favouring the analysis of new and unusual ways (due to the size of economic actors and companies and the sectors from which they originate) of conducting R&D within the SCs of origin and in the new and diversified ones that necessarily arise (see table 2)..

Table 2: R&D activities

Cases	Innovative activities in sustainable supply chains
Diary	R&D in the various supply chain levels Diversification: multi-vertical supply chain integration
Medtech	Joint R&D of cooperatives in research HUB R&D in platformed supply chain.
Agrochemical	Internal R&D shared with suppliers (Supply side integration) OI in know how increasing in partnership Design and engineering of production processes
Agrifoodtech	Research hub R&D and design 'Hub Bite'
Advanced mechanics	Open Innovation Platform with innovative SC: solutions for next generation mobility
Agritech	New R&D in collaboration with cluster partners (Ferrara-Italy) operating in machinery, animal husbandry and poultry farming. New R&D in collaboration with a partner of Milano belonging at the sub-sector 'food supplements'.
Coffetech	AI to increase soil fertility (new plantings on region affected by floods, desertification, fire)
Digital cosmetics (two cases)	NPD for saving scarce resources (water) Radical innovation raw materials AI for data processing and quality control (traceability, digital twin in new product design-engineering-production)

4 Conclusions

The main challenge in comprehending the unintended consequences of digital transformation is our existing knowledge base. Digital transformation and the shift toward sustainable innovative strategies at the level both the firms and the SCs are reshaping many supply chains, raising both practical and theoretical questions about power, collaboration, and ecosystem dynamics. Considering this, interest in supply chain digitalisation have grown significantly in recent years.

Our study makes two primary contributions. First, we extend OI research in no large firms by illuminating how the challenges faced by analysed firms when leveraging digital innovation. Second, our work provides valuable empirical support for OI target strategies understanding (RQ 2). These strategies are not only relevant to no large firms but also extend the interest in them by those businesses and economic and innovation actors that to other firms with limited financial resources and moreover interested in expanding (diversifying) the portfolio of businesses, even diversified SCs, to respond to and even improve growth opportunities arising from the disruptive advent of digital sustainability. We find that among the startups participating in the formation of new production chains, it emerges that those that achieve better performance from the first years of life are those that come from 'contexts' (industrial districts, sustainable innovation ecosystems, research and innovation hubs) where events of sedimentation and growth of knowledge management have occurred in the past. It is as if the localization of knowledge has its own differentiated 'propagation' of innovation: from localized specificities further localized innovative specificities arise which then internationalize and therefore become multi-localized, even if not in a merely replicative sense (traditional model of internationalization) (RQ 1).

The study finds and observes that suppliers-manufacturer relationships should first and then prioritize investments in new digital technologies for the short, medium, and long term regardless of the evaluation of their current operational capabilities. This is the emergence field of the digital supply chain platforms thus finding RQ 3a. Supply chain digital platforms enable the real-time interconnection and sharing of dispersed physical manufacturing resources, data resources, and knowledge resources among multiple actors. This facilitates efficient cyber-physical integration, establishing the foundation for subsequent collaborative development of smart manufacturing service solutions. Digital platforms enable firms to overcome classical information and coordination constraints. Unlike traditional intermediaries (such as brick-and-mortar travel agencies), digital platforms enable firms to overcome classical information and coordination constraints by combining market mechanisms with elements of hierarchical control in hybrid, firm-designed systems. These platforms rely on semi-directed and generative search processes, which go beyond centralized mechanisms to enhance innovation and adaptability in fast-changing environments. In addition, platforms provide a low-cost pathway to scale, offering superior capabilities for environmental scanning, opportunity sensing, and the integration of diverse inputs. This paper also sheds light on how innovative resources interact with other resources to drive servitization, bridging the gap in research between servitization and innovation (RQ 3b). Digital transformation of business models is a SC digital servitization that improve - aiming to revamp and reinvigorate - their operations to better engage, and create new values for their clients, suppliers and communities. The result is proactivity. The advantages of digital transformation are enormous as pointed out by many authors. Digitalisation as transformative servitization interests the processes of the SCBM: they adopt digital technologies to change operations and automate processes. The result is reactivity.

Supply chain platform development, and servitization are important in providing advanced digital technologies solutions. We focus on the notion of knowledge complexity, which reflects both the variety and newly-rarity of the knowledge stock available in a given supply cain ecosystem (RQ 1). Variety as increasing complexity that has positive impact on recombinant knowledge dynamics as it supports the scope for the recombinant generation of new knowledge and eventually leads to augmented rates of introduction of innovations.

This research provides a significant contribution to knowledge to digitalisation, digital transformation, and supply chain relationship related research. Our findings extend existing literature by identifying underexplored unintended consequences of digital transformation in circular economy contexts, particularly in relation to social equity, digital inclusion. This paper can contribute to both theory building and provide important practical implications by: (a) enriching the conceptual understanding of the unintended consequences of digital transformation; (b) providing managers important insights and practical advice for riding on the digitalisation to enhance operations-supply side relationships and supply chain performance. Our results show that the I4.0 technologies and solutions impact the whole SCBMSs.

5 Ethics Declaration

It is stated that for the research presented in this paper, it was not necessary to apply for an ethical authorization.

6 AI Declaration

It is declared that no artificial intelligence tools were used.

The Cascade Paradox: Information Refraction in Hierarchical Organisations, AI-Driven Power Shifts, and the Future of Knowledge Cascades

Noémi Szilvia Lőrincz, Márta Kiss
Corvinus University of Budapest, Budapest, Hungary

Abstract

In knowledge-intensive organisations, the cascade - the sequential relay of strategic information through management layers - is the dominant mechanism by which corporate direction is translated into individual action. Yet cascade practices are rarely neutral conduits: information bends as it travels, shaped by the cognitive, structural, and political properties of each relay agent. This paper introduces information refraction as a theoretical construct to capture this systematic transformation and presents empirical evidence from two complementary datasets spanning the European automotive industry.

The first dataset comprises original mixed-method research within a large European automotive manufacturing organisation: 61 survey respondents stratified across four hierarchical levels (working level, first-line managers, middle managers, and senior managers / divisional heads), supplemented by three focus groups. The second dataset is a multi-organisational AI adoption survey with 37 respondents drawing respondents from OEMs, Tier 1 and Tier 2 suppliers, and adjacent industry actors across Europe, Japan, Germany, Hungary, Portugal, and the United Kingdom.

Together, these datasets reveal a cascade paradox: the actors most responsible for relaying strategy - middle managers - exhibit the lowest strategic comprehension and the highest self-reported limitations in cascade execution; while across the broader automotive ecosystem, AI adoption remains shallow (65% of organisations at pilot or early-exploration stage), fragmented (80%+ limiting AI to less than 20% of production processes), and impeded by identical barriers - lack of internal expertise (73% of respondents) and resistance to change (62%). We argue these two findings are structurally connected: the cascade problem and the AI readiness problem are expressions of the same underlying dynamic - organisations that cannot transmit knowledge faithfully cannot absorb transformative technologies effectively.

We advance a prospective argument with significant implications for knowledge management theory: AI-driven data centralisation will fundamentally alter the cascade's role as a power mechanism. For organisations that invest in AI literacy and knowledge infrastructure, the cascade paradox resolves through genuine democratisation - employees with strong analytical capacity gain direct data access, bypassing refraction. For those that do not, distortions compound. In an automotive sector navigating simultaneous disruption across electrification, supply chain fragility, and geopolitical volatility, cascade quality and AI readiness are not separate strategic priorities - they are the same priority.

Keywords: information cascade, knowledge management, organizational failure, middle management, upward communication

Paper type: Academic Research Paper

1 Introduction

Every organisation has a theory of how strategy becomes action. In most large corporations that theory is the cascade. An executive communicates direction to senior managers; senior managers translate it to middle managers; middle managers relay it to teams. The underlying assumption is elegant: hierarchical relay preserves fidelity while adding contextualisation at each layer.

The practice tells a different story: strategic initiatives lose clarity, critical information is delayed, simplified beyond utility, or withheld entirely. Employees act on incomplete signals. And when things go wrong, the diagnosis rarely identifies the cascade as the failure mode - because cascade dysfunction is invisible by design. It produces not loud errors but quiet erosions: of alignment, of trust, of competitive agility.

This paper calls this phenomenon the *cascade paradox*: the mechanism organisations depend upon most heavily to align human behaviour with strategic intent is simultaneously the mechanism most vulnerable to systematic distortion. We name the core dynamic information refraction - by analogy with optics, where light bends as it passes through media of different density. In organisations, information bends as it passes through layers of different authority, interest, cognitive load, and communicative competence.

The timing of this inquiry is not incidental. Across the automotive industry - among OEMs, Tier 1 suppliers, Tier 2 manufacturers, and adjacent actors - the pressure to adopt and leverage artificial intelligence is accelerating. Yet our multi-organisational survey reveals that AI adoption across European automotive actors remains predominantly shallow: most organisations are at pilot stage or early exploration, and the barriers they

cite - lack of internal expertise, resistance to change, poor data availability - are not primarily technological, they are organisational. They are, in a precise sense, cascade problems.

Our contribution is threefold. First, we present empirical evidence of cascade dysfunction across hierarchical levels within a large automotive manufacturing context, enriched by cross-industry AI readiness data spanning multiple OEMs and supplier tiers. Second, we theorise information refraction with greater conceptual precision than existing literature affords. Third, we argue that the rise of AI-enabled data access will not merely improve cascade efficiency - it will dismantle the cascade's role as the primary mechanism of strategic knowledge diffusion, with profound implications for where organisational power resides.

In the first theoretical section of this paper, we outline the key organizational contexts in which information generation, interpretation, and transmission play a critical role in decision-making. As organizations become increasingly complex and data-intensive, the volume and sophistication of available information grow rapidly, placing greater demands on hierarchical information-processing capacities. While advanced analytical tools and digital systems can enhance local decision-making, they also intensify coordination challenges across organizational levels. In such environments ensuring that relevant insights are accurately communicated upward under conditions of uncertainty and time pressure becomes a significant managerial challenge. Failures in this process can lead to delayed responses, strategic misalignment, and substantial performance losses. Through this

research, we seek to identify these mechanisms and assess how informational cascades shape organizational outcomes in complex operational settings. Furthermore, the paper devotes a whole chapter to important choice situations marked by high uncertainty and technological complexity, when informational cascades are most likely to occur. In such situations, middle management plays a critical role in interpreting, translating, and communicating specialist knowledge to top leadership. The chapter discusses how strategic narratives can eclipse localized technical discoveries, raising the possibility of distorted information flow. It also tackles the organizational challenges of managing risk, accountability, and uncertainty, such as responsibility, trust, and cross-hierarchical cooperation. Understanding these processes becomes increasingly crucial for avoiding strategic blind spots and organizational failure as technological and organizational complexity grows.

The major goal of this research is to discover the essential mechanisms that drive informational cascades within organizational hierarchies, with a focus on the role of middle management in shaping upward communication and strategic interpretation. Based on this purpose, the article addresses the following research question:

How do information cascades mediated by middle management influence upward information flow and strategic decision-making inside organizations?

This study uses a mixed-method research methodology to investigate how informational cascades influence organizational decision-making. It examines how middle management filters, transmits, and suppresses information across hierarchical levels using a combination of qualitative and quantitative methods. The paper aims to document patterns of information flow, upward communication, and decision-making across organizational hierarchies by distributing a questionnaire to the employees of selected major European firms. Additionally, it is possible to investigate the mechanisms, incentives, and limitations that lead to informational cascades and the repression of local knowledge within firms by conducting 3 focus groups with middle and senior managers. By clarifying how informational cascades arise and endure within hierarchical organizations, this work adds to the body of knowledge on organizational decision-making and information flow. The results provide useful information for companies looking to enhance strategic responsiveness and learning by emphasizing the influence of middle management on upward communication. Additionally, the study educates academics and managers on the dangers of systematic knowledge suppression and the circumstances that prevent local ideas from reaching high-level decision-makers. Lastly, it promotes more research into the consequences of informational cascades for long-term organizational success across organizational contexts, functions, and industries.

This work adds to the literature on organizational learning, decision-making, and information flow by expanding our understanding of informational cascades inside hierarchical organizations. It emphasizes how middle management influences the transfer and perception of knowledge during times of strategic uncertainty. The study also has practical implications for senior executives who want to create incentive structures and communication systems that lower the likelihood of knowledge suppression. Its drawbacks include a narrow focus on a small number of firms and managerial positions. Future study should use longitudinal designs and look at additional mediating factors as psychological safety, incentive alignment, and corporate culture.

2 Theoretical Background

Organizations seldom fail due to insufficient knowledge; they fail because pertinent information does not ascend promptly and accurately. Previous studies on informational cascades (Bikhchandani et al, 1992; Bikhchandani et al, 2024) indicate that individuals may withhold their private knowledge when social or hierarchical cues recommend an alternative course. Middle management plays a pivotal role inside businesses, serving as both interpreter and conduit of information between operational levels and senior leadership. Nonetheless, incentive frameworks, conformity constraints, and career risks frequently compel middle managers to comply to prevailing narratives instead of expressing opposing or adverse signals (Dvorak et al, 2025). Consequently, organizational learning failures and strategic blindness result from the systematic filtering, distortion, or silencing of local information (Haryjani et al, 2024). To understand how middle management leads to organizational failure, this paper looks at informational cascades.

Contemporary industries operate in environments characterized by rapid technological change, regulatory pressure, and increasing competitive intensity (Garrido-Moreno et al, 2024). Such conditions place significant strain on organizational information-processing and decision-making capabilities. As markets become more dynamic and complex, organizations face growing challenges in interpreting signals, coordinating responses, and aligning strategic actions across hierarchical levels. The influx of new entrants and disruptive innovations intensifies the need for timely and accurate upward communication. In this context, the ability of firms to adapt depends not only on access to information, but also on how effectively that information is filtered, interpreted, and escalated. Failures in these processes can result in strategic misalignment, delayed adaptation, and sustained competitive disadvantage (Ilmola-Sheppard & Kuusi, 2013). Not just the external environment has significant impact, but the increasing organizational complexity and data availability also have expanded the scope of managerial decision-making across operational and strategic domains. While advanced analytical tools can generate rich local insights, their organizational impact ultimately depends on how such information is interpreted, filtered, and communicated within hierarchical structures. A growing body of literature has examined information processing, sensemaking, and decision-making in organizations (Weick et al, 2005, Eckstein et al, 2025); however, comparatively little research offers analysis of how informational cascades emerge and persist at the middle management level. To address this gap, this paper reviews relevant literature on informational cascades and organizational decision-making and complements it with empirical evidence drawn from large organizations. By examining how middle managers translate and escalate information, the study sheds light on the prevalence and consequences of distorted information flow in complex organizational settings.

2.1 Information cascades in organisational hierarchies

The concept of information cascades emerged from economics and decision theory, describing situations in which individuals rationally discard private information in favour of publicly observable behaviour (Banerjee, 1992; Bikhchandani et al., 1992). Ribeiro et al. (2019) extended the framework to study message distortion in social diffusion chains, finding systematic content alteration as messages propagate without face-to-face interaction. Intra-organisational communication scholarship has addressed related phenomena under different labels: information filtering (Huber, 1991), knowledge stickiness (Szulanski, 1996), and communication distortion (O'Reilly & Roberts, 1974).

What unites these traditions is recognition that hierarchical position creates both motive and opportunity to alter information in transit. Huber and Daft (1987) documented that information richness declines with each relay step; Kiesler and Sproull (1982) observed systematic upward-filtered distortion in manager-to-executive communication. What is less studied - and what our research addresses - is the multi-level dynamics of downward strategic cascade, particularly in manufacturing organisations where cascade is formalised as an explicit management practice.

Nonaka and Takeuchi's (1995) knowledge creation model positions middle managers as 'knowledge engineers' who translate tacit executive vision into explicit operational knowledge. This framing treats the translation function as inherently enabling. Our data suggest it is also structurally vulnerable: translation capacity varies significantly across individuals and layers, and the conditions that support faithful translation - adequate information access, communicative competence, psychological safety to ask clarifying questions - are unevenly distributed.

2.2 The information refraction construct

We propose information refraction as a theoretical construct to describe the multi-dimensional transformation of information as it moves through organisational hierarchy. Distinct from distortion (which implies error) or filtering (which implies simple selection), refraction captures the systematic, structurally predictable bending of meaning induced by the properties of each hierarchical layer through which information passes. We define the *refractive index* of a managerial layer as a composite of four properties:

1. information access - the completeness and richness of what the layer receives;
2. translation capacity - the cognitive ability and communicative skill to convey strategic meaning faithfully;
3. political interest - what the layer gains or loses from transmitting specific content accurately; and
4. structural position - the layer's proximity to executive decision-making and exposure to multiple information streams. When any of these factors is suboptimal, refraction occurs: the message arrives at the next layer altered.

The refraction metaphor carries a further implication with direct relevance to AI disruption: if the medium through which information travels is removed - if employees gain direct, unmediated access to strategic data - the refractive effect disappears. The cascade collapses not because organisations abandon it deliberately, but because the technological conditions that made it necessary no longer obtain.

2.3 AI, data democratisation, and organisational power

A growing body of research examines how AI-mediated knowledge access reshapes organisational power dynamics. Gausen et al. (2023) developed a Consequence-Mechanism-Risk framework identifying that AI knowledge access systems interact non-trivially with existing power structures, potentially reinforcing asymmetries as much as dissolving them. Ide and Talamàs (2025) model the macroeconomic consequences of autonomous AI in knowledge hierarchies, finding that AI displaces humans towards complex problem-solving while restructuring the organisational demand for expertise at different levels. Recent theoretical work on GenAI and organisational structure argues that the technology's consequences for hierarchy depend critically on deployment design: the same technology can upskill or deskill depending on where in the hierarchy it is inserted. This resonates directly with our empirical finding that data access asymmetry - rather than strategic ambiguity - is the binding constraint on cascade fidelity in our research contexts. The technological intervention that dissolves the cascade paradox is not AI per se, but AI-enabled direct access to organisational intelligence.

3 Methodology

3.1 Mixed-method design

This study employs a concurrent mixed-methods design (Creswell & Clark, 2017), integrating quantitative survey evidence with qualitative focus group data, across two complementary research streams. The concurrent structure allows triangulation between within-organisation cascade dynamics (Research Stream 1) and industry-wide AI adoption patterns (Research Stream 2), enabling a theoretically integrated analysis that neither dataset alone could support.

Research Stream 1 was conducted within the European manufacturing division of a large global automotive OEM. The division encompasses several hundred members across multiple European locations. The organisation employs a formally institutionalised cascade communication practice, including regular all-hands briefings, daily team stand-up meetings, and structured one-to-one sessions at each hierarchical level. Survey data were collected across four stratified hierarchical groups, using anonymised digital instruments administered via Microsoft Forms. Table 1 presents the sample structure.

Table 1: Research Stream 1 - Survey Sample Structure

Hierarchical Level	n	Survey Instrument	Additional Qualitative Data
Working Level (< 5 yrs tenure)	7	Stream 1 Survey A	Focus Group 1
Working Level (≥ 5 yrs tenure)	13	Stream 1 Survey A	Focus Group 1
First-Line Managers	11	Stream 1 Survey B	Focus Group 2
Middle Managers	18	Stream 1 Survey B	Focus Group 2
Senior Managers / Divisional Heads	12	Stream 1 Survey C	Focus Group 3
TOTAL	61		3 Focus Groups

Three focus groups - corresponding to the working-level, managerial, and senior-managerial strata - explored lived cascade experience, friction points, and normative expectations of the cascade system. Key quantitative measures included: information reception adequacy (5-point Likert); strategic goal comprehension (5-point Likert); cascade confidence (categorical); and channel preference (multi-select).

Research Stream 2 was conducted to examine AI adoption in the automotive sector. The survey instrument covered AI technology portfolio, adoption maturity stage, departmental diffusion, key drivers and barriers, supply chain integration, production automation depth, quality management integration, staff training readiness, and sustainability/circular economy applications.
The sample (n = 37) was deliberately multi-organisational, spanning the automotive value chain rather than any single company. Respondents were drawn from OEMs (n = 26), Tier 1/2 car parts manufacturers (n = 7), and adjacent actors including professional services, maritime, and agri-manufacturing (n = 4). Geographically, respondents were headquartered across Belgium (n = 19), Japan (n = 5), Germany (n = 3), Hungary (n = 2), the UK (n = 1), Portugal (n = 1), Poland (n = 1), and Spain (n = 1). By role, respondents included management (n = 18), specialists (n = 9), C-suite (n = 7), and technical leads (n = 3). All organisations had 500+ employees with the exception of five mid-size organisations (101–500 employees).

4. Results

The most striking finding from Research Stream 1 is the systematic variation in strategic comprehension and information satisfaction across hierarchical levels. Table 2 presents mean scores across key dimensions.

Table 2: Stream 1 Survey Results by Hierarchical Level (n = 61)

Hierarchical Level	n	Info reception (mean /5)	Goal clarity (mean /5)	Can explain goals to next level
Working Level	20	3.80	3.85	Open text - see 4.2
First-Line Managers	11	3.73	4.27	45% Yes | 45% With limitations | 9% No
Middle Managers	18	3.89	3.78 ⚠	28% Yes | 61% With limitations | 11% No
Senior Managers / HO	12	4.67	4.58	75% Yes | 25% With limitations | 0% No

The data reveal a pronounced comprehension inversion at the middle manager level. Despite being the primary cascade relay point - the actors most responsible for translating strategy to working-level members - middle managers report both the lowest goal clarity (3.78/5) and the highest rates of self-reported limitation (61%) in their ability to explain goals to the next level. This is not a failure of individual capability but a structural phenomenon: middle managers receive partially-filtered information from senior layers, lack systematic access to the analytical context behind strategic decisions, and are expected to re-contextualise that information for operationally diverse teams - often without standardised tools or preparation time.

4.1 The supervisor as information gatekeeper

Working-level respondents identify the manager or supervisor as a primary information source in 65% of cases - the most cited single channel alongside the company portal. This dependence is not passive. Qualitative responses reveal active reliance on the supervisor as interpreter and contextualiser:

"Depending on the type of announcement, but in general I rely a lot on my supervisor for sharing company communication." (Working-level respondent, Vehicle Supply Chain)

This reliance creates a cascade vulnerability: when the gatekeeper's comprehension is limited - as our middle manager data shows - the information arriving at working level is doubly filtered: first by organisational distance from strategy, then by the gatekeeper's interpretation. Several respondents articulate an awareness of this structural inequity:

"If one supervisor is less sharing to employees and other supervisor more - it creates disadvantage in information available to some employees which is difficult to balance." (Working-level respondent, Strategy Planning)

This respondent has identified the core mechanism of information refraction empirically: systematic inequality in information availability as a function of the refractive properties of individual relay agents. Two employees at identical organisational levels in adjacent departments may operate with fundamentally different understandings of corporate strategy - not because the strategy is ambiguous, but because their respective relay agents bend it differently.

A further diagnostic emerges from Focus Group 1: the perception that strategic information sometimes arrives from external news sources before internal cascade. One respondent noted they were *"learning things via news about the company before it was even shared internally".* This is a classic cascade lag indicator - time-sensitive information circumventing the relay chain through external channels because internal relay is too slow.

4.2 The middle management paradox

Middle managers exhibit a distinctive pattern: their information reception score (3.89/5) is adequate - they receive information - but their goal clarity score (3.78/5) is the lowest in the sample, and their qualitative responses reveal why. They receive information stripped of the strategic context that would allow faithful re-contextualisation. As one middle manager respondent describes the situation: 'communications on different tasks - there is a lot of noise. Need to simplify messages, visualise objectives and link to the higher goals.' This is a precise description of refraction: the signal arrives amplified in volume but reduced in coherence, and the manager must perform signal extraction before re-transmission - a task for which they often lack adequate raw material.

Focus Group 2 (managerial level) surfaces the same dynamic from within: managers explicitly request standardised 'slide decks for complex topics' as cascade support tools, and advocate for 'consistency in messaging to avoid confusion.' These are not requests for more information - they are requests for better-structured information that reduces the refractive burden at the relay point.

One working-level respondent articulates the ideal from the receiving end: 'Be a filter but do not over-filter the information, assuming I don't need to know on my level.' This captures the fundamental tension of middle management's cascade role: filtering is necessary, but over-filtering is the precise mechanism by which strategic intent dies in transit.

4.3 Senior management: high fidelity, high distance

Senior managers and Heads of Division report the strongest outcomes: 4.67/5 for information reception, 4.58/5 for goal clarity, and 75% confident in explaining strategy to the next level. Structurally expected - they receive information closest to source. But the high-fidelity position carries a design assumption: that they will faithfully and completely transmit their superior comprehension downward. One senior respondent's comment challenges this assumption:

'Honestly, I don't know the divisional strategy. Was it shared with all members?' - a striking admission of cascade opacity even at senior level in one organisational unit.

Focus Group 3 (senior level) reveals a shared appetite for structural discipline: standardised cascade processes, supporting documents, and quality-controlled messaging. The irony is that the actors closest to strategic information are simultaneously the most articulate about the need for cascade infrastructure - infrastructure that the system currently lacks.

4.4 Integration: the cascade paradox in the age of AI

4.2.1 The Structural connection between cascade dysfunction and AI unreadiness

Read in isolation, our two datasets tell two different stories: one about how information bends in hierarchical relay chains, another about how AI adoption in automotive is slower and shallower than discourse suggests. Read together, they reveal a single structural dynamic.

Organisations that rely on cascade as their primary mechanism of strategic knowledge diffusion share three characteristics with organisations that struggle to absorb AI: they are information-asymmetric (different actors have access to different quality and volume of data); they are translation-dependent (meaning is not self-evident but requires human intermediation at each relay point); and they are politically mediated (what gets shared,

and how, reflects the interests of the relay agent as much as the intent of the sender). These three characteristics define both cascade dysfunction and AI adoption failure.

The barriers that 73% of our Stream 2 respondents cite - lack of internal expertise - is precisely what cascades were historically supposed to develop: translational capacity at each organisational layer. The cascade was the knowledge management solution. It is now also the knowledge management problem. And the same dynamic - inadequate translation at the point of relay - is what prevents AI outputs from becoming organisational intelligence.

4.2.2 The inflection point: what AI-enabled data access changes

We are at the threshold of a structural shift. The centralisation of organisational data in cloud platforms, combined with AI-enabled query and synthesis capabilities - large language models, real-time analytics, intelligent search, predictive dashboards - creates the technical precondition for a qualitatively different information architecture. When employees can query organisational data directly, contextualise it against their role, and generate actionable insight without managerial relay, the refractive medium is removed.

This shift creates what we term the cascade collapse scenario: not a catastrophic failure but a structural obsolescence of the cascade as the primary mechanism of strategic information diffusion. The cascade does not disappear - but it transforms from a necessity (the only way information can travel) into a choice (one channel among many, selected for its interpretive value rather than its positional monopoly).

In this emerging architecture, the power dynamics of organisational knowledge shift profoundly. Currently, internal politics partly function by controlling information flow: the actor who decides what gets shared, with whom, and in what frame holds structural power. In an AI-enabled environment with democratised data access, this power diminishes. Employees with high analytical capacity - regardless of hierarchical position - can navigate data directly, form evidence-based positions, and contribute strategic insight without requiring the relay chain's approval. The 'talent dividend' of AI accrues to those with cognitive and analytical depth, not those with privileged access to cascaded information.

4.5 Two scenarios: democratisation or amplified dysfunction

The theoretical implication splits into two divergent futures, contingent on organisational investment decisions being made now.

Scenario A - The democratisation dividend

Organisations that invest systematically in AI literacy, data infrastructure, and equitable access architecture will experience genuine knowledge democratisation. Working-level members with strong analytical capacity - currently constrained by the refractive chain above them - will be liberated to operate on the basis of direct data access. The cascade paradox resolves: the middle manager who currently struggles to explain divisional strategy because they lack analytical context will, in this scenario, have that context directly available. Their role shifts from information relay agent to interpretive partner - a qualitatively higher-value function.

For automotive OEMs and their supplier networks, this scenario represents a significant competitive acceleration. The speed at which supply chain disruptions are diagnosed, production decisions are made, and strategic pivots are executed depends on the density of intelligence throughout the organisation - not just at the top. Scenario A multiplies that density.

Scenario B - The amplified dysfunction

Organisations that fail to invest in AI readiness, data quality, and workforce capability will not experience the cascade problem dissolving - they will experience it amplifying. The arrival of AI tools that employees begin to use ad hoc, without governance or interpretive training, generates a new form of refraction: AI-mediated distortion. Data that is unstructured, ungoverned, and person-dependent - common in manufacturing environments with legacy systems - produces unreliable AI outputs. Employees who cannot evaluate those outputs critically propagate AI-generated misinformation through the same structural mechanisms as before, but faster and at greater scale.

Our Stream 2 data suggests that many organisations are currently positioned closer to Scenario B than Scenario A: 57% lack trained staff for AI output interpretation, QMS integration is absent in 52% of cases, and supplier AI collaboration is rejected by half the sample. These are not minor readiness gaps - they are the infrastructure preconditions for AI-enabled knowledge democratisation, and they are largely absent.

Table 3: Current vs. AI-Enabled Information Architecture - Structural Contrasts

Dimension	Cascade Architecture (Current)	AI-Enabled Architecture (Emerging)
Information flow direction	Sequential downward relay through layers	Simultaneous multi-directional; available at point of need
Interpretive authority	Held by relay agent (managers)	Distributed; AI provides synthesis layer
Speed of diffusion	Governed by relay chain frequency (weekly, monthly)	Near real-time to point of need
Quality determinant	Each relay agent's comprehension and fidelity	Data governance quality and AI literacy
Power mechanism	Information access asymmetry	Analytical and contextual capacity
Working-level position	Structurally dependent on supervisor interpretation	Can self-serve, self-contextualise
Middle management role	Information relay - translation under resource constraint	Interpretive partner - analytical collaborator
Primary failure mode	Refraction: meaning bent in transit	Amplification: unreliable AI outputs propagated at scale
Competitive implication	Alignment gaps slow strategic execution	AI literacy divide creates winner/loser split between orgs

4.6 Theoretical contributions

This paper makes three principal theoretical contributions. First, the information refraction construct provides a more analytically precise account of intra-organisational cascade dysfunction than prior notions of distortion or noise. By specifying the refractive index as a multi-dimensional property encompassing access, translation capacity, political interest, and structural position, we produce a framework that predicts where and why refraction occurs - not merely that it does. This operationalisability is the construct's key theoretical advantage.

Second, the middle manager paradox - the relay agent with the lowest strategic comprehension at the highest-volume cascade point - is a structural finding that challenges Nonaka and Takeuchi's (1995) enabling framing of middle management knowledge engineering. Middle managers are not simply translators; they are translators who receive systematically impoverished inputs and are expected to produce enriched outputs. The structural conditions for faithful translation are unevenly distributed, and the layer most responsible for the translation function is the layer most underserved by the system.

Third, the cascade collapse argument advances a prospective theoretical contribution: as AI-enabled data access becomes structurally available, the organisational theory of cascade becomes increasingly anachronistic. Knowledge management scholarship requires frameworks for the post-cascade organisation - in which the research question shifts from 'how do we relay information faithfully?' to 'how do we build organisational capacity to use information intelligently?' Our bi-dataset approach demonstrates how empirical cascade research and AI adoption research can be theoretically integrated rather than conducted in separate silos.

4.7 Practical implications for automotive organisations

For OEMs and their supplier networks, our findings generate three urgent areas of focus. First, organisations should diagnose their cascade architecture empirically - using stratified, cross-level surveys of the kind deployed here - before designing AI strategy. Cascade dysfunction is the condition into which AI will be deployed. Organisations that understand their cascade failure modes before AI adoption will design more resilient AI architectures. Those that do not will replicate their cascade problems at machine speed.

Second, cascade resilience interventions should target the middle manager layer as the highest-leverage point. This means providing direct access to the analytical material supporting strategic decisions (not just conclusions); standardising cascade support materials; and treating communicative and analytical competence as core management development priorities - not soft skills, but operational competencies.

Third, and most urgently, organisations must begin investing now in the AI literacy and data governance infrastructure that will determine which bifurcated scenario materialises. The window for proactive design is narrowing rapidly. Our data shows that the barriers to AI adoption are organisational, not technological - and organisational barriers are what leadership teams are uniquely positioned to address. Technical readiness without human readiness produces systems that cascade distortion at industrial scale.

5 Conclusions

The cascade is one of the most ubiquitous and least examined mechanisms in organisational life. Across a large European automotive manufacturing organisation and a multi-OEM, multi-supplier ecosystem spanning European automotive actors, our research reveals that cascade practice is simultaneously essential and systematically flawed - not because the concept is wrong, but because the structural conditions under which it operates reliably produce information refraction. Meaning bends as it travels through organisational layers, and the bending is not random: it is structured by the refractive properties of each relay agent, most critically at the middle management level.

The cascade paradox is both an empirical finding and a theoretical provocation. It demands that knowledge management scholars take seriously the political, cognitive, and structural dimensions of information relay within hierarchical organisations. It also demands temporal urgency: the cascade is not merely an inefficient relic of pre-digital management practice. It is the mechanism through which AI-generated intelligence will - or will not - reach the people and processes that can act on it.

Across the broader automotive ecosystem, our multi-organisational data reveals that AI adoption is shallow, human readiness is lagging, and the barriers are organisational rather than technological. This is not a pessimistic finding - it is a clarifying one. The organisations that will navigate the disruptions of electrification, supply chain fragility, and geopolitical volatility most successfully are not those that deploy the most sophisticated AI. They are the ones that build the human and structural capacity to use whatever AI they deploy - the capacity to receive information, understand it, act on it, and pass that understanding faithfully to others.

In the end, the cascade paradox and the AI readiness problem are the same problem: an organisation's knowledge is only as good as its weakest relay point. And the relay points that matter most are not the algorithms. They are the people.

6 Limitations and Future Research

While this paper represents a theoretically rich context, the cascade paradox's prevalence in other organisational types requires further investigation. The multi-organisational breadth compensates partially for this limitation but does not permit the depth of hierarchical analysis. The prospective AI argument is necessarily theoretical: the transformation it describes is in early stages of emergence. Our data establishes that most organisations are not yet positioned to realise the democratisation scenario. Longitudinal research tracking cascade dynamics as AI access is deployed at scale will be essential to test the bifurcated scenario predictions empirically.

7 Ethics Declaration

Prior to participation, all interviewees were provided with written information detailing the purpose of the study and the procedures for data handling. Informed consent was obtained from all participants based on the information provided. To ensure confidentiality, participants are represented anonymously and in a non-identifiable manner, in accordance with their stated preferences.

8 AI Declaration

In the development of this paper, the grammar correction and language refinement processes were supported by the use of DeepL Write. The tool assisted in enhancing the clarity, coherence, and fluency of the text without altering the substantive content or interpretation of the research findings. A critical review and editing process was undertaken by the authors to ensure the accuracy and alignment of the outputs with the intended meaning. We also used the Claud program for brainstorming and gathering reference materials. The final manuscript is a reflection of the authors' intellectual input and analytical interpretation.

Abstract

Sustainability has emerged as a critical global challenge, compelling industries to integrate environmental considerations into their core strategies. The main objective of this study is to examine the direct influence of green transformational leadership and the mediating roles of green knowledge management and green motivation in achieving a sustainable competitive advantage. Primary data collected from 157 firms belonging to the mining sector are analyzed using PLS-SEM technique. The findings reveal that green transformational leadership significantly enhances sustainable competitive advantage, both directly and through the mediating mechanisms of green knowledge management and green motivation, which enable organizations to systematize environmental knowledge, aligning individual and organizational goals, and fostering proactive employee behaviors toward sustainability. These results contribute to clarify how leadership-driven sustainability visions are translated into organizational capabilities and extend the knowledge-based view by showing how sustainability contexts intensify firms' dependence on internal knowledge orchestration and motivational alignment. In industries where environmental challenges are unavoidable, competitive advantage is less about external positioning and more about the effective internal mobilization of knowledge resources. In this regard, this investigation contributes to sustainability research by shifting the focus from external compliance and outcomes to internal organizational processes that sustain competitive advantage over time. From a managerial perspective, the results suggest that firms seeking sustainable competitive advantage should invest in environmentally oriented leadership development, as well as in the design of robust green knowledge management systems and motivational practices, since leaders play a critical role in signalling the strategic importance of sustainability, but enduring advantages arise when environmental knowledge is institutionalized and employees are intrinsically motivated to apply it. For policymakers, the results underline the importance of supporting organizational capabilities related to leadership development and knowledge management, rather than relying exclusively on regulatory enforcement. This study shows that sustainable competitive advantage in environmentally sensitive industries is fundamentally a knowledge-based phenomenon, by integrating leadership, knowledge management, and motivation into a coherent framework, thereby offering new insights into how organizations can transform sustainability pressures into strategic opportunities through internal knowledge-driven mechanisms. It is concluded that leadership practices promoting environmental stewardship are essential in transforming operational frameworks to meet sustainability challenges and achieve a sustainable competitive advantage, leveraging organizational knowledge resources and fostering employee motivation to align the firms' environmental and economic objectives.

Keywords: Knowledge management, leadership, motivation, sustainability, PLS-SEM.

Paper type: Academic Research Paper.

1 Introduction

In the contemporary era, sustainability has emerged as a global challenge, capturing the attention of governments, businesses, and civil society alike, and the escalating impacts of climate change, resource depletion, and environmental degradation have underscored the urgent need for a shift toward sustainable development (Chomachaei *et al.*, 2024; Lyu *et al.*, 2024). Firms across industries are increasingly held accountable for their environmental footprints, facing regulatory pressures and heightened societal expectations to adopt practices that minimize harm to the natural environment, and the growing awareness of humanity's impact on ecosystems has prompted a fundamental reevaluation of traditional business practices, emphasizing the necessity of integrating environmental considerations into core organizational strategies, so that achieving entrepreneurial sustainability is essential for ensuring long-term economic viability and environmental stewardship (Ishaq *et al.*, 2024; Quttainah *et al.*, 2024). Positioned within the mineral-rich expanses of Kazakhstan, mining activity stands as one of the most important sectors of the nation's economy, blending its storied legacy with contemporary innovation to address the mounting global emphasis on

sustainability, making an important contribution to national GDP and global mineral markets, which are facing growing demands to integrate sustainable practices into its operations (Tazhibekova *et al.*, 2020; Atakhanova *et al.*, 2023; Kunarbekova *et al.*, 2024).

As one of the world's leading producers of essential minerals, Kazakhstan's mining sector plays a key role in driving the national economy as well as meeting global demands for resources, but these operations often come with significant environmental challenges, including resource depletion, habitat destruction, and greenhouse gas emissions which, coupled with increasing regulatory scrutiny and societal expectations for environmental responsibility, underscore the urgent need for transformative approaches to sustainability within the industry (Alimbaev *et al.*, 2020; Denissova *et al.*, 2023; Omurova *et al.*, 2024). Despite its significance, limited research has explored how leadership within the mining industry can catalyze sustainability outcomes and, specifically, the role of green transformational leadership, a leadership style that combines visionary guidance with a commitment to environmental principles, on fostering firms' sustainable competitive advantage remains underexplored (Sujati *et al.*, 2023; Zhong *et al.*, 2023; Hu *et al.*, 2024; Onifade *et al.*, 2024). This study seeks to address this gap by analyzing the role of green transformational leadership as a driver of sustainable competitive advantage in the mining sector, examining its direct influence and the mediating effects of green knowledge management and green motivation. Existing literature highlights the direct benefits of leadership on business sustainability but often fails to delve into the mechanisms that translate leadership into measurable sustainability outcomes (Razzaque *et al.*, 2024; Sajjad *et al.*, 2024).

2 Theory and Hypothesis

In this study, green knowledge management, which refers to the systematic sharing, integration, and application of sustainability-related knowledge within organizations, with the aim of enabling firms to innovate, optimize resource usage, and align their operations with environmental goals, and green motivation, which captures the intrinsic drive among employees to engage in environmentally responsible behaviors, are analyzed to provide insights into the main mechanisms through which sustainability-focused leadership can drive superior organizational outcomes (Ahmed *et al.*, 2021; Khan *et al.*, 2024). By fostering green knowledge management and green motivation, leaders can build resilient organizations capable of facing the dual imperatives of growth and sustainability, so that together, these variables can explain the ways in which green transformational leadership influences sustainable competitive advantage and builds long-term resilience within firms, by promoting shared values, and an organizational culture that prioritizes sustainability. Kazakhstan's mining industry, as a leading contributor to employment and foreign trade, provides an ideal context for exploring these dynamics, inasmuch as the sector's substantial environmental footprint necessitates a revaluation of its traditional business practices (Mahmood & Orazalin, 2017; Zarubin *et al.*, 2021; Raihan & Tuspekova, 2022).

Addressing these challenges requires leadership that fosters a culture of sustainability and, in this sense, the concept of green transformational leadership emerges as a transformative force that inspires organizations to adopt practices that harmonize economic and environmental goals, enhancing the capacity of enterprises to respond to regulatory pressures, innovate in resource efficiency, and reduce their environmental impact, acting as catalysts for embedding sustainability into the strategic and operational frameworks of mining firms (Tian *et al.*, 2023; Janjua *et al.*, 2024; Amegboleza & Ülkü, 2025) Furthermore, when leaders prioritize the dissemination of sustainability-related knowledge, they can create an environment where employees are equipped to understand the relevance of their actions to the organization's environmental goals, building the technical competencies necessary for implementing eco-friendly practices and fostering a deeper connection between employees' day-to-day tasks and the broader sustainability objectives of the firm, thus ensuring that sustainability is a tangible operational priority by establishing systems that effectively capture, share, and utilize environmental insights (Younis & Hussain, 2023; Shafait & Huang, 2024).

In connection with the above, this kind of leadership can influence the workforce by fostering a shared sense of purpose centered on environmental responsibility, so that through the reinforcement of shared values and the consistent integration of green principles, employees may perceive their roles as integral to the organization's success in achieving sustainability goals, understanding how their individual contributions connect to the broader environmental and organizational outcomes, which may affect their level of commitment, innovation, and proactive behaviors (Huang *et al.*, 2023; Ansari & Khan, 2024). The resource-based view underscores the significance of unique organizational resources, such as environmental knowledge and employee dedication, positioning environmental knowledge as a critical asset for improving operational efficiency and enabling strategic differentiation (Aslam *et al.*, 2024; Samadhiya & Agrawal, 2024). Building on this foundation, self-determination theory offers a complementary perspective by highlighting the role of motivation in fostering individual engagement and performance, unveiling the way in which leaders can inspire

employees to internalize organizational sustainability goals, cultivating a sense of ownership and personal responsibility for environmental initiatives, and creating an engaged workforce that actively seeks innovative solutions to environmental challenges, contributing meaningfully to the organization's sustainability agenda (Chong *et al.*, 2024; Patwary *et al.*, 2024).

Adding further depth to this framework, social identity theory provides valuable insights into the dynamics of collective action, establishing that individuals derive a sense of identity and belonging from their association with groups that embody shared values and objectives, so that, in the context of sustainability, employees who perceive their organization as genuinely committed to environmental stewardship may be more likely to develop a shared identity centered on these values, strengthening collective efforts, fostering collaboration, and enhancing the organization's ability to address complex environmental challenges through cohesive and unified action (Aggarwal & Agarwala, 2023; Rana & Arya, 2024). When applied to industries like mining, where the balance between operational efficiency and environmental sustainability presents unique challenges, these theoretical frameworks highlight the critical role of leadership-driven mechanisms to guide the integration of green knowledge management practices and fostering a shared green identity, facilitating the development of innovative solutions and strengthening a corporate culture that prioritizes sustainability as a strategic imperative, thus underscoring the transformative potential of leadership in shaping resilient organizations that can successfully face the complexities of a global economy increasingly defined by environmental consciousness.

Although previous studies have explored the influence of green transformational leadership on firms' sustainability, they have not sufficiently examined its influence on achieving a sustainable competitive advantage, nor how green knowledge management and green motivation mediate this relationship, particularly in environmentally sensitive sectors like mining (Özgül & Zehir, 2023; Xin & Wang, 2023; Abbas, 2024). This study seeks to fill this gap by providing empirical evidence from the mining industry in Kazakhstan, extending the understanding of how leadership, knowledge, and motivation interact to drive sustainability outcomes, offering a comprehensive view of how organizations can adapt to modern environmental challenges. Therefore, this article contributes to the literature by providing empirical evidence of the impact of green transformational leadership on sustainable competitive advantage, highlighting the mediating roles of green knowledge management and green motivation, challenging the existing paradigms by demonstrating the specific mechanisms through which leadership can drive sustainability outcomes in a context marked by significant environmental and economic stakes. For scholars, practitioners, and policymakers, these findings offer valuable insights into leveraging leadership and organizational dynamics to achieve superior environmental performance and a sustainable competitive advantage. Following this introduction, subsequent sections will present the theoretical background supporting the hypotheses, the methodology employed, the empirical analysis conducted, a discussion of the findings, and, finally, the conclusions, which synthesize the insights and offer actionable recommendations for practitioners and policymakers.

Based on the above, the following hypotheses are proposed:

- *Hypothesis 1 (+): Green transformational leadership has a positive effect on sustainable competitive advantage.*
- *Hypothesis 2 (+): There is a mediating effect of green motivation in the relationship between green transformational leadership and sustainable competitive advantage.*
- *Hypothesis 3 (+): There is a mediating effect of green knowledge management in the relationship between green transformational leadership and sustainable competitive advantage.*
- *Hypothesis 4 (+): Green knowledge management and green motivation have a double mediating effect in the relationship between green transformational leadership and sustainable competitive advantage.*

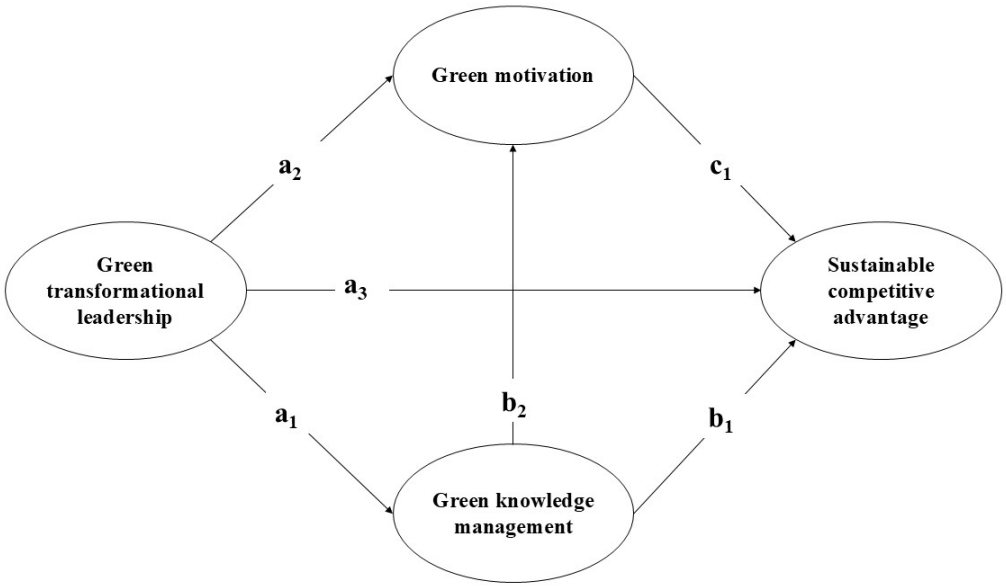

Figure 1. Nomogram of the proposed model

H1 = a3: Green transformational leadership → Sustainable competitive advantage; H2 = a2 x c1: Green transformational leadership → Green motivation → Sustainable competitive advantage; H3 = a1 x b1: Green transformational leadership → Green knowledge management → Sustainable competitive advantage; H4 = a1 x b2 x c1: Green transformational leadership → Green knowledge management → Green motivation → Sustainable competitive advantage.

3 Methodology

The mining industry in Kazakhstan is one of the most important for the national economy, contributing significantly to industrial and regional development while serving as a foundation for the growth of associated industries. According to the National Bureau of Statistics of the Republic of Kazakhstan, in 2023 the mining industry was composed of 1579 active firms, employing around 150,000 people, which is essential due to its high wages, which are more than double the national average, and the share of GDP from the mining industry in the industrial sector is 47%, and 35% in the total production of goods. Kazakhstan ranks among the top global producers of key mining resources, being the leading producer of uranium, with significant reserves of chromium, copper, gold, and zinc and, in terms of export, mining products accounted for nearly $10.5 billion in 2023, contributing 17.5% of Kazakhstan's total export value. Technological innovation is also shaping the sector, driven by large enterprises such as Kaz Minerals or Kazzinc, which have embraced Industry 4.0 principles, integrating AI for operational efficiency, predictive maintenance, and resource optimization, e.g., Kaz Minerals has achieved productivity rates ten times higher than similar operations globally by adopting automated systems and drone technology, and it has increased investments in copper, gold, and other metals aligned with global renewable energy trends suggest a promising trajectory (World Bank, 2023). This research focuses on the Kazakh mining sector as a context for exploring green transformational leadership and its effects on sustainable competitive advantage, with mediating roles of green knowledge management and motivation, providing interesting insights into sustainable strategies critical for enhancing the competitiveness and global positioning of the industry.

Data collection for this study involved distributing a questionnaire to Chief Executive Officers of mining firms in Kazakhstan during the period from September 9 to November 22, 2024, using the Qualtrics platform and Microsoft Outlook as dissemination tools. A total of 157 valid responses were collected, which corresponds to a response rate of 9.94%. The minimum sample size was determined using the minimum R^2 method as outlined by Hair *et al.* (2016). For a model with a maximum of three predictors and a minimum R^2 value of 0.480, a sample size of at least 38 was required. Additionally, calculations using the G*Power tool indicated that for significance levels of 5% and 1%, and a medium effect size, the minimum sample sizes needed were 74 and 108, respectively. The collected sample of 157 firms significantly exceeds these thresholds, enhancing the reliability of the results by providing a robust dataset that reduces the likelihood of statistical errors and increases the generalizability of the findings to the broader population of firms in the Kazakh mining sector.

To ensure consistency, reliability, and validity, the variables included in this study were measured using previously established scales. The independent variable, green transformational leadership, was assessed using six items from Chen and Chang (2013), while the dependent variable, sustainable competitive advantage, was evaluated with five items adapted from de Guimarães *et al.* (2018). The mediating variables, green knowledge management and green motivation, were measured using five and four items from Sahoo *et al.* (2023) and Úbeda-García *et al.* (2022). Data analysis was conducted using the PLS-SEM technique via the SmartPLS software, which is particularly suited for this study due to its ability to handle complex models with multiple constructs and indicators while providing robust predictive insights, being particularly valued for its accuracy and its focus on explaining variance in dependent variables (Hair *et al.*, 2012; Hair *et al.*, 2019a).

4 Results

The overall model fit was evaluated using the Standardized Root Mean Squared Residual (SRMR) yielding 0.072 < 0.08, aligning with the guidelines provided by Hu and Bentler (1998) and Hair *et al.* (2019a). Following this, the measurement models were assessed to ensure the constructs' reliability and validity, and to ensure the integrity of the research, discriminant validity is evaluated through Heterotrait-Monotrait ratio (HTMT). Moreover, using the methodology recommended by Hair *et al.* (2019b), the structural model was evaluated to provide a detailed and methodical examination of the theoretical constructs in the research framework, which involves analyzing direct, indirect, and total effects to confirm the proposed hypotheses and deepen the understanding of the relationships within the model. The model's predictive capabilities were assessed using R^2 values, with benchmarks of 0.25, 0.50, and 0.75 representing weak, moderate, and strong predictive power, respectively, as outlined by Hair *et al.* (2019a). The proposed model demonstrates robust explanatory power, accounting for 48.0%, 53.2%, and 63.5% of the variance in green knowledge management, green motivation, and sustainable competitive advantage, respectively, which validates the theoretical framework and emphasizes the critical interplay among environmental leadership, knowledge, and employee motivation to generate a sustainable competitive advantage.

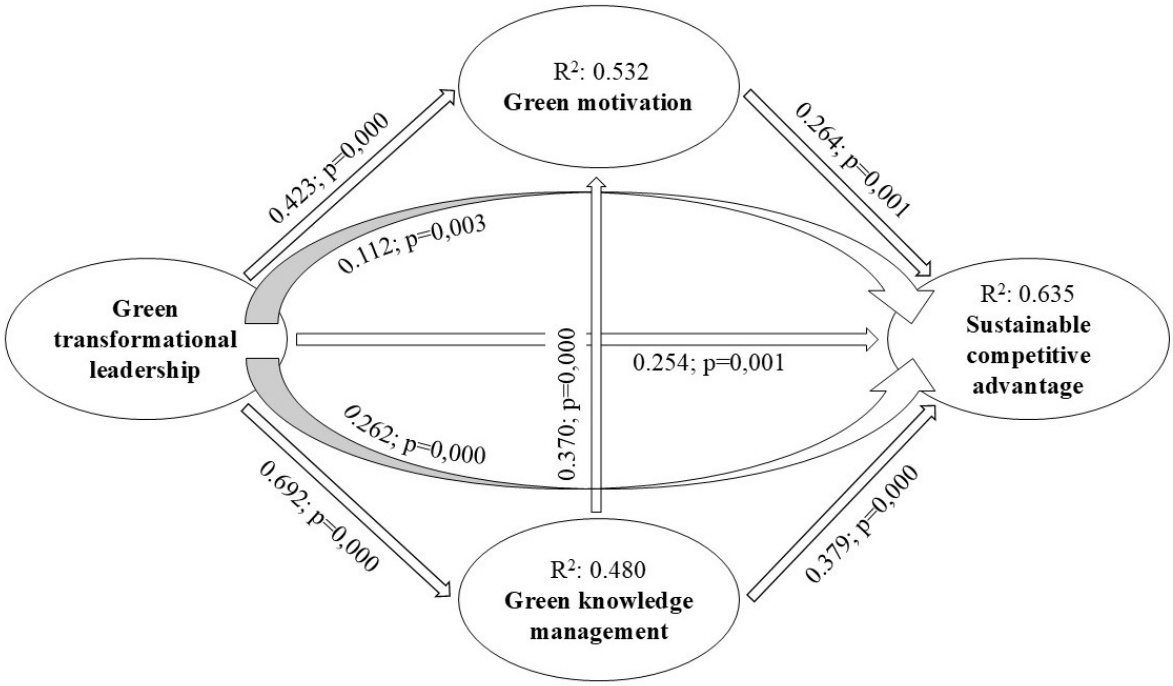

Figure 2. Direct and indirect relationships

This research offers significant contributions to the discourse on sustainable competitive advantage by integrating green transformational leadership within the framework of the Kazakh mining industry, increasing the understanding on how these firms can achieve a sustainable competitive advantage addressing their ecological footprint, and contributing to broader goals of sustainable development and economic resilience. The results evidence a positive and significant relationship between green transformational leadership and sustainable competitive advantage (H1), the mediating effects of green motivation (H2) and green knowledge management (H3), and the double mediating effect of these variables (H4). By exploring the role of green

transformational leadership alongside the mediating influences of green knowledge management and green motivation, it is established a way for integrating sustainability into core business strategies that transcends traditional operational models, which can offer firms a competitive edge while addressing environmental challenges in a global market increasingly defined by sustainability demands.

5 Conclusions

Sustainability has emerged as a key driver of long-term competitiveness and environmental responsibility in Kazakhstan's mining industry. This study emphasizes the pivotal role of green transformational leadership in embedding sustainability into the strategic and operational practices of mining companies, revealing that effective leadership fosters an environmentally conscious knowledge management system that aligns employees' motivation and efforts with broader sustainability goals, reshaping traditional business models to reduce environmental impact. The findings highlight how green knowledge management and green motivation mediate the link between leadership and sustainable competitive advantage, channeling the influence of leaders by systematically capturing, saving, and sharing environmental knowledge, and enhancing the motivation of the employees to act in an environmentally responsible manner, ensuring that their values align with organizational sustainability objectives, fostering a deeply engaged workforce committed to achieving green outcomes, which have a positive impact on the development of a sustainable competitive advantage, through their potential effects on innovation and operational efficiency.

Despite its valuable contributions, this study is not without its limitations. The reliance on cross-sectional data limits the ability to draw causal inferences about the relationships examined, so that future longitudinal studies could offer deeper insights into how these dynamics evolve over time. Moreover, the study focuses specifically on the mining industry in Kazakhstan, which, while offering a rich and relevant context, may limit the generalizability of the findings to other sectors or regions with different environmental and economic conditions. In addition, while the constructs of green transformational leadership, green knowledge management, and green motivation are explored comprehensively, other potentially relevant variables, such as organizational learning capacity or external stakeholder engagement, were not included, which could provide additional dimensions to the analysis. These limitations, however, do not diminish the study's contributions but rather highlight areas for future research to build upon.

Integrating Farmers' Behaviors into Agricultural Index-Based Insurance: A Knowledge-Based Theoretical Framework

Abstract

Agricultural index-based insurance has emerged as an important mechanism for managing climate-related risks; however, existing frameworks largely treat farmers' behavior as exogenous, overlooking how knowledge-driven adaptive responses to early-warning signals may dynamically mediate crop losses. This study proposes behavior-based index insurance (BBII), a theoretical framework that extends multi-hazard index-based insurance models by incorporating a behavioral compliance component into actuarial pricing. Specifically, the framework introduces an adaptive behavior index (ABI) as a composite metric that captures farmers' behaviors in response to early-warning signals across three dimensions: compliance with recommended actions, response timing, and intervention intensity. By integrating the ABI into the vulnerability module, BBII allows yield sensitivity to vary as a function of farmers' behavior, rather than relying on the multi-hazard index alone, thereby generating a dynamic tick value that scales payouts per unit of multi-hazard index variation according to behavior-adjusted yield sensitivity. This mechanism results in a behavior-sensitive premium structure in which premiums decrease with higher adaptive behavior and increase under low compliance. The proposed framework reconceptualizes insurance as an active risk-governance mechanism rather than a passive compensation mechanism, creating financial incentives for proactive adaptive behavior. By endogenizing adaptive behavior within index insurance design, this framework advances a dynamic, knowledge-driven approach to agricultural risk management that aligns pricing incentives with effective climate adaptation.

Keywords: index-based insurance; adaptive behavior index; climate risk management; early-warning systems; actuarial pricing.

Paper type: Academic Conceptual Paper

1 Introduction

Climate change poses significant and escalating challenges to agriculture, threatening food security, rural livelihoods, and national economies (Raza et al., 2019; Janni et al., 2024; Saleem et al., 2025). Temperature and precipitation, the fundamental climatic variables, regulate the entire crop growth cycle, from planting to harvest (Agnolucci et al., 2020). Deviations beyond optimal thresholds of these variables within each specific crop growth cycle can induce physiological stress, disrupt plant development, and ultimately reduce crop yields (Aslam et al., 2021; Moore et al., 2021; Chen et al., 2022; Angon et al., 2024; Muffler et al., 2024; Vandana et al., 2024; Zhang et al., 2025). Beyond direct physiological impacts, climate change may also alter planting and harvesting schedules, introducing greater uncertainty into farm-level decision-making and undermining the predictability upon which agricultural systems depend (Shah et al., 2024; Battaglia et al., 2025; Saleem et al., 2025).

As climate variability intensifies, adopting structured risk management strategies and decision support systems has become an urgent priority, enabling farmers to make appropriate decisions under current and future climate conditions (Menalled et al., 2026). Agricultural climate risk management is a multidisciplinary process encompassing the identification, assessment, and response to climate-related risks, with the ultimate aim of enhancing resilience and reducing potential damage to farming systems and rural livelihoods (Selvaraju et al., 2012). At the farm level, risk reduction measures, such as soil and water management, operationalize adaptation by embedding climate responsiveness directly into practice (Saleem et al., 2025). At the institutional level, effective risk management requires broad stakeholder collaboration, engaging agricultural extension services, meteorological agencies, financial institutions, and local cooperatives, to ensure that climate information reaches farmers in a real-time, credible, and actionable form (Booth et al., 2020; Parnell and Gangwish, 2023).

Agricultural insurance is a critical risk management mechanism to support and stabilize farmers' income (Chen et al., 2025; Hou and Wang, 2025). Despite its potential, traditional indemnity-based insurance models remain poorly suited to agricultural systems due to the systemic nature of climate-related risks, difficulties in verifying individual losses, and high transaction and claim-assessment costs (Sgroi and Sciancalepore, 2022;

Mateos-Ronco, 2025), limitations that are becoming increasingly evident (Ardakani et al., 2026). In response, index-based insurance models have emerged as a more tractable financial instrument, circumventing these limitations by linking payouts to objectively measurable climate indices rather than individually verified losses (Gesualdo et al., 2024; Zhu et al., 2025). Accordingly, a recently developed multi-hazard index-based insurance model represents a structured advancement, connecting climate-related risks to financial risk through hazard indices, vulnerability estimation, and actuarial pricing mechanisms (Ardakani et al., 2026).

While the multi-hazard index-based insurance model offers a robust representation of hazard intensity, severity, and exposure, it relies on a largely exogenous and static treatment of vulnerability, thereby overlooking the role of farmers' behavior and adaptive responses to early-warning signals. This represents a consequential gap, as farmers' decisions regarding input management, irrigation timing, and harvesting schedules directly mediate the relationship between climate-related risks and realized losses yet are not reflected in existing index construction or pricing frameworks. Recent advances in sensor-based agricultural decision systems demonstrate the feasibility of monitoring field and crop conditions in near real time at decision-relevant scales (Capone et al., 2025). In parallel, behavior-based pricing models, widely applied in usage-based insurance, provide a theoretical basis for incorporating behavioral compliance into premium calculations (Tselentis et al., 2016; Li et al., 2025). Together, these developments indicate the emergence of a new generation of index-based insurance models in which risk, vulnerability, and pricing are jointly shaped by hazard exposure and adaptive behavior.

Therefore, this study aims to theoretically extend the multi-hazard index-based insurance model (Ardakani et al., 2026) by incorporating a behavioral compliance component that accounts for farmer responses to climate-related early-warning signals. Specifically, the proposed framework introduces a behavior-based adjustment into the actuarial pricing structure, whereby premium calculations reflect not only hazard exposure, but also the degree to which farmers adopt recommended adaptive practices following the issuance of alerts. Hence, the model reframes insurance not merely as a passive compensation mechanism, but as an active risk-governance tool that creates financial incentives for proactive adaptation and thereby strengthens the link between early-warning systems and on-farm decision-making. This theoretical contribution is particularly relevant in the context of advancing sensor technologies and real-time farm monitoring, which increasingly make behavioral compliance observable and verifiable at scale. The proposed framework thus carries implications not only for actuarial design, but also for agricultural policy, extension services, and the broader institutional architecture of climate risk management.

The remainder of the paper is organized as follows. Section 2 reviews the role of data-driven decision-support systems and smart agricultural technologies in agricultural risk management, with emphasis on data availability, advanced sensing and analytics. Section 3 introduces the proposed theoretical framework that incorporates farmer behavior into index-based insurance design, presents its mathematical formulation, and discusses implications for actuarial pricing. Section 4 concludes by outlining implications for insurance design and policy, and by identifying directions for future empirical validation and practical implementation.

2 Background: Smart Technologies for Agricultural Risk Management

Resilient agriculture requires cooperative and coordinated actions across numerous sectors, while farmers' behaviors and decisions remain a particularly critical determinant (Savari et al., 2023; Song et al., 2025). Farmers' timely and appropriate responses to emerging climate signals can substantially reduce crop losses (Minoli et al., 2022; Ricart et al., 2023). Translating climate signals into on-farm actions and practices, however, is not straightforward; it depends on farmers having access to real-time, relevant, and actionable guidance, which underscores the need for effective decision support systems (Palutikof et al., 2019; Constable et al., 2022). A decision support system is an interactive computer-based platform that assists decision-making by integrating data, models, and tools (Rinaldi and He, 2014). In agriculture, decision support systems assist farmers in selecting appropriate practices and strategies to improve productivity, efficiency, and sustainability (Zhai et al., 2020; Fang et al., 2021; Mora et al., 2018; Di Gangi et al., 2023; Behera et al., 2025; Goud et al., 2025). The effectiveness of agricultural decision support systems therefore depends fundamentally on the availability of high-quality and timely data (Fang et al., 2021).

Data are the core operational input for decision support systems and a fundamental requirement for data-driven decision-making (Power, 2008). In agriculture, the availability of timely data is particularly critical due to the sector's strong dependence on environmental and climatic conditions, under which climate variability directly affects crop growth, yield, and resource efficiency (Mishra & Mishra, 2024). As climate variability intensifies, traditional intuition-based agricultural practices are increasingly inadequate for managing production risks and uncertainty (Arora, 2019; Kumar et al., 2023). In response, the agricultural sector is progressively shifting toward data-driven practices that rely on systematic data collection and analytical tools to

enhance productivity, efficiency, and resilience (MacPherson et al., 2022; Araújo et al., 2023). However, the true value of agricultural data lies in its ability to provide actionable insights that support timely, informed, and resilient decision-making (Carletto, 2021; Leal et al., 2024).

Smart agriculture is increasingly relying on advanced data collection and processing methods to enhance decision-making and operational efficiency (Basnet and Bang, 2018; Gamage et al., 2024; Soussi et al., 2024). Emerging data-collection technologies such as the Internet of Things (IoT), unmanned aerial vehicles (UAVs), satellite-based remote sensing, and robotic sensing platforms are enabling high-resolution, real-time monitoring of crop, soil, and environmental conditions (Padhiary et al., 2025). IoT sensor networks consist of distributed, connected sensors deployed in the field to continuously collect soil, crop, and environmental data in real time (Mansoor et al., 2025). UAVs are aerial platforms equipped with imaging sensors that provide high-resolution, flexible, and timely observations of crop health, soil conditions, and pest infestations (Xing et al., 2025). Satellite-based remote sensing (earth observation) uses satellites to deliver large-scale, repetitive measurements for monitoring crop growth, land use, and environmental variability (Nakalembe et al., 2021). Robotic sensing platforms are autonomous ground-based systems that integrate proximal sensors and vision technologies for detailed, in-field crop assessment (Łągiewska et al., 2025).

Data analysis and analytics techniques are subsequently essential for transforming raw data into actionable decisions (Sarker, 2021). Data analysis focuses on examining, cleaning, transforming, and interpreting data to understand historical or current phenomena by identifying patterns, trends, and relationships. It is typically descriptive or diagnostic and aims to explain what has happened or why it occurred (Devore, 2007; Gudivada, 2025). In contrast, data analytics is a broader and more comprehensive discipline that includes data analysis as a core component while extending beyond it toward prediction and decision support (Basnet and Bang, 2018; Gudivada, 2025). Rather than solely interpreting past data, data analytics emphasizes forecasting future outcomes and recommending actions, thereby supporting proactive and data-driven decision-making across complex systems (Abdul-Azeez et al., 2024). Moreover, data analytics techniques integrate advanced computational methods, automation, and technologies such as machine learning (Rejeb et al., 2025) and artificial intelligence (Mishra and Mishra, 2024) to analyze large and complex datasets on a continuous basis (Waqas et al., 2025).

Artificial Intelligence of Things (AIoT) integrates advanced sensing infrastructures with data analytics and artificial intelligence to enable learning, prediction, and adaptive decision-making (Benfradj et al., 2024). Unlike traditional IoT systems that primarily support data collection, AIoT architectures can interpret high-frequency sensor data and generate context-aware responses through machine-learning-driven analytics (Singh & Krishnamurthi, 2024). In agriculture, AIoT underpins precision farming by combining real-time monitoring of soil, crops, and environmental conditions with advanced analytics to support timely management decisions (Chowdhury et al., 2025). From a risk-management perspective, these capabilities strengthen early-warning systems and enable the observation of adaptive farmer responses, thereby providing a practical foundation for frameworks that move beyond static vulnerability representations and motivate the integration of behavior into index-based insurance design.

3 Methodology: Behavior-Based Index Insurance (BBII)

Behavior-based index insurance (BBII) extends the multi-hazard index-based insurance model (Ardakani et al., 2026) by incorporating farmers' behavior into the actuarial pricing mechanism. In contrast to the multi-hazard index-based insurance model, where payouts depend exclusively on a climate-related index, BBII integrates adaptive behavior into the vulnerability component of the insurance model. This allows insurance pricing to reflect both hazard exposure and farmers' responses to early-warning alerts. The BBII framework consists of four integrated modules: a hazard module, a behavioral module, a modified vulnerability module, and a financial pricing module. The hazard component remains unchanged from the original index construction (Ardakani et al., 2026), while behavioral adaptation is introduced through an adaptive behavior index (ABI), which interacts with hazard intensity to modify yield sensitivity and risk exposure.

3.1 Hazard module

The hazard module defines the multi-hazard index (Equation 1), which aggregates the effects of multiple climate hazards across different crop growth stages. The index captures the deviation of observed hazard levels from their respective critical thresholds and assigns stage-specific importance weights reflecting crop sensitivity during phenological development (see Ardakani et al., 2026 for details of the index construction process).

$$MHI = \sum_{i}^{n}\sum_{s}^{m} w_{is} \times (H_{is} - H_{critical}) \quad (1)$$

where *MHI* denotes the multi-hazard index, w_{is} and H_{is} represent the stage-specific weight and the value of climate hazard *i* during growth stage *s*, respectively. $H_{critical}$ refers to the critical threshold associated with each hazard.

3.2 Behavioral module

To explicitly account for behavioral response dynamics within the proposed insurance framework, this study introduces a behavior-dependent index, which is designed to quantify farmers' real-time responses to early-warning alerts generated by digital decision-support systems. While composite indices have been widely used to summarize farmers' adaptive behavior by aggregating multiple actions into a single index, existing applications largely focus on ex-post adoption of adaptation measures rather than on process-oriented responses to warnings (Song and Zhu, 2025). Early-warning systems are fundamentally action-oriented: their effectiveness depends not only on the accuracy of hazard detection, but also on how end users process warnings and translate them into timely and appropriate actions (Coffey et al., 2015). Recent warning-response research conceptualizes behavior as a multi-dimensional construct in which information reception, response timing, and intensity of action jointly determine risk-reduction outcomes (Xu et al., 2026).

Accordingly, to incorporate adaptive decision-making into the insurance framework, a behavior-dependent index, named the ABI, is introduced. The ABI quantifies the degree to which farmers respond to early-warning alerts issued by digital decision-support systems. Behavioral performance is measured based on three complementary dimensions: compliance with recommended actions following an alert, representing whether farmers implement the prescribed intervention, response timing, capturing the promptness of action relative to the issuance of the warning, and the intervention adequacy, reflecting whether the scale or intensity of the response is sufficient given the anticipated severity of the hazard. Mathematically, the ABI is defined as follows (Equation 2):

$$ABI_t = \sum_{i}^{n} w_i(R_{it} \times T_{it} \times V_{it}) \quad (2)$$

where *ABI* represents the aggregated behavioral score at time *t*, R_{it} denotes the degree of compliance with recommended actions for hazard *i*, T_{it} measures the timeliness of the response relative to the warning issuance, and V_{it} reflects the adequacy of intervention intensity. The parameter w_i denotes a hazard-specific weight. The multiplicative structure of Equation 2 reflects the conceptual assumption that effective adaptive response requires the simultaneous satisfaction of all three behavioral conditions: compliance without timeliness, or prompt action without adequate intensity, is assumed to result in diminished protective effectiveness. The ABI values close to one indicate highly responsive and timely adaptation behavior.

3.3 Vulnerability module

The vulnerability module describes the relationship between crop yield, climate hazards, and farmers' responses. Unlike previous formulations (Ardakani et al., 2026) that assume a fixed yield response to the climate hazard index, the BBII framework allows the sensitivity of yield to farmers' behavior rather than the hazard exposure alone. Accordingly, yield is modeled as (Equation 3):

$$Y_t = \beta_0 + \beta_1 MHI_t + \beta_2 ABI_t + \beta_3 (MHI_t \times ABI_t) + \epsilon_t \quad (3)$$

where *Y* denotes observed crop yield at time *t*, MHI_t represents the multi-hazard index (i.e., cumulative hazard intensity and severity), and ABI_t captures farmers' behavioral adaptation. The interaction term reflects the moderating effect of farmers' behavior on yield sensitivity to hazard exposure. The parameters β_1, β_2, and β_3 represent the marginal effects of hazard intensity, behavioral adaptation, and their interaction, respectively, while ϵ_t represents the error term.

The inclusion of the interaction term allows the marginal impact of climate hazard index on yield to vary as a function of farmers' behavioral adaptation. The sensitivity of yield to hazard exposure is therefore obtained by differentiation with respect to the *MHI* (Equation 4):

$$\frac{dY_t}{dMHI_t} = \beta_1 + \beta_3 ABI_t \quad (4)$$

In the insurance framework, the tick value represents the monetary change in yield per unit change in the hazard index. In this study, a dynamic tick is therefore defined as (Equation 5):

$$\text{tick} = \frac{\text{dY}}{\text{dMHI}} \times \text{P} = (\beta_1 + \beta_3 \text{ ABI }) \times \text{P} \qquad (5)$$

where *P* denotes the market price of crop. Under this dynamic tick structure, farmers exhibiting higher behavioral adaptation experience lower yield sensitivity to hazard exposure, resulting in smaller expected losses.

3.4 Financial module

The financial module determines the insurance premium using an option-pricing structure in which payouts depend on climate hazard-index thresholds. Because the tick value depends on farmers' behavioral adaptation, the expected payout and resulting premium automatically incorporate behavioral effects. Premium values are computed using a Black-Scholes pricing method (Equations 6-7):

$$\text{Premium}_{\text{call}} = \text{M} \times \text{e}^{-\text{rT}}\, \text{N}(\text{d}_2) \qquad (6)$$

$$\text{Premium}_{\text{put}} = \text{M} \times \text{e}^{-\text{rT}}\, \text{N}(-\text{d}_2) \qquad (7)$$

Where *M* denotes the maximum payout level, *r* represents the risk-free interest rate, and T denotes the duration of the coverage. The parameter $\mathcal{N}(.)$ represents the cumulative distribution function of the standard normal distribution. The term d_2 is defined as (Equation 8):

$$\text{d}_2 = \frac{\text{Ln}\left(\frac{\text{I}_{tr}}{\text{I}_{ex}}\right) + (\text{r} - \frac{\sigma^2}{2})\text{T}}{\sigma\sqrt{\text{T}}} \qquad (8)$$

where I_{tr} represents the trigger *MHI* level, I_{ex} represents the exit *MHI* level, and σ denotes the standard deviation of the normalized *MHI.*

Because the tick value is defined as a function of behavioral adaptation, the expected payout distribution shifts according to the value of ABI_t. Higher levels of adaptive behavior reduce yield sensitivity to hazard exposure, thereby lowering the magnitude of potential losses and, consequently, reducing the actuarially fair premiums.

4 Conclusion

This study introduces the BBII model as a theoretical extension of the multi-hazard index-based insurance model that explicitly endogenizes farmers' behavior within vulnerability estimation and actuarial pricing. By integrating a behavior-based index into the vulnerability module, the framework allows yield sensitivity to climate hazards to vary dynamically with observed behavioral adaptation, which in turn, affects tick values and insurance premiums. This dynamic linkage ensures that insurance pricing reflects not only hazard exposure but also the degree to which farmers respond to early-warning signals through adaptive on-farm actions. Thus, the BBII model addresses a central limitation of conventional index-based insurance models, which treat vulnerability as independent of farmer decision-making processes. In particular, by making yield sensitivity explicitly contingent on adaptive behavior, the BBII model yields a behavior-sensitive premium structure in which effective responses to early-warning signals are associated with lower expected losses and more favorable pricing outcomes.

Methodologically, the proposed framework preserves the core structure of the multi-hazard index-based insurance framework while introducing a behavior-hazard interaction that directly links adaptive responses to pricing outcomes through a dynamic tick mechanism. This approach aligns premium determination with both climate hazards and farmers' behavior, reinforcing the role of early-warning signals and data-driven decision support in agricultural risk management. Rather than changing the index trigger, the BBII model adjusts yield sensitivity and payout magnitude based on farmers' behavior, preserving transparency while allowing premiums and losses to better reflect behavioral differences. The framework is also consistent with ongoing advances in sensor-based monitoring, data analytics, and AIoT-enabled decision-support systems, which increasingly make adaptive farmers' responses observable and measurable in real time.

Future research should focus on the empirical implementation and validation of the BBII framework. Key priorities include developing practical methods to operationalize the ABI using observational data, testing alternative specifications of the behavior-hazard interaction, and evaluating the performance of behavior-sensitive pricing across different farming systems and hazard conditions. Further work is also needed to address institutional and policy issues related to behavioral data governance and sharing, the design of incentives that encourage farmer participation, and coordination between insurance providers and digital decision-support systems issuing early-warning alerts. Addressing these challenges will be essential for translating behavior-based insurance concepts into practical and equitable agricultural risk-management instruments. Overall, the BBII model provides a flexible foundation for advancing dynamic, behavior-aware approaches to agricultural risk management and for strengthening the integration between climate adaptation and risk-transfer mechanisms.

The Impact of Knowledge Asymmetries on Business–IT Alignment Dynamics

Fabrizio Amarilli
Dublin City University, Dublin, Ireland

Abstract

Shared Domain Knowledge (SDK) between business and IT executives is a crucial antecedent of business-IT alignment success. However, existing research conceptualizes SDK as a unidimensional attribute varying primarily in magnitude, assuming increasing shared knowledge uniformly improves alignment. This aggregated view cannot explain why organizations with similar SDK levels experience markedly different alignment trajectories. This study investigates how knowledge asymmetry configurations affect business-IT alignment by decomposing SDK into a multidimensional profile. Drawing on knowledge management theory, we develop a framework specifying four core knowledge dimensions: technical-strategic IT knowledge distribution, feasibility-possibility knowledge calibration, boundary-spanning knowledge, and temporal-relational knowledge. These dimensions interact to create distinct patterns of knowledge asymmetry with predictable alignment dynamics. We conducted a longitudinal comparative case study of three manufacturing companies implementing enterprise systems over 15 to 24 months. Data included semi-structured interviews with CEOs, CIOs, and key stakeholders, supplemented by project documentation and assessment reports. Our analysis identified three patterns. Bridging Asymmetry occurs when extreme knowledge gaps are compensated by one executive's dual competencies enabling effective translation, producing successful alignment despite persistent asymmetry. Complementary Asymmetry emerges when neither party possesses boundary-spanning capability, requiring external intervention for partial alignment. Aspirational Asymmetry arises when both parties share high strategic IT knowledge but diverge in feasibility understanding, creating expectation-reality gaps leading to knowledge atrophy. Our findings make three contributions. First, we demonstrate that knowledge configuration matters more than aggregate level in determining alignment outcomes. Second, we identify boundary-spanning knowledge as the critical mechanism through which asymmetries either enable or constrain alignment. Third, we reveal that high SDK can generate problems through unrealistic expectations and success-induced complacency, challenging the assumption that more shared knowledge invariably improves outcomes. These findings advance theoretical understanding of alignment's social dimension and offer practitioners diagnostic tools for managing knowledge asymmetries effectively.

Keywords: Business IT alignment, Social alignment, Shared domain knowledge, Knowledge management.

Paper type: Academic Research Paper.

1 Introduction

Business-IT alignment remains a perennial concern for researchers and practitioners (Henderson and Venkatraman, 1993; Luftman et al., 2017). Over three decades of research, scholars have identified multiple dimensions through which alignment manifests. Among these, the social dimension has received particular attention for enabling mutual understanding between business and IT executives (Reich and Benbasat, 1996, 2000). This understanding is operationalized as Shared Domain Knowledge (SDK), defined as the degree to which business and IT executives understand and can participate in each other's domains (Reich and Benbasat, 2000; Preston and Karahanna, 2009). While existing research treats SDK as a crucial alignment antecedent, most studies conceptualize it as a single attribute varying from low to high (Johnson and Lederer, 2010). We challenge this monolithic view, proposing instead that SDK constitutes a multidimensional knowledge profile whose configuration shapes alignment dynamics in distinct ways.

The dominant conceptualization assumes increasing shared knowledge improves alignment (Reich and Benbasat, 2000; Preston and Karahanna, 2009), yet this aggregated view obscures critical variation. Several research strands hint at SDK's multidimensional character. Studies of CIO capabilities distinguish technical from strategic IT knowledge (Peppard et al., 2011; Chun and Mooney, 2009). Research on IT project failures identifies gaps between understanding technological possibilities versus implementation feasibility (Keil et al., 2000; Lyytinen and Robey, 1999). Work on cross-functional collaboration emphasizes that domain expertise alone is insufficient without boundary-spanning mechanisms (Carlile, 2004; Levina and Vaast, 2005). Despite these insights, no framework systematically integrates these dimensions or examines how their configuration affects alignment. Drawing on knowledge management theory (Carlile, 2004; Levina and Vaast, 2005), we decompose SDK into four dimensions: technical-strategic IT knowledge distribution, feasibility-possibility knowledge calibration, boundary-spanning knowledge, and temporal-relational knowledge (see Table 2 for full

operationalization). These dimensions do not contribute additively to alignment. Rather, their specific configuration creates distinct patterns of knowledge asymmetry with different alignment dynamics. Our research question asks: How do different configurations of knowledge asymmetries affect the business-IT alignment process?

We conducted a longitudinal comparative case study of three manufacturing companies implementing enterprise systems over 15 to 24 months. Our analysis identified three distinct patterns. Bridging Asymmetry occurs when extreme knowledge gaps are compensated by one party's dual competencies enabling effective translation. Complementary Asymmetry emerges when neither party possesses boundary-spanning capability, requiring external intervention. Aspirational Asymmetry arises when both parties share high strategic IT knowledge but diverge in feasibility understanding, creating expectation-reality gaps leading to knowledge atrophy.

This study makes three contributions. First, we demonstrate that knowledge configuration matters more than aggregate level. Second, we identify boundary-spanning knowledge as a critical mechanism through which asymmetries either enable or constrain alignment. Third, we challenge the assumption that higher SDK invariably improves alignment, showing how high strategic IT knowledge can generate problems through unrealistic expectations and success-induced complacency.

2 Literature Review

Business-IT alignment refers to the degree of congruence between business objectives and IT capabilities, encompassing both the process through which this fit is achieved and the state of alignment itself (Chan and Reich, 2007). Over three decades, scholars have proposed multiple dimensions through which alignment manifests (Henderson and Venkatraman, 1993; Reich and Benbasat, 2000). Reich and Benbasat (2000) distinguish between intellectual alignment, concerning the fit between business and IT strategy, and social alignment, addressing the state in which executives understand and are committed to business and IT missions, objectives, and plans. Subsequent research expanded this to include operational alignment, referring to congruence between business and IT processes and structures, and strategic alignment at the organizational level (Gerow et al., 2014). Social alignment has received sustained attention as an antecedent condition. Gerow et al.'s (2014) meta-analytic review demonstrates that social alignment influences both intellectual and operational alignment, which affect organizational performance, positioning it as foundational.

Within social alignment, Shared Domain Knowledge serves as a central component (Reich and Benbasat, 2000; Preston and Karahanna, 2009). SDK refers to executives' ability to understand and participate effectively in each other's key processes (Reich and Benbasat, 2000, p.82). Preston and Karahanna (2009) identify SDK as one of four antecedents of IS strategic alignment. Johnson and Lederer (2010) demonstrate that CEO/CIO mutual understanding correlates positively with strategic alignment and IS contribution to organizational outcomes. These studies establish SDK as an empirically validated predictor of alignment success, yet conceptualize it as a unidimensional construct varying primarily in magnitude.

This aggregated view overlooks substantive variation in knowledge composition. Research on CIO capabilities suggests different knowledge types produce different outcomes. Peppard et al. (2011) distinguish technical, business, and interpersonal competence, noting that effective IT leadership requires mastery across multiple domains. Chun and Mooney (2009) document a shift from technical management toward strategic partnership reflecting changing knowledge requirements. Bassellier et al. (2001) develop an IT competence measure encompassing explicit and tacit knowledge in technical and managerial dimensions, demonstrating that knowledge types cannot be reduced to a single scale. Armstrong and Sambamurthy (1999) distinguish between knowledge of IT's strategic potential and technical implementation requirements. These studies indicate that knowledge nature matters, not merely quantity.

A second research stream examines discrepancies between understanding technological possibilities and operational realities. Ewusi-Mensah (1997) identifies the gap between initial expectations and feasibility assessments as a critical failure factor. Keil et al. (2000) find that decision-makers often persist with failing initiatives because their understanding of what technology should deliver obscures recognition of what it can achieve under prevailing constraints. Lyytinen and Robey (1999) argue that organizations frequently fail to adjust expectations when confronted with infeasibility evidence, suggesting systematic difficulty in calibrating possibility against feasibility knowledge.

Knowledge management scholarship provides theoretical resources for understanding how distributed expertise is integrated across boundaries. Carlile (2004) demonstrates that knowledge integration depends on actors' capacity to recognize dependencies, establish common meanings, and negotiate conflicting interests. Levina and Vaast (2005) identify boundary spanning competence as an emergent practice requiring ongoing

relational work. Majchrzak et al. (2012) reveal that performance depends on actors who can integrate dispersed expertise. Pawlowski and Robey (2004) find that successful integration of business and technical knowledge requires individuals who understand both domains and can translate between them. This literature establishes that knowledge overlap alone does not guarantee effective collaboration; boundary-spanning mechanisms are essential.

Temporal aspects of knowledge have received less systematic attention despite their documented influence. Orlikowski and Yates (2002) argue that timing, rhythm, and duration shape how work unfolds and technologies are adopted. Sabherwal and Robey (1995) note that alignment must be understood as a temporal phenomenon rather than a static state. Brown and Grant (2005) observe that misalignments between business planning cycles and IT development timelines create persistent coordination challenges. Xue et al. (2008) demonstrate that temporal characteristics of IT investments moderate the relationship between governance structures and decision outcomes.

The literature reveals multiple knowledge dimensions that existing SDK frameworks do not explicitly theorize. Technical knowledge differs from strategic knowledge; understanding possibilities differs from understanding feasibility; domain expertise differs from boundary-spanning capability; and awareness of temporal dynamics shapes how knowledge is applied. Current conceptualizations cannot account for configurations where executives possess high knowledge in one dimension but low in another, nor explain why such configurations produce systematically different outcomes. A multidimensional framework specifying how knowledge types interact offers potential to resolve these gaps.

3 Methodology and Theoretical Framework

This study employs a multiple case study approach to investigate how knowledge asymmetry configurations affect business-IT alignment. Three organizations undertaking alignment initiatives through enterprise system implementations served as research sites over 15 to 24 months, enabling analysis of how knowledge configurations evolved and shaped alignment dynamics.

Case study methodology is appropriate for investigating complex social processes embedded in organizational contexts (Eisenhardt, 1989; Yin, 2014). Our research question asks "how" knowledge configurations affect alignment, requiring a method that accommodates emergent findings. The multidimensional nature of SDK demands rich contextual data capturing interplay between knowledge dimensions and organizational dynamics (Langley, 1999).

The three cases provide theoretical sampling across contexts and outcomes. Company 1 is a family-owned sports nutrition manufacturer (200 employees, €52M revenue) that hired a new CIO and undertook transformation following an unsuccessful ERP implementation. Company 2 operates in climate solutions (200 employees, €42M revenue), implementing enterprise applications following external assessment. Company 3 is a large European manufacturer that launched a 24-month alignment initiative implementing a comprehensive enterprise system.

Data collection followed established protocols (Miles and Huberman, 1994). Primary data came from semi-structured interviews with key informants. Interviews lasted 60-90 minutes and were recorded and transcribed where permitted; field notes supplemented non-recorded conversations. Secondary data included project documentation, steering committee minutes, external assessment reports, and internal communications, enabling triangulation and providing temporal markers.

Table 1: Data Sources

Case	Interviews	Informants	Secondary Sources	Time Period
Company 1	6 interviews	President, CEO, CIO (3 meetings), CFO, Head of Operations, Head of Sales	Project documentation, external assessment report, financial communications	2019-2020
Company 2	8 interviews	CEO, CFO, IT Manager/CIO, IT Staff, Head of Production, Head of R&D, Sales/Marketing Manager, Head of Post-Sales	Project documentation, steering committee minutes, external assessment report (Fondazione Politecnico di Milano), supplier presentations	2018-2019
Company 3	11 interviews	CEO, CIO, External consultants, Project team members	Steering committee documentation, project reports, university assessment reports	2019-2021

Data analysis proceeded through iterative coding and pattern recognition (Strauss and Corbin, 1998). Initial open coding identified knowledge gaps, translation difficulties, expectation mismatches, and coordination challenges. These codes were organized into higher-order categories corresponding to four knowledge dimensions emerging from knowledge management and alignment literatures. For example, when the Company 2 CEO stated "*I don't understand anything; there is no reason for me to stay here*," this was coded as "low technical IT knowledge." The CIO's statement that the system represented "nothing special" was coded as "inability to articulate strategic value." The CFO's need for "*someone with credibility to say this guy is not saying nonsense*" revealed absent boundary-spanning capability. Patterns emerged when similar configurations appeared across cases with similar outcomes.

The analytical framework specifies four knowledge dimensions derived from research on CIO capabilities, knowledge boundaries, and organizational learning.

Table 2: Knowledge Dimensions Framework

Dimension	Sub-Dimensions	What It Measures	Key References
Technical-Strategic IT Knowledge Distribution	Technical IT knowledge; Strategic IT knowledge; Business domain knowledge	How IT knowledge (technical vs strategic) and business knowledge are distributed between CEO and CIO	Bassellier et al., 2001; Peppard et al., 2011; Chun and Mooney, 2009
Feasibility-Possibility Knowledge Calibration	Possibility knowledge; Feasibility knowledge; Expectation gaps	Whether executives share realistic understanding of achievable outcomes versus theoretical capabilities	Keil et al., 2000; Lyytinen and Robey, 1999; Ewusi-Mensah, 1997
Boundary-Spanning Knowledge	Convergent knowledge; Complementary knowledge; Translation capability	Whether knowledge overlaps or requires integration, and who possesses bridging capability	Carlile, 2004; Levina and Vaast, 2005; Pawlowski and Robey, 2004; Majchrzak et al., 2012
Temporal-Relational Knowledge	Temporal alignment; Mutual knowledge; Supplier ecosystem knowledge	Understanding of time horizons, pacing, mutual constraints, and supplier dynamics	Orlikowski and Yates, 2002; Sabherwal and Robey, 1995; Brown and Grant, 2005

This framework guided data collection and analysis, enabling systematic comparison while remaining open to emergent patterns.

4 Results

Our analysis of the three cases revealed distinct patterns in how knowledge asymmetries shape alignment processes. Rather than organizing findings by individual case, we present results according to three emergent patterns identified through systematic cross-case comparison. Each pattern is characterized by a specific configuration of knowledge dimensions and produces predictable alignment dynamics. The patterns demonstrate that knowledge distribution and bridging capability matter more than aggregate knowledge levels in determining alignment outcomes. Table 3 provides a cross-case comparison across the four knowledge dimensions, revealing the configurations that differentiate the three patterns.

Table 3: Cross-Case Comparison

Dimension	Bridging	Complementary	Aspirational
CEO IT Knowledge	Zero technical; very low strategic	Low technical; low-medium strategic ("IT faith" not knowledge)	Low-medium technical; high strategic
CIO IT Knowledge	High technical; high strategic	High technical; low-medium strategic	High technical; high strategic
CIO Business Knowledge	HIGH (consulting background; "*speaks CEO's language*")	LOW (technical focus; cannot translate value)	High (business-savvy; understands operations)
Feasibility-Possibility Gap	Bridged by CIO translation	CEO questions investment itself (backward-looking)	High expectations on both sides create reality gap
Boundary-Spanning	CIO exclusively (personal capability)	NOBODY internally (external actors required)	Both initially (steering committee); plateaued
Temporal Alignment	CIO manages (adapts to seasonality)	Misaligned (CEO backward-looking; budget vicious circle)	Initially aligned; drifted (internal vs. external tempo)

Dimension	Bridging	Complementary	Aspirational
Key Mechanism	Personal translation substitutes for convergence	External compensation for double gap; demonstration over articulation	Expectation-reality gap; knowledge atrophy from success-induced complacency
Alignment Outcome	Success despite asymmetry	Partial success via external support	Initial success, then drift
Fragility Source	Individual dependence	Externally sourced capability	Knowledge plateau in dynamic environment

4.1 Pattern 1: Bridging asymmetry

The first pattern emerges when extreme knowledge asymmetry is compensated by one executive's dual competencies enabling translation. Case 1 exemplifies this through a critical feature absent in the other cases. The CEO possessed limited IT knowledge ("*zero IT skills*" and "*very limited commitment to IT*") and had experienced a failed ERP project. By contrast, the newly hired CIO brought deep technical expertise and consulting experience that equipped him with business domain knowledge. The critical capability distinguishing Case 1 from Cases 2 and 3 was that the CIO "*could understand and speak the language of the two managers/owners*."

This boundary-spanning capability produced successful alignment despite persistent asymmetry. The CEO never developed IT literacy, unlike Case 3 where both executives developed shared understanding. Instead, the CIO performed continuous translation, a capability absent in Case 2 where the CIO lacked business knowledge. When confronting supplier dependencies, the CIO presented choices in business terms owners could evaluate, such as paying the IT supplier versus hiring internal developers. Trust became the enabling mechanism: "*they trusted him and developed trust in IT*."

Cross-case comparison reveals why this pattern succeeded where others struggled. Unlike Case 2's double gap, Case 1's CIO could translate in both directions. Unlike Case 3's eventual plateau, Case 1 sustained alignment through continuous translation. However, this pattern exhibits structural fragility. The observation that owners "thought I would do everything" reveals absent institutional structure to sustain alignment should the CIO depart.

4.2 Pattern 2: Complementary asymmetry

The second pattern materializes when neither party possesses boundary-spanning knowledge, creating a double gap. Case 2 provides the clearest instantiation. The CEO demonstrated low technical IT knowledge, leaving a technical presentation with the explanation "*I don't understand anything; there is no reason for me to stay here*." More significantly, his strategic IT knowledge took the form of "*strategic IT faith*" rather than understanding, a distinction not observed in Cases 1 or 3. He approved a relevant investment and established governance structures, yet his reasoning revealed a backward-looking temporal frame. When confronted with the investment proposal, he asked "*we used this information system for more than 20 years and our market position is still good... what is the performance that will be improved*?" This inverted competitive logic contrasts sharply with Case 3's forward-looking awareness.

The CIO profile presented a mirror-image deficit. While technically proficient, the Company 2 CIO lacked the business domain knowledge that enabled Case 1's successful translation. His budget proposals failed repeatedly, and when articulating the ERP system's value, he offered only that it represented "*nothing special*, *we put in place what we should have done before*." This inability to connect technical capability to business outcomes created a "*budget vicious circle*" where each failed translation reduced trust, which constrained resources, which further degraded articulation capability. No such dynamic emerged in Case 1, where business fluency prevented communication breakdowns, or Case 3, where both parties shared sufficient strategic IT knowledge.

Partial alignment required sustained external intervention, a dependency absent in Cases 1 and 3. The University assessment team and IT suppliers performed the boundary-spanning function no internal actor could provide. The CFO's statement captured this: "*I need someone who has the credibility*, *competence and courage to say in front of me that this guy [the CIO] is not saying nonsense*." The CEO's inability to evaluate competing claims created political vulnerability, as when the Head of Production claimed "*the old system has much less bugs*" to justify resistance.

The Company 2 CIO developed "*demonstration over articulation*," pursuing bottom-up operational evidence when value arguments failed. This compensating mechanism succeeded in commercial functions where value was directly observable but failed in production where resistance could be sustained through appeals to the CEO's technical uncertainty.

4.3 Pattern 3: Aspirational asymmetry

The third pattern arises when both parties possess high strategic IT knowledge but diverge in understanding what is feasibly achievable, a configuration absent in Cases 1 and 2 where knowledge levels differed substantially. Case 3 manifested this pattern across 24 months. Both CEO and CIO demonstrated sophisticated awareness of IT's transformative potential, contrasting with Case 1's zero CEO knowledge and Case 2's "strategic IT faith" without understanding. The steering committee enabled collaborative knowledge development, leading to the observation that "we are speaking the same language," an achievement not attempted in Case 1 and not achieved in Case 2.

The alignment problem emerged not from knowledge deficits but from knowledge calibration failures. High possibility knowledge on both sides generated aspirational expectations that feasibility understanding could not match. As the deployed system stabilized, knowledge development plateaued. The organization's knowledge became past-oriented, focused on achievements rather than emerging competitive requirements. One executive's concern captured this temporal drift: "technology and competitors are moving fast and I suspect that one day we will realize that we are lagging behind." This gradual erosion differs fundamentally from Case 1's sustained individual-dependent alignment and Case 2's chronic translation failures.

The knowledge atrophy mechanism operated through success-induced complacency. The project's successful completion created a sense that alignment had been "solved," obviating continued knowledge investment. Simultaneously, the internal tempo shifted toward maintenance while external competitive tempo accelerated. Supplier ecosystem knowledge developed earlier, when the organization learned "we will never be their priority" with large vendors, was not sustained. This temporal drift distinguishes Case 3 from Case 1, where the CIO continuously adapted, and Case 2, where temporal misalignment existed from the beginning.

Cross-case comparison reveals that high shared domain knowledge does not immunize organizations against alignment drift. When knowledge convergence plateaus and temporal orientation shifts from future to past, even sophisticated leadership teams can lose alignment with evolving requirements. The mechanism differs fundamentally from Cases 1 and 2, where the problem was insufficient knowledge or absent bridging capability rather than knowledge becoming static.

4.4 Cross-pattern synthesis

Table 4 synthesizes the defining characteristics of each pattern, highlighting the specific knowledge configurations and mechanisms that differentiate them.

Table 4: Summary of Knowledge Asymmetry Patterns

Pattern	Knowledge Configuration	Critical Dimension	Alignment Dynamic	Key Quote	Risk Factor
Bridging Asymmetry	Extreme CEO-CIO gap + CIO has dual competencies (IT + business)	Boundary-Spanning	CIO translates effectively; CEO delegates without understanding	"*He could speak the language of the entrepreneur*"	Over-dependence on individual; if CIO leaves, bridging disappears
Complementary Asymmetry	CEO has "strategic IT faith"; CIO has technical skills but no business knowledge	Boundary-Spanning + Technical-Strategic Distribution	Double gap requires external boundary-spanners; demonstration over articulation	"*I need someone who has credibility to say this guy is not saying nonsense*"	Alignment capability externally sourced; non-transferable
Aspirational Asymmetry	Both have high strategic IT knowledge but feasibility understanding diverges	Feasibility-Possibility + Temporal-Relational	High expectations create reality gaps; knowledge becomes past-oriented	"*Technology and competitors are moving fast and I suspect we are lagging behind*"	Success-induced complacency; static knowledge in dynamic environment

The cases' patterns show that knowledge asymmetries produce distinct and predictable alignment dynamics. The configuration of knowledge across dimensions matters more than aggregate knowledge levels. Bridging capability emerges as the critical differentiator between successful alignment despite asymmetry (Case 1) and coordination failures requiring external compensation (Case 2). High strategic knowledge shared between executives (Case 3) produces different challenges from those observed when knowledge levels differ

substantially (Cases 1 and 2). These findings challenge the prevailing assumption in SDK literature that increasing shared knowledge uniformly improves alignment

5 Discussion and conclusion

Through longitudinal analysis of three cases, we identified three knowledge asymmetry patterns that shape alignment dynamics. Our findings offer theoretical and practical contributions.

5.1 Theoretical Contributions

Our primary contribution lies in decomposing SDK from a unidimensional attribute into a multidimensional profile. Existing research assumes increasing shared knowledge improves alignment (Reich and Benbasat, 2000; Preston and Karahanna, 2009). We demonstrate that this aggregated view obscures critical variation. Organizations with similar aggregate SDK levels experience markedly different trajectories depending on knowledge distribution across technical, strategic, boundary-spanning, and temporal dimensions. Case 1 shows successful alignment despite zero CEO IT knowledge because the CIO's business knowledge enabled translation. Case 2 shows struggles despite moderate knowledge levels because neither party could bridge domains. Configuration, not quantity, determines outcomes.

Second, we identify boundary-spanning knowledge as a critical dimension largely absent from existing SDK frameworks. Traditional research focuses on what executives know but neglects whether anyone can integrate knowledge across boundaries (Carlile, 2004; Levina and Vaast, 2005). Our findings reveal that boundary-spanning capability functions as the mechanism through which asymmetries either enable or constrain alignment. Internal bridging (Case 1) produces different dynamics than its absence (Case 2), even when knowledge gaps appear similar. Alignment research should assess not only knowledge levels but also translation mechanisms.

Third, our findings challenge the assumption that higher SDK invariably improves alignment. The aspirational asymmetry pattern shows how high strategic IT knowledge can generate problems through unrealistic expectations and success-induced complacency. Case 3's knowledge atrophy demonstrates that convergent knowledge can plateau when organizations conclude alignment has been permanently achieved. Knowledge management in alignment contexts requires ongoing investment rather than one-time achievement.

5.2 Practical Contributions

Our framework offers diagnostic value. Organizations can assess their knowledge configuration across four dimensions to identify which pattern characterizes their situation, enabling pattern-specific strategies. Organizations exhibiting bridging asymmetry should recognize dependence on key individuals and develop institutional mechanisms to reduce vulnerability. Those exhibiting complementary asymmetry face different challenges. The double gap requires developing internal boundary-spanning capability or securing reliable external support. Demonstration over articulation can compensate when value articulation fails. Organizations exhibiting aspirational asymmetry must guard against success-induced complacency, maintaining future-oriented knowledge investment and periodically reassessing gaps between internal tempo and external competitive dynamics.

5.3 Limitations and Future Research

Our study has limitations suggesting future research directions. First, our sample comprises three manufacturing companies implementing enterprise systems. Patterns may not exhaust all configurations, and different patterns may emerge in service industries, public sector organizations, or non-Western contexts. Quantitative research testing the framework across larger samples could validate patterns and identify additional configurations. Second, our longitudinal data spans 15 to 24 months. Longer observation might reveal how patterns evolve. Can organizations transition between patterns as configurations change? Third, our focus on knowledge dimensions may underemphasize other factors such as organizational structure, governance mechanisms, or cultural characteristics. Future research could examine how context moderates relationships between knowledge configurations and alignment outcomes.

6 Conclusions

This study challenges the simplistic view of Shared Domain Knowledge in alignment research. We show that SDK is multidimensional and that knowledge configuration is more important than aggregate level. Our

framework reveals three distinct patterns of knowledge asymmetries that shape alignment processes. Bridging Asymmetry indicates that large gaps can be mitigated through individual dual competencies. Complementary Asymmetry shows that double gaps need external intervention. Aspirational Asymmetry highlights that high shared knowledge can create issues due to expectation-reality gaps and knowledge atrophy. These findings enhance theoretical understanding by identifying mechanisms through which knowledge configurations influence alignment dynamics. For practitioners, the framework provides diagnostic tools for evaluating knowledge configurations and implementing targeted management strategies. Despite limitations, our multidimensional framework offers valuable theoretical insights and practical guidance for managing knowledge asymmetries in business-IT alignment.

A KM-Based Approach to Service Value Co-Creation and Co-Destruction

Nina Gerges, Paulo Selig, Gregorio Varvakis
EGC/UFSC, Florianopolis, Brazil

Abstract

This study analyzes value co-creation (VCC) and value co-destruction (VCD) in knowledge-intensive services from a knowledge management perspective. According to the dominant service logic, value is co-created in interactions between companies and customers. However, value can also be destroyed by failures in relational, communicative, or resource integration. The study's objective was to propose managerial guidelines to mitigate VCD and promote VCC in this context.
The study employed a qualitative, applied, and prescriptive approach through design science research (DSR). A literature review was conducted, along with seventeen semi-structured interviews with managers, experts, and clients from three small companies operating in the Florianópolis region in the segments of human resources consulting, quality certification, and brand strategy. Based on thematic data analysis, an analytical framework comprising three central dimensions was developed and validated: Communication and Engagement, Knowledge Resources, and Relationship and Collaboration.
The results indicate that communication problems, fragmented channels, low client participation, a lack of knowledge sharing, and difficulty understanding the service act as inhibitors of VCC and catalysts of VCD. Conversely, trust, frequent alignment, clear objectives, access to experts, continuous learning, and collaboration strengthen value creation. Additionally, it was found that team turnover, excessive dependence on experts, and resistance to change increase the risk of value destruction.
As a practical contribution, seven knowledge management (KM)-based management guidelines focused on client leadership engagement, knowledge sharing, organizational learning, and retention of critical knowledge were proposed. In conclusion, KM is essential for mitigating losses and maximizing benefits in knowledge-intensive services.

Keywords: value cocreation, value codestruction; knowledge intensive service, knowledge management; service.

Paper type: Academic Research Paper

1 Introduction

Service organizations, particularly those offering knowledge-intensive services (KIS), have taken on a central role in contemporary economies. In this context, knowledge becomes a strategic asset capable of sustaining competitive differentiation and guiding decisions in complex environments, rather than merely a supporting resource (Grant, 1996; Nonaka and Takeuchi, 1995). Knowledge management (KM) reinforces this perspective, highlighting the creation, integration, and application of knowledge as the foundation of sustainable organizational performance (Nonaka, Krogh, and Voelpel, 2006).

Meanwhile, the dominant service logic has transformed the understanding of value by shifting the focus from unilateral delivery to relational and contextual construction. According to this view, value is not solely produced by the company but is co-created through interactions among those involved in the service. Value is then determined by the beneficiary based on the user experience (Vargo and Lusch, 2016). Customers thus cease to be passive recipients and begin to play an active role in the process.

Co-creation of value (CCV) has been extensively studied for its role in collaboration, engagement, and the integration of competencies between companies and customers. Models such as DART highlight elements such as dialogue, access, transparency, and risk assessment (Prahalad and Ramaswamy, 2004). Other approaches suggest that CCV occurs across multiple touchpoints, depending on reciprocal relationships and the joint mobilization of resources (Payne, Storbacka, and Frow, 2008; Grönroos, 2012).

However, an exclusively positive view is limited because the same process can lead to the co-destruction of value (CDV). Failures in resource integration, knowledge gaps, misaligned expectations, and communication barriers can compromise the service experience and reduce perceived value (Plé and Chumpitaz, 2010). Thus, CDV occurs when interactions cease to generate benefits and begin to produce additional costs for those involved.

Despite theoretical advances, gaps persist in integrating CCV and CDV, particularly in knowledge-intensive services. Therefore, this study proposes a Knowledge Management approach to analyze both phenomena. Through qualitative research grounded in design science research, the study develops an analytical framework

centered on three dimensions: communication and engagement, knowledge resources, and relationships and collaboration. The framework seeks to contribute to theoretical advancement and managerial practice.

2 Literature Review

The literature on services, value, and knowledge management has evolved significantly alongside the increasing significance of services in modern economies. Initially influenced by manufacturing logic, studies began emphasizing quality, customer experience, and the strategic role of services in generating competitive advantage (Heineke and Davis, 2007). Services are now understood as dynamic processes characterized by simultaneity, intangibility, heterogeneity, and perishability, in which customer participation is essential (Fitzsimmons and Fitzsimmons, 2000; Shostack, 1987).

A main paradigm shift occurred with the Dominant Service Logic, which redefined service as applying competencies for another's benefit and positioned value as the result of interactions (Vargo and Lusch, 2007; 2016). From this perspective, customers cease to be passive recipients and begin acting as co-producers, with value determined by their experience (Lusch and Vargo, 2014). Thus, service is understood as an open system in which different actors integrate resources, especially knowledge, to generate benefits (Ballantyne and Varey, 2006).

The concept of value evolves toward the logic of value in use, which is understood as the relationship between the benefits and sacrifices perceived by the customer (Järvi, Kähkönen, and Torvinen, 2018). Value emerges from the interactions between companies and customers and is co-created through the integration of resources and competencies (Vargo, Maglio, and Akaka, 2008; Grönroos, 2012). Value co-creation is a relational, dynamic process in which dialogue, engagement, and knowledge sharing play central roles.

The DART model, comprising dialogue, access, risk assessment, and transparency (Prahalad and Ramaswamy, 2004), stands out among the main theoretical models presented in Figure 1. Payne, Storbacka, and Frow (2008) propose a process-based view that is rooted in company and customer processes and touchpoints. Grönroos (2012), on the other hand, emphasizes that value emerges from the experience of the service itself. All these models acknowledge knowledge as an indispensable strategic resource.

As a counterpoint to the predominantly positive approaches, literature on value co-destruction has emerged. This perspective acknowledges that service interactions can also generate losses. Co-destruction is defined as a process that reduces the well-being of at least one party (Plé and Chumpitaz, 2010) and is associated with failures in resource integration, misaligned expectations, and limitations in participants' capabilities. The main identified factors include a lack of information, a lack of trust, operational errors, inadequate communication, and coordination failures, particularly in B2B relationships (Vafeas, Hughes, and Hilton, 2016). Figure 1 presents the main models and factors related to value co-destruction.

Their consequences include increased costs, loss of customers, and the need to mobilize additional resources to restore service (Plé, 2013). Thus, an integrated review of the literature shows that co-creation and co-destruction are influenced by three central dimensions: communication, knowledge, and relationships. In this context, Knowledge Management plays a strategic role, as the proper creation, sharing, and application of knowledge can enhance value creation and mitigate value destruction.

Elements of Value Co-creation in Services	
Author	Description
Plé and Chumpitaz (2010)	Failure to integrate resources
	Mismatch in expectations
Vafeas, Hughes and Hilton (2016)	Lack of confidence
	Inadequate Communication
	Power imbalance or dependence
Lintula, Tuunanen and Salo (2017)	Objectives and intentions that are divergent or misaligned
	Resources: absence, misuse, or loss
	Mismatch in expectations
Järvi, Kähkönen and Torvinen (2018)	Lack of information
	Trust between the customer and the company
	Lack of clear expectations

3 Methodological Procedures

The study aimed to propose guidelines to mitigate co-destruction and promote the co-creation of value in knowledge-intensive services. This is a qualitative, applied, and prescriptive study that seeks to understand organizational phenomena and propose practical solutions (Merriam, 2009; Creswell, 2010).

The methodological approach was based on the Design Science Research (DSR) framework, which is suitable for studies focused on problem-solving through the development of artifacts (Hevner, March, and Park, 2004). Three main artifacts were developed: (i) an analytical framework on the co-creation and co-destruction of value; (ii) a data collection instrument based on semi-structured interviews; and (iii) management guidelines grounded in Knowledge Management.

The methodological process was structured in four stages (Figure 2).

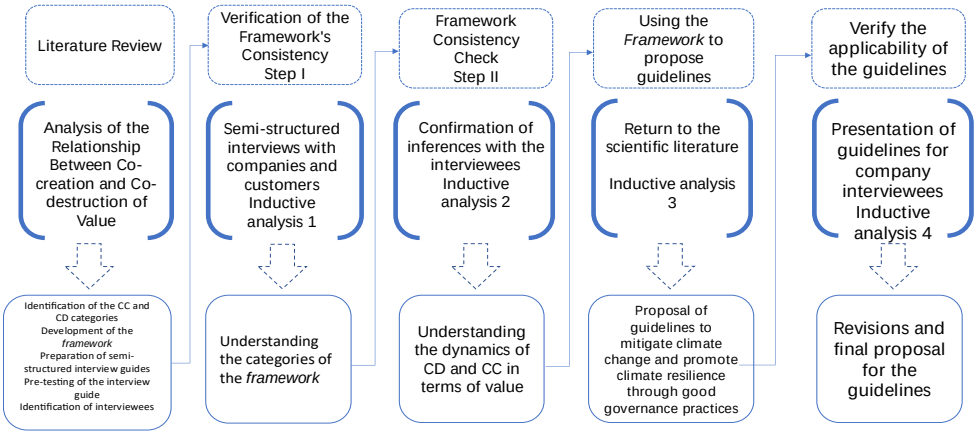

Figure 2: Methodological Process
Source: prepared by the authors

The first phase consisted of a systematic literature review to identify theoretical gaps and related models. Based on inductive analysis, an initial framework comprising three categories was developed: communication and engagement, knowledge resources, and relationships and collaboration. An interview guide was developed and reviewed by experts. Following a pilot test, the guide was refined.

The second stage involved collecting empirical data through 17 interviews conducted between January and July of 2021 with managers, experts, and clients from three small companies in the Florianópolis region that operate in human resources consulting, quality certification, and brand strategy.

The third stage involved analyzing the interview data using thematic analysis and validating the inferences with the participants through triangulation and analytical refinement.

The fourth stage consisted of developing management guidelines by integrating empirical findings with the theoretical framework. Managers from the participating companies evaluated these guidelines, allowing for final adjustments and practical validation.

In summary, the adopted methodological procedures allowed for the articulation of scientific rigor and practical applicability. DSR was appropriate for developing managerial solutions and advancing knowledge about the relationship between knowledge management, co-creation, and co-destruction of value in knowledge-intensive services.

4 Proposed Framework

Gerges (2023) proposed a framework that integrates the theoretical concepts of value co-creation and co-destruction in services. The framework seeks to develop an analytical model to understand and manage interactions between companies and customers (Figure 3). The framework was developed through a systematic review of literature that identified recurring elements in various models, which were then adapted to the context of knowledge-intensive services.

In the field of value co-creation, Prahalad and Ramaswamy (2004) are notable for their emphasis on dialogue, access, risk, and transparency. Payne, Storbacka, and Frow (2008) emphasize service encounters and touchpoints. Grönroos (2012) emphasizes accessibility and communication. Leclercq, Hammedi, and Poncin (2016), on the other hand, incorporate resource integration, engagement, and learning.

Concurrently, studies on the co-creation of value have identified factors that can compromise interaction outcomes. Plé and Chumpitaz (2010) point out failures in resource integration and misaligned expectations. Vafeas, Hughes, and Hilton (2016) point to communication problems, a lack of trust, and power imbalances. Lintula, Tuunanen, and Salo (2017) organize these factors into three dimensions: communication, resources, and expectations. Järvi, Kähkönen, and Torvinen (2018), on the other hand, emphasize informational clarity and relationship quality.

A comparative analysis revealed commonalities between the two fields, particularly regarding communication, resources, knowledge, expectations, trust, and engagement. Based on these findings, the elements were grouped into three categories: (1) communication and engagement, (2) resources and knowledge, and (3) relationships and collaboration.

The first category involves dialogue, information exchange, and conditions that enable interaction. This category includes channels, platforms, and contact environments. Failures in this dimension tend to hinder the co-creation of value.

The second category emphasizes knowledge as the primary resource in knowledge-intensive services. This category encompasses access to knowledge, practical integration by the client, and renewal through learning and innovation generated during interactions.

The third category addresses relational factors that influence the quality of interaction. These factors include alignment of expectations, trust, transparency, collaboration, commitment, and balance of power. Weakened relationships tend to compromise the co-creation of value.

Consolidating these categories resulted in a framework (Figure 3) representing the encounter between company and customer as a dynamic, interdependent space. These categories are complementary and can occur simultaneously throughout the service. The model also recognizes the cumulative nature of interactions, wherein past experiences influence future perceptions.

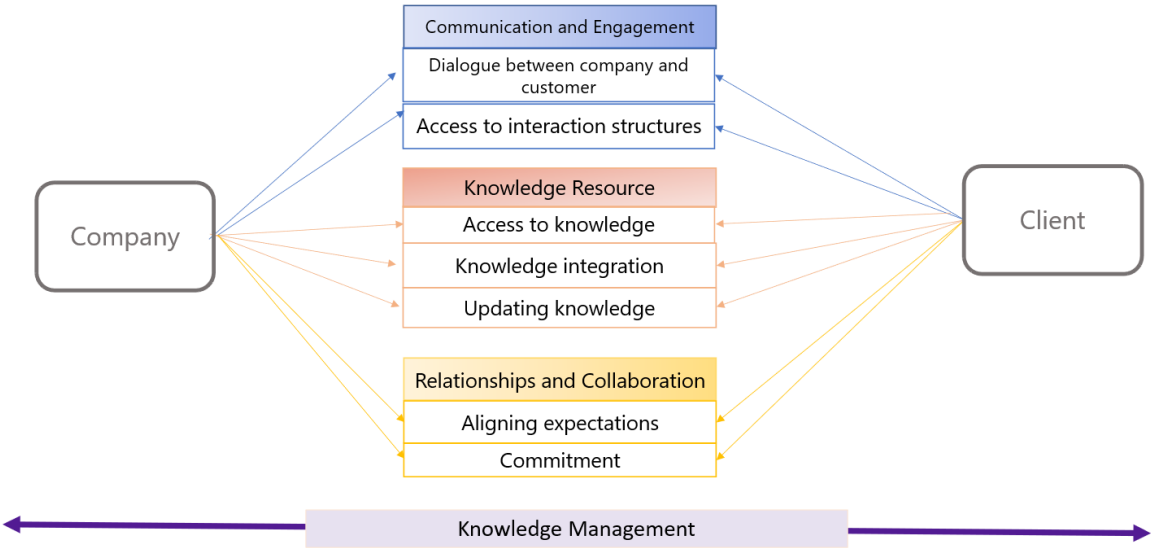

Figure 3: Framework
Source: prepared by the authors

In addition to its analytical function, the framework is prescriptive, providing a basis for guiding questions and management guidelines to mitigate co-destruction and promote the co-creation of value.

5 Discussions

Guiding questions based on the theoretical elements of each category were used to analyze both companies and customers. In the Communication and Engagement dimension, we investigated aspects related to dialogue, the nature of communication between the parties, the main barriers encountered, the channels used, and the ease of accessing contact channels. The Knowledge Resource category aimed to understand how knowledge was shared, accessed, applied, and transformed throughout the service delivery process (Figure 4). The Relationship and Collaboration category addressed trust, alignment of expectations, commitment, transparency, and cooperation among the involved parties. The findings confirm that CCV and CDV emerge from interactions

between customers and companies, as well as from both parties' ability to access, integrate, and utilize resources throughout the service.

The main inhibitors of CCV are concentrated in the Communication and Engagement category. They are particularly related to channel fragmentation, difficulty accessing information, and the multiplicity of decision-makers—factors that increase the complexity of interactions. Furthermore, a lack of customer knowledge, which is linked to the Knowledge Resource category, limits their active participation in the value-creation process. Conversely, the main catalysts for CCV are associated with the Relationship and Collaboration category, including frequent alignment between parties, trust in experts, access to specialists, and clarity of objectives. These factors are reinforced by knowledge sharing, tool use, and learning from service experience.

VDC is mostly caused by issues related to the knowledge resource, such as team turnover, negative past experiences, excessive reliance on experts, and client resistance to change. Difficulties understanding the service and communication failures also contribute to VDC. These results demonstrate that poorly managed knowledge can contribute to value destruction.

Table 1: Data Collection Instrument for the Knowledge Resource Category

Elements	Questions	Authors
Tool for use by the service provider		
Access to knowledge	Do you have any procedures or processes in place to determine whether a customer has the necessary knowledge base for the contracted service?	Prahalad and Ramaswamy (2004); Payne, Storbacka, and Frow (2008); Grönroos (2012)
	Did you help the client gain access to the basic knowledge required for the service? How?	
Knowledge integration	How did you help the client apply the knowledge provided through the service within their company?	Plé and Chumpitaz, 2010; Lintula, Tuunanen, and Salo, 2017
	What obstacles did the client face in applying the knowledge provided through the service?	
Updating knowledge	Do you know if the client gained new insights from the service provided?	Leclercq, Hammedi, and Poncin (2016)
	In your opinion, what obstacles prevented the client from gaining new insights? How did you help them with that?	
Tool for use by the client		
Access to knowledge	Did your company receive any training or background information before hiring the service?	Prahalad and Ramaswamy (2004); Payne, Storbacka, and Frow (2008); Grönroos (2012)
	Did Company X provide you with the necessary expertise to perform the service? How?	
Knowledge integration	Has your company been able to apply the knowledge provided through the service?	Plé and Chumpitaz, 2010; Lintula, Tuunanen, and Salo, 2017
	How did you go about applying that knowledge in your company? Did Company X help? How?	
Updating knowledge	Do you think your company has gained new insights from the work performed? Can you give an example?	Leclercq, Hammedi, and Poncin (2016)
	Did Company X assist with this process? How did that happen?	

Source: prepared by the authors

The three categories of the framework operate simultaneously and interdependently, forming a dynamic system of interactions. In this environment, episodes of CCV and CDV can coexist and alternate throughout the service, necessitating continuous, adaptive management. Seven guidelines based on knowledge management emerge from this systemic understanding, as shown in Figure 4.

The first guideline involves engaging the client's leadership, reducing resistance, and aligning expectations by actively involving decision-makers. The second guideline is to ensure expert participation to facilitate access to knowledge and reduce critical dependencies. The third guideline proposes fostering the use of information and communication systems and structuring information flows and shared repositories. The fourth guideline involves knowledge sharing to reduce asymmetries between the company and the client and promote collaboration. The fifth guideline seeks to stimulate continuous learning throughout the service to strengthen competencies and innovation. The sixth guideline involves continually iterating on customer needs and service objectives to enable adjustments in response to contextual changes. The seventh guideline recommends retaining and integrating team knowledge to minimize the impact of turnover and preserve organizational memory.

Figure 4: Guidelines for Mitigating CDV and Promoting CCV in Knowledge-Intensive Services
Source: prepared by the authors

Taken together, the guidelines translate empirical findings into practical guidance and demonstrate that the effective management of knowledge-intensive services depends on the interplay between communication, knowledge, and relationships. Rather than isolated actions, these are complementary mechanisms that transform complex interactions into ongoing opportunities to co-create value and mitigate co-destruction.

6 Final Considerations

This study analyzed value co-creation (VCC) and value co-destruction (VCD) in knowledge-intensive services from a knowledge management perspective. It validated a three-category framework: Communication and Engagement, Knowledge Resources, and Relationships and Collaboration. The results demonstrate that VCC and VCD arise from the interactions between companies and customers and are influenced by how knowledge is accessed, shared, and applied throughout the service.

From a theoretical standpoint, failures in communication and engagement were found to inhibit VCC, while the absence of knowledge sharing was found to be the main catalyst for VCD. Conversely, strengthening relationships and collaboration, particularly through trust and alignment, fosters value creation. The study also highlights the roles of client leadership and experts, as well as challenges related to information systems, learning, and turnover.

As a key contribution, seven guidelines based on GC were proposed: engage client leadership, ensure expert participation, foster information and communication systems, share knowledge, encourage learning, iterate service needs and objectives, and retain team knowledge.

In practice, these guidelines allow for the systematization of existing actions and the incorporation of new management practices. A limitation of this study is its empirical scope. Future studies may broaden the scope of contexts and utilize quantitative and technological approaches. In conclusion, GC is essential for transforming interactions into continuous processes of shared value generation.

Artificial Intelligence and Marketing Creativity: A Thematic Synthesis of Disruption, Human-AI Collaboration, and Strategic Transformation

Olufemi Afolabi[1], Oluseye Jegede[2]
[1] Global Banking School, Leeds, United Kingdom
[2] Footprint School of Business, London, United Kingdom

Abstract

This study examines the transformative role of artificial intelligence in reshaping marketing creativity, with particular emphasis on human–AI collaboration, organisational capability, and strategic outcomes. Drawing on a theory-driven thematic synthesis of thirteen peer-reviewed journal articles and academic theses, the paper advances a socio-technical perspective in which creativity is no longer viewed as an exclusively human attribute but as an emergent outcome of interaction between intelligent systems, human judgement, and institutional contexts. The analysis integrates Innovation Diffusion Theory, the Technology Acceptance Model, and socio-technical systems theory to examine how AI capabilities, human creative agency, organisational design, and governance mechanisms jointly produce marketing creativity outcomes.
The findings indicate that AI significantly expands the scope, speed, and diversity of idea generation, thereby redefining the early stages of the creative process. Generative AI systems enable rapid production of alternative headlines, visuals, layouts, and narratives, fundamentally altering ideation capacity and lowering the marginal cost of creative experimentation. However, increased ideation does not necessarily translate into enhanced creative value. Human agency remains central, mediating the relationship between AI capability and meaningful marketing outcomes through evaluative judgement, narrative construction, and strategic alignment. Without deliberate human involvement, AI-generated outputs tend toward statistical normativity, limiting originality and emotional depth. Human evaluative competence thus becomes the critical bottleneck in converting generative abundance into brand-relevant, culturally sensitive, and strategically coherent creative outputs.
The study demonstrates that organisational readiness, including AI literacy and evaluative competence, critically shapes the effectiveness of AI-augmented creativity. Firms with stronger strategic and evaluative skills are better positioned to translate AI-generated ideas into coherent campaigns, avoiding homogenisation and ethical missteps. Ethical governance and legitimacy emerge as foundational conditions influencing both market acceptance and performance. Issues of privacy, transparency, authenticity, and authorship actively shape consumer trust and the symbolic legitimacy of brand communications, forming part of the creative system rather than external constraints.
The paper argues that AI does not diminish creativity but redistributes it, shifting competitive advantage from idea generation to interpretation, coordination, and ethical stewardship. Under AI augmentation, creativity increasingly resides in the selection, shaping, legitimisation, and strategic deployment of ideas rather than in their initial production. The study concludes that innovation-driven, human-centred integration of AI is essential for sustained differentiation and strategic transformation. Organisations should prioritise evaluative capability development, design human–AI collaboration with clear role delineation, and embed ethical governance within creative workflows. In this reconfigured landscape, creativity remains central to marketing success, residing in human judgement, organisational design, and ethical stewardship within AI-enabled marketing systems.

Keywords: Artificial Intelligence, Marketing Creativity, Human–AI Collaboration, Global Innovation Systems, Organisational Capability, Ethical Governance

Paper Type: Academic Research Paper

1 Introduction

Creativity has long been positioned as a core human capability underpinning marketing and advertising effectiveness. Traditionally, creative advantage has been associated with imagination, intuition, cultural sensitivity, and narrative judgement, supported by qualitative insight and experiential knowledge. However, the rapid diffusion of artificial intelligence (AI), particularly generative and predictive systems has fundamentally altered how creative work is produced, evaluated, and deployed within marketing systems (Pagani & Wind, 2024; Davenport et al., 2023).

Historical waves of technological disruption in advertising from print and broadcast media to digital platforms and programmatic advertising have consistently reshaped creative production and media strategy. AI represents the latest and arguably most transformative phase in this trajectory, enabling the generation of copy, visuals, and video content at unprecedented speed and scale (Huang & Rust, 2021). While early marketing

technology research framed AI primarily as an efficiency-enhancing tool for segmentation, targeting, and optimisation (McDowall, 2018), more recent scholarship suggests a deeper creative reconfiguration, with AI increasingly involved in ideation, experimentation, and content production (Pagani & Wind, 2024).

At the strategic level, AI is widely characterised as a disruptive technology capable of reshaping organisational structures, creative workflows, and competitive dynamics (Păvăloaia & Necula, 2023). Global expenditure on AI-enabled advertising tools is projected to exceed US$100 billion by 2030 (Statista, 2024), reflecting widespread industry adoption. However, despite this enthusiasm, empirical clarity regarding AI's impact on *creative quality*—as opposed to operational efficiency—remains limited. Industry metrics often conflate automation speed with genuine creative effectiveness, obscuring questions of originality, emotional resonance, and authenticity.

Crucially, the integration of AI into advertising creativity is not frictionless. Conventional creative practice relies heavily on human perception, intuition, and narrative sensemaking, which do not naturally align with data-driven, algorithmic systems (Lee & Cho, 2020; Zaki, 2019). Over-reliance on automation risks producing predictable and emotionally shallow outputs. Yet, when applied in partnership with human judgement, AI can reveal latent insights, suggest novel combinations, and enhance creative productivity (Rust, 2020). Understanding how AI can be integrated creatively—rather than merely efficiently—therefore represents a central theoretical and practical challenge for contemporary marketing.

Despite a growing body of work, existing research remains fragmented across marketing, information systems, psychology, design, and futures studies. Empirical findings are heterogeneous, and theoretical integration is limited. This study addresses these gaps through a theory-driven thematic synthesis of thirteen peer-reviewed articles and academic theses at specifically explore the context of artificial intelligence and marketing creativity, guided by the following research questions:

- *How is AI reshaping creativity in marketing and advertising?*
- *What forms of human–AI collaboration emerge across creative contexts?*
- *What strategic, organisational, and ethical implications arise from AI-driven creative disruption?*

2 Literature Review

2.1 AI as a disruptive force in marketing and advertising

AI is widely recognised as a general-purpose disruptive technology whose implications extend beyond efficiency gains to strategic transformation (Păvăloaia & Necula, 2023). In advertising, disruption manifests through automated content production, predictive analytics, and real-time personalisation at a scale unattainable through traditional methods (Huang & Rust, 2021).

From a diffusion perspective, the adoption of AI reflects patterns described by Innovation Diffusion Theory (IDT), including perceived relative advantage, compatibility with existing creative workflows, complexity, trialability, and observability (Rogers, 1962). While AI offers clear operational advantages, adoption rates vary considerably across organisations due to concerns over creative autonomy, loss of originality, and cultural fit within creative teams (Huang & Rust, 2021). Trialability—such as piloting AI tools on limited campaigns—has emerged as a key mechanism for reducing perceived risk and enabling gradual integration.

Complementing this organisational view, the Technology Acceptance Model (TAM) highlights the importance of individual perceptions of usefulness and ease of use in shaping AI adoption (Davis, 1989). In creative advertising contexts, perceived usefulness extends beyond productivity to include perceived contribution to idea quality, relevance, and engagement. Perceived ease of use is particularly salient, as complex tools can generate resistance among creative professionals, undermining adoption even where strategic benefits are evident (Stone et al., 2020).

Integrating IDT and TAM provides a more holistic understanding of AI adoption in advertising, capturing both organisational diffusion dynamics and individual creative acceptance. However, neither framework alone adequately addresses questions of creative agency, authorship, and emotional resonance, necessitating a broader socio-technical perspective.

2.2 Creativity, AI, and advertising practice

Creativity in marketing is traditionally defined by outputs that are both novel and useful. AI complicates this definition by introducing non-human agents into the creative process. Rather than replacing creativity, AI increasingly functions as a collaborator—supporting ideation, variation, and testing, while humans retain responsibility for evaluation, narrative coherence, and strategic alignment (Rust, 2020; Pagani & Wind, 2024).

Empirical studies in advertising contexts show that generative AI can alleviate cognitive constraints such as "blank-page" anxiety and accelerate experimentation (Albakry et al., 2025). Predictive analytics and recommendation systems further support creative decision-making by identifying patterns in consumer behaviour and preferences (Pradeep et al., 2018). However, when creative production becomes overly dependent on algorithmic outputs, results may converge towards statistically average forms, reducing distinctiveness and emotional depth (Rathore, 2016).

These findings reinforce the view of creativity as a socio-technical phenomenon, emerging from interaction between humans, algorithms, organisational routines, and governance structures (Ameen et al., 2022). Effective creative integration therefore depends not on technological sophistication alone, but on how human–AI collaboration is designed and managed.

2.3 Human–AI collaboration and creative agency

Across the reviewed literature, a recurring theme is the reconfiguration of creative agency. Pagani and Wind (2024) highlight tensions between autonomy and assistance, as creators negotiate control over AI-generated outputs. Similarly, Ameen et al. (2022) caution that creativity may become constrained if AI-generated "defaults" dominate decision-making.

Amankwah-Amoah et al. (n.d.) extend this concern to the creative industries more broadly, arguing that authenticity and the "human touch" may become strategic differentiators in AI-saturated markets. These findings suggest that collaboration design—how tasks and authority are allocated between humans and AI—is central to creative outcomes.

2.4 Governance, ethics, and legitimacy

Ethical concerns cut across all strands of the literature. McDowall (2018) emphasises privacy and data governance as existential issues for future marketing systems. Albakry et al. (2025) highlight originality and academic integrity concerns in AI-supported creative education, while Amankwah-Amoah et al. (n.d.) stress legitimacy and trust in creative outputs.

Despite consensus on the importance of governance, the literature offers limited operational guidance, revealing a critical gap between normative concerns and practical implementation.

3 Theoretical Framework and Propositions

3.1 Conceptual foundations

Drawing on marketing creativity theory, disruptive innovation theory, and socio-technical systems theory, this study conceptualises AI-augmented marketing creativity as an *emergent outcome of human–AI collaboration embedded within organisational and governance structures*. Rather than treating AI as a standalone technological input, the framework positions creativity as jointly produced through interactions among AI capabilities, human judgement, organisational design, and ethical–regulatory constraints (Ameen et al., 2022; Pagani & Wind, 2024; McDowall, 2018).

The framework integrates four core constructs:

1. **AI Creative Capability** (e.g. generative ideation, variation, recombination, speed, scale)
2. **Human Creative Agency** (e.g. strategic framing, evaluative judgement, narrative sensemaking)
3. **Organisational & Governance Context** (e.g. workflows, skills, ethics, privacy, legitimacy)
4. **Marketing Creativity Outcomes** (e.g. novelty, usefulness, brand fit, market performance)

3.3 Propositions Development

Proposition 1 (P1): AI Creative Capability and Ideation Expansion

AI creative capability positively influences the volume and diversity of marketing ideas generated, thereby expanding the ideation space available to marketers.

Rationale:

Generative AI excels at rapid variation and recombination of creative elements, enhancing divergent thinking in advertising contexts (Pagani & Wind, 2024; Pradeep et al., 2018). However, novelty at scale does not equate to creative value without human evaluation.

Proposition 2 (P2): Human Creative Agency as Mediator

Human creative agency mediates the relationship between AI creative capability and marketing creativity outcomes.

Rationale:

AI lacks contextual sensitivity to brand meaning, cultural nuance, and emotional storytelling. Human judgement remains essential for framing problems, assessing relevance, and legitimising creative outputs (Ameen et al., 2022; Rust, 2020).

Proposition 3 (P3): Collaboration Design and Role Clarity

Clearly defined human–AI collaboration roles strengthen the positive effect of AI creative capability on marketing creativity outcomes.

Rationale:

Advertising studies show that creativity improves when AI is positioned as an ideation assistant rather than a decision authority, preserving human autonomy and evaluative control (Pagani & Wind, 2024; Albakry et al., 2025).

Proposition 4 (P4): Organisational Capability as Moderator

Organisational AI literacy and evaluative capability positively moderate the relationship between human creative agency and marketing creativity outcomes.

Rationale:

Firms with stronger strategic and evaluative skills are better able to translate AI-generated ideas into coherent campaigns, avoiding homogenisation and ethical missteps (AbouElgheit, 2025; McDowall, 2018).

Proposition 5 (P5): Governance and Legitimacy

Ethical governance mechanisms moderate the impact of AI-augmented creativity on market performance.

Rationale:

Consumer trust, perceptions of authenticity, and compliance with privacy and transparency norms shape acceptance of AI-enabled advertising (Amankwah-Amoah et al., n.d.; McDowall, 2018).

Proposition 6 (P6): Disruptive Competitive Outcomes

AI-augmented marketing creativity enables disruptive business model innovation when integrated with strategic repositioning.

Rationale:

AI lowers creative production costs and entry barriers, benefiting smaller firms, but sustained advantage depends on complementary organisational change (AbouElgheit, 2025; Păvăloaia & Necula, 2023).

Integrated Contribution

By integrating advertising-specific adoption theories (IDT, TAM) with socio-technical creativity frameworks, this study advances marketing theory in three ways:

- **Conceptual:** Reframes advertising creativity as a human–AI system outcome rather than an individual capability.
- **Strategic:** Explains how AI-enabled creativity contributes to disruption without eroding differentiation.
- **Governance-oriented:** Positions ethics and legitimacy as central moderators of creative value.

4 Methodology

4.1 Research design

This study adopts a qualitative, theory-driven thematic analysis to examine how artificial intelligence reshapes creativity within marketing and advertising contexts. The methodological approach is explicitly guided by the proposed theoretical framework, which conceptualises marketing creativity as an outcome of human–AI interaction, shaped by organisational capabilities and governance conditions.

Given the exploratory and integrative nature of the research questions, a qualitative synthesis was considered more appropriate than a quantitative meta-analysis. The reviewed studies vary considerably in design, scope, and empirical focus, and do not report comparable effect sizes. Instead, this study seeks to identify patterns of meaning, convergence, and tension across the literature, consistent with interpretive approaches commonly used in marketing theory development.

4.2 Data sources and selection criteria

The analysis draws on thirteen academic sources that specifically looked at the interphase between artificial intelligence and marketing creativity, including peer-reviewed journal articles, systematic reviews, and examined theses. These sources were selected using three criteria:

- Explicit engagement with artificial intelligence in marketing, advertising, or creative industries
- Conceptual or empirical treatment of creativity, innovation, or strategic transformation
- Scholarly credibility and relevance to contemporary marketing practice

The inclusion of doctoral theses alongside journal articles enabled the incorporation of future-oriented and practice-embedded insights that are often under-represented in journal literature.

4.3 Analytical Procedure

The analysis followed a structured yet flexible six-stage thematic process, informed by the theoretical framework:

- Familiarisation through repeated reading of each source
- Initial coding of key concepts linked to AI capability, human agency, creativity outcomes, organisational context, and governance
- Axial coding, linking concepts to the relationships proposed in the framework
- Theme refinement, ensuring consistency across sources
- Framework mapping, aligning themes with propositions P1–P6
- Interpretive synthesis, integrating findings into a coherent explanatory narrative

Throughout the process, attention was paid not only to areas of agreement but also to contradictions and boundary conditions, strengthening analytical depth.

5 Results and Discussion

This section presents and discusses the findings of the thematic analysis in direct relation to the theoretical framework. Rather than treating results and discussion as separate stages, the analysis is integrated, allowing empirical insights from the reviewed literature to be interpreted through the lens of the proposed propositions

(P1–P6). Academic sources are embedded within each subsection to demonstrate how existing scholarship informs, supports, or nuances the findings.

5.1 AI Creative capability and the expansion of ideation (P1)

Across the reviewed literature, there is strong agreement that AI significantly expands the volume, speed, and diversity of creative ideas available to marketers. Generative AI systems enable rapid production of alternative headlines, visuals, layouts, and narratives, fundamentally altering the early stages of the creative process. Pagani and Wind (2024) show that AI tools increase exploratory breadth in marketing creativity by enabling users to test multiple creative directions in parallel, something that would be impractical using purely human labour.

Similarly, Albakry et al. (2025) demonstrate that in advertising and digital content design contexts, AI-supported ideation enhances creative confidence and lowers psychological barriers associated with "blank-page" problems. These findings align with broader observations in the disruptive technology literature, which positions AI as a catalyst for efficiency and experimentation across business functions (Păvăloaia & Necula, 2023).

However, the literature also reveals a consistent qualification: greater ideation capacity does not guarantee superior creativity. While AI can generate novel combinations at scale, it lacks contextual sensitivity to brand values, cultural nuance, and strategic intent. As Ameen et al. (2022) argue, novelty alone is insufficient in marketing contexts where usefulness and relevance are equally central to creative effectiveness. The findings therefore support Proposition 1 while reinforcing the need to distinguish between idea quantity and creative value.

5.2 Human creative agency as a mediating mechanism (P2)

The analysis highlights human creative agency as a central mediating force between AI capability and marketing creativity outcomes. Across conceptual, empirical, and futures-oriented studies, humans retain responsibility for problem framing, evaluative judgement, and narrative sensemaking, even as AI contributes to idea generation.

Ameen et al. (2022) emphasise that creativity in AI-augmented environments emerges from interaction rather than substitution. Their theoretical work argues that without deliberate human involvement, AI-generated outputs tend towards statistical normativity, limiting originality in strategic contexts. Pagani and Wind (2024) provide empirical support for this claim, showing that marketers who actively engaged in iterative evaluation and refinement produced more distinctive and strategically aligned creative outputs than those who relied heavily on default AI suggestions.

The reviewed theses further reinforce this point. McDowall (2018) anticipates that while automation will reshape marketing work, human judgement will remain central in navigating complexity, ambiguity, and ethical trade-offs. Collectively, these findings strongly support Proposition 2, positioning human agency as an indispensable mechanism through which AI-enabled creativity is translated into meaningful marketing outcomes.

5.3 Human–AI collaboration design and role clarity (P3)

Beyond individual agency, the findings suggest that how collaboration between humans and AI is structured plays a critical role in shaping creative effectiveness. Studies consistently indicate that creativity is enhanced when roles are clearly delineated, with AI positioned as a support for ideation and variation, and humans retaining control over selection and strategic direction.

Pagani and Wind (2024) observe that ambiguity in role allocation can lead to over-reliance on AI-generated outputs, reducing critical engagement and creative confidence. This is echoed in educational research by Albakry et al. (2025), where students produced stronger creative work when AI was used as a co-creative assistant rather than an authoritative source.

These findings align with socio-technical perspectives on creativity, which emphasise the importance of system design in shaping outcomes (Ameen et al., 2022). Proposition 3 is therefore supported: clear collaboration design strengthens the positive relationship between AI capability and creative outcomes, while poorly designed interaction risks undermining creative quality.

5.4 Organisational capabilities and skill readiness (P4)

The analysis further reveals that organisational context significantly conditions the effectiveness of AI-augmented creativity. Firms with higher levels of AI literacy, strategic competence, and evaluative capability were better positioned to harness AI-generated ideas productively.

AbouElgheit (2025) demonstrates that small marketing firms can leverage generative AI to disrupt established competitors, but only when AI adoption is combined with strategic repositioning and skill development. This finding resonates with McDowall's (2018) argument that technological innovation alone is insufficient; organisational learning and capability building are essential for sustained advantage.

The literature also suggests that evaluative skills—such as assessing creative fit, ethical risk, and market relevance—become more important as AI lowers the cost of idea generation. These findings provide strong support for Proposition 4, highlighting organisational capability as a positive moderator of human creative agency.

5.5 Governance, ethics, and market legitimacy (P5)

Ethical and governance considerations emerge as structural conditions, rather than secondary concerns, shaping the outcomes of AI-enabled creativity. Issues related to data privacy, authenticity, transparency, and authorship recur across the literature.

McDowall (2018) identifies privacy regulation and public trust as key uncertainties influencing the future of marketing innovation. In creative contexts, Amankwah-Amoah et al. (n.d.) argue that excessive automation risks eroding authenticity, potentially undermining consumer trust in creative industries. Albakry et al. (2025) similarly highlight concerns around originality and ethical use of AI-generated content in educational and creative practice.

These insights collectively support Proposition 5, suggesting that governance mechanisms moderate the relationship between creativity and market performance. Where ethical oversight is embedded within creative workflows, AI-enhanced creativity is more likely to be perceived as legitimate and trustworthy.

5.6 AI-Augmented creativity and disruptive outcomes (P6)

The findings indicate that AI-enabled creativity can contribute to disruptive innovation, particularly for smaller and more agile organisations. By reducing creative production costs and accelerating experimentation, AI opens opportunities for new market entrants and alternative service models (AbouElgheit, 2025).

However, disruption is shown to be contingent on strategic integration. Firms that adopted AI tools without revising their business models or value propositions achieved limited competitive benefit. This finding is consistent with disruptive innovation theory and with broader assessments of AI as a general-purpose technology whose impact depends on complementary organisational change (Păvăloaia & Necula, 2023).

Proposition 6 is therefore supported, with the important caveat that AI-enabled creativity only becomes disruptive when embedded within coherent strategic and organisational transformation.

6 Integrated Discussion and Theoretical Contribution

Taken together, the findings indicate that AI does not erode the importance of creativity in marketing; rather, it redistributes creative value across the marketing system. Where creativity was previously treated as a predominantly human capability expressed through ideation and artistic execution, it is increasingly constituted through socio-technical interaction, a coordinated assemblage of generative tools, human evaluative judgement, organisational routines, and governance mechanisms. In this sense, AI shifts the creative "centre of gravity" from the production of ideas to the selection, shaping, legitimisation, and strategic deployment of ideas, thereby reconfiguring the locus of advantage from *creative generation* to *creative governance and sensemaking* (Ameen et al., 2022; Pagani & Wind, 2024).

6.1 Reconfiguring the creative production function: from scarcity to abundance

A central implication concerns the transformation of the creative production function under conditions of idea abundance. Generative models reduce the marginal cost of producing copy, layouts, imagery, and variations close to zero, enabling continuous iteration and large-scale experimentation. This creates a structural inversion: historically, ideation was scarce and evaluation comparatively manageable; with AI, ideation becomes plentiful while evaluation becomes the bottleneck. This bottleneck is not simply managerial, it is epistemic. Human actors

must determine what is *good*, *appropriate*, *distinctive*, and *brand-consistent* in environments where the system can output thousands of plausible artefacts quickly.

This shift helps explain why many organisations report gains in efficiency without commensurate gains in distinctiveness. Generative systems are trained to reproduce statistically likely patterns, which can elevate baseline competence while increasing the risk of normative convergence, creative outputs that are fluent and polished yet strategically generic. The implication is that competitive advantage will increasingly depend on differentiated evaluative capacity: the ability to impose a distinctive interpretive frame, curate outputs with cultural and brand sensitivity, and translate ideas into coherent narratives rather than simply generating content at scale.

6.2 Human creative agency as strategic control, not residual involvement

The results support the view that human agency is not a symbolic residue left after automation; it is the principal mechanism of strategic control in AI-augmented creativity. Specifically, humans retain responsibility for problem framing (deciding what the campaign is *for*), evaluative judgement (deciding what *counts as quality*), and narrative sensemaking (deciding what the idea *means* for the brand and its audiences). These functions are difficult to formalise because they involve tacit knowledge, cultural interpretation, and value-based decision-making. In marketing, such judgements are inseparable from questions of legitimacy: what a brand can credibly say, what an audience will find authentic, and what constitutes acceptable persuasion.

Consequently, the contribution of AI to creativity is conditional. AI can expand the ideation space and accelerate iteration, but its outputs require human governance to avoid hollow novelty (new but irrelevant) or fluent sameness (well-written but interchangeable). This aligns with socio-technical perspectives that treat creativity as emergent from interaction rather than located in a single agent (Ameen et al., 2022). It also clarifies why creativity increasingly resides in coordination: the orchestration of tools, people, and standards across the creative pipeline.

6.3 Collaboration design as a micro-foundation of creative performance

A deeper theoretical implication is that collaboration design, how roles, authority, and accountability are allocated between humans and AI functions as a micro-foundation of marketing creativity outcomes. The findings suggest that "AI as generator, human as evaluator" is not merely a convenient division of labour; it constitutes a mechanism that protects autonomy, sustains critical engagement, and mitigates default dependency. When role boundaries are ambiguous, creative teams may accept AI outputs as authoritative suggestions, reducing critical scrutiny and narrowing exploration. In contrast, when AI is structured as an exploratory engine and humans as interpretive governors, teams are more likely to use AI outputs as prompts for divergence rather than templates for replication.

This insight extends system-level marketing creativity theory by specifying *how* socio-technical systems shape outcomes: not through AI adoption per se, but through interaction protocols (briefing practices, prompt governance, review routines, approval rights, and feedback loops). These organisational "interaction grammars" determine whether AI increases variety and distinctiveness or merely amplifies speed and volume.

6.4 Organisational capability: the rise of evaluative competence and creative ops

At the organisational level, the findings imply that AI shifts marketing capability requirements away from pure creative talent and towards evaluative competence, AI literacy, and what might be termed *creative operations* (creative ops): the routines and infrastructures that manage high-throughput creative experimentation. Under AI augmentation, firms must develop capacity for:

- Brand constraint articulation (codifying tone, values, exclusions, and boundaries in usable form)
- Quality assurance systems (human review, bias checks, factual verification, and compliance screening)
- Performance learning loops (linking creative variants to engagement, conversion, and brand metrics without reducing creativity to short-term click optimisation)
- Asset governance (rights management, disclosure standards, provenance tracking, and auditability)

This reframes the organisation as a creative system rather than a collection of creative individuals. It also clarifies why AI may advantage smaller and agile firms: where evaluation routines and governance are well designed, AI lowers production costs and increases responsiveness. However, absent strong organisational capabilities, the same tools can create operational noise—many outputs, weak coherence, and diluted brand meaning.

6.5 Governance and legitimacy as constitutive, not peripheral

A major contribution of the synthesis is the demonstration that governance is not an external constraint applied after creativity occurs. Rather, governance is constitutive of creative value in AI-mediated marketing. In practice, questions of privacy, transparency, bias, authenticity, and authorship do not merely affect legal exposure; they shape consumer perceptions of trust and the symbolic legitimacy of brand communications. In AI-enabled contexts, the conditions under which content is created and targeted become part of the meaning of the message itself.

This is especially important because AI systems rely on data and probabilistic inference, which raises legitimacy concerns across the creative pipeline: the origins of training data, the fairness of targeting logic, the transparency of synthetic content, and the ethics of personalisation. The findings therefore advance the argument that market performance depends not only on the novelty and usefulness of creative outputs, but also on perceived legitimacy—whether audiences regard the communication as credible, respectful, and authentic. This responds directly to futures-oriented concerns about disruption, trust, and agency (McDowall, 2018), and reinforces the need to theorise governance as a moderator of creative effectiveness rather than an afterthought.

6.6 Theoretical contribution: creativity as a socio-technical, strategic system

Collectively, these insights extend marketing creativity theory in three ways.

First, the synthesis advances a system-level ontology of creativity, treating creative outcomes as emergent from interactions between AI capability, human judgement, organisational design, and governance. This moves beyond individual-centric creativity models and offers a more realistic account of how creativity is produced within contemporary marketing organisations (Ameen et al., 2022).

Second, it clarifies a strategic mechanism through which AI influences competitive advantage: AI expands ideation, but differentiation increasingly depends on evaluative and narrative capabilities that are unevenly distributed across firms (Pagani & Wind, 2024). As such, AI may raise the average quality of market communications while simultaneously intensifying competition around brand distinctiveness, cultural resonance, and trust.

Third, it positions legitimacy and ethics as central moderators of creative value creation, demonstrating that governance mechanisms shape not only compliance but also market acceptance. This directly addresses concerns raised in innovation and futures literature regarding the social viability of AI-driven marketing systems and the continuing centrality of human agency in navigating ambiguity and normative trade-offs (McDowall, 2018).

In summary, the integrated discussion indicates that AI is best theorised not as a creative agent that replaces human creativity, but as a general-purpose creative infrastructure that changes the economics, speed, and scope of creative work. Under this view, marketing creativity increasingly resides in human judgement, organisational design, and ethical stewardship, the capabilities that convert generative abundance into meaningful, differentiated, and legitimate brand communication.

7 Conclusion

This study set out to address key gaps in the literature by examining how artificial intelligence is reshaping creativity in marketing and advertising, with particular attention to human–AI collaboration and the strategic, organisational, and ethical implications of AI-driven disruption. Drawing on a theory-driven thematic synthesis of thirteen peer-reviewed journal articles and academic theses, the study provides an integrated explanation of AI-enabled creativity as a socio-technical and strategic system, rather than as a purely technological or efficiency-oriented phenomenon.

In response to the first research question, the findings demonstrate that AI is fundamentally reconfiguring, rather than replacing, marketing creativity. Generative and analytical AI tools significantly expand ideation capacity by enabling rapid production and exploration of creative alternatives. However, this expansion shifts the locus of creative value away from idea generation towards judgement, evaluation, and sensemaking. Creativity in AI-augmented contexts is therefore less concerned with producing ideas and more concerned with selecting, shaping, and legitimising them within brand, cultural, and market constraints. This challenges traditional views that locate creativity primarily in individual inspiration or artistic talent, and instead positions creativity as an outcome of structured interaction between humans, intelligent systems, and organisational arrangements.

Addressing the second research question, the analysis highlights the central role of human–AI collaboration design in shaping creative outcomes. Across the literature, effective collaboration is characterised by clear role allocation, with AI supporting exploration, variation, and experimentation, while humans retain authority over framing, evaluation, and narrative coherence. Human creative agency emerges not as a residual presence but as a necessary mediating mechanism that translates AI capability into meaningful marketing outcomes. Where such agency is weakened, AI-generated outputs tend to converge towards generic forms, undermining differentiation and strategic relevance.

In relation to the third research question, the study shows that AI-driven creative disruption has uneven strategic and organisational effects. Firms with stronger evaluative capabilities, higher levels of AI literacy, and clearer strategic intent are better positioned to convert AI-generated ideas into effective marketing outputs. While AI can act as a catalyst for creative disruption—particularly for smaller and more agile firms—such outcomes depend on complementary investments in skills, organisational learning, and business model innovation. Ethical and governance considerations also play a central role. Issues of privacy, transparency, authenticity, and legitimacy actively shape how AI-enabled creativity is perceived and accepted in the marketplace, forming part of the creative system rather than functioning as external constraints.

Overall, the study advances marketing creativity theory by shifting attention from individual-centric models towards system-oriented frameworks that integrate technological, organisational, and ethical dimensions. Practically, the findings suggest that organisations seeking to benefit from AI should prioritise evaluative and strategic capability development, design human–AI collaboration thoughtfully and embed ethical governance within creative workflows. In conclusion, artificial intelligence represents not the end of marketing creativity, but its reconfiguration. Creativity remains central to marketing success, increasingly residing in human judgement, organisational design, and ethical stewardship within AI-enabled marketing systems.

8 Ethics Declaration

This study employed a theory-driven thematic synthesis of publicly available, peer-reviewed academic literature and published doctoral theses. No primary data collection involving human participants, animals, or sensitive personal data was conducted. As the research draws exclusively on secondary sources already in the public domain, formal ethical clearance from an institutional review board was not required. All sources have been appropriately cited and referenced in accordance with standard academic practice.

9 AI Declaration

Artificial intelligence tools were used in the development of this paper for research assistance, writing support, and image generation. Specifically, an AI-powered conversational assistant (Kimi, developed by Moonshot AI) was used to support literature synthesis, refine argumentation, and assist with the drafting and editing of manuscript sections. The AI tool was employed as a collaborative writing aid, with the author retaining full responsibility for all analytical judgements, theoretical interpretations, and final editorial decisions. All substantive claims, propositions, and conclusions were critically evaluated and validated by the author prior to inclusion. Additionally, AI-powered image generation tool was used to produce visual material included in this paper. This image was generated to illustrate conceptual frameworks and was reviewed and approved by the authors for accuracy and relevance to the research content. The authors acknowledges that AI-generated outputs were treated as provisional drafts requiring human oversight, verification, and refinement. All cited sources were independently checked against original publications, and the author assumes full accountability for the intellectual integrity, accuracy, and originality of the final submitted work.

Abstract

This paper investigates how knowledge management (KM) practices manifest in industrial small and medium-sized enterprises (SMEs) and explores the role of process mapping as a mechanism for enabling the codification, sharing, and reuse of knowledge. While prior literature has extensively examined KM and process management as distinct streams, limited attention has been paid to their integration, especially within SMEs characterized by informal structures and fragmented knowledge practices. Adopting a qualitative, exploratory research design, the study combines a structured literature review with an empirical investigation based on semi-structured interviews conducted with a cluster of seven industrial SMEs. The literature review highlights three consistent findings: KM and Business Process Management (BPM) are mutually reinforcing; digitalization enhances the visibility and traceability of processes. However, these streams remain largely disconnected, revealing a gap in understanding how knowledge becomes operationally embedded within processes. The empirical findings show that SMEs demonstrate strong capabilities in knowledge creation and in increasing the adoption of digital tools, but struggle to translate this potential into structured, reusable organizational knowledge. Key KM dimensions such as reuse, decision traceability, and flow clarity remain underdeveloped. Process mapping emerges as a critical yet underutilized enabler: although firms recognize its importance, it is often implemented in a fragmented or purely descriptive manner, without explicit linkage to KM objectives. The study offers three main contributions. First, it proposes an integrated perspective that connects KM and process-based approaches. It also provides empirical evidence of the misalignment between knowledge generation and its codification within SMEs and, finally, it highlights process mapping as a foundational infrastructure for transforming tacit and dispersed knowledge into structured organizational assets. The findings suggest that investments in digital technologies and artificial intelligence are insufficient to improve KM outcomes unless supported by clearly defined and shared process structures. Future research should further explore how process mapping, process mining, and AI can be jointly leveraged to enhance knowledge-intensive operations in SMEs.

Keywords: Knowledge Management, Process Mapping; Industrial SMEs, Artificial Intelligence.

Paper type: Academic Research Paper

1 Introduction

In the contemporary economy, knowledge is widely recognized as a strategic resource for competitiveness, innovation, and organizational adaptability. The foundational literature on knowledge management (KM) has clarified that knowledge does not coincide with mere information: Davenport define it as a “fluid mix of framed experience, values, contextual information, and expert insight”, while Ikujiro Nonaka shows that organizational knowledge is generated through a “continuous dialogue between tacit and explicit knowledge”(Nonaka, 1994). A particularly relevant aspect of this paper is that such knowledge does not remain confined to individuals or documents but is also embedded in “routines, processes, practices, and norms” (Davenport et al., n.d.). In other words, KM becomes truly observable when it is translated into organizational arrangements, operational practices, and process structures.

This perspective becomes even more significant in industrial contexts characterized by service-oriented logics. The transition from product-centered models to solution- and service-oriented models makes knowledge a primary driver of value creation: what matters is not only designing and producing effectively, but also capturing, interpreting, and reusing knowledge generated throughout the offering's lifecycle, from operations to after-sales activities. In this regard, studies have shown that knowledge management is connected to organizational performance, highlighting that KM should be understood as a mechanism for enhancing the value organizations create (Schiuma et al., 2012a). In parallel, in service firms, the principle of “efficiency-of-use” tends to be replaced by “availability-to-use”: knowledge generates value to the extent that it is available, accessible, and reusable within processes. In recent years, this discussion has been further enriched by digital transformation, Industry 4.0, and the adoption of artificial intelligence (AI) tools. The literature shows that KM,

digitalization, and Industry 4.0 are converging into an increasingly structured research field (De Bem Machado et al., 2022). From an AI perspective, Jarrahi et al., (2023) underline that intelligent systems can support the main dimensions of KM—knowledge creation, storage, retrieval, sharing, and application—but only when they are effectively integrated with people, infrastructures, and organizational processes. This leads to a first key point: the presence of digital or AI tools does not automatically translate into effective knowledge management.

This issue is particularly evident in small and medium-sized industrial enterprises (SMEs). A well-established body of literature shows that KM practices in SMEs are often informal, fragmented, highly dependent on individual experience, and rarely supported by formalized systems and processes (Cerchione et al., 2016, 2015). More recent studies confirm that even amid increasing digitalization, SMEs tend to adopt traditional, isolated tools without developing a coherent knowledge management architecture (Castagna et al., 2020). Furthermore, the review by Durst et al., (2023) highlights that the field of KM in SMEs is rapidly expanding yet remains fragmented across loosely connected research streams, including knowledge sharing, capabilities, innovation, entrepreneurship, and digitalization. In this context, knowledge continues to be generated "in practice," but struggles to be codified, traced, and systematically reused. It is precisely at this point that process mapping becomes relevant. If, as (Davenport et al., n.d.) argue, knowledge is embedded in routines and processes, then process mapping is not merely a tool for operational efficiency, but also a mechanism for making knowledge visible within the organization. Recent literature on data-driven techniques shows that mapping actual workflows enables the identification of bottlenecks, deviations, tacit knowledge embedded in practices, and discrepancies between designed and executed processes (Lorenz et al., 2021). Even more critically, Wijnhoven et al., (2023) demonstrate that, in SMEs, the understanding and reconstruction of processes are particularly challenging due to the absence of clear de jure models and the ambiguity of information system semantics. This makes process mapping not a methodological accessory, but a potential enabling condition for knowledge codification, decision traceability, sharing, and reuse in service-intensive contexts.

Despite these advancements, a significant gap remains in the literature. Contributions on KM in SMEs have mainly focused on practices, barriers, and systems. However, there remains a lack of explicit integration among these streams that explains how knowledge is embedded and made manageable within operational and service processes in industrial SMEs, and what role process mapping plays in the transition from experiential, dispersed knowledge to codified, reusable organizational knowledge. This paper positions itself precisely at this theoretical and empirical intersection. The research question guiding the study is as follows: how do knowledge management practices manifest in industrial SMEs, and what role does process mapping play in enabling the codification, sharing, and reuse of knowledge within operational and service processes? The expected contribution is threefold. From a theoretical perspective, the paper connects KM and process perspectives into a unified interpretative framework. From an empirical standpoint, it provides qualitative evidence from a cluster of industrial SMEs, a context that remains underexplored from an integrated perspective. From a methodological perspective, it combines a structured literature review, structured interviews, and coded data analysis to examine the extent to which knowledge remains informal or, conversely, is translated into observable process structures supported by digital tools. Consistent with this positioning, the methodology of the paper is articulated into two complementary phases. The first consists of a structured literature review based on Scopus queries combining the terms knowledge management, SMEs, service, process mapping/process mining, digital transformation, and AI, followed by screening and thematic analysis of the selected contributions. The second phase is a qualitative empirical study based on structured interviews conducted with seven firms belonging to an industrial cluster; the responses were subsequently codified into a dataset and analyzed using Python through descriptive matrices, heatmaps, gap analysis, and lexical analysis. In this way, the paper integrates bibliographic and empirical evidence to investigate whether and how processes make knowledge truly visible, shareable, and reusable.

2 Methodology

This study adopts a qualitative and exploratory research design aimed at investigating the role of process mapping in enabling knowledge management practices within industrial SMEs. The methodological approach combines a structured analysis of the academic literature with an empirical investigation based on semi-structured interviews conducted within an industrial cluster. This dual approach allows for the integration of theoretical insights and empirical evidence, providing a comprehensive understanding of the phenomenon under study.

The first phase of the research consists of a structured literature review conducted using the Scopus database, which was selected due to its broad coverage of peer-reviewed journals and its relevance for management and engineering studies. The objective of this phase was to identify and systematize the main

contributions at the intersection of knowledge management, SMEs, servitization, process mapping, and digital transformation. The search query was designed to capture the multidimensional nature of the research topic and included the following keywords:

("knowledge management" OR "organizational knowledge") AND ("SMEs" OR "small AND medium enterprises") AND ("process mapping" OR "business process management" OR "process mining") AND ("servitization" OR "product-service systems" OR "service") AND ("digital transformation" OR "artificial intelligence") AND (LIMIT-TO (SUBJAREA , "BUSI") OR LIMIT-TO (SUBJAREA , "ENGI")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (LANGUAGE , "English"))

The search was conducted without restricting the initial time window, thereby including both foundational and recent contributions. The results were then filtered based on document type (articles and reviews), language (English), and relevance to the research objectives. Abstracts and full texts were screened to exclude contributions that were not directly related to knowledge management practices or that did not provide insights into process-related dimensions.

The selected articles were analyzed using a thematic approach, focusing on four main streams: (i) knowledge management foundations and processes, (ii) KM in SMEs, (iii) servitization and service-oriented transformation, and (iv) process mapping and process mining. This analysis revealed a fragmentation of the literature across these streams and highlighted a lack of integration between knowledge management and process-based perspectives, particularly in SME contexts. The literature review thus served both to ground the research theoretically and to identify the gap addressed by the empirical investigation.

The second phase of the study is based on an empirical investigation conducted within a cluster of industrial SMEs. The cluster represents a collaborative environment involving firms and research institutions, aimed at fostering knowledge exchange and supporting innovation processes. The companies involved operate in manufacturing sectors characterized by high technical complexity and increasing service orientation, making them particularly relevant for the study of knowledge management in product-service contexts.

The selection of firms was driven by their participation in the cluster initiative and by their willingness to engage in a structured reflection on knowledge management practices. While the firms differ in size, organizational structure, and technological maturity, they share characteristics typical of SMEs, including limited process formalization and a strong reliance on individual expertise. Data were collected through semi-structured interviews conducted with key organizational actors, including managers and technical experts involved in operational and decision-making processes. The interview protocol was designed to explore how knowledge is created, codified, shared, and used within the organization, as well as the role of processes and digital tools in supporting these activities. Attention was devoted to identifying critical issues and perceived barriers in managing knowledge, as well as to understanding the role of process mapping practices, where present.

Following data collection, the interview responses were transcribed and systematically codified into a structured dataset. Each response was analyzed and mapped onto a set of analytical dimensions derived from the literature review, including knowledge creation, codification, sharing, use, reuse, process mapping, decision traceability, digital tools, and technology effectiveness. To enable comparison across firms, each dimension was evaluated on a three-point scale, with values indicating the degree of presence or maturity of the specific practice. This coding process transformed qualitative data into a semi-quantitative dataset, enabling the identification of patterns and differences across cases.

The resulting dataset was organized in a tabular format and subsequently analyzed using Python. The analysis included constructing a matrix representation of the data, visualizing it with heatmaps, calculating descriptive statistics, and developing gap analysis indicators to identify misalignments across key dimensions. In addition, a textual analysis of interview responses was conducted by extracting and processing the answers, enabling the identification of recurring themes and dominant concepts through word frequency analysis.

3 Literature Review

Recent literature converges on a key point: in industrial SMEs, process mapping is not merely a descriptive exercise, but a cognitive and organizational infrastructure that makes knowledge more visible, transferable, and reusable. When processes are explicitly represented through maps, "as-is/as-designed" models, roles, inputs/outputs, handoffs, exceptions, and document flows, tacit knowledge dispersed within operational practices is progressively translated into more stable organizational knowledge. In industrial SMEs, this role becomes even more critical, as value creation depends on integrating production processes, service processes, usage data, customer interactions, and decision-making activities across the entire lifecycle of the offering.

Digitalization and, more recently, artificial intelligence further amplify this role, but only when a sufficiently standardized and governed process foundation is in place.

3.1 KM, process orientation and SMEs

Knowledge does not generate value in an abstract way, but rather when it is embedded within the processes that support performance and value creation. Schiuma et al., (2012) emphasizes the link between knowledge management and performance improvement, while Schiuma et al., (2012b) interpret knowledge processes as mechanisms of value creation. This perspective is particularly consistent with industrial SMEs, where knowledge is often embedded in people, routines, and operational relationships rather than in formalized systems. Indeed, reviews on KM in SMEs clearly show that such firms are characterized by resource constraints, low levels of formalization, and a strong reliance on human and contextual knowledge—factors that make a lightweight yet process-embedded infrastructure crucial for stabilizing knowledge (Centobelli et al., 2019; Cerchione et al., 2016; Durst et al., 2023). More recent studies on SMEs also demonstrate that KM practices influence both internal performance and external relational capabilities, but their effectiveness depends on their integration into organizational processes rather than on their isolated existence(Rošulj et al., 2024).

From this, an important theoretical implication emerges: process mapping is valuable for KM because it allows knowledge to be "attached" to a sequence of activities, actors, decision rules, and documents. In other words, it makes organizational knowledge identifiable within the workflow and, therefore, manageable. Bitkowska, (2020), in an empirical study of Polish firms, explicitly demonstrates that Business Process Management positively influences knowledge management processes. The statement is clear: "Business Process Management has a positive influence on Knowledge Management processes"(Bitkowska, 2020). This finding is consistent with (Atkočiūnienė et al., 2022), who demonstrate that KM processes positively affect business processes and that business processes mediate the relationship between KM and value creation. The relationship, therefore, is not linear but mediated: knowledge generates value when it flows through processes that are observable, improvable, and measurable.

3.2 Process mapping as an enabler of coding, traceability, sharing and reuse

The first mechanism is codification. Mapping a process means defining activities, inputs, outputs, responsibilities, control points, exceptions, and required knowledge; in other words, it involves transforming what was previously situated, implicit, and fragmented into a shared organizational artifact. (Bitkowska, 2018) even interprets the Business Process Management Centre of Excellence as a source of knowledge, that is, as a structure that collects, organizes, and disseminates process-related knowledge. Even more explicitly, Sarnikar and Deokar (2017), from a design science perspective, show that process-based knowledge management systems support knowledge-intensive processes precisely because they link knowledge needs to the context in which the process is performed. For SMEs, this translates into reduced dependence on individual experts, increased replicability of effective practices, and faster onboarding, training, and standardization. The second mechanism is traceability. Here, the literature on event logs and process mining complements traditional process mapping approaches. Lorenz et al., (2021), in a make-to-stock manufacturing context, observe that traditional mapping methods "only provide static snapshots of process flows" (p. 4870), whereas process mining enables the dynamic mapping of real processes and the identification of deviations, bottlenecks, and non-value-adding activities. Wijnhoven et al., (2023), in an SME case study, further show that incomplete de jure models hinder the identification of workarounds and that human interpretation of results is necessary to activate triple-loop organizational learning. This theoretical point is highly relevant to this study: traceability does not depend solely on data but on the alignment between expected and actual processes. In the absence of a robust reference map, even digital analysis loses explanatory power. The third mechanism is sharing. Process maps function as boundary objects, providing a common language across functions and roles and, in firms, also across production, after-sales, maintenance, and customer interface activities. In this sense, mapping does not simply clarify "who does what," but makes knowledge visible, discussable, and negotiable by highlighting where it is generated, validated, interrupted, or lost. The review by Thiede et al., (2018) is particularly relevant in this regard, as it shows that organizational process mining has mainly been applied in single-system and single-organization contexts, while cross-system, cross-organizational, and service-oriented analyses remain underexplored. This gap is precisely what makes the case of industrial SMEs integrating internal processes and customer services particularly relevant. The fourth mechanism is reuse. When knowledge is codified and traced within processes, it can be retrieved and applied in subsequent contexts, such as anomaly management, training, process redesign, standardization, continuous improvement, and customer-oriented decision-making. Atkočiūnienė et al., (2022) show that KM processes should not be treated separately but integrated into business processes to

maximize value creation. In other words, reuse is not simply the retrieval of information, but the organization's ability to reintegrate validated knowledge into subsequent operational and decision-making cycles

4 Theoretical Gap

The analyzed literature highlights three robust findings. Business Process Management (BPM) and Knowledge Management (KM) are mutually reinforcing: processes structure knowledge, and knowledge, in turn, improves processes (Atkočiūnienė et al., 2022; Bitkowska, 2020; Schiuma et al., 2012b). Moreover, digitalization expands the potential of this relationship by transforming process mapping into a dynamic analysis of real processes (Goel et al., 2024; Lorenz et al., 2021; Wijnhoven et al., 2023). Finally, in servitization contexts, the relevance of process mapping increases because critical knowledge is distributed across production and service activities, customer interactions, and usage data (Castagna et al., 2020; Kohtamäki et al., 2020; Pirola et al., 2020).

However, these streams remain largely disconnected. The literature on BPM and KM rarely addresses the specific context of service-oriented industrial SMEs.

This leads to a clear theoretical gap: there is a lack of an integrated framework that explains how and under which conditions process mapping concretely enables KM outcomes—such as codification, traceability, sharing, and reuse.

5 Analysis

The empirical analysis is based on a cluster of seven industrial SMEs operating in manufacturing sectors characterized by high levels of technical complexity and an increasing orientation towards service-based offerings. The firms are part of a structured research initiative aimed at exploring knowledge management practices and digital transformation trajectories within industrial ecosystems. To ensure confidentiality, all companies have been anonymized. Despite differences in organizational structure and market positioning, they share typical SME characteristics, including limited process formalization, strong reliance on individual expertise, and the adoption of digital tools that are not always fully integrated into organizational practices.

5.1 Data structure and analytical framework

Data were collected through semi-structured interviews and subsequently codified into a structured dataset. Each interview response was mapped onto a set of analytical dimensions derived from the knowledge management literature, including knowledge creation, codification, sharing, use, reuse, process mapping, decision traceability, digital tools, and technology effectiveness. Each dimension was evaluated using a three-point scale, enabling both cross-case comparison and aggregation of results. The dataset was then analyzed using Python-based techniques, including matrix visualization, descriptive statistics, gap analysis, and textual analysis of interview responses, allowing for a combined quantitative and qualitative interpretation of the findings.

5.2 Cross-firm analysis of KM and process dimensions

The matrix visualization, in Figure 1, provides a comprehensive overview of how knowledge management and process-related dimensions are distributed across the analyzed firms. The results reveal a clear heterogeneity in the adoption of process-oriented practices. While some firms exhibit relatively structured approaches to process mapping, others show limited formalization, confirming the uneven diffusion of process-based management within SMEs.

At the same time, dimensions related to knowledge creation and digital tools tend to display consistently higher values across firms. This suggests that organizations can generate knowledge through their operational activities and have access to technological infrastructures that could potentially support knowledge management processes. Hoever, this potential is not systematically translated into structured organizational knowledge. In contrast, dimensions such as reuse, decision traceability, and flow clarity show lower and more fragmented scores. This indicates that knowledge, although generated, is rarely formalized, tracked, or reused across organizational processes. As a result, knowledge remains largely embedded in individual experience and localized practices rather than being incorporated into shared organizational structures. These findings support the idea that, in the absence of explicit process integration, knowledge management remains informal and difficult to scale.

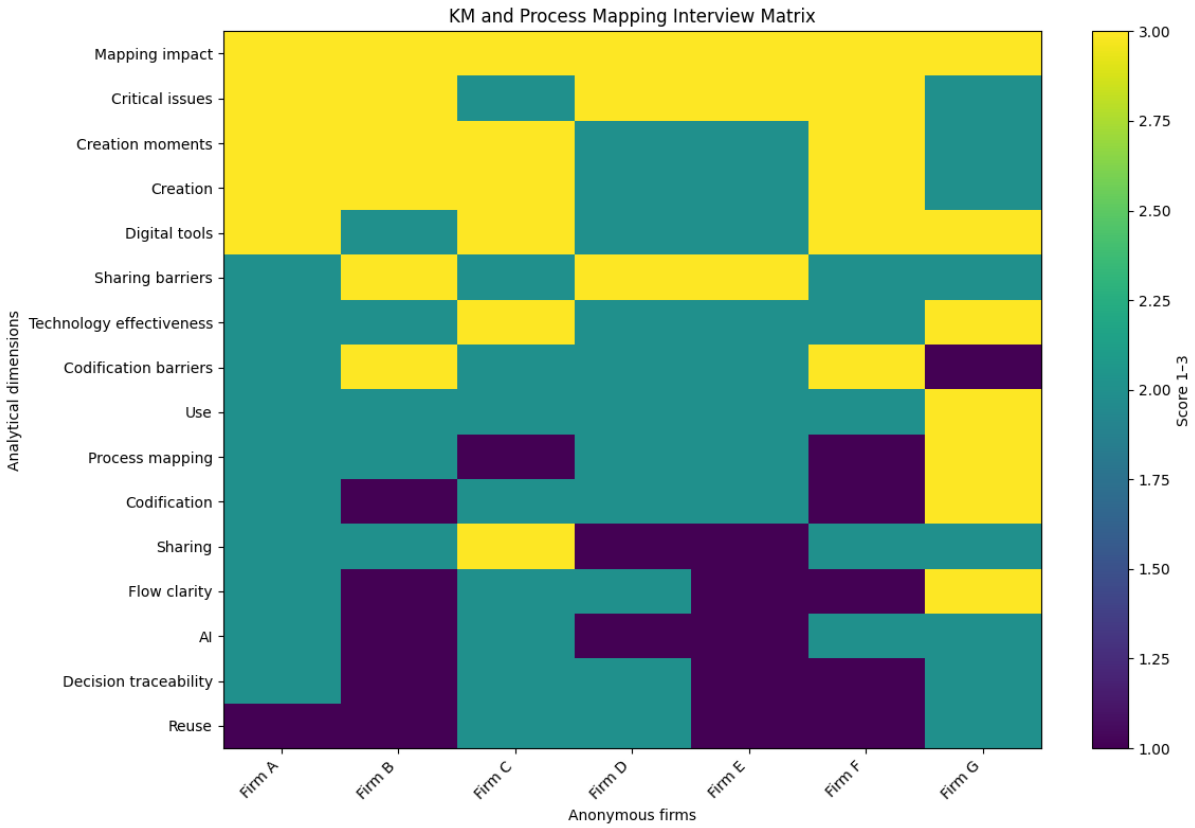

Figure 1 - Heatmap of KM dimensions across firms

5.3 Descriptive analysis of KM dimensions

The analysis of average scores further clarifies the overall maturity of knowledge management practices across the investigated dimensions. Higher values are observed in dimensions such as mapping impact, knowledge creation, and digital tools, suggesting that firms recognize the importance of knowledge and its role in addressing operational challenges. In particular, the high score associated with mapping impact indicates that organizations perceive process mapping as a potentially valuable mechanism for improving knowledge management, even when its practical implementation remains limited.

However, lower scores emerge for dimensions such as reuse, decision traceability, and flow clarity. This highlights a structural limitation in the way knowledge is managed within these organizations. While knowledge is generated and partially supported by digital technologies, it is not effectively embedded into processes that enable systematic reuse and informed decision-making. The relatively moderate score of process mapping itself further reinforces this interpretation, suggesting that although its importance is acknowledged, it is not consistently implemented or integrated with other knowledge management practices.

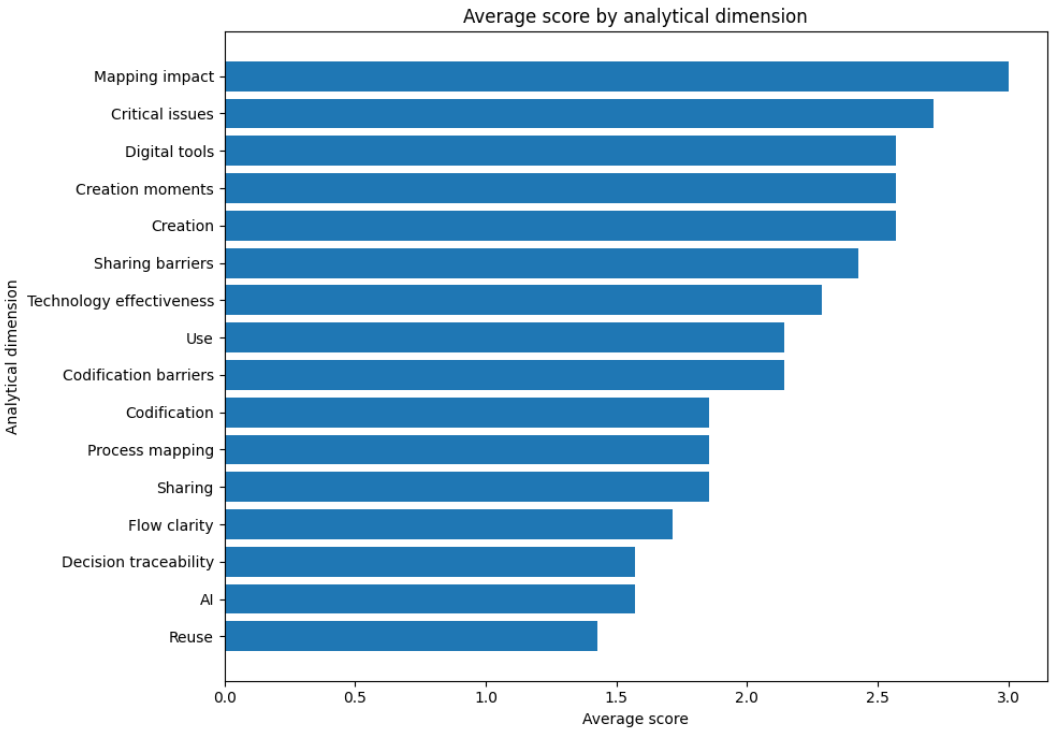

Figure 2 - Average KM maturity across analytical dimensions

5.4 Gap analysis across firms

The gap analysis provides deeper insight into the structural misalignments that characterize knowledge management practices within the analyzed firms. A consistent pattern emerges when comparing knowledge creation with codification. In most cases, the ability to generate knowledge exceeds the capacity to formalize it, indicating that knowledge remains tied to operational experience rather than being translated into structured and reusable organizational assets. A similar misalignment is observed between the presence of digital tools and their effective use. While firms report having technological solutions available, these are not always fully exploited to support knowledge management processes. This confirms that the mere presence of digital infrastructure does not guarantee effective knowledge integration, particularly when it is not embedded within clearly defined processes. Perhaps the most significant gap concerns the relationship between process mapping and knowledge reuse. Even when process mapping practices are present, they do not systematically lead to improved knowledge reuse. This suggests that process mapping, when not explicitly connected to knowledge management objectives, remains a descriptive or operational tool rather than a mechanism for enabling organizational learning.

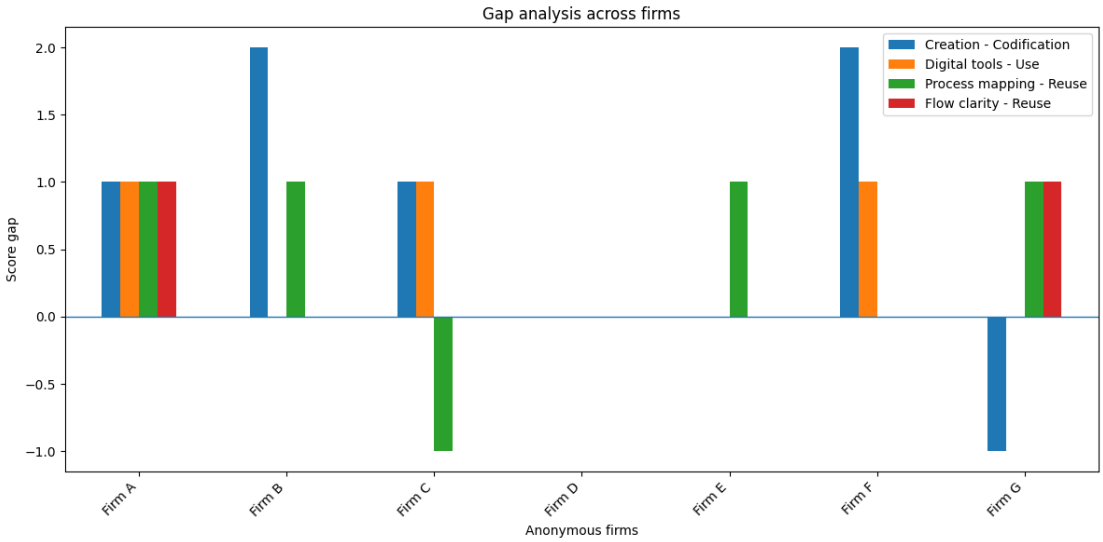

Figure 3 - Cross-firm gap analysis of KM

6 Conclusion

This study set out to investigate how knowledge management practices are enacted within industrial SMEs and to explore the role of process mapping in enabling the codification, sharing, and reuse of organizational knowledge, particularly in service-oriented contexts. By combining a structured literature review with an empirical analysis based on interviews, the paper provides both theoretical and practical insights into the relationship between knowledge and processes. The findings highlight a consistent pattern across the analyzed firms. Knowledge is actively generated through operational activities and supported, at least in part, by digital tools. However, the absence of structured, integrated processes hinders the transformation of this knowledge into reusable organizational assets. Dimensions such as reuse, decision traceability, and flow clarity remain underdeveloped, confirming that knowledge often remains embedded in individual experience rather than being systematically managed.

Process mapping emerges as a critical, yet underutilized, mechanism for addressing this gap. While firms recognize its importance, implementation is often partial and not fully integrated with knowledge management practices. As a result, the potential of process-based approaches to support learning, decision-making, and service delivery remains largely untapped.

From a theoretical perspective, this study contributes to the literature by integrating knowledge management and process-based views, highlighting the central role of processes in making knowledge visible, transferable, and reusable. From a managerial standpoint, the results suggest that investments in digital tools or AI are insufficient without a structured approach to process mapping and knowledge integration.

The study is subject to limitations, primarily related to the qualitative nature of the analysis and the limited number of firms involved. Future research could extend the sample, adopt longitudinal approaches, or further explore the integration between process mapping, digital technologies, and AI in knowledge-intensive and service-oriented contexts.

7 Ethics Declaration

The authors declare that this study did not involve personal sensitive data, or experiments requiring formal ethical approval. The empirical investigation was conducted through voluntary semi-structured interviews with company representatives. All the collected information was anonymized and treated confidentially. The study complies with the ethical standards of academic research.

8 AI Declaration

The authors declare that artificial intelligence (AI) tools were used exclusively to support language revision and text editing during the preparation of this manuscript. All intellectual contributions, interpretations, methodological choices, and final revisions remain the sole responsibility of the authors.

AI-Supported Decision-Making in Medical Device Procurement: From Ad Hoc Criteria to Meta-Criteria and Value Configurations

Mattia Barsanti, Salvatore Tallarico, Luisa Pellegrini, Riccardo Dulmin, Simone Lazzini, Marco Praticò
University of Pisa, Pisa, Italy

Abstract

Medical device (MD) procurement is a strategic area of non-clinical decision-making in healthcare, as purchasing choices affect not only cost containment but also quality of care, patient safety, and long-term health system sustainability. In competitive tenders, however, evaluation criteria are often highly heterogeneous and device specific. This limits the possibility of systematically comparing procurement decisions across tenders and of understanding the evaluative logics that guide final decisions. Within this context, artificial intelligence (AI) may support procurement not by replacing human judgement, but by structuring fragmented information, identifying recurrent value dimensions, and enabling a more reflexive comparison between AI-generated outputs and observed human decisions.

This study investigates how AI can support decision-making in MD procurement. It focuses on tender documents managed by a regional central purchasing body in Italy and develops a research design structured into four phases: tender document analysis and data extraction; recoding specific-criteria into higher-level meta-criteria; construction of AI-based value configurations; and comparison of these configurations with observed procurement decisions. The paper reports the preliminary results of the first two phases.

The paper reports the preliminary results of the first two phases. As regards the first phase, approximately 500 tenders were identified. After excluding non-MD tenders, price-only procedures, incomplete cases, and non-interpretable documents, the final dataset consisted of 172 tender documents. Preliminary analysis identified three recurring document formats and corresponding extraction schemas.

As regards the second phase, the first results show that device-specific evaluation criteria can be recoded into broader meta-criteria, such as versatility of use, patient safety, operator safety, interoperability, and degree of clinical certainty. These meta-criteria provide the analytical basis for comparing tenders involving different types of MDs and for integrating AI appropriately into procurement decision-making. By preserving traceability to the original criteria while enabling broader comparability, they support AI-based procurement governance and may contribute to accountability and organizational learning by supporting a more explicit justification of procurement decisions over time.

Keywords: Artificial Intelligence, MD, tender, public health, meta-criteria

Paper type: Academic Research Paper

1 Introduction and Theoretical Background

Medical device (MD) procurement represents a critical area of non-clinical decision-making in healthcare, with direct implications for cost containment, quality of care, and the long-term sustainability of health systems. Purchasing decisions – particularly those managed by central purchasing bodies through competitive tenders –

play a pivotal role in shaping not only economic efficiency but also the effectiveness and safety of care delivery. In this context, procurement processes are expected to incorporate a plurality of evaluation dimensions, including technical performance, clinical quality, lifecycle costs, maintenance requirements, training needs, and supplier-related characteristics (Hinrichs-Krapels et al., 2022; Miller et al., 2019).

Within this scenario, artificial intelligence (AI) emerges as a potentially transformative yet still underexplored tool. Research from supply chain management and public procurement suggests that AI (e.g., machine learning–based Natural Language Processing (NLP)) can support complex decision-making processes and, under controlled conditions, match or outperform traditional analytical approaches (Long et al., 2023). Specifically, this body of literature highlights the potential of AI to assist across several phases of the procurement process, including supplier evaluation, tender matching, data analytics, and decision support (Balkan & Akyuz, 2025; Siciliani et al., 2023; Allal-Chérif et al., 2020).

Empirical studies have begun to explore these applications in public procurement contexts. For instance, focusing on the data analytics phase, Nai et al. (2023) show that machine learning models can detect anomalous procurement patterns and identify tenders at higher risk of legal disputes. Similarly, in the decision-support phase, Acikalin et al. (2024) develop predictive models based on textual analysis of EU procurement notices,

demonstrating that the linguistic and structural quality of tender documentation can influence outcomes such as participation rates and cost overruns.

In addition, a key potential contribution of AI lies in its ability to reconstruct the implicit evaluative logic that has guided previous choices and hence generate outputs grounded in past decisions (e.g., rankings, scores, or recommendations) that can serve as benchmarks for the new decision Specifically, these AI-generated outputs can support decision-makers to identify to what extent current decisions are consistent with expectations and analyse where divergences between AI-based recommendations and actual human decisions occur. This may prompt reflection on why differences arise – whether due to contextual changes, evolving priorities, or hidden/unintended shifts in evaluative logic, subjective weightings, or inconsistencies in the interpretation of criteria – issues already recognized in procurement and supplier evaluation contexts (Rainy & Chowdhury, 2022; Kufile et al., 2022).

At the same time, AI can contribute to a more foundational challenge: the structuring of procurement information. Tender documents are often heterogeneous, unstructured, and poorly standardized, limiting their usability for systematic analysis. AI – particularly NLP based approaches – can extract, organize, and formalize information from these documents, transforming them into structured knowledge bases suitable for evaluation, comparison, and predictive modelling (Siciliani et al., 2023). This phase is not merely technical but strategic, as it enables more consistent application of evaluation criteria and supports the development of data-driven procurement practices.

Importantly, the adoption of AI also opens opportunities beyond decision support. By making evaluation criteria and decision logics more explicit, AI can help uncover implicit assessment frameworks, provide manufacturers with structured information derived from past tenders on the key evaluation dimensions, and thereby enable them to better align their offerings with evaluation logics, increasing their ability to compete effectively and succeed in future tenders.

Despite these opportunities, the application of AI to MD procurement remains limited and largely experimental (Guida et al., 2023), partly because the highly regulated and multidimensional nature of this context makes the concrete integration of AI more challenging than in other domains due to significant governance and regulatory challenges, including data quality, integration into existing workflows, algorithmic transparency, and accountability (Balkan & Akyuz, 2025; Khan et al., 2024). Robust oversight, continuous monitoring, and clear attribution of responsibility are essential to ensure trust and legitimacy in AI-supported decision-making, particularly in the public healthcare sector (Bosmans et al., 2021; Muehlematter et al., 2021; Angehrn et al., 2020).

In addition, limited attention has been paid to how AI systems can leverage historical tender data to generate predictive outputs meaningfully confronted with human procurement decisions. Rather than replacing human judgment, such comparisons allow identification of possible misalignments and support critical assessment of the robustness of procurement decisions (Siciliani et al., 2023).

To address these issues, this study proposes shifting the focus from *ad hoc* criteria tailored to specific MDs to higher-level evaluative dimensions, referred to as meta-criteria. For instance, meta-criteria abstract from device-specific technical attributes (e.g., balloon catheter size) and capture broader dimensions of value, such as clinical adequacy (e.g., Dimension, weight, and footprint). By abstracting from *ad hoc* criteria to meta-criteria, AI models can capture more stable and comparable evaluative logics across tenders and identify context-specific value configurations expected in terms of meta-criteria. By explicitly engaging with emerging literature on AI-based decision support in public procurement, this study conceptualizes predictive outputs not as substitutes for human judgment, but as reflexive tools that support critical assessment of procurement decisions and their robustness (Cernăzanu-Glăvan & Bulzan, 2025; Zorina & Bikir, 2025). By explicitly identifying where and why a decision diverges from expected value configurations, this approach strengthens accountability in public procurement (Aboelazm & Dganni, 2025; Guida et al., 2023).

The focus is on procurement processes managed by a central purchasing body at the regional level in Italy, a context characterized by variability in tender structures and evaluation practices (Atella & Decarolis, 2019; Borsoi et al., 2017). Within this setting, the study explores not only the comparison between AI-generated outputs and human decisions, but also the preliminary and critical phase of transforming unstructured tender documentation into a structured and analysable knowledge base. By doing so, it aims to assess how AI can enhance comparability, transparency, and consistency in procurement decisions, while also shedding light on the underlying evaluative logics that shape them.

At its current stage, however, the study presents only the initial outputs of this research agenda. These include the systematic analysis of tender documents, their classification, the extraction of evaluation criteria, an initial recoding into higher-level meta-criteria (at this stage only partially defined), and the preliminary

construction of a structured dataset. These phases represent the foundational phase necessary to enable subsequent AI-based modelling and decision-support analyses.

Accordingly, the broader research project is guided by the following research question:

RQ. How can AI support decision-making in MD procurement?

2 Methodology

The research project is structured around four distinct phases

1. Tender documents analysis and data extraction (see section 2.1),
2. Recoding of evaluation criteria into meta-criteria (see section 2.2),
3. Combination of meta-criteria to construct AI-based value configurations,
4. Comparison of these configurations with observed human procurement decisions.

Below, we detail the first two phases, which are currently underway.

2.1 Tender document analysis and data extraction

Tender documents are analysed to identify the evaluation criteria used in the procurement of MDs. The overall objective is to assess both the availability and the structure of the data contained within these documents, and to determine whether the information is suitable for training predictive models, including machine learning and neural network approaches, in line with the objectives of the research. This assessment considers not only the content of the documents – such as the presence of detailed and structured evaluation data – but also their volume, which is a critical factor for the development of reliable AI models. In this way, the analysis provides key insights into the quality, consistency, and adequacy of the dataset, while simultaneously informing the data extraction process.

Data extraction is performed using a generative AI chatbot based on a family of large language models. The accuracy and reliability of the extracted data are ensured through systematic manual validation, carried out by comparing the outputs with the original tender documents.

2.2 Recoding of evaluation criteria into meta-criteria

The meta-criteria were identified using a bottom-up approach. Initially, as the extracted data included not only evaluation criteria but also other features (such as suppliers name, manufacturer nationality, lot IDs, and assessment scores), only the evaluation criteria themselves were selected for further processing. These criteria were then grouped into meta-criteria designed to be applicable across different tenders, enabling greater generalisability. Meta-criteria are conceived as abstract categories that capture recurrent evaluative patterns across different procurement contexts.

To ensure their validity, the identified meta-criteria were compared with established criteria commonly found in recognised frameworks for MD evaluation in the literature (for example, EUnetHTA's Core Model), such as safety, usability, clinical appropriateness, and organisational impact. This comparison was intended to verify whether the meta-criteria were supported by the literature and thus robust for use in this context.

This approach allows the meta-criteria to be both grounded in the empirical data and aligned with established evaluative dimensions, ensuring both relevance to the specific procurement context and broader comparability across tenders.

3 Results

This section presents results by methodological phase.

3.1 Tender document analysis and data extraction

The analysis is based on tender documents retrieved from the official website of ESTAR (Regional Technical and Administrative Support Agency of Tuscany). The choice of this procurement body is particularly relevant due to the high level of centralisation of public procurement in Tuscany, which results in a single, unified online repository where all tender-related documentation is systematically published. This feature enables access to a large volume of documents and ensures data completeness across the entire procurement process, from tender specifications to final award decisions.

At the beginning of the research (January 2026), approximately 500 tenders classified under the furniture category were identified. Since this category includes heterogeneous items (e.g. pharmaceuticals, MD, office

furniture, and supplies), an initial filtering phase was required to isolate only MD-related tenders, reducing the dataset to approximately 250 cases.

The second selection stage consisted of excluding tenders based exclusively on price, as they do not provide multidimensional evaluation criteria. Additional exclusions concerned cases with incomplete evaluation data (e.g. absence of criterion-level scores) and documents whose structure did not allow reliable interpretation or comparison. The final dataset consists of 172 tender documents.

Each tender may include multiple lots, with each lot representing a specific procurement unit associated with a given MD or group of devices. In some cases, tenders include more than 100 lots; considering that multiple suppliers may participate in each lot, a single tender document can generate a large number of observations. As a result, it is possible to derive up to 200 - 300 distinct observations from a single document.

The preliminary analysis indicates that the available documentation appears sufficiently rich to support the development of a structured dataset. At this stage, the available evidence supports the feasibility of proceeding with the data extraction process.

Once the dataset was defined, a preliminary examination of the documents highlighted a significant degree of heterogeneity in structure, terminology, and data presentation formats. This variability represented a critical methodological challenge, as it limited the possibility of directly applying a uniform data extraction approach.

To address this issue, the documents were first classified into structurally homogeneous groups (Figure 1). This phase enabled the identification of recurring patterns in how evaluation data were organised and constituted the basis for a systematic extraction strategy. Three main document structures were identified: (i) documents in which each criterion is presented in a separate table containing the evaluations of all participants; (ii) documents where each participant is associated with an individual table reporting all criteria; and (iii) documents structured as a matrix, where rows correspond to criteria and columns to participants.

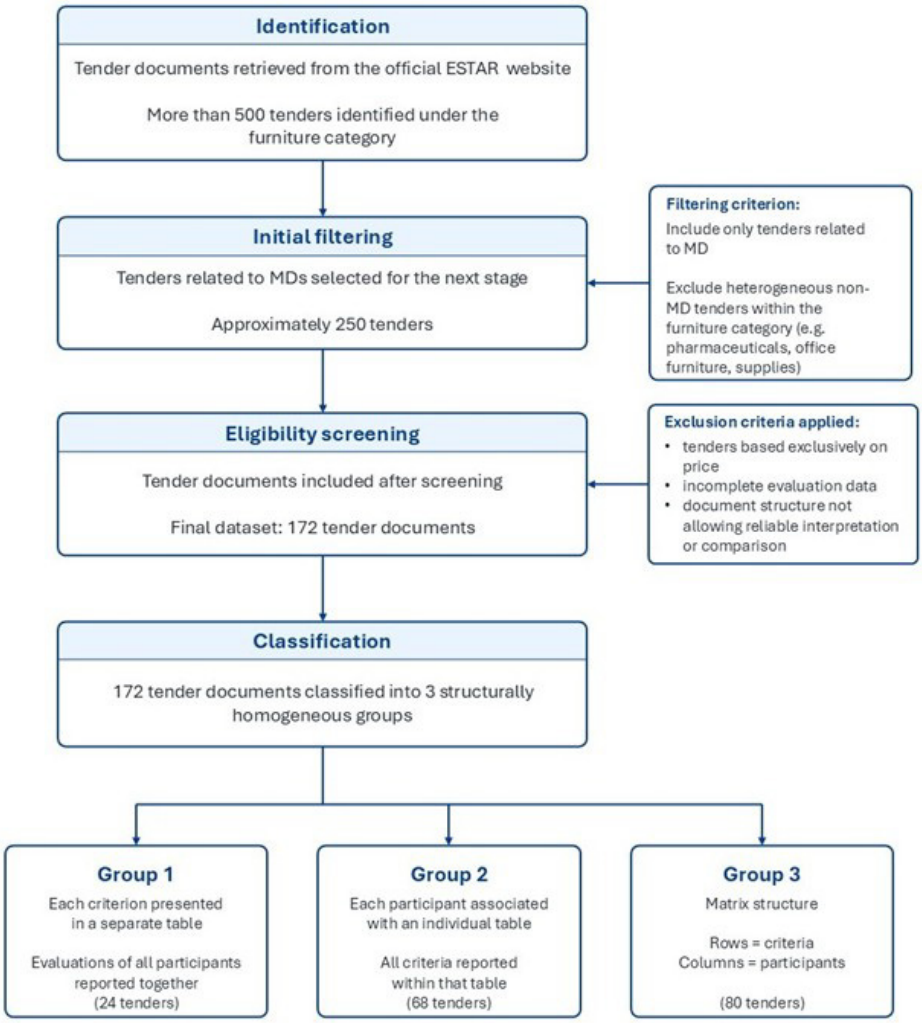

Figure 1: PRISMA diagram of the tender selection process

Based on this classification, tailored extraction schemas were defined for each document group, reflecting the specific organisation of information. The extraction process focused primarily on evaluation criteria, while also capturing complementary variables such as tender identifier, lot number, lot description, product category, participating suppliers, awarded supplier, scores, and final outcomes. This approach allowed the transformation of heterogeneous and partially unstructured documents into a consistent and analysable dataset.

The data extraction process is inherently iterative. Initial extraction is performed following a defined approach, but subsequent analysis of the extracted data may lead to refinements in the extraction strategy, requiring a return to earlier phases and adjustments to the procedure.

The outputs generated through AI-assisted extraction were systematically validated through manual comparison with the original tender documents, ensuring the accuracy and reliability of the collected data.

At the current stage, data have been extracted for a subset of documents corresponding to document structure (i). The same extraction procedure will be progressively adapted and extended to the remaining document groups in subsequent iterations.

3.2 Recoding of evaluation criteria into meta-criteria

Device-specific evaluation criteria were recoded into broader evaluative dimensions, referred to as meta-criteria. This phase addresses one of the main challenges in the analysis of MD procurement, namely the high level of specificity and heterogeneity of tender criteria, which limits comparability across different procurement procedures.

Although individual criteria often refer to highly specific technical or functional attributes, they nonetheless reflect more general evaluative logics. The coding process therefore enabled a shift from highly device-specific attributes to higher-level value dimensions that can be meaningfully compared across tenders.

Thus, meta-criteria were conceived as higher-level analytical categories capable of capturing recurring evaluative logics across different procurement contexts. Importantly, they do not replace the original criteria but provide a layer of abstraction. To preserve the original meaning assigned by the contracting authority, each criterion was retained in its original formulation and linked to its corresponding meta-criterion. This double-coding approach avoids information loss and ensures full traceability between the source document, the specific tender criterion, and the broader evaluative dimension identified during the analysis.

As noted, the research is still ongoing and currently situated in the second phase of the study, which focuses on the recoding of criteria into meta-criteria.

Accordingly, meta-criteria presented in Table 1 should be considered as preliminary results.

Table 1: List of identified meta-criteria

Meta-criterion	Description	Examples of criteria belonging to
Ergonomics, handling, and ease of use	It refers to the extent to which a MD is designed to be intuitive, comfortable, and practical for operators during use. This meta-criterion captures aspects related to physical interaction with the device – such as grip, manoeuvrability, and control – as well as the simplicity and efficiency of performing key tasks (e.g., positioning, insertion, or operation), with the aim of reducing user effort, improving procedural fluidity, and supporting safe and effective use in clinical settings.	· Ergonomics and ease of use of radiofrequency catheters · Ergonomics of the handle · Degree of ergonomics of the grip · Ease of one-handed application · Ease of use of the inflation system and maintenance of the achieved pressure · Ease of inserting the transfer catheter into the guide · Ease of positioning and possible removal · Greater practicality of use, understood as the presence and handling of the applicator
Versatility of use	It refers to the extent to which a MD meet different clinical needs and use scenarios, by offering a wide variety of configurations, sizes, functional options, formats, and compatible uses. This supports clinicians in selecting the most appropriate solution across diverse patients, procedures, and operational contexts.	· Breadth of the range of forceps offered (e.g., shape of the jaws, serration, presence or absence of fenestration) · Breadth of the range of jaw lengths · Breadth of the range of sizes and shapes · Breadth of the range of balloon lengths · Breadth of the range of lengths and diameters · Breadth of the field of view with the assembled kit · Possibility of use during radiotherapy sessions · Possibility of performing procedures at both lumbar and cervical levels

Meta-criterion	Description	Examples of criteria belonging to
Patient safety	It refers to the extent to which a MD minimizes risk associated with its use on patients, encompassing both the procedure itself and the post-procedure phase. It includes risks related to the behaviour of the healthcare operator or the patient (e.g., in the dosing and administration of substances used in combination with the MD) or linked to organizational aspects (e.g., storage methods of the technology, learning curve, operator training	· Safety features · Safety function (patient bypass function that can be activated manually and automatically) · Impermeability (protection from external agents) · Protective sheaths that facilitate passage through the mesh · Safety and perfect sealing of connections welded to the tube
Operator safety	It refers to the extent to which a MD minimizes risks of infection, radiation, etc., to which the healthcare operator is exposed during the MD use.	· Greater safety of closure after use · Availability of safety connectors with a leak-proof valve ("Clave Connector") for the administration of antineoplastic drugs · Safety system: ergonomic and easy to activate (the safety system features a tip protection designed to prevent accidental needle sticks, ensuring operator safety; it activates easily but is slightly bulky)
Interoperability	Ability of the device to connect, integrate, or function properly with other devices, instruments, equipment, accessories, or information systems already present in the clinical setting.	· Ease of connection to the bronchoscope · Ease of attachment to the aspirator · Possibility of direct connection to the ECG monitor without switch systems
Degree of clinical certainty	It refers to the extent to which the MD use is supported by available clinical evidence and scientific documentation. It captures the degree of certainty regarding the expected impact of the technology on patient health, considering the quality, quantity, and relevance of the existing evidence for the specific technology and target population. It may include, for example, the availability of clinical studies, follow-up data, peer-reviewed publications, evidence from comparable devices, and the robustness of the reported clinical outcomes.	· Clinical evaluation: presence of follow-up clinical studies and scientific literature, taking into account the high level of evidence · Literature: presence of clinical studies · Selected PubMed studies related to the offered product · Number of clinical studies published on PubMed related to the offered product · Presence of randomized clinical studies published in journals with an IF ≥ 10, demonstrating the possibility of discontinuing dual antiplatelet therapy after 30 days · Presence of randomized clinical studies on long-term outcomes, with reference to the number of patients enrolled in the studies and the IF of the journals in which they were published
Dimension and weight	It refers to the physical characteristics of a MD in terms of size, weight, volume, and spatial requirements. This meta-criterion captures the extent to which the device's dimensions are compatible with the clinical setting, procedural space, transport, storage, installation, or anatomical constraints.	· System size/footprint · Volume and weight · Anchoring and transport system; size and weight of the equipment · Prosthesis footprint in the aortic root or left ventricle · Balloon catheter size · Electrode size

Meta-criterion	Description	Examples of criteria belonging to
Material properties and biocompatibility	It refers to the MD physical, technical, biological, and construction-related characteristics. This meta-criterion captures the quality and suitability of the materials used, their technical properties, their compatibility with biological tissues, and the accuracy and reliability of the device's construction. It reflects how material composition and manufacturing quality contribute to the device's safety, durability, and suitability for its intended clinical use.	· Biocompatibility: the biocompatibility of the proposed devices will be evaluated · Materials used for the products: quality and technical characteristics of the materials intended to be used · Quality of the material

4 Discussion and Conclusion

This paper reports the empirical findings from phases 1 and 2 of a research project investigating how AI can support decision-making in MD procurement, with particular attention to its role in structuring unstructured tender data, identifying higher-level evaluative dimensions (meta-criteria), and enabling comparisons between AI-generated outputs and human procurement decisions. Specifically, phase 1 focused on the analysis and structuring of tender documents, while phase 2 involved the recoding of device-specific criteria into higher-level meta-criteria. Data extracted from the first documents analysed enabled the identification of an initial set of meta-criteria, including versatility of use, patient safety, operator safety, and interoperability. The development of AI-based value configurations and their systematic comparison with human procurement decisions is left to future work. These preliminary results provide the foundational knowledge base and evaluative dimensions required for subsequent AI-based modelling and decision-support analyses.

Once the overall methodology has been fully implemented, the study may contribute both theoretically and practically. From a theoretical perspective, it may provide insights into how AI can influence decision-making in the healthcare sector (Weissman, 2025; Cresswell et al., 2023), particularly in MD procurement. From a managerial perspective, several contributions can be envisaged. By making explicit the evaluative logics implicitly emerging from past procurement decisions, AI-based value configurations could provide decision-makers with a structured representation of how decisional criteria are combined in practice, beyond those formally stated in tender documents (Siciliani et al., 2023). Moreover, comparing human decisions with these configurations could support the assessment of decision consistency and robustness, highlighting potential misalignments that may warrant managerial attention rather than necessarily indicating suboptimal choices (Guida et al., 2023; Siciliani et al., 2023). Such comparisons

5 Future Directions

As noted, this study is part of ongoing research. At present, the work is positioned within the second phase of the methodology, namely the identification of meta-criteria. However, the first phase is also still in progress, as data extraction has so far been completed for only one of the identified groups of documents. It is reasonable to expect that the extraction of data from the remaining document groups may reveal additional features, potentially leading to a refinement of subsequent outputs – particularly those related to Phase 2 – in order to achieve a more robust and comprehensive definition of meta-criteria.

Once Phase 2 is completed, the research will proceed to Phase 3, in which meta-criteria will be combined to construct AI-based value configurations within specific procurement contexts. Phase 4 will then compare these configurations with observed human procurement decisions, relying primarily on predictive performance metrics and on the systematic analysis of cases in which AI-based recommendations and human decisions diverge. This comparison will make it possible to assess alignment, identify divergences, and support a more reflexive evaluation of procurement decision-making processes.

More specifically, the next stages will not only focus on the comparison between AI-generated outputs and human decisions, but also on the critical phase of transforming unstructured tender documentation into a structured and analysable knowledge base. This process is expected to contribute to improving comparability, transparency, and consistency in procurement decisions, while also providing insights into the underlying evaluative logics that shape them.

6 Ethics declaration

Ethical clearance was not required for this study, as the research was based exclusively on publicly available tender documents.

7 AI Declaration

AI tools were used in two limited and controlled ways within this study. First, AI-based tools were employed for language editing to improve clarity and readability of the manuscript. Second, as described in the methodology, data extraction from tender documents was performed using a generative AI chatbot based on a family of large language models. This process was conducted under strict human supervision, and all extracted data were systematically validated through manual comparison with the original tender documents to ensure accuracy and reliability. No AI system was used for autonomous analysis without human oversight.

Training Project Managers through Games and Simulations: A Literature Review

Teresa Anna Rita Gentile[1], Ernesto De Nito[2]
[1] University of Padova, Padova, Italy
[2] University of Salerno, Italy

Abstract

The present research aims to verify how teaching methodologies based on games and simulations promote the training of soft skills of project managers. Specifically, through a review of the literature, the types of soft skills that project managers can acquire if they follow training courses based on simulations and games are identified.
The methodological approach we have adopted is quantitative and marked by two phases. In the first phase, we identify the topics consistent with the objective of the survey, with the help of the Scopus database, for the period from 1999 to 2024. In the second phase, we analyze, firstly, the content of the articles consistent with reference to teaching methodologies based on games and simulations for the training of project managers and, secondly, we try to identify what types of soft skills they develop.
As regards the main descriptive data of the first phase, two main elements emerge. First of all, with reference to the overall figure of publications found on the subject (n = 298) for each year, it emerges that starting from the period 2015 there is an increasing increase in publications and in 2023 there are as many as n = 66 publications. Secondly, most of the documents found are present in the area of Social Sciences (n=122), Business, Management and Accounting (n=99).
With reference to the second phase, it emerges that many methods based on simulations and business games allow project managers to acquire specific soft skills such as leadership, communication skills, teamwork, to be able to develop the decision-making process and to be able to solve problems.
This article has theoretical implications, as it aims to fill the gap in the current literature on simulations and games to encourage the study of soft skills in project management.
In addition, it has important implications from a practical point of view, as it allows HR managers to plan training courses characterized by simulations and games that include the development of soft and hard skills in an integrated way.

Keywords: Project manager, training, soft skills, games, simulations

Paper type: Academic Research Paper

1 Introduction

Knowledge-intensive organizations (KIOs) are characterized by being places where people possess the skilled skills and experiences necessary to perform complex tasks that require autonomy, judgment, and the ability to solve complex tasks (Makami and Marche, 2016). Furthermore, in these KIOs there is an increasing tendency to work with "project-based" methods because considerable amounts of work are managed that require the presence of the figure of the project manager (Cheng, et al., 2005). As we know, the project manager should possess several skills to be able to lead the group he is responsible for in the successful achievement of the project objectives (Project Management Institute, 2017; Stevenson and Starkweather, 2010). Precisely for this reason, the project manager should be equipped with a combination of skills that include technical but also transversal skills such as: experience, communication skills, adequate training, knowledge of project management methodologies and the functioning of certain business processes, organizational skills, problem solving skills, time management and team management skills and decision-making skills (Pons et al., 2024; Wyskwarski, 2021). At the same time, according to Alvarenga et al. (2020), soft skills such as communication skills, commitment, and leadership would be very important for the success of the project and would be more important than technical skills. Thanks to these soft skills, the project manager would be able to better interact with the other members of the group to achieve the behavior of the latter in accordance with the project objectives (Xue, et al., 2020). According to this approach, it is appreciable not only to recognize soft skills, but also to identify which teaching methodologies are easier to use to train and develop these soft skills in project managers.

In the literature it is discussed whether, in order to consistently train the manager in the diligent execution of the project, it is necessary to opt for training programs implemented in the classroom (Buganza et al. 2013; Siddique et al. 2022) or for those carried out in workplaces where games and simulations are used (Long and Mawdesley, 2010). Many studies have looked at training courses for PMs delivered through gamification. For example, some articles have focused on how game-based techniques allow future PMs to acquire these skills

(Barnabè et al. 2023; Baccarani et al. 2014) or to allow project managers already in service to develop their skills (Abidin and Fathi, 2019). However, the analysis of the main literature shows that the focus on games and simulations for the acquisition of the project manager's soft skills is a little-covered topic (Kearney, et al., 2024).

Precisely for this reason, the aim of this article is to verify, through a review of the literature, whether teaching methodologies based on games and simulations support the acquisition of soft skills by project managers.

The article is divided like this. First of all, the main reference literature is reported, then the paragraph on methodology is exposed, then the main results obtained are shown and discussed and, finally, the conclusions are presented.

2 Main Literature

When we talk about training project managers in soft skills, such as those related to leadership, communication, conflict management and teamwork, the development of critical thinking or the ability to make decisions, we refer to training programs that can take place in the classroom or on the job. In the first case, the focus is on the acquisition of knowledge (Al-Nabae and Sammani, 2019), as students are allowed to learn a lot in theoretical terms, also through self-study, using materials and suggestions provided by the teacher (Johar et al. 2016). In on-the-job learning, on the other hand, there is a tendency to make project managers understand how to correctly carry out certain activities, especially if they are complex projects (Thamhain, 1991), as they are placed in real work situations, through simulations and games (Medina, 2006).

This modality allows project managers to learn quickly and to develop networking and dialogue with other colleagues who are involved in projects (Palotie et al., 2017). In fact, the use of games and simulations can be effective in making a project manager understand how to join a team, create a database or set up a new process to relate to other professional colleagues (de los Ríos Carmenado et al. 2012), acquire both technical and soft skills (Hellström et al., 2023; Seager et al., 2011) and meet specific learning or training needs (de Freitas, 2006).

Specifically, games are teaching methods that allow to re-propose real work situations in which players following a strategy and through collaboration with other players are able to make a decision (Gooding and Zimmerer, 1980; Piraveenan, 2019). In concrete terms, it happens that project managers in training put themselves in the shoes of players, formulate some strategies, then on the basis of the assignment of some values, they are able to collect information, analyze it and make decisions (Potter, 1968) and also have the opportunity to experience the consequences of these choices on the other actors involved (Martin et al. 2014).

In this way, project managers participating in the games can put their theoretical knowledge into practice and refine their soft skills and be able to develop specific skills that are difficult to acquire with traditional teaching methods (Bočková et al. 2015).

Instead, simulation-based teaching methods place aspiring project managers in a situation similar to the one they might encounter in the workplace (Noe et al. 2006), so that they can experience the activities of managing a project (Nascimento et al., 2013) and solve complex situations (Castronovo et al. 2017).

These forms of learning are characterized by the use of special simulators which, also with the help of suitable software (Martin et al. 2014), are able to generate unstructured scenarios and learning environments suitable for guaranteeing useful feedback to solve the problems that project managers may encounter in the work context (Akiyoshi et al. 2012). In concrete terms, project managers are assigned a simulation of a project to be implemented in a group, also through the use of platforms, in which they are asked to solve some problems and achieve the goal of the project through the exploitation of their hard and soft skills (Jaccard and Riboni, 2010).

Through this simulation-based method, the project manager can develop decision-making and critical thinking techniques and can acquire greater teamwork and problem-solving skills (Chernikova et al. 2020).

Yet, the topic of teaching methodologies characterized by simulations and games to make project managers acquire transversal skills is little covered in the literature (Long and Mawdesley, 2010; Kearney et al., 2024).

In light of this, the aim of this research is to verify, through a review of the main literature, whether teaching methodologies based on games and simulations can facilitate the training of soft skills of project managers.

3 Methodology

We used a quantitative methodological approach characterized by two phases.

In the first step, we identified the items through the use of the Scopus database. We used this database over others because Scopus in its research considers many sources, includes open access publications and publications written in languages other than English and also proposes a longer time frame (Valderrama-Zuriàn et al. 2015).

We queried the Scopus database by entering the following search string: ("project manag") AND ("training") OR ("education") AND ("soft skill") OR ("behavioral") AND ("game") AND ("simulation"), indicating as the period 1999-2024. We chose this long time frame for our investigation because there has been an increased use of the Project Manager figure in organizations around the world. We have considered for the research only articles, conference proceedings and book chapters written in English. In addition, we excluded those articles that contained keywords far from the string of our search.

On the basis of the identified articles (n=1,770) we built the Prisma model (Liberati et al., 2009; Kelly et al., 2016) according to the scheme better illustrated in figure 1.

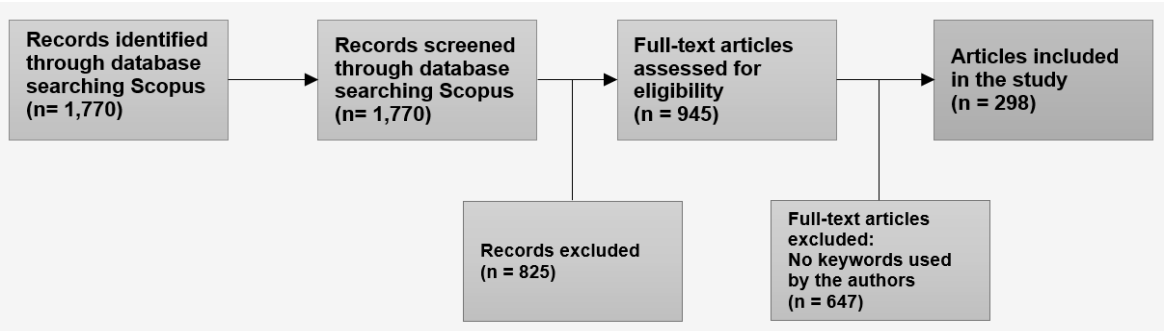

Figure 1: PRISMA flowchart.
Sources: adapted from Liberati et al., 2009; Kelly et al., 2016

In the second phase we studied, within the final sample of the articles found (n=298), the articles dealing with two specific topics: (i) Social Sciences (n=122) and (ii) Economics, Management and Accounting (n=99), as their contents are more consistent with the objectives of the research. We proceeded first with the study of the abstracts identified in these two topics (n=211) to verify their consistency with the research objective. Thus, we have deepened the content of the coherent articles identified within the aforementioned two themes, considering two fundamental aspects. Firstly, we select, from the relevant contributions, those that use methodologies based on games and simulations in the training of project managers and, secondly, we try to identify what types of soft skills they develop.

4 Initial Results and Discussion

With reference to the first phase of the research, from the data collected by the Scopus database and reported in the PRISMA flowchart (figure 1) it emerges that the n=1770 articles found in the aforementioned database became n=1395 because only those written in English were considered, then selecting only articles, conference proceedings and book chapters we arrived at n=945 items. Finally, excluding articles that had keywords other than those indicated in our search string, we identified a total sample of n= 298 documents.

Within this sample, the following descriptive data emerged.

First, Figure 2 shows that the number of articles published in journals (n=220) is higher than those of book chapters (n=58) found and those referring to conference proceedings (n=20).

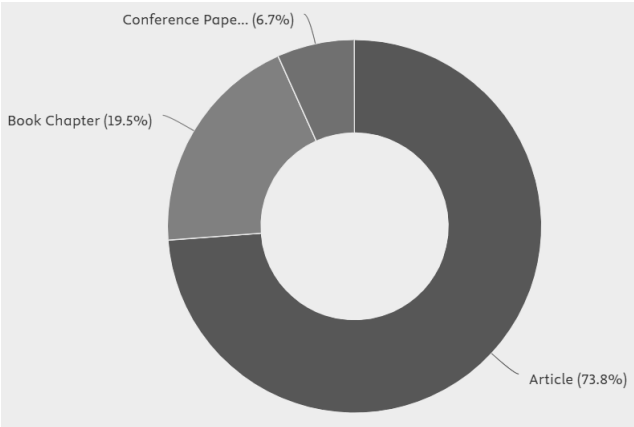

Figure 2: Number of documents found by type 1999-2024.
Source: Scopus Elsevier B.V. (2026)

Furthermore, secondarily, it emerges from figure 3 that most of the documents found are present in the areas of Social Sciences (n=122), Business, Management and Accounting (n=99), Computer Science (n=89) and Engineering (n=70). In the other areas there is a lower number of documents found.

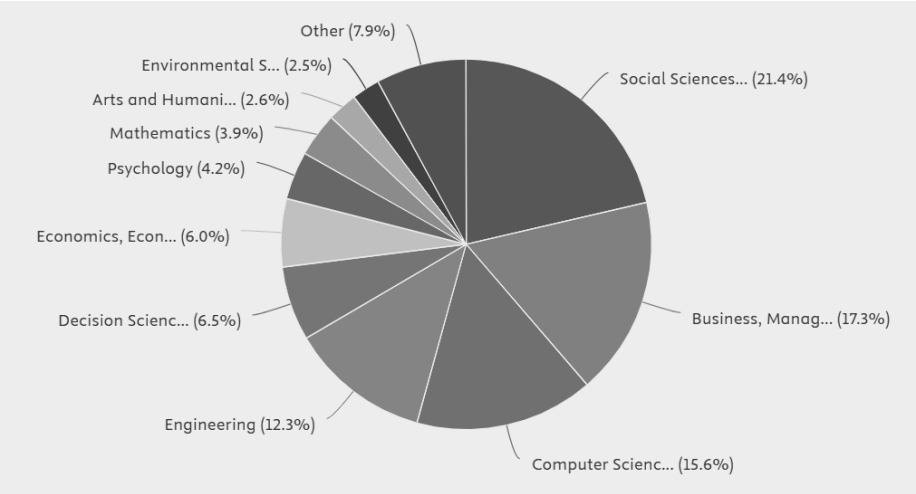

Figure 3: Number of documents by subject area 1999-2024.
Source: Scopus Elsevier B.V. (2026)

Thirdly, with reference to the overall data of publications on the subject for each year in the period 1999-2024 (see figure 4), it can be observed that at the beginning of the period in 2000 there was a feeble attention to the phenomenon (n=5 items) which almost disappeared in the following years until it had a slight decrease in 2010 (n=3 documents). Only starting from 2014 (n=6 articles) and 2015 (n=9 items) is there an increasing increase in publications and, in fact, in 2023 there are as many as n=66 publications.

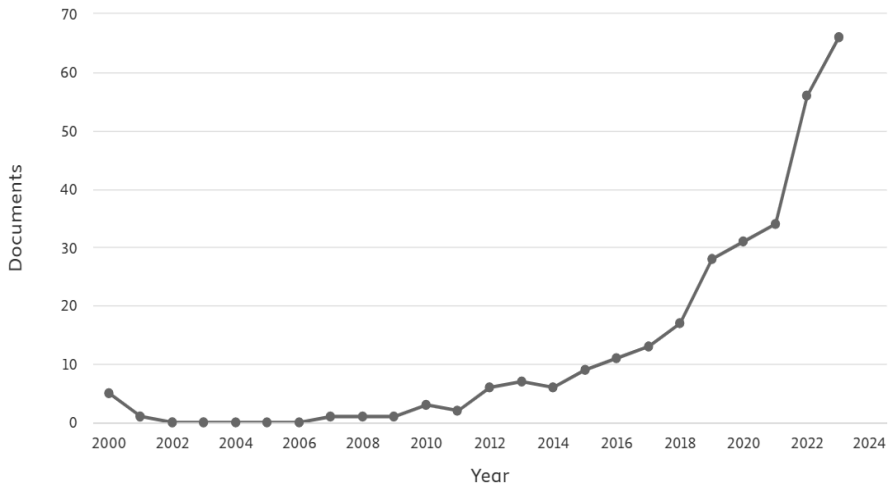

Figure 4: Publications for each year in the research 1999-2024.
Source: Scopus Elsevier B.V. (2026)

As regards the countries of origin of the authors or publishers - in the case of books or conference proceedings - (figure 5) it can be deduced from this analysis that most of the publications collected are related to the United States (n=60), followed by China (n=35) and the United Kingdom (n=27). For Europe we have 10 items that belong equally to Germany and Spain, while only n=8 items belong to France and n=7 items to Italy. These last two data are not present in the aforementioned graph.

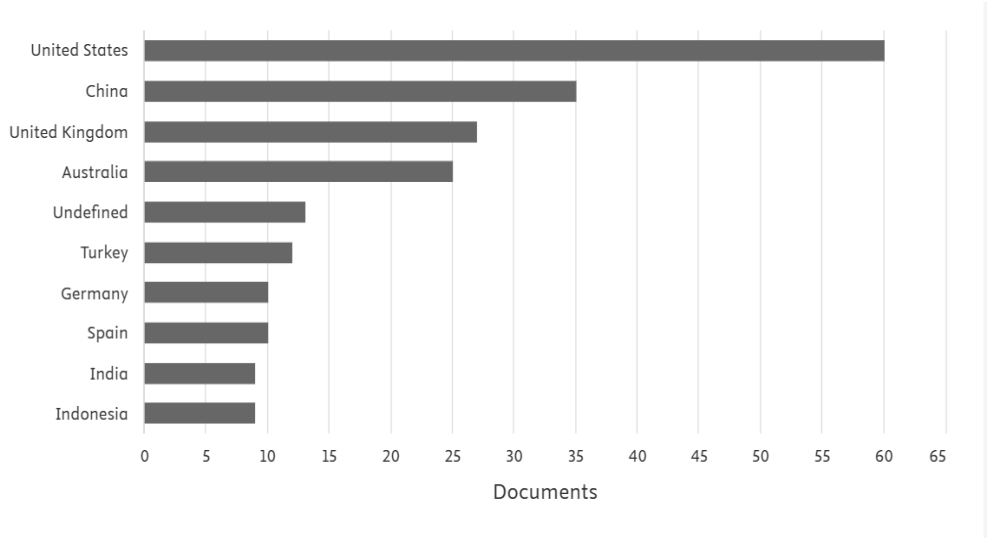

Figure 5: Number of documents by author/publisher membership 1999-2024.
Source: Scopus Elsevier B.V. (2026)

In the second phase of our research, we analyzed the articles (n=221) related to the topics: (i) Social sciences and (ii) Economics, management and accounting which are the most present in the field of the articles found according to figure 3.

We have carried out a meticulous analysis of the abstracts of the above-mentioned articles, from which it emerged that only n=19 articles are consistent with our investigation, as they consider simulations and games as the main methodologies for the training of PMs, as can be seen from table 1 below

Table 1: Number of articles on simulations and business games found.

No.	Author(s)	Year	Title	Game used	Type of soft skill developed

18	Zwikael and Gonen	2007	*Project execution game (PEG): training towards managing unexpected events*	*Simulation game*	*Decision making Problem-solving*

In the light of a brief reading of these 19 articles, the following reflections emerge.

First of all, it would seem to be the possibility of making project managers, especially those who work in certain sectors, acquire soft skills related to problem solving and the ability to make decisions through games and simulations (Akiyoshi et al., 2012; Bonazzi et al., 2013; Castronovo et al., 2017; Gonen and Israeli, 2016; Hamada et al., 2013; Monga et al., 2017; Nascimento et al., 2013; Rumeser and Emsley, 2019; Zwikael and Gonen, 2007). This need arises from the fact that a good PM can be faced with problems of various kinds during the implementation of projects and only if he possesses these "soft skills" can he achieve the goal of the project smoothly (Crawford, 2000).

Secondly, many simulation- and game-based methods allow project managers to acquire soft skills related to leadership and the promotion of critical thinking (Barnabè et al., 2023; Zoroja et al., 2019).

In addition, many games and simulations allow project managers to acquire new techniques to be able to work in a team (Alves, 2022; Habouba-Belinky and Parush, 2020; Geithner and Menzel, 2016; Korman and Johnston, 2010; Sluka, 2019) or to develop and improve communication skills (Jaccard et al., 2022).

Finally, it can be said that training techniques based on games and simulations, through the guaranteed safe environment, offer the possibility for aspiring project managers to gain practical experience, to be able to proceed by trial and error, to work in teams and to take an active role (Fahmi et al., 2021) and to improve the learning and development of project management (Abidin and Fathi, 2019).

5 Conclusions

This article aims to detect, through a review of the literature, how teaching methodologies based on games and simulations are able to support the training of soft skills of project managers.

The main results obtained show that in the period studied, from 1999 to 2024, simulation-based methods and business games allowed aspiring PMs to develop particular soft skills, such as those related to leadership and critical thinking (Zoroja et al., 2019); or those of problem-solving and decision-making (Bonazzi et al., 2013) or, finally, those related to teamwork (Sluka, 2019) or communication (Jaccard et al., 2022).

In any case, we have been able to see that methods based on play and simulations, although they have the advantage of allowing aspiring PMs to proceed in a safe environment, having the possibility of making trials and mistakes, require a lot of time for their conception and for the construction of the phases of the game (Fahmi et al., 2021). In addition, these teaching methods could generate forms of competition with the other members of the group among the different PMs involved in the game, since, due to the identification with the characters to be played in the game, the desire to win instinctively emerges in each of them (Farooq et al., 2022).

This article has theoretical implications, as it aims to fill the gap in the current literature on simulations and games to encourage the study of soft skills in project management. In addition, it could try to link the theme of the project manager's human resources development within the Kolb (1984) learning cycle, trying to re-propose the four phases and identify the new knowledge learned.

In addition, it has important implications from a practical point of view, as it could help HR managers to plan training courses characterized by teaching methods based on the use of simulations and games to develop not only soft skills, but also to think about designing courses for the integrated development of soft and hard skills.

The main limitation of this study is to be linked not only to the fact that it presented data without statistics with specific formulas, but also to the type of database used for the review of the literature. In fact, Scopus, although it enjoys excellent notoriety and reliability, has some critical issues in data generation, as it does not consider resources that have not yet been indexed.

Finally, we decided to consider only publications in English as a survey sample, ignoring other languages, since we assumed that the theme of the project manager was more felt by Western culture.

There is the intention for the near future to implement an empirical analysis involving some PMs, in the construction sector, to understand what types of soft skills need to be increased and to understand whether or not the use of teaching methods based on simulations and games is suitable for achieving this goal.

6 Ethics Declaration

The authors did not use ethical data that required the approval of the relevant committee.

7 AI Declaration

The authors did not use artificial intelligence tools to develop the article's content.

Abstract

Knowledge management (KM) research has long recognised that organisational knowledge extends beyond codified information to include tacit, experiential, and relational forms of knowing. However, contemporary organisations increasingly rely on artificial intelligence (AI) and data-driven systems that privilege abstraction, codification, and optimisation. While these systems enhance efficiency and scalability, they risk marginalising embodied and contextual knowledge that is essential for creativity, innovation, and sustainability. This paper addresses this tension by examining how organisations can develop intelligent knowledge systems while preserving the embodied foundations of human knowing. Drawing on qualitative data from 21 semi-structured interviews with innovation leaders, managers, and artists across ten European organisations, the study investigates how arts-based initiatives (ABIs) generate and mobilise embodied knowledge in organisational contexts. ABIs, defined as structured engagements embedding artistic practices within organisational processes, provide a unique empirical setting to explore knowledge that is experiential, sensory, and difficult to codify. The findings reveal that embodied knowledge constitutes a distinct form of organisational knowledge that operates through experience rather than representation. Its integration into organisational processes depends on relational translation mechanisms, including intermediaries, boundary artefacts, and collaborative practices that bridge artistic and technical domains. At the same time, AI-enabled systems emerge as a structural pressure toward abstraction, privileging codified knowledge and reinforcing optimisation logics. This creates a tension between efficiency-driven knowledge systems and the forms of knowing required for innovation under uncertainty. The paper introduces the concept of embodied knowledge governance, which explains how organisations can recognise, integrate, and sustain experiential knowledge alongside codified and AI-mediated knowledge. This framework highlights the importance of translation, interaction, and organisational conditions that preserve contextual meaning. The findings further show that embodied knowledge plays a critical role in sustainable innovation by enabling long-term, systemic thinking and expanding value perspectives beyond short-term performance. This study contributes to KM, AI, and innovation research by advancing understanding of knowledge plurality in organisations and by highlighting governance as a key mechanism for balancing intelligent systems with human creativity and sustainability.

Keywords: embodied knowledge; arts-based initiatives; knowledge governance; artificial intelligence; sustainable innovation

Paper type: Academic Research Paper

1 Introduction

The increasing integration of artificial intelligence (AI) into organizational processes is fundamentally reshaping how knowledge is created, managed, and applied (Raisch & Krakowski, 2021). Contemporary knowledge management (KM) systems are increasingly oriented toward abstraction, codification, and data-driven decision-making, privileging forms of knowledge that can be captured, stored, and recombined at scale (Nonaka and Takeuchi, 1995; Nonaka and von Krogh, 2009). While these developments enhance efficiency and scalability, they also raise critical concerns regarding the marginalisation of experiential, contextual, and embodied forms of knowing that underpin creativity, interpretation, and long-term innovation. This tension is particularly visible in innovation contexts. Organizations face growing pressure to develop intelligent knowledge systems capable of supporting decision-making under uncertainty, while simultaneously responding to sustainability challenges that require long-term, systemic thinking rather than short-term optimisation. However, dominant approaches to intelligent knowledge remain largely detached from the embodied and relational dimensions of knowledge through which meaning is constructed and shared. As one innovation leader observed, *"You know, how do you convince people of large scale risks? Not through presentations. Through the manifestation of the experience"* (B1). This highlights a fundamental limitation of abstraction-driven knowledge systems: they struggle to capture and communicate forms of knowledge that are experiential, affective, and situated. Despite extensive research on knowledge creation and transfer, existing KM literature has largely

treated embodied knowledge as a residual category of tacit knowledge, rather than as a primary knowledge asset in its own right (Nonaka and von Krogh, 2009). At the same time, emerging research on AI and intelligent knowledge systems has focused predominantly on issues of data, algorithms, and decision support, with limited attention to how these systems interact with human experiential knowing. In parallel, research on arts-based initiatives (ABIs) has demonstrated their potential to stimulate creativity, disrupt dominant cognitive frames, and support innovation capabilities (Schiuma, 2011; Berthinier-Poncet et al., 2025). However, this literature has primarily examined creativity and capability development, leaving open the question of how artistic practices shape knowledge governance in AI-enabled organizational contexts. This creates a significant research gap at the intersection of KM, AI, and innovation studies. While organizations increasingly rely on intelligent systems to manage knowledge, we still lack understanding of how embodied, experiential forms of knowledge are generated, preserved, and governed within such systems. This gap is particularly important in the context of sustainable innovation, where addressing long-term societal and environmental challenges requires integrating diverse forms of knowledge, including those that cannot be easily codified or quantified. To address this gap, this paper examines how arts-based initiatives (ABIs) enable the creation and mobilisation of embodied knowledge, and how such knowledge interacts with emerging AI-driven knowledge systems. ABIs, defined as structured and sustained engagements that embed artistic practices within organizational processes (Schiuma, 2011), provide a unique empirical setting in which experiential, affective, and relational forms of knowledge are foregrounded. By analysing how organizations engage with artistic practices, we are able to explore how embodied knowledge is produced, translated, and governed in practice.

Drawing on qualitative data from 21 interviews with innovation leaders, managers, and artists across multiple industries, the study investigates how organizations navigate the tension between embodied and abstract knowledge. The findings show that artistic practices generate distinct forms of knowledge that are not easily reducible to codified representations, but instead operate through experience, interpretation, and interaction. For example, innovation teams emphasised the importance of engaging directly with experiential artefacts rather than relying on abstract representations, as these artefacts enable shared understanding across disciplines and functions.

Building on these insights, the paper develops a conceptual framework of embodied knowledge governance, which explains how organizations can integrate experiential and AI-mediated forms of knowledge without reducing one to the other. In doing so, the paper contributes to three streams of literature. First, it extends KM research by positioning embodied knowledge as a central organizational asset. Second, it contributes to emerging debates on AI and knowledge governance by conceptualising AI as a mediating force that reshapes, rather than replaces, human knowing. Third, it advances research on sustainable innovation by showing how the governance of knowledge influences organizations' ability to address long-term societal challenges.

2 From Knowledge Management to AI Knowledge Governance and Embodied Knowledge

KM research has traditionally distinguished between explicit and tacit knowledge, emphasising processes through which knowledge can be created, shared, and applied within organisations (Nonaka and Takeuchi, 1995). Subsequent developments in KM theory have extended this perspective by recognising the importance of knowledge conversion, social interaction, and context in shaping knowledge processes (Nonaka and von Krogh, 2009). Despite these advances, dominant KM approaches remain strongly oriented toward codification, standardisation, and systematisation. This orientation reflects the increasing reliance of organisations on formal knowledge systems designed to store, retrieve, and recombine information efficiently. While such systems enable scalability and coordination, they also privilege forms of knowledge that can be abstracted from their context. As a result, experiential, affective, and embodied forms of knowing are often marginalised, even though they play a critical role in creativity, interpretation, and innovation. This tension between abstraction and experience has become more pronounced as organisations adopt digital and data-driven knowledge infrastructures.

The growing integration of artificial intelligence (AI) into organisational processes further reinforces the abstraction of knowledge. AI-enabled systems rely on data aggregation, pattern recognition, and algorithmic recombination, which favour knowledge that can be formalised and encoded (Zuboff, 2019). In this context, knowledge is increasingly treated as a resource to be optimised, raising questions about how meaning, context, and ethical considerations are preserved. Recent research on AI and knowledge governance highlights concerns regarding over-reliance on data-driven decision-making, loss of contextual understanding, and the displacement of human judgment (Verganti et al., 2020). While AI can enhance decision-making capabilities, it also introduces new challenges related to transparency, accountability, and the interpretation of knowledge outputs. In particular, AI systems tend to reproduce and recombine existing knowledge rather than generate fundamentally

new perspectives, which may limit their contribution to radical innovation. However, existing studies have largely focused on technical and managerial aspects of AI implementation, with limited attention to how AI interacts with embodied and experiential forms of knowledge (Jarrahi, 2018). As organisations increasingly rely on intelligent systems, understanding how these systems reshape knowledge processes becomes critical, particularly in contexts requiring creativity, interpretation, and long-term thinking.

In parallel, research on arts-based initiatives (ABIs) has demonstrated the capacity of artistic practices to introduce alternative modes of knowing into organisational contexts. ABIs are defined as structured and sustained engagements that embed artistic processes, practices, or actors within organisations to address managerial and innovation challenges (Schiuma, 2011). Unlike traditional problem-solving approaches, artistic practices operate through ambiguity, experimentation, and sensory engagement, enabling individuals and teams to explore new perspectives and meanings. Empirical studies show that ABIs can disrupt dominant cognitive frames, enhance creativity, and support organisational learning (Berthoin Antal, 2019; Meisiek and Barry, 2018). More recent work has emphasised their role in developing innovation capabilities and facilitating transformation within organisations (Berthinier-Poncet et al., 2025). However, this literature has primarily focused on creativity enhancement and capability development, rather than on the nature of the knowledge produced through artistic practices. Artistic practices generate forms of knowledge that are inherently embodied, relational, and experiential. These forms of knowledge are often communicated through artefacts, performances, or shared experiences rather than through formal representations. As such, they challenge conventional KM approaches and raise questions about how such knowledge can be recognised, integrated, and governed within organisations.

Sustainable innovation introduces an additional layer of complexity to organisational knowledge processes. Unlike conventional innovation, which is often driven by short-term performance and efficiency, sustainable innovation requires long-term orientation, systemic thinking, and the integration of diverse value perspectives (Schaltegger et al., 2016). Addressing sustainability challenges involves dealing with uncertainty, ambiguity, and competing priorities, making it difficult to rely solely on codified or data-driven knowledge. Recent research emphasises that sustainable innovation depends on the ability of organisations to integrate multiple forms of knowledge, including scientific, experiential, and societal knowledge (Boons and Lüdeke-Freund, 2013). This requires moving beyond purely technical or economic perspectives toward more holistic approaches that consider social and environmental implications. In this context, embodied and experiential knowledge becomes particularly important, as it enables actors to interpret complex situations, engage with stakeholders, and explore alternative futures. Despite this recognition, limited attention has been paid to how organisations govern different forms of knowledge in sustainability-oriented innovation processes, particularly in the presence of AI-driven systems.

Bringing these streams together reveals a significant gap in the literature. While KM research has acknowledged the importance of tacit knowledge, it has not fully addressed the role of embodied and experiential knowledge as organisational assets. Research on AI has focused on data-driven knowledge systems but has largely overlooked how such systems interact with non-codifiable forms of knowing. At the same time, studies on ABIs have demonstrated their creative and transformative potential but have not examined their implications for knowledge governance in AI-enabled environments. This paper addresses this gap by examining how embodied knowledge generated through artistic practices is produced, translated, and governed within organisations increasingly shaped by AI-driven knowledge systems. By focusing on the interaction between embodied, digital, and AI-mediated knowledge, the study develops a framework of embodied knowledge governance that explains how organisations can balance efficiency with meaning, and optimisation with sustainability. Figure 1 illustrates the embodied knowledge governance framework.

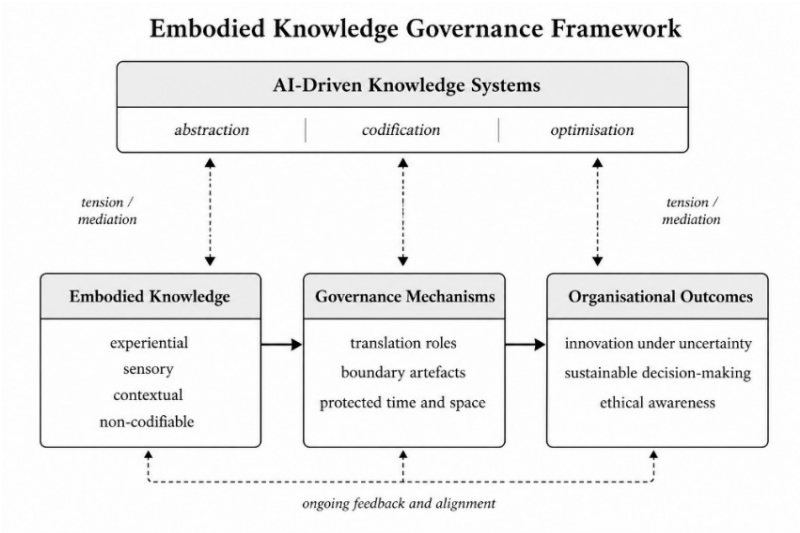

Figure 1: Embodied Knowledge Governance Framework

3 Methodology

This study adopts a qualitative, interpretive research design aimed at exploring how organisations generate, translate, and govern embodied forms of knowledge in the context of arts-based initiatives (ABIs). Given the exploratory nature of the research question and the focus on under-theorised knowledge processes, a qualitative approach is particularly appropriate for capturing rich, context-dependent insights (Gioia et al., 2013). The study builds on an empirical dataset originally developed to examine the role of ABIs in fostering innovation capabilities. While the initial research focused on dynamic capabilities, the richness of the data allows for a secondary, theoretically informed analysis centred on knowledge processes, AI-related tensions, and sustainability. This approach aligns with established practices in qualitative research, where existing datasets are re-analysed to address new research questions (Heaton, 2004). Rather than examining static organisational attributes, the study adopts a process-oriented perspective, focusing on how knowledge is produced, shared, and transformed through interaction, experience, and interpretation. This perspective is particularly relevant in contexts where knowledge cannot be fully codified and where meaning emerges through practice.

The empirical material consists of 21 semi-structured interviews conducted between November 2023 and March 2024 with both organisational actors and artists involved in ABIs (Appendix A). The sample includes: 16 interviews with organisational participants (e.g. innovation managers, R&D leaders, designers, producers, marketing directors), 5 interviews with professional artists collaborating with organisations on innovation initiatives. The organisations represented operate across a range of industries, including consumer electronics, automotive, gaming, telecommunications, consulting, luxury goods, and manufacturing. They vary in size and structure, ranging from SMEs to large multinational corporations, and are located across several European countries. This diversity of contexts enhances the analytical robustness of the study by capturing variation in how ABIs are implemented and experienced. Interviewees were selected using a purposive sampling strategy, focusing on individuals with direct experience of arts-based innovation practices. Snowball sampling was also employed to identify additional participants with relevant expertise. The inclusion of both organisational actors and artists allows for a multi-perspective understanding of how embodied knowledge is generated and interpreted. Interviews lasted between approximately 25 and 80 minutes, were conducted online, and were recorded and transcribed verbatim. The full dataset comprises over 17 hours of recorded material, resulting in more than 200 pages of transcripts. To ensure validity, transcripts were reviewed using a member-checking process, allowing participants to verify and clarify their statements.

Data analysis followed an inductive–deductive approach, combining grounded insights from the empirical material with theoretical concepts from KM, AI governance, and innovation literature (Gioia et al., 2013). The analysis proceeded in three stages: First-order coding (inductive stage): Initial open coding identified key themes emerging from the data, focusing on how interviewees described: experiential and embodied practices, knowledge sharing and communication, interactions between artistic and organisational actors, tensions between exploration and structured processes. At this stage, particular attention was given to how respondents articulated differences between experiential knowledge and formal representations. Second-order coding (theory-informed stage): Codes were then grouped into higher-order themes reflecting recurring patterns across cases. These themes included: embodied knowledge creation, translation and mediation mechanisms,

abstraction and systematisation pressures, sustainability and long-term thinking. Insights from KM and AI literature were used to interpret these patterns, particularly in relation to knowledge codification and governance. Aggregate dimensions (conceptual stage): In the final stage, these themes were synthesised into broader conceptual categories, leading to the development of the embodied knowledge governance framework. This stage involved iterative movement between data and theory to ensure conceptual coherence and theoretical contribution. Throughout the analysis, the research team engaged in iterative comparison and discussion to ensure consistency and reliability of coding decisions, following established qualitative research practices (Gioia et al., 2013).

4 Findings

The analysis reveals that arts-based initiatives (ABIs) generate and mobilise embodied forms of knowledge that interact in complex ways with abstraction-driven organisational systems. Across cases, four interrelated findings emerge concerning the nature of embodied knowledge, its translation within organisations, and its implications for AI-enabled knowledge governance and sustainable innovation.

4.1 Embodied knowledge as experiential and non-representational

The first finding shows that artistic practices generate knowledge that is experiential, situated, and difficult to codify. Rather than being expressed through formal representations such as reports or models, this knowledge is communicated through direct engagement, materialisation, and shared experience. Interviewees consistently emphasised that certain types of understanding cannot be conveyed through abstract representations alone. As one innovation leader explained: "*you know, how do you convince people of large scale risks? Not through presentations. Through the manifestation of the experience*" (B1). This highlights that embodied knowledge operates through experience rather than description, requiring individuals to engage directly with artefacts, prototypes, or situations. Such knowledge is not easily reducible to the forms required by conventional KM systems, which rely on codification and transferability. Similarly, artistic collaborators described their work as rooted in experimentation, intuition, and material engagement: "*my work takes the form of performance projects, where I generally call on materials or skills and hybridise them to come up with new perspectives and proposals…* "(A1). Together, these insights suggest that embodied knowledge is not simply tacit knowledge that has yet to be codified, but rather a distinct mode of knowing that resists abstraction. This challenges dominant KM assumptions that knowledge can always be translated into formal representations.

4.2 Translation as a relational and mediated process

The second finding shows that embodied knowledge does not automatically integrate into organisational processes; it requires active translation across domains. This translation is both relational and organisational. It involves bridging differences in language, logic, and expectations between artistic, technical, and managerial actors. In practice, this role is often performed by intermediaries such as producers or innovation leaders.

As one interviewee noted: "*it's very much a job for producers or production associates… to do this translation work… it's the ability to speak all the languages that means that, at the end of the day, your team will feel understood, whoever they are.* " (B8). Translation is therefore not simply about communication, but about reframing knowledge in ways that make it actionable across domains. At the same time, translation is not unilateral. It depends on the capacity of artists and technical actors to engage with each other's perspectives: *"you absolutely have to let the tech guys… you have to give them the space to understand that vision and amend it and make it evolve… otherwise you end up with… 'no, I can't do it'."* (B8). This highlights that translation is a co-constructed process, where knowledge evolves through interaction rather than being transferred intact. Failure to establish such translation mechanisms often results in the marginalisation of artistic insights.

4.3 AI and abstraction as pressures on embodied knowledge

The third finding concerns the role of AI and system-based knowledge architectures. While AI is not yet fully embedded in these practices, it emerges in the data as a structural pressure toward abstraction, optimisation, and standardisation. Interviewees repeatedly contrasted experiential knowledge with system-based representations, pointing to the limitations of abstraction. This tension becomes more pronounced in contexts where organisations rely on formal systems, roadmaps, and predictive tools. One respondent described how innovation processes are constrained by structured planning systems: "*Most of what designers are here to do is, let's be frank, serve the bottom line and the roadmaps of the next couple of years. And I'm afraid that is incredibly stifling to anything but incremental innovation."* (B1). Similarly, organisations were described as operating within

highly optimised systems that prioritise efficiency over exploration: *"we have optimised systems for 3 to 5 years to do things a certain way… and that actually hurts us at the end of life."* (B1).

These insights align with concerns in AI governance literature regarding over-reliance on data-driven optimisation. The findings suggest that AI-enabled systems intensify existing tendencies toward abstraction, making it more difficult for organisations to recognise and act upon embodied forms of knowledge. At the same time, interviewees implicitly distinguished artistic knowledge from system-based intelligence by emphasising its originality: *"they developed new product concepts… they have been very innovative and driven by art."* (B13). This suggests that embodied knowledge plays a complementary role to AI: rather than replacing human creativity, AI systems amplify the importance of non-recombinative, experiential insight. This interpretation is further supported by broader organisational practices. For instance, companies such as B1,2 and B10,11,12 explicitly frame AI as a tool for efficiency, optimisation, and decision-making at scale, reinforcing abstraction-driven knowledge processes. At the same time, these organisations emphasise responsible AI and sustainability goals, highlighting the need to balance data-driven systems with human-centred and contextual understanding. This pattern is consistent with industry practices, where organisations increasingly deploy AI to optimise processes and support decision-making, while recognising the need to preserve human judgment and contextual understanding.

4.4 Embodied knowledge and the reorientation toward sustainable innovation

The fourth finding connects embodied knowledge to sustainability. Across cases, artistic practices were associated with a shift from short-term optimisation toward long-term, systemic thinking. Interviewees highlighted how current innovation systems prioritise efficiency and output, often at the expense of sustainability: *"we have optimised systems …to do things a certain way…" "there is no way there is absolutely no commitment to solving this until we change the parameters…"* (B1). In contrast, artistic practices were described as enabling reflection on broader implications, including environmental and societal impact. This is particularly evident in discussions of constraints and responsibility: *"once you have to do things differently… creatives respond extremely well to those kind of constraints."* (B1). This suggests that embodied knowledge supports sustainable innovation by enabling holistic understanding of systems, fostering ethical reflection, and encouraging alternative value perspectives beyond efficiency. In this sense, ABIs do not only enhance creativity but also contribute to a reorientation of innovation processes toward sustainability and responsibility.

Taken together, the findings show that embodied knowledge is a distinct and non-codifiable form of organisational knowledge; Its integration depends on relational translation mechanisms; AI and system-based approaches create pressures toward abstraction. Embodied knowledge plays a critical role in enabling sustainable, long-term innovation. Table 2 provides illustrative quotes supporting each key finding.

5 Discussion

5.1 Reframing knowledge: from abstraction to embodied knowledge assets

This study extends knowledge management (KM) theory by reframing embodied knowledge as a first-order organisational asset, rather than a residual category of tacit knowledge. While prior research acknowledges the importance of tacit knowledge (Nonaka and Takeuchi, 1995; Nonaka and von Krogh, 2009), it has largely assumed that such knowledge can ultimately be articulated, codified, or transferred. Our findings challenge this assumption. The empirical evidence shows that artistic practices generate forms of knowledge that are inherently experiential, relational, and non-representational, and therefore resist full abstraction. Rather than being "uncaptured" knowledge, embodied knowledge operates through direct engagement, materialisation, and shared experience. This suggests a need to move beyond the traditional explicit–tacit dichotomy toward a more nuanced understanding of knowledge plurality. In this perspective, embodied knowledge is not simply a precursor to codification but constitutes a distinct epistemic mode, with its own logic of creation, validation, and transmission. Recognising this distinction is critical for organisations seeking to harness creativity and innovation in increasingly complex environments.

5.2 AI and the paradox of intelligent knowledge systems

The findings also contribute to emerging debates on artificial intelligence (AI) and knowledge governance by highlighting a fundamental paradox (Raisch & Krakowski (2021): the more organisations invest in intelligent, data-driven systems, the more they risk marginalising the forms of knowledge required for radical and sustainable innovation. AI-enabled systems rely on abstraction, standardisation, and recombination, privileging

knowledge that can be formalised and processed algorithmically (Zuboff, 2019; Verganti et al., 2020). However, the study shows that innovation—particularly under conditions of uncertainty—depends heavily on embodied, contextual, and experiential knowledge that cannot be easily encoded. Rather than positioning AI as a substitute for human cognition (Jarrahi, 2018), the findings suggest that AI functions as a mediating force that reshapes knowledge hierarchies within organisations. Specifically, AI intensifies the privileging of codified knowledge over experiential knowing, the dominance of optimisation logics over exploratory thinking, and the tension between efficiency and meaning. This leads to a reconfiguration of knowledge governance challenges. The key issue is no longer simply how to manage knowledge, but how to balance different forms of knowing within AI-enabled systems. This paradox is also reflected in organisational practice, where firms simultaneously invest in AI-driven optimisation and promote responsible AI and sustainability agendas.

5.3 Embodied knowledge governance

Building on these insights, the paper introduces the concept of embodied knowledge governance. Embodied knowledge governance refers to the set of organisational practices, structures, and mechanisms through which firms recognise, legitimise, and integrate embodied forms of knowledge, mediate their interaction with codified and AI-driven knowledge systems, and preserve their contextual and experiential integrity over time. Unlike traditional KM approaches, which focus on codification and storage, embodied knowledge governance emphasises translation rather than transfer, experience rather than representation, and interaction rather than extraction.

Table 1: Contrasting Codified and Embodied Knowledge Modalities

Dimension	Codified Knowledge	Embodied Knowledge
Form	Explicit, documented	Experiential, sensory
Transfer	Replicable	Context-dependent
AI compatibility	High	Low
Role in innovation	Incremental	Radical / exploratory
Role in sustainability	Efficiency	Meaning / responsibility

The findings suggest that effective embodied knowledge governance relies on three key mechanisms:

1. Translation mechanisms - Embodied knowledge must be actively translated across domains through intermediaries (e.g. producers, innovation leaders) who bridge artistic, technical, and managerial logics.
2. Boundary artefacts - Experiential artefacts (e.g. prototypes, demonstrations, performances) serve as mediating devices that allow embodied knowledge to be engaged without being reduced to abstract representations.
3. Protected spaces and temporal horizons - Embodied knowledge requires organisational conditions that allow exploration, including longer time horizons and protection from short-term performance pressures.

Together, these mechanisms enable organisations to integrate diverse knowledge forms without collapsing them into a single dominant logic.

5.4 Implications for sustainable innovation

The concept of embodied knowledge governance also provides new insights into sustainable innovation. Sustainable innovation requires organisations to move beyond short-term efficiency toward long-term, systemic value creation (Schaltegger et al., 2016). This, in turn, depends on the ability to integrate multiple forms of knowledge, including those that capture ethical, social, and environmental dimensions. The findings show that embodied knowledge plays a critical role in enabling such integration. By engaging individuals in experiential and relational processes, artistic practices foster reflection on long-term consequences, expand value frameworks beyond economic performance, and support the exploration of alternative futures. At the same time, the dominance of optimisation-driven systems—often reinforced by AI—can undermine these processes by prioritising efficiency and predictability. This creates a tension between intelligent knowledge systems and sustainable innovation objectives. Embodied knowledge governance provides a way to address this tension by ensuring that experiential and ethical considerations are not displaced by data-driven decision-making. In this sense, sustainable innovation is not only a matter of technological development, but also of how knowledge is governed within organisations. In this sense, embodied knowledge does not only counterbalance optimisation-driven systems but also enables proactive engagement with sustainability challenges by supporting reflexivity, ethical deliberation, and long-term orientation.

6 Conclusions

This paper examined how organisations can develop intelligent knowledge systems while preserving the embodied foundations of human creativity and judgment. Addressing a critical gap at the intersection of knowledge management, artificial intelligence, and sustainable innovation, the study explored how arts-based initiatives (ABIs) generate, translate, and govern embodied forms of knowledge within organisational contexts. Drawing on qualitative evidence from 21 interviews with managers and artists, the findings demonstrate that embodied knowledge constitutes a distinct and essential mode of knowing that cannot be fully captured by abstraction-driven systems. While organisations increasingly rely on AI-enabled knowledge infrastructures, these systems tend to privilege codified, optimised, and recombinable knowledge, thereby marginalising experiential and contextual understanding. The study shows that this creates a fundamental tension between intelligent knowledge systems and the forms of knowing required for innovation under uncertainty and sustainability challenges. To address this tension, the paper introduced the concept of embodied knowledge governance, which explains how organisations can recognise, integrate, and sustain experiential knowledge alongside codified and AI-mediated knowledge. This framework highlights the importance of translation mechanisms, boundary artefacts, and organisational conditions that enable embodied knowledge to remain actionable without being reduced to abstraction.

The study contributes to three streams of literature. First, it extends KM research by positioning embodied knowledge as a primary organisational asset, rather than a residual form of tacit knowledge. Second, it advances emerging debates on AI and knowledge governance by conceptualising AI as a mediating force that reshapes knowledge hierarchies, rather than replacing human knowing. Third, it contributes to sustainable innovation research by demonstrating that knowledge governance is a critical enabler of long-term, responsible innovation, particularly in contexts characterised by uncertainty, complexity, and competing value systems.

For practitioners, the findings suggest that organisations should move beyond a sole focus on codification and optimisation when designing knowledge systems. Instead, they should recognise the strategic value of experiential and embodied knowledge, invest in roles and structures that support cross-domain translation, create organisational conditions that allow exploration and interpretation over time, and ensure that AI-enabled systems are used in ways that augment rather than replace human judgment. In particular, organisations aiming to pursue sustainable innovation must ensure that their knowledge systems are capable of integrating ethical, contextual, and experiential considerations, rather than relying exclusively on data-driven optimisation.

This study is subject to several limitations. While it provides rich qualitative insights, it does not examine the operational deployment of AI systems directly; rather, AI emerges as an interpretive and governance concern within the data. Future research could extend these findings through longitudinal or ethnographic studies of organisations actively integrating AI into knowledge management and innovation processes. Such research would be particularly valuable in examining how embodied knowledge is transformed, preserved, or displaced over time.

7 Ethics Declaration

This study is based on qualitative interviews conducted with organisational participants and professional artists. All participants provided informed consent. Data were anonymised to ensure confidentiality.

8 AI Declaration

AI tools were used to support the structuring and editing this manuscript. All content generated was critically reviewed and revised by the authors. The final responsibility for the content and its accuracy remains with the authors.

Abstract

This study identifies and empirically validates a microfoundational mechanism based on the Intelligent Knowledge Management Model (MIGC) to explain how knowledge systems mediated by artificial intelligence (AI) enable the twin transition in artisanal production contexts. Although the literature has extensively analyzed the relationship between digitalization and sustainability, a critical gap persists in the understanding of the microfoundational processes through which these transformations emerge in environments of low technological intensity and strong cultural roots.

Through a combined approach of design science and participatory action research, an intervention in a rural ceramics system in Guanajuato, Mexico, is implemented and evaluated. The model integrates AI, energy monitoring and artisanal knowledge within an architecture aimed at the recombination of knowledge and the development of organizational capacities. The data were collected over 12 months through energy audits, production records and qualitative fieldwork.

The results show a 19.6% reduction in energy intensity and a 14.2% reduction in production defects, along with improvements in process stability, traceability and decision-making. Beyond these results, the study identifies a recursive microfoundational mechanism in which AI does not act as an automation tool, but as a cognitive infrastructure that facilitates the recombination of tacit and explicit knowledge, activating the reconfiguration of organizational capacities and generating sustainable results.

This finding allows us to reconceptualize the twin transition as a socio-cognitive process based on the articulation of knowledge, rather than as a direct consequence of technological adoption. Likewise, the study demonstrates that dynamics of innovation ecosystems can emerge at microterritorial scales and that their effectiveness depends on the interaction between technology, agency and knowledge structures.

Overall, the results establish that sustainability in contexts of low technological intensity does not depend on intensive automation, but on the design of knowledge architectures that integrate artificial intelligence, local knowledge and organizational agency, opening new lines of research on the scalability of these processes.

Keywords: Artificial intelligence; Knowledge recombination; Knowledge management; Twin transition; Microfoundations; Artisanal production; Sustainable production; Innovation ecosystems

Paper type: Academic Research Paper

1 Introduction

The climate crisis and accelerated digitalisation are shaping a double structural transformation of contemporary economies. However, the distribution of digital and energy skills is profoundly unequal. While industrial ecosystems are moving towards decarbonization supported by smart technologies, rural production systems, particularly artisanal ones, remain lagging behind in terms of digital infrastructure, energy autonomy and access to technological innovation (Aklilu et al., 2025; Zhang et al., 2024). Recent literature has conceptualized this process as a "twin transition", understood as the coordinated integration between digital transformation and environmental sustainability (Ben Youssef, 2025). However, empirical evidence has predominantly concentrated on large organizations, smart cities, and high-tech manufacturing sectors, leaving unexplored how this transition can be operationalized in peripheral economies based on tacit knowledge and community organizational structures, as well as in regional green innovation ecosystems (Zhang et al., 2024). This limitation reveals a relevant theoretical tension: although the twin transition is often framed as a process driven by technological adoption, the underlying mechanisms that enable its outcomes remain insufficiently explained, particularly at the microfoundational level (Breiter et al., 2024). Consequently, little is known about how knowledge systems allow transformation processes to be activated in traditional productive contexts with limited resources.

In parallel, innovation ecosystem theory has evolved towards approaches that emphasize knowledge flows, dynamic capacities, territorial governance, and multilevel relationships between public, private, and territorial actors (Costa & Moreira, 2022; Ferreira et al., 2023; West & Olk, 2024; Shin et al., 2023).However, these perspectives maintain a macrostructural emphasis and do not explain how, at the micro level, processes of reconfiguration of capacities are activated when technologies such as artificial intelligence are introduced in artisanal production contexts. In this context, the central problem of this study is the absence of microfoundational explanations on how knowledge systems mediated by artificial intelligence reconfigure capacities in artisanal production environments. In particular, key questions persist, such as the following: how are energy capacities reconfigured, how are tacit and scientific knowledge recombined? And how is cultural identity preserved by avoiding processes of substitutive automation? Based on this, this study addresses the following research question: How can knowledge systems mediated by artificial intelligence enable the twin transition in rural artisanal productive ecosystems? Based on the above, the present work makes three main contributions:

First, it identifies a microfoundational mechanism that explains how artificial intelligence enables the reconfiguration of capacities at the micro level in artisanal production systems.

Second, it reconceptualizes the twin transition as a process of knowledge recombination, rather than as a direct result of technological adoption.

Third, it incorporates technological agency as a key explanatory dimension, showing that the appropriation and meaningful use of digital tools constitutes a structural condition for sustainable transformation.

2. Theoretical Framework

2.1 Knowledge ecosystems and micro-foundations

Innovation ecosystems are conceptualized as interdependent configurations of actors that co-create value through the exchange and recombination of knowledge (Öberg & Alexander, 2019; Thomas & Ritala, 2025). Likewise, these ecosystems include institutional relationships, public policies and territorial dynamics that influence innovative performance (Costa & Moreira, 2022; Shin et al., 2023). More recently, the approach has incorporated the notion of microfoundations, recognizing that dynamic capacities are activated through specific cognitive and organizational processes (Breiter et al., 2024). In rural contexts, knowledge functions as a territorial common good, deeply incorporated into productive practices and social relations. Dynamic capabilities (sensing, harnessing and reconfiguring) allow structures to be adapted to environmental pressures. However, in artisanal systems these capacities are not formalized; they depend on tacit knowledge and accumulated experience.

2.2 Twin transition in traditional production systems

Digital transformation is aimed at optimizing processes through computer technologies. The twin transition involves a socio-technical reconfiguration that integrates digitalization and environmental sustainability in a structural way (Ben Youssef, 2025). In traditional systems, tensions emerge:

- risk of cultural homogenization.
- external technological dependence.
- displacement of local knowledge.

Therefore, the twin transition requires contextualized mediation rather than simple technological incorporation (Zhang et al., 2024).

2.3 AI as a cognitive mediator

AI can be understood as augmented intelligence infrastructure. Instead of automating, it amplifies human capacity for analysis and decision-making. To this end, two mechanisms are central:

- Digital twins: energy and process simulation.
- Knowledge recombination: structured integration of heterogeneous knowledge (Marino & Quatraro, 2023; Nan, 2024).

In artisanal environments, AI facilitates correlations between material intuitions and technical data, activating processes of reconfiguration of capabilities.

2.4 Women's technology agency

The theory of self-determination states that autonomy, competence and belonging sustain intrinsic motivation (Vansteenkiste et al., 2006; Abós et al., 2019). In rural communities led by women, technology can strengthen cohesion and resilience if it is integrated in a participatory manner (see Figure 1).

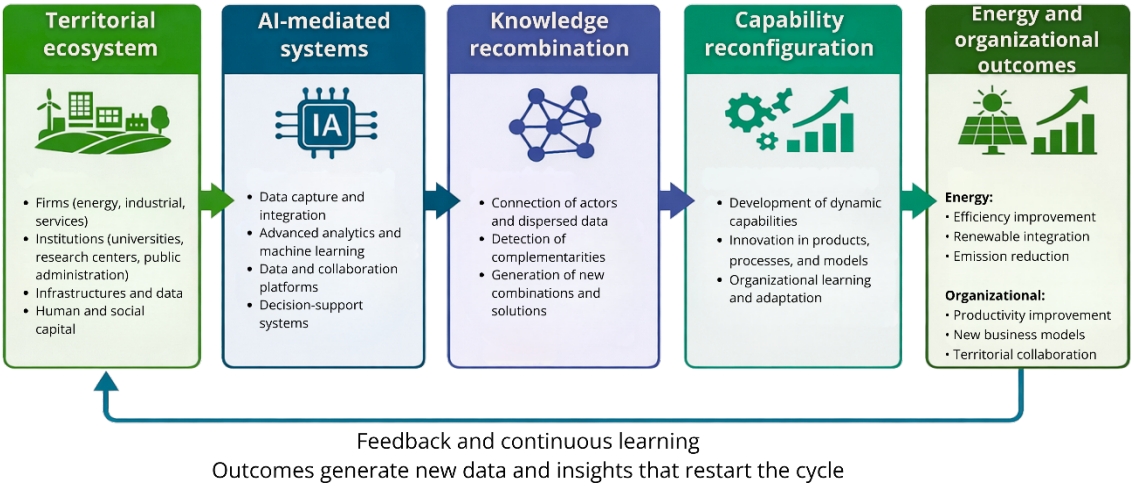

Figure 1. Microfoundational mechanism of AI-mediated twin transition

3 Methodology

3.1 Research design

The study adopts the Design Science Research (DSR) approach to the design, implementation and evaluation of an organizational artifact: the Intelligent Knowledge Management Model (MIGC). This approach is relevant when the goal is to solve a complex practical problem by building and iteratively validating a theoretically grounded artifact. The process followed the classic phases of DSR:

- identification of the problem,
- definition of artifact objectives,
- design and development,
- demonstration in real context,
- empirical evaluation,
- Communication of results.

In order to strengthen the contextual validity and organizational appropriation of the model, the design was integrated with a participatory action research approach, allowing co-creation processes with productive actors and iterative adjustment cycles based on continuous feedback. Beyond its practical orientation, DSR allows for the identification of generative mechanisms, making it suitable for microfoundational theorizing (Breiter et al., 2024).

3.2 Case selection

A women-led artisanal ceramics company in Dolores Hidalgo, Guanajuato, Mexico, was selected through purposive sampling. The choice responded to theoretical-analytical criteria:

- High energy intensity in cooking processes.
- Dependence on traditional ovens with high thermal inefficiency.
- Predominance of intergenerational tacit knowledge.
- Limited prior digitalization.
- Explicit willingness to participate in experimental processes.

The case constitutes a critical environment to analyze the twin transition (digital and energy) in traditional production systems (Ben Youssef, 2025; Zhang et al., 2024).

3.3 Data collection

The intervention lasted 12 months, combining quantitative and qualitative methods to ensure triangulation and analytical robustness. To this end, the following data were collected:

- Systematic energy audits (kWh per production batch).
- Longitudinal measurement of defect rate (%).
- Structured digital recording of process parameters.
- 18 semi-structured interviews with owners and operators.
- Participant observation during complete production cycles.
- Documentary analysis of routines and historical records.

Quantitative data were analyzed by pre-post-intervention comparison, while qualitative data were thematically coded to identify microfundamentals of capacity reconfiguration as shown in Table 1 below.

Table 1: Five-phase intervention model.

Phase	Objective	Dynamic Capability On	Indicators
Diagnosis	Establish energy and organizational baseline	Sensing	kWh/lot; defect rate
Recombination	Experimental redesign of cooking parameters	Utilization	% reduction in defects
AI Mediation	Implementation of data-driven decisional support	Reconfiguration	Digital logs; Assisted decisions
Solar integration	Incorporation of photovoltaic energy into the process	Reconfiguration	% solar energy used
Institutionalization	Formalization of routines and protocols	Stabilization	Documented protocols; Internal Adoption

4 Results

4.1 Reconfiguration of energy capacities

This section presents the empirical results derived from the intervention, without theoretical interpretation. The quantitative results show a significant reconfiguration of energy and operational capacities after the implementation of the Intelligent Knowledge Management Model. Energy intensity was reduced by 19.6%, thermal variability by 17%, and the proportion of defective batches by 14.2% compared to baseline. Additionally, a decrease in the dispersion of the cooking cycles was observed, as well as greater stability in the thermal parameters recorded during the production process. This stabilization allowed to reduce critical deviations and improved consistency between batches.

Table 2: Comparative pre- and post-intervention indicators.

Indicator	Baseline	Pilot	Variation
Energy intensity	100%	80.4%	−19.6%
Defective batches	100%	85.8%	−14.2%
Thermal variability	100%	83%	−17%

Together, the results show simultaneous improvements in energy efficiency, product quality, and process control.

4.2 Hybridization and recombination of knowledge

A systematic process of integration between artisanal knowledge and digitized technical parameters was observed. During the intervention, the participants began to use data records to complement their decisions based on experience and the implementation of digital tools made it possible to correlate variables with specific productive results such as:

- Temperature.
- Cooking time.
- Energy consumption.

This correlation facilitated the identification of previously unformalized patterns, consistent with recent approaches that explain how knowledge recombination increases innovation capacities when heterogeneous cognitive domains are integrated (Marino & Quatraro, 2023; Nan, 2024; Wang et al., 2023). Likewise, a progressive transition from decisions based exclusively on intuition to decisions based on data was recorded,

keeping practical experience as a central reference. This process gave rise to a hybrid workspace where tacit knowledge and explicit knowledge were used in a complementary way.

4.3 Augmented decision architecture

The incorporation of energy dashboards modified the dynamics of decision-making within the organization. The performance indicators were integrated into weekly productive meetings, structuring discussions around shared metrics, where it was observed:

- Increased frequency of adjustments in production parameters.
- Reduction of uncertainty associated with cooking processes.
- systematic documentation of decisions.
- Greater operational traceability.

In addition, the available information made it possible to anticipate deviations and make preventive, rather than corrective, adjustments. This change was reflected in greater coordination among the participants and in better planning of production cycles. These findings dialogue with the notion of dynamic capacities and knowledge ecosystems (Breiter et al., 2024; Ferreira et al., 2023).

4.4 Technology Agency

The qualitative analysis shows an increase in the perception of autonomy and technical competence among the participants (Abós et al., 2019). The interviews show that the direct use of digital tools allowed the operators to:

- Interpret data independently.
- Actively participate in decision-making.
- Engage in controlled experimentation.

Likewise, a strengthening of collective decision-making was observed. In addition, the weekly meetings incorporated indicators as a central element of discussion, facilitating agreements based on shared information.

Table 3: Qualitative evidence of reconfiguration and agency.

Dimension	Evidence	Interpretation
Autonomy	Independent use of dashboards	Technological appropriation
Competition	Experimenting with metrics	Active learning
Collective decision	Meetings with shared indicators	Internal coordination

Overall, the qualitative results indicate a greater appropriation of digital tools, as well as an evolution in the dynamics of interaction and decision-making within the production system.

5 Discussion

This study challenges the dominant assumption that digital transformation automatically precedes sustainability outcomes. The findings show that, in artisanal production contexts, sustainability does not emerge from technological adoption per se, but from internal processes of knowledge recombination mediated by artificial intelligence (Marino & Quatraro, 2023; Nan, 2024). In this sense, the twin transition is configured as a socio-cognitive process rather than as an exclusively technological phenomenon.

Unlike approaches focused on digital investment or infrastructure deployment, the results show that transformation is activated when AI is integrated into organizational routines as a cognitive mediator, enabling new ways of interpreting, articulating and using existing knowledge.

5.1 From digital infrastructure to cognitive mediation

The literature on twin transition has tended to conceptualize digitalization as an exogenous enabler of sustainability, mainly at macro levels (Aklilu et al., 2025; Ben Youssef, 2025). This study challenges that premise by demonstrating that the transformative impact of AI depends on its internalization into concrete organizational practices. Instead of operating as an automation tool, AI functioned as cognitive infrastructure, reconfiguring the way the organization processes information and makes decisions. This finding shifts the focus from technological adoption to cognitive integration, suggesting that digitalization only generates value when it modifies the internal logics of action. In this sense, the results broaden the focus on dynamic capabilities by showing that the transition to more advanced stages does not depend solely on the accumulation of digital

resources, but on the ability to incorporate them into recurrent adaptive processes (Breiter et al., 2024). Empirical evidence indicates that the key is not to "have data", but to use it systematically in decision-making. Likewise, the study qualifies the literature on digital ecosystems by showing that technology does not replace pre-existing knowledge structures, but rather reconfigures them (Costa & Moreira, 2022; Ferreira et al., 2023; Liu et al., 2025).

In this context, it is important to highlight that AI acted as a translation mechanism that made it possible to articulate tacit and explicit knowledge, reducing cognitive friction and enabling new combinations.

5.2 The microfoundational mechanism

The main contribution of the study lies in the identification of a microfoundational mechanism that explains how AI translates into sustainable outcomes. Unlike linear models, the findings suggest a recursive process in which technology and knowledge co-evolve. AI does not generate direct impact; Its effect is produced through the recombination of heterogeneous knowledge. This recombination activates organizational reconfiguration processes, which in turn generate improvements in energy and production performance.

Sustainability, therefore, is not an immediate result of digitalization, but an emerging consequence of changes in organizational capabilities. This finding extends the literature on knowledge recombination by demonstrating that value does not lie only in the accumulation of knowledge, but in its ability to articulate different domains and complementary cognitive structures (Nan, 2024; Wang et al., 2023). In addition, AI plays a central role in reducing the cognitive distance between tacit knowledge and formal metrics, facilitating more controlled experimentation processes (Marino & Quatraro, 2023). From the perspective of innovation ecosystems, the case shows that dynamics of co-creation, exchange and articulation of knowledge are not exclusive to macro environments, but can emerge in small and territorially situated configurations (Costa & Moreira, 2022; Shin et al., 2023; Thomas & Ritala, 2025; West & Olk, 2024). This suggests that ecosystems should not be understood only as external structures, but also as internal processes of cognitive coordination.

5.3 Motivation and agency as catalysts

A distinctive contribution of the study is the incorporation of the motivational dimension as part of the twin transition process. The results show that the transformation not only implied technical changes, but also a reconfiguration in the perception of autonomy and competence. Evidence suggests that technological appropriation strengthened participants' agency, consistent with self-determination theory postulates about autonomy, competence, and intrinsic motivation (Vansteenkiste et al., 2006; Abós et al., 2019). This finding contrasts with views that associate digitalization with labor substitution, showing instead its potential as an empowerment mechanism. In this context, knowledge recombination was accompanied by motivational recombination.

The integration of digital tools not only expanded technical capabilities, but also reinforced confidence in decision-making. This indicates that the effectiveness of the twin transition depends on the alignment between technological infrastructure and human agency, but also as internal processes of cognitive coordination.

5.4 Border conditions

The results allow us to identify conditions that delimit the scope of the proposed mechanism. First, organizational cohesion facilitated the integration of data into collective decision-making processes. The existence of trust and internal communication allowed digital information to be translated into coordinated action.

Second, participatory governance was key to the appropriation of the tools. The incorporation of indicators in deliberative spaces made it possible to transform data into concrete decisions.

Third, technological appropriation was a determining factor.

Evidence suggests that, without internalization by users, AI would have remained an external resource with no significant impact.

These conditions indicate that the mechanism identified is not automatic or universal, but contingent on specific organizational configurations.

5.5 Theoretical implications

The results allow us to identify conditions that delimit the scope of the proposed mechanism. First, organizational cohesion facilitated the integration of data into collective decision-making processes. The

existence of trust and internal communication allowed digital information to be translated into coordinated action.

Second, participatory governance was key to the appropriation of the tools.

The incorporation of indicators in deliberative spaces made it possible to transform data into concrete decisions.

Third, technological appropriation was a determining factor.

Evidence suggests that, without internalization by users, AI would have remained an external resource with no significant impact.

These conditions indicate that the mechanism identified is neither automatic nor universal, but contingent on specific organizational configurations (see Figure 2).

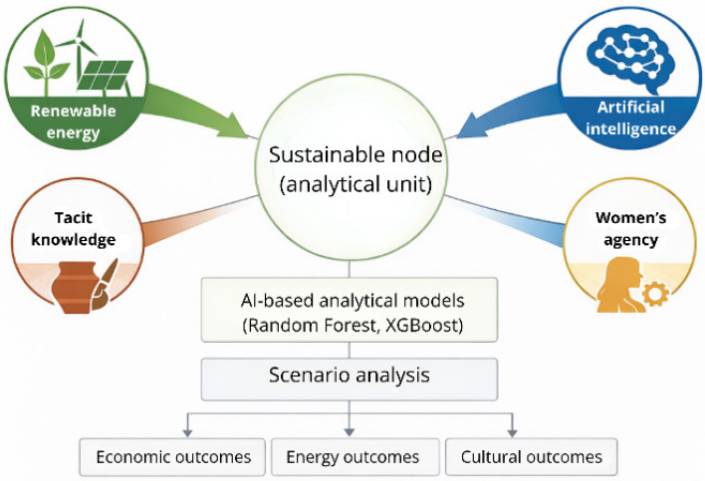

Figure 2. Smart node for micro-territorial sustainability.

Taken together, these findings suggest that the twin transition should be theorized not as a technology-driven transformation, but as a microfoundational knowledge-mediated process in which artificial intelligence functions as a cognitive infrastructure that enables the recursive reconfiguration of capabilities.

6 Implications

This study allows us to derive relevant implications at the organizational, systemic and conceptual levels. At the organizational level, the implementation of AI in artisanal environments is viable when an incremental and participatory approach is adopted. The impact does not depend on technological sophistication, but on the ability to integrate AI into productive routines and decision-making processes.

At the systemic level, small-scale productive units can operate as innovation microecosystems, consistent with recent approaches to regional and territorial ecosystems and public innovation policies (Costa & Moreira, 2022; Ferreira et al., 2023; Shin et al., 2023; Zhang et al., 2024). The progressive integration of digital tools facilitates the articulation between tacit knowledge and structured data. In intervention design, effectiveness depends on the technological appropriation by the actors. Finally, the scalability of the twin transition depends on:

- AI integration.
- Recombination of knowledge.
- Organizational agency.

7 Limitations

This study has limitations that should be considered. First, it is a unique case study in the pilot phase. Second, the timing of the study is limited, making it impossible to evaluate long-term effects. Third, although agency strengthening and technological appropriation were documented, these dimensions were mainly addressed through qualitative evidence.

Further studies could incorporate psychometric instruments to measure:

- Autonomy.
- Jurisdiction.

· Motivation.

Likewise, the proposed mechanism may be sensitive to specific contextual conditions.

8 Conclusions

This study demonstrates that the twin transition is not a direct result of technological adoption, but a micro-foundational process of a socio-cognitive nature mediated by knowledge systems. Empirical evidence shows that artificial intelligence does not generate sustainable impact directly, but acts as a cognitive infrastructure that enables the recombination of knowledge and the reconfiguration of capabilities (Liu et al., 2025; Nan, 2024). The main contribution lies in the identification of a recursive mechanism through which the integration between tacit and explicit knowledge activates dynamics of organizational reconfiguration (Marino & Quatraro, 2023; Nan, 2024). Likewise, the study demonstrates that processes typical of innovation ecosystems can emerge at microterritorial scales (Thomas & Ritala, 2025; West & Olk, 2024). In this framework, the twin transition is redefined as an emerging, contingent and potentially scalable process.

Abstract

The dual transition, understood as the convergence of digital transformation and environmental sustainability, has emerged as a central strategic paradigm for territorial development and innovation policy. However, existing scholarship has predominantly focused on urban, industrial, and technologically mature environments, leaving rural and artisanal production systems underexplored. This gap is theoretically significant because conventional innovation ecosystem frameworks insufficiently explain how innovation emerges in contexts where tacit, culturally embedded knowledge constitutes the dominant productive resource. To address this limitation, this study introduces the concept of Intelligent Knowledge Ecosystems (IKEs), defined as socio-technical and territorially embedded configurations in which collective intelligence, knowledge recombination, and accessible digital-environmental capabilities interact to generate adaptive, inclusive, and sustainable innovation processes. Unlike conventional innovation ecosystems, which frequently emphasize formal institutional arrangements and market-oriented value creation, IKEs position tacit community knowledge as a strategic innovation asset and conceptualize technology as an enabler of collective learning rather than as an exogenous driver of transformation. Methodologically, the research adopts a participatory action research design implemented over a 12-month intervention in an artisan ceramic production community in Dolores Hidalgo, Guanajuato, Mexico. The study involved 48 participants, including artisans, university students, researchers, and institutional actors. Data were collected through semi-structured interviews, co-creation workshops, and field observations, and analyzed using thematic coding and process tracing to identify causal mechanisms underpinning ecosystem emergence and innovation dynamics. The findings indicate that innovation in this context does not emerge through isolated technological adoption, but through structured processes of knowledge recombination between traditional artisanal expertise and contemporary digital and sustainability-oriented tools. These interactions improved productive efficiency, supported more sustainable production practices, strengthened local capabilities, and reinforced cultural identity. The study contributes in three principal ways. First, it advances innovation ecosystem theory by proposing the IKE construct as a more inclusive and context-sensitive framework. Second, it provides empirical evidence from a traditionally underrepresented setting. Third, it offers a transferable model for integrating universities, communities, and accessible technologies in support of territorially grounded dual transition strategies.

Keywords: Dual transition, innovation ecosystems, knowledge recombination, intelligent knowledge ecosystems (IKEs), collective intelligence, participatory action research

Paper type: Academic Research Paper

1 Introduction

The dual transition, referring to the convergence between digital transformation and environmental sustainability, has become a defining strategic framework in contemporary economic and territorial development policy (Kovacic et al., 2024; Quirico & Baber, 2024). This paradigm reflects the growing recognition that digital technologies and sustainability objectives should not be addressed as separate domains, but as interconnected drivers of systemic transformation. In this context, digital technologies are increasingly positioned not merely as instruments of automation, but as enablers of new production models characterized by greater adaptability, resource efficiency, and environmental responsiveness (Chen et al., 2023; Ying & Jin, 2024).

At the territorial level, the dual transition requires a reconceptualization of innovation processes beyond conventional industrial and urban ecosystems. Contemporary scholarship increasingly acknowledges the importance of collaborative structures involving firms, institutions, governments, and civil society in generating innovation capacity (Oliveira & Rua, 2025; Pattinson et al., 2023). However, these frameworks remain strongly biased toward formal, technologically advanced, and market-driven environments, thereby marginalizing contexts where innovation emerges through informal, tacit, and culturally embedded practices. This omission is particularly problematic in artisan communities, where production systems are deeply rooted in inherited

knowledge, empirical experimentation, and collective cultural memory. Such contexts represent complex socio-technical environments in which tacit knowledge is not peripheral, but foundational to productive activity and local resilience (Yang, 2024). Despite their relevance, these systems have historically remained peripheral within innovation ecosystem literature, limiting theoretical understanding of how digital and sustainability transitions may unfold in such environments (Heaton & Min, 2025). At the same time, recent scholarship has emphasized knowledge recombination as a central mechanism of innovation, highlighting how the integration of previously distinct knowledge domains can generate novel solutions and adaptive capabilities (Xiao et al., 2022; Yu & Yu, 2024). Yet, existing research has largely examined recombination in formal R&D-intensive settings, leaving important questions unanswered regarding how such mechanisms operate in low-technology, territorially embedded production systems.

This theoretical gap is compounded by conceptual ambiguity regarding the role of technology in innovation ecosystems. In dominant perspectives, technology frequently appears as an exogenous catalyst that accelerates transformation through efficiency gains or infrastructural modernization. However, this framing underestimates the extent to which innovation may emerge through socially mediated learning processes, collective experimentation, and contextual adaptation rather than through technological sophistication alone.

To address these limitations, this study proposes the concept of Intelligent Knowledge Ecosystems (IKEs) as a theoretical framework capable of explaining innovation dynamics in territorially embedded, culturally grounded, and resource-constrained environments. Rather than conceptualizing innovation as a product of formal institutional architecture alone, IKEs emphasize the interaction between collective intelligence, knowledge recombination, and accessible technological mediation. Empirically, the study examines a participatory intervention conducted in an artisan ceramic production community in Guanajuato, Mexico, where university actors, artisans, and institutional stakeholders collaboratively engaged in sustainability-oriented innovation processes. This case offers a relevant setting to analyze how dual transition mechanisms can emerge in contexts typically excluded from mainstream innovation ecosystem discourse. The research addresses the following question: How do Intelligent Knowledge Ecosystems enable dual transition processes in rural artisan production systems? This study makes three primary contributions.

First, it introduces and theoretically defines the concept of Intelligent Knowledge Ecosystems as an extension of innovation ecosystem theory.

Second, it empirically demonstrates how knowledge recombination and collective learning operate as mechanisms through which innovation emerges in culturally embedded production contexts.

Third, it provides a practical and transferable framework for linking higher education institutions, local communities, and sustainability-oriented technologies in support of inclusive territorial development.

2 Theoretical Framework

2.1 Innovation ecosystems and the limits of dominant perspectives

Innovation ecosystems are commonly understood as dynamic networks of interdependent actors that collaboratively create value through the exchange of knowledge, resources, and capabilities (Oliveira et al., 2025; Pattinson et al., 2023). These ecosystems are generally characterized by distributed innovation processes, open collaboration, institutional interdependence, and adaptive governance structures that facilitate collective value creation beyond traditional firm-centered models. Public policy has also been increasingly recognized as a significant driver of ecosystem performance, particularly where institutional arrangements and innovation governance influence knowledge exchange and collaborative competitiveness (Costa & Moreira, 2022). Within this literature, knowledge recombination has emerged as a particularly important mechanism for innovation generation, referring to the integration of existing knowledge components into novel configurations capable of producing adaptive and competitive outcomes (Xiao et al., 2022; Luo, 2022). Diverse actor configurations are frequently associated with enhanced innovation capacity because heterogeneous knowledge domains create conditions for experimentation, iterative learning, and organizational adaptation (Yu et al., 2024).

However, despite their explanatory value, dominant ecosystem perspectives remain limited in at least two important respects. First, they disproportionately privilege urban-industrial contexts characterized by formal institutional arrangements, advanced infrastructure, and technologically mature innovation systems. Second, they tend to conceptualize knowledge primarily in codified or organizational terms, underrepresenting tacit, experiential, and culturally embedded forms of knowledge that are central in traditional productive communities.

These limitations are especially relevant in artisan production systems, where innovation frequently emerges through informal experimentation, collective adaptation, and intergenerational knowledge transmission rather

than through conventional R&D structures. As a consequence, mainstream ecosystem theory remains insufficiently equipped to explain how innovation emerges in territorially embedded contexts where cultural knowledge functions not merely as heritage, but as an active, productive resource.

2.2 Dual transition and contextual sustainability

The dual transition framework conceptualizes digital transformation and environmental sustainability as mutually reinforcing pathways for contemporary economic and territorial development (Kovacic et al., 2024; Quirico & Baber, 2024; Døblen, 2023). This perspective reflects the increasing recognition that sustainable transformation cannot be pursued independently of technological adaptation, nor can digital modernization be considered neutral in environmental terms. Instead, digital technologies are increasingly positioned as strategic enablers of eco-innovation, environmental monitoring, process optimization, and sustainable organizational transformation (Chen et al., 2023; El Samad, 2024; Indiran et al., 2025; Tsouri, 2022). Nevertheless, the implementation of dual transition trajectories remains highly uneven across territorial contexts. While technologically mature industrial environments may rapidly integrate advanced digital infrastructures, rural and culturally embedded production systems often face structural constraints, including limited technological access, reduced institutional support, fragmented innovation capabilities, and dependency on traditional production practices.

This unevenness suggests that dual transition should not be interpreted as a universal technological diffusion pathway. Rather, it must be understood as a context-sensitive socio-technical transformation process in which sustainability outcomes depend on how external technologies are adapted to local cultural, productive, and institutional realities. In artisan communities, this contextual dimension becomes particularly important because productive sustainability is deeply intertwined with inherited tacit knowledge, localized experimentation, and socio-cultural identity. Therefore, dual transition in such settings cannot be reduced to technological modernization alone; it requires adaptive mechanisms capable of integrating digital tools with culturally embedded productive intelligence.

2.3 Knowledge recombination and collective intelligence

Knowledge recombination provides a critical explanatory mechanism for understanding innovation in heterogeneous and territorially embedded environments. Rather than conceptualizing innovation as the production of entirely new knowledge, recombination theory emphasizes the strategic reconfiguration of existing knowledge domains into novel combinations capable of generating adaptive solutions and innovation outcomes (Xiao et al., 2022; Luo, 2022). In artisan production contexts, this process acquires distinctive characteristics because innovation does not primarily emerge through formal scientific research or structured technological development, but through interactions between tacit artisanal expertise, practical experimentation, academic mediation, and external technical knowledge. The integration of these domains creates hybrid innovation pathways that differ significantly from conventional firm-based innovation models.

Recent scholarship has also emphasized that the structure and dynamics of knowledge networks significantly influence innovation performance, particularly where heterogeneous relationships facilitate distributed creativity and adaptive recombination (Yu et al., 2024). In this sense, innovation depends not only on the existence of diverse knowledge resources but also on the capacity of actor networks to articulate, interpret, and transform them collaboratively. This perspective aligns with broader notions of collective intelligence, where distributed actors jointly generate problem-solving capacity through interaction, shared interpretation, experimentation, and contextual adaptation (Yang, 2024). Innovation in territorially embedded systems should therefore be understood not as an isolated invention, but as an emergent socio-cognitive process arising from collective knowledge interaction (see Figure 1).

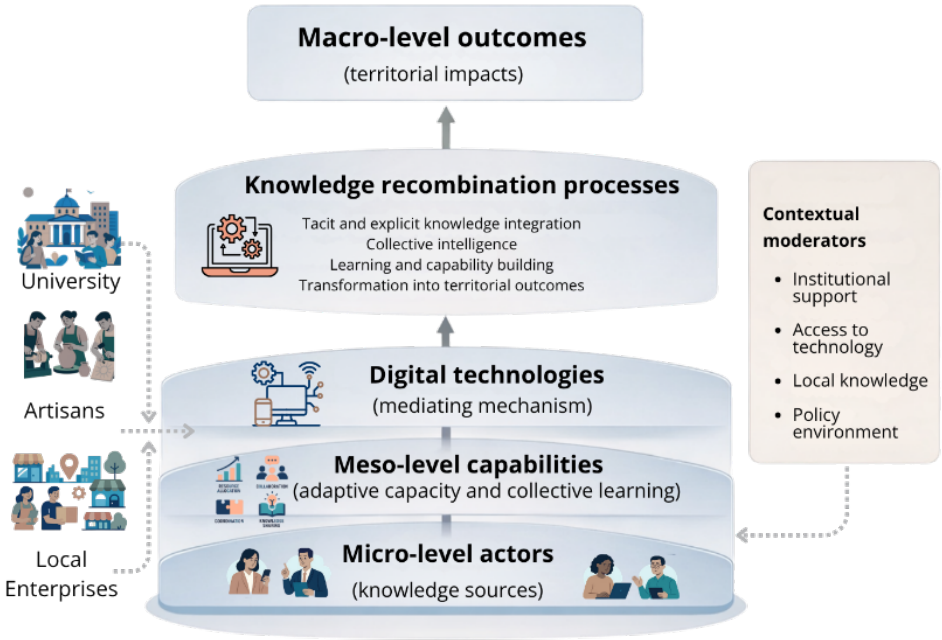

Figure 1. Conceptual model of Intelligent Knowledge Ecosystems that integrates actors, processes, technologies and results. Source: Authors.

2.4 Intelligent Knowledge Ecosystems (IKEs)

In response to these theoretical limitations, this study proposes Intelligent Knowledge Ecosystems (IKEs) as a novel conceptual framework. IKEs are defined as:

territorially embedded socio-technical systems in which collective intelligence, knowledge recombination, and accessible digital-environmental capabilities interact to enable adaptive, inclusive, and sustainable innovation.

As illustrated in Figure 1, the IKE framework integrates four core dimensions:

- Actors.
- knowledge processes.
- enabling technologies.
- innovation outcomes.

Unlike traditional innovation ecosystems, which emphasize institutional structure and economic exchange, IKEs explicitly incorporate tacit community knowledge, cultural identity, and contextual adaptation. Technology within IKEs is not conceptualized as an external determinant of change, but as an enabler of collective learning, experimentation, and knowledge articulation. Similarly, unlike knowledge networks focused on information circulation, IKEs emphasize transformation through recombination and contextual application. This conceptual distinction positions IKEs as an analytically distinct construct designed to explain innovation dynamics in underrepresented territorial contexts.

3. Methodology

3.1 Research design

This study adopts a Participatory Action Research (PAR) design, selected because of its suitability for contexts where knowledge generation is inseparable from intervention, collaboration, and social transformation. Unlike conventional observational methodologies, PAR enables researchers to actively engage with participants in iterative cycles of diagnosis, experimentation, implementation, and reflection, thereby making it particularly appropriate for analyzing emergent innovation dynamics in territorially embedded socio-technical systems. The methodological rationale also responds directly to the conceptual foundations of Intelligent Knowledge Ecosystems (IKEs). Because the proposed framework emphasizes collective intelligence, knowledge recombination, and contextual adaptation, a passive observational design would be insufficient to capture the mechanisms through which innovation emerges. Instead, PAR enables the activation and observation of knowledge interactions in real time.

As illustrated in Figure 2, the methodological design followed a cyclical structure in which intervention and analysis evolved simultaneously. This design allowed the research not only to document outcomes but also to trace the causal mechanisms through which ecosystem dynamics emerged. The intervention unfolded across four iterative phases.

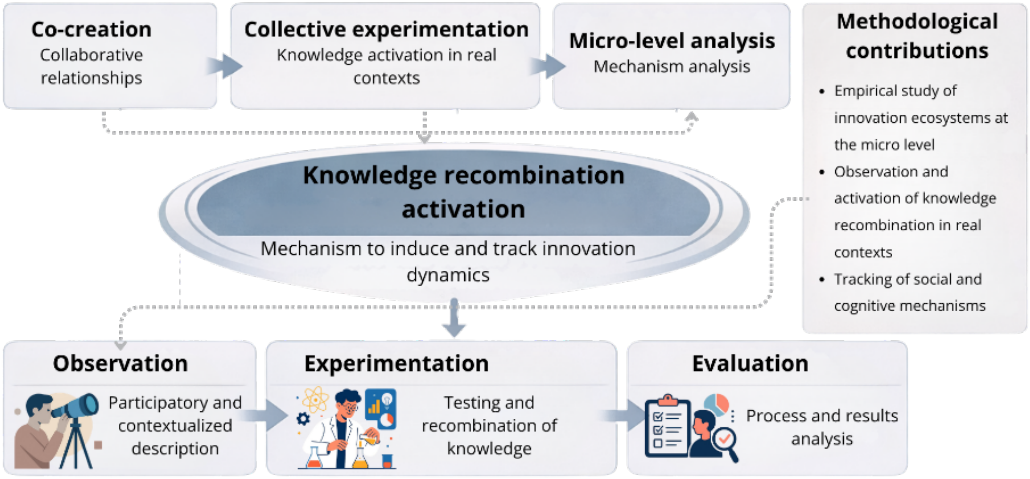

Figure 2. Methodological design based on participatory action research for the activation of knowledge recombination in innovation ecosystems at the micro level. Source: Authors.

1. The first phase involved diagnostic exploration, during which researchers engaged with local actors to identify productive challenges, sustainability constraints, and existing knowledge practices. This stage established the contextual baseline and clarified ecosystem conditions.
2. The second phase focused on collaborative planning, where artisans, students, and academic facilitators co-designed intervention strategies, emphasizing practical experimentation and mutual learning.
3. The third phase consisted of implementation and co-creation, during which workshops, technological experimentation, and sustainability-oriented interventions were conducted.
4. The fourth phase involved reflection, interpretation, and ecosystem consolidation, allowing participants to evaluate outcomes, refine practices, and collectively reinterpret the innovation process.

This cyclical structure strengthened methodological coherence while addressing reviewer concerns regarding insufficient explanation of research procedures.

3.2 Case study

The empirical setting for this study was the project "Tradición y Cultura Viva: Energía Creativa para la Sustentabilidad en la Artesanía de Guanajuato", implemented in the Lindavista neighborhood of Dolores Hidalgo, Guanajuato, Mexico. This setting represents a highly relevant case for studying dual transition in underrepresented territorial contexts. Dolores Hidalgo possesses a strong artisan identity centered on ceramic production, where productive practices rely heavily on inherited tacit knowledge, experiential learning, and culturally embedded techniques. At the same time, the community faces structural constraints related to technological access, productive competitiveness, environmental sustainability, and market adaptation.

These characteristics make the setting analytically valuable because it combines high cultural knowledge intensity with low formal technological sophistication. Rather than functioning merely as a passive context, the territory itself constituted an active component of the ecosystem, shaping interaction patterns, innovation constraints, and adaptation opportunities.

3.3 Participants

The study involved 48 participants, selected through purposive sampling to maximize heterogeneity of knowledge sources and ecosystem interaction. Participants included 22 artisans, whose expertise in ceramic production represented the tacit and culturally embedded knowledge base of the ecosystem. The study also involved 18 university students from the Industrial/Business Management Engineering program, who acted as technological intermediaries, learners, and co-creators.

Additionally, 8 researchers and institutional actors participated, including academic staff, project facilitators, and local stakeholders responsible for ecosystem articulation. This composition was methodologically intentional. Rather than treating participants as isolated respondents, the research positioned them as ecosystem actors whose interactions generated the dynamics under analysis.

The inclusion of heterogeneous participants strengthened the possibility of observing recombination processes between tacit, academic, and technical knowledge domains.

3.4 Data collection

Data collection was conducted over a 12-month intervention period, enabling longitudinal observation of ecosystem evolution and innovation dynamics. To strengthen empirical robustness, the study employed methodological triangulation, the study employed methodological triangulation, combining multiple qualitative sources and interaction settings.

First, 25 semi-structured interviews were conducted with artisans, students, and institutional actors. These interviews explored perceptions regarding innovation, sustainability, technological adaptation, and collaborative learning.

Second, six co-creation workshops were implemented as intervention spaces where ecosystem actors collaboratively developed and tested solutions. These workshops served simultaneously as empirical sites of innovation activation and observation.

Third, field observations were conducted throughout productive activities and collaborative sessions. These observations allowed researchers to capture interaction patterns, adaptive practices, and real-time decision-making dynamics.

This triangulated strategy increased empirical depth while enabling both outcome documentation and mechanism tracing. of observing recombination processes between tacit, academic, and technical knowledge domains.

3.5 Analytical strategy and rigor

Data were analyzed using a qualitative process-oriented approach combining thematic coding and process tracing. The analysis proceeded in three stages:

The first stage involved open coding, aimed at identifying emergent categories associated with knowledge recombination, collaboration, sustainability practices, and technological mediation.

The second stage involved axial coding, where relationships between categories were examined to identify ecosystem patterns and causal connections.

The third stage employed process tracing, allowing the reconstruction of event sequences through which innovation dynamics emerged.

This analytical strategy was particularly important because the objective was not simply descriptive documentation, but explanation of underlying causal mechanisms. To enhance rigor and trustworthiness, several validation strategies were applied. First, data triangulation was achieved through multiple empirical sources. Second, source triangulation was ensured through the participation of heterogeneous actor groups. Third, iterative member reflection was incorporated through ongoing interaction with participants during the action research process. These procedures strengthened interpretive validity and methodological rigor (see Table 1).

Table 1: Data collection and analysis framework.

Method	Description	Participants	Purpose
Interviews	Semi-structured	25	Identify knowledge processes
Workshops	Co-creation sessions	48	Activation and collaborative learning
Observation	Fieldwork	All	Contextual Understanding

4 Results

4.1 Knowledge recombination as the central innovation mechanism

The findings indicate that innovation within the ecosystem did not emerge through isolated technological adoption, but through structured processes of knowledge recombination. Consistent with recombination theory, innovation was generated through the integration of previously distinct knowledge domains (Xiao et al.,

2022). However, unlike formal innovation environments, the recombination observed here involved tacit artisanal expertise interacting with technical and academic knowledge.

Artisans contributed a deep experiential understanding of ceramic materials, firing behavior, pigment preparation, and production routines.

Students and researchers introduced external knowledge related to monitoring, experimentation, documentation, and process optimization.

The interaction between these domains produced adaptive innovations rather than direct technological substitution. This finding strengthens the theoretical argument that innovation in territorially embedded systems emerges through socio-cognitive recombination rather than technological determinism.

4.2 Technology as a learning mediator rather than an external driver

One of the most significant findings concerns the role of technology. Contrary to conventional narratives in dual transition literature, technology did not operate as an autonomous transformation engine. Instead, it functioned as a mediator of collective learning. Digital and accessible tools were introduced through participatory processes, allowing actors to gradually integrate them into existing productive routines. Students played an intermediary role by translating technical knowledge into accessible applications, while artisans adapted these tools to their practical realities. This resulted in forms of technological appropriation rather than passive adoption. Technologies supported:

- Temperature monitoring.
- Production documentation.
- Process organization.

More importantly, these tools made previously implicit production processes visible, enabling reflection, experimentation, and collaborative decision-making. Thus, digitalization acted less as infrastructure and more as cognitive mediation within the ecosystem.

4.3 Sustainability and productive efficiency

The intervention also generated measurable sustainability-oriented improvements. Participants reported greater productive consistency through improved firing process control, reduced material waste, and more efficient energy use. Adjustments in kiln loading, thermal monitoring, and production sequencing contributed to lower operational inefficiencies. These outcomes suggest that sustainability improvements emerged not from advanced technological infrastructure, but from context-sensitive adaptation and learning. This finding directly addresses reviewer concerns regarding whether the results represent empirical observations or merely expected outcomes. The evidence indicates that sustainability gains were observable consequences of ecosystem interaction.

4.4 Cultural identity as a strengthened rather than threatened dimension

A particularly important finding concerns cultural identity; a common assumption in modernization discourse is that technological intervention erodes traditional practices. However, the findings suggest the opposite.

Participants reported that innovation processes reinforced appreciation for local knowledge, encouraged reinterpretation of traditional techniques, and enhanced product differentiation.

Rather than replacing artisanal identity, innovation increased its perceived value.

This suggests that dual transition in culturally embedded systems need not produce homogenization, but may instead strengthen socio-cultural resilience.

4.5 Ecosystem emergence through collective intelligence

Across the intervention, innovation increasingly shifted from isolated problem-solving toward distributed collective intelligence. Knowledge sharing became more intentional, experimentation more collaborative, and decision-making more distributed. These patterns indicate the emergence of ecosystem properties rather than isolated collaborative episodes. The findings therefore empirically support the IKE framework proposed in Figure 1, demonstrating how actors, knowledge processes, enabling tools, and sustainability-oriented outcomes interact dynamically.

5 Discussion

The findings of this study provide important theoretical and practical insights into how innovation emerges in territorially embedded production systems that have traditionally remained underrepresented in mainstream ecosystem scholarship. The first major contribution concerns the reconceptualization of innovation ecosystems. Conventional literature has predominantly framed innovation ecosystems as formal interorganizational configurations driven by firms, institutions, and market-oriented exchange (Oliveira et al., 2025; Pattinson et al., 2023). However, the empirical evidence presented here demonstrates that innovation may emerge under fundamentally different structural conditions. In the case examined, innovation did not depend on formal R&D infrastructure, advanced technological sophistication, or institutional complexity. Instead, it emerged through socially mediated processes of interaction, collective experimentation, and contextual adaptation among heterogeneous actors.

These findings extend ecosystem scholarship by demonstrating that innovation ecosystems are not inherently restricted to technologically mature industrial environments. Rather, ecosystem dynamics may emerge wherever diverse actors interact through mechanisms capable of enabling knowledge transformation, adaptive experimentation, and collaborative problem-solving. From this perspective, the concept of Intelligent Knowledge Ecosystems (IKEs) is not proposed as a semantic variation of conventional innovation ecosystems, but as an analytically distinct construct designed to explain innovation dynamics in contexts where tacit, cultural, and territorially embedded knowledge constitute the primary innovation resource.

The second major contribution concerns the explanatory role of knowledge recombination. Existing scholarship has identified recombination as a central mechanism for innovation generation, particularly in technologically intensive or formally structured environments (Xiao et al., 2022; Luo, 2022). However, empirical evidence from rural and artisan production systems remains comparatively limited. The present findings demonstrate that recombination operates effectively even in environments characterized by low formal technological maturity. More importantly, the nature of recombination differs significantly from dominant innovation models. Rather than combining codified scientific or organizational knowledge, the ecosystem analyzed here recombined tacit artisanal expertise, experiential production knowledge, academic mediation, and accessible technological inputs. Innovation therefore, emerged not through technological substitution but through socio-cognitive hybridization. This expands recombination theory into underrepresented territorial contexts and suggests that innovation capacity may depend less on technological intensity than on the architecture of interaction through which heterogeneous knowledge domains are articulated.

A third theoretical contribution relates to dual transition scholarship. Much of the existing literature conceptualizes dual transition primarily through macro-level perspectives focused on policy, infrastructure, and institutional transformation (Kovacic et al., 2024; Quirico & Baber, 2024). While these perspectives offer valuable insights, they often understate how digital and environmental transitions materialize at micro-territorial scales. The findings presented here indicate that dual transition may emerge through localized participatory learning processes rather than exclusively through top-down infrastructure deployment.

Technology played a fundamentally different role from that assumed in many deterministic transition narratives. Rather than functioning as an autonomous transformation engine, technology operated as a mediator of collective learning, knowledge articulation, and adaptive experimentation. This shifts the conceptual interpretation of dual transition away from technological determinism toward a socio-technical adaptation perspective grounded in collaborative learning. Another important contribution concerns cultural sustainability. Mainstream modernization narratives frequently position innovation and tradition as opposing forces, implying that technological intervention necessarily weakens local identity or traditional productive knowledge. However, the empirical evidence suggests the opposite. Artisans did not perceive technological mediation as threatening authenticity. Instead, the innovation process increased awareness of the strategic value of local knowledge and strengthened confidence in culturally grounded productive practices. This finding expands sustainability debates by incorporating sociocultural resilience alongside environmental and economic performance.

Finally, the study contributes to understanding the role of universities in ecosystem formation. Higher education institutions are often framed as knowledge producers, technology transfer actors, or innovation intermediaries. However, the findings suggest a more active and structurally significant role. In the present case, the university functioned not merely as an external provider of expertise but as an ecosystem orchestrator that enabled interaction between heterogeneous knowledge domains, facilitated collaborative experimentation, and created the socio-technical conditions required for adaptive innovation. This interpretation aligns with emerging perspectives from triple helix and university ecosystem scholarship, which increasingly recognize universities as strategic actors in sustainability-oriented innovation systems (Secundo et al., 2024; Shkarupeta et al., 2024).

Rather than transferring knowledge unidirectionally, the university contributed to collective learning, knowledge translation, and ecosystem stabilization. This expands conventional interpretations of university engagement by positioning higher education institutions as catalytic actors within territorially embedded dual transition processes.

6 Conclusions

This study examined how innovation emerges in artisan production contexts under the framework of the dual transition and proposed the concept of Intelligent Knowledge Ecosystems (IKEs) as a new analytical lens for understanding these dynamics. The findings demonstrate that innovation in territorially embedded communities does not depend primarily on formal institutional complexity or advanced technological infrastructure. Instead, it emerges through structured processes of collective intelligence, knowledge recombination, and contextual technological mediation. This insight represents the central contribution of the study; By introducing IKEs, the research extends conventional innovation ecosystem theory toward culturally grounded and territorially sensitive environments traditionally underrepresented in mainstream scholarship. The empirical findings validate this framework by showing how heterogeneous actors collaboratively generate innovation capacity through adaptive interaction. The study also contributes to dual transition scholarship by demonstrating that digital and environmental transformation can emerge from participatory ecosystem processes at the micro-territorial level. This challenges deterministic narratives that equate transformation with technological sophistication.

Equally important, the findings reveal that innovation and cultural preservation are not inherently contradictory. On the contrary, innovation processes may reinforce cultural identity when technological mediation is designed around contextual adaptation and collective ownership. In practical terms, the study provides a transferable model for universities, communities, and policy actors seeking more inclusive innovation pathways. Ultimately, Intelligent Knowledge Ecosystems offer a promising framework for rethinking sustainable territorial innovation in contexts where knowledge is cultural, distributed, and deeply embedded in local practice.

The New Organizational Knowledge Dynamics Model that Integrates Human and Artificial Knowledge

Abstract

The emergence of Generative Artificial Intelligence (GenAI) and its explosive applications challenges the structure, functionality and efficiency of the Knowledge Management Systems (KMS). GenAI processes data, information, and human knowledge and generates artificial knowledge that belongs to the sciences of the artificial. KMS have been designed to create, share, transfer, and use human knowledge. The basic theory of organizational knowledge creation dynamics has been developed by Ikujiro Nonaka and Hirotaka Takeuchi and illustrated as the well-known SECI (Socialization, Externalization, Combination, Internalization) model. Knowledge is created through a series of transformations between tacit knowledge and explicit knowledge, and scaling up from individuals to teams and organizations. GenAI transformed KMS into hybrid systems composed of people and machines. The problem now is how to integrate human knowledge with artificial knowledge to enhance the efficiency of the KMS. From a practical viewpoint, the problem is how to augment the SECI model with artificial knowledge such that it can represent the new Hybrid Knowledge Management Systems (HKMS). The difficulty comes from the fact that human knowledge and artificial knowledge are two distinct constructs, and they cannot be mixed entirely. Human knowledge is a synthesis of rational, emotional, and spiritual knowledge, while artificial knowledge is exclusively rational. Therefore, the augmentation of each stage of the SECI model with artificial knowledge cannot be a solution because tacit or emotional knowledge is embodied. The models published so far focused on this solution, ignoring the fact that tacit knowledge cannot be integrated directly with artificial knowledge. The purpose of this research is to show a new perspective on augmenting the SECI model with artificial knowledge. We consider a separate cycle for artificial knowledge that mirrors the structure of the SECI cycle, and an interaction between them through the process of combination (i.e., the only process that is based exclusively on explicit knowledge). Therefore, the new complex model is composed of two cycles (i.e., the human knowledge and the artificial knowledge cycles), which are interconnected through the combination process.

Keywords: human knowledge, artificial knowledge, GenAI, SECI model, knowledge creation dynamics

Paper type: Academic Research Paper

1 Introduction

The theory of knowledge creation dynamics within Knowledge Management Systems (KMS) was initiated by Nonaka (1994) and further developed by Nonaka and Takeuchi (1995, 2019), Nonaka, Toyama, and Hirata (2008), and Konno (2024). This theory reflects the cyclic transformations between tacit knowledge and explicit knowledge on the epistemological axis, and the upscaling of knowledge integration from individuals to teams and organizations along the ontological axis. Based on these theories Nonaka and his co-authors developed the well-known SECI (Socialization, Externalization, Combination, Internalization) model. Socialization is the process of tacit knowledge sharing between people by seeing and imitating. It is a knowledge sharing using non-verbal communication because tacit knowledge is an embodied knowledge (Davenport & Prusak, 2000; Hadjimichael & Tsoukas, 2019; Polanyi, 1983; Tsoukas, 2011). Socialization is performed within a social context. Externalization is the process of transformation of tacit knowledge into explicit knowledge in the brain of a certain individual. This transformation is achieved through natural or symbolic language, analogies, and metaphors (Lakoff & Johnson, 1999; Pinker, 2008). Therefore, explicit knowledge can be transferred between people as a result of using natural language. We may say that explicit knowledge is codified knowledge. Combination is the process of explicit knowledge sharing within a social context. Ideas expressed by individuals are integrated, amplified and refined until a final agreement is achieved. Combination is based exclusively on explicit or rational knowledge. It is the most powerful process for knowledge co-creation and upscaling along the ontological axis. Internalization is the process of transformation of explicit knowledge into tacit knowledge at the individual level. It contributes to a better understanding of the events and phenomena as a result of learning. The whole knowledge cycle develops in time, generating a knowledge spiral (Nonaka & Takeuchi, 2019). This time dimension is a third dimension of the whole knowledge creation process.

The emergence of artificial knowledge that is generated through the interaction between people and Generative Artificial Intelligence (GenAI) requires an augmentation of the SECI model to integrate it. However,

artificial knowledge is different from human knowledge, although its roots are human data, information and knowledge (Baker, 2023, 2025; Bratianu, 2025; Di Vaio et al., 2024; Kurzweil, 2024; Lee & Qiufan, 2024). While human knowledge is a synthesis of rational, emotional, and spiritual knowledge (Bratianu & Bejinaru, 2019, 2020), artificial knowledge is exclusively rational and explicit (Russell & Norvig, 2023). Human knowledge is created within a semantic field, while artificial knowledge is generated by GenAI based on syntactic rules and statistical distributions of words within a given database. Computers do not think. They make algorithms to work and generate artificial knowledge. "Current GenAI models don't think or create things *per se*, but instead generate new things from parts of old things found in its database. (The term "things" in this context being images, videos, numbers, or text, depending on the GenAI application you are using). A GenAI output is the model's best prediction of what you are seeking" (Baker, 2025, p. 11). Artificial knowledge is generated by a series of mathematical algorithms that process a huge database. If the input data contains errors, the resulting artificial knowledge will incorporate those errors. Users should never trust the content of artificial knowledge. Instead, they should check it all the time against some evidence. While human knowledge represents a *justified true belief* (Audi, 2011; Nonaka & Takeuchi, 1995), artificial knowledge does not reflect such a true belief. All of these arguments demonstrate that integrating human knowledge with artificial knowledge implies a new perspective of organizational knowledge creation dynamics that creates a knowledge gap in the literature. As a consequence, we formulate the following research question:

> *RQ: How to augment the SECI model with artificial knowledge within the hybrid knowledge management systems in knowledge-intensive organizations?*

The structure of this paper is as follows: after this short introduction, we perform a critical literature review, then we show the method used for the present research, followed by the results and discussions. Finally, there is a section of concluding remarks and research limitations.

2 Literature Review

The purpose of our critical literature review is to analyse some proposed models for augmenting the SECI model with artificial knowledge as a result of the interaction between people and GenAI applications within the hybrid knowledge management systems. Jarrahi et al. (2023) analyse the partnership between AI and knowledge management, considering knowledge creation, knowledge storing and retrieving, knowledge sharing, and knowledge application. Knowledge creation may occasionally start from scratch. More frequently, it is a process of restructuring and recombination of the known facts within a new perspective. GenAI cannot think and cannot develop experiential knowledge (Kolb, 2015). However, it has the capability of performing a complex statistical analysis of huge databases and identifying unknown correlations between them. Based on them, GenAI creates new patterns for the prediction of new evolutions. "As a result of this capacity to derive their own rules based on similar patterns in the data, deep-learning AI can discover patterns in the available data sets previously unknown to the organization" (Jarrahi et al., 2023, p. 88). GenAI is very efficient in searching for data, information and knowledge integrated in the huge databases, classifying, organizing, storing and retrieving explicit knowledge. Also, it is of great help in amplifying knowledge sharing by connecting people with similar knowledge interests, regardless of the space and time separating them. The authors introduce the concept of *human-AI symbiosis* that reflects a new aspect of the interaction between people and AI that leads to achieving collaborative intelligence. However, they stress the fact that this process refers only to explicit knowledge. Tacit knowledge remains an attribute of the human agents.

Harfouche et al. (2022) developed a recursive theory of knowledge augmentation by integrating human intuition and knowledge in artificial intelligence to augment organizational knowledge. The authors focus on the human-GenAI interaction and design a new framework for organizational knowledge creation by augmenting the SECI model. "The Recursive Theory of Knowledge Augmentation (the KAM model) explains how tacit and explicit knowledge held by individuals and organizations can be simultaneously enlarged and enriched through the recursive process enabled by human-in-loop Informed AI" (Harfouche et al., 2022, p. 2). The approach aims at integrating human knowledge into the data-driven machine learning process, having the SECI model as a basic framework. From a practical viewpoint, the authors transformed the 2X2 matrix of the tacit-explicit knowledge transformations contained in the SECI model into a 3X3 matrix of the tacit-explicit-artificial knowledge transformations. Therefore, the new augmented matrix contains the SECI knowledge transformations (i.e., socialization, externalization, combination, and internalization) and five new processes that include artificial knowledge. *Alimentation* is the transformation of tacit knowledge into artificial knowledge. It is about how human intuition feeds the training of the Machine Learning. *Aggregation* is the transformation of explicit knowledge into artificial knowledge. The authors show that the human-in-the-loop Informed AI (IAI) was trained using explicit object-based knowledge. *Amplification* is the reverse process of the transformation of artificial

knowledge into explicit knowledge. The human-in-the-loop IAI can amplify experts' explicit knowledge. *Reflection* is the transformation of artificial knowledge into tacit knowledge. The authors consider that new artificial knowledge can contribute to human reflection and tacit knowledge creation. The last new process is called *fusion*, and it refers to the transformation of artificial knowledge into another artificial knowledge. "It results from the recursive loops needed to design, train, test, and implement a human-in-the-loop IAI in an organization. The outputs of the first loop of Alimentation, Aggregation, Amplification, and Reflection can set off or trigger a second loop" (Harfouche et al., 2022, p. 10). The analysis of the new framework shows that tacit knowledge has direct interaction with artificial knowledge through alimentation and reflection, although tacit knowledge is embodied (Hadjimichael & Tsoukas, 2019; Nonaka & Takeuchi, 1905; Tsoukas, 2011) and cannot have such a direct interaction. This is a weakness of the new framework and of the idea that the SECI model can be augmented through mixing human and artificial knowledge.

Böhm and Durst (2025) were driven by the same idea of augmenting the SECI model with artificial knowledge, but they sought another approach. They kept the structure of the SECI model and proposed a mix between human knowledge and artificial knowledge within each stage of the model. The result is the GRAI – Generative Receptive Artificial Intelligence model. The basic idea of the GRAI model is to consider each stage of the SECI model and propose its extension by integrating artificial knowledge. For instance, for socialization, the authors consider that "virtual environments or platforms could be created where people in different (geographical) locations can interact in real time, fostering socialization regardless of physical distance. These platforms can simulate face-to-face interactions, enabling spontaneous exchanges of tacit knowledge" (Böhm & Durst, 2025, p. 4). The authors face the problem like Harfouche et al. (2022): misunderstanding of tacit knowledge and the mechanism of socialization designed by Nonaka and Takeuchi (1995, 2019) in SECI. People can work with virtual environments and digital platforms using their explicit knowledge, not tacit knowledge. In the vision of Nonaka and Takeuchi (1995, 2019), socialization means the exchange of tacit knowledge through non-verbal communication. Digital platforms imply first transforming tacit knowledge into explicit knowledge using natural or symbolic languages, and only then performing any exchange of that knowledge. The same problem appears when considering externalization and internalization due to tacit knowledge. The only process open to mixing human and artificial knowledge remains combination. Therefore, the GRAI model designed for SECI model augmentation with artificial knowledge does not work. It is necessary to consider some other approaches.

The purpose of this paper is to show that this barrier of tacit knowledge can be overcome if we let the SECI model be as it is and consider a new cycle for artificial knowledge. The new cycle can be connected with SECI model through the combination stage because it is the only process involving exclusively explicit knowledge.

3 Methodology

This is a conceptual paper aiming at developing a new model for knowledge creation within hybrid knowledge management systems in knowledge-intensive organizations. It is based on a critical literature review, the theory of knowledge fields and knowledge dynamics (Bratianu & Bejinaru, 2019, 2020), the theory of knowledge creation dynamics (Nonaka & Takeuchi, 1995, 2019), and the design science research (Gregor & Hevner, 2013; Hevner et al., 2004). The theory of knowledge fields and knowledge dynamics states that we should understand knowledge as a complex integration of three basic fields: rational knowledge, emotional knowledge, and spiritual knowledge. The theory of knowledge dynamics states that a field of knowledge can be transformed into another field of knowledge (e.g., rational knowledge can be transformed into emotional knowledge or spiritual knowledge). The theory of knowledge creation developed by Nonaka and Takeuchi (1995, 2019) is incorporated in the SECI model that has been described above. The theory of design science research shows how to create artefacts that offer solutions to identified problems in information science, engineering, and management. Those artefacts can be new concepts, ideas, models, or theories within the specificity of the sciences of the artificial (Simon, 1996). According to Henvner et al., "Design science addresses research through the building and evaluation of artefacts designed to meet the identified business need. The goal of behavioural science research is truth. The goal of design science is utility" (Hevner et al., 2004, pp. 79-80).

4 Results and Discussion

As discussed in the previous sections, the proposed augmented models of the human knowledge creation model developed by Nonaka and Takeuchi (1995, 2019), focused on enlarging the SECI model with new processes which are specific to artificial knowledge. This approach ignores the embodied nature of tacit knowledge and creates a false solution. Our approach is to design a new cycle focusing only on artificial knowledge and to connect it with the SECI model through the combination stage, because combination is based on exclusive rational or explicit knowledge. To design a balanced complex model, it is necessary to imagine an

artificial knowledge-generating model that is similar to the human knowledge-creation cycle and that has the capacity to interact with it. We propose a cycle composed of the following stages: combination, artificialization, synthetization, and humanization (CASH) (See Figure 1).

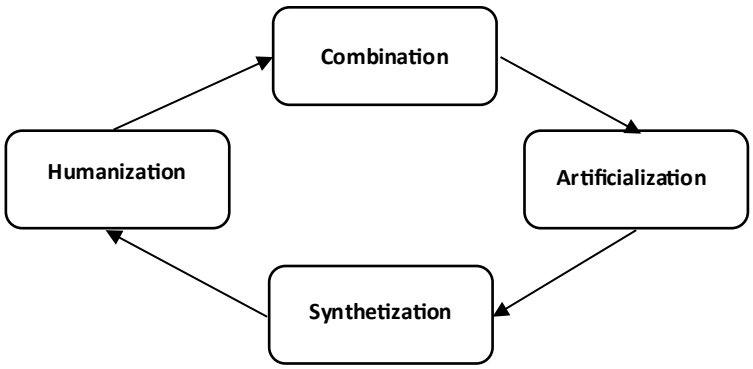

Figure 1: The CASH cycle for the artificial knowledge
(Source: Authors' research)

Combination is the same stage as for SECI model. It is the stage where explicit knowledge from individuals is amplified and integrated with artificial knowledge produced by GenAI. For the CASH cycle, combination means the data selection and its structuring to form the input for the artificial knowledge process. *Artificialization* is the next stage where human data, information, and knowledge are transformed into machine language to be processed. *Synthetization* is the stage where the GenAI algorithms transform the input data into predictive patterns by finding correlations within the huge database used for their training. *Humanization* is the stage where the result existing in the machine language is transformed into humanlike texts, images or videos. It is essential for the interaction between humans and machines. The cycle ends in combination, where it interacts with the SECI model. Therefore, the new model we propose is composed of both these knowledge cycles, SECI and CASH, which interact through the combination stage.

The CASH cycle processes only data, information, and knowledge expressed in a rational or explicit form, overcoming the barrier of dealing directly with tacit knowledge. This is a new perspective that brings value to the proposed CASH cycle and its connection with the SECI cycle. The proposed cycle can be evaluated at this stage using an analytical evaluation (Hevner et al., 2004).

- *Clearly define the model structure*. The CASH model has a similar structure to SECI. It is composed of four stages that contain transformations from the human data, information, and knowledge into artificial data, information, and knowledge and vice versa. Therefore, it is comparable and compatible with the SECI model.
- *Check logical consistency*. The flow of artificial knowledge is continuous and without any barriers because it follows mathematical consistency. Also, the conflict with tacit knowledge has been removed from the cycle.
- *Assess completeness*. The cycle is complete because the final output is the result users need. It is expressed in natural language, which makes the interaction between humans and machines much easier than otherwise.
- *Evaluates parsimony*. The CASH cycle is rather simple and has no redundant elements.
- *Perform ontological analysis*. The cycle starts and ends with the process of combination, which is shared with the human knowledge cycle, and then is performed only by the computer.
- *Theoretical grounds*. The CASH cycle is based on mathematical theories and neural architecture which are specific GenAI applications (Baker, 2023, 2025; Russell & Norvig, 2023).

Figure 2 shows how the SECI cycle interacts with the CASH cycle, forming a new complex framework that is totally different from the GRAI and KAM models discussed in the literature review section.

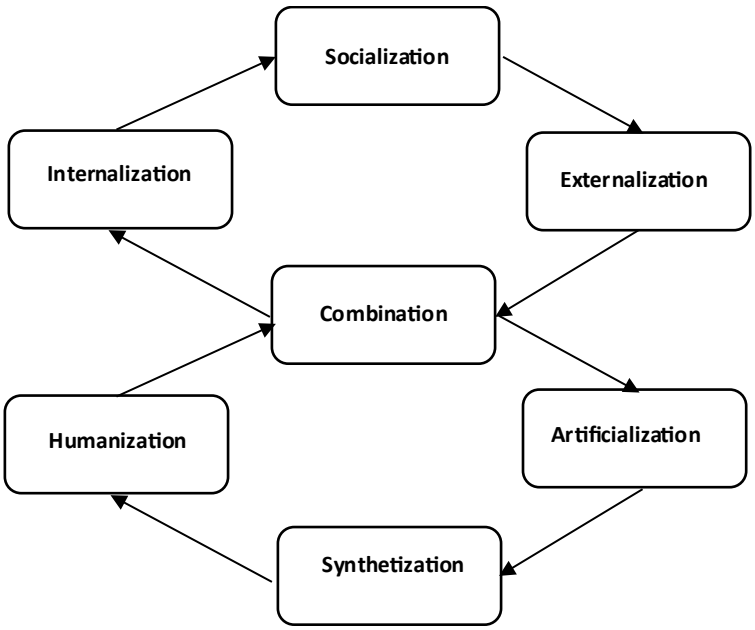

Figure 2: The complex SECI-CASH framework for integration of human and artificial knowledge (Source: Authors' research)

Looking at the new framework, we can see that organizational knowledge creation is a complex process composed of human and artificial knowledge, and the flow of knowledge does not create a spiral anymore. The flow of knowledge suggests a Möbius-strip model, which is more appropriate for the hybrid knowledge management systems than the augmented models proposed so far in the literature (Böhm & Durst, 2025; Harfouche et al., 2022). The new model suggests an interactive and iterative process of knowledge creation that leads to the idea of a strange attractor from the theory of complexity (Bird, 2003).

5 Conclusions

The purpose of this paper is to design a new model for organizational knowledge creation capable of integrating human and artificial knowledge. This new framework is requested by the hybrid knowledge management systems that include GenAI applications. The proposed augmented models of the SECI knowledge cycle focus on considering each of it stage a mixing place for both human and artificial knowledge. Therefore, socialization, externalization, combination, and internalization are augmented with artificial knowledge. However, tacit knowledge is embodied and cannot be mixed together with artificial knowledge that is exclusively rational or explicit. Therefore, augmenting socialization, externalization, and internalization with artificial knowledge makes no sense from the theory of knowledge creation developed by Ikujiro Nonaka and Hirotaka Takeuchi.

The present paper comes with a new perspective on considering a new cycle dedicated to artificial knowledge and being capable of interacting with the human knowledge creation cycle. The interaction can occur at the stage of combination, which contains only explicit knowledge. The new cycle has a similar structure to the SECI cycle and has the capacity to interact with it. It contains the following stages: combination, artificialization, synthetization, and humanization. Combination appears as a shared stage between both cycles because it contains exclusively rational or explicit knowledge. Artificialization is the stage where the human data input is transformed into a machine representation. Synthetization is the stage of mathematical algorithms that realize deep learning through neural networks. Its output represents new patterns based on correlations between the elements of the input data. Humanization is the process of transformation of those patterns expressed in machine language into products expressed in natural language, images or video, which constructs a humanlike dialogue with the users. The cycle is closing or starting a new iteration in the stage of combination. Together, both cycles (i.e., SECI and CASH) constitute a new framework that is capable of generating organizational knowledge for the hybrid knowledge management systems. This new framework distinguishes the present research from those already published (i.e., GRAI and KAM models).

The limitation of the present paper comes from the fact that it is conceptual, without empirical validation. That validation will constitute a further direction of our research.

Abstract

The rapid diffusion of Generative Artificial Intelligence (GenAI) is deeply transforming knowledge-intensive work, thanks to its ability not only to automate repetitive tasks but also, and more importantly, to enhance workers' capabilities for creating new knowledge. This is particularly evident in creative sectors where novelty is critical and new knowledge is continuously generated to provide fresh stimuli to the market daily, as in the fashion industry. Despite this, limited empirical research has examined how marketing professionals integrate GenAI into their work. This study addresses this gap by investigating the factors that affect the adoption and use of GenAI among fashion marketing professionals, who are tasked daily with generating innovative ideas to engage potential customers and guide them towards purchasing their company's products. To this aim, the study applies the Diffusion of Innovation Theory as a conceptual interpretative lens to examine the integration of GenAI among 30 purposely selected fashion marketing professionals. This theory, one of the frameworks that current research is using to investigate GenAI adoption processes, assumes that the diffusion of a new technology is influenced by five factors: relative advantage, compatibility, complexity, trialability, and observability. Data were gathered through semi-structured interviews and thematically analysed using MAXQDA software. The analytical process used a hybrid coding strategy, in which the five theory factors provided the deductive structure, while inductive themes were developed to capture the specific knowledge implications of human-AI collaboration. The findings of the investigation shed light on the current usage, benefits, and challenges of employing GenAI to support the knowledge-intensive work of fashion marketing experts. From an academic perspective, it confirms the usefulness of the Diffusion of Innovation framework for investigating the adoption of this new technology. At the same time, it offers valuable insights for marketing experts on the use of GenAI to support their professional activities. The usual limitations of interview-based studies regarding the generalizability of results are acknowledged.

1 Introduction

The emergence of Generative Artificial Intelligence (GenAI) is rapidly and deeply changing the landscape of knowledge work, thus affecting the long-term competitiveness of companies (Bharti et al., 2025). Both practitioners and scholars widely acknowledge that GenAI is influencing cognitive work (Noy and Zhang, 2023; Harreis et al., 2023), not only by automating repetitive tasks, but also, and more importantly, by enhancing workers' capabilities, particularly in the creation of new knowledge (Raisch and Krakowski, 2021).). This is why the literature increasingly uses the term "human-AI collaboration" to describe the active and participative nature of GenAI's contribution to knowledge creation (Brynjolfsson et al., 2025). The resulting knowledge can be viewed as a dynamic capability that, by integrating the capacities of both humans and generative systems, enables firms to survive and thrive in increasingly complex environments. Consequently, latecomers risk losing their competitive edge in such an evolving landscape. This is particularly true in creative sectors, where new knowledge is continuously generated to provide fresh stimuli to the market, as in the fashion industry. Evidence of this can be seen in the rapid and widespread adoption of GenAI tools by fashion companies (Amed et al., 2024). In view of the above, the present study aims to investigate the factors that affect the adoption and use of GenAI as an innovative technology in the fashion industry. Our focus is on professionals in marketing, as their work is knowledge-intensive. In fact, they are tasked with generating innovative ideas daily that engage potential customers and guide them to purchase the products of the company they represent.

GenAI supports these professionals by streamlining key cognitive tasks, including automated content creation, concept visualization, product design, and hyper-personalization (Harreis et al., 2023; Park and Ahn, 2024; Taraghi et al., 2025). This research employs a qualitative methodology grounded in Rogers' (2003)

Diffusion of Innovation model to examine the integration of GenAI among 30 purposively selected fashion marketing professionals. In particular, the study addresses the following research question:

RQ: How do fashion marketing experts perceive and adopt Generative AI in their knowledge-intensive work practices?

2 Background of the study

2.1 Generative AI and Knowledge Work

Generative AI is reshaping knowledge work by extending automation beyond routine tasks to complex cognitive activities. Unlike traditional AI systems, which primarily support structured decision-making, GenAI enables the creation of new content, ideas, and solutions, thus directly contributing to knowledge generation processes (Raisch and Krakowski, 2021). Recent studies highlight its ability to enhance productivity and quality in knowledge-intensive tasks, particularly in domains such as writing, design, and problem-solving (Noy and Zhang, 2023; Kirchner et al., 2026).

Rather than substituting human expertise, GenAI fosters new forms of human–AI collaboration, in which individuals and intelligent systems jointly participate in creative and analytical processes (Brynjolfsson et al., 2025). In this context, AI acts as a co-creator, augmenting human capabilities and enabling the recombination of knowledge in novel ways. This interaction can be conceptualized as a dynamic capability, allowing organizations to continuously adapt and innovate in increasingly complex environments. GenAI is not only a tool for efficiency, but also a driver of transformation in how knowledge work is performed, particularly in creative and innovation-driven sectors.

2.2 Generative AI in Creative Industries and Fashion

GenAI is gaining rapid traction in creative industries, where the production of novel and engaging content is central to value creation. By enabling the generation of text, images, and design concepts, GenAI supports creative processes such as ideation, storytelling, and visual development, thereby augmenting rather than replacing human creativity (Harreis et al., 2023; Raisch and Krakowski, 2021).

The fashion industry represents a particularly relevant context for the adoption of GenAI. Characterized by fast-paced innovation cycles and high demand for originality, fashion relies heavily on continuous knowledge creation, especially within marketing and design functions. Recent industry reports highlight the growing use of GenAI tools for applications such as automated content creation, concept visualization, trend forecasting, and personalized customer engagement (Amed et al., 2024; Park and Ahn, 2024).

Despite these developments, the integration of GenAI into creative workflows remains uneven, with organizations facing challenges in meeting skill requirements, integrating tools, and aligning with existing practices (De Cremer et al., 2023). However, despite the growing relevance of GenAI in creative industries, there is still a limited understanding of how these technologies are adopted and integrated at the individual level, particularly within knowledge-intensive marketing roles. In particular, the mechanisms through which professionals perceive, evaluate, and incorporate GenAI into their daily practices remain underexplored. This gap highlights the need for a more fine-grained understanding of individual adoption processes, which can be effectively examined through established technology adoption frameworks.

2.3 Technology Adoption and the Diffusion of Innovation Framework

The adoption of emerging technologies has been examined through several frameworks, including Diffusion of Innovation (DOI), Unified Theory of Acceptance and Use of Technology (UTAUT), and Technology-Organization-Environment (TOE) (Huy et al., 2024; Qu and Kim, 2025; Pokar, 2025). Among these, DOI (Rogers, 2003) is particularly suited to this study, as it focuses on how individuals perceive and adopt new technologies. The theory identifies five key attributes influencing adoption: relative advantage, compatibility, complexity, trialability, and observability (Table 1). Building on this framework, the present study applies the five DOI attributes to examine how fashion marketing professionals perceive and adopt GenAI in their work practices.

Table 1: DOI attributes (Rogers, 2003; García-Avilés, 2020; Noy and Zhang, 2023; Harreis et al., 2023)

DOI attribute	Description
Relative advantage	The degree to which GenAI is perceived as offering benefits over existing practices, such as improved efficiency, productivity, and creativity.
Compatibility	The degree to which GenAI aligns with existing values, work practices, and technological infrastructures.
Complexity	The perceived difficulty of understanding and using GenAI, including the required skills and effort.
Trialability	The extent to which GenAI can be tested before full adoption.
Observability	The visibility of the outcomes and results of GenAI use to others, which may be perceived positively or negatively

3 Research Method

This study adopts a qualitative approach, using the DOI framework as its conceptual lens (Rogers, 2003). The five DOI attributes guide the analysis of how individuals, fashion marketing experts, perceive and integrate GenAI into their knowledge-intensive work practices.

Data were collected through semi-structured interviews with 30 fashion industry professionals from 13 countries (Table 2), recruited via purposive sampling on LinkedIn (Etikan et al., 2016). The sample included a range of roles, from traditional marketing positions to emerging AI-related profiles, ensuring diversity in experience and perspectives. Interviews were conducted online via Zoom between March and October 2025, recorded with consent, and anonymized.

The data were analyzed using a hybrid deductive–inductive thematic approach supported by MAXQDA (Fereday and Muir-Cochrane, 2006; Silver and Lewins, 2014). The five attributes provided the initial coding structure, while inductive themes were developed to capture the knowledge implications of GenAI use. The analysis followed the six phases of thematic analysis (Braun and Clarke, 2006), ensuring rigor and consistency (Yin, 2011). Coding was conducted iteratively, with continuous refinement of themes, and representative quotes were used to support each category and ensure analytical rigor.

4 Findings and Analysis

4.1 Respondent's profile

The respondents represent a diverse group of professionals working across different areas of the fashion industry. Their ages range from early-career individuals to highly experienced professionals with several decades in the industry. Many participants are also actively engaged at the intersection of fashion and technology, with experience in digital fashion, AI-driven initiatives, or technology-oriented roles. Regarding tools, respondents reported an extensive use of GenAI applications in their daily work. Text-based tools such as ChatGPT are widely used for content creation, idea generation, and as a general support for organizing information, conducting research, and refining concepts. Visual tools, particularly Midjourney, play a central role in generating images, supporting creative exploration, and developing marketing visuals. More specialized applications were also mentioned, including AI-powered chatbots for customer interaction, sentiment analysis tools for monitoring feedback, and AI-integrated design software such as Clo3D. Some respondents reported using advanced or custom-built solutions tailored to specific business needs, such as AI systems for content automation, sales support, or product design.

The following sections examine how these professionals perceive and use GenAI, structured according to the five attributes of the DOI framework.

Table 2: Profile of respondents

Interview	Gender	Age	Years of experience	Title	Country
Int1	Woman	38	10	Fashion marketing expert	Italy
Int2	Woman	43	20	Business owner, fashion designer	Trinidad and Tobago
Int3	Woman	40	10	Business owner, handicraft designer	Canada
Int4	Woman	43	4.5	Lecturer in Fashion marketing and branding	UK
Int5	Woman	33	8	Conscious denim designer	US
Int6	Woman	56	12	Digital (AI) fashion creator	Canada
Int7	Man	45	5	Digital project manager	Italy

Interview	Gender	Age	Years of experience	Title	Country
Int8	Woman	37	13	Chief operating officer	Italy
Int9	Woman	37	15	Fashion innovation expert	Italy
Int10	Woman	34	14	Business owner, fashion designer	Bulgaria
Int11	Woman	40	4	Fashion journalist	Iran
Int12	Woman	50	25	Visual designer & AI creative director	Switzerland
Int13	Woman	48	20	Digital marketing expert	Austria
Int14	Woman	37	14	Business owner, fashion designer	Egypt
Int15	Man	43	20	Business owner, sports manufacturer	Belgium
Int16	Woman	57	35	Digital fashion designer	US
Int17	Woman	55	38	Business owner, creative designer	Italy
Int18	Woman	54	35	Business owner, creative designer	Italy
Int19	Man	64	40	Business owner, visual creator	Italy
Int20	Woman	33	10	Sale engineer	Italy
Int21	Woman	55	34	Fashion tech founder	US
Int22	Woman	43	20	Fashion designer, GenAI creator	Italy
Int23	Woman	24	1	Fashion marketing expert	Italy
Int24	Woman	37	15	Fashion marketing expert	Canada
Int25	Woman	58	30	3D product developer/ consultant	US
Int26	Woman	27	5	Fashion innovation consultant and designer	Switzerland
Int27	Woman	43	20	Business owner, designer	Portugal
Int28	Woman	25	4	Fashion sales and marketing expert	UK
Int29	Woman	31	10	Fashion e-commerce expert	India
Int30	Woman	43	20	Product design lead, GenAI expert	Portugal

4.2 Relative advantage

Table 3 outlines sub-themes of relative advantage, showing how GenAI improves performance over traditional methods. Frequency reflects how many respondents mentioned each sub-theme, indicating relevance.

Most respondents emphasize that GenAI is primarily valued for boosting efficiency and saving time, thereby making workflows faster and more productive. They also note increased creativity and better customer personalization. Cost and resource optimization are deemed important, too, especially through reduced reliance on traditional processes. Some respondents highlight benefits for business sustainability. Overall, GenAI is perceived to offer advantages across efficiency, creativity, and cost savings.

Table 3: Sub-themes for Relative Advantage

Sub theme	Description	Quotes	Frequency
Efficiency and Time Compression	GenAI accelerates workflows and can enable partial task automation, reducing time and human effort.	"… with AI, your efficiency is improved, your productivity becomes 2x" (Int29) "… what AI can do in a couple of minutes would take humans days or weeks" (Int15)	27
Augmented Creativity and Ideation	GenAI enhances creative processes by supporting ideation, inspiration, and the generation of novel concepts.	"… it's the fastest way of ideation and having, doing a more accurate brainstorm also, getting immediate response or ideas to present to clients" (Int27) "... it's opening up a door to next level creativity" (Int13)	23
Customer Experience and Personalizatio n	GenAI enables more personalized, interactive customer experiences, thereby improving engagement and relevance.	"… AI tool helps us to make more personalized connections with the customer … Make messages more friendly. More personalized for every customer" (Int14) "… analyze what your customer is looking for, and generate descriptions like in real time for the product" (Int9)	22

Sub theme	Description	Quotes	Frequency
Cost and Resource Optimization	GenAI reduces reliance on traditional production resources (e.g., photoshoots, teams), leading to significant cost savings.	"So basically, photo shooting is being replaced and significantly optimized … the savings are substantial in this regard" (Int30) "A third factor is certainly cost, because with the same budget as before, we might now be able to carry out more or more complete activities" (Int18)	20
Sustainability and Process Optimization	GenAI supports more sustainable practices by reducing physical production, waste, and overproduction.	"You can try a lot of things without having to spend money on real products. So, you can use this for tests, and in terms of environmental benefits, it's huge" (Int27)	8

4.3 Compatibility

Table 4 outlines the sub-themes related to compatibility and shows that compatibility is mainly driven by how easily GenAI can be integrated into existing workflows and used as an augmenting tool rather than a full replacement. Respondents emphasize its role as a co-creator, supporting creative and marketing activities while aligning with brand identity and industry-specific requirements. At the same time, compatibility is shaped by organizational readiness, including skills and openness to change, as well as constrained by ethical, legal, and trust-related concerns. The respondents' overall opinion is that compatibility can be missing, as it depends on how well the GenAI use fits with specific work practices, brand values, and the capabilities of both individuals and organizations. Furthermore, ethical, legal, and trust issues afflicting current tools contribute to lowering their compatibility.

Table 4: Sub-themes for Compatibility

Sub theme	Description	Quotes	Frequency
Task, Brand, and Industry Fit	Compatibility depends on how well GenAI aligns with specific work tasks, brand identity, and industry context. This includes its ability to support creative and marketing activities while maintaining brand DNA and adapting to sector-specific expectations.	"… to create images that express a concept an idea that transfer the values of the brand which translates into images" (Int23) "… AI cannot be useful because when you combine the traditional handicraft with modern handicraft, it has specific customers and the niche market is not very big" (Int3)	30
Integration and Augmentation of Existing Practices	GenAI is perceived as compatible when it can be integrated into existing workflows and used as a tool that augments, rather than replaces, human practices. This includes its role as a co-creator that supports and enhances existing expertise.	"AI is just another tool… like Photoshop" (Int24) "This shift, this co-creation and coexistence with the machine can be carried throughout the entire pipeline" (Int18)	29

Table 4: Sub-themes for Compatibility (cont.)

Sub theme	Description	Quotes	Frequency
Organizational Readiness and Capability	Compatibility is influenced by individuals' and teams' readiness to adopt GenAI, including their openness to change, skills, and ability to integrate new technologies into existing practices.	"I think mostly the mindset, because technically, they are easy to learn, it's just that if people don't want to learn them, then, well, they won't, you know" (Int26) "It's a new technology. Not all team can understand it. So I give them more courses to be with me in this transformation …" (Int14)	23
Ethical, Legal, and Trust Barriers	Compatibility is constrained by concerns related to ethics, data privacy, copyright, and customer trust.	"… the privacy, copyright issues are the biggest challenges" (Int8) "... the risk is that you create an image that can be similar to a real existing person and there can be some legal problems …" (Int23)	16

4.4 Complexity

Table 5 illustrates the key points of complexity associated with GenAI use, arising from both the effort required to use it and the uncertainty of its outcomes. Respondents highlight the need for specific skills and continuous learning, as well as difficulties in controlling outputs and achieving reliable, high-quality results. In addition, fragmented workflows and the need to combine multiple tools increase operational complexity. This is further reinforced by a gap between expectations and actual performance, along with ethical and risk-related concerns such as privacy and data security. Overall, complexity reflects both technical and organizational challenges that can limit effective adoption.

Table 5: Sub-themes for Complexity

Sub theme	Description	Quotes	Frequency
Output Uncertainty and Control Limitations	GenAI use is characterized by uncertainty in outputs, limited control over results, and inconsistencies in quality and accuracy.	"… sometimes it's the AI, it's not the right answer for everything. You have to understand where and when and how to use it" (Int27) "… because we all know AI makes so many mistakes right now" (Int21)	20
Skill Intensity and Learning Curve	Although GenAI tools are accessible, effective use requires specific skills (e.g., prompting, domain knowledge) and continuous learning due to rapid technological evolution.	"You need to know how to use it before actually like doing it" (Int28) "So I have some mistakes. Take a time to learn it and integrate it in our projects" (Int14) "… it's not like you are coming from day one and start getting results, nice results, usable results. No, you have to learn. Someone has to teach you" (Int30)	20
Expectation–Reality Gap	There is a mismatch between expectations of AI capabilities and actual performance, leading to frustration and dissatisfaction.	" … one of the things that is very mystifying about AI is that everything is possible. (Int27) "… GNI isn't always capable of replicating a high-quality product. It's still not always possible to create something as good as a filmed video, an image, or a photo" (Int12)	17
Workflow Fragmentation and Tool Ecosystem Complexity	The need to combine multiple tools and manually adjust outputs creates fragmented workflows, reducing overall efficiency.	"… for someone like me, with a limited budget, one of the biggest difficulties is gaining access to truly professional tools, which often come with very high costs" (Int22) "Another major challenge … is the overwhelming number of tools available, and the ability to choose which ones to use" (Int18)	13
Ethical and Risk-Related Complexity	Concerns related to privacy, intellectual property, and misuse of AI outputs add an additional layer of complexity to adoption.	"The biggest challenge definitely has two sides: one is ethical, and the other is legal—it's the legal side" (Int18) "… the challenge… is the privacy and data security, because we know very well what you share with ChatGPT" (Int8)	11

4.5 Trialability

Table 6 summarizes trialability sub-themes, showing how GenAI can be tested before full adoption. GenAI denotes strong trialability due to its ease and speed, enabling quick idea testing, prototyping, and low-cost experimentation. Respondents emphasize flexible, iterative testing as a key benefit. However, scaling to professional use introduces challenges, such as maintaining brand consistency, quality, and control. Reliability and output limitations can also reduce effectiveness. According to the experts, trialability is high early on but more limited in large-scale applications.

Table 6: Sub-themes for Trialability

Sub theme	Description	Quotes	Frequency
Ease and Accessibility of Experimentation	GenAI enables fast, low-cost, and low-effort experimentation, allowing users to rapidly prototype ideas, explore multiple alternatives, and test concepts with audiences. This encourages iterative exploration in the early stages.	"… the key benefit of AI in marketing, it's a fast testing of ideas, flexibility of the process" (Int24) "Let's say we like to consider ourselves pioneers—not because AI itself is new (we know well that it began decades ago), but because its wide adoption has really accelerated only in recent years" (Int17)	20
Iterative Testing and Creative Exploration	Users can continuously refine, adjust, and iterate on output, enabling dynamic experimentation and creative exploration across multiple variations and ideas.	"… the key benefits, definitely the flexibility of the process. You can adjust, redo, rethink in seconds " (Int24) "And ever since then, I've just been like, really, you know, playing around with it, trying with … all the new tools that are coming out" (Int16)	18
Reliability and Validity Limitations of Experimentation	The outcomes of GenAI experimentation are often limited by issues of quality, realism, and consistency, reducing the reliability of testing results and making it difficult to draw actionable conclusions.	"There are some try-on tools that are really good on some kind of clothes but really bad on some others … the technology is not enough developed" (Int23) "… even though you're getting multiple attempts, I've found it still is not as accurate as I would like it to be. So in the end, I unsubscribe from that software" (Int2)	16
Constraints in Scaling Experimentation	While initial experimentation is easy, applying GenAI in professional and large-scale contexts becomes more complex due to brand constraints, organizational requirements, and the difficulty of maintaining consistency and control.	"Post-production is still necessary because even the best models, despite being guided and trained over the years … still aren't able to deliver exactly what's needed" (Int12) "… but then it began to work very good and in the late two years things have changed constantly day by day and the results are pretty different" (Int19)	15

4.6 Observability

Table 7 presents the sub-themes associated with observability, focusing on how the outcomes of GenAI use become visible to others. External observability of results obtained with GenAI is not straightforward because it depends on the visibility of GenAI use and its outcomes to others, which can attract significant attention and curiosity. Respondents highlight that AI-related content often gains visibility due to its novelty, while increasing realism and detectability shape whether users recognize AI involvement. Once visible, these outcomes are interpreted differently by audiences, leading to both positive and negative reactions depending on perceptions of authenticity and expectations. In sum, observability in this context encompasses not only the visibility of results but also how others perceive and evaluate them.

Table 7: Sub-themes for Observability

Sub theme	Description	Quotes	Frequency
Visibility and Attention Effects	The use of GenAI increases visibility and attracts attention, as the novelty and "AI label" generate curiosity, media coverage, and audience engagement.	"I've also used a few posts created by AI on my LinkedIn, which had over 80,000 views" (Int15) "…. when a person or a company will start to use it and then they will see the benefits and the benefits will be shared to like the big public let's say then after everyone will start to use it" (Int28)	20

Sub theme	Description	Quotes	Frequency
Detectability and Transparency of AI Use	Observability depends on the extent to which AI use is recognizable, either through the detectability of AI-generated outputs or through explicit disclosure.	"I mean, the beginning, it was very difficult to have a video that looked natural. Now people don't even know the difference between an AI, I can't even tell myself" (Int16) "They have gone full gen AI on everything and it does look slightly strange and weird and its kind of you get that uncanny valley feel from it" (Int4)	18
Interpretation of Visible Outcomes	Once visible, GenAI outputs are interpreted differently by audiences, leading to varied reactions depending on perceived realism, authenticity, and expectations.	"Customers didn't take it quite well because they felt somehow betrayed by the brand choosing to avoid humans as models" (Int7) "The response was very positive and the client itself felt like it was also working on that because we were tweaking the outfits" (Int27)	18

5 Discussion and Conclusion

Fashion marketing professionals perceive GenAI as a technology that significantly enhances efficiency, especially content generation and ideation (Noy and Zhang, 2023). The high frequency of efficiency- and creativity-related benefits indicates that they primarily adopt GenAI to accelerate workflows and expand creative output, but the value is realized only when the technology can be effectively embedded within existing workflows and aligned with brand identity and creative standards where GenAI is an active co-creator partner and enable a combination of human creativity and machine efficiency (Raisch and Krakowski, 2021). This explains why compatibility-related factors, particularly integration and task–brand fit, are among the most important in respondents' opinions.

The findings also reveal a fundamental tension between ease of access and depth of use. While GenAI is highly accessible and supports rapid experimentation, effective and sustained use requires developing new forms of knowledge, and experts must learn to guide outputs, evaluate quality, and manage iterative processes. This indicates that knowledge work is shifting from creation to orchestration (Raisch and Krakowski, 2021) and . explains the strong presence of complexity-related sub-themes, particularly those linked to skill requirements and output uncertainty. Therefore, adoption is not simply about using a new tool, but about developing the capabilities needed to control and integrate it into professional practice (Kirchner et al., 2025). We can also see this tension in trialability, where experimentation is easy and accessible, while challenges related to quality arise when scaling up use. As a result, adoption is not a linear progression from trial to full use, but a staged process in which practical constraints moderate early enthusiasm. In the context of digital fashion marketing, GenAI outputs are highly observable, which increases awareness and attention. However, unlike traditional assumptions in diffusion theory, this visibility does not consistently reinforce adoption. Instead, interpretations of visible outputs vary, with both positive and negative reactions depending on perceived authenticity and quality. This suggests that adoption is influenced not only by functional performance but also by how outcomes are socially interpreted and evaluated (Brüns and Meißner, 2024).

As a conclusion, the adoption of GenAI in fashion marketing is best understood as a dynamic process. Professionals adopt GenAI to enhance productivity and creativity. Still, its effective use depends on its integration into existing knowledge systems, the development of new skills, and the management of audience perceptions. This highlights that GenAI does not simply improve knowledge work but reshapes it, requiring a shift in how knowledge is created, controlled, and evaluated.

6 Limitations, Implications, and Future Directions

From a theoretical perspective, the findings extend the DOI framework by showing that attributes such as observability and trialability are more dynamic and context-dependent in the case of GenAI.

From a practical perspective, organizations should view GenAI not only as a productivity tool but also as a capability that requires new skills and organizational adaptation. They should invest in developing employees' AI-related skills, particularly in guiding and evaluating outputs. GenAI should be strategically integrated into existing workflows through a phased approach, starting with pilot use cases. Strong quality control and governance mechanisms, supported by human oversight, are essential to ensure accuracy and alignment with brand identity. While experimentation is relatively easy, scaling requires addressing reliability and integration challenges, suggesting a staged adoption from experimentation to controlled deployment and broader

integration. Finally, firms must carefully manage customer perception and trust by adopting clear communication strategies and ensuring appropriate transparency in customer-facing applications.

This study has limitations, including its industry-specific focus and participants' early-stage GenAI adoption, which may limit generalizability. Future research could extend these insights through cross-industry and longitudinal studies.

7 Ethics declaration

Participation was voluntary, with informed consent obtained from all participants. No sensitive data was collected, and all responses were anonymized and handled in accordance with data protection regulations. Formal ethics approval was not required under institutional guidelines.

8 AI declaration

We used ChatGPT 5.3 to revise and correct the written text and rename the theme's label.

The Hidden Cost of Flexibility: Knowledge Visibility in Flexible Work Arrangements

Elina Pentjusa, Elina Gaile-Sarkane
Riga Technical University, Riga, Latvia

Abstract

Flexible work arrangements have become a defining feature of contemporary organizations, yet their implications for organizational knowledge processes remain insufficiently theorized. Existing research has primarily examined flexible work through employee autonomy, wellbeing, productivity, retention, and work-life balance. While these perspectives are important, they provide only a partial account of how flexible work reshapes the creation, sharing, retention, and renewal of organizational knowledge. This paper argues that flexible work should be understood not only as a human resource management or work design issue, but also as a knowledge governance issue.

The paper develops a conceptual framework explaining how flexible work arrangements influence knowledge visibility in organizations. Flexible work is treated as a multidimensional construct comprising spatial, temporal, and organizational flexibility rather than as a single uniform practice. Drawing on tacit knowledge theory, organizational knowledge creation, situated learning, communities of practice, technology affordance theory, transactive memory systems, and knowledge governance, the paper argues that the knowledge effects of flexibility are conditional. Flexible work may strengthen knowledge processes by supporting autonomy, focused work, digital traceability, and access to distributed expertise, but may also weaken tacit knowledge transfer, newcomer learning, shared interpretation, and expertise visibility when knowledge processes are not intentionally governed.

The main contribution is the development of a flexibility-knowledge visibility framework. The framework explains how different forms of flexibility affect organizational knowledge through four mechanisms: tacit knowledge transfer, digital and social visibility, transactive memory, and participation in learning communities. The paper develops five propositions for future empirical research and outlines governance mechanisms for maintaining knowledge visibility in flexible work contexts. The argument is not that flexibility is inherently harmful. Rather, knowledge fragmentation emerges when organizations redesign where and when work occurs without redesigning how knowledge becomes visible, accessible, interpretable, and renewable.

Keywords: Flexible work arrangements; knowledge visibility; tacit knowledge; hybrid work; knowledge governance

Paper type: Academic Research Paper

1 Introduction

Flexible work arrangements have become a lasting feature of contemporary organizational life. Remote work, hybrid work, flexible schedules, and digitally mediated collaboration have changed not only where and when work is performed, but also how employees interact, learn, coordinate expertise, and participate in organizational knowledge processes. Much of the existing discussion has examined flexible work through outcomes such as autonomy, job satisfaction, productivity, work-life balance, and employee retention (Allen, Golden, & Shockley, 2015; Gajendran & Harrison, 2007; Kossek & Lautsch, 2018). These perspectives are important, but they do not fully explain how flexible work affects the visibility, transfer, and renewal of organizational knowledge.

This gap is significant because organizational knowledge is not limited to codified information. It also includes tacit knowledge, situated judgement, shared routines, relational understanding, and knowledge of who holds relevant expertise (Nonaka, 1994; Polanyi, 1966; Wegner, 1987). Such knowledge is often developed through observation, informal correction, peripheral participation, and repeated interaction in communities of practice (Brown & Duguid, 1991; Lave & Wenger, 1991; Wenger, 1998). When work becomes spatially distributed, temporally asynchronous, and digitally mediated, these knowledge processes do not disappear, but their conditions change.

This paper argues that flexible work should be understood as a knowledge governance issue. The central question is not whether flexible work is good or bad for organizations, but under what conditions flexibility supports or weakens knowledge creation, sharing, retention, and renewal. Flexible work may improve autonomy, reduce interruptions, support focused work, and increase access to distributed expertise. At the same time, it may reduce tacit learning, weaken ambient awareness, fragment shared context, and make

expertise less visible if knowledge processes are left to emerge informally (Cheng, Sun, Zhong, & Li, 2023; Hesselbarth, Alfes, & Festing, 2024; Majchrzak, Faraj, Kane, & Azad, 2013).

The paper addresses the following research question: How do flexible work arrangements reshape organizational knowledge visibility, and what governance mechanisms are required to protect knowledge creation, sharing, retention, and renewal in flexible work contexts?

To answer this question, the paper develops a conceptual framework that treats flexible work as a multidimensional construct. Spatial flexibility concerns where work is performed, temporal flexibility concerns when work is performed, and organizational flexibility concerns how work is coordinated, mediated, and governed. This distinction is important because different forms of flexibility have different implications for tacit knowledge transfer, digital visibility, expertise coordination, and newcomer learning (Allen et al., 2015; Hesselbarth et al., 2024).

The paper contributes by shifting flexible work research from individual-level outcomes toward organizational knowledge visibility. It also extends knowledge management literature by explaining how flexible work changes the socio-technical conditions through which knowledge becomes visible, transferable, and governable.

2 Theoretical Background

2.1 Flexible work arrangements as a multidimensional construct

Flexible work arrangements refer to work practices that provide discretion over where, when, and how work is performed. The concept includes remote work, hybrid work, flexible schedules, asynchronous collaboration, compressed working time, and digitally mediated coordination. However, treating flexibility as a single category is analytically weak because different forms of flexibility produce different organizational consequences (Allen et al., 2015; Kossek & Lautsch, 2018).

This paper distinguishes between spatial, temporal, and organizational flexibility. Spatial flexibility concerns where work is performed, temporal flexibility concerns when work is performed, and organizational flexibility concerns how work is coordinated through roles, routines, platforms, and managerial practices. This distinction is central because each dimension creates different knowledge risks: spatial flexibility may reduce informal observation, temporal flexibility may weaken shared rhythms, and organizational flexibility may either reduce or intensify fragmentation depending on the quality of knowledge systems and governance routines.

Recent research supports the need for this more differentiated view. Cheng et al. (2023) show that flexible work arrangements influence knowledge sharing through mechanisms such as workplace loneliness and task interdependence. Hesselbarth et al. (2024) argue that technology-driven work arrangements should be understood from a complexity perspective rather than as simple work location choices. Eng, Aboagye, Bergsten, and Strömberg (2025) further show that flexibility may affect innovation, productivity, and organizational attractiveness differently depending on organizational context.

2.2 Organizational knowledge as tacit, social, and technological

Organizational knowledge includes explicit knowledge that can be documented, tacit knowledge that is embedded in experience, and social knowledge that is sustained through relationships and practice (Nonaka, 1994; Polanyi, 1966; Spender, 1996). In knowledge-intensive organizations, performance depends not only on access to information, but also on interpretation, judgement, shared context, and the ability to locate relevant expertise (Grant, 1996; Nonaka & Takeuchi, 1995).

Knowledge visibility describes the extent to which knowledge, expertise, reasoning, and learning opportunities are accessible and interpretable within an organization. It is broader than information availability: a document may be accessible without being understood, a decision may be recorded without its reasoning being visible, and expertise may exist without being identifiable to those who need it. Thus, knowledge visibility concerns the social and technical conditions that make knowledge locatable, interpretable, and applicable.

Flexible work changes knowledge visibility in two opposing ways. Digital tools can increase visibility by creating searchable records, shared repositories, project histories, and communication traces (Leonardi, 2014; Treem & Leonardi, 2013). At the same time, flexible work may reduce visibility when interaction moves into private channels, when employees have fewer informal encounters, or when digital communication captures information but not context (Majchrzak et al., 2013). The central issue is therefore not the presence or absence of technology, but whether technology and social routines jointly support knowledge interpretation.

2.3 Tacit knowledge, social learning, and flexible work

Tacit knowledge is difficult to formalize because it is rooted in experience, practice, and situated judgement (Polanyi, 1966). Nonaka's (1994) theory of organizational knowledge creation explains that knowledge develops through interaction between tacit and explicit forms. The SECI model identifies socialization, externalization, combination, and internalization as key processes through which organizational knowledge is created and renewed (Nonaka & Takeuchi, 1995).

Situated learning theory adds a further dimension. Lave and Wenger (1991) argue that learning occurs through participation in social practice. Newcomers develop competence through legitimate peripheral participation, gradually moving from observation to fuller involvement. Communities of practice sustain knowledge through shared repertoires, mutual engagement, and collective interpretation (Brown & Duguid, 1991; Wenger, 1998). In flexible work contexts, these learning processes may be weakened if employees, especially newcomers, lose access to informal observation, shadowing, and low-threshold questions.

However, co-presence is not the only basis for learning. Digital communities, virtual mentoring, recorded demonstrations, transparent discussion channels, and structured reflection routines can support learning across distance when they are deliberately connected to real work practices (Leonardi, 2014; Majchrzak et al., 2013; Wenger, 1998).

2.4 Digital affordances and transactive memory

Digital work technologies shape knowledge processes through affordances, understood as possibilities for action that emerge from the relationship between users and technology (Majchrzak et al., 2013; Treem & Leonardi, 2013). Collaboration platforms may support knowledge sharing by making conversations searchable, decisions traceable, and expertise networks more accessible.

Yet digital visibility is selective. It may make documents and messages visible while leaving informal reasoning, judgement, and contextual cues hidden. Although digital tools can support knowledge sharing by making communication visible, their effect depends on how employees use technology and how organizations structure interaction (Leonardi, 2014). In flexible work settings, digital systems may therefore create either knowledge integration or knowledge fragmentation.

Transactive memory systems theory explains why expertise visibility is critical. Teams perform more effectively when members know who knows what and how to access relevant expertise (Lewis, 2003; Ren & Argote, 2011; Wegner, 1987). Flexible work may strengthen transactive memory by making expertise searchable across locations. It may also weaken transactive memory if employees have fewer opportunities to observe who solves problems, who is trusted, and who holds practical experience beyond formal job descriptions.

2.5 Knowledge governance in flexible work

Knowledge governance refers to the organizational mechanisms through which knowledge creation, sharing, transfer, and use are shaped by structures, routines, incentives, technologies, and managerial practices (Foss, Husted, & Michailova, 2010; Grandori, 2001; Heiman & Nickerson, 2004). This perspective is important because knowledge outcomes are not produced by flexible work arrangements alone. They depend on how organizations design the conditions for interaction, documentation, learning, and expertise coordination.

In flexible work contexts, knowledge governance becomes more important because informal coordination can no longer be assumed. Managers must decide which knowledge should be documented, which interactions require synchronous discussion, which learning processes require social exposure, and which tools should be used for different knowledge purposes. Governance therefore refers to deliberate knowledge design rather than excessive control.

This paper therefore defines knowledge governance for flexible work as the intentional design of social and technical mechanisms that make organizational knowledge visible, accessible, interpretable, and renewable across distributed work arrangements.

3 Methodology

This paper is designed as a conceptual academic research paper based on an integrative literature review and theory-building logic. A conceptual approach is appropriate when the aim is to clarify constructs, connect fragmented research streams, and develop propositions for future empirical research (Torraco, 2005; Whetten, 1989). The purpose is to develop a theoretically grounded framework explaining how flexible work changes the conditions under which organizational knowledge becomes visible, transferable, and renewable.

The review process was concept-driven rather than purely systematic. Literature was selected from five interrelated domains: flexible work arrangements, remote and hybrid work, knowledge management, organizational learning, and digital work technologies. Priority was given to peer-reviewed journal articles, recent post-pandemic studies, and foundational theoretical works that remain central to knowledge management and organizational learning. The inclusion logic followed three criteria. First, sources were included if they helped define flexible work as a multidimensional construct. Second, sources were included if they explained knowledge processes such as tacit knowledge transfer, knowledge sharing, situated learning, knowledge creation, and expertise coordination. Third, sources were included if they addressed mechanisms through which technology, distance, flexibility, or coordination affect knowledge visibility.

The analytical process involved four stages. The first stage was construct clarification. Flexible work arrangements were separated into spatial, temporal, and organizational flexibility in order to avoid treating flexibility as a single uniform variable (Allen et al., 2015; Kossek & Lautsch, 2018). The second stage was mechanism identification. The literature was examined to identify knowledge mechanisms that are likely to be affected by flexible work. Four mechanisms were selected as central to the framework: tacit knowledge transfer, digital and social visibility, transactive memory, and participation in learning communities.

The third stage was theoretical integration. Foundational knowledge theories were combined with contemporary digital work literature to explain different aspects of knowledge visibility: tacit and explicit knowledge (Nonaka, 1994; Nonaka & Takeuchi, 1995; Polanyi, 1966), situated learning and communities of practice (Brown & Duguid, 1991; Lave & Wenger, 1991; Wenger, 1998), digital affordances (Majchrzak et al., 2013; Treem & Leonardi, 2013), transactive memory systems (Lewis, 2003; Wegner, 1987), and knowledge governance (Foss et al., 2010; Grandori, 2001).

The fourth stage was framework development. The flexibility-knowledge visibility framework was developed by comparing the potential benefits of flexible work with the risks it creates for knowledge visibility. The resulting propositions are conditional rather than deterministic because the effects of flexibility depend on the form of flexibility, the nature of work, digital affordances, and knowledge governance mechanisms.

4 Conceptual Framework and Propositions

The conceptual framework explains how flexible work arrangements influence organizational knowledge visibility. It starts from the premise that flexible work does not directly determine knowledge outcomes; rather, it changes the socio-technical conditions under which knowledge is created, shared, interpreted, retained, and renewed.

The framework links three dimensions of flexibility - spatial, temporal, and organizational - to four knowledge mechanisms: tacit knowledge transfer, digital and social visibility, transactive memory, and participation in learning communities. These mechanisms shape outcomes such as knowledge integration, fragmentation, newcomer learning, innovation capacity, and organizational memory. Knowledge governance is positioned as the key moderating condition because it determines whether flexible work is supported by routines, technologies, and managerial practices that preserve knowledge visibility (Foss, Husted, & Michailova, 2010; Grandori, 2001; Heiman & Nickerson, 2004). The proposed framework is summarized in Table 1.

Table 1: Flexible work dimensions and knowledge governance responses

Flexible work dimension	Knowledge risk	Core mechanism	Governance mechanism
Spatial flexibility	Loss of tacit learning	Reduced observation	Mentoring, shadowing, purposeful co-presence
Temporal flexibility	Weaker shared interpretation	Delayed feedback	Decision logs, feedback cycles, synchronous discussion
Organizational flexibility	Tool-based fragmentation	Dispersed knowledge systems	Integrated platforms, documentation standards
Flexible work dimension	Knowledge risk	Core mechanism	Governance mechanism
High task interdependence	Expertise opacity	Weaker transactive memory	Expert directories, project histories, communities of practice
Newcomer integration	Formal but shallow learning	Reduced peripheral participation	Hybrid onboarding, guided participation, real work exposure

Table 1 summarizes the central logic of the framework. Spatial flexibility threatens tacit learning, temporal flexibility affects shared interpretation, and organizational flexibility creates risks when digital tools multiply

information without preserving context. High task interdependence may weaken transactive memory, while newcomer integration becomes vulnerable when onboarding is detached from real work participation. These risks can be reduced through governance mechanisms that reconnect flexibility with observation, interpretation, documentation, expertise visibility, and situated learning.

The framework rests on three assumptions. First, flexible work is multidimensional and should not be collapsed into a single variable because spatial, temporal, and organizational flexibility affect different knowledge mechanisms (Allen, Golden, & Shockley, 2015; Hesselbarth, Alfes, & Festing, 2024). Second, knowledge visibility is not the same as information availability: digital tools may increase access to information while leaving meaning, context, and expertise unclear (Leonardi, 2014; Majchrzak, Faraj, Kane, & Azad, 2013). Third, the relationship between flexibility and knowledge outcomes is conditional. Flexible work may support knowledge integration when governance mechanisms are strong, but generate fragmentation when organizations rely on spontaneous knowledge flows under distributed conditions.

4.1 Spatial flexibility and tacit knowledge transfer

Spatial flexibility changes where work is performed and therefore affects access to proximity-based learning. In co-located settings, employees often learn by observing how experienced colleagues interpret problems, handle exceptions, and make situated decisions. This type of learning is central to tacit knowledge transfer because tacit knowledge is practical, experiential, and difficult to fully codify (Nonaka, 1994; Polanyi, 1966). When employees work remotely or in hybrid arrangements, these informal learning opportunities may become less frequent and less visible.

The risk is strongest where work requires judgement, exception handling, or high task interdependence. Since competence develops through participation in practice, not only formal instruction, reduced access to observation, shadowing, and informal correction may weaken practical knowledge transfer (Lave & Wenger, 1991).

Proposition 1: Spatial flexibility is more likely to weaken tacit knowledge transfer when work requires situated judgement, informal observation, and high task interdependence.

4.2 Temporal flexibility and shared interpretation

Temporal flexibility changes when employees work and how much time they share with colleagues. Flexible schedules and asynchronous collaboration may support autonomy and focused work, but they may also weaken shared interpretation. Knowledge sharing is not only the movement of information between individuals. It also involves questioning, clarification, feedback, and collective sensemaking (Nonaka & Takeuchi, 1995; Weick, 1995). When employees work at different times, misunderstandings may remain unresolved for longer and shared meanings may develop more slowly.

This does not imply that asynchronous work is ineffective. Rather, temporal flexibility requires explicit routines for interpretation. Routine updates may be asynchronous, but ambiguous problems, innovation work, conflict resolution, and learning processes often require richer interaction. Without such routines, formal communication may still produce fragmented understanding.

Proposition 2: Temporal flexibility is more likely to produce knowledge fragmentation when asynchronous work is not supported by explicit feedback routines, decision documentation, and shared interpretation practices.

4.3 Organizational flexibility and digital knowledge visibility

Organizational flexibility concerns how work is coordinated through structures, routines, roles, and digital technologies. In flexible work settings, digital platforms often become the main infrastructure for communication, coordination, and knowledge access. They can strengthen knowledge visibility by making communication persistent, searchable, and accessible across locations, but may also hide context, interpretation, and tacit reasoning (Leonardi, 2014; Treem & Leonardi, 2013).

For this reason, digital visibility should not be equated with knowledge visibility. A repository may contain information without showing why it matters, how it should be interpreted, or who can explain its practical use. Flexible work may therefore strengthen knowledge processes only when digital tools are supported by shared norms for documentation, interpretation, access, and ownership (Majchrzak et al., 2013).

Proposition 3: Digital tools strengthen knowledge visibility in flexible work only when they are supported by shared norms for documentation, interpretation, access, and knowledge ownership.

4.4 Transactive memory systems and expertise coordination

An important element of organizational knowledge is knowing who knows what. Transactive memory systems allow teams to coordinate distributed expertise by developing shared awareness of members' knowledge domains (Lewis, 2003; Wegner, 1987). Flexible work may support this process by making expertise searchable across locations. At the same time, it may weaken expertise visibility because employees have fewer opportunities to observe problem-solving, informal referrals, and trust-based expertise recognition.

This creates expertise opacity: relevant knowledge may exist, but employees may not know where it resides or whom to consult. Because formal job titles and digital profiles rarely capture practical expertise, expertise visibility requires both technical infrastructure and social interaction.

Proposition 4: Flexible work is more likely to weaken transactive memory when expertise is not made visible through social interaction, transparent project histories, and accessible knowledge networks.

4.5 Knowledge governance and organizational outcomes

The framework proposes knowledge governance as the key condition linking flexible work to organizational knowledge outcomes. Knowledge governance refers to the intentional design of structures, technologies, routines, and managerial practices that shape knowledge creation, sharing, transfer, and use (Foss et al., 2010; Grandori, 2001). In flexible work contexts, governance becomes especially important because informal knowledge flows can no longer be assumed to arise from regular co-presence.

Knowledge governance should not be understood as excessive control. Its purpose is to make knowledge visible and usable by defining which interactions require synchronous discussion, how decisions are documented, where knowledge is stored, how newcomers access practice, and how expertise is made visible. When these mechanisms are absent, flexibility may increase individual autonomy while weakening collective knowledge visibility. When deliberately designed, flexible work may preserve autonomy while strengthening knowledge integration.

Proposition 5: Flexible work arrangements are more likely to support knowledge creation, sharing, retention, and renewal when organizations adopt deliberate knowledge governance mechanisms rather than relying on spontaneous knowledge flows.

5 Discussion and Implications

The framework developed in this paper contributes to the literature by reframing flexible work as a knowledge visibility problem. Existing research has mainly examined flexible work through individual outcomes such as autonomy, job satisfaction, wellbeing, productivity, and work-life balance (Allen et al., 2015; Gajendran & Harrison, 2007; Kossek & Lautsch, 2018). This paper extends that discussion by showing that flexible work also changes the organizational conditions under which knowledge is observed, interpreted, transferred, and renewed.

The first theoretical contribution is the separation of flexible work into spatial, temporal, and organizational flexibility. This distinction responds to the limitation of treating flexibility as a uniform arrangement. Spatial flexibility changes access to observation and informal learning; temporal flexibility changes feedback cycles and shared interpretation; organizational flexibility changes the technological and managerial infrastructure through which knowledge is coordinated. This provides a more precise basis for analysing flexible work outcomes and avoids deterministic claims that flexibility is either inherently beneficial or harmful.

The second contribution is the concept of knowledge visibility. Knowledge visibility refers not only to whether information is stored or accessible, but whether employees can understand its meaning, locate relevant expertise, and participate in the social processes through which knowledge becomes useful. This distinction matters because flexible work may increase documentation while still reducing shared understanding. Organizations may therefore appear knowledge-intensive at the level of digital records while becoming less knowledge-integrated at the level of practice. The broader theoretical contribution is the integration of knowledge management, digital work, and organizational learning perspectives into a single framework of flexible work as a socio-technical knowledge condition.

Managerially, organizations should not govern flexible work only through attendance rules or productivity indicators. They should also ask whether knowledge is visible, transferable, and interpretable. Knowledge governance should include critical knowledge mapping, decision logs, documentation standards, feedback routines, mentoring, guided newcomer participation, and communities of practice.

These implications are especially relevant for hybrid organizations. Flexible work may function well for experienced employees who already understand organizational routines, informal systems, and expertise

networks. The same arrangement may be more difficult for newcomers, cross-functional teams, or employees working on ambiguous and interdependent tasks. Flexible work policies should therefore be differentiated according to task interdependence, knowledge intensity, employee experience, and the degree of tacit knowledge involved.

The propositions provide a basis for future empirical research. Future studies could test whether spatial flexibility has stronger effects on tacit knowledge transfer in interdependent teams, whether decision logs and mentoring reduce knowledge fragmentation, and whether newcomer learning differs between formal onboarding and situated participation in hybrid work contexts.

6 Conclusions

This paper developed a conceptual framework explaining how flexible work arrangements reshape organizational knowledge visibility. The central argument is that flexible work should be understood not only as a matter of autonomy, productivity, or location choice, but also as a knowledge governance issue.

The paper contributes by distinguishing between spatial, temporal, and organizational flexibility and by explaining how each dimension affects different knowledge mechanisms. Spatial flexibility may reduce access to tacit learning and informal observation. Temporal flexibility may weaken shared interpretation when feedback and clarification are delayed. Organizational flexibility may strengthen digital traceability but may also produce tool-based fragmentation when information is dispersed without clear meaning or ownership. These effects depend on task interdependence, digital affordances, learning access, expertise visibility, and knowledge governance.

The proposed framework advances knowledge visibility as a bridge between flexible work and knowledge management research. Flexible work can support sustainable and knowledge-intensive organizations, but only when autonomy is matched with governance mechanisms that protect tacit learning, shared interpretation, expertise visibility, and newcomer participation.

7 Ethics declaration

This paper is conceptual and does not report empirical research involving human participants, personal data, or organizationally identifiable data. Therefore, ethical clearance was not required.

8 AI declaration

The Possible Effects of Digital Transformation on Social Enterprises and NGO

Maria Vittoria Prudentino, Paola Canestrini, Federica Bandini
University of Bologna. Bologna, Italy

Abstract

Existing research offers limited insight into how digital transformation unfolds in Social Enterprises (SEs). This study examines what drives SEs to engage in digital transformation, the facilitating and hindering factors, and work-related risks. Drawing on a theoretical framework integrating Dynamic Capabilities, Digital Social Innovation enablers and barriers, and Corporate Digital Responsibility, it adopts a qualitative multi-method case study based on a group interview and a focus group with managers from Italian SEs. The findings show that digital transformation is filtered through SEs' anthropocentric orientation. In the SEs studied, it is triggered by concrete organizational and social needs and leads to a reconfiguring process tailored to mission preservation. More specifically, digital transformation unfolds through processes of sensing, seizing, and reconfiguring, in which organizations identify unmet social and organizational needs, adopt technologies through gradual and context-sensitive approaches, and adapt internal structures, competences, and external partnerships over time. Digital transformation depends on a combination of human, organizational, and environmental factors, with hybrid competences, bottom-up experimentation, and ecosystem collaboration emerging as key enablers, while resource constraints, uneven digital literacy, and resistance to change pose obstacles. These barriers are not only structural but also reflect concerns related to service quality, inclusion, and mission coherence. The implications of digital transformation for work are actively filtered through mission-oriented values and responsibility-oriented practices, while digital technologies are predominantly framed as tools for mission augmentation rather than work substitution. In this respect, digital transformation in SEs appears to be governed through embedded responsibility-oriented logics, which shape how risks such as dehumanization and job displacement are anticipated and managed. Overall, the study contributes to research on digital transformation by showing how anthropocentric, mission-driven organizations interpret and enact digital change. It also suggests that other sectors may learn from SEs that maintaining a human-centered approach can help mitigate ethical and organizational risks associated with digital transformation.

1 Introduction

Management studies identify Digital Transformation (DT) as one of the crucial and most pervasive challenges of recent decades (e.g. He et al., 2020; Brown et al., 2024). Moving beyond a technology-centric view, this literature emphasizes the organizational and human foundations of DT, including digital skills development, internal capability building (D'Angelo et al., 2024), and workforce arrangements (Dong et al., 2025). Social Enterprises (SEs) are as well increasingly engaging in DT (Yáñez-Valdés et al., 2023). Positioned at the intersection of market, public policies, and civil society (Nyssens, 2006), they respond to collective needs through socially oriented products, services, and models (Bandini, 2016; Defourny and Nyssen, 2017; Murray et al., 2010), thereby generating social innovation (Sottini et al., 2025). Despite this growing interest, studies on DT in SEs remain scarce. This is relevant because SEs are human-centered and mission-driven organizations (Vickers et al., 2025), where the implications of digital technologies for beneficiaries, workers, and communities are particularly salient.

While initial studies have begun to explore DT in SEs (Fan et al., 2025), knowledge of its organizational and ethical dimensions remains limited. Also, the ethical implications, particularly regarding labor, of DT within SEs remain underexplored compared to other sectors (Hanelt et al., 2021; Maiolini et al., 2025).

Hence, this study addresses the following research questions:

- *RQ1a: "What drives social enterprises to undertake digital transformation and how do they implement it at the organizational level?"*
- *RQ1b: "What are the enabling factors and obstacles SEs face in undertaking digital innovations?"*
- *RQ2: "How does digital transformation affect work in social enterprises, and how are potential risks of job loss and dehumanization addressed?"*

This research adopts three theoretical lenses. For RQ1a, the Dynamic Capabilities (DCs) (Teece, 1997; 2007). For RQ1b, frameworks on Digital Social Innovation (Buck et al., 2025; Buonocore et al., 2024). For RQ2, Corporate

Digital Responsibility (Lobschat et al., 2021). The study adopts a qualitative multi-method case study design (Yin, 2014), combining a group interview and a follow-up focus group with Italian SE managers.

The originality of this study lies in identifying how DCs unfold in SEs' DT, uncovering SE-specific enabling and hindering factors, and showing how their human-centered orientation limits risks of job loss and dehumanization. These findings suggest that the SE model may offer insights transferable beyond the sector.

2 Literature Review

Digital innovation refers to the use of digital technologies to develop new products, processes, and business models, reshaping organizational structures and capabilities and constituting DT (Nambisan et al., 2017; Hinings et al., 2018; Mergel et al., 2019; Hanelt et al., 2021; Nadkarni et al., 2021; Vial, 2019). In SEs, research has primarily examined digitalization through social innovation, highlighting how digital technologies support solutions to unmet social needs and enable collaboration across actors (Murray et al., 2010; Moulaert et al., 2013; Grassi and Toschi, 2021; Sottini et al., 2025; Qureshi et al., 2021; Yáñez-Valdés et al., 2023). SEs generate broader value-creation dynamics and rely on diverse technologies—from ICTs to AI—to support inclusion and service delivery (Gregori and Holzmann, 2020; Del Giudice et al., 2019; Bobsin et al., 2018; Sansone et al., 2023; Jong and Ganzaroli, 2023; Chen and Wang, 2024; Duong et al., 2025; Faludi, 2023; Turja et al., 2020). However, existing research focuses mainly on what technologies enable, offering limited insight into how transformation unfolds in anthropocentric organizations.

Prior studies identify enabling and constraining factors, including institutional conditions and digital infrastructure (Galindo-Martín, 2023; Li, 2023; Bhattacharyya, 2021; Vaño, 2025), as well as organizational challenges such as skill gaps and resource constraints (Sansone et al., 2023; Buonocore et al., 2024). Enabling factors span human, organizational, and environmental dimensions (Buck et al., 2025), while key challenges include technological change, stakeholder alignment, impact measurement, regulatory uncertainty, ethical dilemmas, and scalability (Buonocore et al., 2024).

DT also entails risks, including job displacement, dehumanization, and broader societal inequalities (Parasuraman and Riley, 1997; Khogali and Mekid, 2023; Cattaneo et al., 2025; Puntoni et al., 2020; Gursoy et al., 2025; Bircan and Özbilgin, 2025; Rothe et al., 2022). Digital technologies can simultaneously enable value creation and generate unintended consequences related to care services, data use, and AI (Čaić et al., 2018; Breidbach and Maglio, 2020; Zuboff, 2015; Madianou, 2021), raising concerns about exclusion, privacy, and misalignment with societal needs (Van Holstein et al., 2021; Zamani and Vannini, 2025; Shankar, 2024; Vaño, 2025). In this context, SEs' anthropocentric nature is crucial: they prioritize social value creation and relational well-being (Mair and Martí, 2006; Zahra et al., 2009; Smith et al., 2013; Santos, 2012; Dacin et al., 2010; Shepherd et al., 2023; Kummitha, 2025; Brieger et al., 2020), making responsible digital innovation a fundamental requirement.

3 Theoretical Framework

This study is structured around three research questions, each linked to a specific theoretical lens. For RQ1a we draw on Dynamic Capabilities (DCs) (Teece et al., 1997; Teece, 2007) conceptualize how organizations adapt through sensing, seizing, and reconfiguring, and have been applied to markets, public organizations, SEs, and DT (e.g. Piening, 2013; Vézina et al., 2018; Vallaster et al., 2019; Ince and Hahn, 2020; Bhardwaj et al., 2021; Pirotti et al., 2021) as well as to DT (Ellström et al., 2021; Chen et al., 2022; Kowalski et al., 2024; De La Torre and De La Vega, 2025) although their application to SE DT remains limited. For RQ1b, the study draws on Digital Social Innovation frameworks (Buck et al., 2025; Buonocore et al., 2024) to examine enabling and hindering factors of DT in SEs. Finally, for RQ2, Corporate Digital Responsibility (Lobschat et al., 2021) is used to analyze how organizations govern digital technologies through shared values, norms, and practices (Elliott and Copilah-Ali, 2024; Gursoy et al., 2025; Wirtz et al., 2022; Kummitha, 2025; Vaño, 2025; Gigauri et al., 2023; Zhou et al., 2025).

4 Methodology and Research Context

This study adopts a qualitative case study design (Yin, 2014) based on a group interview (Frey and Fontana, 1991) followed by a focus group (Morgan, 1996) with managers of Italian SEs. Participants were selected through purposive, criterion-based sampling to ensure information-rich cases (Saunders and Townsend, 2016; Plakoyiannaki and Budhwar, 2021). The sample included six participants from four SEs and, while not intended to be representative, provided sufficient depth for the exploratory aims of the study. The sequential use of the two methods enabled triangulation and cross-validation of findings (Jick, 1979; Eisenhardt, 1989; Christofi et al., 2024), as well as a more reflexive interpretation of participants' accounts (Robinson and Kerr, 2015). Data were

audio-recorded, transcribed verbatim, and analyzed using a hybrid inductive–deductive approach (Gioia et al., 2013; Strauss and Corbin, 2014; Saldaña, 2016). Initial open coding was followed by theory-driven analysis. Additional details on the research protocol, participant characteristics, interview guidelines, and coding procedures are available from the authors upon request.

Italy was selected as the empirical context due to its pioneering role in the development of SEs (Poledrini and Tortia, 2020; Defourny and Nyssens, 2010), particularly social cooperatives (Thomas, 2004). At the European level, SEs are increasingly recognized as key actors in the digital transition (European Commission, 2021; 2022; 2023), although empirical evidence confirms that Italian SEs still mainly rely on basic technologies, while advanced tools remain marginal (0.9%–9.8%) (ISTAT, 2021). Key barriers include limited financial resources, low digital culture, shortages of qualified personnel, and limited investment in innovation and training (ISTAT, 2021), in line with broader European trends (European Commission, 2023).

5 Findings and Discussion

DT in the SEs analyzed unfolds through sensing, seizing, and reconfiguring processes, consistent with prior research (Hinings et al., 2018; Hanelt et al., 2021; Nadkarni et al., 2021; Teece, 1997; 2007), but with a mission-oriented character. In the sensing phase, transformation is driven by concrete organizational and social needs rather than technological imperatives. Organizations assess internal inefficiencies, staff workload, and unmet social needs, extending beyond market-oriented opportunity recognition to include relational service quality and beneficiaries' well-being (Bhardwaj et al., 2021; Pirotti et al., 2021). In the seizing phase, technologies are introduced to improve efficiency and service quality by automating non-relational tasks and reallocating resources toward higher-value activities: "all administrative and bureaucratic aspects (…) can undergo processes of automation simplification, and digitalization(…) making it possible to redirect investments toward roles that generate higher added value". At the same time, they support users and staff, particularly in care contexts: "technology makes it possible to move beyond pharmacological approaches and improves the psychophysical well-being not only of service users but also of caregivers". Transformation is implemented gradually and through bottom-up processes rather than top-down imposition: "it is not technology that has to fit into the organization; rather, the organization must be able to open up and understand where technology can actually be adopted". Training and skill development emerge as central, alongside the attraction of specialized competencies (D'Angelo et al., 2024). The reconfiguring phase involves longer-term changes, including process revision, cultural adaptation, and competence development: "digital transformation is a long-term process (… that) affects organizational processes and people". It also includes strengthening external partnerships and, in some cases, governance transformation. Overall, these findings extend DCs applications to SEs (Piening, 2013; Vézina et al., 2018; Ince & Hahn, 2020; Fan et al., 2025), showing that capabilities are enacted through a dual orientation of adaptation and mission preservation.

DT is further shaped by human, organizational, and environmental conditions (Qureshi et al., 2021; Yáñez-Valdés et al., 2023; Buonocore et al., 2024; Buck et al., 2025). At the human level, hybrid competences combining technical, relational, and "translational" abilities enable alignment between technological and social needs (D'Angelo et al., 2024), while cultural resistance and limited digital literacy represent key barriers, as staff may "do not understand why a way of working that had worked until the day before needs to be changed". At the organizational level, mission alignment, identity, data use, and bottom-up experimentation act as enablers, whereas resource constraints significantly limit investments: "the first and main obstacle is the resource constraint, and some smaller organizations are not even able to overcome this initial barrier". Limited access to funding further reinforces these constraints. At the environmental level, collaboration with partners and beneficiary integration support innovation, while opportunity sensing and societal problem understanding enable meaningful applications. Data emerge as both enablers and challenges due to cybersecurity and management issues. These findings suggest that enabling and hindering factors are not merely structural but are organizationally interpreted, reflecting concerns related to service quality and mission coherence, while collaboration and experimentation extend prior work on SE value creation (Gregori & Holzmann, 2020; Del Giudice et al., 2019).

Finally, DT in SEs is grounded in shared values, norms, and practices oriented toward human agency. In high-relational contexts, technology is framed as support rather than substitution: "in the Social Economy, there is no risk of substitution because many activities have a strong relational component. Technology plays a role of augmentation rather than substitution". This aligns with the mission-driven nature of SEs (Ebrahim et al., 2014; Molecke & Pinkse, 2020; Fan et al., 2025; Vickers et al., 2025) and contrasts with broader concerns about job displacement and dehumanization (Parasuraman & Riley, 1997; Khogali & Mekid, 2023; Cattaneo et al., 2025; Zhou et al., 2025). At the level of norms, digital adoption is gradual and participatory, enabling workload

redistribution: “Digital technologies can be used to improve process efficiency by trying to free up resources from repetitive activities where people do not add value”. This is accompanied by training and attention to data protection. At the level of practices, these principles translate into concrete behaviors: “training is necessary to prevent a disconnect between staff and the organization” [A1], while “beyond technological facilitation, there is human facilitation”. Overall, these findings extend the CDR framework (Lobschat et al., 2021) by showing that responsibility is embedded ex ante in SEs, where DT is governed through participatory and mission-oriented practices.

6 Conclusion and Implication

This study examined how SEs undertake digital transformation, which factors enable or hinder this process, and how work-related risks are addressed in an anthropocentric organizational context. By combining a group interview and a focus group with Italian SE managers, it offers an exploratory but theoretically grounded account of digitalization as a process concerned not only with efficiency, but also with mission delivery and the protection of relational forms of work. The study highlights that digital competence in SEs should be understood holistically, as both technical proficiency and the organizational ability to mobilize skills, exercise judgment, and govern digital technologies consistently with social mission and stakeholder responsibilities (D’Angelo et al., 2024; Blanka et al., 2022; Fan et al., 2025; Lobschat et al., 2021).

The findings also suggest that higher education institutions can support SEs by fostering integrated digital skill development combining technical, ethical, and relational dimensions. From a policy perspective, they point to the need for partnerships among universities, public bodies, and SEs, dedicated financial support for digitalization, and monitoring of social impacts to ensure mission-consistent outcomes. More broadly, the SE context offers insights for organizations seeking digital transformation without compromising human agency, inclusion, and relational value.

The study has limitations: anthropocentric values may mitigate risks of dehumanization and job displacement, but such risks may not be absent in the long term; the small qualitative sample supports analytical insight rather than generalization; and managerial perspectives may underrepresent frontline workers, beneficiaries, and technology partners. Future research could adopt longitudinal, comparative, and multi-actor designs to examine how sensing, seizing, reconfiguring, and responsibility-oriented practices evolve across contexts, and how digital topics are integrated into SE training programs.

Abstract

The aging population is a major systemic challenge of the 21st century, reshaping healthcare demand, organizational structures, and knowledge dynamics. In highly aged countries like Japan, demographic pressures expose fragmentation in care pathways and the limits of purely structural or technological solutions. This paper sees Knowledge Management (KM) and Relational Capital (RC) are strategic assets that enable healthcare organizations to turn aging from a liability into a catalyst for learning, coordination, and innovation.

The study examines the interplay between KM and RC within a university-hospital ecosystem, specifically analyzing Kansai Medical University (KMU) and its affiliated hospital in Japan. It employs an Interventionist Research approach, using six months of participant observation, institutional documentation, and interviews to deepen the integration of knowledge translation into routine organizational processes.

The results indicate that KMU functions as a relational nexus where clinical, organizational, and community knowledge converge. Formal procedures, such as interprofessional rounds, digital repositories, and structured training, enhance knowledge generation and dissemination, whereas informal, trust-based networks promote the exchange of tacit knowledge. Collectively, these processes strengthen coordination, resilience, and continuity of care in response to population shifts.

The study emphasizes that traditional Japanese caregiving concepts are culturally ingrained in senior care, yet are increasingly implemented through modern knowledge and relational frameworks. In this setting, RC links hospital services with community-based care, facilitating integrated models in which clinical transitions are processes of knowledge translation supported by relational continuity.

Digital technologies, such as telemedicine, digital platforms, and AI-driven tools, augment these dynamics by improving service delivery and enabling trust-based interactions in virtual settings. Nonetheless, the research shows that technology is effective only when integrated within robust relational and knowledge frameworks, functioning as an enabler rather than a replacement.

The university serves as a pivotal coordinator of the healthcare knowledge ecosystem, integrating education, research, and care delivery while ensuring the stability of knowledge flows across many stakeholders. The study proposes the relational hub as an empirically grounded configuration that renders KM and RC observable and actionable within healthcare ecosystems. It implies that effective responses to aging require organized knowledge-sharing systems, intentional development of research collaborations beyond hospital confines, and a university-led coordination role to promote innovation.

Keywords: Knowledge Management; Relational Capital; Aging Population; Healthcare Ecosystems; Interventionist Research

Paper type: Academic Research Paper

1 Introduction

The aging population poses a significant systemic challenge for healthcare systems in the twenty-first century. Rising life expectancy, chronic illnesses, and multimorbidity heighten the need for long-term, integrated care while revealing organizational fragmentation, workforce shortages, and coordination challenges. Japan is a particularly salient context because its demographic profile exposes the tensions between rising care demands and the sustainability of healthcare provision earlier than in many other nations (Bratianu et al., 2024; Sudo et al., 2018).

The primary challenge lies in both clinical capacity and the ability to generate, disseminate, and use knowledge across professional and organizational boundaries. KM is crucial for converting fragmented information into actionable insights, enhancing decision-making, and fostering innovation in complex care environments (Abubakar et al., 2019; El Morr and Subercaze, 2010; Nonaka et al., 1996; Tsoukas and Vladimirou,

2001). Healthcare organizations often struggle to integrate specialized expertise, standardized processes, and patient data in a cohesive way. This is especially vital in geriatric care, where continuity depends on collaboration among hospitals, primary care providers, rehabilitation agencies, families, and communities.

RM enhances KM by fostering trust-based relationships, institutional collaborations, and cooperative practices that facilitate knowledge dissemination and coordinated efforts. The dynamics of senior care in Japan are shaped by cultural values of self-help (Ji-jo), mutual aid (Go-jo), social solidarity (Kyo-jo), and government care (Ko-jo), which continue to inform community-based care arrangements (Hatano et al., 2017; Sudo et al., 2018). At the same time, digital technologies are expanding opportunities for knowledge dissemination, telemedicine, and remote coordination; yet their effectiveness depends on integration within comprehensive knowledge ecosystems (Bagnoli et al., 2019; Biancone et al., 2021; Ito et al., 2017; Song, 2024).

This research examines how KM and resource coordination jointly enhance healthcare responses to aging, using KMU and its affiliated hospital as a case study. The university is viewed not merely as an educational entity but as a facilitator of a multifaceted knowledge ecosystem that integrates care, research, training, and community participation (Granstrand and Holgersson, 2020; Massaro et al., 2022; Secundo et al., 2018; Thomas et al., 2021).

This study examines the following research question:

RQ: Which knowledge management and resource coordination solutions are most effective in addressing the issues posed by an aging population within a healthcare ecosystem?

2 Literature Review

Healthcare is inherently knowledge-intensive. Clinical practice relies on established evidence, professional knowledge, experiential learning, and ongoing assessment of patient situations. Consequently, KM in healthcare transcends mere information storage; it encompasses the processes of knowledge creation, sharing, translation, and application to enhance care and organizational performance (Abubakar et al., 2019; El Morr and Subercaze, 2010; Nonaka et al., 1996; Tsoukas and Vladimirou, 2001). The significance of KM in aged care increases because patients frequently have multiple comorbidities, longer care trajectories, and a need for coordinated interventions over time. Knowledge translation is essential to connect evidence, professional competencies, and practical care practices (Bratianu et al., 2024; Dal Mas et al., 2020).

The literature indicates that knowledge processes in healthcare are seldom efficient when conducted in isolation. They rely on relationships that facilitate collaboration among various stakeholders, especially physicians, nurses, therapists, administrators, patients, and caregivers. RC denotes the value produced by trust-based relationships and the networks that facilitate the transfer of information across organizational borders. In healthcare ecosystems, RC enhances co-production, fosters coordination, and advances patient-centered integration (Cobianchi et al., 2022; Hatano et al., 2017; Zamboni et al., 2024). Relational structures are integral to KM; they are essential for the circulation of tacit information and the appropriate interpretation of codified knowledge.

Digital transformation adds a new dimension to these processes. Telemedicine, e-health platforms, remote monitoring, and AI-assisted technologies can expedite diagnosis, enhance accessibility, and expand the data available for clinical decision-making (Bagnoli et al., 2019; Biancone et al., 2021; Ito et al., 2017). Nonetheless, large volumes of data do not inherently become valuable knowledge. Their value depends on organizational practices that enable interpretation, dissemination, and appropriate use (Obenshain, 2004; Song, 2024; Wickramasinghe et al., 2009). From a KM perspective, digitization facilitates knowledge transfer rather than replacing human discernment and relationship continuity.

An expanding body of research highlights the significance of universities within knowledge ecosystems. Universities produce scientific knowledge, educate professionals, and increasingly serve as intermediaries linking many stakeholders in innovation processes (Granstrand and Holgersson, 2020; Massaro et al., 2022; Secundo et al., 2018; Thomas et al., 2021). In healthcare, the orchestration function is particularly pertinent given demographic aging, which necessitates ongoing education, interdisciplinary training, and aligning hospital procedures with community needs. Nonetheless, empirical research demonstrating the interaction between KM and resource capabilities in daily organizational routines to tackle aging-related difficulties remains scarce. This paper addresses that gap through an interventional case study of KMU.

3 Methodology

The study adopts interventionist research (IVR), a qualitative approach that combines theoretical ambition with close engagement in organizational settings. IVR is particularly appropriate when the objective is to understand how knowledge processes unfold in practice and how actors make sense of organizational issues

while responding to them in real time (Lukka and Wouters, 2022). The approach also allows the researcher to alternate between an insider position, needed to observe routines and interactions, and an outsider perspective, useful for linking empirical observations to broader conceptual debates.

The empirical setting is the KMU complex in Hirakata, Osaka Prefecture, comprising the university campus and the affiliated university hospital. KMU was selected because it combines advanced medical specialization, strong links with the local healthcare network, and a clear educational mission. Its institutional identity, grounded in the principle of Jijinshinkyo (benevolence, compassion, and empathy) is reflected in a broader medium-term vision that connects education, research, healthcare delivery, rehabilitation, business management, and social contribution. This makes KMU a particularly suitable setting for examining how knowledge and relationships are orchestrated in response to demographic aging.

Data collection lasted six months and involved three complementary sources. First, participant observation enabled the researcher to follow meetings, lectures, inter-professional interactions, and everyday practices across the KMU ecosystem. Second, institutional documentation and public materials were analyzed to reconstruct organizational structures, strategic priorities, and partnership development. Third, semi-structured interviews with key stakeholders were conducted to validate emerging interpretations and to explore how actors understood the roles of KM, RC, and digital transformation in elderly care. Data analysis followed an iterative logic, moving back and forth between field evidence and the KM literature to identify recurring patterns of knowledge creation, knowledge translation, coordination, and ecosystem orchestration.

4 Findings

The analysis shows that KMU functions as a relational hub where clinical, organizational, and community knowledge converge. The rising incidence of chronic and age-related conditions, including stroke, cardiovascular diseases, and neurodegenerative disorders, pressures not only clinical services but also the ability to circulate knowledge across departments. In this environment, elderly care depends on how quickly lessons learned in one unit can inform decisions in another. Knowledge sharing is therefore embedded in routines such as interdepartmental meetings, case discussions, and coordinated transitions between acute care and follow-up services.

Formal KM mechanisms play a central role in this process. Interprofessional rounds, shared repositories, and regular training activities create spaces where codified knowledge can be updated and disseminated, while also allowing professionals to collectively interpret the implications of new cases. These routines strengthen the hospital's absorptive capacity by making it possible to recognize relevant knowledge, integrate it into practice, and adapt it to local needs. At the same time, tacit knowledge remains essential. Informal exchanges among doctors, nurses, pharmacists, therapists, and support staff transmit experiential insights that cannot be fully captured in protocols but are fundamental for elderly patients whose conditions evolve over time and often require nuanced judgment.

RC makes these knowledge processes durable across institutional boundaries. Field evidence indicates that the traditional Japanese principles of Ji-jo, Go-jo, Kyo-jo and Ko-jo are not only cultural values but also organizing principles that sustain continuity of care. At KMU, the transfer of elderly patients from the acute hospital to local facilities, rehabilitation services and home-based care is treated as a knowledge translation process: information, clinical reasoning and responsibility are transferred together. Trust among KMU, smaller hospitals, clinics and community actors enable this circulation of knowledge and reduces the risk of fragmentation. Home care, visiting nursing and rehabilitation services therefore appear as extensions of the hospital's knowledge network rather than as separate domains.

Digital technologies expand, but do not replace, these relational and knowledge infrastructures. KMU is investing in telemedicine, AI-assisted diagnostics, remote monitoring and mobile hospital services able to reach peripheral areas. These tools extend the visibility of patient conditions and create new opportunities for coordination, especially for older adults with mobility constraints or limited family support. Yet their contribution is meaningful only when data are interpreted collectively, embedded in clinical routines and linked to trusted channels of communication. In this sense, digital transformation enhances virtual relational capital by connecting patients and professionals at a distance, but it remains dependent on the human and organizational conditions of KM.

The university dimension is decisive in stabilizing these mechanisms over time. KMU does not simply provide clinical services; it educates students, residents, and young doctors, recruits many of its own graduates, and organizes continuous learning through research centers, simulation activities, and interdisciplinary training. This educational role helps preserve knowledge continuity despite workforce turnover and regulatory constraints. It also supports the development of shared geriatric competencies across professions, which is essential in a

context where elderly care cannot be managed through narrow specialization alone. Community engagement initiatives and international collaborations further expand the ecosystem, positioning KMU as a platform through which local and global knowledge can be connected.

5 Discussion

This paper analyzed the role of KM and RC in addressing demographic aging in the healthcare sector, using the case study of KMU in Japan. The findings indicate that successful aged care depends on the ability to synchronize the generation, sharing, and translation of knowledge among hospital departments, community partners, and digital platforms. RC facilitates these processes by maintaining trust-based teamwork and continuity of care, while the university functions as an orchestrator that aligns education, research, and service delivery.

This research enhances KM literature by emphasizing the strategic importance of knowledge infrastructures in senior care and by defining the relational hub as the organizational framework through which KM and RC are operationalized. It also offers practical insights for healthcare managers and policymakers: demographic aging should be addressed through system-wide knowledge initiatives rather than discrete technology or structural interventions.

The study has limitations. It is based on a single case and employs a qualitative, interpretive framework. Future research may analyze various healthcare ecosystems, assess the long-term effects of specific KM strategies, and investigate how digital tools transform knowledge governance in aged care across diverse institutional contexts.

6 Ethics Declaration

Under the applicable institutional requirements for this study, formal ethical clearance was not required. The research was based on participant observation in organizational settings, analysis of institutional documentation and semi-structured interviews focused on professional roles and organizational practices. Participation was voluntary, participants were informed about the purpose of the study, and informed consent was obtained before data collection.

7 AI Declaration

AI tools were solely used to check language consistency, and not to generate new content.

Abstract

This study examines the ethical and behavioural implications of technology-enabled knowledge management (KM) systems, challenging the dominant view of digital technologies as neutral tools that merely facilitate knowledge processing. Instead, it conceptualises KM systems as sociotechnical infrastructures that actively shape how knowledge is produced, shared, evaluated, and legitimised within organisations. Building on insights from the knowledge management, organizational behaviour, and information systems literature, this study develops an integrated conceptual framework that links technological design features to employee behaviour and knowledge-sharing outcomes through embedded ethical risks.

Adopting an integrative and theory-building methodology, this research synthesises interdisciplinary literature to identify recurring mechanisms through which digital KM infrastructures influence organisational dynamics. The analysis highlights three interrelated dimensions of ethical risk: (1) surveillance and visibility, (2) control and standardisation, and (3) power asymmetries and transparency. These dimensions are conceptualised as embedded governance mechanisms that regulate not only the flow of knowledge but also the behavioural and epistemic conditions under which employees engage in knowledge-sharing practices.

The findings show that increased visibility and traceability, while enhancing coordination and accountability, may reduce psychological safety when associated with monitoring and evaluation, leading to self-censorship and selective participation. Similarly, standardisation and codification processes tend to privilege explicit and measurable knowledge, contributing to epistemic narrowing and limiting organisational knowledge diversity. Finally, algorithmic opacity and information asymmetries undermine perceptions of procedural fairness and organisational trust, weakening employees' willingness to contribute. These dimensions interact to produce reinforcing effects that encourage defensive behaviours, such as knowledge hiding and risk-averse participation, ultimately constraining organisational learning.

By linking these technological features to micro-level mechanisms, such as trust, intrinsic motivation, perceived fairness, and psychological safety, this study demonstrates that ethical risks are not external constraints but endogenous components of KM systems that shape knowledge-sharing outcomes. This study advances four theoretical propositions that explain how these mechanisms operate individually and in combination.

This study contributes to KM theory by integrating behavioural and ethical perspectives into the analysis of digital infrastructures, reframing KM systems as instruments of knowledge governance. It also provides practical implications, suggesting that organisations should prioritise transparency, participatory design, and psychologically safe environments to foster more inclusive and sustainable knowledge-sharing practices.

Paper type: Academic Research Paper

1 Introduction

In contemporary organisations, digital technologies increasingly function as core infrastructure through which knowledge is produced, circulated, evaluated, and institutionalised (Karasti et al., 2016). Knowledge management (KM) systems, collaborative platforms, algorithmic decision-support tools, and AI-based repositories no longer merely support knowledge-related activities; they actively contribute to shaping how knowledge is rendered visible, legitimate, and actionable within organizational contexts (Dipasquale et al. 2024).

Despite this growing centrality, much of the KM literature has traditionally conceptualised technology as an enabling and largely neutral instrument, emphasising its potential to enhance efficiency, innovation, and organizational learning (Yan et al., 2025). While this instrumental perspective has been analytically productive, it tends to underplay how the integration of digital technologies into everyday knowledge practices reconfigures the conditions under which knowledge is produced and used within organizations.

Research on organizational behaviour and information systems suggests that technologies do not operate in isolation from social contexts but interact with norms, expectations, and behavioural patterns within organisations (Mueller et al., 2016). From this perspective, digital knowledge infrastructures shape not only the circulation of knowledge but also the conditions under which it is shared, evaluated, and recognised within organizational settings. However, despite the growing recognition of these dynamics across adjacent fields, their ethical and behavioural implications remain weakly integrated into mainstream KM theorising. Ethical concerns are often treated as secondary or normative add-ons rather than analytically relevant mechanisms shaping knowledge-related behaviours (Hong et al., 2023). As a result, the link between digital KM technologies, employee behaviour, and organizational learning outcomes remains insufficiently investigated. Against this backdrop, this study aims to critically examine technology-enabled KM systems as potential instruments of knowledge governance (Buuren, 2009), focusing on the ethical risks embedded in their design and use. Rather than framing ethics as an external constraint, this study conceptualises ethical risks as organizational features that operate endogenously, shaping employee behaviour, trust, and willingness to engage in knowledge sharing (Wang, 2016; Lin, 2007).

The primary objective is to develop an integrated conceptual framework that explains how ethical risks embedded in digital KM infrastructures influence key behavioural processes (Khanal, 2025) —such as perceived fairness, psychological safety, intrinsic motivation, and organizational trust — and, in turn, affect the quality and sustainability of knowledge sharing within organisations (Durst and Zieba, 2019). In doing so, this study advances a behaviourally grounded and organizationally informed understanding of technology-enabled KM, contributing to ongoing debates on the governance implications of digital knowledge infrastructures.

2 Theoretical Framing

In contemporary organisations, digital knowledge management systems operate as socio-technical infrastructures that shape how knowledge is shared, evaluated, and made actionable (Thomas, 2024), embedding behavioural and ethical implications within everyday work practices. These dynamics become particularly salient in knowledge-intensive settings, where knowledge sharing relies heavily on relational and psychological conditions such as trust, intrinsic motivation, and psychological safety (Lin, 2007; Wang, 2016). Prior research in organizational behaviour shows that when work practices become more visible, standardised, or subject to automated evaluation, employees tend to adjust their behaviours in ways that affect openness, voice, and willingness to contribute (Sherf et al., 2020).

Applied to technology-enabled KM systems, this suggests that increased traceability, codification, and algorithmic mediation may simultaneously support coordination while introducing new tensions into the social foundations of collective learning (Sánchez-Vera, 2025). On the one hand, digital infrastructures can enhance access to knowledge and organizational memory (Borgman et al., 2019); on the other hand, they may reshape how individuals perceive risks associated with sharing knowledge, how they interpret evaluation processes, and how they position themselves within organizational knowledge dynamics (Gibson et al., 2022).

This perspective highlights the need to move beyond a purely functional view of KM technologies and consider their role as organizational mechanisms that structure both behavioural responses and epistemic processes. In particular, technological features such as visibility and traceability, codification and standardisation, and algorithmic evaluation can be understood as distinct but interrelated dimensions through which digital infrastructures shape the production, interpretation, and valuation of knowledge within organisations (Alavi and Leidner, 2001; Turulja and Bajgoric, 2018).

3 Methodology

This study adopts an integrative conceptual approach aimed at theory development through a systematic synthesis of the existing literature. Rather than conducting a purely systematic review or narrative overview, this study follows an integrative logic that combines insights from multiple research streams to build a theoretically grounded framework (Bonte et al., 2024) on the ethical and behavioural implications of technology-enabled KM systems.

The literature selection process was guided by the objective of capturing interdisciplinary contributions relevant to the intersection of knowledge management, organizational behaviour, human resource management, and information systems. Seminal and recent studies were identified through targeted searches in major academic databases (i.e., Scopus and Web of Science), complemented by backward and forward citation tracking to ensure coverage of both foundational works (Hirt et al., 2021) and emerging debates on digital technologies and algorithmic governance in KM contexts (Turulja and Bajgoric, 2018).

Moreover, the selection of the proper works followed a relevance-based logic, focusing on contributions that explicitly addressed the role of digital technologies in shaping knowledge processes, employee behaviour, and organizational dynamics. Particular attention was paid to studies examining visibility, control mechanisms, algorithmic systems, and their implications for trust, motivation, and knowledge sharing.

The analytical process consisted of iterative and abductive readings of the selected literature to identify recurring themes, conceptual tensions, and underlying mechanisms. Through this process, the study identified three interrelated dimensions, surveillance and visibility, control and standardization, and power asymmetries and opacity, as key ethical risk areas embedded in digital KM infrastructures.

These dimensions were not derived inductively from a single stream of literature but emerged from the cross-fertilisation of insights across disciplines. Thus, framework development follows a theory-building logic, in which concepts and mechanisms are progressively integrated and refined to explain how technological features influence micro-level behavioural processes and, ultimately, knowledge-sharing outcomes.

By adopting this integrative approach, this study moves beyond the fragmented analyses of KM technologies and provides a coherent conceptual model that connects technological design, ethical risk, and organizational behaviour.

4 Findings

The literature review identifies three interrelated dimensions of ethical risk in technology-enabled KM systems. Rather than functioning solely as infrastructures for knowledge storage and exchange, these systems operate as sociotechnical arrangements that shape the behavioural, epistemic, and power conditions of knowledge sharing. The analysis highlights three key dimensions-surveillance and visibility, control and standardisation, and power asymmetries and opacity-which jointly configure how knowledge is produced, evaluated, and circulated within organisations. These dimensions do not act in isolation; instead, they function as embedded governance mechanisms that influence both the content of knowledge shared and the conditions under which employees are willing to contribute.

Surveillance and Visibility: Regulating Knowledge Sharing Behavior

Digital KM systems increasingly render knowledge-related activities visible, traceable, and auditable, thus transforming knowledge sharing into an observable organizational practice. This visibility enhances coordination and accountability by making expertise, contributions, and interactions more transparent (Varis et al., 2023). However, research consistently points to a fundamental visibility–behaviour paradox in this context.

When visibility is perceived as linked to monitoring or performance evaluation, employees engage in self-regulatory behaviours to minimise personal risk (Sherf et al., 2020). These include self-censorship, selective participation, and a preference for sharing “safe” and noncontroversial knowledge. Thus, knowledge sharing shifts from a collaborative activity to strategically managed behaviour shaped by concerns over reputation, evaluation, and potential misuse.

This dynamic undermines psychological safety and reduces the willingness to engage in voice behaviour, with potential consequences for knowledge diversity and organizational learning. In this sense, visibility operates as a mechanism of behavioural regulation, capable of both enabling coordination and constraining openness, depending on how it is designed and governed

Control and Standardization: Regulating What Counts as Knowledge

The second dimension concerns the increasing reliance of KM systems on codification and standardisation, which privilege knowledge that is explicit, structured, and measurable (Yan et al., 2025). While these features support efficiency, comparability, and scalability, they introduce a distinct ethical risk related to the epistemic structuring of organizational knowledge.

The literature highlights how KM systems embed an architectural bias toward explicit knowledge, marginalising tacit, contextual, and experiential forms (Garrick and Chan, 2017). This results in a process of epistemic filtering, whereby only knowledge that can be codified within predefined templates becomes visible and legitimate in the organisation.

This dynamic extends beyond knowledge storage to shape employees’ behaviour. Individuals adapt their contributions to fit standardised formats, aligning their thinking with system requirements rather than the intrinsic complexity of the phenomena they seek to describe. Over time, this leads to epistemic narrowing, reducing the diversity of perspectives and constraining exploratory and reflective forms of sense-making (Introne et al., 2020).

Thus, standardisation functions as a mechanism of epistemic regulation, defining what knowledge "counts" organizationally and subtly redirecting knowledge production toward measurable and system-compatible forms of knowledge.

Power Asymmetries and Opacity: Regulating Knowledge Valuation and Authority

The third dimension concerns the emergence of power asymmetries and opacity associated with algorithmic and AI-based KM systems. These technologies redistribute decision-making authority toward system designers, managers, and algorithmic processes, creating what has been described as a form of algorithmic governance or "algocracy" (Vladimir, 2025).

A central feature of this transformation is structural opacity. Algorithmic systems often operate as black boxes, making it difficult, if not impossible, for employees to understand how their knowledge is evaluated, ranked or utilised (Ajunwa, 2020). This opacity generates significant information asymmetries, whereby organizational actors controlling the system possess substantially more knowledge than those who are subject to it (Bergh et al., 2019).

These asymmetries produce both behavioural and relational consequences for the parties involved. From a behavioural perspective, opacity limits employees' ability to strategically engage with KM systems because the criteria governing evaluation remain unclear. From a relational perspective, it undermines perceptions of procedural fairness and organizational trust because employees cannot verify the impartiality or legitimacy of algorithmic decisions (Lee, 2018).

Moreover, literature highlights the risk of epistemic injustice, whereby algorithmic systems systematically privilege certain forms of knowledge while marginalising others, often reproducing existing organizational biases. In this sense, power asymmetries and opacity function as mechanisms of authority concentration, shaping not only how knowledge is evaluated but also who is recognised as a legitimate knowledge contributor.

Integrated Mechanisms: From Ethical Risk to Knowledge-Sharing Outcomes

The three dimensions identified in this study, surveillance and visibility, control and standardization, and power asymmetries and opacity, configure a multi-layered system through which technology-enabled KM shapes knowledge-sharing processes. These dimensions operate jointly to influence not only the extent to which employees are willing to share knowledge but also the forms that such knowledge can take and the criteria through which it is evaluated and recognised within the organisation.

This integrated configuration works through a set of micro-level behavioral mechanisms, most notably psychological safety, perceived fairness, organizational trust, and intrinsic motivation, which seem to mediate the relationship between KM infrastructure and knowledge-sharing outcomes (Yin et al., 2020). In this sense, the ethical risks embedded in digital KM systems are not external constraints but endogenous factors that shape how individuals interpret and engage with knowledge-sharing practices.

When these mechanisms are undermined, for instance, through excessive visibility linked to evaluation, rigid standardisation that constrains expression, or opaque systems that obscure decision-making processes, employees are more likely to adopt defensive behaviours such as self-censorship, knowledge hiding, and risk-averse participation. Although these responses are individually rational, they may collectively reduce knowledge diversity, limit exploratory learning, and weaken the overall effectiveness of knowledge management processes.

Conversely, when such ethical risks are mitigated through transparent governance arrangements, participatory system design, and organizational environments that support trust and psychological safety, KM systems can sustain more open and generative knowledge exchange. Under these conditions, digital infrastructure contributes to the development of more resilient and inclusive knowledge ecosystems.

5 Discussion and conclusion

The findings of this study support a theoretical reframing of technology-enabled knowledge management (KM) systems, shifting their interpretation from neutral infrastructures that facilitate knowledge processes to organizational arrangements that actively shape the behavioural and epistemic conditions under which knowledge is produced, shared and evaluated (Cristofaro and Bañón-Gomis, 2026). While the KM literature has traditionally emphasised the enabling role of digital technologies in supporting coordination and organizational learning (Alavi & Leidner, 2001), this study shows that these systems simultaneously embed normative assumptions, control mechanisms, and power configurations that influence how individuals engage with knowledge practices.

This perspective suggests that KM systems seem like forms of embedded governance, structuring not only the circulation of knowledge but also the conditions of participation, recognition, and evaluation of knowledge.

In this sense, ethical risks are not external to KM systems but are intrinsic features of their design and operation. Building on this reframing, this study conceptualises these dynamics as a set of interrelated mechanisms through which ethical risks shape knowledge-sharing processes.

The findings indicate that the effects of KM systems on knowledge sharing cannot be understood by isolating single technological features but must be interpreted as the outcome of interacting mechanisms that simultaneously shape behaviour, knowledge boundaries, and evaluative processes.

Based on these findings, this study advances a set of theoretical propositions that articulate how the identified dimensions translate into knowledge-sharing outcomes.

Proposition 1.

When visibility and traceability in KM systems are associated with monitoring and evaluation, they tend to reduce psychological safety and promote self-regulatory behaviours, such as self-censorship and selective knowledge sharing. This finding suggests that the effectiveness of visibility depends on how it is interpreted by organizational members: when framed as control rather than coordination, it shifts knowledge sharing from an intrinsically motivated activity to risk-managed behaviour.

Proposition 2.

The codification and standardisation embedded in KM systems tend to privilege explicit and measurable knowledge, contributing to the processes of epistemic narrowing. As a result, employees are likely to align their contributions with system-compatible formats, reducing the diversity and exploratory nature of organizational knowledge. This implies that KM systems do not merely capture knowledge but actively shape its form, favouring standardisation over interpretive richness and thereby constraining sensemaking processes.

Proposition 3.

The opacity and information asymmetries associated with algorithmic KM systems undermine perceived procedural fairness and organizational trust, thereby weakening employees' willingness to engage in knowledge-sharing practices. This highlights that trust in KM systems is not only a function of outcomes but also of the perceived legitimacy and transparency of the processes through which knowledge is evaluated and valued.

Proposition 4.

The interaction of surveillance, standardisation, and opacity produces reinforcing effects that amplify defensive behaviours, knowledge hiding, and risk aversion, ultimately constraining organizational learning. This suggests that ethical risks operate systemically, with combined effects that exceed the impact of individual dimensions and generate self-reinforcing dynamics.

Thus, these propositions point to a paradoxical dynamic: KM systems designed to enhance knowledge circulation may, under certain governance configurations, constrain openness, reduce the diversity of contributions, and limit learning processes. Taken together, these insights suggest that the effectiveness of technology-enabled KM systems depends not only on their technical capabilities but also on the configuration of ethical and governance conditions that shape their use.

From a practical standpoint, these findings indicate that organisations should carefully consider how visibility, codification, and algorithmic evaluation are implemented in KM systems. Overly rigid or opaque configurations may unintentionally discourage knowledge sharing, whereas approaches that emphasise transparency, participatory governance, and psychological safety may foster sustainable and inclusive knowledge practices.

5.1 Theoretical Implication

This study contributes to the advancement of knowledge management theory by introducing a more integrated understanding of the relationship between technology, behaviour, and epistemic structures. First, it extends the literature of KM, highlighting the role of digital technologies in structuring organizational processes beyond efficiency and performance, highlighting their capacity to regulate behaviour, define knowledge boundaries and redistribute authority.

Second, this study strengthens the connection between KM and organizational behaviour by explicitly theorising the micro-level mechanisms through which technological systems influence knowledge sharing. While prior research has acknowledged the importance of factors such as trust, motivation, and psychological safety (Wang, 2016), these elements have often been treated as contextual variables rather than outcomes of technological design. By demonstrating how visibility, standardisation, and opacity shape these mechanisms, this study repositions them as endogenous to KM systems rather than as external moderators.

Third, this study introduces an ethical–epistemic perspective to KM research, emphasising that technologies not only influence how knowledge is shared but also what knowledge is recognised and valued. This perspective contributes to emerging debates on the "dark side" of digital technologies (Aldhafferi, 2018) by demonstrating

that KM systems can simultaneously enable and constrain knowledge processes, depending on how they structure visibility, codification, and control.

In doing so, this study positions the issues of epistemic diversity, fairness, and inclusion as central theoretical concerns within KM research.

Finally, the framework developed in this study offers a basis for future research. Identifying ethical risks as mechanisms that mediate the relationship between KM technology and knowledge sharing outcomes opens new avenues for empirical investigation.

Future research may explore how different configurations of KM systems shape employee behaviour across organizational contexts, how governance arrangements influence these dynamics, and how organisations can balance efficiency with inclusiveness and epistemic diversity.

Future research could investigate sector-specific variations in KM governance, the role of leadership in mediating ethical risks, and the long-term implications of algorithmic KM systems for organizational learning and innovation.

6 Ethics Declaration

No ethical approval was required for this study. The paper is based on a conceptual and theory-building approach that relies exclusively on the analysis and integration of existing literature. It does not involve human participants, personal data, or any form of empirical data collection.

7 AI Declaration

The authors declare that generative artificial intelligence (AI) tools, specifically ChatGPT, were used solely to improve the clarity and quality of the English language in the manuscript. The authors' native language is Italian, and AI support was limited to linguistic refinement. All ideas, arguments, and intellectual contributions remain entirely those of the authors.

Abstract

Small and medium-sized enterprises (SMEs) are increasingly exposed to sustainability expectations arising from value chains, finance, and reporting infrastructures. Yet their responses often remain fragmented. Existing explanations usually stress resource scarcity, but fragmentation is also a knowledge problem: firms may recognise the relevance of sustainability while lacking the cognitive frames, governance routines, and prioritisation devices needed to turn diffuse concerns into coordinated action. This paper examines whether a structured self-assessment architecture can be interpreted not only as a measurement instrument but also as a developmental knowledge device. The study is situated within the broader National FSINDEX Observatory and reports evidence from a consolidated analytical subset of 15 Italian SMEs assessed between 20 January and 17 February 2026. Empirically, the paper relies on a document-based comparative analysis of the transversal FSINDEX report already produced for the participating firms. FSINDEX is a guided self-assessment tool organised around 50 ordinal items across five areas: Vision and awareness, Brand and corporate culture, Market drivers, Circular economy and social issues, and Governance. The analysis combines overall scores, area-level distributions, cluster positioning, and the recurring quick wins suggested in the consolidated report. The sample shows an average maturity score of 166.3 out of 250, with a range from 138 to 190. The strongest areas are Brand and corporate culture and Circular economy and social issues, while Market drivers and Governance remain the weakest. The pattern suggests that sustainability is more advanced as awareness and operational sensitivity than as a formal model of governance and market positioning. Recommended quick wins converge around governance and compliance, reporting and key performance indicators, people and welfare, and supply-chain formalisation. This concentration indicates that the main bottleneck is not simple awareness, nor primarily technology adoption, but the organisational work required to codify dispersed sustainability knowledge, assign responsibility, stabilise metrics, and sequence action. The paper contributes to knowledge management and sustainability pedagogy research by showing how a self-assessment observatory can function as a learning infrastructure for SMEs. It also refines the debate on sustainability maturity tools by arguing that their relevance lies less in classificatory precision alone than in their capacity to make strategic priorities discussable, comparable, and actionable.

Keywords: Sustainability pedagogy; knowledge management; SMEs; organisational learning; strategic prioritisation.

Paper type: Academic Research Paper

1 Introduction

Small and medium-sized enterprises are increasingly drawn into sustainability transition dynamics through customer requirements, supply-chain expectations, financial relationships, and evolving reporting frameworks. Recent European developments, including the Corporate Sustainability Reporting Directive and the subsequent encouragement of voluntary SME-oriented reporting standards, confirm that the sustainability agenda now affects firms far beyond the population directly subject to formal reporting mandates. For SMEs, however, response patterns remain uneven. Prior research has linked this unevenness to familiar structural constraints such as scarce managerial time, limited financial slack, and weak formalisation (Revell et al., 2010; Martins et al., 2022; European Commission, 2025). These constraints matter, but they do not fully explain why organisations that already recognise sustainability as strategically relevant still struggle to convert that recognition into coherent priorities.

A second issue is interpretive rather than purely resource-based. Sustainability confronts decision makers with ambiguous signals, heterogeneous standards, and the possibility of symbolic or performative responses that improve external appearance more than organisational substance (Delmas and Burbano, 2011; Lyon and Montgomery, 2015; Bernini and La Rosa, 2024; Santos et al., 2024). In SMEs, where strategy is often concentrated around owner-managers and close operational circles, fragmented sustainability action may therefore be understood as a knowledge problem: how environmental, social, and governance concerns are noticed, interpreted, discussed, codified, and prioritised inside the firm.

This paper addresses that problem by linking sustainability pedagogy and knowledge management. The central proposition is that structured self-assessment can do more than classify maturity. Under certain conditions, it can operate as a learning device that externalises tacit judgements, creates a shared vocabulary, identifies gaps, and translates diffuse sustainability concern into prioritised organisational action. The paper examines this proposition through the National FSINDEX Observatory, a broader initiative currently involving 20 SMEs, from which the present paper analyses the first consolidated subset of 15 firms.

The study asks three questions. First, how can a structured sustainability pedagogy architecture support leadership competences for intelligent knowledge management in SMEs? Secondly, how are strategic priorities distributed across the five FSINDEX areas in the analysed sample? Thirdly, what does the recurrence of similar gaps and quick wins suggest about the role of an observatory setting as a shared learning infrastructure?

The paper makes two contributions. Theoretically, it connects responsible management competence development with knowledge-based explanations of how SMEs build the capacity to interpret and mobilise sustainability knowledge (Cohen and Levinthal, 1990; Grant, 1996; Laasch et al., 2023). Empirically, it provides evidence from a structured comparative analysis showing that many SMEs are not in a condition of sustainability absence, but in a transitional condition in which awareness has outpaced governance, metrics, and market translation. The argument is deliberately cautious. The paper does not claim longitudinal proof of competence change. Rather, it shows how the architecture of FSINDEX and the patterning of its outputs illuminate the organisational work through which sustainability becomes manageable.

2 Theoretical Background

2.1 Sustainability pedagogy and responsible management competencies

Education for sustainable development has increasingly been defined as a transformative process rather than the transmission of a stable body of content. UNESCO (2020) frames sustainability learning as a lifelong process integrating cognitive, social, emotional, and behavioural dimensions. In related work on transformative learning, sustainability-related change involves shifts in meaning perspectives, critical reflection, and the reconstruction of assumptions through experience and dialogue (Mezirow, 1991; Grund et al., 2024). Competence-oriented scholarship has translated this pedagogic insight into more operational terms. Sustainability competence frameworks emphasise systems thinking, anticipatory reasoning, normative judgement, strategic action, and interpersonal capabilities as the basis for addressing complex sustainability problems (Wiek et al., 2011; European Commission, Joint Research Centre, 2022; Brundiers et al., 2021).

Within management studies, this debate has evolved into a broader discussion on responsible management competences. Rather than reducing responsibility to compliance or ethical intention, this literature defines competence as a layered combination of intellectual, behavioural, and personal capabilities required to judge, negotiate, and act across ethical, social, and environmental tensions (Laasch et al., 2023). Such competences include future orientation, critical judgement, stakeholder sensitivity, reflexivity, and the capacity to act in situations marked by ambiguity and competing claims. This is particularly relevant for SMEs, where formal functional boundaries are often weak and strategic decisions depend on the interpretive capacity of a small number of actors.

A pedagogic approach to sustainability in SMEs must therefore be practical, contextual, and developmental. It is less likely to depend on formal classroom settings than on situated devices that provoke reflection, comparison, and action. The significance of assessment lies precisely here. If designed developmentally rather than punitively, assessment can become part of pedagogy by enabling managers to see relationships, surface blind spots, and sequence change. In this sense, sustainability pedagogy in SMEs is inseparable from the instruments through which knowledge is structured and discussed.

2.2 Knowledge management, organisational learning, and strategic prioritisation in SMEs

Knowledge management provides a complementary explanation for why sustainability transitions stall or consolidate. Organisational learning research has long shown that firms depend on processes of knowledge acquisition, distribution, interpretation, memory, and institutionalisation (Huber, 1991; Crossan et al., 1999; Argote and Miron-Spektor, 2011). The absorptive capacity tradition further clarifies that new knowledge rarely becomes useful without prior capabilities to recognise, assimilate, and apply it (Cohen and Levinthal, 1990; Zahra and George, 2002). For sustainability problems, this challenge is amplified because firms must connect external expectations, internal routines, and long-term implications under conditions of uncertainty and temporal tension (Bansal and DesJardine, 2014).

Knowledge-based views of the firm help explain why this is difficult. Organisational knowledge does not emerge automatically from information availability; it requires integration mechanisms, routines, and interpretive interaction (Grant, 1996; Nonaka, 1994; Nonaka and Takeuchi, 1995). In SMEs, the literature suggests both an advantage and a vulnerability. Close proximity between decision makers and operations can support rapid experimentation and the rapid circulation of practical knowledge, yet weak formalisation can leave learning highly person-dependent and difficult to stabilise (Bos-Brouwers, 2010; Johnson, 2017). Sustainability initiatives may thus appear in the form of isolated practices, motivated individuals, or customer-led adaptations without becoming a durable organisational capability.

This problem becomes visible in strategic prioritisation. Sustainability requires firms to decide which issues matter, which actions come first, and which routines deserve investment. That sequence is never neutral. It reflects how managers classify problems, perceive trade-offs between exploration and exploitation, and judge the relationship between internal readiness and external positioning (March, 1991; Feeney et al., 2023). When prioritisation fails, firms may oscillate between symbolic narratives and disconnected initiatives. Hence the growing relevance of self-assessment and maturity models aimed at SMEs. Existing contributions show that diagnostic tools can help structure reflection and identify developmental pathways, but they are often treated as classificatory instruments rather than as socio-cognitive infrastructures for learning (Vásquez et al., 2021; Murè et al., 2024; Cicchini et al., 2024).

The present paper develops this latter perspective. It interprets FSINDEX as a developmental knowledge device: an artefact that does not merely describe sustainability maturity but helps organise attention, comparability, and action. This interpretation is especially pertinent when the instrument is embedded in an observatory setting where repeated patterns across firms can support benchmarking and peer-oriented learning (Wenger, 1998; Osagie et al., 2018).

3 Research Design

3.1 Research setting and the National FSINDEX Observatory

The research is situated within the National FSINDEX Observatory, a broader initiative aimed at supporting SME sustainability learning through structured self-assessment, collective benchmarking, and targeted developmental guidance. While the wider observatory currently involves 20 SMEs, this paper reports the first consolidated evidence available for 15 firms whose FSINDEX materials were completed between 20 January and 17 February 2026. The analysed subset covers heterogeneous sectors, including footwear, agriculture, agro-food, agrochemicals, logistics, ICT, graphic industry, electrical materials, construction, and industrial manufacturing.

The observatory logic is important for interpretation. The participating firms are not treated as isolated cases alone but as members of a common learning architecture in which results can be read comparatively. The empirical material available for this paper does not include full longitudinal evidence, nor direct interview transcripts. What is available is the transversal analytical report consolidating the 15 firm-level outputs. Accordingly, the paper adopts a document-based comparative design and uses the broader observatory mainly as the conceptual and organisational setting within which the 15-firm subset is positioned.

3.2 FSINDEX as a developmental knowledge device

FSINDEX is a proprietary strategic self-assessment tool developed by Forethinking Srl SB. It is not designed as a certification scheme or an external ESG rating. Its declared purpose is diagnostic and developmental: to help SMEs structure sustainability-related knowledge and translate it into prioritised improvement trajectories. The instrument comprises 50 items, ten for each of five areas: Vision and awareness; Brand and corporate culture; Market drivers; Circular economy and social issues; and Governance. Each item is scored on an ordinal scale from 1 to 5, generating a maximum of 50 points per area and 250 overall.

The operational threshold used in the consolidated report is 39 points per area. This threshold is not treated as a strict pass-fail criterion but as an interpretive maturity benchmark. In practical terms, the instrument yields more than a score. It produces an area profile, highlights strengths and weaknesses, and associates them with suggested quick wins. In this respect, FSINDEX can be read as a device for codifying managerial perceptions, translating them into a common vocabulary, and exposing where organisational learning needs to occur first. Its analytical relevance therefore lies in the relationship between scores and the action logic that accompanies them.

Table 1: Research setting and FSINDEX design

Element	Specification
Research setting	National FSINDEX Observatory
Empirical subset	15 SMEs
Compilation period	20 January 2026 to 17 February 2026
Instrument structure	50 ordinal items, 10 per area, 1-5 scale
Areas	Vision and awareness; Brand and corporate culture; Market drivers; Circular economy and social issues; Governance
Maximum score	50 per area; 250 overall
Interpretive benchmark	39/50 per area
Outputs used in this paper	Overall scores, area scores, cluster positioning, recurring quick wins, directional scenario

3.3 Sample, materials, and analytical strategy

Methodologically, the paper adopts an embedded multiple-case comparative analysis based on the consolidated transversal report. The analysis uses three layers of evidence already integrated in that source: first, the numerical distribution of scores across the five areas; secondly, the cross-case positioning of firms by total score; thirdly, the pattern of quick wins associated with recurring developmental needs. The quick-win scenario is explicitly directional and non-predictive. It estimates plausible improvements in the areas directly activated by the recommended actions, with a cap at 50 points per area, and should therefore be read as a maturation trajectory rather than a forecast.

The analytical strategy is interpretive and comparative. Rather than testing causal relations statistically, it examines how the distribution of weaknesses and recommended actions reveals the organisational conditions under which sustainability knowledge becomes actionable. This approach is suitable for the present stage of the observatory because it allows cross-case synthesis without overstating what the available material can support.

4 Findings

4.1 Cross-sectional maturity profile of the 15 SMEs

The first result is that the sample does not depict an SME population starting from zero. The average total score is 166.3 out of 250, equivalent to 66.5% of the theoretical maximum. Scores range from 138 to 190, indicating substantial dispersion but not a polarity between highly mature and wholly inactive firms. Four firms fall into an advanced cluster with at least 180 points, six belong to a solid but non-homogeneous cluster between 165 and 179, two lie in a transitional range between 145 and 164, and three remain in a category requiring more substantial structuring below 145.

This distribution suggests an intermediate condition of sustainability maturity. Sustainability has entered managerial agendas across the sample, but the translation of this attention into stable systems remains uneven. The most developed cases are not necessarily those with complete formalisation in every area; rather, they are firms in which at least some domains of sustainability appear sufficiently structured to support an integrated profile. Conversely, the weakest cases still display areas of partial advancement, which indicates that even lower-scoring firms are engaged in sustainability-related practices, albeit in fragmented form.

The directional scenario reinforces this interpretation. If the suggested quick wins were implemented in a prudent manner, the average score would rise from 166.3 to 177.3, corresponding to an average gain of 11 points. The magnitude of this projected improvement is modest but meaningful. It implies that much of the near-term developmental potential lies not in radical transformation, but in converting existing awareness into more ordered and governable routines.

4.2 Recurring patterns across the five FSINDEX areas

The area distribution makes the central bottlenecks visible. The strongest average scores are recorded in Brand and corporate culture and Circular economy and social issues, both at 34.4 out of 50, followed closely by Vision and awareness at 34.2. Governance scores 33.0, while Market drivers is clearly the weakest area at 30.3. Only one firm exceeds the 39-point benchmark in Market drivers, whereas five do so in Governance.

Table 2: Area-level results in the analysed sample

Area	Mean	Firms above 39/50	Maximum	Minimum
Vision and awareness	34.2	3/15	42	26
Brand and corporate culture	34.4	4/15	43	27
Market drivers	30.3	1/15	41	21
Circular economy and social issues	34.4	3/15	41	29
Governance	33.0	5/15	43	20

Three patterns emerge from this distribution. First, sustainability is stronger as awareness and operational sensitivity than as a model of governance. The firms appear more prepared to recognise environmental and social impacts, discuss internal culture, and report selective practices than to anchor sustainability in formal roles, procedures, incentive systems, and control mechanisms. The transversal report explicitly contrasts relatively robust answers on risk awareness, energy, inclusion, safety, welfare, and environmental measurement with weaker answers on formal governance devices, structured stakeholder engagement, privacy, and compliance mechanisms.

Secondly, the internal symbolic and cultural side of sustainability appears more developed than its external market translation. The sample includes several firms whose culture-related scores signal openness to innovation, internal sensitivity, and employer attractiveness, yet these same firms often score poorly on eco-design, sustainable offer configuration, monetisation of sustainability, or customer recognisability of sustainability value. This gap is theoretically important. It indicates that sustainability knowledge may circulate internally as conviction or aspiration without yet becoming a stable value proposition.

Thirdly, the maturity profile is selective rather than systemic. The cross-sectional report notes the presence, in different firms, of life-cycle assessment, environmental product declarations, welfare initiatives, emissions monitoring, and early sustainability reporting efforts. These are not trivial signals. They suggest that sustainability has already generated technical and organisational experimentation. Yet the experiments often remain project-based or entrepreneur-led rather than translated into an integrated and durable management system. The sample therefore reveals a shift from marginality to partial institutionalisation, not full consolidation.

4.3 Quick wins as mechanisms of prioritisation and organisational learning

The quick wins provide the clearest indication that FSINDEX is functioning as more than a diagnostic scoreboard. Across the 15 firms, the suggested actions converge around a limited set of recurring levers: governance and compliance in 11 cases, reporting and key performance indicators in 10, people and welfare in 10, supply chain and procurement in 7, stakeholder engagement in 6, and product and innovation in 4.

Table 3: Recurring quick-win levers across the sample

Quick-win lever	Occurrences
Governance and compliance	11/15
Reporting and KPI	10/15
People and welfare	10/15
Supply chain and procurement	7/15
Stakeholder engagement	6/15
Product and innovation	4/15

The concentration is analytically revealing. Most recommended actions are not primarily technological. They concern formalisation, measurement, internal capability building, and accountability. In other words, the first developmental task for these SMEs is to convert sustainability from scattered initiative into organised knowledge. Quick wins do this by reducing complexity. They identify where responsibility should be assigned, where information should be stabilised in metrics, where people-related routines should be strengthened, and where value-chain visibility should be improved.

This helps explain the directional scenario. Governance is the area expected to improve most, followed by internal structuring related to Vision and awareness and supply-chain organisation. Market drivers improve less rapidly because commercial repositioning depends on prior internal ordering. A firm can rarely translate sustainability into a credible offer if its data, governance, and responsibilities remain unstable. The quick wins therefore perform a sequencing function. They do not simply recommend action; they establish the order in which action is likely to become effective.

5 Discussion

The findings support a reinterpretation of assessment in SME sustainability management. The main contribution of FSINDEX is not exhausted by the scores it generates. Its deeper value lies in its capacity to structure managerial attention. By transforming broad sustainability concerns into area-based profiles and associated quick wins, the instrument makes the transition from awareness to prioritisation visible and discussable. This is why the evidence is best understood through a knowledge management lens.

The first research question concerned leadership competences for intelligent knowledge management. The present cross-sectional material does not allow a direct measurement of competence change over time. Nonetheless, the patterns observed are consistent with the view that FSINDEX creates enabling conditions for competence development. The instrument requires managers to articulate sustainability judgements across multiple domains, confront asymmetries between internal culture and external positioning, and engage with actionable recommendations. These are not merely reporting acts. They involve interpretation, comparison, and decision sequencing, all of which are core components of intelligent knowledge management.

The second question asked how strategic priorities are distributed across the five areas. Here the evidence is direct. Priorities are concentrated less on radical product innovation than on the organisational foundations that make later strategic differentiation possible. The severe weakness of Market drivers, contrasted with comparatively higher scores in awareness and culture, shows that the central bottleneck is the conversion of sustainability knowledge into market-facing strategic architecture. From the perspective of absorptive capacity, the firms appear to have progressed further in recognising and valuing sustainability signals than in assimilating them into stable routines and exploiting them competitively (Cohen and Levinthal, 1990; Dzhengiz and Niesten, 2020).

This interpretation also aligns with organisational learning theory. The sample suggests movement from intuitive and project-based responses toward more institutionalised forms of learning, but with uneven progression across levels. Sustainability appears to have reached the stages of noticing, discussing, and selectively experimenting, yet often remains under-institutionalised in governance structures and performance systems (Crossan et al., 1999; Argote and Miron-Spektor, 2011). In Nonaka's terms, dispersed practical understandings are present, but the mechanisms required for durable conversion and integration remain incomplete (Nonaka, 1994; Nonaka and Takeuchi, 1995).

The third question concerned the observatory setting. Again, the present evidence is indirect but meaningful. The recurrence of similar quick wins across heterogeneous sectors suggests that the participating SMEs share a common developmental grammar. This is precisely what makes an observatory valuable. It does not merely collect cases; it reveals patterned bottlenecks that can be addressed through benchmarking, shared language, and peer-oriented learning. The concentration of recommended actions around governance, reporting, people, and supply chain implies that many SMEs can benefit from a relatively standardised developmental infrastructure before moving into more differentiated sustainability strategies. This resonates with research showing that competence development in sustainability-related roles is strongly supported by peer learning and learning climate rather than by formal instruction alone (Osagie et al., 2018).

The findings also have implications for the debate on symbolic compliance. Because FSINDEX is not designed as an external rating or legitimacy signal, it partly displaces the incentives associated with performative disclosure. Its logic is developmental rather than reputational. That does not eliminate the risk of self-report bias, but it does alter the purpose of the exercise. The central output is a prioritised improvement trajectory rather than a public score for external comparison. In this sense, the instrument may reduce some incentives associated with greenwashing by focusing managerial attention on internal gaps and next-step actions rather than external claims (Delmas and Burbano, 2011; Lyon and Montgomery, 2015).

Practically, the paper suggests that SMEs need lightweight but structured infrastructures for sustainability learning. The analysed firms do not primarily lack goodwill. They lack codified routines, comparable metrics, clear responsibilities, and pathways for converting sustainability into market and governance architecture. Instruments such as FSINDEX can therefore be valuable not because they simplify reality excessively, but because they render complexity governable at a scale compatible with SME conditions.

6 Conclusions

This paper has argued that FSINDEX is best understood not only as a sustainability maturity instrument but as a developmental knowledge device. Using a document-based comparative analysis of 15 SMEs within the broader National FSINDEX Observatory, the study showed that the main bottlenecks in the sample lie in Governance and especially Market drivers, while Vision and awareness, Brand and corporate culture, and Circular economy and social issues are comparatively more developed. The resulting picture is one of

intermediate maturity: sustainability is present, but often still fragmented, selectively formalised, and only partially translated into strategic priorities.

The paper contributes to the literature by linking sustainability pedagogy, responsible management competences, and organisational learning in an SME setting. Its main empirical insight is that self-assessment becomes strategically meaningful when it produces not just a diagnosis but a sequence of quick wins that codifies knowledge gaps and organises action. For practice, the implication is that support infrastructures for SMEs should prioritise governance, metrics, people-related routines, and supply-chain visibility as the foundations upon which stronger market-facing sustainability strategies can later be built.

The study has clear limitations. It relies on self-assessment material, which raises the possibility of self-report bias. It is cross-sectional rather than longitudinal and is based on a consolidated transversal report rather than raw firm-level protocols. The directional scenario attached to the quick wins is heuristic and should not be mistaken for a prediction. Future research should follow the broader observatory over time, incorporate direct qualitative evidence from participating firms, and test whether the learning dynamics suggested here translate into measurable changes in strategic behaviour, reporting quality, and market positioning.

7 Ethics Declaration

The paper reports a document-based comparative analysis of organisational self-assessment materials and aggregated cross-case evidence. No identifiable personal data are analysed in the manuscript, and no experimental procedures involving human participants are reported. No formal ethical clearance reference is reported for the present paper.

8 AI Declaration

OpenAI ChatGPT was used in the preparation of the present manuscript for language support, structural consolidation, and drafting assistance. All empirical inputs, source selection, interpretation of findings, reference checking, and final scholarly responsibility remain with the authors. No AI-generated material was included without human review and revision.

Abstract

Telemedicine has progressively evolved from a complementary digital service into a structural component of contemporary care models. This transition has transformed telemedicine into a complex intervention whose effectiveness depends not only on technological performance, but also on the dynamic interactions among organizational processes, professional practices, patient engagement, infrastructural conditions, and governance arrangements. Although established multidimensional frameworks, such as Health Technology Assessment (HTA), provide robust methodological foundations for evaluating health technologies, their application at the regional ecosystem level still presents relevant challenges. In particular, traditional assessment approaches often struggle to capture the adaptive nature, contextual variability, stakeholder interdependencies, and systemic trade-offs that characterize telemedicine as a socio-technical system. Against this background, a persistent gap remains between the theoretical recognition of telemedicine complexity and the availability of operational tools capable of monitoring such complexity in an integrated and decision-oriented manner. This study addresses this gap by proposing the Telemedicine Ecosystem Monitoring and Evaluation Framework (TEMEF), an HTA-informed and context-sensitive model designed to support the evaluation of telemedicine systems in regional healthcare contexts. Rather than replacing existing evaluative approaches, TEMEF aims to complement them by translating multidimensional assessment principles into a structured, multi-stakeholder monitoring architecture. Using a Proof of Concept (PoC) methodology, the paper describes the transition from conceptual design to the development of a survey-based evaluation system tailored to four key stakeholder groups: patients and caregivers, physicians, healthcare managers, and technology providers. The framework integrates five main evaluative domains—clinical, organizational, technological, experiential, and economic—allowing system performance to be examined both at an aggregate level and through stakeholder-specific perspectives. To assess the internal coherence of the scoring logic and the interpretability of the analytical outputs, AI-generated synthetic stakeholder profiles were used to conduct a preliminary stress-test of the framework and its analytical dashboard interface. This procedure enabled the exploration of plausible configurations of stakeholder alignment and misalignment, highlighting how apparently positive aggregate performance may conceal critical tensions across domains or actor groups. The resulting model provides policy makers and healthcare decision-makers with an operational framework for interpreting telemedicine not as an isolated technological solution, but as a regional healthcare ecosystem. TEMEF supports evidence-informed governance by making visible systemic trade-offs, implementation bottlenecks, and areas requiring targeted improvement, thereby contributing to the sustainable integration of telemedicine into evolving care delivery models.

Keywords: Telemedicine, Healthcare Innovation, Multistakeholder Framework, Exploratory Study, Regional Healthcare Systems

Paper type: Academic Research Paper

1 Introduction

In the contemporary landscape of public health, digital transformation represents one of the primary strategic directions for investment and the development of healthcare systems (Rabbani et al., 2025). The implementation of increasingly sophisticated Information and Communication Technology infrastructures does not merely respond to a need for technological modernization; rather, it aims for a strategic objective: optimizing the efficiency and effectiveness of service delivery. Within this scenario, telemedicine has established itself as the solution of choice for mitigating the factor of distance, which has historically represented a critical barrier to equity in access to care. Due to its ability to overcome geographical boundaries and facilitate contact between physicians and patients, it has long been at the center of international policy agendas as a key instrument of e-health (Ricci et al., 2023) However, telemedicine has now moved beyond being a simple "alternative" to in-person visits to become a pillar of modern care models. It enables proactive care pathways and ensures genuine integration between the hospital environment and the patient's home, addressing the challenges posed by chronic diseases and the demand for proximity medicine (Li et al., 2025; Ricci et al., 2023;

Rogers et al., 2022). This transition, accelerated by the pandemic emergency and now crystallized in national digitalization plans, has highlighted that telemedicine cannot be reduced to a mere technological artifact. How, then, do we define the value of an ecosystem where digital infrastructures, professional competencies, patient needs, and governance rules interact in a dynamic and unpredictable manner? The answer lies in recognizing telemedicine as a complex socio-technical system: a living environment whose performance depends not only on software but on the quality of the relationships and processes it enables (Greenhalgh et al., 2017; Khodadad-Saryazdi, 2021). It is precisely this intrinsic complexity that makes its implementation (Ross et al., 2016) and evaluation an ongoing methodological challenge. While the literature has produced numerous models to analyze individual aspects of this phenomenon, such contributions often remain fragmented (Chang, 2015; Souza et al., 2021). The difficulty emerges particularly when the unit of analysis shifts from a single local application to an entire regional system. The primary limitation of traditional models is not a lack of rigor, but rather the difficulty in capturing the interdependencies between various actors and the nuances of implementation contexts. This critical issue is confirmed by recent reflections in the field of HTA: the work of Baghbanian et al. (2025) highlights that current HTA, despite having progressively expanded its scope beyond traditional domains, continues to encounter difficulties in capturing the dynamic interactions, contextual factors, and long-term impacts associated with health interventions. Based on this premise, the present study introduces the Telemedicine Ecosystem Monitoring and Evaluation Framework (TEMEF). This is not a proposal intended to replace existing frameworks, but rather an HTA-informed and context-sensitive approach designed to operationalize systemic complexity. The contribution of this work lies in translating theoretical constructs into a multi-stakeholder structure that recognizes and values the diverse perspectives of patients, physicians, managers, and providers. In this perspective, regional telemedicine is treated as a complex intervention and a multi-level socio-technical system. Its evaluation cannot be limited to the isolated measurement of clinical outcomes or technological performance; it must also include stakeholder interdependencies, implementation feasibility, adaptive capacity, contextual variability, and potential tensions between objectives of efficiency, quality, accessibility, and sustainability. In light of these premises, the paper pursues a dual objective. On one hand, it intends to contribute to the debate on the limitations of current evaluative approaches, showing how regional telemedicine requires models capable of explicating system complexity rather than merely summing distinct evaluative domains. On the other hand, it proposes an initial operational response to this need through a multi-stakeholder framework that translates dimensions of system complexity into empirically observable constructs. In this sense, the contribution of this work lies not in proposing yet another multidimensional frame for telemedicine, but in the attempt to bridge the gap between the theoretical recognition of complexity and its effective operationalization into evaluative tools applicable to regional contexts, providing a support tool for policy decision-makers to systematically evaluate system performance through the use of concrete indicators measurable over time.

2 Theoretical Background

The healthcare system is a fundamental pillar of socio-economic development, yet it faces unprecedented political, economic, and social pressures (Chiuchisan et al., 2014; Kelly & Young, 2017). Today's global environment—characterized by climate change, migration flows, and environmental degradation—challenges the resilience of traditional healthcare models, necessitating an accelerated pace of adaptation (Benis et al., 2021; Kim et al., 2014). Within this context, digital transformation emerges as a critical driver for reshaping organizational models toward greater integration and sustainability (Konopik, 2023; Reis et al., 2018). While digital platforms are now essential for orchestrating data exchange in systems that historically lacked integrated structures (Baby & Chandran, 2022; Essen et al., 2023; Gleiss et al., 2021), their implementation remains challenging due to the multidimensional and interconnected nature of the healthcare environment (Konopik, 2023). These challenges have led to the progressive adoption of Complexity Thinking in healthcare (Khan et al., 2018). Recognizing that healthcare is inherently complex (Plsek & Greenhalgh, 2001), it requires adaptive responses rather than traditional reductionist solutions (Ashby, 1991). Consequently, healthcare is increasingly described as a complex system (Begun JW et al., 2003), in which the connectivity between actors generates interdependencies, and the actions of a single participant can create 'ripple effects' throughout the entire structure. This complexity is further enhanced by the system's hierarchical organization across nested micro, meso, and macro levels (Khan et al., 2018). Addressing global issues such as limited access, operational inefficiencies, and rising costs (Yeganeh, 2019), therefore, requires innovative and scalable solutions—like telemedicine—capable of navigating these intricate interdependencies to improve the quality of care (Tabish & Nabil, 2015). In this context, Sood et al. (2007) summarize the broad concept of telemedicine in this definition "*Telemedicine being a subset of telehealth, uses communications networks for delivery of healthcare services*

and medical education from one geographical location to another, primarily to address challenges like uneven distribution and shortage of infrastructural and human resources." Although telemedicine has been part of the healthcare discourse for decades, its implementation expanded dramatically during the COVID-19 pandemic, acting as a mandatory catalyst for digital health adoption (Rabbani et al., 2025). Despite this widespread implementation, its evaluation remains a significant methodological challenge. Traditional evaluation frameworks, most notably HTA have provided a robust basis for assessing medical technologies through multidimensional lenses, such as clinical effectiveness and economic sustainability (Kidholm et al., 2012; Kristensen et al., 2017). However, as telemedicine shifts from a niche tool to a structural component of regional healthcare, traditional HTA models often encounter difficulties in capturing the full spectrum of its systemic impact. Current evaluative efforts indicate that telemedicine assessment has largely evolved along sectoral and partial trajectories. Some research streams prioritize clinical performance and health outcomes (Gonçalves-Bradley et al., 2018; Zhang et al., 2025), while others focus on information-system characteristics and technology-mediated interaction (Zhang et al., 2025). Still, other studies emphasize data quality, operational processes, and implementation requirements (Talwar et al. 2023). Although these specializations yield valuable insights, such contributions often remain fragmented and difficult to compare, especially when the unit of analysis transitions from a singular service or pilot initiative to a complex regional system. This critical issue is echoed in recent reflections within the HTA field. Specifically, Baghbanian et al. (2025) point out that while HTA has expanded beyond its original clinical and economic domains, it still struggles to account for the dynamic interactions, contextual factors, and long-term sustainability inherent in complex interventions. In such systems, evaluation cannot be a static or reductionist process. Instead, it requires a "complexity-informed" approach capable of monitoring geographic variability, stakeholder engagement, and implementation feasibility (Baghbanian et al., 2025). For a regional telemedicine ecosystem to be truly performant, the evaluation must embrace a multi-stakeholder perspective, where the divergent views of patients, physicians, and managers are treated as essential diagnostic signals of systemic trade-offs and misalignments.

3 Methods

The innovative nature and systemic complexity of TEMEF necessitated a methodological approach structured into two macro-phases: conceptual design and functional validation, establishing this study as a PoC. As shown in Figure 1, the methodological process is divided into five key steps: literature review; definition of the framework's conceptual architecture; development of a multi-stakeholder survey; generation of "twin profiles" for internal pre-testing; and the development of a preliminary scoring logic and dashboard visualization.

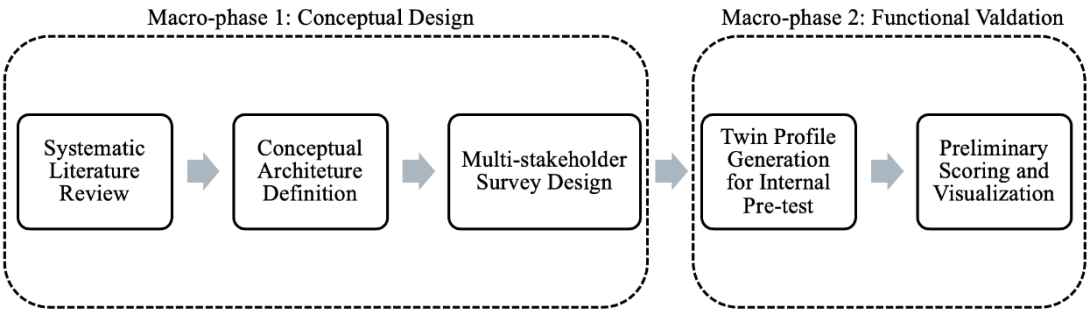

Figure 1: Methodological structure of the TEMEF PoC.

The framework stems from a systematic literature review conducted in Scopus using a query built around the terms "telemedicine" and "platform", selecting peer-reviewed journal articles written in English and published between 2020 and 2025 in subject areas consistent with the focus of the study, including engineering, information systems, management, economics, and decision sciences. This combination was chosen to prioritize contributions that analyze telemedicine through the lens of platform-based structures, which are increasingly recognized as essential for orchestrating data exchange and multi-stakeholder integration within complex healthcare environments. By focusing on "platforms", the review filtered for studies aligned with the socio-technical and systemic nature of the TEMEF, moving beyond traditional, fragmented views of e-health tools. This initial search returned 77 contributions. After title and abstract screening, 48 articles were selected as relevant. The excluded articles were not directly focused on telemedicine platforms, lacked an empirical or methodological basis, or were duplicates or partially overlapping studies. The included contributions were analyzed by extracting information on study context, technological focus, methodological approach, main

findings, and enabling or critical factors. These contributions helped us identify the main assessment dimensions considered in the literature, as well as the conceptual and evaluative models most frequently adopted, and confirmed a significant methodological gap: although theory widely recognizes the multidimensional nature of healthcare value, operational tools remain fragmented. Available evidence, while relevant, often appears difficult to compare and is rarely translatable into integrated decision-support systems—a critical issue that emerges prominently when the object of evaluation is a complex system within a regional healthcare context. To overcome this fragmentation, TEMEF integrates five fundamental domains—clinical, organizational, technological, experiential, and economic—into a unified architecture. The framework's development combined empirical literature with the analysis of established models (such as HTA, Donabedian's paradigm, the Chronic Care Model, NASSS, and UTAUT). While these provide solid foundations for interpreting telemedicine as a socio-technical system, they exhibit a recurring limitation: the difficulty of operationalizing complex theoretical constructs into empirically observable indicators. Consequently, the framework remains consistent with established evaluative traditions, including HTA, but distinguishes itself by translating these dimensions into a multi-stakeholder structure tailored for regional telemedicine systems. To translate these theoretical constructs into observable variables, a differentiated survey was designed. Four sets of questionnaires (5-point Likert scale) were developed for: patients/caregivers, physicians, managers, and technology providers. In this PoC phase, the survey demonstrates the feasibility of capturing divergent perspectives within a common monitoring logic, transforming systemic tensions into actionable data. Given the preliminary nature of the study, internal pre-testing was not conducted on a real-world sample but through Digital Twin Agents: synthetic profiles generated via AI. These agents were constructed to ensure a systematic coverage of the ecosystem's key configurations, specifically incorporating diverse age groups, varying levels of digital literacy and socio-economic backgrounds, distinct clinical conditions, different territorial contexts, and varying degrees of prior experience with telemedicine. These profiles were then used to complete the questionnaires, providing the data necessary to test the framework's analytical capacity. The resulting responses were transformed into synthetic indicators through a multi-level aggregation process. Items were mapped to a homogeneous scale and once normalized, aggregated following a hierarchical structure reflecting the framework's architecture. Initially, questionnaire items are grouped to generate scores for specific sub-dimensions; subsequently, these converge into the five main macro-dimensions. This bottom-up approach ensures full data traceability, allowing decision-makers to trace an overall score back to specific critical issues identified by a particular stakeholder category. The final step of this scoring procedure consists of synthesizing the results into a composite performance index. This TEMEF Overall index should not be interpreted as a simple arithmetic mean, but as a synthetic representation of the "health status" of the telemedicine system, so each domain score was computed by aggregating the questionnaire constructs associated with that specific dimension and rescaling the resulting value on a 1–100 scale. The TEMEF Overall Index was then calculated as the average of the five domain scores, thus providing a synthetic representation of the multidimensional performance profile generated by the simulated stakeholder responses. The strength of this logic lies in its ability to highlight systemic trade-offs: a high global index score may, in fact, conceal significant misalignments between underlying dimensions. In this sense, TEMEF scoring acts as a diagnostic signal, directing policy makers' attention toward domains where the gap between stakeholder expectations and operational results is most pronounced, thereby facilitating targeted, evidence-based governance interventions. Finally, the indicators were represented through a Power BI dashboard, conceived as an analytical environment to explore results by dimension, sub-dimension, and stakeholder group. As shown in Figure 2, this interface currently serves as a functional mockup and a demo decision support tool. At this stage, the dashboard does not constitute a continuous monitoring system but rather a preliminary interface to test the framework's usability and the clarity of the generated outputs.

Figure 2: Multidimensional Framework Validation Dashboard

4 Results and Discussion

The preliminary application of the TEMEF framework highlighted the potential of the proposed architecture to generate a multi-level and coherent representation of telemedicine system performance, supporting its operational feasibility as a synthesis tool for complex contexts, such as regional telemedicine systems. The results derive from simulated responses generated by synthetic stakeholder profiles and are therefore closely dependent on the assumptions embedded in the construction of those profiles. In this sense, TEMEF does not merely produce an average score; it offers a critical interpretative structure useful for exploring the distribution of value across different levels of analysis and among the various stakeholder involved. Even if, once the framework is applied to real-world populations, this scoring could be computed through a fuzzy logic methodology to better incorporate the inherent subjectivity and uncertainty of human perceptions, moving beyond the representative averages used for synthetic agents. This approach is aligned with the multidimensional logic of HTA, yet it integrates a multi-stakeholder perspective, allowing for the observation of interdependencies that traditional models often struggle to capture. The application produced an Overall Index of 65/100, suggesting a generally positive level of system maturity, although with relevant differences across domains. The clinical dimension emerged as the strongest area, with a score of 78, indicating that the platform appears particularly aligned with the objective of supporting care processes, clinical decision-making, and patient management. The economic dimension also showed a positive performance, with a score of 70, suggesting a favorable evaluation in terms of sustainability and value generation. The technological and organizational dimensions reported intermediate scores, respectively 66 and 65, pointing to an acceptable level of infrastructural and organizational readiness, while also indicating potential areas for refinement. By contrast, the experiential dimension obtained the lowest score, equal to 58, suggesting that user experience, usability, and digital literacy may represent critical issues for the full adoption of the platform. The results obtained should not be interpreted as static empirical evidence, but rather as a functional demonstration of the framework's ability to process heterogeneous data and deliver an analytical reading that ranges from the global composite index to the granularity of individual clinical, organizational, technological, experiential, and economic dimensions. The primary value emerged from this testing phase lies in the system's ability to make explicit the convergences and, more importantly, the divergences between the perspectives of the actors within the ecosystem. In the context of regional telemedicine, such divergences do not constitute mere informational noise; instead, they represent fundamental diagnostic signals of potential misalignments between strategic expectations and operational reality. By making these areas of friction visible, TEMEF enables policy makers to identify systemic trade-offs that a purely synthetic indicator would tend to obscure, such as the potential conflict between technological scalability and experiential acceptability for the end user. In this perspective, complexity is not isolated as a standalone variable but acts as a transversal logic permeating the entire framework. The five selected dimensions function as lenses through which to intercept crucial operational manifestations, such as stakeholder interdependence, the adaptive capacity of organizations, and the tensions between competing objectives. While the decision to limit the analysis to five macro-areas inevitably involves a degree of abstraction, this simplification proved functional for creating a tool that is both rigorous and flexible, capable of adapting to the institutional and territorial specificities of different regional contexts. The dashboard developed in Power BI completes this process, providing an analytical environment where the translation of theoretical constructs into clear visual outputs facilitates an informed, evidence-based decision-making process. However, it is essential to

reiterate the nature of this study as a PoC: the configurations analyzed derive from a testing phase conducted with synthetic profiles and should not be read as definitive results on the functioning of specific real-world services. The contribution lies in the proof of the model's operational translatability and its aptitude for supporting healthcare governance. Future developments must necessarily include empirical validation in the field to test the robustness of the indicators in real-world settings, potentially integrating TEMEF with more advanced dynamic modeling techniques, such as agent-based simulations, to better capture emerging phenomena. The ultimate goal remains the refinement of a tool capable of simulating stakeholder interactions and observing the evolution of trade-offs over time, transforming evaluation from a mere inspection act into strategic support for the sustainable innovation of local healthcare.

5 Ethics Declaration

This research did not require ethical approval, as it is based exclusively on publicly available secondary data and does not involve human participants, personal data, or sensitive information.

6 AI declaration

Artificial intelligence tools were used to support grammar and language refinement, item refinement, internal consistency checks, and the generation of synthetic stakeholder profiles and simulated responses for the preliminary pre-test. All outputs were critically reviewed and revised by the authors, who retain full responsibility for the study. AI was not used to collect empirical data or to replace empirical or psychometric validation.

Managing Knowledge for Including Persons with Disabilities in Organizational Contexts

Abstract

The 2030 Agenda of the United Nations promotes the inclusion of Persons with Disabilities (PwD) in the workplace as a core element of an organization's social responsibility (SR). Respecting this right to inclusion in the workplace is especially imperative for public sector organizations (PSOs), because of their institutional role and the intrinsic link between the public values they embody, such as solidarity, justice, equity, and social inclusion, and SR principles. However, merely implementing work accommodations, as defined by various international and national legislations, such as that of Italy, may not be enough to make PwD feel genuinely included in the workplace. To address these issues, knowledge of disability and inclusion principles must be carefully managed as an intangible resource to help employees recognize the importance of including PwD as an organizational SR value. Socialization mechanisms play a pivotal function in facilitating the transfer and internalization of knowledge within organizations. In these terms, informal controls (cultural and personnel controls) may represent a powerful tool for modelling and transferring knowledge, thereby affirming the principles of workplace inclusion for PwD. Based on self-determination theory, this study examined how the managerial use of informal controls experienced by non-executive employees in PSOs influences their prosocial behaviours towards PwD via the indirect effect of organizational identification. This prosocial outcome is particularly important in PSOs, as it represents an expression of the core role of public employees as public servants. To test the research hypotheses, data were collected by administering questionnaires to a sample of Italian municipal employees. Regression analysis verified all the hypothesized paths. This study has contributed to the emerging body of research on integrating SR principles into management control systems within PSOs. In doing so, it has also shed a light on the neglected role of informal controls as factors shaping and transferring the knowledge of inclusion values toward PwD to public employees.

Keywords: Knowledge management, Informal controls, Disability and inclusion principles, Public employees, Italy.

Paper type: Academic Research Paper

1 Introduction

The UN 2030 Agenda has promoted workplace inclusion (WI) of Persons with Disabilities (PwD) as a core element of organization's social responsibility (SR). Specifically, the European Employment Equality Directive and the European Disability Strategy 2021-2030 established the right of PwD to work on a fair and equal basis with other employees and to benefit from measures that support their integration into the workforce while avoiding any form of discrimination. Respecting this right to inclusion in the workplace is especially imperative for public sector organizations (PSOs), because of their institutional role and the intrinsic link between the public values they embody, such as solidarity, justice, equity, and social inclusion, and SR principles (Aguilera et al., 2007; Abdelmotaleb & Saha, 2019; Hammon, Gillis, and Icenogle, 2023). However, merely implementing work accommodations, variously defined by legislation in several countries, including Italy, may not be enough to make PwD feel genuinely included in the workplace (Shore et al., 2018; Waisman-Nitzan, Gal, and Schreuer, 2019; Coll & Mignonac, 2023), beyond limiting the effectiveness of disability management practices within PSOs (Palumbo, Hinna, and Manesh, 2023).

Knowledge, beliefs, and organizational culture around disability and inclusion need to be more deeply shaped so that PwD feel recognized, respected, and valued by colleagues for their diverse abilities (Randel et al., 2018; Mor-Barak et al., 2021).

To this end, PSOs should adopt approaches that dynamically nurture and manage knowledge, as an intangible resource, helping employees be aware of the relevance of PwD inclusion as an organizational SR value (Lee & Choi, 2003; Nelissen et al., 2017).

Socialization mechanisms play a pivotal function in facilitating knowledge transfer and internalization processes within organizations (Nonaka & Takeuchi, 1995; Pinho et al., 2012). Being embedded in organizations that encourage the progressive homogenization of values and goals increases their understanding, learning and

interiorization (Ravishankar and Pan, 2008; Kassa & King, 2023). These intangible processes of knowledge transfer make employees more psychologically empowered, thereby lending to behaviours aligned with organizational principles, goals, and expectations.

In PSOs contexts, promoting social-relational mechanisms aimed at spreading awareness of the value of inclusion among PwD, influencing the micro-foundations of employees' SR, could induce inclusive prosocial motivations and behaviours as an expression of their role as public servants (Grant and Gino, 2010; Abdelmotaleb & Saha, 2019).

The managerial use of informal controls, namely cultural and personnel controls, may serve these purposes by, respectively, building shared norms and values and inducing desired employee behaviour (Merchant and Van der Stede, 2007).

Research on the integration of SR principles within management control systems (Norris & O'Dwyer, 2004; Johnstone, 2019) suggests extending their traditional role of aligning employees' motivation and behaviour with the organization's expectations to support broader organizational implementation goals (Gond et al., 2012; Laguir, Laguir, and Tchemeni, 2019; Van der Kolk, Van Veen-Dirks, and ter Bogt, 2019). From this SR-oriented perspective, informal controls can be a powerful tool for modelling and transferring knowledge, fostering the affirmation of the principles of workplace inclusion for PwD.

At the individual level, the influences on employees resulting from managerial use of these controls can be usefully interpreted through the assumptions of self-determination theory (Ryan & Deci, 2000b; Gagné & Deci, 2005). According to this theory, when an individual engages with the organization and their need for belonging is satisfied, a series of positive effects are produced on the process of organizational identification (OI) and the internalization of organizational goals and values at the individual level. Effective managerial use of cultural and personnel controls may enable the alignment of employees' values and goals with those of the organization, by helping to fulfil the need for relatedness, that is, one's sense of belonging and significance within the reference community (Ryan & Deci, 2000b). Indeed, satisfying this need for consistency between personnel and organizational identity increases OI, promoting the internalization of PSOs' goals and values, including those related to the principles of disability and inclusion. Therefore, it is likely that the use of personnel and cultural controls, acting on the affective-relational dimensions of SR (Aguilera et al., 2007; D'Aprile & Talò, 2014), contributes to increasing employees' propensity to engage in prosocial behaviours towards PwD.

Previous studies have highlighted the links between prosocial behaviours and organizational inclusion (Ertas, 2014; Hammon, Gillis, and Icenogle, 2023; Nelissen et al., 2017), but few have investigated the role of management control systems in promoting inclusive principles and behaviours toward PwD (Tucker & Nash, 2023; Raucci & Paolini, 2025).

Building on this premise, the study explores the influence of managerial use of cultural and personnel controls, experienced by non-executive employees in PSOs, on their prosocial behaviours toward PwD via the indirect effect of OI.

This study contributed to the emerging research on integrating SR principles into management control systems (Norris & O'Dwyer, 2004; Gond et al., 2012; Johnstone, 2019) within PSOs. In particular, it shed light on the neglected role of cultural and personnel controls as factors shaping and transferring the knowledge of inclusion values toward PwD to public employees. This is a relevant topic in the context of PSOs because, by leveraging the micro-foundations of SR, it explores how perceptions of managerial use of informal controls can induce employees' inclusive prosocial behaviours toward PwD, as an expression of their nature as public servants (Bennett, 2011; Abdelmotaleb & Saha, 2019).

To test the research hypotheses, we collected data by administering questionnaires to a sample of employees in Italian municipalities.

The paper is structured as follows: Section 2 illustrates the theoretical framework and research hypotheses; Section 3 describes the sample and methodology; Section 4 presents the results; and Section 5 provides discussions and conclusions.

2 Background

PSOs should strengthen the integration of SR principles into their core values (Aguilera et al., 2007; Aguinis & Glavas, 2012), adopting management approaches that make employees aware of the relevance of PwD inclusion as an organizational value. Engaging employees in building and sharing the value of inclusion within the organizational context (Bennett, 2011) would allow them to develop a personal sense of SR (D'Aprile & Talò, 2014) and engage in inclusive prosocial behaviours toward colleagues with disabilities.

Building an inclusive work environment allows all internal stakeholders, especially those with disabilities, to experience a sense of belonging to their organizations, while feeling free to express their differences and

uniqueness (Metallo, Ricci, and Migliaccio, 2009; Migliaccio, 2019; Mor Barak, Luria, and Brimhall, 2021). Empirical evidence on the perceptions of inclusive work environments (Oware & Mallikarjunappa, 2021; Palumbo, Hinna, and Manesh, 2023) highlights improvements in the workplace well-being, attitudes, and behaviours of all employees, with broader positive effects on individual and organizational performance.

To achieve these goals, PSOs should foster and manage knowledge processes regarding the value of inclusion for the organization, to convey to employees not only formal notions of this principle, but also a deeper individual understanding of the ethical and SR implications of inclusion for PwD (Aguilera et al., 2007; Burns & Jollands, 2020; Pinho et al. 2012).

Indeed, knowledge management practices enable the collection, codification, sharing, and legitimization of knowledge related to disability, the rights of PwD, and the organizational value of inclusion, fostering a socio-organizational infrastructure capable of transforming institutional values into shared operational knowledge. In this regard, public management studies highlight the role of knowledge transfer and, in particular, knowledge socialization mechanisms, beyond those based on documents, in making knowledge sharing among employees effective (Nonaka & Takeuchi, 1995; Renaudin et al., 2018; Kassa & King, 2023).

When knowledge of the value of inclusion for PwD is effectively transferred to employees, fostering processes of internalizing this value, they learn that disability is not merely an individual issue, but the result of the interaction between the individual and organizational barriers (Butler & Ferlie, 2020; Yildiz et al., 2024). This changes employees' interpretative framework toward inclusion, which no longer appears as a discretionary concession, but as a collective responsibility of the organization to which socially responsible individual behaviours must be aligned. The knowledge thus internalized tends to translate into prosocial behaviours of inclusion toward PwD, such as helping, cooperating, adapting interactions, supporting accommodation, countering stereotypes, encouraging participation in decision-making, etc. (Grant and Gino, 2010; Sanclemente et al., 2024). Indeed, these inclusive prosocial behaviours emerge more easily when the employee has both knowledge and signals from the organization that legitimize such actions (Nelissen et al., 2017; Raucci & Paolini, 2025).

These cognitive purposes regarding the value of inclusion for the organization can be incorporated into the traditional purposes of using management control systems to pursue the integration of SR objectives into the functions of these systems, as suggested by recent studies (Gond et al., 2012; Johnstone, 2019; Laguir, Laguir, and Tchemeni, 2019). In this sense, management control systems would support internal knowledge management processes regarding the value of inclusion for PwD and increase the congruence of employee goals and behaviours with those of the organization (Norris & O'Dwyer, 2004; Tessier & Otley, 2012; Van der Kolk, Van Veen-Dirks, and ter Bogt, 2019).

Adopting Merchant and Van der Stede's (2007) conceptual model, management control systems can function as formal mechanisms (such as results and action controls) and informal mechanisms (such as personnel or culture controls) to induce alignment between individual and organizational goals. Informal controls, operating according to the dynamics of social control, focus attention on employees' values and behavioural dimensions. Personnel controls foster behavioural congruence with organizational expectations by employing human management practices. Cultural controls aim to shape, communicate, and disseminate the organization's core values, principles, and norms among employees. Several studies have highlighted that these informal controls, if appropriately employed in management control systems, can be as effective as formal controls in influencing organizational performance (Laguir, Laguir, and Tchemeni, 2019; Goebel & Weißenberger, 2017).

The interface between management control systems and micro-SR outcomes is an emerging topic in the PSOs context. In these organizations, which have complex objectives and responsibilities related to public value (Abdelmotaleb and Saha, 2019; Bracci et al., 2019; Burns & Jollands, 2020), the attitudinal and behavioural potential of cultural and personnel controls can be crucial as a tool for transferring knowledge of the value of inclusion to PwD. Previous studies have highlighted the links between organizational inclusion and prosocial behaviours driven by individual perceptions of SR (Aguinis and Glavas, 2012; Ertas, 2014; Nelissen et al., 2017; Hammon, Gillis, and Icenogle, 2023). However, few studies have explored the role of management control systems, and, more specifically, informal controls, in promoting principles of organizational inclusion toward PwD (Tucker & Nash, 2023; Raucci & Paolini, 2025).

The use of personnel and cultural control as drivers of employee micro-SR can be explored by adopting self-determination theory (Ryan & Deci, 2000b). This theory posits that individuals aim to satisfy fundamental needs such as competence, autonomy, and relatedness. This latter need is satisfied when employees interact with internal organisational stakeholders. A sense of relatedness facilitates belonging and individuals' identification with organizational goals and values (Gagné & Deci, 2005). By satisfying employees' need for belonging, cultural and personnel controls enable them to share the organization's values and transfer knowledge into employees' interpretative frameworks. This process deepens their emotional attachment and emotional bond with the

organization, fostering identification with the SR goals and values conveyed by the PSO (Aguilera et al., 2007; D'Aprile & Talò, 2014). OI dynamics (Abdelmotaleb & Saha, 2019; Coll & Mignonac, 2023; Smidts et al., 2001) foster employees' perceptions that expectations and norms exist that are consistent with their personal identity and that they should actively participate in the pursuit of the organization's SR values. Therefore, it is likely that, through these micro-SR influences, personnel and cultural controls increase employees' propensity to align with the inclusive values conveyed by their PSOs, activating inclusive prosocial behaviours toward PwD.

Based on this rationale, we hypothesize that:

- *Hp 1: Cultural control positively influences organizational identification of public employees.*
- *Hp 2: Personnel control positively influences organizational identification of public employees.*
- *Hp 3: Organizational identification positively influences prosocial behaviours toward PwD among public employees.*

3 Methods

An empirical analysis was conducted on a sample of Italian municipalities. We focused on municipalities from the ISTAT demographic range of 20,000- 59,999 residents, which is representative of a significant proportion of Italian municipalities. Then, we selected those municipal entities with over 50,000 residents and at least 200 staff members, as, based on the Italian regulation (2009 'White Paper on Accessibility and Urban Mobility', L.D. 75/2017 and L. 227/2021), these municipalities are required to implement disability management practices and appoint a figure responsible for them. This selection process allowed to identify 19 municipalities, of which 9 agreed to participate in the survey.

A survey was conducted to collect data from non-executive employees, assuring them privacy and confidentiality. Cultural and personnel controls were each measured using 5 items based on Merchant and Van der Stede (2007), as adopted by Van der Kolk, Van Veen-Dirks, and ter Bogt (2019) (a sample items includes "Employees know what is expected from them from the prevailing culture" for cultural control and "'Many opportunities for training and education are being offered" for personnel control). OI was measured using 5 items from Smidts et al.'s (2001) scale, which assess employees' emotional attachment and affective bond to their organization through items such as "I experience a strong sense of belonging to my organization". Prosocial behaviour towards PwD was evaluated using a 4-items scale developed by Grant (2008), who assess this behaviour by measuring the reasons beyond the motivation to work (e.g., "I am motivated to do my work because I care about benefiting others through my work").

The final sample included 411 employees. Preliminary analyses were conducted to evaluate the psychometric soundness of the measures. Internal consistency was assessed using Cronbach's alpha coefficients, and exploratory factor analyses were employed to verify the scales' convergent and discriminant validity. Descriptive statistics and bivariate correlations were computed for all variables. The model was tested using a linear regression.

4 Findings

The hypotheses testing, which resulted from regression analysis, showed that cultural and personnel controls had a positive significant effect on OI ($\beta = 0.42$, $p \leq 0.001$ and $\beta = 0.36$, $p \leq 0.001$, respectively). This result is consistent with the assumption that the managerial uses of informal controls contribute to satisfying employees' need for belonging and build organizational identity.

Figure 1 represents the evidence.

Figure 1: Regression analysis

The findings also revealed a positive and significant relationship between OI and prosocial behaviour towards PwD (b = 0.38, p £ 0.001). Thus, strengthening employees' ties with the organization and its goals allows for a substantial increase in the WI of PwD. To this end, results highlighted the importance of reinforcing the relational dimension induced by informal controls as a possible means of knowledge management and transfer, capable of reinforcing the relations of public servants with the public values and goals of the organization where they work. Thus, all the paths hypothesized were verified.

5 Discussion and Conclusions

This study investigated whether and how informal controls—specifically cultural and personnel controls—support prosocial behaviours toward PwD within PSOs. To address this aim, we conducted an empirical survey-based analysis involving non-executive employees working in Italian municipalities.

Overall, the results aligned with the mechanisms posited by self-determination theory (Gagné & Deci, 2005). In particular, both cultural and personnel controls appeared to foster congruence between public employees' values and objectives and those promoted by their organization, thereby strengthening OI. This evidence is consistent with earlier work showing that cultural and personnel controls can satisfy employees' need for relatedness (Van der Kolk, Van Veen-Dirks, and ter Bogt), facilitating the circulation and internalization of shared organizational values. In PSOs, such values often include SR principles, whose foundations are interwoven with public value and its multiple institutional roots (Abdelmotaleb and Saha, 2019; Bracci et al., 2019). In addition, the findings indicated that stronger OI, reflecting a more intense affective attachment to the organization and to the goals pursued by public servants, reinforced employees' relationship with the public service mission by conveying more prosocial behaviour toward PwD. Taken together, the empirical evidence supported all the hypothesized paths.

By doing so, the study added to existing knowledge on the motivational implications of how informal elements of management control systems are used, focusing specifically on public employees who do not hold managerial responsibilities. Building on this, the study contributed to emerging debates on connecting management control systems with the micro-foundations of SR (Johnstone, 2019) in PSOs (Aguinis and Glavas, 2012; Hammon, Gillis, and Icenogle, 2023). More specifically, the analysis brings attention to the often-overlooked role of cultural and personnel controls in shaping and transmitting PwD inclusion-related knowledge and values to public employees. It also highlighted the importance of employees' perceived experience of control, which remains underexplored in this stream of research (Tessier and Otley, 2012). In this way, the paper informed the growing literature on SR micro-outcomes (Aguilera et al., 2007; Aguinis and Glavas, 2012; Hammon, Gillis, and Icenogle, 2023) within the still relatively under-investigated setting of PSOs (Raucci and Paolini, 2025).

From a practical standpoint, public management should embed social inclusion as an internally driven principle rather than treating it primarily as a response to external requirements. An internal orientation may enable organizations to mobilize diverse knowledge drivers to build a culture that extends beyond workplace adjustments and more fully reflects the SR principles that characterize PSOs. In this respect, public managers should aim to integrate and coordinate personnel and cultural controls more closely with human resource management practices, which are directly implicated in disability management.

Promoting inclusion "from within" through tighter alignment between personnel and cultural controls and human management practices may support the co-construction of sustainable development pathways, helping PSOs to pursue the wider public values and objectives they are expected to embody. Encouraging inclusive prosocial behaviours toward PwD may facilitate the effective implementation of disability management practices, moving beyond a narrow focus on accommodations toward a deeper cultural orientation grounded in SR. Such behaviours are likely to yield benefits for PwD (performance, well-being, and turnover intentions) and for service relationships with PwD as external stakeholders of public services.

Notwithstanding these insights, the research was subject to limitations. The evidence relies on survey data and a relatively small set of observations, which constrains generalizability because responses may reflect the specific organizational context and respondents' subjective interpretations. Future research should expand the sample to verify whether the observed relationships hold across other municipalities and across different types of PSOs. Moreover, subsequent studies should examine the role of additional intervening factors that may shape these dynamics.

Absorptive Capacity in Complex Public Organizations: The Role of AI

Silvia Amélia Fonseca de Oliveira, Nathália Berger Werlang
Universidade Federal de Santa Catarina, Florianópolis, Brasil

Abstract

Artificial Intelligence has emerged as a relevant enabler of Knowledge Management, particularly in complex public organizations exposed to large volumes of external information and increasing demands for innovation and public value creation. In such contexts, international missions constitute strategic channels for accessing external knowledge through cooperation networks, foreign institutions, and professional interactions. However, while organizations may effectively identify and acquire valuable knowledge through these initiatives, significant challenges often remain in converting it into institutional learning and sustained organizational outcomes. Accordingly, the objective of this article is to understand how AI can act as a facilitating element of Absorptive Capacity in public organizations characterized by high organizational complexity and intense cooperation with international networks. The study adopts a qualitative single-case study design conducted in a federal public organization. Empirical evidence was generated through documentary analysis and 18 semi-structured interviews with public servants assigned to international missions in different countries and international organizations. Data were analyzed through content analysis supported by Atlas.ti, using the refined AC model proposed by Todorova and Durisin (2007) as the analytical framework. The findings indicate that AC is manifested in the context of international missions, particularly in the stages of recognition of value, knowledge acquisition and assimilation. Public servants assigned abroad perform functions analogous to gatekeepers, connecting the organization to strategic knowledge sources and international networks. Prior knowledge, technical expertise, and relational embeddedness were identified as critical antecedents supporting these early absorptive processes. However, significant bottlenecks emerge in the later stages of transformation and exploitation. The results reveal weaknesses in knowledge diffusion routines, fragmented feedback cycles, dependence on individual actors, and institutional memory losses associated with personnel turnover. Based on these findings, the article argues that AI may strengthen organizational learning processes through intelligent scanning, information filtering, knowledge repositories, pattern recognition, and decision-support systems. Such mechanisms may help public organizations reduce information overload, improve knowledge circulation, and convert externally acquired knowledge into innovation and sustained public value. Nevertheless, AI should complement rather than replace human judgment, contextual interpretation, and relational capabilities.

Keywords: Absorptive Capacity; Artificial Intelligence; Knowledge Management; Public Organizations; International Missions.

Paper type: Practical Paper

1 Introduction

Contemporary public organizations increasingly operate in complex, networked, and interorganizational environments characterized by information overload, institutional fragmentation, and growing expectations regarding the creation of public value. In such contexts, external knowledge generated through international cooperation and cross-boundary interactions often holds significant strategic potential. However, public organizations frequently struggle to systematically internalize, disseminate, and apply the knowledge acquired through these initiatives. This challenge highlights the relevance of Absorptive Capacity (AC), understood as an organizational capability to recognize the value of external knowledge, acquire it, assimilate it, transform it, and apply it (Cohen and Levinthal, 1990; Todorova and Durisin, 2007; Zahra and George, 2002).

In the public sector, AC assumes particular importance due to governance complexity, bureaucratic structures, and accountability demands (Ajmal et al., 2025; Fagundes et al., 2025; Harvey et al., 2010; van der Graaf et al., 2021). Although public organizations are increasingly exposed to valuable external knowledge sources, prior studies indicate persistent difficulties in converting such knowledge into institutionalized practices, innovation, and improved service delivery (Elbashir et al., 2022; Pinho et al., 2024; Waheed, 2025). Empirical evidence also suggests that while acquisition and assimilation processes are more visible, transformation and exploitation often remain constrained by fragmentation, rigid routines, and limited coordination (Ajmal et al., 2025; Van der Graaf et al., 2021; Castro et al., 2022; Pinho et al., 2024; Waheed, 2025).

These challenges become particularly salient in the context of international missions, which can function as strategic arenas for organizational learning by providing access to external knowledge and opportunities for collaboration (Françoso and Vonortas, 2023; Jin and Wang, 2021; Mori et al., 2025). Nevertheless, the knowledge generated in such initiatives is often dispersed across individuals, weakly codified, or insufficiently shared internally (Murray et al., 2011; Stark, 2018; van der Graaf et al., 2021; Zhou et al., 2021).

At the same time, recent developments in Knowledge Management (KM) have emphasized the growing potential of Artificial Intelligence (AI) to support information filtering, semantic analysis, knowledge retrieval, and decision support (Su et al., 2022). AI may enhance organizational capabilities to process large volumes of heterogeneous information and transform dispersed inputs into actionable knowledge (Mohan, 2025; Zhou, 2021). From this perspective, AI emerges as a promising enabling mechanism for strengthening absorptive capacity processes.

Despite growing interest in both AC and AI-enabled knowledge management, limited attention has been given to how AI can support specific AC processes in public organizations. Based on empirical evidence from international missions: **how can Artificial Intelligence facilitate the absorption of external knowledge in complex public organizations**?

Accordingly, the objective of this article is to understand how AI can act as a facilitating element of Absorptive Capacity in public organizations characterized by high organizational complexity and intense cooperation with international networks.

Methodologically, this study adopts a qualitative research design grounded in the AC model proposed by Todorova and Durisin (2007). Empirical findings from international missions are used to identify recurrent barriers and enabling conditions associated with absorptive processes. Building on these findings, the article advances a conceptual discussion on how AI tools and practices may help overcome such barriers.

This article contributes to the literature in three ways. First, it extends AC research to the context of public-sector international missions as strategic learning environments. Second, it connects empirical evidence on AC barriers with emerging debates on AI-enabled knowledge management. Third, it offers practical insights for managers seeking to improve the conversion of externally acquired knowledge into public value through more intelligent and systematic organizational processes.

2 Theoretical background

This section discusses AC, its relevance in public organizations, and the potential role of AI in supporting knowledge processes.

2.1 Absorptive Capacity as a Dynamic Capability

The concept of AC was introduced by Cohen and Levinthal (1989, 1990) to describe an organization's ability to recognize the value of external knowledge, assimilate it, and apply it for productive purposes. Their perspective establishes AC as a cumulative learning capability rooted in prior related knowledge, emphasizing that existing knowledge shapes the organization's ability to identify and integrate new information.

Building on this foundation, Zahra and George (2002) distinguish between Potential Absorptive Capacity (PACAP), composed of acquisition and assimilation, and Realized Absorptive Capacity (RACAP), related to transformation and exploitation. Their contribution highlights that access to knowledge does not automatically lead to productive use, making social integration mechanisms essential for reducing the gap between potential and realized value.

Todorova and Durisin (2007) revisit this model by reintroducing the stage of recognition of value and conceptualizing AC as a recursive process characterized by feedback loops among stages. They also emphasize the relevance of power relationships, which may act as filters or barriers affecting the assimilation, transformation, and use of external knowledge.

The operationalization of AC often depends on gatekeepers, individuals positioned between internal systems and external knowledge sources (Cohen and Levinthal, 1990). These actors play a central role in environmental scanning, knowledge acquisition, and translating information into organizationally meaningful forms (Murray et al., 2011). In international contexts, they also mediate norms, practices, and sensitive information across institutional boundaries (Françoso and Vonortas, 2022). By maintaining ties with both external partners and internal structures (Graf, 2010), gatekeepers help reduce communication gaps and cognitive incompatibilities (Daghfous, 2004).

These theoretical developments suggest that AC is particularly relevant in environments characterized by complexity, interdependence, and continuous interaction with heterogeneous external knowledge sources.

2.2 Absorptive Capacity in Public Organizations

Although originally developed in private-sector settings, AC has become increasingly relevant in Public Administration, where organizations face institutional complexity, multiple stakeholders, bureaucratic

constraints, and growing expectations regarding efficiency, innovation, and public value creation. In such contexts, the ability to identify, internalize, and apply external knowledge becomes strategically important.

Elbashir et al. (2022) demonstrate that the assimilation of business intelligence systems in public organizations depends substantially on the effective incorporation of external knowledge. In this sense, AC may function as a compensatory mechanism for structural deficiencies, such as limitations in talent retention, thereby enabling more robust data-driven decision-making processes.

Recent studies have also challenged the linearity traditionally associated with AC models. Butler and Ferlie (2020) argue that, in public organizations, knowledge acquisition unfolds as a continuous, relational, and co-creative dynamic rather than through discrete sequential phases. Similarly, Fagundes, Tumelero and Fagundes (2025) introduce the concept of AC metaroutines, suggesting that knowledge absorption occurs through recursive and iterative sequences of organizational practices.

Taken together, these findings indicate that AC in Public Administration should be understood not merely as a set of organizational capabilities, but as an emergent, path-dependent, and socially embedded process whose effectiveness depends on conditions that enable the transformation of knowledge into sustained public value.

2.3 Artificial Intelligence in Knowledge Management

Recent debates in Knowledge Management have emphasized the growing relevance of AI as a potential enabler of processes that transform large volumes of heterogeneous information into organizationally useful knowledge (Zhou, 2021; Mohan, 2025). In knowledge-intensive environments, AI may support information filtering, pattern recognition, semantic analysis, summarization, and decision support.

Prior studies also suggest that digital capabilities may reinforce AC. Joshi et al. (2010) mobilized AC theory to explain how information technology tools strengthen knowledge capabilities, while Mao et al. (2017) and Ma et al. (2021) indicate that technological competence and IT infrastructure may operate in synergy with AC to promote agility, performance, and adaptive capacity.

From this perspective, AI may contribute to specific dimensions of AC. In recognition and acquisition stages, AI can support environmental scanning and automated retrieval of relevant information. During assimilation, AI tools may facilitate classification, summarization, and interpretation of dispersed content. In transformation processes, AI may help identify patterns, combine heterogeneous knowledge sources, and reveal actionable insights. In exploitation, AI-based systems may support decision-making and implementation processes.

These contributions are particularly relevant in public organizations, which often face information fragmentation, interdepartmental silos, and what Zhou, Chen and Han (2021) describe as data stickiness. Under such conditions, AI may help reduce analytical overload, improve knowledge flows, and strengthen organizational learning. However, the adoption of AI in public settings also requires governance, transparency, data quality, and human oversight. Its value depends not only on technological availability, but also on the organization's preexisting AC to interpret, adapt, and apply digitally supported knowledge processes.

3 Methodology

This study adopts a qualitative single-case study design with an exploratory and descriptive orientation. The empirical setting is a federal public organization whose international missions constitute strategic arenas for external knowledge acquisition, interorganizational interaction, and organizational learning. A qualitative approach was considered appropriate because it enables an in-depth understanding of complex organizational phenomena, particularly those involving tacit knowledge flows and learning processes across organizational boundaries.

Three complementary data collection techniques were employed. First, a bibliographic review was conducted using databases such as Scielo, Web of Science, and Scopus to consolidate the theoretical background and support the selection of the AC framework. Second, documentary research involved the analysis of regulations, institutional documents, and digital sources related to the organization's international activities. Third, and most centrally, semi-structured interviews were conducted with public servants directly involved in missions abroad.

The empirical corpus comprises 18 interviews with public servants assigned to international missions in different countries and international organizations. A semi-structured interview protocol was developed to ensure comparability while preserving flexibility for emerging issues. The protocol was organized into four sections aligned with the research objectives: (1) prior knowledge and external knowledge sources; (2) routines and processes related to recognition of value, acquisition, assimilation, transformation, and application of external knowledge; (3) contingent factors such as social integration, power relationships, feedback mechanisms, and internal/external interactions; and (4) suggestions for organizational improvement.

Data were analyzed through content analysis following Bardin (2021), comprising pre-analysis, material exploration, and treatment of results through inference and interpretation. Coding procedures were initially guided by predefined categories derived from the refined AC model proposed by Todorova and Durisin (2007), while remaining open to emergent categories arising from the empirical material. Atlas.ti (version 25) was used to support data organization and coding procedures.

The methodological strategy unfolded in two complementary stages. First, the qualitative case study examined how AC processes manifest in international missions, identifying recurrent barriers, enabling conditions, and organizational routines related to external knowledge use. Second, these findings were conceptually reinterpreted in light of recent literature on AI in KM. Rather than treating AI as an empirically observed phenomenon, the study uses the literature to explore how AI-enabled mechanisms can strengthen AC in public organizations operating in international contexts.

4 Results and Discussion

The empirical analysis of international missions in a public organization indicates that AC is clearly manifested in the public sector. Public servants operating abroad perform key gatekeeper functions in mediating external knowledge flows. The findings suggest that early absorptive stages, particularly recognition of value, acquisition, and initial assimilation, tend to operate more effectively than later stages.

4.1 Absorptive Capacity Dynamics in International Missions

The empirical findings indicate that international missions constitute strategic organizational environments in which AC becomes clearly observable in practice. In these settings, public servants assigned abroad operate at the interface between the organization and external institutional environments, facilitating access to new information, cooperation opportunities, operational practices, and international knowledge sources. This evidence reinforces the relevance of AC in public-sector contexts characterized by interorganizational interaction and external dependence.

A first relevant finding concerns the antecedents of AC. The study identified a wide diversity of external knowledge sources accessed during missions abroad, varying according to the profile and specific responsibilities of each mission. These sources include formal institutional channels, professional networks, interpersonal relationships, and situational interactions developed in the host environment. Access to these sources is described by interviewee 10, when he mentions "*meetings with local authorities, participation in events and seminars, technical visits to local institutions, in addition to direct contact with attachés and liaison officers from other countries*". Such diversity confirms the importance of external knowledge exposure as a precondition for absorptive processes, while also indicating that different international positions may require differentiated KM strategies.

The results further suggest that prior knowledge held by public servants plays a decisive role in enabling absorptive dynamics. Accumulated experience within the organization was shown to be particularly relevant for recognizing the value of external knowledge, especially in contexts where preparation processes for missions were limited or operational guidance was insufficient. Prior technical expertise, familiarity with organizational routines, and previous experience in related areas enhanced the ability of individuals to interpret external signals and identify strategically relevant information. These findings are consistent with Cohen and Levinthal (1990) and Todorova and Durisin (2007), who emphasize prior knowledge as a critical antecedent of AC.

Regarding the core dimensions of AC, the recognition of value emerged as strongly dependent on the profile and competencies of the civil servant assigned to the mission. The ability to identify relevant information was influenced by technical background, contextual understanding, and relational positioning within international environments. In this sense, the recognition stage does not appear automatic, but rather contingent upon individual and contextual conditions, as mentioned by interviewee E4, when stating that "*I would not say that the management guided me much, because what guided me was my own experience*".

Similarly, knowledge acquisition was described as a recurrent and relatively effective process, supported by institutional embeddedness and broad social networks. Access to relevant knowledge often occurred through formal cooperation arrangements as well as informal interactions with external actors. This result highlights the transversal role of social integration mechanisms in strengthening the early stages of AC, particularly in international and interorganizational settings.

The findings also indicate that these public servants perform functions analogous to gatekeepers, acting as boundary-spanning actors who connect external environments with internal organizational units. They mediate information flows, translate external practices into organizationally meaningful knowledge, and facilitate the

circulation of strategic insights within the institution. This interpretation is aligned with the gatekeeper concept discussed by Cohen and Levinthal (1990), Daghfous (2004), Graf (2010), and Murray et al. (2011).

Overall, the evidence suggests that AC is concretely manifested in the context of international missions, particularly in the stages related to recognition of value and acquisition of external knowledge. However, although the organization demonstrates strong potential AC, the conversion of individually acquired knowledge into institutional learning depends on subsequent mechanisms of assimilation, transformation, and application. These later-stage constraints are examined in the following section.

4.2 Structural Bottlenecks in Knowledge Transformation and Exploitation

The findings indicate that although international missions function as effective channels for external knowledge acquisition, significant barriers emerge when such knowledge must be internalized, disseminated, and converted into organizational action. The transition from individual learning to institutionalized organizational knowledge remains a challenging process, often interrupted by structural and cognitive limitations related to information processing, coordination, and KM routines.

A critical and often overlooked factor in this dynamic is institutional amnesia. As highlighted by Stark (2018), the erosion of organizational memory caused by leadership changes and personnel turnover undermines policy continuity and weakens accumulated learning. In the absence of robust retention mechanisms, such as institutional memory systems or structured repositories, public organizations face difficulties consolidating past experiences and preserving strategically valuable knowledge over time.

In addition to memory-related constraints, the empirical evidence reveals severe weaknesses in organizational feedback loops. Although public servants assigned abroad routinely submit reports and strategic information, from the experience reported by the interviewees, feedback from central units is frequently fragmented, informal, or absent. According to interviewee 11 "*communication fails both in sending and returning, this ends up generating a disincentive in the production and transfer of knowledge*", leading the servers to seek feedback on their own initiative. This interruption in communication cycles appears associated with structural overload in headquarters units, which often lack sufficient capacity to process, analyze, and respond to the large volume of information generated simultaneously across international representations.

The absence of effective feedback produces an informational vacuum that discourages continued engagement by gatekeepers and weakens strategic alignment between external missions and internal organizational priorities. At the same time, the reception and processing of externally sourced knowledge remain weakly systematized. Reporting practices depend heavily on bureaucratic procedures and individual proactivity, transforming learning into episodic events rather than continuous organizational routines.

Consequently, externally acquired knowledge frequently encounters limited screening capacity, insufficient categorization mechanisms, and low diffusion across internal units. These findings suggest a persistent gap between PACAP and RACAP, in which valuable knowledge is identified and acquired but only partially transformed into institutional learning, innovation, and sustained public value.

4.3 How AI May Strengthen Absorptive Capacity

The empirical findings reveal that the main limitations of AC in the studied public organization are concentrated not in the identification or acquisition of external knowledge, but in its subsequent conversion into institutional learning and organizational action. Gaps in knowledge diffusion, weak feedback cycles, fragmented memory systems, and excessive dependence on individual actors indicate persistent barriers in the transition from PACAP to RACAP. In this context, AI may be understood as a relevant enabling mechanism for strengthening the later stages of absorptive processes.

During assimilation processes, AI may contribute to the organization, classification, and summarization of externally acquired knowledge. One of the recurrent bottlenecks identified in the empirical evidence concerns the large volume of reports, documents, and fragmented information flows that central units often struggle to process. In this regard, natural language processing tools and intelligent repositories may facilitate the codification of dispersed information, transforming heterogeneous inputs into searchable and structured organizational knowledge.

AI may be particularly valuable in addressing institutional amnesia and weak feedback loops, two central constraints identified in the findings. Intelligent memory systems can preserve accumulated experiences, retrieve lessons learned from previous missions, and support continuity despite personnel turnover. Likewise, automated feedback systems may improve communication between central units and staff deployed abroad, helping sustain recursive learning cycles essential to absorptive capacity.

However, the contribution of AI should not be interpreted as purely technological or deterministic. Its effectiveness depends on governance arrangements, data quality, transparency, and human oversight. Most importantly, AI can strengthen absorptive processes only when organizations possess the managerial willingness and organizational routines necessary to interpret and apply digitally supported knowledge.

Therefore, rather than replacing existing human capabilities, AI should be understood as an augmenting capability that supports gatekeepers, strengthens organizational memory, improves knowledge circulation, and facilitates the conversion of externally acquired knowledge into innovation and sustained public value.

The analysis suggests that AI can strengthen the absorptive capacity of public organizations operating in international contexts through three interrelated mechanisms: organizational memory, feedback enhancement, and knowledge dissemination. First, AI systems may support the capture, storage, retrieval, and recombination of knowledge generated through international missions and dispersed networks, helping reduce personnel turnover risks and institutional amnesia. Second, AI may reinforce feedback loops through intelligent filtering, prioritization, and routing of externally acquired knowledge to relevant units, reducing cognitive overload and improving responsiveness in strategic decision-making. Third, AI may expand knowledge dissemination across organizational boundaries through pattern recognition, connection mapping, and collective sense-making from heterogeneous sources.

Figure 1 synthesizes these propositions by illustrating the flow of knowledge from its identification at interorganizational boundaries to its conversion into organizational outcomes. International missions are positioned as gatekeepers, acting as boundary-spanning actors who identify, access, and mediate relevant external knowledge through networks, partnerships, events, and institutional interactions.

This externally sourced knowledge is then processed through AI-enabled mechanisms represented as an intermediate enabling layer. Rather than replacing human actors, AI functions as a support capability that filters information, stores content, facilitates retrieval, identifies patterns, and supports learning processes. In doing so, AI helps organizations manage large volumes of heterogeneous information beyond manual processing capacity. Three reinforcing functions receive particular emphasis in the model:

1. Storage and Retrieval: Representing organizational memory infrastructure, ensuring retention and retrieval of processed knowledge;
2. Feedback: Representing feedback loops. A return arrow connects Feedback directly to gatekeepers abroad, showing that generated intelligence returns to guide new acquisitions and close the learning circuit;
3. Dissemination of Knowledge: Illustrating collective sense-making, where generated intelligence is distributed internally.

Finally, an exit arrow demonstrates that the consolidation of this AI-mediated knowledge governance culminates in incremental innovation and increasing public value, the primary objective of the public organization.

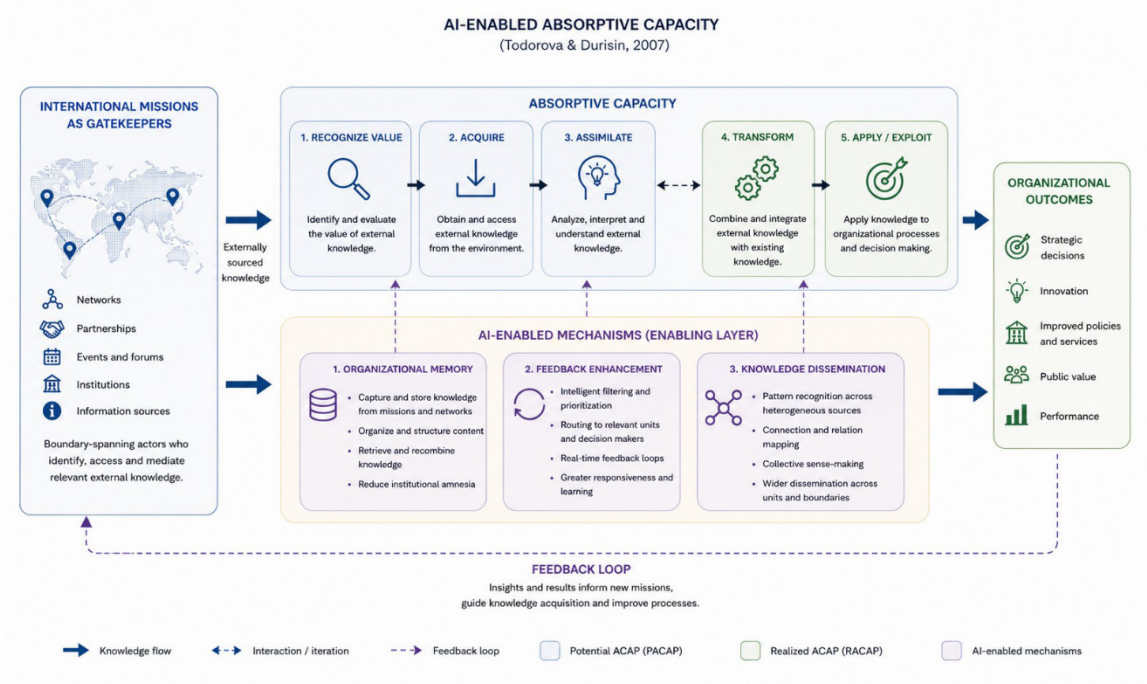

Figure 1: Artificial Intelligence as a vector to strengthen Absorptive Capacity in public context

5 Conclusions

This article achieved its objective by identifying how AC processes unfold in international missions and by proposing how AI may facilitate their different stages in complex public organizations. The results demonstrate that AC is clearly manifested in the context of international missions, particularly in the stages related to recognition of value and acquisition of external knowledge. Public servants assigned abroad operate as gatekeepers, connecting the organization to external knowledge sources. Prior knowledge and technical expertise were shown to be important antecedents supporting these early absorptive processes.

However, the findings also reveal persistent bottlenecks in the later stages of AC. Transformation, and effective application of externally acquired knowledge remain constrained by fragmented routines, weak feedback cycles, insufficient mechanisms for knowledge diffusion, dependence on individual actors, and institutional memory losses associated with personnel turnover. As a result, the organization demonstrates stronger PACAP than RACAP, indicating difficulties in converting external learning into sustained organizational outcomes and public value.

In this context, the study argues that AI may represent an important enabling capability for strengthening absorptive processes. AI tools can support knowledge processing, organizational memory, and decision-making routines, helping public organizations reduce information overload, improve knowledge circulation, and strengthen the transition from PACAP to RACAP. Nevertheless, AI should not be interpreted as a substitute for human judgment, expertise, or relational capabilities. Public servants remain central in interpreting context, exercising discretion, building trust, and translating knowledge into legitimate organizational action. Therefore, the greatest potential of AI lies in augmenting, rather than replacing, human capabilities.

From a theoretical perspective, this article contributes by extending AC research to the context of public-sector international missions and by advancing the dialogue between AC and KM through propositions on how AI may support absorptive processes. From a practical perspective, the findings suggest that managers should focus not only on acquiring external knowledge, but also on developing routines capable of assimilating, transforming, and applying it.

This study presents some limitations. First, it is based on a single-case study within one public organization. Second, the empirical data did not investigate the direct use of AI in the studied context, but treated AI as a conceptual proposition derived from empirical barriers and supporting literature.

Future research may advance this agenda by conducting empirical studies on the actual implementation of AI tools in public organizations and their effects on AC processes. Comparative studies across countries, agencies, and governance contexts may also deepen understanding of how AI interacts with organizational culture, leadership, and institutional constraints. Longitudinal research would be particularly valuable for examining whether AI-supported routines generate sustained learning outcomes over time.

In conclusion, the study suggests that the challenge faced by complex public organizations is not merely to access external knowledge, but to transform it into collective intelligence and public value. In this process, human actors remain indispensable, while AI may serve as a powerful complementary capability for enhancing learning, coordination and innovation.

6 Acknowledgements

We would like to thank the public servers who participated in the interviews for the original study.

7 Ethics declaration

The original research was authorized by the studied organization and approved by the Research Ethics Committee of the Federal University of Santa Catarina, in accordance with National Health Council regulations. Participants were informed about the study objectives, voluntary participation, and confidentiality safeguards through an informed consent form. Data were securely stored and used exclusively for academic purposes. No significant risks or direct benefits were identified, although the study may indirectly contribute to improving knowledge management practices within the organization.

8 AI declaration

Generative Artificial Intelligence tools (ChatGPT and NotebookLM) were used to support language refinement, text structuring, editorial revision, and figure development. All generated outputs were critically reviewed, interpreted, and validated by the authors, who remain fully responsible for the final content, arguments, and conclusions of this study.

Influence of Artificial Intelligence (AI) on Organizational Knowledge Creation (OKC) in Workplace Meetings

Shuyun Zhao[1], Krishna Venkitachalam[1,2]
[1] Estonian Business School, Tallinn, Estonia
[2] Ajman University, UAE

Abstract

Workplace meetings are important to organizations' daily operations, and knowledge creation is a valuable outcome of these meetings. Despite the increasing use of AI in meetings, its influence on OKC remains unexamined. This study uses the SECI model as the theoretical framework and aims to explore how AI influences the OKC process before, during, and after workplace meetings.

This study adopted a qualitative interpretive approach to explore and understand a new and complex phenomenon. Eight semi-structured interviews were conducted between March and April 2026 with employees from 3 countries and across different industries who regularly use AI in work-related meetings. Data were analyzed using the thematic analysis method with deductive-inductive coding.

The findings show that AI encourages people to engage in social interaction. In externalization, AI enables the articulation process via several mechanisms. AI enhances combination by connecting large amounts of existing codified knowledge from multiple sources. In the last mode, AI empowers individuals in internalizing knowledge. A conceptual framework is proposed that maps AI's influence in the SECI model and indicates the primary work meeting phases.

The study's qualitative nature and narrow scope restrict how broadly its findings can be statistically generalized. Second, it focuses solely on the SECI model as the analytical lens. Third, the rapid evolution of AI means the findings are time-bound. Future research can focus on AI-facilitated meetings across a wider array of organizations, apply diverse theoretical models to OKC, and scrutinize the dynamic effects of AI on this phenomenon.

The study extends the SECI model by including AI's influence in the four knowledge conversion modes in workplace meetings. Essentially, it sheds light on how AI in meetings reshapes the way organizations create knowledge, possibly enabling more effective AI application and use.

Keywords: artificial intelligence, organizational knowledge creation, SECI, workplace meetings

Paper type: Academic Research Paper

1 Introduction

Workplace meetings refer to "purposeful work-related interactions occurring between at least two individuals that have more structure than a simple chat but less structure than a lecture" (Rogelberg et al., 2025, p. 416). Researchers have identified various types of meetings. They can be differentiated by whether they are scheduled or unscheduled, or by different purposes such as discussion of ongoing projects, routine business status updates, quality, policy, and compliance. With advances in technology, virtual and hybrid meetings are becoming increasingly popular beyond traditional in-person meetings (Abidi et al., 2023). Meetings are a core component of how organizations function, irrespective of their cultural background, industry sector, or scale. They can serve as a forum for idea generation, debate and discussion, and creative thinking, leading to action plans for the next steps (Lawson et al., 2009), with the creation of new knowledge as a valuable outcome. The adoption of AI tools for meeting mediation has grown rapidly, encompassing those for meeting preparation, real-time transcription, summary generation, and support for follow-up activities. The growing use of AI is reshaping how knowledge is created in workplace meetings.

Organizational studies suggest that AI will work in synergy with human workers (Jarrahi et al., 2023), especially with the development of generative AI (Alavi et al., 2024). AI supports all four modes of the SECI model to varying degrees. For example, AI can facilitate socialization by removing physical constraints among remote teams or by connecting people with shared interests (Böhm and Durst, 2026). In externalization, people's tacit knowledge is converted to explicit knowledge via continuous dialogue with ChatGPT (Sumbal and Amber, 2025). In combination, AI can integrate fragmented resources (Almufadda and Almezeini, 2022), analyze large data sets, and uncover new patterns (Faulconbridge et al., 2024). Lastly, AI supports internalization by providing personalized assistance, recommendations, and tailored explanations and examples (Sumbal and Amber, 2025). Meetings exemplify the four modes: socialization through direct interaction, externalization by articulating thoughts, combination by integrating different knowledge bases, and internalization by applying new concepts to one's work. However, AI's role in knowledge creation in meetings is significant and warrants further

examination. Therefore, this study aims to explore the following research question: How does AI influence the organizational knowledge creation process before, during, and after workplace meetings?

The findings reveal that AI has an uneven influence on organizational knowledge creation in workplace meetings across the four SECI modes and in different meeting phases: it encourages socialization, enables articulation, enhances combination by linking various knowledge sources, and empowers individuals in internalization. This paper extends the SECI model by incorporating the influence of AI in each mode and indicating the primary meeting phase of its occurrence. It also highlights the importance of human-AI collaboration in creating new knowledge. This paper is organized as follows. The following section reviews the literature on OKC and its relevance to AI-facilitated meetings. The methodology part explains how data were collected through semi-structured interviews and analyzed using the thematic approach. The findings section is organized around four themes as per the SECI model, followed by a conceptual framework. The discussion and conclusions are presented at the end.

2 Literature Review

2.1 Organizational knowledge creation

OKC is commonly considered the first step for managing organizational knowledge and plays an important role in fostering innovation (Bettiol et al., 2023). By definition, it is "the process of making available and amplifying knowledge created by individuals as well as crystallizing and connecting it with an organization's knowledge system" (Nonaka et al., 2006, p. 1179). The process involves the conversion between tacit and explicit knowledge – tacit knowledge is deeply embedded in one's experiences, intuition, and expertise and is hard to articulate, while explicit knowledge is codified or articulated in a formal manner (Venkitachalam and Schiuma, 2022).

The SECI model depicts four knowledge conversion modes: socialization, externalization, combination, and internalization (Nonaka and Takeuchi, 1995). In socialization, through shared experiences, interactions, and observations, tacit knowledge is transferred among individuals; externalization is the process by which tacit knowledge is codified or articulated into explicit form; in combination, existing explicit knowledge is reorganized and synthesized into more systematic forms; internalization is the process for individuals to learn from the reorganized explicit knowledge and absorb it as their own tacit knowledge (e.g. Nonaka and Toyama, 2003, Lievre and Tang, 2015, Canonico et al., 2020). These processes remain important today as AI shapes how knowledge is created in organizations. For example, Zhang et al. (2025) expanded the model incorporating AI, using interpretation Ba and decision-making Ba to replace the original ones in externalization and combination. He et al. (2025) proposed that generative AI serve as a Ba by facilitating the interaction among employees. Workplace meetings provide a shared space for knowledge creation, particularly in virtual or hybrid formats, and offer an important lens for examining how AI influences the OKC process.

2.2 Workplace meetings and AI mediation - Context for OKC

Workplace meetings are key to organizational operations, which are shaped at the individual, group/team, and organizational levels. They also provide a context in which the organizational knowledge-creation process can be directly observed. In a two-year study of 43 team meetings, Hubers et al. (2016) demonstrated that meetings enabled all four modes in the SECI model, while identifying the iterative nature of knowledge creation within meetings and the cyclical nature across meetings. Each knowledge conversion mode has its distinctive characteristics in meetings, as the remainder of this section demonstrates.

First, meetings serve as an important socialization mechanism that connects individuals and promotes close interactions, thereby encouraging the exchange of knowledge (Lawson et al., 2009). Through repeated interactions, meetings help participants build trust, respect, shared norms, and mutual understandings - all of which are preconditions for knowledge creation. Socialization requires active maintenance – in effective teams, this is evident in pre-meeting interactions, social activities during meetings, and follow-up mechanisms. In remote teams, however, the extent of socialization is greatly reduced compared to co-located teams for various reasons. As a result, organizations rely on collaborative technologies such as teleconferencing, videoconferencing, and electronic meeting systems to increase socialization (Oshri et al., 2007).

Next, meetings are places where tacit knowledge is expressed and heard by peers (Nonaka and Konno, 1998). This is done via three complementary mechanisms: verbal, visual, and written. First, meetings are fundamentally constituted by talk (Asmuß and Svennevig, 2009). Second, visual artifacts, such as PowerPoint presentations (Kaplan, 2011) or similar tools, can be used for articulating one's thinking. Third, meetings typically involve

various written documents, such as a written agenda outlining the topics to be discussed before the meeting and minutes after the meeting (Gutmann, 2016). However, the externalization of tacit knowledge in meetings can be constrained, for example, not everyone's voice can be heard (Bohacova and Heide, 2024).

Third, combination occurs in meetings by organizing and integrating explicit knowledge from different participants or sources into more synthesized forms (Nonaka and Takeuchi, 1995). Various explicit inputs are brought to meetings, such as handouts, graphs, and reports (Henkel, 2007). In turn, various new explicit artifacts, such as minutes, notes, and action lists, are produced after meetings (Gutmann, 2016), which can be fed into subsequent meetings (Jarzabkowski and Seidl, 2008).

Fourth, internalization is less evident during meetings but more evident after meetings, when participants need to apply explicit knowledge to their work practices. Even though internalization can be less dominant during meetings, team members were observed to briefly reflect on the project progress or their own learning process (Hubers et al., 2016). This mode involves embodying explicit knowledge into action (Nonaka and Konno, 1998), for example, by developing action plans for employees to follow after meetings (Kauffeld and Lehmann-Willenbrock, 2012). In addition, as collaborative work passes through a series of successive meetings (Jarzabkowski and Seidl, 2008), the internalized knowledge is carried back to discussions, which iterates the knowledge creation process (Nonaka and Takeuchi, 1995).

AI is increasingly integrated into meetings, reshaping how knowledge is created before, during, and after meetings. Meeting-specific AI assistants, such as those in Zoom, Google Meet, and Microsoft Teams, provide live transcription, translation, and summarization (Suduc and Bizoi, 2022), while generative AI tools like ChatGPT can enhance the four modes of the SECI model (Sumbal and Amber, 2025), supporting both meeting preparation and post-meeting knowledge internalization. However, using AI has its shortcomings, especially around the nuances of knowledge. Minute-taking, for example, is not just about recording notes but also about prioritizing topics contextually and building a common understanding among. Transcription accuracy is another common issue, which may be affected by the use of different languages (Arakawa et al., 2025). While prior literature illustrates both AI's the advantages and the shortcomings, its influence on organizational knowledge creation remains underexplored.

3 Methodology

This study examines how employees experience and interpret AI-mediated knowledge creation in workplace meetings. Because the phenomenon of adopting AI in meetings is recent and highly context-dependent, this study adopts a qualitative interpretive approach (Myers, 2025). We conducted semi-structured interviews with employees with regular experience using AI in work-related meetings. Qualitative interviews allow the flexibility to explore themes further and capture unanticipated insights. We employed a convenience sampling method: participants were recruited through the researchers' personal networks, followed by snowball sampling. In total, we conducted 8 interviews between March and April 2026 with participants in diverse roles across organizations in three countries and across different industries. Table 1 illustrates the background of participants.

Table 1: Profile of participants

Interview	Participant's Role	Industry	Organization Country
1	Senior technical expert	Autonomous driving	China
2	Software engineer	Healthcare	China
3	Legal counsel	Entertainment	China
4	Chief governance officer	Fintech	Estonia
5	Staff software engineer	Technology	Estonia
6	Legal manager	Cosmetics	China
7	Strategic business architect	Financial services	Estonia
8	Brand partnerships manager	Social media	UK

The interviews were conducted via videoconference platforms (Zoom or iFLYREC) in either Chinese or English, according to the participant's preference, and lasted 30-80 minutes, averaging 59 minutes. The conversations followed a semi-structured interview guide built around a set of open-ended questions and grounded in the SECI model, allowing the interviewer to probe and ask follow-ups to clarify meaning and pursue unanticipated themes. The interviews were audio-recorded with participants' consent and fully transcribed. For the interviews conducted in Chinese, the original language was used for coding and analysis, to preserve participants' own expressions and avoid interpretive loss (Abfalter et al., 2021). The Chinese transcripts were translated into English with AI assistance and reviewed word by word to ensure faithful representation of participants' meaning.

We used thematic analysis (Braun and Clarke, 2006) to analyze the collected data. A hybrid coding approach (Fereday and Muir-Cochrane, 2006) was used. In line with the interview guide, the initial codebook includes a set of a priori codes derived from three dimensions: the SECI framework, the temporal phases of meetings, and participants' evaluations of AI's effect on organizational knowledge creation. Additional codes were generated inductively as new patterns emerged. We iteratively refined the codebook by applying the newly surfaced codes. This process is done via the tool ATLAS.ti.

4 Findings

The findings show that the four SECI modes unfold unevenly across different meeting phases, while AI is also used to varying degrees before, during, or after meetings. Accordingly, AI's influence on organizational knowledge creation in different meeting phases is unevenly distributed. In total, four key themes emerged from the data, one for each SECI mode.

4.1 Theme 1: Socialization is AI-encouraged

On the one hand, AI has a limited influence on socialization, supported by strong participant opinions such as *"whether AI is involved doesn't make much difference" (Interview 1)*, *"I really don't think this has much to do with AI" (Interview 5)*, and *"it will not affect interaction with others at all" (Interview 3)*. The constraint lies in the nature of tacit knowledge, which is deeply embedded in human minds. Examples include detecting whether a candidate is using AI to answer during interview meetings, or deciding which product development demand is the most urgent.

"… I'm only recording the transcription, that's it. But what I'm doing is looking at the body language of the candidate … they cannot hide their eyes … when they answer, they always look in a very concrete direction, and then I automatically decline." (Interview 4)

"… The first human judgment factor is the urgency of the requirement. Business teams usually say everything is urgent… You will have to make your own judgment … or more broadly, your work experience." (Interview 2)

On the other hand, participants acknowledge the indirect supporting role of AI in specific aspects of socialization. The first is that AI can sometimes help participants read between the lines of obscure communication, whether in internal meetings with managers, colleagues, or external meetings with customers (Interview 7, 8).

"… when British people make decisions, especially those involving risk, they may not explicitly state it … AI will then interpret the manager's words … it may summarize that your manager currently prefers all three options together, or that all three options are feasible. So, my suggestion would be choosing the one you personally prefer and then confirming it again with your manager." (Interview 7)

Second, AI reallocates meeting participants' attention from notetaking to the people in the room, also allowing the speaker to focus on expressing their ideas without interruption.

"… You may need to interrupt the process to take notes. But if you use AI, this problem basically does not exist anymore, because I know AI is helping me record everything." (Interview 2)

Third, AI subtly smooths communication by helping people understand each other by removing the barrier of accent or listening ability (Interview 5), removing background noise or showing captions during internet issues (Interview 6), and providing real-time translation (Interview 4, 8). It can also give people the freedom to learn each other's fields before or after meetings, reducing the need for explanations during the meetings.

"… With AI's help, one can learn about that field beforehand, so the meeting is more efficient." (Interview 1)

"… For example, some things don't necessarily need to be explained in full during a meeting. After the meeting … they can just use AI to summarize it. This may save some time in the socialization process." (Interview 5)

In summary, socialization – the conversion of tacit knowledge among individuals through shared experience or interactions – is the mode that has been least transformed by AI in the meeting context. Yet AI can indirectly support this mode by encouraging some interaction.

4.2 Theme 2: Externalization is AI-enabled

Documentation is key to externalization, as it efficiently turns tacit knowledge into written texts that can be stored for future use. This process generates different types of explicit outputs, including original audio or video recordings, transcripts, or a minute or summary.

"… an important way of turning tacit knowledge into explicit knowledge is documentation … AI saves a lot of effort, particularly in that process of textualization." (Interview 1)

"…It keeps the original audio … provides the full meeting transcript translated from the original recording … presents a summarized version as well. So, it gives you all three versions." (Interview 2)

"… First help is transcribing it, quickly and qualitatively. Second is restructuring and organizing it in a reusable form." (Interview 4)

In terms of quality, AI is considered a better notetaker than ordinary people. It not only generates easy-to-read summaries quickly but also filters out irrelevant content. From the users' points of view, they do not need to worry about grammar or flow.

"… AI is very powerful when it comes to note-taking or summarizing. The notes generated by AI are usually quite readable. In contrast, when you take notes yourself … the result is not very easy to read." (Interview 2)

"… when you say something to ChatGPT, you don't have to pay attention to grammar, and what you say might be a little incoherent, but you know the AI understands you." (Interview 5)

"… They will use AI to help make the document flow more smoothly and logically. In addition, non-native English speakers may use AI to help correct grammar mistakes … Although the person is still the main creator, AI helps package the content in a more refined and polished way." (Interview 8)

However, the notes generated by AI are not without flaws - one thing frequently mentioned by several participants is the loss of meaning, importance, or context in the summaries it produces. One participant illustrated the situation with a backward-installed camera case, a serious error that needs urgent correction. The top priority makes it unnecessary to explain anything else; by merely mentioning this issue, everyone knows what to do immediately after the meeting. However, for AI, this is a simple fact: AI may or may not include it in the summaries (Interview 1). In a similar vein, AI misses the priorities of tasks in developing demands, which are usually decided by project managers (Interview 2). In the case where there is a lack of company-specific context, such as internal adjustments or customizations, it is difficult for AI to accurately externalize them (Interview 5). To improve the quality, users need to provide contextual content to AI.

"… we would write a few A4 pages of content, copy and paste it into AI first, and set that as our background information … We had a saying at the time, … 'Learn to prompt, prompt to learn.' … meaning you need to explain what your context is." (Interview 7)

"… accuracy is related to the glossary. That means names, company-specific terms, personal names, or other specific terminology. We manage the glossary separately. We have taught AI to use certain terms in specific ways. Every time I find a mismatch … I add that term to a glossary that AI can access." (Interview 4)

In summary, externalization – the process that converts individuals' tacit knowledge into explicit form – is the mode that has been strongly transformed by AI in the meeting context. It claims that AI strongly enables externalization via several mechanisms, such as generating transcriptions and minutes, with output quality generally satisfactory though sometimes requiring human editing. However, because of the nature of tacit knowledge, AI can lose meaning, importance, or context.

4.3 Theme 3: Combination is AI-enhanced

AI enhances the combination process by effectively and efficiently synthesizing across various sources. Before AI, one participant's workflow using search engines was: opening a webpage, checking its relevance, opening more webpages to identify better sources, or making a summary. Now the tasks are done by AI - although the underlying process is somewhat similar, it becomes far more efficient (Interview 2). This efficiency is also evident within organizations. In the past, internal portals such as wikis or SharePoint were used to maintain a centralized knowledge base, which required continuous management and special efforts. AI can now integrate knowledge from more scattered internal sources, including memos, policies, procedures, and standards. In this way, AI reduces manual effort while also improving the richness of knowledge (Interview 4). Another participant also stresses AI's strong capability to integrate knowledge from the company's internal knowledge base (Interview 5).

However, participants stress that AI's influence on knowledge combination occurs primarily in the pre- or post-meeting phases, not during the meeting itself, because meetings often focus on a specific topic or subtask rather than on cross-field synthesis. In practice, the knowledge generated from meetings may be transformed into other organizational artifacts.

"… Any meeting should have a clear topic. It should focus on a small theme, a specific direction, a sub-task, … there is usually little cross-disciplinary or cross-topic discussion … After the summary is done and the meeting ends, the key question is what to do with the documents and knowledge that have been produced and accumulated from the meeting." (Interview 1)

"…Usually, the knowledge we gain from meetings ends up elsewhere. It may be turned into development tasks, business requirements, or similar items. Then it is decomposed and stored elsewhere. So later, I am more likely to review those sources, rather than the meeting outputs directly." (Interview 4)

In summary, combination - the synthesis of existing explicit knowledge into a more organized form - is enhanced by AI, though constrained by the meeting context. AI helps integrate and synthesize explicit knowledge. However, because of the scope of meetings, the use of AI in this mode is not significant.

4.4 Theme 4: Internalization is AI-empowered

Participants express the idea that AI empowers the internalization process, which mostly occurs after meetings. One participant gave the example of after-training meetings, describing AI's role as a "tutor" or "study buddy" that helps your learning using existing material (Interview 1). The other participant has stopped using traditional search engines and is using AI instead to help master new knowledge. By comparing the results generated by different AI agents and finding the most suitable results, the participant can be further empowered (Interview 2).

"… before AI, you really had to spend a lot of time reading code, talking to people, or reading internal documents before you could become a very experienced employee. But now, … the threshold has become much lower. You can just ask AI … it can basically act as a proxy for an expert." (Interview 5).

However, despite the positive attitudes towards the benefits of AI in accelerating internalization, there is one negative example worth noting. "I became lazy", as stated by one participant, expressing the worry of the weakening influence of AI on an individual's motivation to acquire new knowledge.

"… Without AI, I would actively try to learn a lot of new knowledge … As a result, my understanding of that issue would become more comprehensive … I can clearly feel that this is an obvious difference: people really have become lazier, because knowledge has become too easy to obtain." (Interview 7)

In summary, people are empowered by AI in the process of internalization – the process that involves the absorption of explicit knowledge into one's tacit knowledge. It claims that AI serves as a companion in the internalization mode; however, the negative influence of AI is that the overdependency on AI weakens one's own ability and motivation to learn.

5 Toward a Conceptual Framework - Discussion and Conclusion

Based on the thematic findings, we propose a conceptual framework that depicts AI's influence on knowledge creation in workplace meetings (see Figure 1). It integrates two aspects: first, a mapping of AI's influence across the SECI modes; second, a temporal dimension indicates the primary meeting phase(s) during which AI influences knowledge creation.

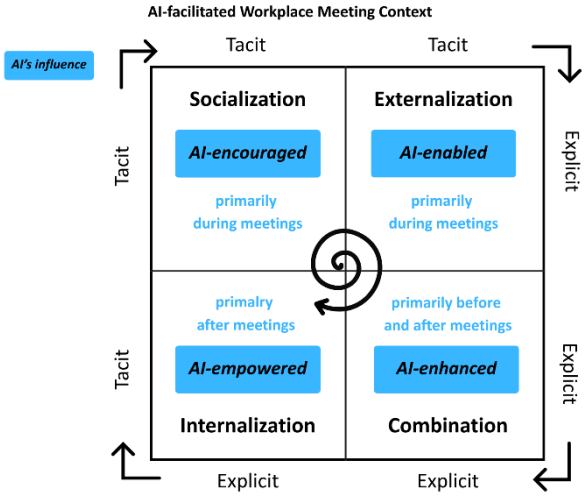

Figure 1: AI's influence in SECI-based framework of organizational knowledge creation in workplace meetings

The diverse impact of AI across the SECI modes in workplace meetings offers a profound understanding: humans and AI can partner in various ways to generate novel knowledge. This bears a strong resemblance to the contrast between tacit and explicit knowledge. AI handles codified knowledge well, but humans remain central for tacit knowledge, as socialization shows. "Learn to prompt, prompt to learn" – a slogan coined by one participant in the company to encourage people to better collaborate with AI (Interview 7) – captures the nature

of this collaboration. Currently, AI might struggle with the nuances of specific organizational contexts, which can affect its results. Metaphors from participants suggest diverse human-AI collaboration models: an assistant, a manual worker, or J.A.R.V.I.S. (the AI assistant from the Iron Man movies); second, a tutor or study buddy; and the last, a knowledge expert, a wise man.

By examining these patterns, the study deepens our understanding of AI's impact on organizational knowledge creation in workplace meetings. The proposed framework demonstrates AI's influence on knowledge creation within each SECI mode. Relative to other SECI-based frameworks, including those re-examining Ba with AI (Zhang et al., 2025, He et al., 2025), and GRAI (Generative, Receptive Artificial Intelligence) as an evolutionary step beyond SECI (Böhm and Durst, 2026). The SECI framework's fundamental conversion modes remain unchanged by our approach, but we broaden its application by adding AI's impact on workplace meetings. For example, the study's practical implications highlight the importance of employees understanding how to communicate with and instruct AI for improved knowledge creation.

This study has a few acknowledged limitations. The study's qualitative nature and narrow scope limit the statistical applicability of its findings. It exclusively uses the SECI model to analyze how organizations create knowledge, whereas other theories can be considered for future research. Third, AI technology is advancing rapidly, meaning the results are not current and might overlook AI's expanding influence on how organizations generate knowledge. Further research should investigate AI-assisted meetings across diverse organizations or contrast findings between various organizational types. Alternative theories or frameworks for how organizations create knowledge can also provide analytical viewpoints. Given AI's ongoing development, we should examine its increasing role in workplace knowledge creation during meetings and beyond.

6 Ethics Declaration

The research did not need ethical clearance.

7 AI Declaration

The initial transcripts were generated by the videoconferencing platforms (Zoom and iFLYREC) with their built-in AI transcription tools. Claude Opus 4.7 was used to clean the transcripts by removing filler words and marking low-confidence sections, and to translate Chinese transcripts to English. The transcripts were reviewed verbatim against the original recordings, and the translations were reviewed word by word.

Beyond Marketplace Reviews: Transformer-Based Sentiment Analysis of YouTube Influencer Ecosystems

Laura Nucera, Davide D'Emiliano, Andrea De Mauro
LUISS University, Rome, Italy

Abstract

Online reviews and influencer-centred social media conversations jointly shape product understanding in digital markets, yet they are still often studied as separate streams. This gap is especially relevant in the beauty sector, where product evaluation depends on subjective experience, perceived efficacy, tolerability, routine fit, and trust in peer-generated accounts. This study develops a cross-platform comparison of Amazon reviews and YouTube comments related to three active skincare products from the same brand, to examine whether the emotional profiles emerging from marketplace reviews differ from those found in influencer-centred comment spaces, and whether YouTube comments reveal needs, doubts, and advice-seeking signals that remain less visible in marketplace environments. The analysis is based on a replicable pipeline that combines data collection, filtering, text preparation, and transformer-based emotion detection using RoBERTa GoEmotions. The findings show that Amazon and YouTube do not produce equivalent emotional profiles. Across the three products, Amazon tends to concentrate emotional expression around admiration and approval, whereas YouTube comments display a broader and more fragmented emotional repertoire. The paper contributes theoretically by integrating review research and influencer ecosystems within a common comparative perspective, methodologically by proposing a transparent cross-platform workflow, and managerially by showing how YouTube-centred social listening can support the detection of consumer concerns that remain underrepresented in marketplace reviews.

Keywords: business model; digital platforms; human–AI interface; intelligent knowledge; data governance.

Paper type: Academic Research paper

1 Introduction

In contemporary digital ecosystems, online reviews are central to consumer decision-making. Despite this centrality, much of the literature continues to favour sentiment analysis of text-based reviews published on brand-led environments like Amazon, while paying less attention to evaluative content produced in influencer-led communication spaces, such as YouTube. This gap is particularly relevant in the beauty sector, where brands operate within multi-platform ecosystems in which company-sanctioned spaces coexist with more spontaneous, socially mediated discursive environments. In this scenario, YouTube's relevance to the customer journey is supported by market evidence and literature, which suggests that conversations around video reviews act as an 'extended focus group,' producing rich insights into consumer needs, preferences, and evaluations (Kabel et al., 2024). From these premises, the research gap that motivates this study is twofold. First, the literature still tends to treat marketplace reviews and conversations developed in influencer spaces separately, without building a systematic comparative framework between sources that, from the consumer's perspective, jointly contribute to the formation of product perceptions. Second, much research continues to operate through aggregate categories of positive or negative polarity, which are not always sufficient to capture finer differences in emotional profiles. Emotions with the same valence can produce different effects, and emotional language is often contextual and difficult to reduce to simplified classifications (Mustak et al., 2024). For this reason, cross-platform comparison requires an analytical framework capable of preserving differences across socio-technical contexts while simultaneously making different forms of evaluative expression comparable. From this perspective, transformer models such as BERT and RoBERTa are particularly relevant for analysing sentiment and emotions, although they require explicit attention to the limitations and biases of available benchmarks (Aka Uymaz & Kumova Metin, 2022; Demszky et al., 2020). In light of this, the study develops a cross-platform comparative analysis of online opinions on beauty products. It compares texts from company-sanctioned platforms and influencer spaces. The goal is to understand how each environment contributes to the development of emotional sentiment profiles and which emotional dimensions differ across channels. The expected contribution is threefold. Theoretically, the study links eWOM, online reviews, and research on influencer communication. Methodologically, it offers a comparative logic for analysing diverse texts. Empirically and managerially, a multi-source sentiment reading helps identify emerging themes, perceived issues, and weak signals.

The research questions follow from this framework and guide comparison between official brand communications and influencer-led social conversations:

- *RQ1: How do emotional profiles differ between marketplace review environments and influencer-led social conversations in beauty product discourse?*
- *RQ2: What consumer concerns, doubts, and interpretive signals emerge in influencer-led social conversations that remain less visible in marketplace reviews?*

2 Literature Review

The literature on user-generated content highlights the value of online reviews in digital marketplaces, demonstrating how they reflect more than simple satisfaction or dissatisfaction. In the beauty sector, this centrality is even more pronounced, as reviews of cosmetics and skincare products help interpret practical aspects such as skin compatibility, tolerability, side effects, suitability for individual needs, and perceived risk reduction (Oh, 2020). Kim et al. (2025) emphasise the role of readability, perceived reviewer trustworthiness, and identity cues, while Jia et al. (2023) show that reviews published on marketplaces have a more immediate impact on sales than content on third-party platforms because they are closer to the moment of purchase. Overall, online reviews guide the interpretation of products characterised by high uncertainty and strong personal involvement. However, their effectiveness depends not only on the text, but on the interaction between information quality and the platform's selective mechanisms: visibility and position influence review adoption (Alzate et al., 2024), authenticity and trust signals strengthen their reliability (Liu and Dawod, 2025), while review environments impact brand loyalty and eWOM (Tran et al., 2025). Platforms like Amazon are therefore not simple repositories of opinions, but socio-technical environments that select, amplify, and make certain voices more persuasive. This is precisely where a limitation of the literature emerges: studies on marketplaces clarify helpfulness, trust, and risk reduction, but often treat the marketplace as an almost self-sufficient context, isolating it from other discursive environments that contribute to product perception (Matassi & Boczkowski, 2021; Mustak et al., 2024). From this perspective, YouTube represents a profoundly different context. Unlike marketplaces, which are dominated by review-oriented texts, YouTube creates a richer, more relational, and narrative environment. Beauty channels are perceived not only as entertainment spaces, but also as places for pre-purchase research, learning, and indirect product observation. Lee and Lee (2022) show that these channels foster both information acquisition and vicarious experiences that partially compensate for the lack of direct contact with the product. Kabel et al. (2024) suggest that spontaneous online conversations can be valuable sources for identifying needs expressed in natural language, as they offer rich, contextualised data on the current use of products and services. This literature explains influencers' persuasive mechanisms but focuses primarily on outcomes such as purchase intention, trust, and engagement. The gap in this research, therefore, lies in the fact that we know fairly well why creators are influential, but less so how evaluative and emotional signals differ between marketplace reviews and conversations generated around creator-driven content. A second line of inquiry concerns the most suitable analytical level for studying these texts. The distinction between sentiment analysis and emotion detection is crucial because it refers to two different levels of interpretation of the evaluative discourse. Traditional sentiment analysis reduces the text to a general polarity - positive, negative, or neutral - offering a synthetic measure of the overall orientation. However, this reduction is often insufficient in the beauty sector, where texts rarely express univocal judgments and combine appreciation, doubt, disappointment, curiosity, or relief with respect to different dimensions of the consumer experience. For this reason, recent literature is moving towards more granular models, capable of distinguishing not only the general tone, but also specific aspects and differentiated emotions (Aka Uymaz & Kumova Metin, 2022; Mustak et al., 2024; Mouyassir et al., 2024; Ng et al., 2024). Mouyassir et al. (2024) and Ng et al. (2024) show that transformer models improve the ability to capture this internal plurality. Emotion detection thus adds a further layer, as texts with the same valence can convey different affective states and different interpretive implications. In this context, the GoEmotions benchmark by Demszky et al. (2020), with 27 emotional categories and one neutral one, represents an important step towards finer taxonomies. Finally, the literature on cross-platform comparison shows that cross-platform comparison cannot be treated as a simple descriptive extension of analysis. Digital platforms offer different affordances, usage practices, and relational logics, which influence the production, circulation, and interpretation of content (Matassi & Boczkowski, 2021). This gives rise to the concept of analytical comparability: reviews and comments are not comparable because they are structurally identical, but because they represent different and complementary expressions of evaluation, interpretation, and reaction within the same consumption domain. The value of comparison lies in recognizing these differences as part of the object of study, not as methodological noise. The interpretative robustness of research therefore

depends not on the total elimination of biases, but on their explicitness and treatment as an integral part of the comparison itself.

3 Methodology

This study adopts a cross-platform comparative design to examine how consumer discourse differs between marketplace review environments and influencer-driven social conversations. Amazon reviews and YouTube comments serve as empirical contexts to compare two distinct forms of user-generated content. The empirical context is the beauty industry, where product evaluation is highly experiential. The analysis focuses on three active skincare products from the same brand, a choice that reduces cross-brand variability and keeps the comparison focused on platform effects and discursive environments, rather than differences in brand positioning. Amazon reviews were collected using the Apify scraper. Because the scraper imposed a limit on the number of reviews that could be retrieved, a proportional sampling strategy was adopted based on the distribution of star ratings observed on Amazon UK for each product. Amazon UK was selected to maintain linguistic consistency with the English-speaking scope of the study. For each product, a final set of 100 Amazon reviews was created, and review titles and bodies were merged into a single text field to preserve the evaluative content of each review as a single unit of analysis. The YouTube dataset was constructed through a multi-step workflow implemented in KNIME and integrated with Python. Three query formulations were used for each product: "review," "first impressions," and "wear test," as they are common in beauty discourse on YouTube and capable of capturing different product-centered video contexts. Candidate videos were retrieved via the YouTube Data API and then cleaned by removing duplicates, incomplete records, and entries with missing identifiers. Video-level metadata was added via a second API request, and only videos that met minimum quality criteria, including a minimum threshold of 50 comments, were retained. Comments were then extracted using a Python script that queried the commentThreads endpoint, managed pagination, and saved the comment text along with contextual metadata, including comment ID, author, publication date, like count, video title, video ID, and query type. Duplicate comments and records with missing text were removed before export. The study focuses on English-language content. Amazon reviews were collected from Amazon UK, while YouTube comments were filtered for English-language content, despite potentially coming from a broader set of English-speaking users. This difference is recognized as a limitation of the cross-platform design, as platform composition and audiences may partially overlap with geographic and cultural variations. Because YouTube comment sections contain many message types that are not directly comparable with marketplace reviews, all extracted YouTube comments were subjected to a preliminary ChatGPT-based classification phase. The same prompt structure was applied to all three products, modifying only the name of the focal product. Each comment was assigned to one of five unique categories: comment_creator, target_review, other_product, advice_oriented, and uncertain. The goal of this phase was to isolate comments directly relevant to the focal product and functionally comparable to Amazon reviews. Comments classified as target_review were used in the main cross-platform comparison of emotions, as they report evaluations, experiences, results, effects, or reactions to the product. Prior to validation, a gold standard was developed, defining the five categories through operational definitions, positive examples, borderline cases, and tiebreak rules. Comments reporting a clear personal experience with the focal product were assigned to target_review, while comments providing advice or asking about usage instructions, product compatibility, frequency of use, or skin type suitability were assigned to advice_oriented. The uncertain class was narrowly defined as a residual category for comments that were too short, irrelevant, incomprehensible, or impossible to reliably assign to one of the other classes. To validate the ChatGPT-based classification, a stratified sample of 300 comments was re-annotated independently by the first author using the default gold standard, without access to the model's predictions. The sample was balanced by product and by ChatGPT-predicted class, with 100 comments per product and 20 comments for each predicted class within each product.

Table 1. Validation metrics by product

product_name	n_comments	accuracy	cohen_kappa
Peeling Solution	100	0,71	0,6375
Hyaluronic Acid Serum	100	0,76	0,7
Salicylic Acid Solution	100	0,92	0,9

Table 2. Human–ChatGPT classification confusion matrix (%)

	chatgpt_comment_creator	chatgpt_target_review	chatgpt_other_product	chatgpt_advice_oriented	chatgpt_uncertain
human_comment_creator	81,25%	9,38%	3,12%	1,56%	4,69%
human_target_review	4,26%	87,23%	4,26%	2,13%	2,13%
human_other_product	0%	8,33%	76,67%	10%	5%
human_advice_oriented	5%	6,67%	10%	78,33%	0%
human_uncertain	4,35%	5,8%	5,8%	7,25%	76,81%

The validation of the ChatGPT-based classification showed an overall accuracy of 79.67% and a Cohen's κ of 0.746. Following the pre-set decision rule (κ ≥ 0.61 = substantial, Landis & Koch, 1977), the LLM-assigned labels were retained for the full corpus. The confusion matrix shows strong overall agreement between human and ChatGPT annotations, with the highest consistency for target_review, followed by comment_creator, advice_oriented, uncertain, and other_product. However, the matrix also reveals systematic ambiguities, especially between other_product and advice_oriented, where product comparisons are often interpreted as requests for guidance. Additional confusion appears between comment_creator and target_review, suggesting that comments directed at the creator may sometimes be read as evaluations of the target. The uncertain category present some misclassifications spread across advice_oriented, target_review, and other_product, indicating that vague or short comments are often forced into more specific categories by the model. The final product-level datasets underwent light text cleaning in Python. User mentions, hashtags, URLs, and redundant whitespace were removed, but no aggressive normalisation was applied. This choice was made to reduce technical noise while preserving the informal and context-dependent texture of user-generated discourse.

Emotion detection was carried out using SamLowe/roberta-base-go_emotions, a RoBERTa-based model fine-tuned on the GoEmotions benchmark. Instead of retaining only the first predicted emotion, the model was run with top_k=None in order to extract the full score distribution across the 28 GoEmotions labels. For each comment, the pipeline stored the scores for all 28 GoEmotions labels, the top three emotions, and their associated model scores. The full emotion-score distribution was then aggregated into five macro-emotional categories: positive, negative, uncertainty, cognitive, and neutral. The positive category includes emotions such as admiration, approval, gratitude, joy, love, optimism, and relief. The negative category includes anger, annoyance, disappointment, disapproval, disgust, fear, nervousness, remorse, and sadness. The uncertainty category includes confusion and curiosity. The cognitive category includes realization and surprise. The neutral category includes the neutral label. For each comment, macro-emotion scores were computed by summing the scores of the emotions belonging to each macro-category. The dominant macro-emotion was also identified as the macro-category with the highest aggregated score. However, the main comparative analysis relies on the weighted macro-emotion distribution rather than only on the dominant label, since weighted scores preserve the multidimensional emotional profile of each comment. Because GoEmotions was fine-tuned on Reddit comments, model performance on Amazon and YouTube text is not guaranteed. To validate the classifier in-domain, we manually re-annotated a stratified random sample of 150 valid texts. We report Cohen's κ between the model and the human gold standard at the five macro-category level (Positive / Negative / Cognitive / Uncertainty / Neutral), κ = 0.75 (accuracy = 0.83). Since the validation supports more reliable agreement at the macro-category level, the inferential analysis in §4 is conducted at the macro-category level, while fine-grained results are presented as descriptive.

4 Results

4.1 Differences in weighted macro-emotions across platforms

The aggregate distribution of weighted macro-emotions shows a clear difference between marketplace reviews and influencer-led conversations. Amazon reviews are strongly concentrated around positive emotions, which represent approximately two-thirds of the overall weighted emotional profile. YouTube comments, on the other hand, exhibit a more distributed emotional structure: positive emotions remain present, but have a much lower relative weight, while negative, uncertainty, and neutral components increase.

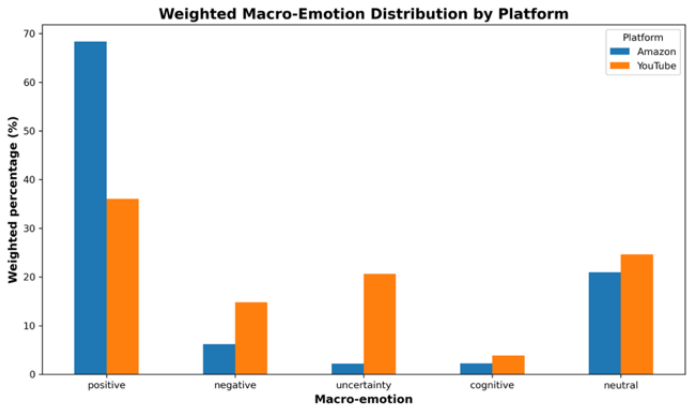

Figure 1 – Weighted Macro-Emotion Distribution by Platform

4.2 Product-level robustness check

The product-level heatmap confirms that a single product does not drive the aggregate pattern. In all three cases analysed, YouTube comments show a lower positive component than Amazon reviews. The difference is particularly marked for Peeling Solution, followed by Hyaluronic Acid and Salicylic Acid. At the same time, YouTube shows higher values for the negative components for all products and higher values for uncertainty, especially for Peeling Solution, potentially associated with concerns about frequency of application, skin sensitivity, irritation, and compatibility with other products. These results suggest that influencer-led conversations become particularly informative when the product requires interpretation, caution, or practical guidance. The product-by-product comparison reinforces the aggregate result, but also shows that the intensity of the difference between platforms varies based on product characteristics and perceived risk level.

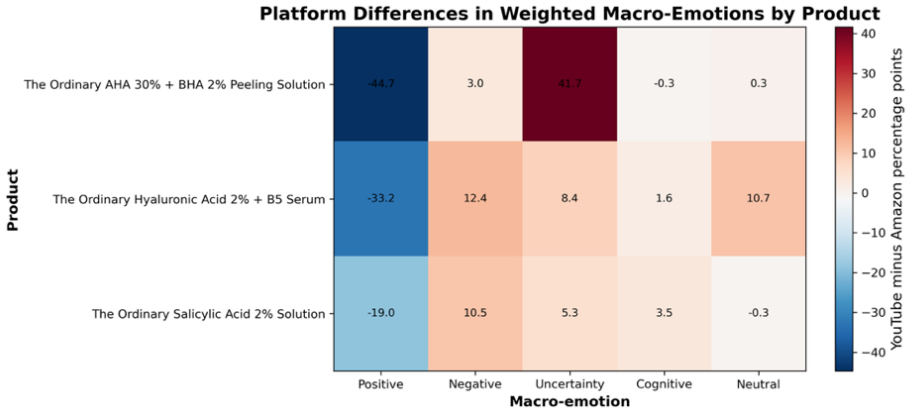

Figure 2 – Platform Differences in weighted Macro-Emotions by Product

4.3 Specific emotions and emotional ambiguity

The distribution of the top ten emotions helps better interpret the results observed at the macro-category level. Amazon reviews are strongly driven by positive emotions, particularly admiration and, to a lesser extent, approval. This confirms that marketplace reviews tend to express direct appreciation and more concentrated evaluative judgments. YouTube comments, instead, are less concentrated around a single positive emotion. The neutral category is particularly visible, as is curiosity, along with other emotions such as confusion, sadness, gratitude, disapproval, and love.

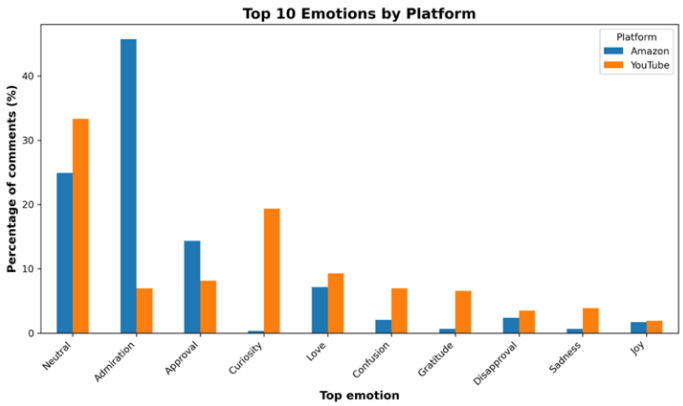

Figure 3 – Top 10 Emotions by Platform

Further evidence emerges from the average margin between the first and second emotions detected by the model. Amazon reviews show a higher average margin, indicating that RoBERTa more clearly identifies a dominant emotion. YouTube comments, however, show a lower average margin, suggesting greater emotional ambiguity or the coexistence of different emotional signals.

5 Discussion and Conclusions

This study compared marketplace reviews and influencer-led social conversations to understand whether these two digital environments reveal different emotional profiles and information needs in the context of beauty products. The results confirm that the two sources are not interchangeable: even when the comparison is based on balanced samples and YouTube comments filtered for product relevance, marketplace reviews and influencer-led conversations display different emotional structures. In answer to RQ1, regarding the differences between emotional profiles in the two environments, the results show that marketplace reviews are characterized by a greater concentration of positive emotions. Emotional expression on Amazon appears more stable, evaluative, and oriented toward synthetic product judgments. In contrast, YouTube comments display a more heterogeneous emotional profile, with a lower concentration of positive emotions and a greater presence of negative components, uncertainty, and cognitive processing. In response to RQ2, regarding additional signals emerging in influencer-led conversations, the results indicate that YouTube makes doubts, requests for clarification, uncertainties about use, and weak signals related to practical experience with the product more visible. This element emerges both from the emotional analysis, in which uncertainty and cognitive components are more evident in YouTube comments, and from the preliminary classification of comments, which identified a significant presence of content classifiable as advice-seeking. From a theoretical perspective, the study contributes to the literature on user-generated content, online reviews, and influencer ecosystems by showing that platforms are not simply neutral containers of opinions, but discursive environments that shape consumer experience. Marketplace reviews tend to make the final judgment observable, often expressed in a more concise and evaluative form. Influencer-led conversations, on the other hand, allow us to observe the process through which users interpret, negotiate, and contextualize product use. The methodological contribution involves the construction of a comparative and validated pipeline for analyzing heterogeneous content from different platforms. The preliminary classification of YouTube comments using ChatGPT was validated against a human gold standard, showing substantial agreement with human annotation. The emotional classification using RoBERTa-GoEmotions was also validated at the macro-category level, explicitly acknowledging the limitations of transferring a model trained on Reddit to different domains such as Amazon and YouTube. From a managerial perspective, the findings suggest that beauty companies should not rely solely on marketplace reviews to understand consumer perceptions. The latter are useful for monitoring satisfaction, approval, and summary product reviews, but they may be less effective in identifying emerging concerns, difficulties with use, or unclear information needs. Influencer-led social conversations, however, can serve as a particularly useful social listening space for identifying recurring questions, concerns and requests for product education. These insights can support brand communication, the development of FAQs, the selection of content to be shared with creators, and the improvement of instructions for use.

The study has some limitations that should guide the interpretation of the results. The analysis used only one brand and three products. The final comparison is based on balanced samples, not the whole corpus. Only English YouTube comments and Amazon UK reviews directly related to the product were included. The emotion

detection model was applied outside its training context. Thus, these results show cross-platform differences within a specific setting, not universal emotional signatures. Future research could include a program trained for the specific communication environment, more brands, larger samples, other product categories, or the analysis of excluded categories, such as advice-seeking comments.

Despite these limitations, the study shows that comparing platforms allows for a richer understanding of consumers' digital discourse and, in particular, that influencer-led environment make visible dimensions of product interpretation that are only partially observable in brand-led marketplace environment.

6 Ethics Declaration

Ethical clearance was not required for this research, as the study relied exclusively on publicly available online user-generated content and did not involve direct interaction with human participants. The data were analysed in aggregated form, and no personal identifying information is reported in the paper.

7 AI Declaration

AI tools were used to support the preliminary classification of YouTube comments into analytical categories, as described in the methodology section. AI tools were also used to support language editing and reference-format checking. All outputs were reviewed by the authors, who remain fully responsible for the research design, analysis, interpretation of results, and final content of the paper.

Metrics and Value of Intelligent Knowledge: How Organizations Turn AI Options into Decision Capability, and Become More Sustainable

Harald M. Grundner
innoVAVE, Hockenheim, Germany

Abstract

AI, copilots and autonomous agents have drastically lowered the cost of producing information and alternatives. Yet many organizations do not become faster or more effective in decision-making. Instead, they experience option overload, longer alignment cycles and persistent uncertainty at the decisive moment. This paper argues that the bottleneck has shifted from generating knowledge artefacts to building organizational decision capability.

The practitioner message is simple: value is always two-sided: *customer benefit and economic gain for the organization*. Intelligent knowledge is therefore only valuable when it enables better decisions that increase customer benefit and improve value capture. Sustainability in day-to-day management becomes tangible when results and artefacts are reusable: a product (material or immaterial, such as a copilot, agent or prompt) becomes sustainable only if its use repeatedly creates value for users and customers.

We define intelligent knowledge pragmatically as knowledge that makes decisions actionable, accountable and auditable. To measure its value, we propose a metric architecture with three layers. Outcome metrics ask whether decisions improved results and reduced rework and waste. Flow metrics ask whether the right knowledge reached decisions in time and whether it became reusable as a standard or building block. Leadership and governance metrics ask whether decisions are owned, traceable and trustworthy, including disciplined use of AI.

To operationalize the framework, we embed it in a recurring rhythm: Learn – Measure – Build/Test – Decide. Each leaf ends with a decision gate. New insights can force a sharp return and re-entry, ensuring learning is woven back into the process. Each cycle yields two outputs: a decision-ready set for the current decision episode, and a process result that updates knowledge assets (standards, templates, prompts, playbooks) for continuous improvement. An illustrative scenario shows how organizations can transform AI-driven option abundance into calmer, faster and more sustainable decisions by making value criteria explicit and by measuring both decision impact and reusability.

Keywords: Intelligent knowledge; decision capability; knowledge metrics; AI governance; reusability

Paper type: Practical Paper

1 AI Scales Options – Organizations Need Decision Capability

We are witnessing a shift that many still underestimate. In the past, knowledge was expensive, slow, and often difficult to access. Today AI can compress information within seconds, generate alternatives, structure arguments and produce recommendations. The cost of producing knowledge artefacts has collapsed. Yet decisions often do not become easier; they become harder. This is rarely a technology issue. It is a leadership and organizational issue.

The practitioner's anchor is value. Value is not a slogan. Value is a test: customer benefit and economic gain for the organization. If knowledge, a copilot, an agent or a prompt does not improve customer benefit and value capture, it is activity not value. And if the result is not reusable, it is not sustainable in practice. Sustainability becomes tangible when value becomes repeatable: reuse is the day-to-day signal that an artefact creates value more than once.

Decision theory reminds us why this matters. Organizations decide under time pressure, conflicting goals and bounded rationality (Simon, 1947/1997; March, 1994). AI does not remove this reality; it intensifies it by increasing the number of possible paths. AI scales speed and options, but it does not scale responsibility or the capability to learn, test and decide consciously.

In practice, this mismatch creates a familiar pattern: more dashboards, more slideware, more 'evidence', and still a foggy decision meeting. The missing piece is not information. The missing piece is decision capability. The ability to translate knowledge into a decision that is owned, explainable, and resilient to volatility.

This paper provides a measurement and leadership logic to translate AI outputs into decision capability through three metric layers—outcome, flow, and leadership/governance—and an operating rhythm of Learn – Measure – Build/Test – Decide. The aim is not to add reporting. The aim is to make decision quality measurable and improvable, so that knowledge and AI support repeatedly create customer benefit and economic gain.

2 Knowledge Becomes Intelligent In Decision-Making

This paper is not about building larger repositories or optimizing AI performance in isolation. The core is decision capability. The organizational ability to create orientation under uncertainty, make assumptions explicit, test what matters and decide with ownership. The value of knowledge assets and AI artefacts is assessed by their contribution to decision episodes: real choices with consequences.

To avoid confusion, we distinguish three objects. Knowledge assets include documents, standards, lessons learned, routines and tacit expertise. AI artefacts include copilots, agents, models and analytics pipelines. Decision episodes are the moments where options are closed and commitments are made. Knowledge and AI matter because they influence those decision episodes, either by reducing uncertainty or by creating false certainty.

Sustainability becomes concrete when it is linked to reuse. A knowledge asset is sustainable when it can be reused and extended as a standard or building block, because it repeatedly creates value. An AI artefact becomes sustainable when it is used repeatedly in a way that produces valuable outcomes for users and customers, without eroding trust.

This perspective reframes “intelligence”. Intelligence is not a property of a tool alone. It is the quality of the socio-technical system: how people, knowledge and AI work together to produce decisions. In that sense, intelligent knowledge is an organizational capability, not an IT feature.

3 Methodological Positioning: A Practice Framework With Design Intent

This contribution is a practice-oriented framework proposal with design intent. It synthesizes practitioner patterns with selective scientific grounding: bounded rationality and decision processes (Simon; March), knowledge as strategic resource and social process (Grant, 1996; Nonaka and Takeuchi, 1995; Tsoukas, 1996), and governance frameworks for trustworthy AI (NIST, 2023; OECD, 2019/updated; ISO 30401; EU AI Act context).

Design intent means the framework is formulated as an artefact that can be applied, adapted and evaluated. It specifies what should be measured (value realized, value repeatability, and value responsibility), where it should be measured (decision episodes), and how it becomes operational (Cloverleaf rhythm and SIPOC+ workflow).

The framework is conceptual, but not detached. It is grounded in recurring field patterns: decision delays despite abundant information, late rework caused by premature lock-in, unclear ownership that inflates coordination cost, and AI-driven option overload that creates the illusion of progress while decisions remain fragile.

A brief application scenario is used as an illustrative operationalization artefact rather than an empirical proof. At the same time, the framework is designed to be evaluable in future work. A plausible evaluation approach would trace decision episodes before and after adoption: decision cycle time, late-change load, trace completeness, reuse rates of standards or prompt modules, and perceptions of decision clarity and trust.

4 Intelligent Knowledge: Actionable, Accountable, Auditable – And Value-Positive

We define intelligent knowledge pragmatically: knowledge is intelligent when it makes decisions actionable, accountable and auditable. And Knowledge is intelligent when it is value-positive in the practitioner sense: it increases customer benefit and improves value capture.

Actionable means we move from ‘interesting’ to ‘we act’. It is not the amount of information that creates actionability; it is the quality of selection and constraint. In AI-rich environments, actionability often improves when teams explicitly define what they will not pursue and why, because option overload is the enemy of action.

Accountable means responsibility does not disappear into team fog. It means a decision owner is visible, and the organization knows who carries consequences. Accountability is not bureaucracy; it is speed. Where ownership is unclear, decisions turn into endless alignment. Where ownership is clear, debate becomes preparation and decision becomes execution.

Auditable means assumptions, evidence and rationale can later be reconstructed. This supports learning, but it also supports trustworthy AI use. If a decision rationale cannot be reconstructed, the organization loses two things at once: trust and learning. It repeats discussions, redoes analyses, and loses tempo.

The issue is not that we ‘build wrong’. The issue is premature lock-in. That means turning assumptions too early into architecture, specification and commitments, making correction expensive and resource-intensive.

That is where sustainability becomes tangible: fewer premature lock-ins, earlier correction, and less waste of time, resources and trust.

5 Three Metric Layers That Pull The Cycle Toward Value And Reuse

The metric architecture distinguishes three layers. Each layer has two roles: planning (targets) and evaluation (criteria). This dual role matters because metrics should not only judge results after the fact; they should steer the cycle while it runs.

Outcome metrics plan and assess value realized. They make explicit what "better" means for the decision episode: improved customer benefit, improved value capture, fewer late changes, and less rework and waste. *Flow metrics* plan and assess value repeatability. They ensure the right knowledge reaches the decision in time and that the cycle produces reusable standards, prompts, templates or building blocks. *Leadership and governance metrics* plan and assess value responsibility. They ensure decisions are owned and traceable, and AI is used in a disciplined and trustworthy way.

Together, the three layers prevent a common failure mode: organizations measure activity (documents, meetings, prompt usage) while decision quality silently deteriorates. A balanced combination is required: outcome without flow becomes coincidence; flow without governance becomes risk; governance without outcome becomes bureaucracy.

Outcome metrics answer a direct value question: did this cycle improve results and reduce rework and waste? In planning, outcome targets can include higher decision stability, lower late-change load, and measurable improvements in customer benefit or economic contribution. In evaluation, outcome metrics ask whether these effects happened early enough to matter.

Practically, three outcome indicators are often powerful and easy to observe. First, late-change load: how many significant changes occur after a point of commitment. Second, decision stability: how often a decision is revisited because evidence was weak, assumptions were hidden, or ownership was unclear. Third, rework intensity: effort spent correcting avoidable mistakes caused by premature lock-in. These indicators do not replace financial measures; they precede them. Financial results are lagging. Decision quality is the early signal.

A typical outcome blind spot is to equate value with immediate financial metrics only. In early phases, value often appears as learning that prevents expensive detours. If knowledge helps a team avoid a wrong architecture choice, the value is real even before revenue is realized. Outcome metrics should therefore include leading indicators that connect directly to decision quality.

Flow metrics make sustainability measurable. If sustainability means repeatable value, then reuse is the practical indicator that value is not a one-off accident. In planning, flow targets can include shorter time-to-knowledge, higher reuse rate of validated rationales, and better freshness discipline. In evaluation, flow metrics ask: did the right knowledge reach the decision, and did we capture what we learned so it can be reused?

A simple flow indicator is time-to-knowledge: how long it takes to locate decision-relevant information with sufficient trust. Another is reuse-rate: how often standards, templates, prompt modules, or proven decision rationales are reused without rework. A third is assumption transparency: how often assumptions are explicit and testable rather than implicit and politically defended.

Flow metrics also protect against a typical AI failure mode: the production of plausible text that is detached from context, versioning and evidence. When AI outputs are treated as knowledge without provenance, flow looks high, but trust erodes. Flow metrics should therefore include traceability elements such as version clarity, source anchoring, and feedback closure. Did we record what happened after the decision and fold it back into the knowledge base?

Leadership and governance metrics ensure that value is created responsibly and fast. In planning, governance targets include visible decision ownership, trace completeness, and disciplined use of AI support. In evaluation, governance metrics ask whether ownership was real (not symbolic), whether rationale is reconstructable, and whether AI outputs were challenged appropriately.

A key governance indicator is trace completeness: can a third party reconstruct what was assumed, tested and decided? Another is override discipline: when humans override AI recommendations, is the rationale documented and learned from, or does override remain a private act? This is not bureaucracy. It is the mechanism that prevents 'confidence theatre' and enables systematic learning.

In practice, governance metrics also reduce coordination cost. When rationale and ownership are clear, teams spend less time re-arguing old issues. Governance becomes the steering wheel: it keeps the cycle moving clockwise with speed and trust.

Governance metrics are often misunderstood as compliance. The practitioner view is different: governance is a speed enabler because it prevents re-litigation. A decision that is accountable and auditable is less likely to

be reopened later. It reduces the need for defensive documentation. It also supports trustworthy AI use: AI outputs are accepted as hypotheses that must pass explicit gates, rather than as authoritative answers.

For flow metrics, it is useful to distinguish between 'reuse as convenience' and 'reuse as strategy'. Convenience reuse means copying a document. Strategic reuse means reusing a validated rationale, a tested option comparison method, a stable prompt module, or a building block in a modular architecture. Strategic reuse has higher leverage: it increases speed and decision quality simultaneously. Flow metrics should therefore reward strategic reuse, not only copying.

Another practical technique is to separate value creation from value capture explicitly. Customer benefit is not automatically captured as profit; profit is not automatically sustainable. Outcome metrics should therefore include at least one customer-facing indicator (benefit in use, friction reduced, adoption readiness) and one organization-facing indicator (effort avoided, rework reduced, time saved, or risk reduced). This keeps the two-sided value definition alive throughout the cycle.

A practical technique is to treat targets as a contract for speed. Teams often believe that more evidence will always produce better decisions. In reality, the best decisions are those made with sufficient evidence at the right time. Targets define what 'sufficient' means: how much uncertainty is acceptable at this stage, what must be tested now, what can be postponed, and what must never be postponed. This is where the planning role of metrics becomes leadership.

Targets should be formulated as directional improvements rather than as pseudo-precision. For example, "reduce late-change load" is a better starting point than forcing a single number that will be negotiated away. Over time, targets can mature into explicit thresholds, e.g. an agreed trace completeness threshold for decision readiness, or a reuse rate target for templates and prompt modules. The key is consistency: teams should not change the game mid-cycle.

Metric selection should be conservative. In practice, the goal is not to cover everything. The goal is to make the cycle steerable. A small number of well-chosen measures can change behavior more effectively than a large catalogue. A useful rule is to select metrics that (a) are visible in the decision episode, (b) can be influenced by the team during the cycle, and (c) have a clear value interpretation in terms of customer benefit or economic gain.

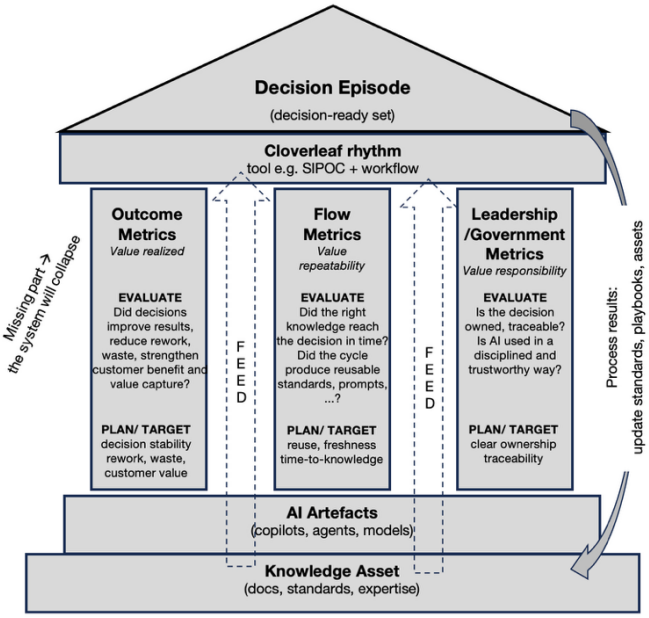

Figure 1. Metrics house: foundation (knowledge assets + AI artefacts), three metric pillars (plan + evaluation), operationalization cornice, and decision episode roof with learning loop back into assets.

6 Learn – Measure – Build/Test – Decide: Cloverleaf Rhythm With Decision Gates

To become everyday reality, the framework is embedded in a leadership rhythm: *Learn – Measure – Build/Test – Decide*. The rhythm is intentionally simple, but it is not linear. Each leaf ends with a decision gate. The gate is the discipline point where a team decides whether it can continue clockwise, or whether new insight forces a sharp return and re-entry.

This “hairpin return” is not failure. It is the mechanism that prevents premature lock-in. Without it, teams move forward with the wrong certainty: they build faster, but they build commitments on unstable assumptions. With it, learning is woven back into the process and the cycle regains traction.

Each gate should be expressed as a value question, not only a process question. Leaf 1 (Learn) asks: do we truly understand customer benefit, or are we only capturing requirements? Leaf 2 (Measure) asks: can we substantiate benefit, cost and impact, or are we merely claiming them? Leaf 3 (Build/Test) asks: did users actually experience the benefit, and what does it really cost? Leaf 4 (Decide) asks: is the decision value-positive, and are we making it reusable? These questions keep the cycle tied to metrics and value.

Importantly, each cycle must yield two outputs. Output A is the decision-ready set for the current decision episode: criteria, evidence, risks, trade-offs, and a recommended commitment with ownership. Output B is the process result: reusable standards, templates, playbooks and prompt modules that strengthen the foundation for the next cycle. With Output B, sustainability becomes tangible: value becomes repeatable through reuse. Without Output B, organizations may deliver once, but they do not improve.

This dual-output logic is also what turns AI tools into sustainable assets. A copilot or agent becomes sustainable when its usage pattern stabilizes into reusable modules: prompt patterns, evaluation checklists, trace templates, and decision rationales. The organization shifts from asking AI for answers to building decision-ready knowledge assets with AI support.

In AI-enabled work, Output B is also where tools become assets. A prompt that helped once becomes a reusable prompt module when it includes: purpose, input assumptions, evaluation criteria, and a trace note on when it should not be used. An agent becomes a reusable building block when it has guardrails: clear boundaries, escalation rules, and a traceable rationale for its recommendations. This turns AI use from ad-hoc interaction into repeatable value creation.

The dual-output logic is the bridge between project work and organizational learning. Output A serves the current decision episode. Output B serves future decision episodes. In practice, Output B should be assigned an owner and a short completion rule: the cycle is not closed until the reusable artefact is stored in a findable place, linked to its context, and tagged as reusable. Otherwise, learning remains local.

The hairpin return becomes valuable when it is socially safe. Teams must be allowed to go back without being accused of ‘losing time’. In practice, this requires leadership language: returning is not failure; returning is avoiding waste. The faster a team can admit “we learned something that changes our direction,” the more sustainable it becomes, because it avoids expensive late corrections.

To make the gates operational, teams should define what is expected at each gate in one sentence. The sentence is not a checklist; it is a boundary. For instance: ‘We can continue when customer benefit is expressed as an outcome in use.’ Or: ‘We can continue when at least one critical assumption has been tested with evidence that would change our mind.’ Such boundary sentences make the gate real.

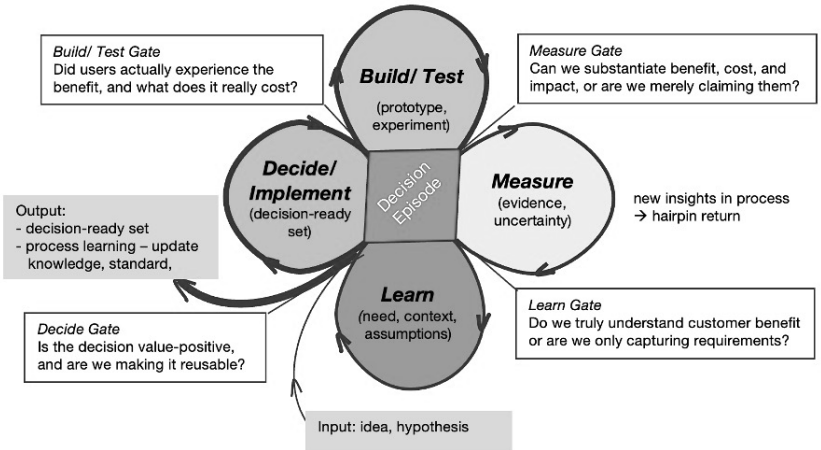

Figure 2. Cloverleaf logic (clockwise): decision gates, sharp return on new insight, and dual outputs (decision-ready set + continuous improvement into knowledge assets).

7 Application Scenario: Turning Option Abundance Into Calm Decisions

A typical example is a development project in a volatile market. Customers themselves do not yet know precisely what they will truly need in twelve months. Cost and sustainability requirements are high. Supply

chains are fragile. At the same time, the organization introduces a copilot that produces alternatives and justifications within seconds. Material explodes, yet decisions slow down.

The reason is missing decision capability. Teams accumulate options but do not close them. Assumptions remain implicit. Criteria are unclear or disputed. Responsibility is diffused. AI then amplifies the pattern: each function can generate its own 'evidence', and meetings become a battle of outputs rather than a synthesis of insight.

Applying the approach begins with defining critical decision episodes. For example, an architecture choice is framed as a decision episode with explicit criteria: customer benefit, total cost, risk exposure, and sustainability impact. The team then structures decision-relevant knowledge: the key assumptions behind each option, what evidence exists, what must be measured, what must be tested, and who owns the final commitment.

Next, the Cloverleaf rhythm is used to drive progress. In Learn, the team clarifies customer benefit beyond requirements by identifying what users are trying to achieve and what trade-offs they accept. In Measure, the team turns claims into testable hypotheses and selects a small set of measures that reduce uncertainty fastest. In Build/Test, prototypes and experiments are run, not to prove everything, but to invalidate weak assumptions early. In Decide, the team commits with ownership and a traceable rationale.

The metric layers act as guardrails. Outcome targets for the architecture decision include reduced late-change load and improved stability of key choices. Flow targets include time-to-knowledge for similar past decisions and reuse of a validated architecture rationale template. Governance targets include clear ownership and trace completeness. During the cycle, the evaluation questions are used in the gates: did we improve results and reduce rework/waste; did the right knowledge reach the decision and become reusable; is the decision accountable and auditable?

The practical effects are usually visible quickly. Discussions become shorter because assumptions are explicit. Conflicts become more factual because criteria are agreed. Decisions become calmer because they are justified by evidence rather than defended by authority or gut feeling. Sustainability becomes tangible because the cycle produces reusable assets: a standard decision template, a prompt module for option comparison, a trace checklist, and a small playbook for future architecture decisions. That process output reduces effort in the next project and increases the probability of value creation repeating.

A third shift is the disciplined capture of reuse. The team produces a decision-ready set and, in parallel, packages the process result into assets: a decision rationale template, a prompt module library entry, a trace checklist, and a short playbook. This is where sustainability becomes measurable. In the next project, time-to-knowledge drops because the team does not start from scratch. The organization becomes faster and more consistent, not because it works harder, but because it reuses what it learned.

A second shift is the explicit handling of uncertainty. The team agrees on a limited number of uncertainty drivers and treats them as the 'learning agenda' of the cycle. Measures and tests are chosen to reduce those uncertainties quickly. This avoids the typical trap of measuring what is easy. It also keeps the process fast because measurement is not a reporting activity; it is a decision activity.

In the scenario, the first visible shift is the quality of questions. Instead of asking the copilot for "the best option," the team asks for option sets framed by value. The prompt is shaped by the gates: customer benefit definition, measurable claims, test design, and decision readiness. This changes the entire dynamic: the copilot becomes an accelerator for structured thinking rather than a generator of plausible narratives.

Supplier	Input	Process step (activity)	Output	Customer	Targets			Cloverleaf stage and questions
					Outcome	Flow	Governance	
Project Manager	Phase result (ideas, risks, status)	Synthesize + prepare gate package (benefit definition, assumptions, open uncertainties, proposed targets)	Decision proposal (release Measure) + trace stub (assumptions& rationale draft)	Decision owner	expected higher decision stability; lower late-change exposure	time-to-knowledge target; reuse candidate identified (standard/ module)	decision owner confirmed; trace structure defined	**Learn** Do we truly understand customer benefits (not only requirements)?
Decision owner	Decision proposal (release **Measure**)	Gate decision + document rationale + release **Measure** + create learning asset seed	Measure leaf release + hypotheses charter (testable hypothesis + measures) + asset backlog entry	Project Manager/ Team	did we improve results, reduce rework-waste enough to proceed?	did the right knowledge reach the decision in time, and did we define reuse deliverables?	is the decision accountable and auditable (assumptions, evidence, plan, ownership)?	**Learn Gate → Measure Release – definition of testable hypothesizes; set of measures**

Figure 3. SIPOC+ decision template linking roles, process steps, outputs and metrics to the Cloverleaf cycle (excerpt).

8 Conclusion: Value, Reuse, And Decision Capability

AI makes many things possible, but value is created by decisions not by possibilities. Value is two-sided: customer benefit and economic gain. Sustainability becomes tangible when value is repeatable through reuse of knowledge assets, prompts, copilots, agents and standards.

Intelligent knowledge is therefore decision capability gained: actionable, accountable and auditable decisions that improve customer benefit, improve value capture, and leave behind reusable assets that strengthen the next cycle. In practice, this means each cycle must produce two outputs: the decision-ready set and the process learning captured as assets. That is how organizations become faster without blind flight, and more sustainable by reducing premature lock-in and waste.

Future work can evaluate the framework through decision-episode tracing in case settings, comparing decision cycle time, late-change load, trace completeness and reuse rates before and after adoption. The key test remains practical: does the organization repeatedly create customer benefit and economic gain, and does it turn learning into reusable assets?

9 Ethics Declaration

No ethical clearance was required for this conceptual/practice-oriented framework paper; no human subject data was collected.

10 AI Declaration

AI tools were used as writing and editing support to draft, translate and structure text. The author reviewed, curated and revised all content and takes full responsibility for the final manuscript.

Artificial Intelligence and Labour Law: The Employers' Obligation to Reskill Workers in the Digital Era

Antonio Capasso, Annabella Lattarulo
Universitas Mercatorum, Rome, Italy

Abstract

Artificial Intelligence is driving unprecedented structural reconfiguration of labour markets, yet regulatory frameworks governing employment relationships remain anchored to twentieth-century industrial paradigms. This paper addresses a critical research gap: the absence of coherent legal frameworks allocating responsibility for workers' reskilling among employers, workers, and public institutions in contexts of AI-driven technological transformation. Drawing on comparative legal analysis and organizational learning theory, this study examines how jurisdictions—specifically Italy, the European Union, the United States, and selected developing countries—approach the regulatory challenge of employer-mandated reskilling obligations. The paper proposes a multidimensional regulatory framework articulated along five core dimensions: legal recognition of reskilling as an employment relationship component, cost-sharing mechanisms, algorithmic oversight, collective bargaining strengthening, and corporate due diligence integration. Through this framework, the paper contributes theoretically to understanding the intersection of technological innovation, labour law, and organizational learning, while offering practical recommendations for legislators and international organizations navigating AI governance in employment contexts. The analysis reveals that while the European Union has advanced more structured approaches through the AI Act, significant implementation inconsistencies persist, and integrations with labour law remain underdeveloped. Conversely, the United States exhibits fragmentation across state-level frameworks, while developing countries face structural barriers to coherent reskilling policies. The paper demonstrates that sustainable AI governance requires reconceptualizing the social contract underlying employment relationships, ensuring that technological transitions develop in alignment with adequate worker protection and organizational learning capacity.

Keywords: Artificial Intelligence, Labour Law, Reskilling Obligations, Organizational Learning, Digital Transformation, Regulatory Framework, Comparative Analysis

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence is catalyzing an unprecedented structural reconfiguration of labour markets globally. Yet the regulatory frameworks governing employment relationships remain largely anchored to paradigms characteristic of twentieth-century industrial organization. This profound misalignment between technological innovation and regulatory adaptation constitutes a significant research gap, particularly regarding the identification and definition of the legal obligations incumbent upon employers in relation to workers' professional reskilling and skills development within contexts of AI-based automation processes and algorithmic management systems.

The scale of this challenge is formidable. The World Economic Forum estimates that AI and automation will lead to the loss of 85 million jobs globally by 2025, while simultaneously creating 97 million new roles. This transition generates a substantial governance challenge: workers displaced by traditional occupational roles must rapidly acquire new skills to participate in emerging labour markets. However, as emphasized in regulatory scholarship, no coherent legal framework currently allocates responsibility for such reskilling among employers, workers, and public institutions. This regulatory vacuum is particularly acute in the absence of international consensus on what constitutes adequate employer responsibility in technological transitions.

The research question guiding this study is therefore: **Which regulatory framework should govern employers' reskilling obligations when artificial intelligence replaces or substantially transforms occupational roles?** This question positions our analysis at the intersection of three critical domains: labour law, artificial intelligence governance, and organizational learning. We argue that sustainable responses to AI-driven labour market transformation require moving beyond traditional legal frameworks to incorporate insights from organizational learning theory, recognizing that reskilling represents not merely a compliance obligation but a fundamental transformation in how organizations acquire, develop, and deploy knowledge capital.

The significance of this inquiry extends beyond academic discourse. It addresses urgent practical concerns: How can employers fulfill their social responsibilities while maintaining competitive viability? What public support mechanisms are necessary to prevent labour market fragmentation? How can collective worker

participation shape technological transitions? These questions demand rigorous comparative analysis grounded in both legal doctrine and organizational theory.

2 Literature Review

2.1 Regulatory Dimensions of AI and Labour Markets

Existing literature examines the effects of Artificial Intelligence on labour markets from multiple disciplinary perspectives, with particular attention to regulatory implications and workers' rights. At the regulatory level, the European Union has taken a leading role through the adoption of the AI Act, although significant implementation inconsistencies and limited integration with labour law remain prominent concerns. From a comparative perspective, recent scholarship highlights substantial differences between Indonesia, the European Union, and the United States in the regulation of workforce governance, investment in human capital, and legal protection of workers affected by automation. Indonesian regulations remain fragmented, thereby hindering workforce reskilling, while the EU's more structured approach provides clearer guidance despite uneven implementation. The United States, notwithstanding its technological leadership, lacks federal AI workforce policies, resulting in regulatory fragmentation at the state level.

2.2 Algorithmic Management and Workers' Rights

With respect to algorithmic management and workers' rights, data-driven technologies tend to erode traditional employment protections, necessitating an integrated legislative adaptation through data protection, non-discrimination safeguards, and collective worker participation in digital human resource governance. Chen (2023) emphasizes that AI-based recruitment systems carry significant discriminatory risks, attributable to algorithmic bias stemming from unrepresentative datasets and distorted design choices. These insights underscore that reskilling obligations cannot be divorced from broader governance challenges around algorithmic fairness and worker dignity.

2.3 Reskilling, Skills Adaptation, and Industry 4.0

Regarding reskilling and skills adaptation, the implementation of Industry 4.0 generates widespread concerns related to job security, privacy, and technological trust, thereby requiring targeted interventions at both individual and organizational levels. From a broader perspective, a decent work framework grounded in job creation, social protection, workers' rights, and social dialogue emphasizes the need for preventive strategies capable of addressing both traditional and emerging risks associated with technological transformation.

Human resource management dimensions emerge prominently in analyses of organizational crisis-response strategies, which offer valuable insights for governing technological transitions. These studies stress the need for innovative solutions capable of balancing business continuity with workers' well-being and dignity during organizational change. This perspective is particularly relevant for understanding reskilling not as a reactive compliance measure but as a proactive organizational learning process.

2.4 Ethical and Human Rights Dimensions

The ethical dimensions of Artificial Intelligence are extensively explored in contemporary literature. Key risks associated with AI adoption include privacy violations, discrimination, unemployment, and security threats, necessitating comprehensive governance frameworks for ethically responsible implementation. Generative AI introduces specific employment-related risks including job losses, misinformation, data breaches, increased inequalities, and technostress, all of which significantly affect employers' responsibilities in technological adoption processes.

2.5 Global Justice Perspectives and AI Colonialism

From a global justice perspective, the concept of AI colonialism highlights how technological development exacerbates international inequalities through labour exploitation and environmental impacts in the Global South. This framework reveals that reskilling obligations cannot be understood solely through formal legal mechanisms but must account for structural inequalities in technological access and knowledge transfer between developed and developing economies.

2.6 Research Gap: Organizational Learning Theory Integration

Notably, existing literature examining AI and labour law has insufficiently integrated organizational learning theory, particularly the foundational scholarship on organizational learning processes (Nonaka and Takeuchi's knowledge creation theory, Argyris and Schön's double-loop learning, and Senge's systems thinking approach). This represents a critical gap, as reskilling constitutes fundamentally a process of organizational knowledge acquisition and dissemination. The absence of explicit engagement with organizational learning scholarship means that regulatory frameworks have largely overlooked how organizations systematically develop absorptive capacity for technological change. This gap is particularly significant for Track 25 of IFKAD (Organisational Learning in the Age of AI), which positions learning as central to sustainable organizational adaptation.

3 Research Framework and Methodology

3.1 Methodological Approach

This study adopts a comparative legal research methodology aimed at examining how different legal systems address the emerging issue of employers' obligations to reskill workers in contexts of artificial intelligence - driven technological transformation. Comparative legal analysis enables the systematic evaluation of regulatory approaches across jurisdictions, identifying both common principles and structural divergences in the governance of labour market transitions.

The research combines doctrinal legal analysis with insights from organizational learning theory. The doctrinal component involves the examination of primary and secondary legal sources - including legislation, regulations, case law, policy documents, and collective bargaining agreements - relevant to reskilling obligations and technological change in employment relationships. Organizational learning theory is incorporated as an analytical perspective to assess whether existing regulatory frameworks effectively support organizations' capacity to adapt to technological change through systematic knowledge development and workforce skill transformation. In this perspective, workforce reskilling is interpreted as a process of organizational knowledge creation and transfer, allowing the analysis to evaluate how legal frameworks influence firms' capacity to develop learning mechanisms and absorptive capacity in response to technological change.

The comparative analysis is conducted through three complementary analytical perspectives.

-First, normative analysis examines how existing legal instruments define, allocate, or fail to address employer responsibilities for workforce reskilling. This dimension focuses on the legal recognition of reskilling obligations within statutory labour law, regulatory policies, and judicial interpretation.

-Second, functional analysis evaluates how different legal systems pursue comparable regulatory objectives through diverse institutional mechanisms despite divergent formal legal structures. For example, collective bargaining agreements may perform regulatory functions similar to statutory provisions in different jurisdictions.

-Third, critical comparative analysis evaluates the effectiveness and coherence of these regulatory approaches by examining their capacity to support organizational adaptation to technological change. Drawing on organizational learning theory, this dimension assesses whether legal frameworks facilitate the development of institutional learning processes necessary for effective reskilling strategies.

3.2 Jurisdictional Selection Criteria

The comparative analysis focuses on four jurisdictional contexts selected according to three explicit criteria: regulatory relevance in the governance of artificial intelligence, diversity of labour law traditions and regulatory approaches, and representativeness of different levels of economic and institutional development.

Italy is included as a developed European jurisdiction characterized by a strong labour law tradition and an evolving regulatory approach to digital transformation. Its position within the European Union, while maintaining a distinct national legal system, provides insight into how supranational regulatory frameworks interact with domestic labour law institutions.

The European Union is examined as a supranational regulatory framework that has developed one of the most advanced legal approaches to AI governance, particularly through the adoption of the AI Act. The EU therefore represents a relevant case for assessing how emerging technological regulation interacts with existing labour law structures and how regulatory harmonization operates across diverse national contexts.

The United States is included as a global technological leader characterized by a decentralized and market-oriented regulatory model. The absence of a comprehensive federal framework addressing AI-related workforce

transitions offers a contrasting case to the more coordinated regulatory approach adopted within the European Union.

Finally, selected developing countries are considered to capture regulatory dynamics in contexts characterized by limited institutional capacity but increasing adoption of AI technologies. These jurisdictions highlight structural constraints affecting the implementation of reskilling policies and provide a broader global perspective on labour governance in technological transitions.

3.3 Analytical Framework

To ensure systematic comparison across jurisdictions, the study applies a five-dimensional analytical framework designed to assess the regulatory governance of employer reskilling obligations in the context of artificial intelligence.

From a knowledge management perspective, these dimensions also allow the evaluation of how regulatory frameworks shape organizational learning processes, particularly the capacity of firms to generate, transfer, and institutionalize new knowledge through workforce reskilling initiatives.

The first dimension, legal recognition, examines whether reskilling is explicitly recognized as an essential component of the employment relationship. This includes the presence of statutory obligations, collective bargaining provisions, or judicial interpretations establishing employer responsibilities for workforce skill development during technological transitions.

The second dimension, cost allocation, analyzes how the financial and organizational burdens of reskilling are distributed among employers, workers, and public institutions, revealing different regulatory philosophies regarding shared responsibility for workforce development.

The third dimension, algorithmic oversight, assesses institutional mechanisms for monitoring algorithmic management practices and their employment effects. These mechanisms may include regulatory supervision, algorithmic auditing procedures, transparency requirements, and institutional bodies responsible for oversight of automated decision-making systems affecting workers.

The fourth dimension, collective bargaining and worker participation, evaluates the role of collective worker participation in negotiating technological change and defining reskilling provisions. This dimension considers statutory frameworks enabling collective agreements as well as institutional mechanisms supporting social dialogue and dispute resolution.

The fifth dimension, corporate responsibility integration, examines how reskilling obligations are embedded within broader corporate governance and due diligence frameworks, including corporate social responsibility initiatives, supply chain accountability mechanisms, and organizational risk management practices.

Together, these five dimensions provide a structured analytical framework enabling systematic comparison of regulatory approaches across jurisdictions while identifying areas of regulatory convergence, divergence, and potential development. Each jurisdiction examined in the study is analyzed according to these five dimensions, allowing a structured comparison of regulatory approaches and highlighting both common patterns and jurisdiction-specific institutional responses to AI-driven labour market transformation.

4 Comparative Analysis of Regulatory Approaches

4.1 European Union Framework

The European Union represents the most developed regulatory response to AI governance through the AI Act. The AI Act establishes risk-based classification of AI systems and prescribes compliance obligations for high-risk applications, including those affecting employment relationships. However, the AI Act's integration with labour law remains underdeveloped. While the Act addresses algorithmic transparency and bias mitigation, it does not explicitly establish employer reskilling obligations.

Within EU member states, labour law traditions provide partially developed reskilling frameworks. Many EU jurisdictions recognize continuing education rights through collective bargaining or statutory frameworks, yet these provisions predate contemporary AI concerns and were not designed to address technological transformation at current scale. The challenge facing EU implementation is achieving coherence between AI governance and labour law modernization across 27 distinct member state systems while establishing enforceable mechanisms ensuring employers fulfill reskilling responsibilities.

4.2 Italian Labour Law Context

Italy exemplifies the challenge of regulatory adaptation within established labour law systems. Italian labour law contains sophisticated worker protection provisions, including continuing education rights within collective agreements. However, explicit legal recognition of reskilling obligations in contexts of AI-driven technological change remains absent from statutory frameworks. Italian jurisprudence has begun addressing algorithmic management issues, yet comprehensive frameworks addressing employer reskilling obligations during AI transitions have not yet crystallized in case law.

The Italian context reveals the insufficiency of traditional labour law categories for addressing contemporary technological challenges. Existing provisions on technological change, while protective, were formulated in industrial contexts and do not adequately address the acceleration and scale of AI-driven labour market disruption.

4.3 United States Fragmented Approach

The United States exemplifies fragmentation resulting from the absence of federal workforce AI policy. While OSHA (Occupational Safety and Health Administration) addresses worker safety, and the Equal Employment Opportunity Commission (EEOC) addresses algorithmic discrimination, no coordinated federal framework addresses employer reskilling obligations. This fragmentation produces varied outcomes across states. Some states have begun developing AI governance frameworks, yet labour-specific provisions remain underdeveloped.

The US market-based approach assumes that competitive labour markets incentivize employers to invest in reskilling without regulatory mandate. However, this assumption may be undermined by structural factors: employers may prioritize immediate cost reduction over long-term workforce development; information asymmetries prevent workers from assessing employer reskilling commitments; and labour market power imbalances limit worker capacity to negotiate reskilling provisions.

4.4 Developing Country Contexts

Developing countries face distinct constraints in establishing reskilling frameworks. Limited institutional capacity for regulatory enforcement, lower per-capita investment in workforce development, and rapid AI adoption imported from developed economies create contexts where reskilling obligations are theoretically recognized but practically difficult to implement. Global justice considerations become acute: developing countries experience AI colonialism dynamics where technological transformation originates from external sources without corresponding capacity-building support.

5 Organizational Learning Framework: Reconceptualizing Reskilling as Institutional Process

5.1 Organizational Learning Theory and Reskilling

A critical contribution of this paper is positioning reskilling within organizational learning theory frameworks. Reskilling should not be understood merely as compliance with employer obligations but as a fundamental process of organizational knowledge creation and capability development. This theoretical reframing opens important analytical possibilities.

According to Nonaka and Takeuchi's knowledge creation theory, organizations develop competitive advantage through systematic conversion of individual tacit knowledge into explicit organizational knowledge. In AI transition contexts, this framework illuminates how organizations must systematically capture and disseminate expertise regarding new technological systems. Reskilling obligations, from this perspective, represent institutionalized processes enabling this knowledge conversion.

Argyris and Schön's concept of double-loop learning is particularly relevant: organizations not only solve immediate problems (single-loop learning) but also examine and modify underlying assumptions (double-loop learning). Technological transitions demand double-loop learning—organizations must not merely update skills (single-loop) but fundamentally reconsider business processes, worker roles, and organizational purposes (double-loop).

Peter Senge's systems thinking approach emphasizes how organizations develop adaptive capacity through shared mental models, team learning, and systemic understanding. AI transitions demand precisely this systemic learning capacity: workers must understand how AI systems integrate with organizational workflows, how algorithmic decisions affect their work, and how to collectively adapt to technological changes.

5.2 Absorptive Capacity and Reskilling

Cohen and Levinthal's concept of absorptive capacity—the organization's ability to recognize, assimilate, and apply new external knowledge—provides crucial analytical tools for understanding reskilling effectiveness. Organizations with higher absorptive capacity more successfully integrate AI technologies because they possess requisite knowledge foundations and institutional mechanisms for technological learning. Reskilling obligations should thus be understood as investments in organizational absorptive capacity for technological change.

This perspective reveals why generic reskilling mandates may be insufficient: merely requiring training hours without ensuring organizations develop systematic capacities for knowledge integration produces compliance without effectiveness. Regulatory frameworks should incentivize organizational learning structures, not merely training provision.

5.3 Addressing the Organizational Learning Gap in Regulatory Frameworks

Most existing regulatory approaches to AI governance and labour law have not explicitly incorporated organizational learning theory. This represents a significant oversight. Regulatory frameworks emphasizing only compliance mechanisms (transparency requirements, bias audits) without requiring systematic organizational learning capacity development may achieve formal compliance while failing to ensure substantive worker protection or organizational adaptability.

The proposed framework therefore recommends that reskilling obligations explicitly require organizations to:

- Establish systematic mechanisms for identifying skills gaps created by AI implementation
- Develop institutional processes for converting tacit worker knowledge into explicit organizational learning
- Create feedback loops enabling workers to participate in continuous organizational adaptation to technological change
- Invest in collective learning mechanisms (communities of practice, cross-functional teams) addressing technological transitions
- Embed reskilling within organizational strategic planning rather than treating it as reactive compliance

6 Five-Dimensional Regulatory Framework: Detailed Analysis

6.1 Dimension 1: Legal Recognition of Reskilling as Employment Relationship Component

Current State: Most jurisdictions lack explicit legal recognition of reskilling as a fundamental employment component during AI-driven technological transitions. Even EU member states with strong worker protection traditions address reskilling through general provisions rather than AI-specific obligations.

Proposed Development: Legal frameworks should explicitly recognize reskilling as a core employer obligation during technological transitions, articulated through statutory provisions clarifying that AI implementation constitutes triggering events for reskilling rights. This recognition should extend beyond minimum training requirements to encompass employer responsibility for ensuring workers develop capability to perform successfully in transformed roles.

Implementation Mechanisms: National labour codes should be amended to define reskilling obligations in technology transition contexts, collective bargaining frameworks should include specific provisions enabling worker participation in defining reskilling needs, and case law development should establish judicial principles clarifying employer responsibilities.

6.2 Dimension 2: Cost-Sharing Mechanisms and Progressive Burden-Sharing

Current State: Cost allocation remains unclear across most jurisdictions, with ambiguity regarding whether reskilling constitutes an employer burden, worker responsibility, or public investment.

Proposed Development: A progressive burden-sharing model should allocate reskilling costs among employers (bearing primary responsibility for organizational transformation), workers (contributing time and learning effort), and public institutions (providing foundational support and ensuring equity across labour market participants). This allocation should reflect both fairness principles and incentive structures: employers implementing AI should bear primary costs, while public systems ensure that workers without employer reskilling access receive comparable support.

Implementation Mechanisms: Tax incentives could subsidize employer reskilling investments; public workforce development systems could be strengthened to provide foundational reskilling for displaced workers; and income support mechanisms could compensate workers during reskilling transitions.

6.3 Dimension 3: Independent Oversight of Algorithmic Management Practices

Current State: Oversight mechanisms addressing algorithmic management employment effects remain underdeveloped across most jurisdictions. While the EU AI Act addresses algorithmic transparency, labor-specific oversight remains limited.

Proposed Development: Independent oversight bodies should monitor algorithmic management practices, including recruitment algorithms, performance evaluation systems, and workplace surveillance technologies. These bodies should possess authority to audit algorithmic systems, receive worker complaints, investigate discriminatory outcomes, and enforce corrective measures.

Implementation Mechanisms: Specialized labour tribunals or ombudsperson offices could be established with algorithmic expertise; mandatory audits could be required for high-risk algorithmic systems affecting employment decisions; and transparency requirements could mandate disclosure of algorithmic decision-making criteria to affected workers and oversight authorities.

6.4 Dimension 4: Strengthening Collective Bargaining as Technological Change Governance Tool

Current State: Collective bargaining provides important protections in jurisdictions with strong labour movements (particularly EU) yet remains underdeveloped as a systematic framework for managing technological transitions. Most collective agreements address reskilling tangentially rather than positioning it centrally.

Proposed Development: Collective bargaining frameworks should be strengthened to enable workers to systematically participate in negotiating technological change, including: determining reskilling requirements, defining quality standards for training provision, establishing oversight mechanisms for algorithmic systems, and ensuring voice in workplace technology implementation.

Implementation Mechanisms: Labour law reforms could establish statutory rights for collective technology negotiation; bargaining structures could be reformed to enable sector-level standard-setting on technological transitions; and dispute resolution mechanisms could be strengthened to address collective disputes regarding reskilling obligations.

6.5 Dimension 5: Integration of Reskilling into Corporate Responsibility and Due Diligence Frameworks

Current State: Corporate social responsibility frameworks and due diligence requirements are increasingly addressing environmental and human rights dimensions but have insufficiently integrated labour transition responsibilities into AI implementation contexts.

Proposed Development: Due diligence standards should be expanded to require enterprises to assess potential reskilling needs before AI implementation, disclose expected labour market impacts, and establish remediation mechanisms when technological changes negatively affect workers. Supply chain responsibility should extend to ensuring reskilling support throughout value networks, not merely within headquarters organizations.

Implementation Mechanisms: Mandatory corporate impact assessments could be required before significant AI implementation; stakeholder engagement processes could ensure worker and community participation in technological transition planning; and remedy mechanisms could provide resources for workers harmed by inadequate reskilling support.

7 Expected Contributions and Practical Implications

7.1 Theoretical Contributions

This paper is expected to make several specific theoretical contributions based on the comparative analysis conducted across Italy, the European Union, the United States, and selected developing countries.

First, the analysis is expected to show that existing legal frameworks do not regulate employer reskilling obligations in a uniform or explicit manner but instead distribute responsibility through fragmented combinations of labour law, vocational training systems, collective bargaining arrangements, and public policy instruments. This finding contributes to labour law scholarship by clarifying that the central legal problem is not

merely the absence of regulation, but the lack of a coherent allocation of responsibility among employers, workers, and public institutions in contexts of AI-driven technological transition.

Second, the comparative analysis is likely to reveal that the most developed regulatory dimensions are not necessarily those directly addressing reskilling obligations. In particular, the European Union is expected to demonstrate stronger development in the areas of algorithmic oversight, transparency, and risk governance, especially through the AI Act, while the legal recognition of reskilling as a distinct employer obligation remains comparatively underdeveloped. This contributes to the literature by showing that advances in AI governance do not automatically translate into equally developed labour law protections concerning workforce transformation.

Third, the study is expected to demonstrate that different jurisdictional models reflect different regulatory philosophies. European systems are likely to rely more heavily on coordinated institutional arrangements involving public authorities, social dialogue, and collective bargaining, while the United States is expected to rely more on decentralized, market-oriented, and firm-level responses. Developing countries, by contrast, are likely to show that limited institutional capacity and uneven access to workforce development systems constrain the practical effectiveness of reskilling frameworks. This comparative insight contributes to interdisciplinary scholarship by identifying how legal institutions shape different models of adaptation to technological change.

Fourth, the paper contributes theoretically by integrating organizational learning and knowledge management perspectives into the legal analysis of AI governance. The analysis is expected to show that most current regulatory frameworks conceptualize reskilling primarily as a training or compliance issue, rather than as a process of organizational knowledge creation, knowledge transfer, and absorptive capacity building. This is an important theoretical contribution because it reframes reskilling as a mechanism through which organizations develop the internal capabilities required to adapt to technological transformation.

Fifth, the five-dimensional framework developed in this study is expected to provide a more precise comparative tool for future research. By distinguishing among legal recognition, cost allocation, algorithmic oversight, collective bargaining, and corporate responsibility integration, the framework makes it possible to identify not only whether a jurisdiction regulates technological transition, but also which dimensions are most developed, which remain weak, and how these dimensions interact. In this sense, the paper contributes both conceptually and methodologically to future comparative research at the intersection of labour law, AI governance, and organizational learning.

7.2 Practical Contributions for Policymakers

The expected findings of the comparative analysis also generate several practical implications for policymakers.

First, the study is likely to show that explicit legal recognition of employer reskilling obligations remains weak across jurisdictions, even where broader worker protection frameworks are relatively developed. This suggests that legislators should move beyond general training provisions and introduce more specific legal standards addressing workforce reskilling in contexts where AI significantly transforms or replaces occupational roles.

Second, the analysis is expected to reveal that cost allocation is one of the most unstable and underdefined regulatory dimensions. In most jurisdictions, it is likely that the burden of reskilling is not clearly distributed among employers, workers, and public institutions. This indicates the need for policymakers to design clearer burden-sharing mechanisms, including public support schemes, employer investment obligations, and protections for workers during retraining transitions.

Third, the comparative findings are expected to demonstrate that AI governance frameworks and labour law frameworks often remain insufficiently integrated. In the European context, for example, the AI Act may provide a relatively advanced structure for regulating algorithmic systems, but this does not necessarily ensure adequate labour protections related to reskilling. Policymakers should therefore strengthen the connection between technological regulation and employment law, ensuring that worker transition issues are addressed directly rather than indirectly.

Fourth, the analysis is likely to show that collective bargaining and social dialogue remain essential institutional mechanisms for governing technological change, especially in jurisdictions with stronger labour law traditions. This suggests that policymakers should reinforce legal frameworks that enable worker participation in decisions concerning AI adoption, job redesign, and reskilling strategies.

Fifth, for international organizations such as the ILO, OECD, and UN agencies, the expected findings indicate that developing countries may face particular structural barriers, including weaker institutional enforcement capacity, limited training infrastructure, and dependence on imported technologies. This suggests the importance of international standards and capacity-building initiatives aimed at supporting more equitable technological transitions across different economic contexts.

7.3 Implications for Business Practice

The paper is also expected to generate practical implications for business organizations adopting AI technologies in employment contexts.

First, the analysis is likely to show that organizations cannot treat reskilling as a purely voluntary or short-term human resource measure if they aim to manage technological transition sustainably. Instead, reskilling should be understood as a strategic organizational process linked to long-term workforce adaptation, institutional learning, and knowledge development.

Second, from an organizational learning perspective, the findings are expected to indicate that effective reskilling depends not only on the provision of training hours, but on the existence of internal mechanisms for identifying skills gaps, transferring knowledge, and integrating new competencies into organizational routines. This means that firms should invest in structured learning processes rather than relying on fragmented or reactive training interventions.

Third, the comparative analysis is likely to reveal that organizations operating in more coordinated institutional environments may benefit from stronger support structures, such as collective bargaining institutions, public training systems, and clearer regulatory guidance. By contrast, firms operating in more fragmented regulatory contexts may bear greater internal responsibility for designing reskilling strategies. This suggests that organizational responses to AI adoption are shaped not only by managerial choice but also by the institutional environment in which firms operate.

Fourth, the study is expected to show that firms introducing AI systems should strengthen their organizational absorptive capacity, namely their ability to recognize, assimilate, and apply new technological knowledge. In practice, this requires not only technical investments, but also the development of feedback loops, cross-functional learning mechanisms, and managerial processes that connect technological innovation with workforce capability development.

Finally, the findings suggest that integrating reskilling into broader frameworks of corporate responsibility and due diligence may become increasingly important for sustainable business governance. Organizations that fail to anticipate workforce transition needs may face not only legal and reputational risks, but also reduced capacity to adapt effectively to technological change. Conversely, firms that embed reskilling within organizational learning strategies are likely to be better positioned to combine innovation, workforce protection, and long-term competitiveness.

8 Conclusions and Future Research Directions

Artificial Intelligence is precipitating structural labour market transformations that existing regulatory frameworks were not designed to address. The absence of coherent legal frameworks governing employer reskilling obligations represents a critical regulatory gap with significant implications for worker welfare, organizational effectiveness, and social stability. This paper has demonstrated that sustainable governance of AI in labour markets requires:

First, explicit legal recognition of reskilling as a fundamental employer obligation during technological transitions, moving beyond optional corporate social responsibility toward binding regulatory requirements;

Second, the integration of organizational learning and knowledge management perspectives into regulatory frameworks, ensuring that reskilling is understood as a process of organizational knowledge creation, capability development, and absorptive capacity building rather than merely compliance-based training;

Third, development of cost-sharing mechanisms ensuring that reskilling investments are distributed equitably among employers, workers, and public institutions;

Fourth, strengthening of collective bargaining and worker participation mechanisms enabling workers to shape technological transitions rather than passively experiencing imposed change;

Fifth, integration of reskilling obligations into corporate due diligence frameworks, ensuring accountability throughout organizational value networks.

The comparative analysis reveals that while the European Union has advanced more developed regulatory frameworks, significant implementation inconsistencies persist and explicit labour law integration remains incomplete. The United States exhibits problematic fragmentation limiting worker protections. Developing countries face structural barriers requiring international support.

Future research should examine: implementation mechanisms for proposed frameworks across diverse jurisdictions; effectiveness assessment of different reskilling approaches utilizing organizational performance indicators; sectoral variations in reskilling needs and appropriate regulatory responses; and mechanisms ensuring global justice in technological transitions between developed and developing economies.

Ultimately, this paper argues that the social contract underlying employment relationships requires reconceptualization for the AI era. Technological innovation should develop in alignment with adequate worker protection and organizational learning capacity, ensuring that AI implementation contributes to inclusive prosperity rather than reproducing or amplifying labour market inequalities.

9 Ethics Declaration

This research did not require institutional ethical approval as it is a theoretical and comparative legal analysis based exclusively on published sources, policy documents, and legal instruments. No human subjects, sensitive personal data, or experimental procedures were involved.

10 AI Declaration

No AI tools were used in the conceptualization, research, or drafting of this paper. All analysis, comparative assessments, and written content were developed through manual research and writing processes.

Artificial Intelligence as Driver of Sustainable Performance in Entrepreneurial Ecosystems

Antonio Cimino[1], Vincenzo Corvello[1], Luca Famà[1], Ciro Troise[2]
[1]University of Messina, Messina, Italy
[2]University of Turin, Turin, Italy

Abstract

Entrepreneurial ecosystems are highly relevant in fostering startup success, as they facilitate access to essential resources and enhance collaboration among diverse actors through the promotion of knowledge and skills exchange. At the same time, the rapid growth in the use of artificial intelligence within organizations is not only profoundly transforming business practices but is also influencing the performance of startups within entrepreneurial ecosystems. Despite the increasing academic and managerial attention to these topics, the literature still presents an important gap regarding how startup behaviors, particularly their dynamic capabilities, influence the adoption of emerging and disruptive technologies such as artificial intelligence, and how such adoption can contribute to improving the sustainability performance of both startups and the entrepreneurial ecosystems in which they operate.

To address this gap, this study proposes a theoretical model that analyzes the role of startups' dynamic capabilities in the adoption of artificial intelligence. Furthermore, the study examines how the adoption of such technologies influences the sustainable performance of startups, considered a key indicator of the overall sustainability of entrepreneurial ecosystems. The model is empirically tested using Partial Least Squares Structural Equation Modeling (PLS-SEM), based on data collected through a self-administered questionnaire from startups listed in the official Register of Innovative Startups in Italy.

The results show that sensing and transforming capabilities positively influence the adoption of artificial intelligence technologies, while seizing capabilities do not exhibit a significant effect. Moreover, it is found that the adoption of artificial intelligence has a positive impact on the sustainability of entrepreneurial ecosystems. These results contribute to enriching the literature on entrepreneurial ecosystems and provide relevant implications for both researchers and policymakers, as well as managers interested in promoting sustainable innovation.

In particular, they highlight the need to strengthen startups' capabilities for adaptation and technological monitoring, as well as to develop targeted support policies that facilitate access to financial resources, managerial skills, and training programs, in order to foster more effective adoption of artificial intelligence and, consequently, improve the sustainability and long-term resilience of entrepreneurial ecosystems.

Keywords: Dynamic Capabilities, Artificial Intelligence, Entrepreneurial Ecosystems, Startups, Sustainable Performance

Paper type: Academic Research Paper

1 Introduction

Entrepreneurial Ecosystems (EEs) provide access to essential resources and improve the collaboration capabilities of startups, thus also facilitating knowledge exchange. Evidence highlights that startups operating within well-structured EEs are better prepared to face innovation-related challenges such as the limited availability of financial resources and restricted access to knowledge (Franco-Leal and Diaz-Carrion, 2020). Although, as stated, these ecosystems play a fundamental role in the success of startups, it is equally important how startups position themselves within them, since the startups behavior can significantly influence the overall effectiveness of the ecosystem. In the literature, the dynamic capabilities framework is often used precisely to analyze startup behavior. When referring to dynamic capabilities, it means the set of organizational competencies that enable firms to adapt, respond effectively, and succeed in rapidly changing business environments (Teece, 2014). At the same time, the success of an ecosystem has also been linked to the sustainability performance of its members (Cobben et al., 2023). If EEs exist and are particularly relevant for the success of startups, the dynamic capabilities of their members and their sustainability performance are therefore very important. For this reason, in recent years researchers have paid increasing attention to this relationship. Russo (2003) used the dynamic capabilities model to analyze how the introduction of new process standards can strengthen the ability of manufacturing facilities to improve environmental performance, thus reducing harmful emissions. Chakrabarty and Wang (2012) adopted this perspective to analyze how firms develop and implement sustainable practices, while Bhupendra and Sangle (2015) provided significant contributions by highlighting the role of dynamic capabilities in pollution prevention strategies. Mousavi et al. (2018) through a survey-based study, demonstrated that the main dimensions of dynamic capabilities have a positive impact on

sustainability-driven innovation. To observe the current scenario comprehensively, it is also necessary to consider that in recent years an increasing number of disruptive technologies have been emerging, which are profoundly reshaping organizations and consequently influencing business performance. Among these technologies, Artificial Intelligence (AI) stands out as one of the most disruptive (Arsenyan and Piepenbrink, 2023; Zhang et al., 2024), driving technological change across different sectors (Almansour, 2023). In this research scenario, a gap emerges regarding the specific study of how startup behavior influences the integration of disruptive technologies into their processes to improve the sustainability of their EEs. To fill this gap, this study proposes a theoretical model that examines how startups' dynamic capabilities influence the adoption of artificial intelligence and how the latter can influence their sustainable performance, a key element for improving the sustainability of EEs.

2 Theory

2.1 Theoretical Model

This study proposes a theoretical model that investigates how start-ups' dynamic capabilities influence AI adoption (AIA) and how this latter can impact startups sustainability performance (SP) and in turn their EE sustainability. Startups' behavior is operationalized through the three core components of the dynamic capabilities framework: sensing (SEN), seizing (SEI), and transforming (TRA) (Teece, 2014). AIA refers to the degree to which startups incorporate AI technologies into their operations and business activities (Almaiah et al., 2022; Chen and Tajdini, 2024), while SP refers to a firm's commitment to environmental and social responsibility in terms of resource efficiency, environmental protection, and long-term sustainability in its operations and business model (Shen et al., 2020; Rauter et al., 2018). The proposed theoretical framework is illustrated in Figure 1.

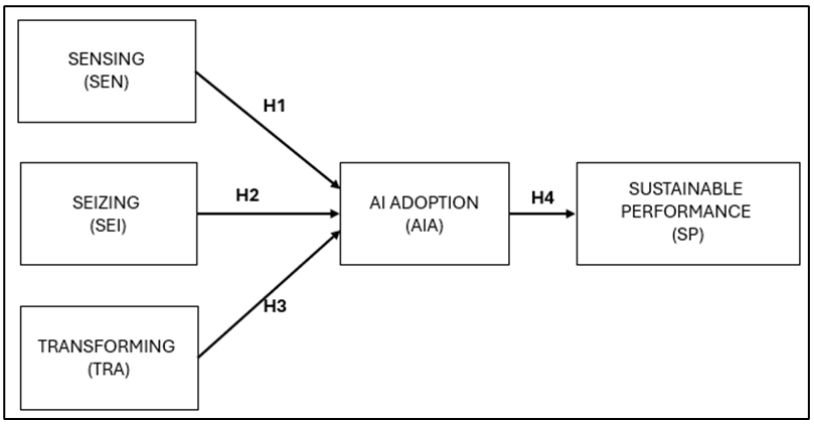

Figure 1: Theoretical model

2.1 Hypothesis development

Dynamic capabilities and Artificial Intelligence adoption

Dynamic capabilities refer to the firm's abilities to adapt, evolve, and maintain competitiveness in dynamic and uncertain environments (Corvello et al., 2023). Teece (2007, 2014) proposes a dynamic capabilities framework articulated around three interrelated components: sensing, seizing and (re)configuring. Sensing implies the ability of a firm to observe the external environment, intercepting and potentially anticipating imminent changes, thus enabling the integration of, for example, new emerging technologies and the capture of new market opportunities (Teece, 2014). Seizing, on the other hand, is the ability to effectively capitalize on the opportunities identified through sensing by allocating resources and developing timely strategies that respond to new opportunities (Teece, 2014). (Re)configuring, referred to as transforming, represents the organization's operational capabilities to realign and reconfigure internal resources, processes, and structures to support all the changes stimulated by the first two components of the framework (Teece, 2014). The literature has consistently highlighted how dynamic capabilities represent an important tool in determining whether and to what extent firms are ready to adopt new technologies (Graham and Moore, 2021; Majhi et al., 2023; Aljarboa, 2024). Based on this literature, we propose that the development of dynamic capabilities significantly improves startups' ability to adopt and implement disruptive technologies such as AI.

H1: Sensing (SEN) positively affects Artificial Intelligence Adoption (AIA) by startups

H2: Seizing (SEI) positively affects Artificial Intelligence Adoption (AIA) by startups

H3: Transforming (TRA) positively affects Artificial Intelligence Adoption (AIA) by startups

Artificial Intelligence Adoption and Sustainable performance

AI is considered one of the most revolutionary and impactful technologies of recent years, as it is radically changing the way companies manage all activities, thus improving performance across a wide range of industries (Arsenyan and Piepenbrink, 2023; Zhang et al., 2024). For the purposes of this study, AIA refers to the degree to which startups integrate AI technologies into their operations and into value-generating processes (Almaiah et al., 2022; Chen and Tajdini, 2024). An increasing number of studies are focusing on the various organizational implications deriving from AIA, highlighting positive results across multiple performance dimensions (Nayal et al., 2021; Belhadi et al., 2021; Abrokwah-Larbi and Awuku-Larbi, 2023; Necula et al., 2024). Building on these results, we therefore propose that the adoption of AI technologies by startups can play a key role in also improving sustainability performance within EEs.

H4: Artificial Intelligence Adoption (AIA) positively influence startups sustainable performances (SP)

3. Methodology

3.1 Measurement instrument

To achieve the research objective of this study, a structured questionnaire-based survey was conducted. Measurement items for each construct were drawn from established scales in the existing literature and, where appropriate, were slightly adapted to fit the specific context of this study. The final questionnaire consisted of 21 items, each measured using a 7-point Likert scale ranging from “strongly disagree” to “strongly agree”. A detailed overview of all scale items is presented in Table 1.

Table 1: Variables and measures

Variable	Items	Measurement items	Source
Sensing (SEN)	SEN1	Our company knows the best practices in the market	Kump and Kessler (2019)
	SEN2	Our company is up to date on the current market situation	
	SEN3	Our company systematically searches for information on the current market situation	
	SEN4	As a company, we know how to access new information	
Seizing (SEI)	SEI1	Our company can quickly relate to new knowledge from the outside	Kump and Kessler (2019)
	SEI2	We recognize what new information can be utilized in our company	
	SEI3	Our company is capable of turning new technological knowledge into process and product innovation	
Transforming (TRA)	TRA1	By defining clear responsibilities, we successfully implement plans for changes in our company	Kump and Kessler (2019)
	TRA2	Even when unforeseen interruptions occur, change projects are seen through consistently in our company	
	TRA3	Decisions on planned changes are pursued consistently in our company	
	TRA4	In the past, we have demonstrated our strengths in implementing changes	
	TRA5	In our company, change projects can be put into practice alongside the daily business	
AI Adoption (AIA)	AIA1	My company is ready to adopt AI technology to generate innovations	Adapted from Almaiah et al. (2022) and from Chen and Tajdini (2024)
	AIA2	My company is willing to upgrade their technology and ready to include AI as part of it	
	AIA3	We have implemented AI in all our company processes	
	AIA4	Relative to the potential of AI for our company activities, our AI implementation is extensive	
	AIA5	AI has substantially changed our business processes	
Sustainable performance (SP)	SP1	Our company has always attached great importance to reducing environmental pollution	Shen et al. (2020), Rauter et al. (2018)
	SP2	Our company gives priority on resource efficiency in production	
	SP3	Our company puts great emphasis on social responsibility	
	SP4	Our company regards product sustainability as its top priority	
	SP5	Our company is focused on building a sustainable business model	

3.2 Data collection and data analysis

The survey was administered via email between November 15, 2024, and January 10, 2025, addressing startups registered in the official Italian Innovative Startup Business Register. Overall, 234 fully completed responses were collected. However, 24 responses contained missing data and were excluded from further analysis, resulting in a final sample of 210 valid responses. This dataset was used to empirically test the proposed research model and hypotheses. Partial Least Squares Structural Equation Modeling was employed for the analysis, given its suitability for studies with relatively small sample sizes (Hair et al., 2021) and its effectiveness in exploratory research settings (Hair et al., 2017).

4 Results

4.1 Descriptive results

Table 2 presents the demographic and organizational characteristics of the startups included in the final sample (n = 210). The majority of the startups operate within the service activities and utilities sector, which accounts for 58% of the sample. This is followed by industry and manufacturing (22%) and ICT (10%). Other sectors such as R&D, crafts, tourism, and healthcare are marginally represented, each comprising 4% or less of the sample. This distribution reflects the prominence of service-based and technology-driven ventures within Italy's innovative startup landscape. In terms of regional distribution, half of the surveyed startups (50%) are located in Northern Italy, followed by 27% in the Central regions and 23% in the South and Islands. This regional concentration aligns with broader economic trends, where Northern Italy traditionally hosts a higher density of entrepreneurial activity and innovation infrastructure. Finally, most startups in the sample are small-sized enterprises: 81% have 10 or fewer employees. Only 11% report having between 11 and 20 employees, while 8% employ more than 20 people. This indicates that the sampled startups are predominantly micro-enterprises, consistent with the early-stage nature of ventures typically found in innovation registries.

Table 2: Characteristics of the sample

Characteristics		Frequency (n)	Percentage (%)
Industry sector	Service activities and utilities	122	58%
	Industry and Manufacturing	45	22%
	ICT	21	10%
	R&D	9	4%
	Crafts	9	4%
	Tourism	2	1%
	Tourism	2	1%
Geographical location	North	105	50%
	Centre	57	27%
	South and Islands	48	23%
Number of employees	≤10	170	81%
	11-20	23	11%
	≥21	17	8%

4.2 Measurement model

To evaluate the measurement model, indicator reliability, internal consistency validity, convergent validity and discriminant validity were conducted. Indicator reliability was confirmed through the analysis of indicator loadings, all of which surpassed the recommended threshold of 0.70, indicating satisfactory individual item reliability (Hair et al., 2021). Internal consistency reliability was assessed using composite reliability (Rho_c), with all constructs exceeding the acceptable benchmark values, thus demonstrating strong internal coherence among the indicators. Convergent validity was evaluated via the Average Variance Extracted (AVE), with all constructs showing AVE values above the 0.50 threshold, confirming that the indicators adequately capture the underlying constructs (Hair et al., 2021). Detailed results for reliability and convergent validity are presented in Table 3. In addition, discriminant validity was assessed using the Fornell-Larcker criterion (Fornell and Larcker, 1981). The analysis confirmed that, for each construct, the square root of the AVE was greater than its correlations with any other construct, supporting the distinctiveness of each latent variable. These results are shown in Table 4 and provide strong evidence for the discriminant validity of the measurement model.

Table 3: Internal consistency and convergent validity

Construct	Rho_C	AVE
SEN	0.869	0.626
SEI	0.854	0.661
TRA	0.912	0.676
AIA	0.936	0.745
SP	0.766	0.625

Table 4: Discriminant validity

Fornell-Larcker					
	SEN	SEI	TRA	AIA	SP
SEN	0.791				
SEI	0.65	0.813			
TRA	0.542	0.635	0.822		
AIA	0.323	0.364	0.472	0.863	
SP	0.468	0.492	0.638	0.733	0.79

4.3 Structural model and hypothesis testing

The results of the hypothesis testing are summarized in Table 5, which reports the path coefficients representing the estimated relationships within the structural model. The table also includes key statistical outputs such as standardized beta (β) values, sample means, standard deviations, t-values, and confidence intervals. Complementing this, Figure 2 visually presents these relationships alongside the R^2 values, providing an overview of the model's explanatory power. The results confirm the predictive validity of the model. Analysis of the structural paths reveals that SEN and TRA capabilities both have a significant positive impact on AIA, thereby supporting hypotheses H1 and H3. In contrast, SEI capability does not show a statistically significant effect on AIA, resulting in the rejection of hypothesis H2. Furthermore, AIA demonstrates a positive and significant relationship with SP, thereby confirming hypothesis H4.

Table 5: Hypothesis testing

Path coefficient	Orig. Mean	Bootstrap Mean	Bootstrap SD	T Stat	2.5% CI	97.5% CI	Result
SEN à AIA	0.144	0.15	0.067	2.142	0.015	0.279	Yes
SEI à AIA	0.084	0.088	0.094	0.901	-0.105	0.263	No
TRA à AIA	0.33	0.333	0.087	3.796	0.161	0.503	Yes
AIA à SP	0.693	0.699	0.045	15.25	0.606	0.785	Yes

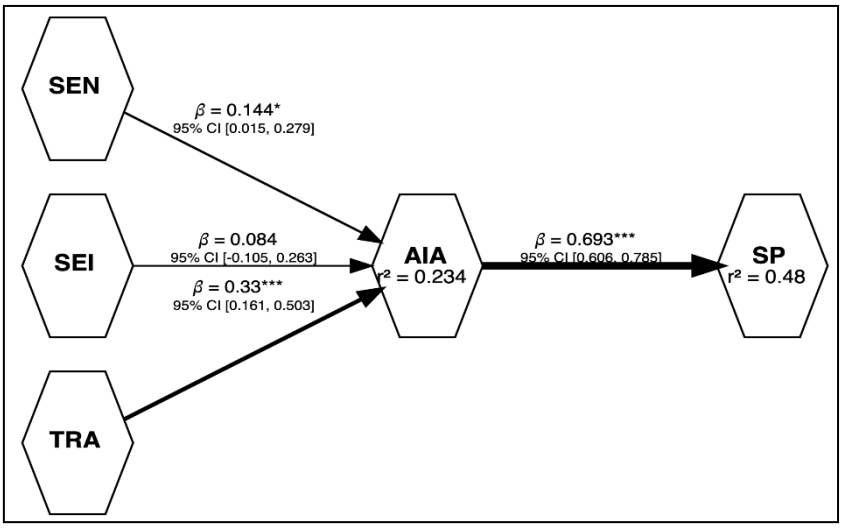

Figure 2: Results of the final model evaluation

5 Discussion

The first set of results highlights how SEN and TRA capabilities have a positive and significant influence on AIA, thus confirming hypotheses H1 and H3. These results therefore confirm that innovative startups, which

operate in dynamic and highly technology-intensive contexts and master the ability to continuously monitor the external environment (sensing) and reconfigure internal processes (transforming), are able to exploit the potential of emerging technologies such as AI. The findings of this study therefore confirm the existing literature that emphasizes the importance of sensing and transforming dynamic capabilities in making firms agile and responsive to technological progress, facilitating the integration of tools such as AI (Majhi et al., 2023; Graham and Moore, 2021; Aljarboa, 2024).

As for the second set of results, it appears that SEI does not have a relevant effect on AIA, thus not supporting hypothesis H2 and contrasting several previous studies that also identified seizing as a key driver of technological adoption (Majhi et al., 2023; Graham and Moore, 2021; Aljarboa, 2024). This misalignment with the results of the existing literature can be explained by the type of companies considered; since these are innovative startups, this type of firms, still in the early stages of development, are able to recognize AI-related opportunities (sensing) and to fairly easily transform their structures and processes (transforming), but encounter practical difficulties such as financial constraints and limited managerial experience, which hinder their ability to seize and effectively implement these opportunities. In other words, while they may have the intent and strategic vision, their execution capability may not be sufficiently mature to translate opportunities into concrete AI adoption. This contextual specificity reflects the structural and operational challenges that innovative startups often face, especially in their early stages.

The study also finds that AIA has a positive effect on startups' SP, thus confirming hypothesis H4. This result supports the growing body of literature indicating that AI technologies can significantly improve firm performance across multiple dimensions, including sustainability outcomes (Nayal et al., 2021; Belhadi et al., 2021; Abrokwah-Larbi and Awuku-Larbi, 2023; Necula et al., 2024). Within the context of entrepreneurial ecosystems, the sustainable performance of individual startups contributes to the overall sustainability of the ecosystem itself (Cobben et al., 2023). As startups adopt AI to improve their environmental, social, and economic outcomes, they collectively strengthen the resilience and long-term sustainability of the ecosystems in which they operate.

6 Implications

The results of this study offer several important practical applications useful for startup founders, innovation policymakers and all stakeholders involved in entrepreneurial ecosystems. First of all, given the importance of sensing and transforming capabilities on AI adoption, all startups should invest in the development of strategic agility and internal adaptability in order to fully exploit new technological opportunities. This goal can be achieved through the creation of mechanisms to continuously monitor technological trends and flexibly reconfigure their processes. Secondly, the absence of a significant relationship between seizing capabilities and AI adoption suggests that early-stage startups may face barriers in execution, such as limited financial or managerial resources. This highlights the importance of targeted support measures, such as access to funding, mentoring, and training, that can help startups move from opportunity recognition to effective implementation. As for the positive impact of AI adoption on sustainable performance, fostering AI readiness within startups can represent a lever to improve the competitiveness of individual firms as well as to advance the sustainability of the broader entrepreneurial ecosystem. Policymakers and ecosystem developers should therefore consider integrating support for digital transformation and sustainability into innovation programs to ensure the long-term resilience of ecosystems.

7 Conclusions

This study helps to better understand how startups' dynamic capabilities influence the adoption of artificial intelligence and how this contributes to improving their sustainable performance, seen as an expression of the sustainability of the entire entrepreneurial ecosystem. Drawing on the dynamic capabilities framework, a theoretical model was developed and then empirically tested through data collected via a survey from innovative startups registered with the Italian Chamber of Commerce. The results show that sensing and transforming capabilities significantly foster AI adoption, with positive effects on startups' sustainable performance. An interesting aspect concerns the seizing capability, which does not show a significant effect on AI adoption, thus offering a more articulated view of the difficulties that startups, especially in their early stages and with limited resources, face when implementing disruptive technologies. Despite the results obtained, the study presents some limitations. First, the use of cross-sectional data, collected at a single point in time, does not allow observation of how the relationships between dynamic capabilities and AI adoption evolve over time. Longitudinal studies could provide a more complete and dynamic view of these dynamics in the long term. Moreover, the sample analyzed is composed exclusively of Italian innovative startups, which may limit the

possibility of generalizing the results to other geographic or sectoral contexts. For this reason, future research could extend the analysis by including startups from other countries or with different levels of maturity, in order to test the robustness of the model in different contexts. Finally, qualitative studies could further explore why, in some cases, seizing capabilities are less effective, offering a deeper understanding of the difficulties related to AI implementation.

7 Ethics Declaration

The authors declare that this study did not require formal ethical approval.

8 AI Declaration

The authors declare that generative AI tools were used exclusively for language proofreading.

Innovation and Sustainability as Judged by the Market

Maria Teresa Bianchi, Raffaele de Socio, Federica Mastrantonio
Sapienza University of Rome, Rome, Italy

Abstract

The aim of this research is to describe the impact of innovative and sustainable investments made by listed companies on their market performance. The research methodology applied to this paper is the qualitative method through the application of the multiple case study analysis. Sources of analysis were company and market data, financial statements and sustainability reports for the financial years 2022, 2023 and 2024 of a sample of Italian listed companies selected for their commitment to innovative and sustainable investments. We investigated the relationship between these investments and their market capitalisation. The results achieved demonstrate a positive relationship between investments and market performance. It emerged that companies which incorporate such investments into their strategies, drawing on their knowledge management expertise, make the market aware of their operational efficiency (as well as creating shared value) and attract investors willing to invest in such companies. In fact, the market views the company's investment commitment favourably, as it is seen as the foundation for greater operational efficiency. Innovative and sustainable investments lead to higher market prices, thereby contributing to growth in market capitalisation. The study focuses not only on the promotion and execution of investments by listed companies, but also on their ability and willingness to both innovate and operate sustainably, by investing substantial resources towards these ends, and on the market's response to such actions. This represents a departure from the traditional literature, which focuses primarily on a company's ability to invest in either innovation or sustainability but has not yet explored the impact that joint investment in both areas may have on market capitalisation.

The paper enriches the existing literature through studies and findings that provide a useful reference point for both the academic and practical implications of developments in research on the adoption of innovative and sustainable corporate investments, and the functional link between these and market reactions.

Keywords: Innovation; Sustainability; ESG; Market capitalisation; Operational efficiency.

Paper type: Practical Paper.

1 Introduction

The study is focused on the impact of innovative and sustainable investments made by listed companies on their market performance.

Today, businesses are expected to demonstrate their value to potential investors and the market, as well as their ability to generate that value.

Including investments aimed at fostering innovation and sustainability in strategic or business plans is a winning strategy for demonstrating operational efficiency to the market and attracting new investors.

The purpose of this research is to understand how the market values innovative and sustainable companies, including in terms of market capitalisation. The research methodology applied to this paper is the qualitative method through the application of the multiple case study analysis. Sources of analysis were company and market data, financial statements and sustainability reports for the financial years 2022, 2023 and 2024 of a sample of Italian listed companies selected for their commitment to innovative and sustainable investments. We investigated the relationship between these investments and their market capitalisation.

We have seen how companies that are most committed to innovative and sustainable investment are valued by investors and rewarded by the market. The research focuses not only on the promotion and execution of investments by listed companies, but also on their ability and willingness to both innovate and operate sustainably, by investing substantial resources towards these ends, and on the market's response to such actions. This represents a departure from the traditional literature, which focuses primarily on a company's ability to invest in either innovation or sustainability but has not yet explored the impact that joint investment in both areas may have on market capitalisation.

The paper enriches the existing literature through studies and findings that provide a useful reference point for both the academic and practical implications of developments in research on the adoption of innovative and sustainable corporate investments, and the functional link between these and market reactions.

The remainder of this paper is structured as follows: section 2 provides a literature review that includes our research question; section 3 shows research methods and multiple case study; section 4 explains our results and discussion; section 5 outlines our conclusions; section 6 and 7 express ethics declaration and AI declaration.

2 Literature Review

The integration of ESG investments remains essential for driving ethical, environmentally sustainable and socially responsible innovation. It is very important, in fact, that the theme of innovation is also combined with social aspects and performance (Deng et al., 2025).

The resource-based view (RBV) argues that companies achieve superior performance by exploiting resources and capabilities that are valuable, rare, inimitable and non-substitutable (Wernerfelt, 1984; Barney, 1991).

In this context, therefore, the implementation of ESG principles does not simply act as an isolated resource, but as a complex system of capabilities developed through innovative investments, supported by environmental processes, human capital and governance routines. Accordingly, investors in these sectors are willing to pay for the risk of innovation in the hope of obtaining higher future returns (Fatemi et al., 2018). It is therefore necessary to define the exact contours of innovation and, above all, to understand how it is interpreted by the entrepreneur – or rather by the entrepreneurship factor (C. Bianchi, 1998; P. Capaldo, 2013) – and by investors (Samy ElDeeb et al., 2025). Bearing in mind that truly innovative investments are directed and channelled towards improving the social pillar (C. Bianchi, 2010).

Recently, companies have focused on the extent to which sustainable investments can increase market value, given their proportional correlation with market capitalisation (Raimo et al., 2020; Aydogmus et al., 2022; Zhou et al., 2022; Ni and Sun, 2023; Espinosa-Mendez et al., 2024).

Although still in its early stages, the integration of ESG measures appears to have the potential to influence a company's financial value and performance (Nirino et al., 2021; Alkaraan et al., 2022; García-Amate et al., 2023) and market value (Lo and Kwan, 2017; Janicka and Sajnog, 2022; Zhou et al., 2022). In fact, with the integration of innovative and sustainable strategies and policies into portfolio theory, ESG could potentially become an essential factor influencing investment in company shares (Li et al., 2022).

Environmental investments reduce energy consumption and waste, thereby lowering operating costs and increasing resource productivity (Wong et al., 2020; Vagnoni et al., 2025). Social investments, including comprehensive employee training and safety systems, strengthen human capital and reduce staff turnover, resulting in fewer operational disruptions and enhanced work efficiency (Bang et al., 2022; Zhang et al., 2022). Furthermore, governance mechanisms, such as board independence and strong internal controls, mitigate agency costs and streamline coordination, thereby refining the efficiency of decision-making (Katti and Raithatha, 2018).

These strategic and innovative processes, linked to ESG practices, manifest themselves in complex organisational capabilities that competitors find difficult to replicate. A positive and direct impact of ESG factors on market capitalisation has been linked to sound sustainable practices fostered by operational efficiency, reputation enhancement, investor attraction and risk management (Nirino et al., 2021; Bofinger et al., 2022; Janicka and Sajnog, 2022; Zhou et al., 2022).

Thus, innovation, combined with sustainability, constitutes a strategic capability that consolidates efficiency, optimises resource utilisation, strengthens human capital, and refines governance frameworks. As research conducted in recent years has shown, integrating corporate social responsibility (CSR) into core strategies strengthens market positioning (Porter and Kramer, 2006).

The results of recent studies (Lee et al., 2026) show that social investments increase operational efficiency, while environmental and governance investments mainly strengthen market performance. Additionally, corporate strategy moderates these relationships; strategic misalignment, such as rigid governance structures within companies, diminishes ESG effectiveness. However, the same study highlights that European companies are leaders in governance and operational efficiency, suggesting that such companies can aspire to consolidate their market performance.

Moreover, the study by Inaba (2026) reveals that companies listed on representative stock indices in 18 countries around the world, with better environmental, social and governance management levels and higher investment in research and development, were both highly valued on the market and had excellent corporate cash flows in the period 2008-2019.

Other recent studies also demonstrate that companies with superior ESG performance enjoy stronger demand and gain legitimacy from stakeholders, such as investors, which improves operational stability and market performance (Zhou et al., 2022; Chen et al., 2023). Hence, stakeholder theory (Freeman, 1984; Freeman et al., 2017) and technology acceptance models suggest that companies should innovate by adopting sustainable practices to increase user trust and acceptance, which are essential for the successful implementation of sustainable technology and for the appreciation of companies in the market.

Analysis of emerging economies (BRICS) also corroborates the thesis that the impact of ESG performance on market capitalisation is positive and significant, regardless of the specific characteristics of the sector and country (Deng et al., 2025).

In relation to the considerations made, the purpose of this article is to answer the following research question: How does the market evaluate innovative and sustainable companies, including in terms of market capitalisation? (RQ1).

3 Research Methods

The research method adopted in this paper was qualitative (Parker and Northcott, 2016), making use of the multiple case study analysis (Stake, 2005).

In particular, we analysed company and market data, financial statements and sustainability reports for the financial years 2022, 2023 and 2024 of a sample of Italian listed companies selected for their commitment to innovative and sustainable investments, and investigated the relationship between these investments and their market performance.

For this research, we utilised the AIDA database, studying and analysing Italian public limited companies listed on the Milan Stock Exchange. Information regarding market capitalisation was also obtained by consulting studies and analyses conducted by "Borsa Italiana".

The sample comprises the 10 listed Italian companies that have distinguished themselves most for their commitment to supporting cutting-edge, innovative and sustainable investments planned over the period under review, 2022–2024.

These are innovative and sustainable companies that have invested tens or, in most cases, hundreds of millions or billions of euros in the sectors we have investigated, achieving excellent market performance in terms of market capitalisation. They are:

- Enel S.p.A. (energy sector);
- Intesa Sanpaolo S.p.A. (banking sector);
- Leonardo S.p.A. (defence, aerospace and security sector);
- Poste Italiane S.p.A. (postal, logistics, financial, insurance and telecommunications sectors);
- A2A S.p.A (energy, environmental and waste management sectors);
- Ferrari N.V. (automotive sector);
- Webuild S.p.A (construction and engineering sector);
- BF S.p.A (agro-industrial sector);
- Prysmian S.p.A. (manufacturing sector – production of cables for the energy and telecommunications sectors; production of optical fibres);
- Terna S.p.A (energy sector – operator and manager of electricity transmission networks).

4 Results and Discussion

The companies in the sample are highly reputable firms, leaders in their respective markets, including at an international level.

Knowledge-based capabilities enable these companies to effectively communicate their commitment to innovation and ESG: indeed, these investments are included in their 2022–2024 Strategic Plan. This approach raises awareness among investors and the market of the company's potential to achieve greater operational efficiency.

The following table provides an overview of the key findings relating to the investments made by the companies in the sample and the market performance achieved over the three-year period 2022–2024.

Table 1: Key findings

Company	Innov. & Sust. Invest. FY 2022 (€ millions)	Innov. & Sust. Invest. FY 2023 (€ millions)	Innov. & Sust. Invest. FY 2024 (€ millions)	Market Cap. FY 2022 (€ billions)	Market Cap. FY 2023 (€ billions)	Market Cap. FY 2024 (€ billions)
Enel S.p.A.	14,334	14,334	14,334	51.104	68.361	69.925
Intesa Sanpaolo S.p.A.	49.750	49.750	49.750	37.978	48.222	68.693
Leonardo S.p.A.	2,000	750.00	750.00	4.637	8.592	14.918
Poste Italiane S.p.A.	656.750	656.750	656.750	11.851	13.311	17.633

Company	Innov. & Sust. Invest. FY 2022 (€ millions)	Innov. & Sust. Invest. FY 2023 (€ millions)	Innov. & Sust. Invest. FY 2024 (€ millions)	Market Cap. FY 2022 (€ billions)	Market Cap. FY 2023 (€ billions)	Market Cap. FY 2024 (€ billions)
A2A S.p.A.	1,833	1,833	1,833	3.900	5.824	6.720
Ferrari N.V.	880.00	880.00	880.00	36.427	55.064	73.838
Webuild S.p.A.	43.667	52.00	250.00	1.362	1.824	2.839
BF S.p.A.	5.900	8.600	3.200	720.2 millions	1.034	1.163
Prysmian S.p.A.	54.00 (12.60 in R&D)	54.00 (21.50 in R&D)	54.00 (32.80 in R&D)	9.133	11.227	17.823
Terna S.p.A.	2,500	2,000	2,400	13.839	15.152	15.285

Source: Authors

The companies in the sample stand out for their significant commitment to innovative and sustainable investment and for the steady growth in their market capitalisation over the three financial years in question.

Based on the results summarised in the table above, we can make the following observations:

- Enel S.p.A. is the company in the sample that has invested the most in innovation and sustainability over the three financial years in question, totalling approximately €43 billion. The market has welcomed this approach and, indeed, its market capitalisation – with the exception of 2024 (when it was slightly lower than that of Ferrari) – has also been the highest in the sample. The expansion achieved in the 2023 financial year was remarkable, with market capitalisation growing by over 30%, from €51 billion to over €68 billion;
- Intesa Sanpaolo S.p.A. has invested approximately €150 million in innovation and sustainability over the three-year period 2022–2024, thereby achieving excellent market performance. In fact, market capitalisation grew from around 38 billion in 2022 to 48 billion in 2023 and up to 68.7 billion in 2024, recording an increase of over 40% between 2023 and 2024. It is one of the companies with the highest market capitalisation in the sample;
- Leonardo S.p.A, thanks to its investments of €3.5 billion between 2022 and 2024, has been rewarded by the market with an 85% increase in market capitalisation (the highest annual percentage change in the sample) between 2022 and 2023, and growth of over 70% between 2023 and 2024. Consequently, market capitalisation has seen extraordinary growth, rising from €4.6 billion in 2022 to approximately €15 billion in 2024: capitalisation has more than tripled over the course of just two financial years;
- Poste Italiane S.p.A. has invested around 2 billion euros over the three-year period, and its market capitalisation has risen steadily between 2022 and 2024: from 11.8 to 17.6 billion, recording an increase of more than 10% between 2022 and 2023 and an increase of over 30% between 2023 and 2024;
- A2A S.p.A has allocated significant investments to innovation and sustainability, totalling 5.5 billion: it ranked third in the sample in terms of investment volume. Between the 2022 and 2023 financial years, the company recorded an increase of around 50% in its market capitalisation, reaching a market capitalisation of nearly €7 billion in 2024;
- Ferrari N.V. has invested over €2.6 billion in innovation and sustainability, and the market has recognised this commitment: in fact, the company achieved the highest market capitalisation in the sample in the 2024 financial year, amounting to 73.8 billion, whilst its market performance in the 2022 (36.4 billion) and 2023 (55 billion) financial years was the best after that of Enel;
- Webuild S.p.A has allocated over €345 million to innovation and sustainability over the three-year period in question, with progressive investments that have boosted 2023 capitalisation by more than 30% compared with 2022. Following the significant increase in investment in 2024, which was five times that of 2023, capitalisation growth over the same period was close to 60%;
- BF S.p.A increased its investment in innovation and sustainability by over 45% between 2022 and 2023 and, during the same period, its market capitalisation exceeded the one-billion-euro mark, up from €720 million in the 2022 financial year (a 40% increase);
- Prysmian S.p.A. has allocated over €160 million to innovation and sustainability over the three-year period, with investment in research and development set to rise between 2022 and 2024, from €13 million to around €33 million. The market has responded positively to this commitment: in fact, market capitalisation grew by over 20% between 2022 and 2023 and by around 60% between 2023 and 2024;

- Terna S.p.A. ranked second in the sample in terms of the volume of investment allocated to innovation and sustainability, at around €7 billion. Its market capitalisation has grown steadily over the three-year period, exceeding €15 billion as early as 2023.

5 Conclusions

The findings of the study enable us to understand how innovative and sustainable companies, which invest significant resources in these areas, are valued and rewarded by the market, thereby addressing the research question.

Indeed, the market views commitment to research, development, innovation and sustainability positively: this is demonstrated by Enel's market capitalisation, which is the highest in the sample (considering the three-year period 2022–2024), even in light of the higher investments made compared to the other companies in the reference sample. These findings are consistent with the literature (Raimo et al., 2020; Aydogmus et al., 2022; Zhou et al., 2022; Ni and Sun, 2023; Espinosa-Mendez et al., 2024).

The companies in the sample stand out for their prudent management of knowledge-based skills, which is reflected in the inclusion of innovative and ESG investments in their Strategic Plans or in the integration of their Sustainability Plan into their Business Plan (as in the case of Terna). Thanks to this ability to communicate their commitment to innovation and sustainability, companies make investors – even the most sceptical ones – aware of their genuine commitment in these areas.

Enel, by investing €43 billion in innovation and sustainability, has attracted the attention of investors focused on ESG issues. The company estimates that ESG share capital, contributed by socially responsible investors (SRI), will amount to 14.9% in 2022, with an ESG free float of 19.4%; in the 2023 financial year, the ESG share capital stands at 17.5% and the ESG free float at 22.9%; in the 2024 financial year, these figures rise to 23% and 30.1% respectively. At Prysmian too, thanks to the innovative and sustainable investments made, "core ESG" or "ESG-focused" investors account for as much as 40–50% of the share capital. This phenomenon is consistent with the studies conducted by Zhou et al. (2022) and Chen et al. (2023).

Companies that promote investment in innovation and sustainability are viewed by the market as being poised for development and growth, thanks to their greater operational efficiency (as argued by Nirino et al., 2021; Bofinger et al., 2022; Janicka and Sajnog, 2022; Zhou et al., 2022) that they are potentially capable of achieving, as well as thanks to the shared value creation they can deliver. Thus, the direct relationship between investment and operational efficiency, in line also with the research conducted by Lee et al. (2026), fosters positive market expectations that have a "cascading" effect on share prices, causing them to rise.

Market performance is therefore correlated with investment and the integration of ESG measures, as highlighted by Lo and Kwan (2017); Janicka and Sajnog (2022); Zhou et al. (2022); and also by Li et al. (2022) and Inaba (2026).

A steady rise in share prices characterised the performance of all 10 companies in the sample over the three-year period under review. This price growth drove the strongest market performance, as measured by market capitalisation, which increased between 2022 and 2024.

The companies examined, spanning various economic sectors, have all adopted an innovative and sustainable strategy, although their investment choices have focused on different areas.

Some companies, such as Intesa Sanpaolo, have prioritised investments in applied research, artificial intelligence (AI), neuroscience and robotics. Others, such as Leonardo, have aligned their investments with the United Nations Sustainable Development Goals (SDGs); in particular, those relating to decent work and economic growth (SDG 8), industry, innovation and infrastructure (SDG 9) and sustainable cities and communities (SDG 11).

Poste Italiane has focused its investments on automation, modernisation and digital transformation: from electric vehicles to solar panels, from smart post boxes to the technological infrastructure of business support systems.

A2A has decided to focus its investment strategy on the circular economy and energy transition; Ferrari has centred its investment plan on technological innovation, research, environmental sustainability and ecological transition.

Webuild's investments have been directed towards "cleantech", i.e. innovative technologies designed to reduce environmental impact, and subsequently towards research and development.

BF has directed its investments primarily towards research and development, as well as innovative activities aimed at adapting to climate change. Prysmian, too, has channelled most of its investments into research and development and the reduction of GHG emissions.

Terna has focused its investments on reducing CO2 emissions, integrating renewable energy sources, the security and resilience of the electricity system, the digitalisation and technological innovation of the grid (AI, robotics, IoT and BIM), decarbonisation and the energy transition.

These results are very encouraging, as they set an example for other companies (including international ones) that are keen to innovate and operate sustainably, whilst also attracting investors and being recognised and rewarded by the market. Consequently, the market demonstrates its interest in companies that not only invest profitably, but also prove capable of effectively communicating, in their strategic or business plans, the investments they make and the innovative and sustainable objectives they aim to achieve. Investors' positive expectations are based on the potential for growth in operational efficiency, thanks to the investments made, and have an impact on rising share prices and market capitalisation.

The limitations of this research lie in the fact that the analysis is based solely on a study of Italian listed companies, although, to date, the cases examined represent highly significant examples. Future studies aim to identify and analyse other international listed companies that have invested in innovation and sustainability, in order to examine the reaction of foreign markets to such strategic choices.

FedHR5.0: A Human-Centric Federated Learning Framework for Organisational Learning and Workforce Competency Development in Healthcare

Fabio Liberti
University of the Chambers of Commerce, Universitas Mercatorum, Rome, Italy

Abstract

Healthcare organisations face simultaneous pressure to digitalise their workforce, redesign learning processes and adopt artificial intelligence in support of human resource decisions, while protecting sensitive employee data and respecting professional dignity - pressures more acute in healthcare than in other knowledge-intensive sectors, and bearing on clinical and administrative cadres alike.

Three research streams have approached this problem in isolation: federated learning in healthcare, privacy-preserving HR analytics, and organisational learning theory engaging with AI as a partner in knowledge management. Federated learning has predominantly addressed clinical data rather than workforce competency data; HR analytics has not been developed at the intersection with federated infrastructures; organisational learning theory has rarely engaged with the constraints that federated, privacy-preserving learning imposes. We position our contribution explicitly at the three-way intersection.

We introduce FedHR5.0, a conceptual framework for privacy-preserving organisational learning and workforce competency development in healthcare. FedHR5.0 combines federated learning, (ε, δ)-differential privacy and transparent governance with a five-module architecture - trust-based, adaptive learning, emotionally-intelligent assessment, ethical AI, and collaborative knowledge exchange. The framework extends the SECI dynamics of Nonaka and Takeuchi toward a generative-AI-aware GRAI cycle, in which tacit–explicit transitions are mediated by an explicit privacy budget that doubles as a trust-building instrument. The artefact is positioned as a Design Science Research *improvement*-type contribution.

Empirical validation is scoped as future work and given a concrete pathway: a multi-hospital pilot, four operationally measurable evaluation axes (model accuracy, effective privacy budget, organisational readiness, worker participation) and a three-phase iterative protocol grounded in Design Science Research.

For HR practice, the framework repositions learning and development as a strategic driver of human–AI collaboration and treats workforce participation as a structural design requirement, applicable to clinical and administrative cadres alike. For research, it offers a starting point for cumulative design knowledge at the emerging intersection of federated learning, organisational learning and human-centric HR analytics.

Keywords: Organisational learning; Federated learning; Healthcare workforce; AI-based learning systems; Workforce transformation.

Paper type: Academic Research Paper.

1 Introduction

Healthcare organisations face simultaneous pressure to digitalise their workforce, redesign learning processes and adopt artificial intelligence in support of human resource decisions, while protecting sensitive employee data and respecting professional dignity. Demographic ageing, accelerated digital health transformation and the diffusion of AI across people management create a constellation of constraints more acute in healthcare than in any other knowledge-intensive sector (Pavuluri et al. 2024, de Kok et al. 2023).

Three research streams have approached this problem in isolation: federated learning in healthcare has matured rapidly but addresses primarily clinical data rather than workforce competency data (Rieke et al. 2020, Chaddad et al. 2024); privacy-preserving HR analytics has begun to engage with transparency and accountability (Tursun-bayeva et al. 2018, Yanamala 2024), yet not at the intersection with federated infrastructures; organisational learning theory has engaged with AI in knowledge management (Jarrahi et al. 2023, Böhm & Durst 2025), but rarely with the architectural constraints federated learning imposes.

We position our contribution within healthcare workforces in their full breadth - clinical and administrative - recognising that recent evidence on health service management workforce capacity (Brommeyer et al. 2022) and on AI's reshaping of health information management (Stanfill & Marc 2019) positions administrative cadres as primary subjects, not residual recipients. Clinical staff exemplify the most acute case of tacit-knowledge dimensions; administrative roles extend the same logic to digital literacy, data governance and change-management capacity.

This paper asks how an integrated, human-centric architecture can support privacy-preserving organisational learning and workforce competency development across networks of healthcare institutions. Our answer is FedHR5.0: a conceptual framework combining federated learning (McMahan et al. 2016), (ε, δ)-differential privacy and transparent governance with a five-module architecture - trust-based, adaptive learning, emotionally-intelligent assessment, ethical AI, and collaborative knowledge exchange. The framework extends the SECI dynamics of Nonaka & Takeuchi (2009) toward a GRAI cycle (Böhm & Durst 2025), in which tacit–explicit transitions are mediated by an explicit privacy budget that doubles as a trust-building instrument.

Section 2 reviews background; Section 3 positions the contribution; Section 4 articulates the framework; Section 5 details methodology; Section 6 discusses implications; Section 7 outlines a validation pathway; Section 8 concludes.

2 Background

2.1 Organisational learning and workforce transformation in healthcare

Healthcare organisations are knowledge-intensive, high-reliability environments in which learning capability is a precondition for quality and safety. The Learning Health System frame consolidates around governance of the learning cycle, staff engagement, data infrastructure, analytical capacity and action loops, with enabling conditions for organisations to act on what they observe (Easterling et al. 2021). The scoping review by de Kok et al. (2023) identifies five attributes - leadership, culture, team development, change management and customer orientation - that distinguish healthcare organisations with mature learning capabilities from those without.

At the individual and team layer, quality-improvement evidence shows that sustainability of change in healthcare depends on learning processes that reach the mental models of practitioners, in line with the classical reading of double-loop learning (Hovlid et al. 2012).

2.2 Reskilling and upskilling in AI-driven contexts

The diffusion of artificial intelligence across organisational functions has reopened debate on reskilling, upskilling and the strategic role of the learning and development function. Jarrahi et al. (2023) argue that AI value materialises only when algorithmic capabilities are co-developed with human learning processes, through internal routinisation and outward-oriented strategic learning. In this reading, the learning function is no longer a support activity but a precondition for AI-driven transformation.

At the operational layer, systematic mappings document AI-enabled adaptive learning systems with personalised content sequencing, real-time feedback and performance analytics (Kabudi et al. 2021, Gligorea et al. 2023).

The transfer of these insights to healthcare workforce development is not automatic. Healthcare workforces - clinical and administrative - combine codified procedural knowledge with tacit, relational and emotional competencies acquired through practice and mentorship. Clinical staff exemplify this duality most acutely, but it extends to administrative and management roles, where digital literacy, data governance and change-management capacity are increasingly tacit and contextual. Recent scoping evidence on health service management workforce capacity confirms that digital health and informatics are reshaping the competencies expected of administrative cadres (Brommeyer et al. 2022), while AI is transforming the role of health information management professionals at the boundary between clinical and administrative work (Stanfill & Marc 2019).

2.3 Privacy, trust and human-centric AI in HR

The integration of AI into HR processes brings its own tensions. People analytics has matured as a research field with explicit value propositions across the employment cycle (Tursunbayeva et al. 2018); its dark sides - surveillance concerns, erosion of employee trust - have been systematised with equal attention (Giermindl et al. 2021). Practitioner-oriented work highlights transparency, privacy and accountability as structural conditions for legitimacy (Yanamala 2024).

A parallel debate frames AI and human judgement as augmentation rather than automation: Raisch & Krakowski (2021) articulate the automation–augmentation paradox, while Fügener et al. (2021) examine human-in-the-loop arrangements where the human risks becoming a downstream executor. AI design for HR must therefore protect human judgement, the relational texture of workplace learning, and employee agency over their data.

These three layers - organisational learning capability, AI-driven reskilling, and the tension between trust and algorithmic HR - justify the three-way intersection occupied by our framework.

3 Related Work

The contribution of this paper sits at the intersection of three streams that have so far remained largely disjoint: federated learning in healthcare, privacy-preserving analytics with a focus on human-resource data, and organisational learning theory engaging with artificial intelligence in competency development. The subsections below review each stream and prepare the positioning of the framework.

3.1 Federated learning in healthcare

Federated learning emerged as a distributed training paradigm in which participants collaboratively build a shared model while keeping data local (McMahan et al. 2016), with subsequent work systematising open challenges around communication cost, heterogeneity and privacy (Li et al. 2019).

In healthcare, cross-institutional model training has been framed as a response to the privacy and regulatory constraints that fragment clinical data (Rieke et al. 2020). Surveys have mapped clinical applications and clarified architectural choices for heterogeneous settings (Chaddad et al. 2024); recent reviews integrate federated learning with privacy-preserving techniques and IoT infrastructures (Abbas et al. 2024); and personalised variants address the non-IID data of multi-hospital networks (Tan et al. 2021).

Two scope limits matter here: federated learning has predominantly addressed clinical rather than workforce data, and contributions specifically targeting competency development in healthcare organisations are scarce.

3.2 Privacy-preserving HR analytics

A parallel stream investigates analytics on human-resource data. The scoping review by Tursunbayeva et al. (2018) clarifies the conceptual boundaries of people analytics, while Giermindl et al. (2021) survey its dark sides - surveillance, erosion of trust - and argue that technical adequacy alone does not warrant legitimacy.

The intersection of federated learning with HR analytics is remarkably under-developed: recent practitioner-oriented work discusses transparency and accountability in AI-enhanced HR processes (Yanamala 2024), and a consolidated governance framework for federated learning has been articulated (Eden et al. 2025). A very recent contribution applies federated learning to a single retention-prediction task on benchmark HR data (B. 2026), but does not propose an integrated architecture and remains task-specific. None of these contributions targets workforce competency data as a framework-level concern.

3.3 Organisational learning, AI-based learning and competency development

The third stream draws on organisational learning theory and on the literature examining how AI reshapes the processes through which organisations create, retain and circulate knowledge. The reference is the knowledge-creating company of Nonaka & Takeuchi (2009), whose four modes of conversion - socialisation, externalisation, combination, internalisation - describe how tacit and explicit knowledge interact within an organisation, and which we read as a substrate liftable to inter-organisational settings when suitable infrastructures exist.

Recent work frames the human–AI relationship in knowledge management as partnership rather than substitution. Jarrahi et al. (2022) map complementary roles along the four classical KM dimensions; Jarrahi et al. (2023) develop the notion of an artificial capital operating in synergy with human capital through reciprocal learning. Böhm & Durst (2025) propose the GRAI extension of SECI, in which generative AI operates as an additional agent within the knowledge-creation spiral, legitimising an inter-organisational reading of knowledge conversion.

At the practical layer, healthcare-specific competency frameworks remain heterogeneous and non-standardised (Batt et al. 2019), while explainable AI components - particularly relevant to trust - have been systematised under the Healthcare 5.0 banner (Saraswat et al. 2022).

The three streams converge on the questions motivating our framework yet remain largely disjoint: federated learning rarely engages with organisational learning theory, organisational learning scholarship seldom discusses federated architectures, and HR analytics has not been developed at the intersection with federated learning for competency development. Positioning FedHR5.0 at this three-way intersection is the genuine novelty we claim.

4 Conceptual Framework: FedHR5.0

4.1 Rationale and overview

FedHR5.0 is a theoretical framework combining federated learning (McMahan et al. 2016, Li et al. 2019), differential privacy and transparent governance to enable privacy-preserving organisational learning in healthcare, where institutions face the twin constraints of protecting sensitive employee data and preserving human dignity in algorithmic HR decisions (Pavuluri et al. 2024, de Kok et al. 2023).

The framework addresses three intertwined challenges: supporting cross-institutional learning on workforce skills without centralising sensitive data; designing AI-based learning systems that enhance rather than replace human judgement (Raisch & Krakowski 2021, Fügener et al. 2021); embedding trust, transparency and employee participation in AI-driven HR practices (Yanamala 2024, Tursunbayeva et al. 2018).

Conceptually, FedHR5.0 reframes federated learning as infrastructure for collaborative HR analytics across health-care organisations (Rieke et al. 2020, Chaddad et al. 2024): institutions train local models on workforce data and share only model updates, while the aggregated global model powers distributed learning platforms for talent management, skill assessment and personalised training.

4.2 A five-module architecture

At the core of FedHR5.0 lies a five-module architecture that operationalises human-centric HR transformation in healthcare. Each module addresses a distinct layer of the socio-technical system - trust, learning delivery, competency assessment, ethical guardrails, and inter-organisational knowledge exchange - and interacts with the others through continuous feedback (Figure 1).

Trust-Based Architecture. The first module establishes the conditions for trust in algorithmic HR decisions. It combines explainable AI components (Saraswat et al. 2022), auditable decision trails and participatory design practices that involve workers in system configuration. Privacy guarantees are communicated to employees not only as technical features but as intelligible commitments over their own data. Governance mechanisms follow the taxonomy of Eden et al. (2025) - procedural, relational and structural elements - to make accountability visible across the federation.

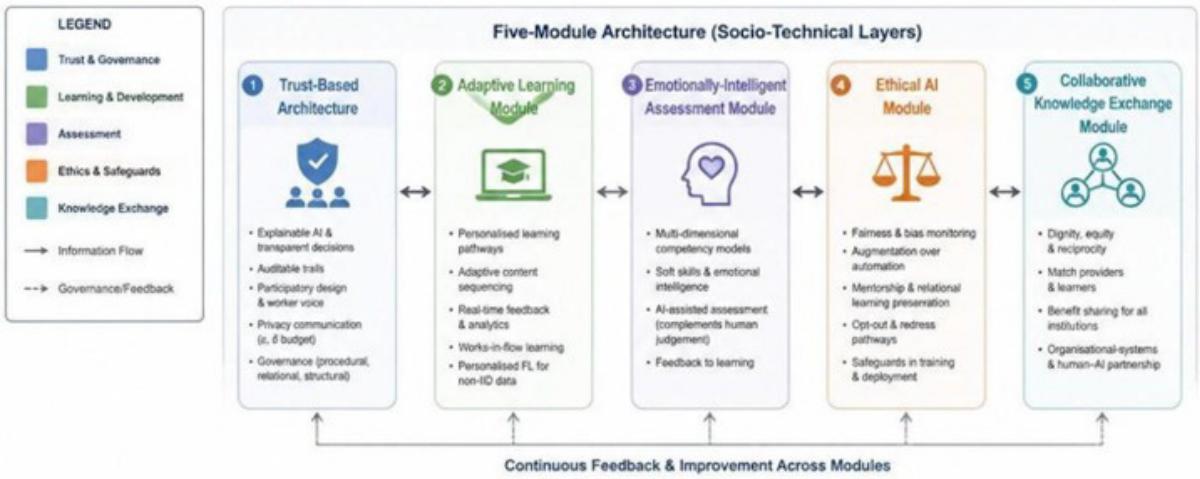

Figure 1: The FedHR5.0 five-module architecture across socio-technical layers, with bidirectional feedback and improvement loops between modules

Adaptive Learning Module. The second module delivers AI-driven personalised learning pathways. It builds on systematic evidence on adaptive learning in AI-enabled educational settings (Kabudi et al. 2021, Glig-orea et al. 2023) and on personalised federated techniques accommodating non-IID data across organisations (Tan et al. 2021). The module provides real-time feedback, adaptive content sequencing and performance analytics embedded in the flow of daily work, supporting continuous learning across heterogeneous clinical environments.

Emotionally-Intelligent Assessment Module. The third module extends competency models beyond cognitive and technical dimensions. It incorporates soft skills, emotional intelligence and relational capabilities into the assessment framework, recognising the centrality of tacit knowledge in healthcare practice (Hoge et al. 2005). The module is informed by recent evidence on AI-assisted evaluation of soft skills (Gafni et al. 2024).

Assessment complements rather than replaces peer and supervisor judgement, and feeds signals back into the adaptive learning module.

Ethical AI Module. The fourth module focuses on ethical guardrails. It embeds fairness constraints into recruitment, performance management and development recommendations; monitors algorithmic bias and deskilling dynamics (Pavuluri et al. 2024, Giermindl et al. 2021); and preserves mentorship and relational learning as core elements of professional development. The design follows the augmentation-over-automation orientation (Raisch & Krakowski 2021): AI extends rather than substitutes human judgement and peer learning. Safeguards are built into both the training pipeline and the deployment layer, including mentorship preservation indicators and opt-out pathways.

Collaborative Knowledge Exchange Module. The fifth module governs the exchange of knowledge across institutions. It prioritises dignity, equity and reciprocity in matching knowledge providers and learners, drawing on organisational-systems approaches to cultural competence (McCalman et al. 2017) and on the human–AI partnership view of knowledge management (Jarrahi et al. 2023). The module also addresses a risk identified in governance reviews of federated learning (Eden et al. 2025): smaller or less-resourced institutions must retain meaningful access to the federated signal, rather than contributing data without benefiting from aggregated insights.

4.3 Extending the SECI Model to Distributed Privacy-Preserving Contexts

From a knowledge management standpoint, FedHR5.0 extends the SECI model (Nonaka & Takeuchi 2009) to a distributed, privacy-preserving setting: the four modes of conversion - originally intra-organisational - are lifted to an inter-organisational space, with local models carrying externalised and combined knowledge sharable without exposing individual-level data. This is aligned with the GRAI logic of Böhm & Durst (2025), in which generative AI operates as an additional agent in the knowledge-creation spiral; differential privacy formalises what leaves each organisation, while federated aggregation re-injects refined knowledge.

5 Methodology

5.1 A design science research approach

We frame the construction of FedHR5.0 within the Design Science Research tradition, following the iterative procedure of Peffers et al. (2007). Within the typology of DSR contributions (Gregor & Hevner 2013), FedHR5.0 is positioned as an *improvement*: the underlying problem is known, but the combined architecture is new. Documentation of design choices follows Brocke et al. (2020) on cumulative design knowledge.

5.2 Formalisation: federated learning with differential privacy

At the technical core, FedHR5.0 relies on standard federated averaging (McMahan et al. 2016). Each healthcare organisation k maintains a local dataset D_k of workforce data; at round t, local models ϑ^t are updated via stochastic gradient descent on D_k and aggregated into a global model k

$$\theta^{t+1} = \sum_k \frac{n_k}{n} \theta_k^t, \qquad n_k = |D_k|, \quad n = \sum_k n_k .$$

The protocol inherits the open challenges systematised in Li et al. (2019), and adopts personalised variants (Tan et al. 2021) to accommodate non-IID distributions across institutions. Figure 2 illustrates the full pipeline, including the differential privacy step described below.

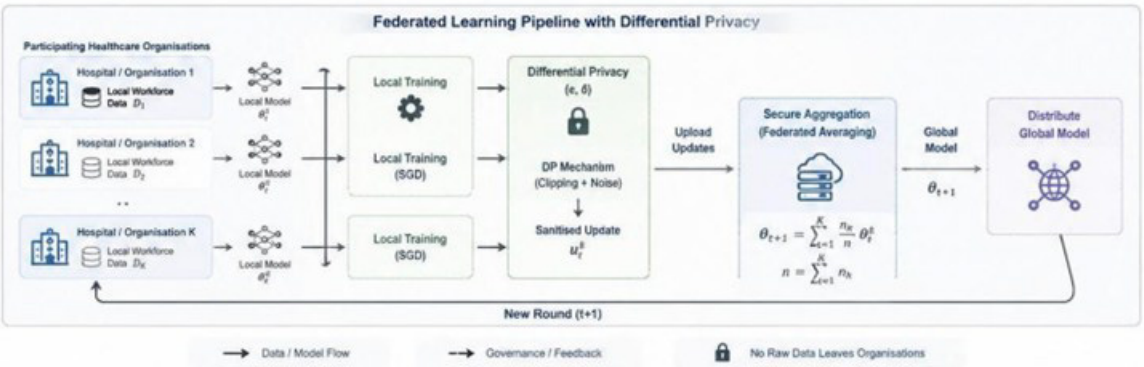

Figure 2: Federated learning pipeline with (ε, δ)-differential privacy: local training on each organisation's workforce data; updates sanitised via clipping and noise; federated averaging; global model broadcast back. No raw data leaves any organisation.

On top of federated aggregation, FedHR5.0 applies (*ε, δ*)-differential privacy to the local model updates before they leave the organisation, in line with the protocols documented in recent reviews of privacy-preserving FL in healthcare (Abbas et al. 2024).

The choice to apply differential privacy *within* each organisation, rather than relying on federated learning alone, deserves explicit justification. Federated learning already prevents raw personal data from crossing organisational boundaries, but local model updates still encode statistical information about individual employees and are potentially vulnerable to inference attacks. Differential privacy provides a formal, quantifiable guarantee on the information any single update can reveal, and makes this guarantee communicable to the workforce as an explicit privacy budget. In FedHR5.0, therefore, differential privacy is not a redundant technical layer, but a *trust-building instrument*: it converts an implicit protection ("your data does not leave the hospital") into an auditable commitment ("the information derived from your data is bounded by *ε, δ*"). This positioning is what allows the trust-based module of the framework (Section 4.2.1) to engage the worker as a participating agent rather than a residual beneficiary.

5.3 Rigour and iteration

We pursue rigour along three axes - utility, feasibility, novelty - per Gregor & Hevner (2013). Utility and feasibility are addressed conceptually here; novelty is argued via the three-way intersection of Section 3. Empirical validation is scoped to Section 7 as a structured pathway.

6 Discussion and Implications

6.1 Theoretical positioning and analytical stance

Our analysis suggests that FedHR5.0 contributes at the three-way intersection of federated learning in healthcare, privacy-preserving HR analytics and human-centric organisational learning, qualifying as an *improvement* contribution (Gregor & Hevner 2013). The framework extends the SECI dynamics of Nonaka & Takeuchi (2009) toward a GRAI-style cycle in which tacit–explicit transitions are mediated by an explicit privacy budget (Böhm & Durst 2025).

6.2 Implications for workforce transformation

The framework bears tangible implications for workforce transformation. First, competency development can be redesigned around multi-dimensional signals: the emotionally-intelligent assessment module (Section 4.2.3) invites HR functions to complement output-based metrics with soft skills, tacit knowledge and emotional intelligence, countering one-dimensional risks of algorithmic HR (Giermindl et al. 2021). Second, personalisation of learning pathways via the adaptive learning module can reasonably be expected to strengthen retention by tying everyday learning practices to employee empowerment and engagement. Third, the framework repositions HR from support activity to strategic driver of human–AI collaboration (Jarrahi et al. 2023), with line managers and CHROs as primary design stakeholders rather than downstream recipients. Fourth, relational learning practices - mentorship, peer learning, communities of practice - enter the architecture as a structural design requirement (Raisch & Krakowski 2021).

6.3 Implementation conditions, readiness, and trade-offs

The framework's actionability rests on a set of organisational preconditions. Drawing on the five attributes of mature learning capabilities (de Kok et al. 2023) - leadership, culture, team development, change management and customer orientation - a federated deployment can be characterised by an implementation checklist that translates each attribute into a concrete precondition, from visible leadership sponsorship to demonstrable change-management capacity. Organisational readiness can be observed along four measurable factors: maturity of data governance, absence of internal information silos, availability of edge or cloud computational resources, and alignment with GDPR and participatory design practices (Pavuluri et al. 2024). Alongside readiness, an explicit register of risks and trade-offs keeps design choices auditable: technically, the tension between privacy budget and global model utility, and between personalisation and equity; organisationally, inter-institutional coordination costs, residual information leakage through model updates, and the risk of eroding worker dignity when transparency is nominal (Fügener et al. 2021). Sustainability of change is itself an observable variable (Hovlid et al. 2012); governance arrangements grounded in the taxonomy of Eden et al. (2025) provide the instrumentation to keep these trade-offs visible.

6.4 Methodological implications and research agenda

These choices raise open methodological questions for DSR in HR contexts: evaluation criteria that reconcile technical privacy budgets with organisational trust metrics, and longitudinal designs to verify augmentation claims over time. Section 7 outlines a concrete validation pathway.

7 Limitations and Future Work

This paper presents a conceptual framework; empirical validation is the principal limitation of the present contribution. Rather than deferring evaluation to an open horizon, we outline a concrete pathway in line with the reviewers' guidance.

Setting. We propose a multi-hospital network in Italy as the primary empirical setting, with an initial cohort of three to five medium-sized institutions (500–1,500 employees each) engaged in workforce competency development. Geographic and dimensional heterogeneity across the network is an asset rather than a confound: it stresses the non-IID robustness that the framework is designed to address.

Evaluation criteria. We propose four operationally measurable axes: (i) global-model accuracy on the workforce-analytics tasks the framework enables, evaluated through standard multi-task machine-learning metrics; (ii) effective privacy budget, verified empirically against the declared (ε, δ) targets under realistic training loads; (iii) an organisational readiness score grounded in the attributes identified by de Kok et al. (2023), measured ex-ante and ex-post via a structured instrument; (iv) a worker participation index combining opt-in rate, consultation of the privacy budget, and engagement with participatory design moments (Easterling et al. 2021).

Methodological approach. A three-phase pilot with iterative DSR cycles (Peffers et al. 2007): (i) readiness assessment and pre-deployment (preconditions verification, federated infrastructure setup, workforce sensitisation); (ii) deployment and observation over six to twelve months on a sub-network, with parallel technical and organisational data collection; (iii) evaluation and design refinement for the next iteration.

8 Conclusions

FedHR5.0 is a conceptual framework for privacy-preserving organisational learning and workforce competency development in healthcare, designed to operate at the three-way intersection of federated learning, human-centric HR analytics and organisational learning theory. Its distinctive contribution lies in the integration of a five-module architecture - trust-based, adaptive learning, emotionally-intelligent assessment, ethical AI, and collaborative knowledge exchange - over a federated-differential-privacy substrate, oriented to clinical and administrative cadres alike, and rooted in an updated reading of the SECI model for the age of generative artificial intelligence (Nonaka & Takeuchi 2009, Böhm & Durst 2025).

Methodologically, the artefact is positioned as an *improvement*-type contribution within the Design Science Research tradition (Gregor & Hevner 2013, Peffers et al. 2007). Empirical validation is scoped as future work and given a concrete pathway in Section 7, with a multi-hospital pilot, four operationally measurable evaluation axes, and a three-phase iterative protocol.

Beyond the immediate artefact, FedHR5.0 invites the research community to accumulate design knowledge at this emerging intersection, in line with the spirit of cumulative design research (Brocke et al. 2020).

9 Ethics declaration

This paper presents a conceptual framework and does not report original empirical research involving human participants, identifiable personal data, or animal subjects. Consequently, no ethical clearance was required for the research described herein.

10 AI declaration

AI-based tools were used selectively during the preparation of this manuscript to support the organisation of the bibliographic synthesis and the preliminary drafting of sections of the text. INSPIRE PM as a Human–AI Hybrid Knowledge Ecosystem for Sustainable Project-Based Organizations

Antonio Bassi
Association Project Management Switzerland

Abstract

Project-based organizations are increasingly exposed to a combination of uncertainty, accelerated technological change, and rising sustainability expectations. In this context, many organizations are investing in digital platforms, analytics capabilities, and artificial intelligence applications, yet they often struggle to transform dispersed project information into reliable and actionable knowledge. The spread of generative AI has intensified this tension: while organizations can now generate answers, summaries, and recommendations at scale, they frequently lack adequate governance mechanisms for knowledge provenance, accountability, privacy, and ethical use. Starting from the INSPIRE PM framework and its broader grounding in Project Management Evolutive (PME), this paper argues that sustainable project performance depends on the ability to build Human–AI Hybrid Knowledge Ecosystems (HA-HKE), that is, socio-technical configurations in which human actors and AI systems collaboratively generate, validate, circulate, and apply project knowledge under explicit governance rules. The paper develops a conceptual architecture for such ecosystems, identifies the key knowledge assets and flows required across the project lifecycle, and proposes a design-oriented research agenda centered on three artifacts: a hybrid knowledge ecosystem blueprint, a decision intelligence loop, and a lightweight governance checklist for responsible GenAI use in project contexts. The paper contributes conceptually by reframing project management as a knowledge ecosystem challenge, methodologically by outlining a design science approach with multiple-case evaluation, and managerially by offering a practical pathway for PMOs and project leaders seeking to combine AI-enabled decision support with sustainability, traceability, and human accountability.

Keywords: Human–AI hybrid knowledge; Knowledge ecosystems; Sustainable project management; Decision Intelligence; Project Management Evolutive (PME)

Paper Type: Academic Research Paper

1 Introduction

Project-based organizations are operating in an environment that is both richer in data and poorer in coherence. On the one hand, projects now generate an unprecedented volume of digital traces: schedules, reports, risk registers, chats, forecasts, dashboards, lessons learned, sustainability metrics, decisions, approvals, exceptions, and stakeholder feedback. On the other hand, the ability to turn this fragmented informational landscape into trustworthy knowledge remains limited. Many organizations still rely on disconnected repositories, isolated tools, weak knowledge governance, and ad hoc interpretive practices. As a consequence, project teams often have access to more information than ever before, but not necessarily to better judgment, better alignment, or better decisions.

This challenge is becoming more acute with the rapid diffusion of generative AI. The problem is no longer access to answers, but the governance of the answers that are produced. In project environments, GenAI can summarize documents, generate reports, suggest actions, classify risks, or support scenario analysis. Yet the expansion of AI-supported output does not automatically imply an increase in knowledge quality. Without adequate controls, AI can accelerate ambiguity, produce plausible but weakly grounded recommendations, obscure provenance, and dilute accountability. What appears as “intelligent support” can easily become a new layer of opacity if organizations do not define who validates what, how outputs are traced, how privacy is protected, and where human responsibility remains non-transferable.

The starting point of this paper is that the central issue is not merely one of technological adoption. Rather, it concerns the design of a socio-technical and organizational environment in which knowledge can be created, validated, and reused in ways that improve project performance while remaining aligned with sustainability objectives. In this regard, the INSPIRE PM framework offers an especially useful lens because it is conceived not as a rigid methodology but as a flexible architecture capable of integrating technology, sustainability, predictive analytics, innovation, responsiveness, and efficiency into project management practice. The broader conceptual grounding in Project Management Evolutive (PME) further reinforces this view by presenting projects as dynamic ecosystems where learning, adaptability, data-informed decision-making, and integrated sustainability are foundational.

Within this perspective, the paper develops the concept of **Human–AI Hybrid Knowledge Ecosystems (HA-HKE)** for project-based organizations. The argument advanced here is that sustainable project performance depends on the organizational capability to orchestrate knowledge assets across a hybrid ecosystem in which human actors and AI systems collaborate under explicit governance rules. This requires moving beyond a "tool adoption" narrative toward a genuine ecosystem design problem: organizations must determine which knowledge matters, where it is generated, how it is validated, how it circulates, who is accountable for it, and how it is linked to sustainability-related decisions.

The paper is guided by three research questions already identified in the extended abstract:

- ***RQ1.*** *What knowledge assets and knowledge flows are essential to enable effective human–AI collaboration across the project lifecycle in a sustainable organization?*
- ***RQ2.*** *Which governance mechanisms are needed to ensure trustworthy AI-augmented project knowledge without undermining human accountability?*
- ***RQ3.*** *How can organizations measure the value of hybrid knowledge ecosystems in terms of project performance, resilience, and ESG outcomes?*

The remainder of the paper addresses these questions by first clarifying the theoretical positioning of the study, then articulating the concept of hybrid knowledge ecosystems, and finally proposing a design-oriented research architecture capable of translating the conceptual model into practical organizational artifacts.

2 From Project Knowledge to Hybrid Knowledge Ecosystems

Project management has always been deeply knowledge-intensive, even when this dimension was not made explicit. Projects are not executed only through tasks and deliverables, but through interpretation, judgment, coordination, negotiation, prioritization, and learning. The formal side of project knowledge is usually visible in plans, schedules, risk logs, requirements, budgets, and reports. The informal side is embodied in experience, tacit expertise, decision rationales, negotiated trade-offs, and local interpretations of uncertainty. In practice, project outcomes depend on the quality of the interaction between these two forms of knowledge more than on the mere existence of documentation.

The problem is that traditional approaches to project knowledge management have often privileged repositories over ecosystems. Knowledge has frequently been treated as something to be stored, archived, and retrieved, rather than as something continuously produced, interpreted, and transformed throughout the lifecycle of the project. The logic of "lessons learned at closure" is useful, but insufficient in environments where decisions must be made rapidly and where relevant knowledge emerges during planning, execution, escalation, exception handling, stakeholder interaction, and post-decision reflection. The spread of AI does not eliminate this challenge; it deepens it. By introducing digital agents capable of generating interpretations and suggestions, AI changes not only the speed of knowledge production but also the epistemic structure of project work.

It is here that the idea of a **Human–AI Hybrid Knowledge Ecosystem** becomes analytically useful. A hybrid knowledge ecosystem may be understood as a socio-technical arrangement in which knowledge assets are created, curated, circulated, validated, and applied through structured interactions among human actors, AI systems, project artifacts, governance rules, and sustainability criteria. The ecosystem perspective shifts the focus away from individual tools and toward the architecture of relationships among actors, assets, decisions, and controls. It foregrounds interdependence, traceability, and learning rather than isolated efficiency gains.

This approach is especially consistent with the INSPIRE PM view. The framework emphasizes that project environments must integrate multiple dimensions that are too often treated separately: innovation, sustainability, responsiveness, predictive capability, efficiency, and the intelligent use of technology. The same reasoning underlies PME, which frames projects as adaptive ecosystems where change is constant and where knowledge is continuously produced through feedback loops, interactions, and evolving constraints. In such a setting, knowledge cannot be reduced to documentation, nor AI reduced to automation. Instead, both must be treated as interdependent components of a wider knowledge ecology.

The significance of this shift is especially visible when sustainability is considered. Sustainable project management is not simply about adding ESG reporting to project closure. It is about embedding environmental, social, and governance considerations directly into decision parameters, planning choices, execution trade-offs, and accountability structures. If sustainability is to influence project outcomes meaningfully, it must be integrated into the knowledge ecosystem itself. It must appear in the criteria by which options are compared, in the indicators that are monitored, in the trade-offs that are documented, and in the decision rationales that are preserved.

3. INSPIRE PM as an Organizing Architecture for Human–AI Collaboration

The conceptual contribution of this paper lies in proposing INSPIRE PM as an organizing architecture for hybrid knowledge ecosystems in project-based organizations. This proposal does not imply that INSPIRE PM should function as a universal procedure. Rather, it suggests that the framework offers a robust conceptual scaffolding for aligning project knowledge, AI-enabled support, governance, and sustainability.

In the context of this study, INSPIRE PM performs at least three functions. First, it provides a way to organize the multiple dimensions that shape project knowledge in hybrid contexts: technology, sustainability, analytics, adaptability, efficiency, and innovation. Second, it supports the move from fragmented tool adoption to ecosystem design, that is, from asking "Which AI application should we use?" to asking "How should knowledge be produced, validated, and governed across the project lifecycle?" Third, it helps connect operational project decisions to broader organizational goals, including ESG commitments, resilience, and learning capacity.

This is particularly important because the adoption of AI in project environments often remains shallow. Organizations may introduce copilots, dashboards, or predictive models without rethinking the institutional logic within which such tools operate. They may generate content faster but still fail to establish who owns the knowledge, who validates it, who is accountable for decisions based on it, and how AI-supported outputs align with sustainability criteria. INSPIRE PM helps address this problem by situating technology within a broader managerial and governance logic rather than treating it as a standalone solution.

The human role remains central in this architecture. AI may support forecasting, classification, summarization, pattern recognition, or option generation, but the framing of the problem, the interpretation of context, the weighting of sustainability trade-offs, and the assumption of accountability remain human responsibilities. This principle is critical not only for ethical reasons but also for managerial ones. Projects are inherently contextual and relational. They involve ambiguity, competing stakeholder interests, constraints that change over time, and outcomes that cannot always be reduced to formal optimization. For this reason, hybrid intelligence in project management should not be understood as a substitution logic, but as an augmentation logic under governance.

4 Essential Knowledge Assets and Knowledge Flows Across the Project Lifecycle

The first research question concerns the knowledge assets and flows required to enable effective human–AI collaboration in sustainable project settings. Answering this question requires moving beyond a narrow focus on data and considering the broader ecology of project knowledge.

At minimum, a hybrid project knowledge ecosystem includes several categories of assets. The first category consists of **structured project artifacts**, such as schedules, requirements, work packages, budgets, change logs, and risk registers. These are the traditional backbone of project control and coordination. The second category includes **decision evidence**, such as assumptions, trade-off rationales, approvals, exceptions, and escalation records. These are often underdeveloped in practice, yet they are essential for accountability, learning, and auditability. The third category includes **contextual and tacit knowledge**, such as expert interpretation, stakeholder expectations, organizational memory, and situational judgment. The fourth category includes **ESG-related knowledge**, such as footprint indicators, compliance constraints, social impact considerations, and sustainability targets. Finally, in AI-enabled settings, there is also a fifth category: **AI-generated artifacts**, including summaries, predictions, recommendations, and classifications.

The critical issue is not only the existence of these assets, but the way they move across the lifecycle. During project initiation, knowledge is strongly strategic: business rationale, stakeholder expectations, sustainability commitments, and problem framing dominate. During planning, the ecosystem structures requirements, design assumptions, scenarios, success criteria, and governance choices. During execution and monitoring, the emphasis shifts toward operational signals, variance analysis, issue escalation, predictive warnings, exception handling, and real-time adaptation. During closure, the ecosystem should consolidate realized outcomes, assess whether sustainability targets were achieved, document decision rationales, and capture reusable learning for future initiatives.

AI can intervene at all these stages, but not in the same way. In initiation, AI may support horizon scanning, stakeholder pattern analysis, or synthesis of prior cases. In planning, it may assist in scenario comparison, requirements classification, or the drafting of structured documentation. In execution and monitoring, it may support anomaly detection, predictive alerts, and summarization of high-volume project communication. In closure, it may accelerate the synthesis of evidence and lessons. Yet the value of these interventions depends on whether the surrounding knowledge ecosystem can absorb them responsibly. AI output becomes useful only when linked to provenance, validation, decision rights, and feedback loops.

This observation also suggests a criterion for knowledge quality in hybrid ecosystems. Knowledge quality is not merely a function of correctness or completeness. In project contexts, it must also include timeliness, traceability, actionability, contextual relevance, and alignment with sustainability objectives. A technically correct output that cannot be trusted, traced, or connected to accountable decision-making is of limited value in a project-based organization.

5 Governance Mechanisms for Trustworthy AI-Augmented Project Knowledge

The second research question addresses governance. This is arguably the most critical dimension, because hybrid knowledge ecosystems can produce value only if they are trusted, and they can be trusted only if governance is explicit.

The first governance mechanism concerns **roles and decision rights**. Hybrid project environments require clarity regarding who owns each category of knowledge asset, who validates AI-generated content, which outputs remain advisory, and which decisions require mandatory human sign-off. If these boundaries are not explicit, organizations risk creating pseudo-automation in which AI-generated content silently acquires authority without corresponding accountability. The use of AI in project environments should therefore be bounded by role definitions that make human accountability visible rather than diffuse it.

A second governance mechanism concerns **provenance**. In project work, decisions often need to be justified ex post, whether for governance purposes, compliance reasons, stakeholder challenges, or organizational learning. When AI contributes to reports, forecasts, or recommendations, actors must be able to identify the origin of the underlying information, the nature of the model's contribution, and the extent to which human interpretation shaped the final output. Provenance is not simply a technical issue; it is a condition of organizational trust.

A third governance dimension concerns **privacy and ethical safeguards**. The abstract explicitly highlights privacy, bias awareness, and ethical constraints as central concerns in AI-enabled project work. This is especially important when project knowledge includes stakeholder data, sensitive commercial information, or ESG-relevant indicators that may have reputational and regulatory implications. Responsible governance requires that organizations distinguish clearly between permissible and impermissible use of data, define review thresholds for sensitive outputs, and maintain safeguards against automation bias and opaque decision-making.

A fourth mechanism concerns **human-in-the-loop review**. The phrase is often used loosely, but in the present framework it should be interpreted precisely. Human review is not satisfied merely because a person receives an AI output. It requires that a human actor has both the authority and the capability to assess the relevance, credibility, and implications of that output before it influences accountable project decisions. This includes the possibility of rejecting, revising, or re-framing the AI-supported suggestion. In other words, the human role must remain epistemically substantive, not ceremonially residual.

For these reasons, the governance of hybrid knowledge ecosystems should be light enough to remain usable, but explicit enough to remain meaningful. Over-bureaucratization would discourage adoption, while under-governance would undermine trust. The governance checklist proposed in this paper is intended precisely as a middle path: a practical mechanism for embedding provenance, accountability, privacy, and bias awareness into project knowledge practices without immobilizing the system.

6 Design Science Research and the Development of Actionable Artifacts

Methodologically, the study adopts a **Design Science Research** approach complemented by multiple-case evaluation, as anticipated in the abstract. This is appropriate because the objective is not only interpretive but also constructive: the research seeks to generate artifacts that can help organizations operationalize the concept of human–AI hybrid knowledge ecosystems in project settings.

The first artifact is an **INSPIRE-based Hybrid Knowledge Ecosystem Blueprint**. Its function is to make visible the architecture of the ecosystem: what knowledge exists, where it is produced, how it circulates, which actors validate it, how AI can intervene, and which controls apply. In practice, such a blueprint would help PMOs and project leaders move beyond vague digital ambition toward a structured operating model for project knowledge.

The second artifact is a **Decision Intelligence Loop** connecting predictive analytics, human judgment, decision logging, and feedback. The purpose of this artifact is to ensure that AI-supported pattern recognition and forecasting do not remain disconnected from actual managerial learning. Prediction alone does not create intelligence. Intelligence emerges when predictive signals are interpreted, linked to explicit criteria, translated into accountable decisions, and then compared with realized outcomes. The loop therefore turns project decision-making into a more traceable and learning-oriented process.

The third artifact is a **lightweight governance checklist for responsible GenAI use in project contexts**. This checklist is intended to address practical concerns such as provenance, privacy safeguards, bias awareness, and human review obligations. Its usefulness lies precisely in its minimalism: many organizations do not fail because they lack sophisticated governance theory, but because they lack operationally usable controls.

The evaluation strategy will involve two to three organizational cases in project-intensive contexts, combining interviews with PMO actors, project managers, data/AI roles, and sustainability leads, document analysis of project artifacts and decision logs, and validation workshops focused on feasibility, usefulness, and organizational fit. This methodological design is particularly suitable because hybrid knowledge ecosystems are inherently context-sensitive. Their form and value are likely to vary according to organizational maturity, regulatory exposure, digital capabilities, and sustainability priorities.

7 Measuring the Value of Hybrid Knowledge Ecosystems

The third research question concerns value measurement. If human–AI hybrid knowledge ecosystems are to be taken seriously as an organizational capability, their value must be assessed in ways that go beyond generic claims about efficiency.

At the level of **project performance**, relevant indicators may include decision cycle time, rework caused by poor information quality, speed of issue resolution, change-request quality, forecast reliability, stakeholder response time, and the quality of project coordination across functions. These indicators make visible whether the ecosystem improves the practical performance of project work rather than merely increasing the volume of digital activity.

At the level of **organizational resilience**, value should be assessed in terms of the ecosystem's capacity to sustain decision quality under uncertainty, adapt when assumptions change, preserve continuity when people or systems shift, and transfer learning from one project context to another. Resilience is especially relevant in project-based organizations because uncertainty is not episodic but structural. A hybrid ecosystem should therefore not only improve routine execution but also strengthen adaptive capacity.

At the level of **ESG outcomes**, the ecosystem should be evaluated according to its ability to make sustainability visible in decision processes. This implies not merely reporting environmental or social indicators after the fact, but incorporating them into the criteria used for planning, trade-off analysis, exception handling, and closure assessment. If a project claims to be sustainable but its ecosystem does not connect decisions to ESG evidence, then sustainability remains rhetorical rather than operational. INSPIRE PM is particularly valuable here because it explicitly positions sustainability as an integrated dimension of project practice rather than an external reporting add-on.

One important implication follows from this: the value of HA-HKE cannot be reduced to cost reduction or speed. It must be measured in a more balanced way, including trustworthiness, learning, traceability, adaptability, and sustainability alignment. This broader value logic is essential if AI is to contribute to genuinely sustainable project management rather than to short-term operational optimization alone.

8 Discussion

The framework proposed in this paper makes three conceptual moves that are significant for both research and practice. First, it reframes project management as a **knowledge ecosystem challenge** rather than only as a matter of methods, tools, or lifecycle control. This shift is necessary because the central problem in contemporary project environments is no longer information scarcity but knowledge fragmentation. Second, it positions AI as a participant in a socio-technical system rather than as an autonomous solution. This prevents the common mistake of interpreting AI outputs as self-validating. Third, it embeds sustainability directly into project knowledge architecture, thereby linking ESG concerns to daily project decisions and not only to post hoc evaluation.

This has important implications for PMOs. In a hybrid ecosystem logic, PMOs can no longer be understood only as custodians of templates, methods, or reporting cycles. They may increasingly need to act as stewards of knowledge architecture, responsible for designing how knowledge is structured, validated, and learned from across project portfolios. This also changes the capability profile required of project leaders. In addition to classical planning and coordination skills, hybrid project environments demand higher competence in evidence validation, AI literacy, model skepticism, knowledge traceability, and sustainability-aware decision framing.

At the same time, this perspective should not be romanticized. The presence of AI in the project environment does not guarantee better outcomes. Poorly designed ecosystems may generate new forms of opacity, shallow automation, misplaced trust, and compliance risk. The concept of HA-HKE is therefore valuable not because it assumes harmony between humans and AI, but because it foregrounds the tensions that must be governed:

speed versus traceability, automation versus accountability, scalability versus privacy, and predictive assistance versus contextual judgment.

9 Contributions, Limitations, and Future Research

The expected contributions of the study are threefold, in line with the extended abstract. First, the paper contributes **conceptually** by reframing project management as an intelligent knowledge ecosystem problem and by integrating socio-technical and sustainability dimensions under the INSPIRE PM architecture. Second, it contributes **methodologically** by proposing a design-oriented research path that translates abstract principles into practical artifacts. Third, it contributes **managerially** by offering PMOs and project leaders a concrete way to think about AI adoption not as isolated tooling, but as an issue of governance, learning, and organizational design.

The current limitation is that the paper remains, at this stage, primarily conceptual and design-oriented. The multiple-case evaluation planned in the abstract is therefore essential for testing whether the proposed artifacts are not only theoretically coherent but also operationally feasible and organizationally useful. Context will matter greatly: hybrid knowledge ecosystems are unlikely to take the same form in highly regulated sectors, sustainability-intensive settings, or digitally immature organizations.

Future research should therefore examine how different sectors, governance maturities, and sustainability priorities shape ecosystem adoption. It should also investigate which combinations of knowledge assets and AI capabilities are most valuable at different project lifecycle stages, how decision logs can effectively incorporate ESG trade-offs, and how organizations can avoid over-dependence on AI-generated recommendations while still benefiting from their analytical power.

10 Conclusion

This paper has argued that the challenge of AI in project-based organizations is not primarily one of access to tools, but one of knowledge ecosystem design. Building on INSPIRE PM and PME, it has proposed the concept of **Human–AI Hybrid Knowledge Ecosystems** as a way of understanding how project knowledge can be created, governed, and applied in organizations that seek both performance and sustainability.

The central claim is that sustainable project outcomes will increasingly depend on the ability to build ecosystems that are trustworthy, auditable, learning-oriented, and explicitly governed. In such ecosystems, AI may accelerate option generation, pattern detection, and predictive support, but humans remain responsible for framing problems, setting decision criteria, validating evidence, and taking accountable decisions. This is not a residual role; it is the condition under which hybrid intelligence remains organizationally legitimate.

INSPIRE PM offers a promising architecture for this transition because it makes it possible to connect innovation, technology, sustainability, responsiveness, predictive capability, and efficiency within a single project management logic. The next step is empirical validation through case-based evaluation, so that the conceptual model and the proposed design artifacts can be refined into deployable governance and operating models for real project-based organizations.

11 Ethics Declaration

This research did not require formal ethical clearance, as it is a conceptual and theoretical study involving no human participants, personal data collection, or processing of sensitive information.

12 AI Declaration

Generative AI tools were used as linguistic and stylistic support in preparing the paper. AI was not used to generate data, findings, or conclusions. The author reviewed and approved the final content and retains full responsibility for it.

Abstract

In the face of intensifying environmental challenges and rapid digital transformation, startups are increasingly expected to pursue sustainable development while navigating severe resource constraints and the inherent liability of newness typical of emerging ventures. Although existing literature acknowledges the critical role of Green Knowledge Management (GKM) in driving corporate sustainability, significant theoretical gaps remain. Prior studies frequently conceptualize GKM as a homogeneous construct, thereby masking the complex operational realities of its underlying dimensions. Furthermore, while Artificial Intelligence (AI) is rapidly altering organizational learning, limited academic attention has explored how AI specifically acts as a dynamic catalyst to enhance green knowledge processes within the entrepreneurial context. To address these critical omissions, this conceptual paper develops a comprehensive framework that elucidates how AI-driven GKM processes positively influence Sustainable Performance (SP) in startups. Drawing upon the Resource-Based View, the Knowledge-Based View, and the Dynamic Capabilities View, the proposed framework models GKM as a multidimensional construct comprising five distinct dimensions: green knowledge acquisition, storage, sharing, application, and creation. The model posits that robust GKM routines function as the core operational infrastructure enabling startups to translate environmental awareness into sustainability outcomes, encompassing long-term economic viability, reduced ecological footprints, and enhanced social responsibility. Crucially, this paper conceptualizes AI not as a generic technological solution, but as an advanced dynamic capability. AI is theorized to positively moderate the framework by acting as a digital catalyst that strengthens the relationship between GKM and SP. By providing analytical velocity and reducing prediction costs, AI empowers startups to overcome human capital limitations, rapidly sense subtle ecological shifts, mitigate trial-and-error risks, and efficiently apply internal knowledge assets to changing market demands. Integrating sustainability, knowledge management, and digital capabilities, this research advances theoretical discourse by deconstructing GKM into specific operational routines and refining the conceptual understanding of AI's moderating role. Ultimately, this conceptual study establishes a foundation for future empirical validation and offers actionable guidance for policymakers and founders to align knowledge routines with AI investments for enduring sustainable performance.

Paper type: Academic Research Paper

1 Introduction

As global industries confront the urgent dual imperatives of digitalization and environmental sustainability, startups have emerged as vital engines of eco-innovation (Costa, 2024). However, unlike large incumbent corporations, startups operate in highly volatile environments characterized by severe resource constraints, high uncertainty, and the inherent liability of newness (Shehzad *et al.*, 2026; Sommer *et al.*, 2009). To survive and thrive amidst such turbulence, these emerging ventures must cultivate robust Knowledge Management (KM) capabilities. Traditionally, KM allows startups to systematically acquire, structure, and deploy intellectual capital to compensate for their critical lack of physical assets (Paoloni *et al.*, 2020). Yet, as the ecological mandate of this "twin transition" intensifies, general knowledge routines are no longer sufficient. Startups must evolve their learning architectures to process complex environmental data and embed ecological objectives into their core operations. Consequently, Green Knowledge Management (GKM) has emerged as a specialized and critical organizational asset, enabling startups to translate environmental awareness into tangible Sustainable Performance (SP) (Adusei, 2026; Nasir *et al.*, 2024).

Despite the acknowledged importance of KM in driving SP, the existing literature exhibits significant theoretical limitations. Primarily, prior studies often conceptualize GKM as a static, homogeneous construct. This monolithic perspective treats environmental knowledge routines as a theoretical black box, failing to capture the complex operational realities of its underlying processes. According to recent scale validations (Yu

et al., 2022), GKM is more accurately understood as a multidimensional construct comprising distinct sub-dimensions: green knowledge acquisition, storage, sharing, application, and creation. Treating these routines as a single variable obscures the specific operational bottlenecks and limits the precision of theoretical models predicting sustainable outcomes.

Furthermore, as the volume and complexity of ecological data continue to expand, traditional manual knowledge routines are becoming increasingly inadequate for startups. Artificial Intelligence (AI) has emerged as a transformative digital capability, fundamentally altering how organizations process information and generate insights (Oyekunle and Boohene, 2024). Recent scholarship explores the nexus of AI, KM, and sustainable outcomes. For instance, Al-Balushi et al. (2025) demonstrated that AI adoption significantly drives green innovation, highlighting specific knowledge practices like green knowledge sharing as critical boundary conditions. Similarly, emerging conceptual frameworks (Cai *et al.*, 2025) suggest that AI and big data analytics serve as crucial digital enablers for startups, strengthening the impact of GKM by accelerating sensing and learning processes. However, these foundational studies tend to either isolate a single facet of KM or treat GKM as an aggregated, macro-level variable. Limited academic attention has explored how AI specifically acts as a dynamic catalyst to enhance the complete, multidimensional pipeline of GKM within the entrepreneurial context. While often labeled as a generic technological solution, the literature lacks a coherent framework articulating how AI-driven capabilities specifically empower startups to accelerate their distinct routines of acquiring, storing, sharing, applying, and creating green knowledge to drive SP.

To address these critical research gaps, this study develops a comprehensive framework that elucidates how AI-driven GKM processes directly drive SP in startups. Drawing upon the Resource-Based View (RBV), the Knowledge-Based View (KBV), and the Dynamic Capabilities View (DCV), this study disaggregates GKM into its five foundational dimensions to map specific pathways of eco-innovation. The proposed model posits multidimensional GKM as the core operational mechanism for achieving sustainability outcomes, while conceptualizing AI as a potent, dynamic enabling capability that positively moderates and strengthens these knowledge-based relationships. Consequently, this paper offers three primary contributions. First, it advances KM theory by unpacking GKM into heterogeneous processes, moving beyond the monolithic approach. Second, it refines the conceptual understanding of AI by theorizing its role as a dynamic digital catalyst tailored to enhance knowledge mechanisms. Third, it provides a robust, proposition-driven theoretical foundation for future empirical research on AI-augmented knowledge processes in sustainable startups.

The remainder of this paper proceeds as follows: Section 2 establishes the theoretical background and defines the core constructs. Section 3 develops the conceptual framework and theoretical propositions. Section 4 discusses theoretical contributions and practical implications. Finally, Section 5 concludes by outlining limitations and avenues for future empirical research.

2 Theoretical Background

2.1 Theoretical foundations: integrating RBV, KBV, and DCV

To conceptualize how startups achieve sustainable outcomes in highly volatile environments, this framework integrates three foundational strategic management perspectives. The RBV (Barney, 1991) postulates that organizations achieve competitive advantages by accumulating tangible and intangible resources that are valuable, rare, inimitable, and non-substitutable. Building directly upon this resource-centric logic, the KBV (Grant, 1996) argues that in complex, high-technology environments, knowledge is the most strategically significant asset a firm can possess. In the context of the twin transition, specialized green knowledge serves as this ultimate strategic asset. Recent systematic reviews affirm that these knowledge and resource perspectives remain the dominant theoretical lenses for understanding how GKM translates into sustainable business performance (Adusei, 2026).

However, the static nature of traditional resource theories renders them insufficient for startups operating in rapidly evolving digital and ecological landscapes. To bridge this gap, the DCV (Teece, 2007) extends these perspectives by emphasizing a firm's dynamic capability to systematically sense, seize, and reconfigure internal and external competences. Through this integrated theoretical lens, this paper establishes a highly complementary dynamic: AI acts as the ultimate digital sensing mechanism providing analytical velocity, while GKM functions as the dynamic operational mechanism responsible for the actual seizing and reconfiguration of organizational resources.

2.2 Green Knowledge Management (GKM) as a multidimensional mechanism

To address this theoretical limitation, this framework draws upon Knowledge Lifecycle Theory (Alavi and Leidner, 2001; Dalkir, 2013), which posits that KM is not a single action but a complex, sequential pipeline of distinct cognitive and social routines. According to this lifecycle perspective, treating green knowledge as a homogeneous entity obscures the specific capability bottlenecks a firm might face. A startup might excel at acquiring external environmental data but fail completely at sharing it internally or applying it to production. Therefore, to accurately map capability development, this framework adopts the multidimensional conceptualization validated by Yu et al. (2022) and strongly corroborated by recent comprehensive GKM empirical models (Abbas and Khan, 2023; Widyanti *et al.*, 2024). Specifically, GKM is defined as a multidimensional construct comprising five distinct, interrelated sub-dimensions that must function as an uninterrupted pipeline to achieve sustainable outcomes:

- Green Knowledge Acquisition: The capability to proactively gather and sense external environmental information, clean technology updates, and stakeholder requirements.
- Green Knowledge Storage: The infrastructural capacity to codify, structure, and securely retain ecological expertise within the organizational memory, preventing knowledge loss due to high employee turnover typical in startups.
- Green Knowledge Sharing: The internal socio-technical mechanisms that facilitate the horizontal diffusion of environmental best practices, fostering a collaborative climate where ecological insights are seamlessly exchanged across human and digital subsystems.
- Green Knowledge Application: The practical execution phase where stored and shared insights are actively mobilized to improve eco-friendly operations, ensure regulatory compliance, and inform sustainable business strategies.
- Green Knowledge Creation: The highest-order cognitive capability, building upon the SECI model of knowledge conversion (Nonaka, 1994), which involves generating novel, proprietary environmental solutions and original eco-innovations.

2.3 Artificial Intelligence (AI) as a dynamic digital catalyst

A central theoretical contribution of this framework is the conceptual elevation of AI. Rather than viewing AI merely as a generic information technology tool, this paper conceptualizes AI as an advanced organizational capability and a dynamic digital catalyst. Building upon foundational theories of AI capability (Mikalef and Gupta, 2021) and the automation-augmentation paradigm (Raisch and Krakowski, 2021), AI represents a transformative cognitive infrastructure. It fundamentally alters an organization's boundaries by not only automating routine technical tasks but also deeply augmenting human intelligence.

In the startup context, these AI capabilities encompass the deployment of statistical, self-learning, and predictive algorithms across various operational levels. By leveraging machine learning, AI substantially reduces the prediction costs associated with highly complex and volatile ecological environments (Agrawal *et al.*, 2022). Through a dynamic capability lens, AI profoundly enhances a startup's ability to process massive ecological datasets in real time. It automates complex pattern recognition and informs shared decision-making, providing the analytical velocity required to tackle sustainability challenges. However, AI alone lacks contextual judgment. By acting as an advanced cognitive extension, AI mitigates the severe human capital constraints typical of emerging ventures, yet it fundamentally relies on the human-centric governance of GKM to translate its algorithmic predictions into trusted, sustainable actions.

2.4 Sustainable Performance (SP)

The ultimate dependent variable in this framework is SP. Moving beyond narrow economic metrics that focus solely on short-term profitability, SP is conceptualized as a multidimensional construct rooted in the Triple Bottom Line approach (Elkington, 1998) and the principles of corporate sustainable development (Bansal, 2005).

Aligned with the comprehensive metrics utilized by Khan et al. (2024), SP in startups is evaluated across three interconnected pillars. Economically, it reflects competitive advantages in cost-saving, operational efficiency, and sustained value creation. Environmentally, it signifies the successful implementation of initiatives to reduce, reuse, and recycle, thereby minimizing the negative ecological footprint of the firm's operations and products. Socially, it encompasses organizational resilience, respect for business ethics, and the pursuit of being a responsible corporate citizen. This multidimensional conceptualization ensures that the outcomes of AI-driven green knowledge routines are evaluated comprehensively, capturing both immediate market viability and long-term ecological impact.

3 Conceptual Framework and Propositions

This section develops a comprehensive conceptual framework delineating the direct and moderating pathways linking GKM, AI, and SP within the specific context of emerging startups.

3.1 The impact of GKM on SP

To achieve SP, startups must move beyond superficial environmental compliance and embed ecological considerations deep within their core organizational routines. According to the knowledge lifecycle perspective, this embedding process critically depends on a robust GKM pipeline. Recent systematic reviews demonstrate that effective green knowledge routines act as independent predictors for corporate sustainability (Adusei, 2026). Specifically, scholars highlight that GKM practices directly enhance sustainable development by fostering green technological innovation, minimizing ecological footprints, and optimizing resource efficiency (Khan *et al.*, 2024; Wang *et al.*, 2022). By systematically managing environmental knowledge, organizations successfully transform green intellectual capital into tangible economic and socio-environmental value (Zhang *et al.*, 2025). Theoretical models increasingly treat GKM not as a singular action but as an integrated system of sequential processes that translates ecological intent into actionable sustainable outcomes (Widyanti *et al.*, 2024). Therefore, contextualizing these mechanisms for emerging ventures, this study posits:

Proposition 1 (P1): *GKM composed of acquisition, storage, sharing, application, and creation, acts as a comprehensive driver positively influencing the SP of startups.*

To unpack this overarching relationship, it is theoretically imperative to examine the distinct operational routines that constitute this pipeline. Because environmental challenges are inherently complex and systemic, the survival of startups in the twin transition depends fundamentally on their boundary-spanning capabilities (De Marchi, 2012). Proactively acquiring external environmental intelligence enables startups to accurately sense rapid regulatory shifts and identify emerging clean technologies before their competitors (Albort-Morant *et al.*, 2016). This early sensing capability serves as a critical defensive mechanism that minimizes institutional risks while simultaneously uncovering lucrative green market niches, directly enhancing long-term economic resilience (Xue *et al.*, 2019). Recent empirical studies validate this mechanism, demonstrating that green knowledge acquisition serves as a critical strategic lever. Specifically, robust knowledge acquisition activities are essential for translating green technological innovation into superior environmental performance (Sahoo *et al.*, 2023). Furthermore, acquiring green knowledge acts as a vital operational mechanism enabling smaller, resource-constrained ventures to successfully convert their strategic environmental intent into SP (Baquero, 2025). Therefore, the ability for startups to rapidly internalize external ecological data is a prerequisite for subsequent knowledge routines and overall sustainability.

Proposition 1a (P1a): *Green knowledge acquisition positively influences the SP of startups.*

Once knowledge is acquired, retention becomes the next critical hurdle. Startups inherently suffer from high employee turnover and the liability of newness. Without structural storage, tacit ecological expertise leaves when key employees depart. Robust digital storage routines convert fragmented human capital into formalized organizational memory. Recent literature emphasizes that the structural preservation of environmental knowledge through the entire knowledge lifecycle is indispensable for maintaining operational continuity and achieving long-term sustainable development (Widyanti *et al.*, 2024). Furthermore, utilizing appropriate technological infrastructure to securely retain green knowledge prevents severe knowledge attrition and creates a reliable database for continuous sustainability improvements (Al-Faouri, 2023; Kordab *et al.*, 2020), safeguarding startups against their liability of newness.

Proposition 1b (P1b): *Green knowledge storage positively influences the SP of startups.*

Furthermore, complex environmental challenges cannot be solved in silos. Internal socio-technical sharing mechanisms foster a collaborative climate that rapidly diffuses green best practices across different functional teams. This horizontal diffusion translates implicit individual awareness into a collective organizational green culture. Recent empirical studies strongly underscore the criticality of this dimension. Specifically within resource-constrained organizational settings, active green knowledge sharing functions as a pivotal mechanism that translates green innovation strategies into tangible sustainability outcomes (Rahman *et al.*, 2026). Moreover, establishing robust internal sharing mechanisms directly drives sustainable business performance and secures long-term competitive advantage (Zairbani and Senthil Kumar, 2025). Facilitating seamless communication across agile teams reduces operational waste and builds a unified entrepreneurial strategy vital for small enterprises' survival (Junejo *et al.*, 2025).

Proposition 1c (P1c): *Green knowledge sharing positively influences the SP of startups.*

Crucially, the materialization of SP relies heavily on execution. Acquired and stored intelligence remains a latent asset until it is practically applied. The knowledge application phase ensures that ecological data is actively

mobilized to optimize energy efficiency, reduce material footprints, and streamline supply chains. Executing these eco-friendly operational adjustments directly mitigates negative environmental impacts while simultaneously strengthening the foundational capabilities required for green innovation (Abbas and Khan, 2023). Consequently, translating theoretical environmental awareness into applied practices is the definitive step for securing comprehensive sustainability in highly dynamic environments where startups operate with limited resources (Rahoo *et al.*, 2026).

Proposition 1d (P1d): *Green knowledge application positively influences the SP of startups.*

Finally, as the highest-order cognitive capability within this multidimensional pipeline, green knowledge creation enables startups to transcend mere regulatory compliance and generate proprietary eco-innovations. By synthesizing and recombining existing environmental insights, startups can develop novel green products, circular business models, and distinct operational paradigms. Recent empirical evidence specifically targeting emerging enterprises confirms that the continuous creation of fresh green knowledge is a decisive factor for achieving sustainable development, particularly when leveraging digital capabilities (Zhuge *et al.*, 2023). Furthermore, generating original ecological solutions allows these ventures to capture premium eco-conscious market segments and establish an enduring green competitive advantage in the modern industrial landscape (Abbas and Khan, 2023). Therefore, the ultimate realization of long-term sustainability hinges on a startup's capacity to continuously invent and deploy novel environmental knowledge.

Proposition 1e (P1e): *Green knowledge creation positively influences the SP of startups.*

3.2 The moderating role of AI as a dynamic catalyst

While multidimensional GKM provides the necessary operational pipeline for sustainability, startups are fundamentally bottlenecked by severe human capital limitations and financial resource constraints. They often lack the sheer manpower required to process massive volumes of ecological data or the financial buffer to absorb the high trial-and-error costs associated with traditional green innovation. Therefore, the actual conversion of green knowledge into SP requires a powerful moderating force to overcome these inherent liabilities.

Operating as an advanced dynamic capability, AI provides this moderating force by fundamentally altering the speed, scale, and efficiency of organizational learning. Recent empirical evidence strongly validates this catalytic function within resource-constrained environments. Specifically, integrating AI into smaller enterprises significantly amplifies the positive impact of green knowledge sharing and dynamic capabilities on sustainable outcomes (Rahman *et al.*, 2026). Furthermore, AI acts as a critical technological boundary condition that strengthens the mechanisms through which organizations convert overall GKM routines into actionable green intellectual capital (Khan *et al.*, 2024; Zhang *et al.*, 2025). When a startup possesses robust GKM routines, AI functions as a digital accelerator for the entire knowledge pipeline. For instance, machine learning algorithms can automate the continuous tracking of global environmental regulations, substantially reducing the time and cost of knowledge acquisition. Similarly, predictive analytics can instantly translate stored ecological data into real-time operational adjustments, maximizing the efficiency of knowledge application.

Furthermore, AI bridges the critical gap between knowledge possession and value realization. In fast-paced startup ecosystems, merely possessing green knowledge does not automatically guarantee SP if that knowledge cannot be deployed rapidly. By utilizing advanced algorithms to simulate eco-friendly product designs and optimize resource allocation, AI significantly reduces the time-to-market for green innovations. Consequently, AI empowers emerging ventures to overcome their size-related disadvantages, ensuring that their internal green knowledge routines are translated into optimal economic and environmental returns at a highly accelerated pace.

Proposition 2 (P2): *AI acts as a dynamic catalyst that positively moderates the relationship between GKM and SP, amplifying the impact of green knowledge routines on sustainable outcomes.*

3.3 Summary of the conceptual model

Synthesizing the theoretical derivations and the propositions outlined above, this study proposes a comprehensive conceptual framework, as illustrated in Figure 1. The model maps the critical architecture through which startups navigate the twin transition despite severe resource and human capital constraints. It positions the five distinct sub-dimensions of GKM as the core operational pipeline driving SP. Crucially, AI is integrated as a dynamic digital catalyst that positively moderates this central relationship, accelerating the conversion of ecological knowledge into tangible economic and socio-environmental value.

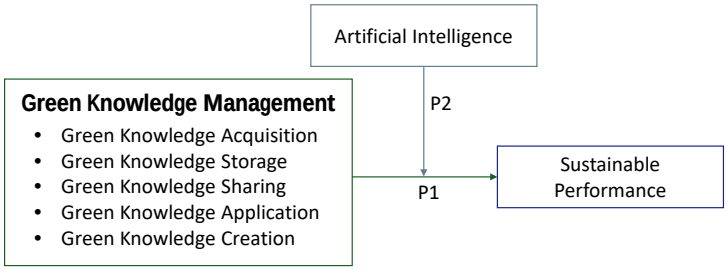

Figure 1: The conceptual framework of AI-driven GKM in startups

4 Discussion

4.1 Synthesizing the core framework

This study set out to address a critical paradox in the modern entrepreneurial landscape: how startups can successfully navigate the highly demanding twin transition of digitalization and sustainability. By integrating the RBV, KBV, and DCV, the developed framework illustrates that sustainable outcomes are not generated by sheer technological adoption alone. Instead, they require a meticulously orchestrated knowledge pipeline. The propositions advanced in this study highlight that GKM acts as the foundational operational infrastructure for sustainable performance, while AI serves as the dynamic digital catalyst that accelerates the flow of intelligence through this system.

4.2 Theoretical contributions

This research advances the intersection of sustainable entrepreneurship, KM, and AI through two primary theoretical contributions. First, it challenges the prevailing monolithic treatment of GKM by leveraging knowledge lifecycle theory to deconstruct it into a five-stage, sequential pipeline: acquisition, storage, sharing, application, and creation. This granular lens establishes that achieving SP relies on the uninterrupted flow of intelligence, where a failure in any single dimension can severely bottleneck the organizational eco-innovation process. Second, the framework refines the conceptualization of AI within the sustainability literature. Rather than viewing AI as a deterministic or universal performance driver, this study positions it as an advanced dynamic capability. This nuanced perspective moves the academic conversation beyond simple technology adoption metrics, theorizing that the true strategic value of AI lies in its ability to catalytically accelerate and optimize these underlying human-centric green knowledge architectures.

4.3 Practical implications

For practitioners navigating the twin transition, this framework offers valuable strategic perspectives across both organizational and institutional levels. Primarily, it cautions startup founders against the unstructured procurement of AI, emphasizing that predictive algorithms generally require a structurally sound data pipeline to deliver meaningful sustainability outcomes. Consequently, resource-constrained ventures are advised to prioritize the foundational routines of acquiring and securely storing green data before expecting digital tools to spontaneously drive SP. Furthermore, while AI significantly accelerates data processing, founders should actively cultivate a collaborative culture, recognizing that human intuition remains essential for sharing complex ecological insights and generating original eco-innovations. At the institutional level, policymakers and public incubators could consider shifting from generic technological grants toward targeted subsidies. By specifically funding AI-augmented storage infrastructures and environmental data-sharing platforms, institutional support can help mitigate capability bottlenecks, assisting startups in transforming stringent regulatory compliance pressures into genuine green innovation capabilities.

5 Conclusions and Future Research

The pursuit of SP in the digital era requires startups to move beyond superficial green posturing and meticulously orchestrate an AI-augmented knowledge pipeline. However, as a theoretical exposition, this paper acknowledges inherent limitations that simultaneously provide clear pathways for future empirical research. Primarily, the absence of quantitative testing means the proposed framework serves as a foundational blueprint requiring rigorous validation. Future researchers are strongly encouraged to empirically test this multidimensional model using advanced statistical techniques, such as Partial Least Squares Structural Equation

Modeling (PLS-SEM). By collecting large-scale, cross-sectional survey data from startups operating in diverse institutional contexts, scholars can quantify the specific path coefficients linking the five GKM dimensions to sustainable outcomes. Crucially, subsequent studies should build upon this framework by exploring the strategic intent or high-level organizational antecedents that drive the initial adoption of these knowledge pipelines. Furthermore, sophisticated moderation analyses should be conducted to investigate whether the accelerating power of AI varies in intensity across the different cognitive phases of the knowledge lifecycle, specifically testing if explicit knowledge routines benefit more from digital catalysts than highly tacit human processes.

6 Acknowledgements

This work has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 101034319 and from the European Union - NextGenerationEU. We also thank the anonymous reviewers for their constructive feedback, which has significantly improved the quality of this manuscript.

7 Ethics Declaration

No ethical approval was required as the study is conceptual in nature and does not involve empirical research.

8 AI Declaration

The authors used Gemini solely for language refinement during the preparation of this paper. The tool provided grammar, phrasing, and proofreading suggestions, which the authors reviewed and incorporated into the manuscript.

Digital ESG Communication in Sustainable Fashion Consumption: Comparing Italy and South Korea

Strazzullo Serena[1], Ianniello Sara[1], Lee Jiyeon[2], Moon Ilkyeong[2]
[1]University of Naples Federico II, Naples, Italy
[2]Seoul National University, Seoul, Korea

Abstract

The fashion industry is increasingly challenged to demonstrate credible sustainability commitments in response to its significant environmental and social impacts, globalised supply chains, and persistent concerns over unsustainable production and consumption patterns. In this context, Environmental, Social, and Governance (ESG) communication has become a central tool by which fashion companies disclose their sustainability efforts and engage consumers. However, the effectiveness of ESG communication in influencing consumer behaviour remains uncertain. This is particularly relevant in digital environments, where sustainability claims are often difficult to verify and where information asymmetry, consumer scepticism, and greenwashing concerns may weaken the credibility of corporate messages. Moreover, consumers' interpretation of sustainability communication may differ across geographical contexts. Hence, the study adopts a narrative literature review approach, focusing on two main streams of research: ESG communication practices in the fashion industry and consumer behaviour studies related to sustainable consumption, with specific attention to Italy and South Korea, two relevant and contrasting contexts.

Building on signalling theory, the study develops an empirical model that integrates the insights emerging from the narrative review with cross-country evidence. In the proposed model, ESG communication practices are conceptualised as sustainability signals. Sustainability predisposition and digital and social influence are introduced as antecedents, shaping consumers' interpretation of these signals. In line with the theory, the interpretation of sustainability signals is expected to influence consumers' behavioural intention, which is linked to actual purchase behaviour, while behavioural barriers are considered as factors that may affect this relation.

In doing so, the study advances a model that can be empirically tested through multi-group analysis to assess whether the proposed relationships operate differently among Italian and South Korean consumers. Generally, the study offers a theoretical and practical foundation for understanding how digital ESG communication becomes meaningful, credible, and behaviourally relevant in different contexts.

Keywords: ESG, digital technologies, fashion industry, trust.

Paper type: Academic Research Paper

1 Introduction

The fashion industry is widely recognised as one of the most environmentally and socially impactful sectors, due to its intensive resource consumption, globalised supply chains, and fast production cycles that generate significant environmental and social externalities (Ronda, 2024). In response to increasing regulatory pressure and societal expectations, firms have gradually integrated Environmental, Social, and Governance (ESG) practices into their strategies, positioning sustainability as a source of competitive advantage and differentiation (Hörisch et al., 2020). At the same time, consumers have become more aware of environmental and ethical issues, showing growing interest in the sustainability performance of fashion products and brands (Sharma et al., 2020). However, despite this increasing awareness, sustainable consumption in fashion remains inconsistent. Consumers often fail to translate pro-environmental attitudes into actual purchasing behaviour, giving rise to the well-documented attitude-behaviour gap (Annunziata et al., 2023; Park & Lin, 2020). This conflict is particularly evident in fashion, where purchasing decisions are influenced by cognitive evaluations, and hedonic, social, and symbolic factors, as well as by habits and price sensitivity (Colasante et al., 2025). As a result, even when consumers express positive attitudes towards sustainability, these do not necessarily lead to consistent behavioural outcomes.

A particularly relevant but still underexplored issue concerns how firms communicate ESG efforts in digital environments and how such communication translates into consumer trust.

From a signalling perspective (Williams & Hodges, 2022), sustainability communication can reduce information asymmetry by making sustainability attributes more observable and interpretable (Fu et al., 2023). However, the effectiveness of these signals depends on their perceived credibility and transparency. Trust literature complements this view by highlighting that consumers respond positively only when information is perceived as reliable, especially in contexts characterised by uncertainty and risk (Tan et al., 2025). In the

absence of credible signals, sustainability claims may generate scepticism and weaken consumer responses, especially in fashion contexts typically exposed to greenwashing (Tan et al., 2025). While prior research has demonstrated that perceived transparency of signals enhances purchasing intention, this mechanism has not been systematically integrated into the study of ESG communication in the fashion domain.

This gap becomes even more relevant when considering cross-country differences (Koszewska et al., 2020; Whang et al., 2015). More broadly, recent review evidence on ESG and consumer behaviour highlights a strong geographical and contextual concentration of findings, calling for a broader consideration of socio-cultural environments in explaining consumer responses (Tripopsakul & Puriwat, 2022). Consumer responses to sustainability cues are not uniform across contexts, as they are shaped by socio-cultural factors, market structures, consumption norms (Whang et al., 2015), shopping habits, and consumption patterns (Colasante et al., 2025). Evidence suggests that different markets may prioritise distinct dimensions of sustainability (Hong & Kang, 2019), such as ethical concerns, economic considerations, or symbolic value, leading to heterogeneous interpretations of ESG communication (Tripopsakul & Puriwat, 2022). This means that consumers in different contexts may also differ in their ability and willingness to process such information. For instance, limited awareness of ESG practices and difficulties in accessing or interpreting firm disclosures can generate significant information resistance, weakening the translation of sustainability preferences into actual purchasing behaviour (Leonelli et al., 2025).

Building on these premises, this study addresses the need to analyse digital ESG communication practices and their influence on purchasing behaviour by comparing Italy and South Korea. Specifically, the analysis builds on a narrative literature review aimed at identifying the most relevant contributions to evaluate contextual differences and relationships linking sustainable fashion consumption with digital ESG communication practices.

Finally, the research proposes an empirical model, grounded in signalling theory, in which digital ESG communication acts as a signal, and consumer interpretation constitutes the main relational pathway leading to purchasing behaviour.

2 Theoretical Background: Signalling Theory in Sustainable Fashion Consumption

The study of sustainable fashion consumption is characterised by a fundamental condition of information asymmetry between firms and consumers. Sustainability attributes, such as ethical sourcing, environmental impact, and labour practices, are not directly observable at the point of purchase and therefore belong to the category of credence attributes. As a result, consumers are unable to independently verify the authenticity of sustainability claims and must rely on external information provided by firms. Within this context, signalling theory has increasingly been adopted to explain how firms communicate unobservable product and process characteristics (Market et al., 1973). According to this theory, firms convey signals under conditions of information asymmetry to reduce uncertainty and influence stakeholders' perceptions (Williams & Hodges, 2022).

In sustainable consumption research, when consumers perceive sustainability signals as clear and verifiable, they are more likely to regard the brand as credible and reliable (Fu et al., 2023; Sansome et al., 2024). Several studies have implicitly or explicitly applied this perspective by examining how sustainability labels, certifications, brand reputation, and communication cues shape consumer evaluations and purchasing decisions (Rese & Baier, 2025). For instance, sustainability labels and certifications have been shown to function as signals of environmental and ethical quality, helping consumers infer product attributes that cannot be directly assessed. Behre & Cauberghe (2025) demonstrate that third-party certification labels can work as credible signals in online fashion because they reassure consumers that sustainability claims are not merely self-declared by the brand. Similarly, Negash & Akhbar (2024) apply signalling theory to second-hand fashion, arguing that information such as seller reputation, product history, condition details, and refurbishment descriptions can reduce uncertainty and increase trust. Huh & Kim (2022) show that green apparel can operate as a social signal, especially among younger consumers, because wearing sustainable products may communicate status, moral awareness, or belonging to a socially responsible lifestyle.

Therefore, signalling theory is employed in sustainable fashion research in two complementary ways: first, to explain how consumers use labels, certifications, seller information, and product transparency to assess whether sustainability claims are trustworthy; and second, to show how sustainable fashion consumption allows individuals to express identity, values, distinction, and social positioning through what they wear.

3 Method

This study aims to investigate how digital ESG communication shapes consumer responses in the sustainable fashion industry, with particular attention to the role of consumer trust and cross-country differences between

Italy and South Korea. Specifically, the research focuses on how fashion companies use digital channels to communicate their ESG practices, and on how consumers interpret these signals. Accordingly, this study adopts a narrative literature review approach (Baumeister & Leary, 1997). The review followed a structured workflow consisting of three main stages: identification, screening, and content analysis.

During the identification phase, an initial pool of articles was collected through a broad search in Scopus using combinations of keywords, such as “sustainable fashion”, “consumer behaviour”, “ESG communication”, and “ESG practice”.

In the second stage, the abstracts were iteratively screened based on conceptual relevance. Studies were retained when they provided meaningful contributions to at least one of the following domains:

- sustainable fashion consumption,
- ESG communication practices,
- and cross-country evidence for Italy and South Korea.

The screening process was then validated through triangulation among the authors and returned 30 available articles for content analysis.

In the final stage, the final pull of studies was analysed through the combined lenses of signalling theory. This interpretive approach enabled the integration of findings into a coherent model.

4 Results

4.1 ESG communication practices

ESG communication, or sustainability communication, refers to the set of messages, activities, and channels through which a company transparently and consistently conveys its commitment to ESG issues, according to Waites (2025). Through ESG communication, firms inform stakeholders about their environmental actions, their alignment with social and corporate values, and the transparency of their governance and managerial practices. The most recent literature reveals that the increasing relevance of ESG factors has progressively reshaped both corporate strategies and consumer evaluation processes (Waites, 2025) and expectations (Su & Teo, 2025). Specifically, we analysed articles based on their E-S-G focus to distinguish communication related to each pillar and discover their impacts on consumer behaviour.

The environmental dimension emerges as particularly salient in shaping consumer responses. Studies consistently show that consumers tend to favour firms perceived as environmentally responsible, and in some cases are willing to pay a premium for products associated with sustainability, especially when such efforts are clearly communicated (Su & Teo, 2025). However, the evidence also suggests that the effectiveness of environmental claims depends strongly on how information is presented and perceived. Transparent and visible communication enhances trust and ethical satisfaction, thereby strengthening green purchase intentions, whereas low salience or ambiguous communication may limit behavioural conversion despite positive attitudes (Gherghina, 2024).

The social pillar further reinforces the relevance of ESG communication for consumer behaviour. The reviewed studies show that communication related to social responsibility, such as fair labour practices, community engagement, and inclusiveness, can directly influence conscious consumption, particularly among socially aware consumers. At the same time, consumers appear highly sensitive to perceived inconsistencies or violations of social expectations, which may undermine trust and negatively affect behavioural responses (Leonelli et al., 2025). These findings suggest that social ESG communication contributes to consumer trust not only by evidencing positive practices but also by reducing perceived ethical risk.

The governance mechanisms, although less directly visible to consumers, play a key role in reinforcing the credibility of environmental and social claims (Su & Teo, 2025). In this sense, governance acts as a foundational mechanism that supports the perceived reliability of ESG communication, thereby strengthening consumer trust even when governance itself is not explicitly evaluated at the point of purchase. Importantly, the reviewed studies converge in highlighting that the effectiveness of ESG communication depends on the integration of the three dimensions and on the coherence of the overall message. Firms that align ESG practices transparently and consistently are more likely to generate consumer trust, loyalty, and willingness to support the brand (Su & Teo, 2025), thereby amplifying their impact on purchase intention and willingness to pay. Finally, the analysis suggests that consumers who actively engage with ESG-related information tend to exhibit stronger behavioural responses, including loyalty and advocacy behaviours (Leonelli et al., 2025). Figure 1 resumes the main evidence in consumer behaviour literature analysing ESG factors, derived from Tan et al.’s (2025) framework:

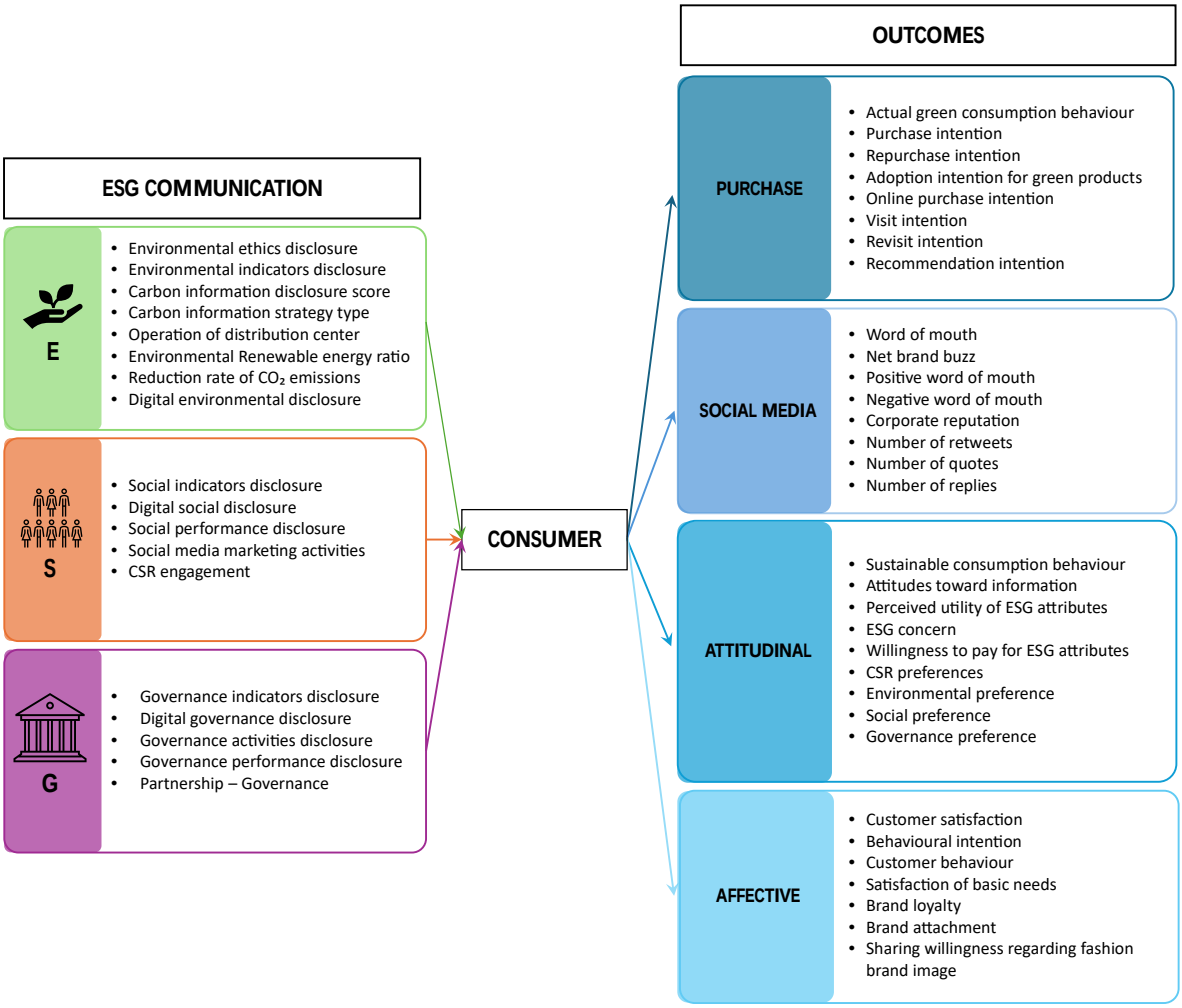

Figure 1: Linking ESG communication with consumer outcomes. Adaptation from Tan et al. (2025).

4.2 Cross-country comparison: Italy and South Korea

Recent ESG-consumer literature shows that consumer responses to sustainability are often context-specific and shaped by differences in regulatory environments, market structures, public awareness, and culturally embedded interpretations of trust, responsibility, and corporate legitimacy. In this respect, Tan et al. (2025) highlight both a marked concentration of studies in East Asia and the need to broaden empirical engagement to strengthen the cross-cultural applicability of existing models. Against this background, focusing on Italy and South Korea is theoretically meaningful. Italy represents a mature fashion context, deeply rooted in manufacturing tradition and closely associated with the cultural legacy of slow fashion, craftsmanship, product quality, and symbolic value. South Korea, by contrast, offers a highly dynamic, digitalised, and competitive market environment in which consumer-brand interactions are more strongly mediated by platforms, technological adoption, and fast-evolving communication practices. To compare the two focal contexts more systematically, the selected studies were grouped into categories based on the variables examined and the main findings reported. A signalling-based interpretation was then added to clarify how each contribution helps explain the reception, decoding, or behavioural effectiveness of sustainability-related cues. Table 1 represents the main findings of the coding process:

Table 1: Extraction of literature coding for cross-country comparison and signalling interpretation.

Category	Country	Key variables	Main finding	Signalling interpretation
Sustainability predisposition	Italy	Environmental knowledge, environmental concern, eco-friendly behaviour	Green purchase intention is positively associated with environmental knowledge, environmental concern, and eco-friendly behaviour (Annunziata et al., 2023).	Consumer predisposition reduces ambiguity in the decoding of sustainability signals.
	South Korea	Idealism, moral intensity	Idealism increases moral intensity, which in turn increases sustainable product purchase behaviour (Hong & Kang, 2019).	Consumer predisposition increases the likelihood that sustainability information is interpreted as meaningful rather than ignored.
Behavioural barriers	Italy	Shopping habits, price sensitivity, second-hand willingness, bio-based preference	Shopping habits shape sustainable fashion uptake; second-hand adoption is weaker than bio-based acceptance (Colasante et al., 2025). Higher prices may lead to greater scepticism towards sustainable products (Fani et al., 2023).	Positive sustainability signals are insufficient when habitual consumption patterns, price orientation, or preference for conventional options dominate the decision process.
	South Korea	Utilitarian value, subjective norms, environmental concern, perceived risk	Intention and behaviour diverge; perceived risk and product-evaluation issues matter for actual uptake Park & Lin (2020).	Behavioural conversion is weakened by perceived risk and product-related uncertainty.
Digital and social influence	Italy	Visible social cues, environmental concern, self-image	Sustainability cues do not always increase preference; visible signalling may reduce preference depending on self-presentation dynamics (Fani et al., 2023).	The effectiveness of sustainability cues depends on whether they are socially acceptable and consistent with the consumer's concerns.
	Italy	Online and traditional purchasing channels	The digital environment is treated mainly as an informational and purchasing channel rather than as a socially embedded relational space (Annunziata et al., 2023).	The digital environment operates primarily as a transmission channel rather than as a relational mechanism reinforcing the signal.
	South Korea	Online interaction, social capital	Social capital strongly affects sustainable fashion purchase intention in a YouTube setting (Kim et al., 2020).	Digital platforms function as socially embedded environments that reinforce signals through interaction and relational validation.
	South Korea, China, Russia	Digital advertising cue, country interpretation	The same digital cue affects consumer evaluation differently across contexts (Whang et al., 2015).	The same signal can be decoded differently, affecting whether it is perceived as credible or persuasive.

Both contexts display a meaningful sustainability predisposition. In Italy, Annunziata et al. (2023) show that environmental knowledge, environmental concern, and eco-friendly behaviour positively affect green purchase intention in the fashion industry. In South Korea, Hong & Kang (2019) show that sustainable fashion consumption is also supported by ethical-cognitive mechanisms, as idealism positively affects moral intensity, which in turn influences purchase behaviour. This suggests that consumers in both countries can be receptive to sustainability information, even though such a predisposition alone does not guarantee behavioural conversion. However, behavioural barriers persist and may explain the well-known attitude-behaviour gap. In Italy, the literature points primarily to economic and habitual constraints. Colasante et al. (2025) show that shopping habits and price orientation remain important barriers to the adoption of more sustainable fashion practices, and related

Italian evidence indicates weaker second-hand adoption and a higher need for economic justification in circular fashion choices. These findings suggest that, even when trust in sustainability communication is present, behavioural response may remain fragile because it competes with price sensitivity, routine purchasing practices, and the enduring attractiveness of fast fashion. In South Korea, by contrast, the barriers appear more perceptual and related to credibility. Park & Lin (2020) and product-evaluation concerns help explain the gap between intention and actual uptake in recycled and upcycled fashion products. Hong & Kang (2019) further indicate that moral intensity matters for purchase behaviour. Hence, while both contexts display barriers to behavioural conversion, these appear more habit-based in Italy and more risk- and perception-based in South Korea. Finally, sustainability claims in fashion retain the nature of credence attributes and therefore require interpretive mechanisms through which information becomes believable. In Italy, online visible sustainability cues do not always strengthen preference and may even backfire when they interfere with self-presentation dynamics, suggesting that trust in sustainability information is more conditional and context-sensitive (Fani et al., 2023). In addition, the digital sphere appears to function mainly as an informational and purchasing environment: Annunziata et al. (2023) distinguish between online and traditional channels when examining green purchase intention, treating digitalisation primarily as a channel condition rather than as a relational space. In South Korea, online cues appear more socially reinforced. Kim et al. (2020) show that, in digital environments, parasocial interaction and especially social capital significantly influence purchase intention for sustainable fashion products, while Whang et al., (2015) show that the same market cue is interpreted differently across countries, indicating that credibility is context-dependent. Thus, in South Korea, digital communication is more embedded in interaction and relational validation than in Italy.

4.3 Empirical model proposal

Building on the previous insights, the proposed empirical model is grounded in signalling theory. This perspective is particularly appropriate in sustainable fashion contexts, where consumers often face information asymmetry and cannot directly assess whether brands' sustainability claims reflect actual ESG practices. However, in digital environments, the mere availability of ESG information is not sufficient to generate favourable consumer responses (Sansome et al., 2024). Accordingly, the model assumes that digital ESG signals influence consumer outcomes through a process of signal interpretation, in line with the literature (Tan et al., 2025). The overall objective is to provide a basis for a future multi-group analysis comparing Italy and South Korea, where the proposed relationships may operate with different intensity across national contexts.

Specifically, ESG signals refer to the set of sustainability-related information and communication practices through which fashion brands disclose their ESG commitments. In line with recent signalling-based studies, these signals may be formal (Behre & Cauberghe, 2025) or informal and market-based (Negash & Akhbar, 2024). Hence, these may include disclosure related to environmental claims, supply-chain information, ethical labour practices, circularity initiatives, certifications, sustainability reports, product-level cues, social media content and messages. ESG signals are therefore not limited to formal reporting but include the broader ecosystem of digital, symbolic, and relational communication through which consumers encounter, evaluate, and make sense of sustainability claims (Fani et al., 2023; Sansome et al., 2024).

As shown in Figure 2, the authors advanced different hypotheses to build the model. First, the positive antecedents of ESG signal interpretation (IS) are derived from the cross-country literature analysis and are conceptualised as two exogenous constructs: sustainability predisposition (SP) and digital and social influence (DSI).

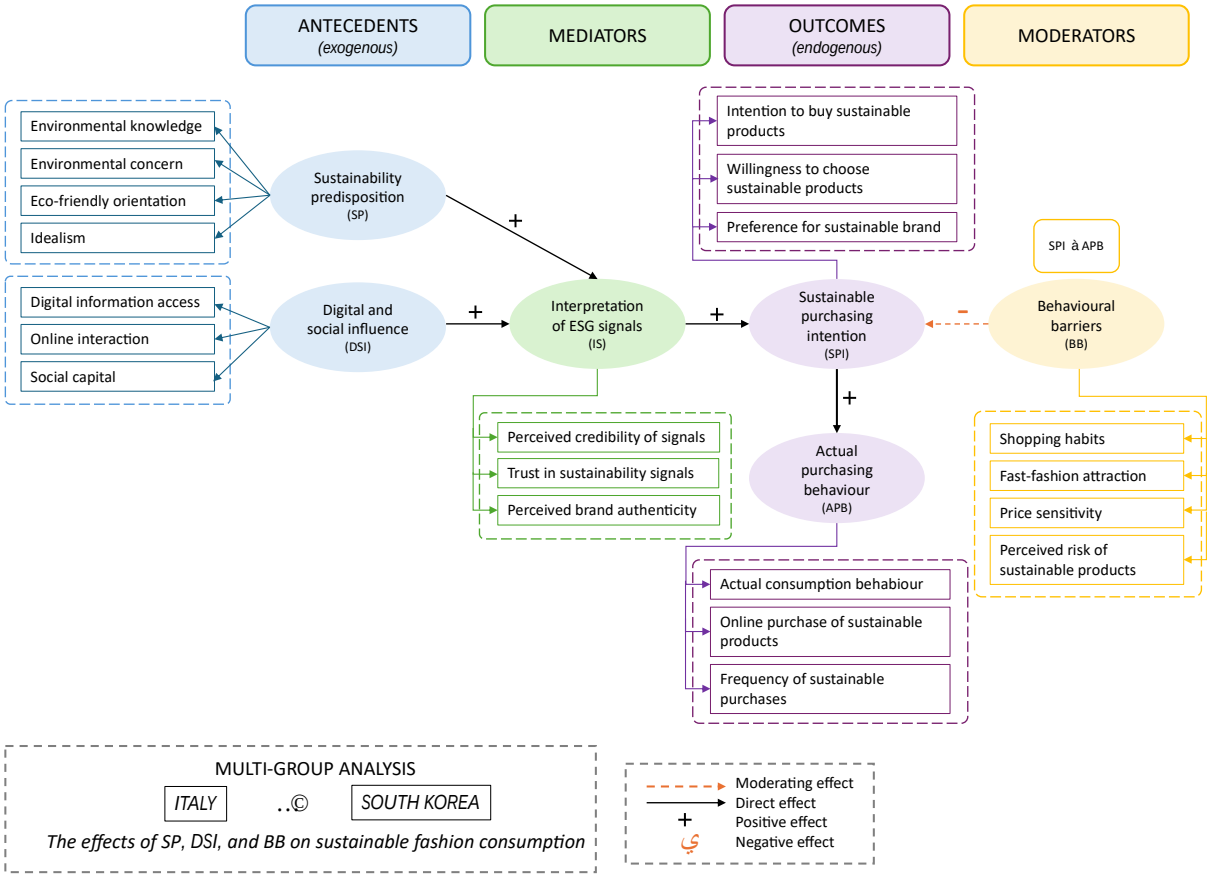

Figure 2: Multi-group empirical model proposal.

SP captures consumers' prior orientation toward sustainability and can be measured through items related to environmental knowledge, environmental concern, eco-friendly behaviour, and idealism. DSI captures the extent to which consumers are exposed to, search for, and validate ESG information through digital and relational channels. This can be measured through items related to digital information access, online interaction, and social capital. These antecedents have a positive influence on the central mediator of the model, which is the interpretation of ESG signals (IS). It captures how consumers make sense of the ESG information provided by fashion brands (Sansome et al., 2024; Tan et al., 2025). It can be measured through items reflecting perceived credibility, trust, and perceived brand authenticity (Fu et al., 2023; Tan et al., 2025). The measurement items derive from theory and literature, which suggest that consumers respond more favourably when sustainability information is perceived as credible, reliable, and aligned with corporate behaviour (Negash & Akhbar, 2024).

Downstream, the model links sustainable purchasing intention (SPI) with actual purchasing behaviour (APB), a positive relation theoretically grounded in the Theory of Planned Behaviour (Ajzen, 1991), according to which intention represents the motivational antecedent of behaviour but does not necessarily guarantee actual action.

Finally, the model introduces behavioural barriers (BB) as negative moderators of the relationship between SPI and APB. These barriers emerged from the cross-country analysis and explain why consumers may not translate favourable intentions into actual sustainable purchases. They include price sensitivity, fast-fashion habits, and perceived risk (as hygiene concerns). Therefore, the model assumes that even when ESG signals are positively interpreted and generate sustainable purchasing intention, BB may reduce the likelihood that such intention becomes actual purchasing behaviour. Thus, the model does not assume that intention automatically translates into behaviour; rather, it explicitly accounts for the intention-behaviour gap that often characterises sustainable fashion consumption.

In this sense, the model integrates ESG communication, consumer interpretation, and behavioural constraints into a single framework suitable for future cross-country empirical testing.

5 Conclusion

This paper addresses the gap concerning how digital ESG communication practices influence sustainable fashion consumption. To address this issue, the study adopts a narrative literature review aimed at integrating

research on ESG communication practices, sustainable fashion consumption, and cross-country differences, focusing on the comparison between Italy and South Korea.

The review shows that ESG communication may not automatically generate trust or sustainable purchasing behaviour. Rather, its effectiveness depends on consumers' ability to interpret ESG information as credible, authentic, and meaningful. Building on signalling theory, the authors therefore develop an empirical model in which digital ESG communication is conceptualised as a set of sustainability signals whose behavioural impact depends on consumers' interpretation of such signals. This interpretation of ESG signals represents the central construct of the model, as it explains how ESG communication becomes relevant for consumer decision-making.

The cross-country analysis further allows the identification of three key constructs: sustainability predisposition (SP), digital and social influence (DSI), and behavioural barriers (BB). SP and DSI are proposed as antecedents of signal interpretation, while BB moderates the relationship between sustainable purchasing intention and actual purchasing behaviour. In conclusion, the model provides a theoretical basis for future empirical testing through multi-group analysis and helps explain how ESG communication may operate differently across national contexts.

5.1 Implications of the study

From a theoretical perspective, the paper extends the application of signalling theory in sustainable fashion consumption by specifying digital ESG communication as a distinct signalling environment. Second, the study advances a more context-based view of sustainable fashion consumption by showing that the same model cannot be assumed to operate identically across national settings. The cross-country comparison further refines this contribution by identifying three contextual dimensions through which Italy and South Korea differ regarding sustainability predisposition, digital and social influence, and behavioural barriers. These differences support the idea that the proposed model retains a common structure across countries, while its internal paths are expected to operate with different intensity across contexts.

The paper also offers relevant practical implications for managers and practitioners in the fashion industry. For fashion firms, the findings suggest that digital ESG communication should not simply increase the quantity of sustainability disclosures but should improve their interpretability, transparency, and credibility. In practical terms, this means moving beyond vague claims and symbolic sustainability rhetoric toward clearer and more verifiable communication formats, such as traceability tools, standardised indicators, and coherent product-level disclosures. However, the model also suggests that the effectiveness of these tools is likely to differ across contexts. In Italy, brands may need to complement ESG communication with clearer demonstrations of consumer value, convenience, and practical relevance, because transparency alone may not overcome economic and habitual barriers. In South Korea, by contrast, digital ESG communication may be more effective when embedded in interactive and socially mediated environments and when supported by visible and credible verification cues.

5.2 Limits and future research directions

The study presents some important limitations. First, the paper is conceptual and does not provide empirical testing of the proposed relationships. Second, the content analysis and the following cross-country comparison rely on a focused and purposive interpretation of existing studies. Third, the study concentrates on the fashion industry; therefore, the generalisability of the model to other ESG-intensive industries should not be assumed automatically. These limitations open several directions for future research. A first direction concerns the operationalisation of digital ESG communication itself, which future studies could unpack into more specific communication formats. A second avenue concerns the empirical validation of the model through multi-group comparative designs between Italy and South Korea. Finally, future research could broaden the contextual scope beyond Italy and South Korea to respond to recent calls for wider contextual coverage in ESG consumer research and to test whether the proposed model holds across other cultural and institutional settings.

Abstract

The management of Cold Chain (CC) logistics is critical to ensuring the safety, quality, and integrity of perishable food products, as even minor deviations from controlled conditions can cause irreversible deterioration and economic losses. However, current monitoring practices, often manual or semi-automated, show limited capability in handling real-time data, constraining risk mitigation and regulatory compliance. The increasing adoption of Internet of Things (IoT) technologies and advanced analytics provides new opportunities to enhance visibility and control across distributed supply chains.

This paper presents TRACING (innovaTive AI fRAmework for Cold chaIN Governance), a design-oriented framework that supports governance in Cold Chain networks through the integration of Data and Process Governance. Following a design science research approach, TRACING is conceptualized as a socio-technical artifact enabling decision-making, coordination, and accountability among multiple stakeholders.

The framework comprises four components: Data Governance (data collection, validation, and quality assessment), Process Governance (process modeling, monitoring, and optimization), Data Analytics (leveraging Process Mining and Artificial Intelligence), and an event-driven architecture enabling real-time communication and interoperability. These components enable the transformation of raw sensor data into structured knowledge, supporting continuous performance monitoring and anomaly detection.

The framework is illustrated through a Cold Chain scenario involving controlled product maturation, showing how the integration of data and process perspectives enables transparency, traceability, auditability, and coordination, ultimately enhancing operational reliability and resilience.

This work bridges the gap between data infrastructures and governance requirements, providing a structured approach to support knowledge-driven decision-making in complex supply chain environments.

Keywords: Cold Chain; Data Governance; Process Governance; IoT; Food Supply Chain

Paper type: Academic Research Paper

1 Introduction

The management of Cold Chain (CC) logistics is a critical challenge in perishable food supply chains, where maintaining controlled environmental conditions is essential to ensure product quality, safety, and regulatory compliance. Even minor deviations can cause irreversible deterioration and significant economic losses (Aung and Chang, 2014), a risk amplified by the increasing complexity of globalized supply chains involving multiple distributed actors.

In this context, the Cold Chain can be viewed as a complex socio-technical system characterized by strong interdependencies, strict environmental constraints, and the need for real-time decision-making. Temperature control and traceability are key to ensuring safety and quality (Aung and Chang, 2014), while inefficiencies in monitoring and management contribute significantly to food loss and waste (FAO, 2019).

Despite existing regulatory frameworks, current monitoring practices often rely on manual or semi-automated procedures based on periodic data collection and fragmented systems. This limits real-time anomaly detection, reduces process visibility, and constrains timely and effective decision-making, which remains largely reactive.

The diffusion of digital technologies, such as Internet of Things (IoT), Artificial Intelligence (AI), and advanced analytics, offers new opportunities to improve Cold Chain monitoring and management (Atzori et al., 2010; Ben-Daya et al., 2019). IoT enables continuous data collection, while analytical methods support pattern and anomaly detection. At the same time, Business Process Management (BPM) provides structured approaches for process modeling and optimization (Dumas et al., 2013). Their integration enhances efficiency and resource utilization (Bocciarelli et al., 2023; Ornari et al., 2025). In addition, Process Mining techniques support process discovery, conformance checking, and performance analysis through the extraction of knowledge from event logs (Striani

et al., 2022), addressing limitations of traditional analysis and simulation approaches (Oldenburg et al., 2025). However, their integration into unified governance-oriented frameworks remains limited.

Existing studies have mainly focused on either data-centric approaches, such as IoT-based monitoring and traceability systems, or process-oriented approaches based on BPM and logistics optimization (Aung and Chang, 2014; Atzori et al., 2010; Ben-Daya et al., 2019; Jedermann et al., 2014; Verdouw et al., 2016). While these contributions advance specific aspects of Cold Chain operations, they often lack integration between data and process governance, limiting the ability to transform data into actionable knowledge for coordination, accountability, and real-time decision-making (Khatri and Brown, 2010; Otto, 2011).

To address these limitations, this paper proposes TRACING, a design-oriented framework aimed at enabling governance mechanisms in Cold Chain networks through the integration of data and process perspectives. The study adopts a Design Science Research approach (Peffers et al., 2007), complemented by the use of a representative application context to illustrate the design and functionality of the proposed artifact.

TRACING is conceptualized as a socio-technical artifact that structures the collection, management, and analysis of data while enabling the modeling and monitoring of operational processes. By integrating Data Governance components with Process Governance mechanisms and advanced analytics techniques, the framework provides a unified environment for managing complex Cold Chain operations.

2 Methodology

This study adopts a Design Science Research (DSR) approach, which is particularly suitable for addressing complex organizational and technological problems through the design and development of innovative artifacts. Design Science Research focuses on the creation and evaluation of artifacts—such as models, methods, and systems—that contribute both to solving practical problems and to advancing scientific knowledge (Peffers et al., 2007). In the context of this research, the TRACING framework is conceptualized as a socio-technical artifact designed to enable governance mechanisms in Cold Chain networks.

The adoption of a DSR approach is motivated by the nature of the problem addressed in this study. Cold Chain environments are characterized by high operational complexity, distributed responsibilities, heterogeneous data sources, and strict requirements for monitoring, traceability, and regulatory compliance. These characteristics require not only analytical investigation but also the structured design of integrated solutions capable of supporting coordination and decision-making across multiple actors, particularly in contexts where data governance and decision rights play a critical role (Khatri and Brown, 2010; Otto, 2011). Therefore, rather than focusing on hypothesis testing or statistical generalization, this research aims to develop a coherent framework that addresses a class of problems related to governance in data-intensive and process-driven environments.

The methodological process follows a structured sequence of activities aligned with Design Science Research principles. First, the problem context is identified through the analysis of Cold Chain operations, with particular attention to challenges related to environmental monitoring, data fragmentation, and process coordination. Second, the objectives of the artifact are defined in relation to the need for improving visibility, traceability, and accountability within distributed supply chains. Third, the artifact is designed by integrating multiple components, including Data Governance mechanisms, Process Governance approaches, and advanced analytical capabilities. Finally, the framework is illustrated through a representative application context in order to demonstrate its structure and potential applicability.

The study adopts a Design Science Research approach (Peffers et al., 2007), complemented by the use of a representative application context to illustrate the design and functionality of the proposed artifact. The selected context refers to a Cold Chain scenario involving the management of perishable products, where environmental conditions and process execution must be continuously monitored and controlled. Within this perspective, the application context is not used for empirical validation in a strict case study sense, but rather as an illustrative domain that allows demonstrating how the framework can be instantiated in practice.

The design of the TRACING framework is grounded in both theoretical and domain-specific knowledge, including contributions on data governance structures, decision rights, and knowledge management in complex organizational environments (Khatri and Brown, 2010; Otto, 2011; Nonaka, 1994; Alavi and Leidner, 2001). From a theoretical perspective, the framework draws on Business Process Management principles for the modeling and monitoring of workflows (Dumas et al., 2013), as well as on process-oriented analytical approaches such as Process Mining. From a domain perspective, the design is informed by knowledge related to Cold Chain operations, including requirements for temperature control, traceability, and compliance with food safety regulations.

The evaluation of the framework is conducted at a conceptual level, focusing on its capability to enable governance mechanisms such as transparency, traceability, accountability, and coordination. This evaluation is based on the internal coherence of the artifact, on the alignment between identified problems and proposed solutions, and on the logical integration of its components. While no quantitative performance assessment is provided, the framework is assessed in terms of its potential to support decision-making and improve process visibility in complex environments.

By adopting a design-oriented methodology supported by an illustrative application context, this study ensures both rigor and relevance. The approach allows developing a structured and theoretically grounded framework while maintaining a strong connection to practical challenges in Cold Chain management.

3 Case Description: Cold Chain Process

The application context considered in this study refers to a Cold Chain scenario involving the management and monitoring of perishable food products, where maintaining controlled environmental conditions throughout storage, transportation, and distribution is essential. Cold Chain logistics encompasses a sequence of interconnected activities aimed at preserving product quality and safety, particularly for temperature-sensitive goods, whose deterioration may occur rapidly in the presence of environmental deviations (Aung and Chang, 2014; Jedermann et al., 2014; Ruiz-Garcia et al., 2010). The process is characterized by the involvement of multiple actors operating across different stages of the supply chain, including producers, logistics operators, storage facilities, and distribution entities. Each actor contributes to the execution of specific activities, which collectively determine the effectiveness of the overall system. The distributed nature of these operations introduces significant coordination challenges, particularly in relation to the synchronization of activities and the management of information flows across organizational boundaries.

The Cold Chain process can be represented through a controlled maturation workflow, which highlights the sequence of operational phases and the interactions among the involved actors. The process includes key stages such as product reception, storage under controlled conditions, maturation management, and distribution. Each phase is associated with specific environmental requirements and operational constraints, requiring continuous monitoring and precise coordination to ensure product integrity.

For this reason, the technology platform must be able to provide alerts useful for monitoring critical temperature values and parameters, enabling real-time monitoring and supporting any corrective actions. Similarly, the platform must support analysis of historical data and critical parameters useful for effective management of the ripening process. Currently, the Wholesaler/Ripener, while retaining this data, does not perform this type of analysis, which could serve as a basis for any improvements compared to previous practices.

Furthermore, the platform will allow for the clarification and formalization of procedures that currently rely heavily on the experience and tacit knowledge of expert operators, who have consolidated the various approaches currently adopted over the years. Finally, the platform will enable a clear and formalized end-to-end view of the ripening process, which can sometimes be a black box for the operators involved.

To further clarify the operational context, the Cold Chain scenario can be described in terms of actors, data generation, and decision-making processes. The main actors involved include producers, logistics operators, storage facilities, and distribution entities, each responsible for specific stages of product handling and environmental control.

Data are generated from both sensor-based systems and operational activities. Sensor data primarily include environmental variables such as temperature, humidity, and storage conditions, continuously monitored throughout the lifecycle of the product. In parallel, event data are produced by process execution, including product reception, storage transitions, handling operations, and shipment events.

These data streams are integrated within the platform to enable the monitoring of key process indicators, such as temperature compliance, duration of storage phases, occurrence of deviations, and frequency of rework or corrective actions. Based on these inputs, the system supports decision-making processes such as anomaly detection, alert generation, process adjustment, and coordination among actors.

Responsibilities are distributed across actors according to process roles, with each stakeholder accountable for specific operational phases and data inputs. This structured integration of data and responsibilities enables traceability and supports compliance with regulatory requirements, while providing a concrete instantiation of the TRACING framework within a Cold Chain context.

A defining feature of Cold Chain processes is the critical role played by environmental variables, particularly temperature, which must be continuously monitored and maintained within predefined thresholds. Deviations from these thresholds can lead to irreversible damage, affecting product quality and safety, and increasing the risk of food loss and waste (FAO, 2019). In addition to temperature, other factors such as humidity and

atmospheric conditions may influence product preservation, further increasing the complexity of process management.

The operational complexity of the Cold Chain is further amplified by the dynamic and uncertain conditions in which these processes take place. Transportation phases are subject to delays, equipment failures, and environmental fluctuations, which may compromise the stability of storage conditions (Yadav et al,2025). Moreover, the involvement of multiple actors and heterogeneous systems leads to data fragmentation, as information is collected through different devices and stored in separate repositories. This fragmentation limits process visibility and reduces the ability of stakeholders to detect anomalies and respond in a timely manner.

From a process perspective, Cold Chain operations generate both sensor data and event data. Sensor data derive from monitoring devices that capture environmental conditions, while event data are associated with the execution of operational tasks. The integration of these data sources is essential to enable a comprehensive understanding of process behavior, as it allows linking environmental conditions to specific operational activities. However, in many real-world scenarios, such integration remains limited, creating a gap between data availability and actionable knowledge.

Another critical aspect concerns regulatory compliance. Cold Chain operations are subject to strict requirements related to the monitoring and recording of environmental conditions at critical control points. The absence of continuous and reliable monitoring mechanisms may lead to non-compliance, exposing organizations to regulatory and reputational risks. In this context, the need for integrated solutions that combine data management, process monitoring, and analytical capabilities becomes particularly evident.

The Cold Chain scenario considered in this study is therefore used as a representative application context to illustrate the relevance and applicability of the proposed TRACING framework. Rather than focusing on quantitative performance outcomes, the analysis emphasizes the structural characteristics of the process and the challenges associated with data integration, coordination, and governance in distributed environments.

From a regulatory perspective, Cold Chain operations are subject to strict requirements related to food safety, traceability, and environmental control. International standards and regulatory frameworks, such as HACCP (Hazard Analysis and Critical Control Points), ISO 22000 for food safety management systems, and European regulations on food traceability (e.g., Regulation (EC) No 178/2002), impose obligations regarding the monitoring and recording of critical parameters throughout the supply chain. These frameworks require the identification of critical control points, continuous monitoring of environmental conditions, and the availability of auditable records. In this context, the integration of data and process governance, as enabled by the TRACING framework, directly supports compliance by ensuring data consistency, traceability, and accountability across all stages of the Cold Chain.

4 The TRACING framework

The TRACING framework is designed as a socio-technical artifact aimed at enabling governance mechanisms in Cold Chain environments through the integration of data management, process monitoring, and advanced analytics. The framework addresses the limitations identified in the previous sections by providing a unified architecture that links data flows, process execution, and analytical capabilities within a coherent system.

The TRACING framework is structured into main components: Data Governance, Process Governance, and Data Analytics. These components interact within a modular and scalable environment and are supported by an Event Driven Architecture, which enables interoperability among heterogeneous systems and supports real-time data processing.

The Data Governance component is responsible for the collection, ingestion, validation, and quality assessment of data generated throughout the Cold Chain, ensuring data reliability and supporting decision-making processes through clearly defined governance mechanisms (Khatri and Brown, 2010; Otto, 2011; Weber et al., 2009). Data are acquired from multiple sources, including sensors and operational systems, enabling continuous monitoring of environmental conditions through IoT-based infrastructures (Atzori et al., 2010; Ben-Daya et al., 2019; Verdouw et al., 2016). Data quality mechanisms ensure consistency, completeness, and reliability, enabling the use of trustworthy data for subsequent analysis.

The Process Governance component enables the modeling and monitoring of operational workflows. Based on Business Process Management principles (Dumas et al., 2013), processes are represented as structured sequences of activities, with clearly defined roles and responsibilities. Workflow monitoring tools allow stakeholders to visualize process execution and identify deviations, while rule-based mechanisms support the generation of alerts and corrective actions.

The Data Analytics component integrates advanced analytical techniques aimed at extracting actionable insights from operational data, particularly through the use of Process Mining methods for process discovery,

conformance checking, and performance analysis (van der Aalst, 2016; van der Aalst et al., 2012; Rojas et al., 2016). These techniques enable the reconstruction of actual process flows, the identification of deviations from expected behaviors, and the evaluation of performance indicators such as delays and rework activities.

The Event Driven Architecture enables real-time communication and coordination among system components. Through an event-based model, the framework supports asynchronous data exchange, ensuring scalability and responsiveness. Events generated by sensors or process activities trigger automated responses, such as alerts and notifications, allowing stakeholders to react promptly to changes in operational conditions.

The integration of these components enables the transformation of raw data into structured knowledge, supporting decision-making and governance. By linking data generation, process execution, and analytical interpretation, TRACING provides a comprehensive and dynamic view of Cold Chain operations, overcoming the fragmentation and limitations of traditional monitoring systems.

To provide a more operational and implementation-oriented representation of the framework, the components described above are further articulated into a layered architecture, shown in Figure 1, which details their functionalities and interactions within the technology platform.

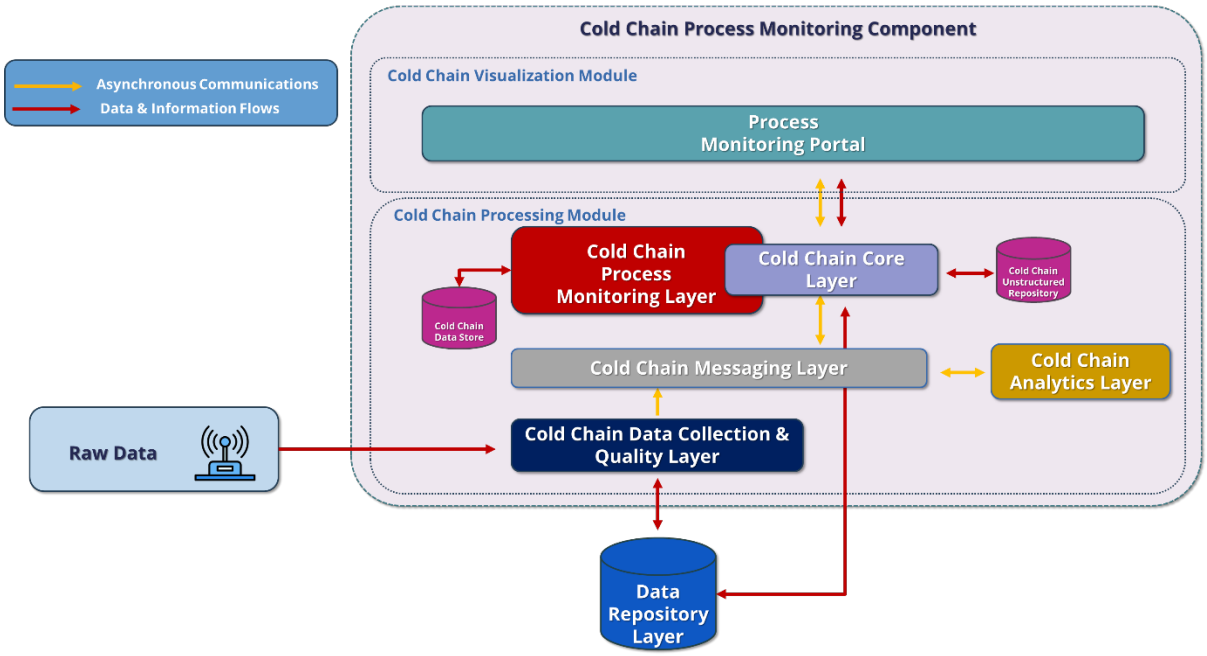

Figure 1: Architecture of the enabling technology platform

5 Results

The platform was applied to a real-world use case at Interfrutta Srl Fatano 1880, a company managing, among others, the maturation and distribution of climacteric fruits. The case demonstrated the capability of TRACING to support controlled maturation cycles by monitoring key variables and providing actionable alerts to prevent spoilage or suboptimal product quality. While the study does not empirically assess governance outcomes, it illustrates how TRACING structures information flows to enable mechanisms such as accountability through data provenance, coordination through process modeling, auditability through event logging, and transparency through shared dashboards. These elements collectively create conditions necessary for transforming raw IoT data into intelligent knowledge usable across networked actors in the Cold Chain.

The process under analysis concerns the ripening operations related to use case. After verifying transport conditions through the analysis of recorded temperature data, the lots of bananas are identified in the company's information systems and sorted according to orders, then addressed either to the ripening phase or to storage. In both cases, they are placed in temperature-controlled rooms: storage is temporary process, while ripening is a process that evolves over time and is managed in a controlled manner throughout all its stages.

During the process, data related to the setpoint temperature values defined during both the ripening and storage phases, the monitored temperature values, and variables related to ethylene emission or air extraction from the chambers are stored within the information systems and converted into log files. Process Mining techniques are applied to these log files.

Process Discovery allows to obtain an initial model on which to analyze performance, as shown in Figure 2. In particular, the focus is on calculating rework for each activity in the ripening process in order to identify potential bottlenecks. Figure 2 reports the number of instances in which activities are reworked more than twice.

ACTIVITY	REWORK
HEATING	9
OPENING RIPINING CHAMBER	16
AIR EXTRACTION	33
ETYLENE EMISSION	8
AIR VALVE CLOSURE	15

Figure 2: Performance analysis highlighting rework activities

Subsequently, process variants that lead to bottlenecks are removed, and the resulting model is the one shown in Figure 3, obtained by reapplying the Discovery algorithm, Inductive Miner (Leemans et al., 2013), to the filtered log.

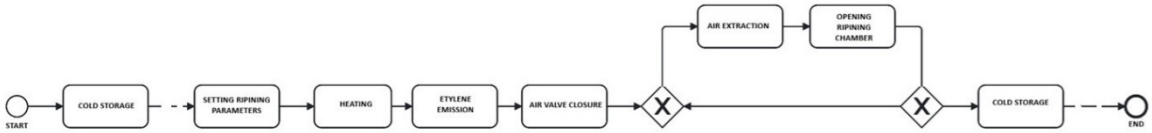

Figure 3: Process Model calculated by Process Discovery algorithm

The validity of the model obtained for the process under consideration is assessed through the application of the Conformance Checking algorithm, specifically Alignment (Van Zelst et al, 2020), which highlights deviations of subsequent acquired log files from the derived process model by computing metrics such as fitness, precision, generalization, and simplicity (Figure 4).

Average Fitness	0.958
Precision	0.561
Generalization	0.778
Simplicity	0.746

Figure 4: Calculated metrics by the Conformance Checking

It can be observed that the model is quite accurate, as the fitness is high, with a moderate level of precision since the model accounts for additional behaviors that are not always present in the real log. Furthermore, it is not rigid, as it shows good generalization, and it is very simple.

6 Enabling Governance Mechanisms

The TRACING framework enables governance mechanisms by structuring the interaction between data, processes, and analytical capabilities. In complex environments such as the Cold Chain, governance emerges from the ability to ensure visibility, coordination, and accountability across distributed actors.

A first key mechanism is transparency, which refers to the ability of stakeholders to access and interpret relevant information regarding process execution and environmental conditions. By integrating data collection and centralized data management, the framework ensures continuous availability of information, reducing uncertainty and enabling informed decision-making.

Traceability is another fundamental mechanism, allowing the tracking of products and processes across the entire supply chain. By linking sensor data with event logs, TRACING enables the reconstruction of process histories, supporting both operational monitoring and retrospective analysis (Aung and Chang, 2014).

Accountability is supported through the explicit representation of roles, responsibilities, and activities within workflows. The alignment between process execution and data records enables the identification of actions performed by specific actors, enhancing responsibility attribution and supporting performance evaluation.

The framework also supports auditability, enabling the reconstruction and verification of past operations. The systematic collection of data and events creates auditable records that facilitate compliance with regulatory requirements and quality standards.

Coordination among actors is enhanced through the event-driven architecture, which supports real-time communication and synchronization of activities. By enabling timely responses to process deviations, the framework improves operational efficiency and reduces risks associated with delays and errors.

This contribution is particularly relevant within the Knowledge Management domain, as it demonstrates how digital infrastructures can support the transformation of data into organizational knowledge through processes of knowledge creation and sharing (Nonaka, 1994; Alavi and Leidner, 2001; Davenport and Prusak, 1998).

By structuring and contextualizing data within process execution, TRACING enables the generation of actionable insights that support decision-making and continuous improvement.

7 Discussion

The TRACING framework contributes to bridging the gap between technological infrastructures and governance-oriented approaches in supply chain management. By integrating data, processes, and analytics within a unified system, the framework enables a more comprehensive understanding of complex operations and supports the emergence of governance mechanisms.

From a theoretical perspective, the framework extends existing research on IoT and Business Process Management by explicitly linking data flows and process execution. This integration enables the transformation of data into knowledge, supporting decision-making and organizational learning.

From a practical perspective, TRACING provides a structured approach for designing digital solutions in Cold Chain environments. The framework enhances visibility, supports real-time decision-making, and improves coordination among actors.

8 Conclusions and Future Research

This paper presented TRACING (innovaTive AI fRAmework for Cold chaIN Governance), a design-oriented framework aimed at enabling governance mechanisms in Cold Chain networks through the integration of data management, process monitoring, and advanced analytics. Grounded in a Design Science Research approach, the study conceptualizes TRACING as a socio-technical artifact capable of addressing the complexity of Cold Chain environments, which are characterized by distributed actors, strict environmental constraints, and the need for real-time decision-making.

The proposed framework contributes to the literature by bridging the gap between data-centric technological infrastructures and governance-oriented approaches in supply chain management. By integrating Data Governance, Process Governance, and analytical components within a unified architecture, TRACING enables key governance mechanisms, including transparency, traceability, accountability, auditability, and coordination. These mechanisms are essential for improving visibility, supporting compliance, and enhancing decision-making in complex and dynamic operational contexts.

A key contribution of this work lies in the structured integration of heterogeneous components, which allows transforming raw data into actionable knowledge. Through the alignment of data flows and process execution, the framework supports a more comprehensive understanding of Cold Chain operations and facilitates the identification of inefficiencies and risks. In this sense, TRACING provides a conceptual foundation for the development of digital solutions that go beyond simple monitoring, enabling knowledge-driven governance in distributed supply chain environments.

From a practical perspective, the framework offers guidance for the design and implementation of integrated platforms capable of supporting real-time monitoring, coordination among actors, and informed decision-making. The modular and scalable nature of the architecture makes it adaptable to different organizational settings and potentially applicable beyond the specific Cold Chain scenario considered in this study.

While the framework is designed to be generalizable, its applicability to other domains requires further investigation.

Future research should focus on exploring the extension of TRACING to other types of supply chains or industrial contexts, as well as the integration of advanced analytical techniques, such as predictive and prescriptive models, to enhance its decision-support capabilities. Finally, the role of organizational and institutional factors, including data governance policies, user adoption, and inter-organizational collaboration, should be investigated to better understand the conditions required for successful implementation.

9 Acknowledgements

The research was part of the research project titled “TRACING - innovaTive AI fRAmework for Cold chaIN Governance”, financed by the cascading call for proposals for research activities conducted by companies,

including in collaboration with public universities, legally recognized private universities accredited by the Ministry of Education, Universities and Research (MUR), and public research institutions, within the scope of Spoke 3 "FOOD SAFETY OF TRADITIONAL AND NOVEL FOODS" of the project "ON Foods (Research and Innovation Network on Food and Nutrition Sustainability, Safety, and Security – Working ON Foods)".

From Frugal to Reverse Innovation: A Knowledge-Based Framework for Upstream Diffusion

Faisal Rasool[1], Gustavo Morales-Alonso[2], Vicky O´Rourke[1], Antonio Hidalgo[2]
[1] Atlantic Technological University, Letterkenny, Ireland.
[2] Universidad Politécnica de Madrid, Madrid, Spain.

Abstract

Frugal innovation (FI) has emerged as a strategic response to resource constraints, enabling firms to develop cost-effective solutions that address essential needs in emerging markets. At the same time, reverse innovation (RI) has gained increasing attention as a mechanism through which such solutions diffuse into developed economies. Despite their conceptual proximity, existing literature has largely treated FI and RI as separate domains, leaving underexplored the mechanisms that enable frugal innovations to transition successfully across contexts. This study addresses this gap, drawing on the knowledge-based view (KBV) and dynamic capabilities (DC) perspective. We conceptualise the transition from FI to RI as dependent on two sequential mechanisms: knowledge transformation (transfer readiness) and market validation and translation. A five stages framework is proposed, which allows reframing reverse innovation as a knowledge transformation and validation challenge rather than merely a cost or design issue. A clear processual link between FI capabilities and RI outcomes is established, while introducing the concept of transfer readiness as a key construct explaining why some innovations remain locally embedded while others achieve cross-context diffusion. At the same time, institutional and ecosystem-level factors are integrated into the explanation of adoption outcomes, providing a structured and nuanced understanding of upstream diffusion, offering implications for both theory and practice, and opening avenues for future empirical research.

Keywords: Frugal Innovation, Reverse Innovation, Knowledge-Based View, Dynamic Capabilities, Upstream Diffusion.

Paper type: Academic Research Paper

1 Introduction

Growing economic pressures, sustainability goals, and widening inequalities have forced organizations to deliver more value with fewer resources. While such pressures have historically been associated with emerging economies, they are increasingly evident in advanced markets (Otto, 2025). Within this context, frugal innovation (FI) has emerged as a distinct approach to innovation, characterized by the development of solutions that meet essential performance requirements while significantly reducing cost and resource intensity (Weyrauch & Herstatt, 2017; Zeschky et al., 2011). FI is characterized by its development in emerging markets. For this reason, upstream diffusion requires not only technical adaptation and favorable market conditions but also the restructuring and validation of knowledge.

Additionally, the concept of reverse innovation (RI) is increasingly gaining recognition in explaining how innovations developed in resource-constrained environments diffuse into advanced markets (Govindarajan et al., 2022; Simula et al., 2015). Furthermore, existing research has largely treated FI and RI as related but distinct domains (Rasool et al., 2026). FI literature explains how innovations emerge under constraints (Brem et al., 2020; Hossain, 2021), whereas RI research focuses on diffusion outcomes and strategic implications (Hadengue et al., 2017; Simula et al., 2015). However, the mechanisms that enable frugal innovations to be transferred and adopted in developed markets remain underdeveloped. Recent work suggests that this gap cannot be explained solely by cost or design considerations. Instead, it reflects deeper challenges related to knowledge transformation and legitimacy (Fisac-Garcia et al., 2025).

Although FI and RI are conceptually related (Rasool et al., 2026), the literature still lacks a clear explanation of the mechanisms that enable constraint-born solutions to become transferable and adoptable in developed markets. Many frugal innovations fail to achieve adoption beyond their original context, despite offering clear economic advantages. Previous research has argued that both internal and external factors play a critical role in this transfer and adoption (Hadengue et al., 2017). However, have failed to provide a unified framework for transferring FI developed in developing economies to developed economies.

This study fills this gap by creating a knowledge-based conceptual framework that describes upstream diffusion as a multi-stage process. Using the knowledge-based view (KBV) and dynamic capabilities (DC), we propose that the shift from FI to RI relies on two sequential mechanisms: knowledge transformation (transfer

readiness) and market validation and translation. These mechanisms clarify how locally embedded innovations become transferable, credible, and adoptable in new environments. Accordingly, the study addresses the research question: *How do frugal innovations transition from resource-constrained contexts to adoption in developed markets?* By integrating FI and RI through a process-oriented perspective, this study contributes to the literature by offering a structured explanation of upstream diffusion and identifying the conditions under which it succeeds or fails.

The paper is organized as follows. After this introduction, a review of prior research is summarized in section 2. Section 3 describes the framework development, and section 4 presents an example to illustrate how the proposed framework operates in practice. Finally, section 5 presents the main conclusions and limitations of the study.

2 Theoretical Background

2.1 Frugal Innovation as a Capability

Early work on FI emphasised affordability and "good-enough" performance (Zeschky et al., 2011). Neverthless more recent research, such as by Rossetto et al. (2023) and López-Sánchez & Santos-Vijande (2022) suggests that FI reflects a distinct way of organising innovation activities rather than merely an outcome. Building on this shift, FI can be more accurately conceptualised as a capability, defined by a set of organisational routines that enable firms to systematically innovate under resource constraints (Hossain, 2020; Rosca et al., 2017). At its core, FI capability comprises several interrelated routines. First, constraint-driven problem framing shapes how firms define innovation challenges under scarcity. Rather than starting from technological possibilities, firms begin with limitations such as affordability thresholds and infrastructure gaps, prioritizing essential functionality over feature maximization (Agarwal & Brem, 2017; López-Sánchez & Santos-Vijande, 2022). Second, resource reconfiguration enables firms to construct solutions under constraint by recombining available components, knowledge, and capabilities in novel ways (Cai et al., 2019). This allows firms to translate constraint-defined problems into workable solutions despite limited resources. Third, iterative and feedback-driven development replaces linear innovation processes (Agarwal et al., 2021). FI are often developed through rapid prototyping, experimentation, and continuous user feedback, allowing firms to refine solutions in real-world conditions (Brem et al., 2020; Hossain, 2020). This iterative logic prioritises functionality and usability over technical perfection. Finally, user-centric simplification ensures that solutions focus on essential needs rather than feature complexity (Fisac-Garcia et al., 2025; Rasool et al., 2026). By eliminating non-critical attributes and emphasizing accessibility, firms create offerings that are both affordable and contextually appropriate (Weyrauch & Herstatt, 2017). As a result, these routines offer a capability that enables firms to generate viable solutions under constraints.

2.2 Reverse Innovation and the Challenge of Upstream Diffusion

Upstream diffusion of FIs into developed markets remains limited and inconsistent, despite their effectiveness in resource-constrained contexts (Agarwal & Brem, 2017; Cunha et al., 2014; Fischer et al., 2021). The difficulty lies not FI ability to provide solutions, but in its ability to function and be accepted within fundamentally different context. At the core of this challenge is a contextual mismatch between origin and target markets (Bhatti et al., 2017; Fischer et al., 2021).

FI are typically optimised for affordability, flexibility, and minimal infrastructure dependence. However, innovations envisioned in developed markets are characterised by formal regulatory systems, standardised processes, higher expectations of reliability, and complex procurement structures (Cunha et al., 2014; Von Zedtwitz et al., 2015). As a result, FIs that perform effectively in developing economies may not meet the technical, institutional, or perceptual requirements of higher income markets. Addressing this mismatch requires more than simple diffusion. Several activities and actions need to be taken before the innovation can be implemented in developed economies (Fischer et al., 2021). This may include meeting regulatory standards (Blind, 2016) and customer expectations of quality and functionality (Bhatti et al., 2017). As reported by Wang & Wang (2024) that often fall victim of perception of low quality even when they are technically adequate and perform necessary functions reliably and consistently.

To no surprise, empirical evidence suggests that many FIs fail to achieve upstream diffusion (Fischer et al., 2021). However, this failure is rarely due to a lack of cost advantage or functional performance (Bhatti et al., 2017). Instead, is often a result of firm's inability to bridge the gap between locally embedded innovation practices and globally standardized expectations (Fischer et al., 2021). To address this, firms need to develop

routines and processes that can translate the built-in tacit embedded knowledge in FI into regular innovation targeted towards developed economies. These routines will shift from viewing RI as a diffusion outcome to understanding it as a process shaped by knowledge transformation and contextual validation.

2.3 Knowledge-Based and Dynamic Capabilities Perspectives

The knowledge-based view (KBV) provides a useful starting point by viewing firms in terms of the knowledge they develop and use, and by emphasizing how this knowledge is structured, integrated, and made transferable across contexts . FIs are not merely products or services but are built on knowledge shaped by local constraints, experiential learning, and context-specific problem-solving processes (Fisac-Garcia et al., 2025; Rasool et al., 2026). A key implication of this view is that not all knowledge is equally transferable (Nair et al., 2015). FIs often rely on tacit, informal, and context-dependent knowledge, which is difficult to articulate, codify, and replicate (Felin & Hesterly, 2007; Nonaka & Takeuchi, 1995). While such characteristics enable flexibility and responsiveness, they also limit the extent to which innovations can be understood, evaluated, and replicated beyond their original environment. As a result, FIs that perform effectively in one context may struggle to travel across different institutional and market settings.

This creates a fundamental tension between local effectiveness and cross-context transferability. For RI to occur, the knowledge underlying frugal solutions must be decoupled from its original context and restructured into a form that can be understood, evaluated, and applied in different environments (Felin et al., 2012). However, KBV alone does not fully explain how this transformation takes place. While it highlights how knowledge is structured and embedded, it offers limited insight into how firms actively reconfigure knowledge in response to new demands. To address this limitation, we draw on the Dynamic Capabilities (DC) perspective, which focuses on the processes through which firms sense opportunities, seize them, and reconfigure their resource base in changing environments (Helfat, 2010; Teece, 2007). DCs are particularly relevant, as they explain how firms reconfigure knowledge and capabilities to align with new environments (Helfat, 2010). Specifically, DC enable two critical processes that are central to upstream diffusion. First, firms must develop the ability to transform knowledge by converting tacit, context-specific insights into explicit, structured, and transferable forms (Felin et al., 2012). This involves structuring knowledge so that innovations can be replicated and evaluated beyond their original context. This transformation is not automatic but requires deliberate effort to externalize and organize knowledge in ways that align with formal systems and standards (Nonaka et al., 2000). Second, firms must reconfigure innovations to achieve contextual alignment, ensuring compatibility with regulatory requirements, user expectations, and institutional structures in developed markets (Bhatti et al., 2017). This includes adapting product features, interfaces, and delivery models, as well as generating evidence to support credibility and acceptance.

Building on this, KBV and DC can explain why FIs are difficult to transfer and how firms address this challenge through knowledge transformation and reconfiguration. However, the specific mechanisms linking FI capability to RI outcomes remain under-specified (Rasool et al., 2026). To address this gap, this study develops a mechanism-based framework that conceptualises upstream diffusion as a sequential process involving two stages: knowledge transformation (transfer readiness) and market validation and translation.

3 Framework Development: A Knowledge-Based Mechanism for Upstream Diffusion

Building on the arguments presented in the previous section, this study conceptualizes upstream diffusion as a sequential and mechanism-driven process linking FI capability to RI outcomes. Rather than viewing RI as a simple diffusion outcome, the framework explains it as the result of two critical transformations: knowledge transformation and contextual validation. The framework consists of five stages, connected by two bridging mechanisms, presented in Figure 1. Each stage represents a distinct phase in the evolution of FIs, while the bridging mechanisms explain how innovations move from local embeddedness to global adoption. Importantly, the process is shaped by stage-specific boundary conditions, which influence both the feasibility and effectiveness of these transformations.

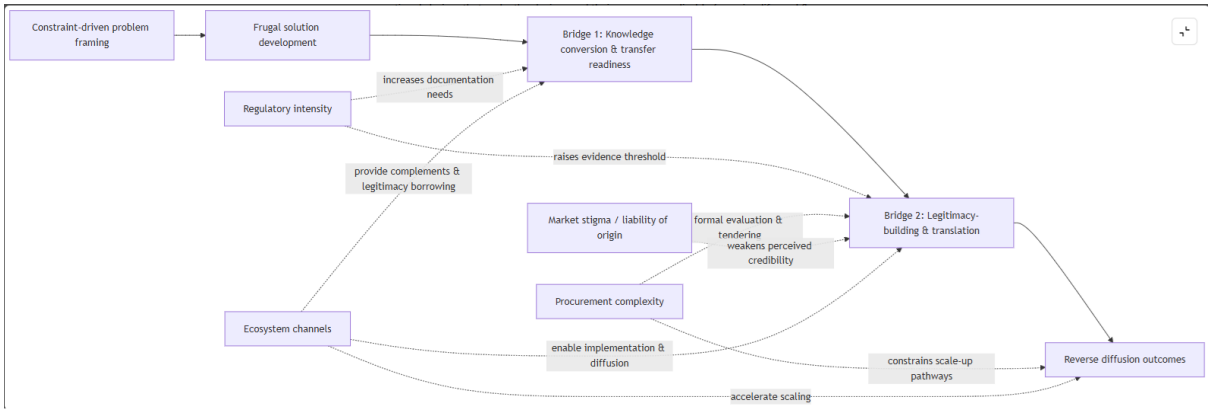

Figure 1: Framework for upstream diffusion

3.1 Stage 1: Constraint-Driven Problem Framing

The process begins with constraint-driven problem framing, where firms define innovation challenges under conditions of scarcity. As discussed earlier, FI capability is rooted in treating constraints such as affordability thresholds, infrastructural limitations, and resource scarcity as design parameters rather than barriers (Agarwal & Brem, 2017; López-Sánchez & Santos-Vijande, 2022). This stage determines the innovation's value logic. Instead of optimizing for performance maximization, firms prioritize essential functionality, accessibility, and cost efficiency. As a result, the innovation is fundamentally shaped by local conditions, embedding assumptions about users, usage environments, and resource availability (Bhatti et al., 2017). However, this localized problem framing introduces the first structural limitation for upstream diffusion. The innovation is not only designed differently but also grounded in context-specific interpretations of value and functionality, which may not align with expectations in developed markets.

3.2 Stage 2: Frugal Solution Development

In the second stage, firms develop solutions by applying FI capability. This involves coordinated routines such as resource reconfiguration, iterative prototyping, and user-centric simplification (Cai et al., 2019; Hossain, 2020). The resulting solution achieves acceptable performance at significantly lower cost, making it highly effective within its original context. However, consistent with the KBV, the knowledge underlying this solution remains largely tacit, experiential, and context dependent (Fisac-Garcia et al., 2025; Rasool et al., 2026). Design decisions are often guided by informal practices and iterative experimentation rather than formalized processes (Felin et al., 2012). At this stage, the innovation is functional but not yet transferable. It lacks the explicit structure required for replication, evaluation, and adoption in different environments. This creates a critical gap between the generation of frugal solutions and their potential for upstream diffusion.

3.3 Bridge 1: Knowledge Transformation (Transfer Readiness)

The first step in moving from locally embedded innovation to a transferable solution is knowledge transformation, referred to here as transfer readiness. Transfer readiness captures how far the knowledge underlying an innovation is structured and made transferable across contexts. It involves turning tacit, context-specific knowledge into explicit and usable forms that can be understood and evaluated beyond the original setting (Felin et al., 2012). From a KBV perspective, this stage represents the externalisation and structuring of knowledge, enabling it to be communicated and evaluated beyond its original context (Felin et al., 2012). From a DCs perspective, it reflects the firm's ability to reconfigure internal routines to align with external requirements (Teece, 2007). This mechanism is a necessary condition for upstream diffusion.

Without transfer readiness, innovations remain tied to their original context, as external actors cannot assess or replicate them. Beyond its core function, knowledge transformation is significantly shaped by regulatory requirements, which determines the level of codification and formalisation required. In highly regulated environments, firms must convert informal and experiential knowledge into externally auditable formats (Blind, 2016), such as technical documentation, compliance reports, and testing protocols. This increases documentation requirements and forces firms to systematically structure their knowledge. As a result, transfer readiness becomes both a technical and institutional construct, shaped by external expectations (Blind, 2016).

3.4 Bridge 2: Legitimacy-Building and Translation

While transfer readiness enables movement across contexts, it does not ensure adoption (Fischer et al., 2021). This stage addresses the challenge of acceptance in developed markets. Legitimacy-building focuses on establishing credibility and reducing uncertainty. Innovations originating from resource-constrained contexts often face scepticism due to perceived quality risks and liability of origin (Bhatti et al., 2017). This creates a credibility gap that must be addressed through activities such as testing, certification, and endorsement (Rao, 1994). Translation, in turn, involves adapting the innovation to align with developed-market expectations. This includes modifying product features, ensuring regulatory compliance, and integrating with existing systems and practices.

The effectiveness of this stage is shaped by market stigma and procurement complexity. Market stigma influences how innovations are perceived, often leading to lower initial credibility (Bhatti et al., 2017). This effect is amplified in formal evaluation settings, where unfamiliar design logics may be interpreted as indicators of lower quality (Fischer et al., 2021). Procurement complexity further constrains adoption by imposing structured evaluation processes that favour established solutions (Uyarra et al., 2014). Firms must therefore ensure that innovations not only perform effectively but also fit within predefined evaluation frameworks. In this context, ecosystem channels play a critical enabling role. Through partnerships with established actors, firms can access complementary capabilities and leverage existing reputational capital, effectively engaging in legitimacy borrowing. This reduces uncertainty and enhances acceptance.

3.5 Stage 5: Reverse Diffusion Outcomes

The final stage focuses on the adoption and scaling of innovations in developed markets, which are shaped by the interaction between ecosystem channels and institutional structures. Ecosystem channels enable implementation and diffusion by providing access to distribution networks, complementary assets, and local market knowledge. They also accelerate scaling by enabling firms to leverage existing infrastructure rather than build new infrastructure (Kapoor, 2018). However, these enabling effects are constrained by procurement complexity, which can limit scale-up pathways (Uyarra et al., 2014). In highly structured systems, even validated innovations may struggle to achieve widespread adoption if they do not align with institutional purchasing mechanisms. As a result, reverse diffusion outcomes depend not only on innovation characteristics but on the alignment between ecosystem support and institutional conditions. Table 1 highlights the stage-wise conditions and failure points in upstream Diffusion.

Table 1**:** Stage-wise conditions and failure points in upstream diffusion

Stage	Key Requirement	If Not Achieved	Outcome
Stage 1–2: Frugal Innovation Development	Functional solution under constraints	Problem–solution misfit	Innovation fails locally
Bridge 1: Knowledge Transformation (Transfer Readiness)	Knowledge structured and transferable	Knowledge remains tacit and embedded	Innovation cannot be transferred
Bridge 2: Market Validation and Translation	Credibility and contextual alignment	Credibility gap or misalignment	Innovation not adopted
Stage 5: Diffusion and Scaling	Alignment with ecosystem and institutions	Structural barriers to scaling	Limited or no diffusion

4 Illustrative Example

To demonstrate how the proposed framework operates in practice, this section presents a stylised illustration based on the development and diffusion of a low-cost portable medical device. Figure 2 summarizes the illustrative example application process. The example is not intended as an empirical case but as a theory-driven application that maps the framework's stages and mechanisms onto a realistic innovation trajectory.

Problem Framing: The innovation originates in a resource-constrained healthcare environment, where access to diagnostic equipment is limited due to high costs, unreliable infrastructure, and a shortage of trained personnel. In this context, the problem is defined in terms of providing accessible and affordable functionality rather than maximizing technical performance. As a result, the innovation team prioritizes portability, low power consumption, and ease of use over advanced features. This reflects a constraint-driven approach, where affordability and usability shape the innovation space.

Solution Development: Building on this framing, the firm develops a portable diagnostic device using simplified components and locally available resources. The development process is iterative, relying on rapid

prototyping and continuous feedback from frontline healthcare workers. The resulting device is cost-effective, robust, and functional within its original context. However, its design logic remains largely implicit, with limited formal documentation or standardization. At this stage, the innovation is effective locally but lacks the structure required for broader diffusion.

Knowledge Transformation: To enter developed markets, the firm must transform the knowledge underlying the device into a form that can be transferred. This involves structuring design and production knowledge so that it can be understood and evaluated beyond the original context. Regulatory requirements play a key role at this stage, as the firm must provide evidence on safety, reliability, and performance. Informal design decisions are translated into formal specifications, and iterative testing is reframed as structured validation. Through these efforts, the device achieves transfer readiness, making it technically transferable across contexts.

Validation and Translation: Despite achieving transfer readiness, the device faces skepticism in developed markets due to its origin and unconventional design. Healthcare providers and regulators question its reliability, creating a credibility gap. To address this, the firm undertakes validation activities such as clinical testing, certification, and pilot implementations (Rao, 1994). At the same time, the device is adapted to align with local expectations, including interface design and system compatibility. Procurement systems pose an additional challenge. Hospitals and public health institutions rely on formal evaluation processes that prioritize standardization and proven track records. These systems may initially weaken perceived credibility, as the device does not fit an established category. To address this, the firm collaborates with established distributors and healthcare allies, leveraging ecosystem channels for access. These partnerships lend credibility, build trust, and ease entry into developed markets.

Diffusion and Scaling: Following successful validation, the device begins to diffuse within cost-sensitive segments of the developed market. Partnerships with established actors provide access to distribution networks and institutional channels, facilitating implementation. These partnerships also support scaling by allowing the firm to leverage existing infrastructure. However, diffusion remains constrained by procurement structures, which limit adoption in more formalized settings. Over time, the device achieves broader uptake where its value proposition aligns with cost and accessibility needs.

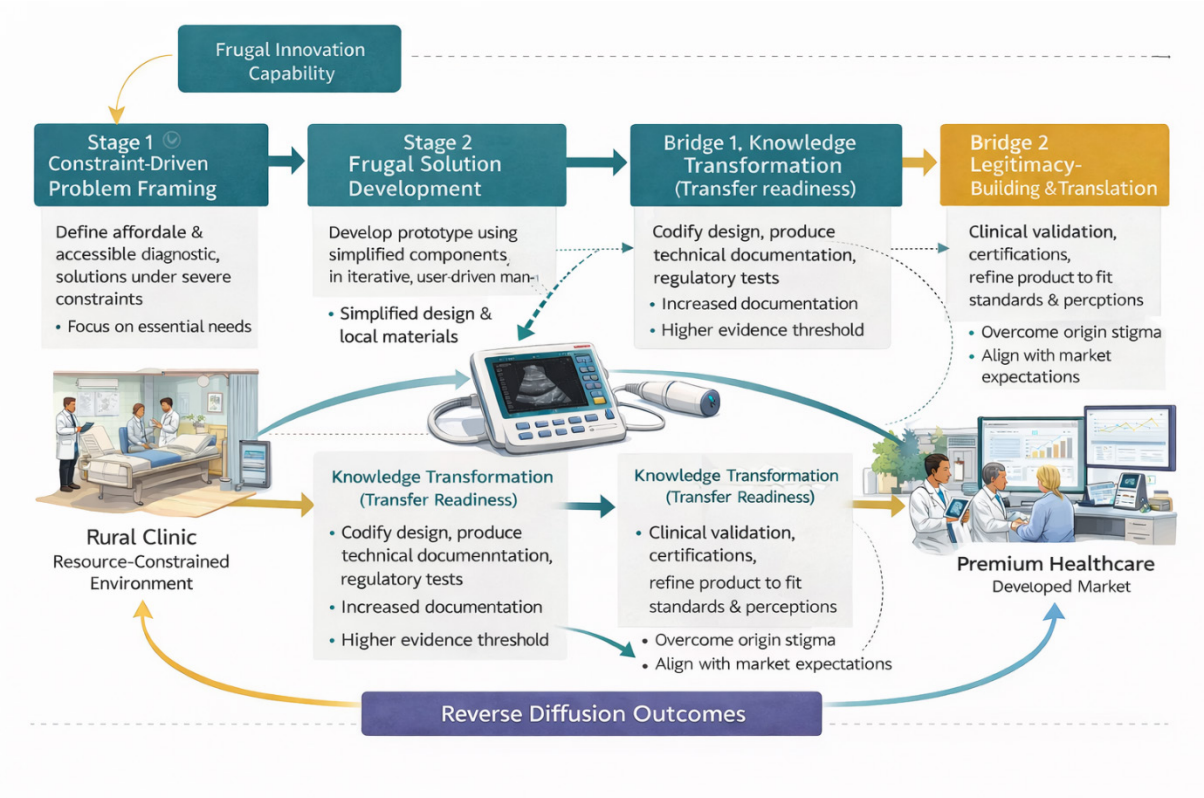

Figure 2: Illustrative example of framework application

5 Conclusions, Implications, and Limitations

This study set out to explain why frugal innovations, despite their demonstrated effectiveness in resource-constrained environments, often fail to achieve adoption in developed markets. By integrating insights from frugal innovation and reverse innovation literatures and grounding the analysis in the knowledge-based view and dynamic capabilities perspective, the study develops a mechanism-based explanation of upstream diffusion. The findings shift the focus from viewing reverse innovation as a diffusion outcome to understanding it as a conditional and staged transformation process, shaped by the structure, transferability, and legitimacy of knowledge.

5.1 Theoretical Contribution

This study makes several contributions to the literature. First, it establishes a clear link between FI capability and RI outcomes. While prior research has examined these domains separately, the connection between them has remained largely implicit. By conceptualising upstream diffusion as a staged process, the study provides a structured explanation of how innovations move from locally embedded solutions to adoption in developed markets. Second, the study reframes RI as a knowledge transformation and validation problem rather than a purely economic or technological one. While cost advantage and market fit remain important, the framework highlights that the primary barrier lies in the nature of the knowledge embedded within frugal innovations. This knowledge is often tacit, context-specific, and embedded in informal practices, which limits its transferability. As a result, successful diffusion depends on the ability to transform this knowledge into structured, evaluable forms and to align it with new contexts. Third, the study introduces transfer readiness as a distinct construct capturing the outcome of knowledge transformation. Unlike related concepts such as absorptive capacity or modularity, transfer readiness focuses on the extent to which internally generated knowledge is structured for external evaluation and replication. Fourth, the study highlights the role of validation and institutional alignment in shaping adoption. Even when innovations are technically transferable, they may fail due to credibility gaps, market stigma, and procurement constraints.

By integrating these factors into a process framework, the study shows that adoption depends not only on technical performance but also on how innovations are evaluated within specific institutional contexts. Finally, the framework explains the heterogeneity observed in reverse innovation outcomes. Rather than attributing success or failure to inherent differences in innovation quality, the study shows that outcomes depend on how effectively firms navigate different stages of the process. Innovations may fail because they are not transferable, not accepted, or not scalable, depending on contextual conditions.

5.2 Implications for Theory and Policy

The findings have important implications for both managers and policymakers. For managers, the framework highlights that success in developed markets requires more than cost-efficient design. Firms must invest in structuring knowledge, generating credible evidence, and aligning innovations with institutional expectations. In particular, developing transfer-ready innovations should be treated as a deliberate capability rather than a by-product of development. Firms must also actively engage in validation and translation activities to ensure that innovations are both credible and contextually aligned.

For policymakers, the findings emphasise the role of regulatory and procurement systems in shaping innovation diffusion. While these systems are necessary for ensuring quality and accountability, excessive complexity can limit the adoption of new solutions. Simplifying certification processes, supporting pilot testing, and fostering collaboration between firms and institutional actors can facilitate the diffusion of frugal innovations in developed markets.

5.3. Limitations and Future Research

While this study offers a structured and mechanism-based explanation of upstream diffusion, several limitations should be acknowledged. First, the framework is conceptual in nature and has not been empirically tested. Although it is grounded in established theoretical perspectives and supported by a theory-driven illustrative example, the proposed relationships and mechanisms require validation through empirical research. Future studies could test the framework using qualitative case studies, longitudinal data, or mixed-method approaches to examine how frugal innovations evolve across different contexts. Second, the framework adopts a firm-level perspective, focusing on how organisations develop, transform, and adapt innovations. While this level of analysis is appropriate for examining capabilities and mechanisms, it may underrepresent broader system-level dynamics. Future research could extend the framework by incorporating ecosystem-level or

institutional perspectives, particularly to explore how policy environments, industry structures, and cross-border collaborations shape reverse innovation outcomes. Third, the concept of transfer readiness, introduced in this study, requires further refinement and operationalisation. While the framework conceptualises it as an outcome of knowledge transformation, additional work is needed to develop measurement approaches and empirical indicators. Future research could examine how transfer readiness varies across industries and how it interacts with other constructs such as absorptive capacity, modularity, or standardisation. Fourth, the framework focuses on a specific pathway of innovation flow from resource-constrained to developed markets. While this captures the essence of reverse innovation, it does not fully account for bidirectional or networked innovation processes, where knowledge flows across multiple contexts simultaneously. Future studies could explore how the proposed mechanisms operate in more complex, multi-directional innovation systems. Finally, while the framework incorporates key boundary conditions such as regulatory intensity, market stigma, procurement complexity, and ecosystem channels, these factors are treated at a conceptual level. Further research is needed to examine how these conditions vary across sectors and regions, and how their interactions influence different stages of the process. Despite these limitations, the framework provides a foundation for future research by offering a mechanism-based and process-oriented perspective on reverse innovation. By identifying key transformation stages and contextual influences, it opens avenues for both theoretical refinement and empirical investigation.

Knowledge Transfer and Innovation Spillovers in Aerospace

Antonio Limongiello, Andrea Tomo
University of Naples Federico II, Naples, Italy

Abstract

The Space Economy is one of the most strategic and innovative sectors of the 21st century, characterized by advanced technologies and new market opportunities (Yablonsky, 2018). Its value chain encompasses public and private actors, spanning upstream and downstream activities (Binci et al., 2022). This innovative environment provides a setting for analysing how knowledge generated in aerospace contexts can be transferred to other industries (Smith, 2013). In this sense, Knowledge Management (KM) provides both a process and an organisational perspective through which knowledge integration and transfer can be understood (Cristache et al., 2025). This paper aims to map the KM practices and innovation processes developed in the aerospace industry and to assess their applicability to other industries. Attention is devoted to the mechanisms through which scientific and technical knowledge is translated into innovations capable of generating market impact through new products, services or organisational models. The study adopts a systematic literature review based on the Web of Science database. The search query combined terms related to aerospace, knowledge management and knowledge transfer. The initial search identified 494 papers. After applying the filters "Article & Proceeding Papers", "Management & Business" and "English", the dataset was reduced to 97 publications. The PRISMA protocol ensured transparency and replicability. Papers were excluded when not aligned with KM or when knowledge was treated as a secondary element within engineering-oriented analyses. The final dataset consists of 57 papers. This study develops a framework for qualitative content analysis based on three dimensions (Snyder, 2019): object of transfer (knowledge, technologies, innovation processes), transfer mechanisms (human-relational, organisational, technological) and sectoral proximity (related, distant, unrelated). The objective is to: a) identify points of convergence between aerospace and other industries; b) classify the main strategies of KM (Ardito et al., 2021); c) provide an overview of good practices supporting learning and innovation dynamics across industries.

Keywords: Knowledge Management, Aerospace Industry, Knowledge Transfer, Cross-sector Spillovers, Innovation

Paper type: Academic Research Paper

1 Introduction

The aerospace industry is undergoing a major transformation from mission-oriented public programs toward a New Space Economy (NSE) shaped by commercial, entrepreneurial and multi-actor logics (Mazzucato & Robinson, 2018; Manotti et al., 2025). In this context, space technologies are increasingly viewed not only as strategic assets, but also as enabling platforms for new markets, industrial applications and cross-sector innovation. Such complexity also makes the aerospace industry a relevant setting for studying knowledge processes. In highly interdependent systems, innovation rarely depends on isolated inventions. It often emerges from the integration of distributed expertise, coordinated routines and cumulative learning across multiple organisations and project stages. These conditions make the management and transfer of knowledge particularly critical (Nonaka, 1994). The aerospace sector requires strong system integration capabilities, coordination across suppliers, cooperative R&D and the management of complex product architectures with many interdependent components (Kim et al., 2022). Collaboration networks are also hierarchical and asymmetric. This affects the distribution of innovation opportunities and access to strategic capabilities (Biggiero & Angelini, 2015). In addition, the innovative performance of space firms is influenced by cluster configuration, technological specialization and interactions with public and private actors in the ecosystem (Teirlinck & Khoshnevis, 2020). Existing studies have already examined important parts of this phenomenon. Some focus on innovation effects generated by public procurement and public-private collaboration. Others analyse inter-organisational transfer frameworks and mechanisms of knowledge movement within and across organisations (Battistella et al., 2016; Castelnovo et al., 2023; Argote et al., 2022). This study addresses the following research questions:

- ***RQ1.*** *What types of knowledge, technologies and innovation processes are transferred or implemented across aerospace and non-aerospace contexts?*
- ***RQ2.*** *Through which human, organisational, relational and technological mechanisms do transfer and implementation processes occur?*
- ***RQ3.*** *How does sectoral proximity shape the transferability and recombination of aerospace knowledge?*

- ***RQ4.*** *How do opportunities and threats associated with transfer and implementation processes affect innovation outcomes and new market applications?*

This study contributes to the knowledge transfer literature by integrating three dimensions (object, mechanism and sectoral proximity) into a unified analytical framework. While prior studies have typically examined these dimensions in isolation (Argote et al., 2022; Battistella et al., 2016; Alberti & Pizzurno, 2015), this research demonstrates that knowledge transfer processes are better understood as multidimensional configurations emerging from their interaction.

2 Theoretical Background

From a KM perspective, competitive advantage does not depend solely on the possession of technological assets but also on the organisational capability to create, integrate, share and apply knowledge effectively across different contexts and levels of analysis (Nonaka, 1994; Argote et al., 2022). The aerospace sector represents a particularly relevant empirical setting because it combines technological complexity, high reliability requirements, cumulative learning processes and advanced problem-solving routines, making it a fertile context for observing how valuable knowledge is generated and redeployed beyond its original boundaries (Teissandier et al., 2026; Wittenborg et al., 2025). Two core concepts underpin this study: knowledge transfer and knowledge implementation (Nonaka, 1994; Argote & Ingram, 2000; Szulanski, 1996). These concepts are analytically distinct yet strongly interconnected within organisational learning and innovation processes. Existing knowledge assets become strategically relevant when organisations implement, transfer and redeploy them across organisational and sectoral boundaries (Okwechime, 2025; Argote & Ingram, 2000). Implementation may involve the replication, adaptation and enactment of routines across organisational contexts (D'Adderio, 2014). The effectiveness of implementation depends on the degree of alignment between new routines and the recipient organisational context (Bertels et al., 2016). Consistent with broader knowledge-to-action perspectives, implementation is strongly influenced by prior problem framing, contextual analysis and the selection of appropriate transfer interventions rather than by adoption alone (Ward et al., 2009). Knowledge transfer is commonly defined as the process through which one organisational unit is influenced by the experience of another (Argote & Ingram, 2000). From an inter-organisational perspective, transfer can be understood as an intentional and goal-oriented interaction between distinct entities through which technological and organisational knowledge is exchanged, recombined or expanded (Battistella et al., 2016).

3 Research Method

This article proposes a systematic literature review using Web of Science. The initial search yielded 494 papers, of which 397 articles were excluded after the application of the following filters: ("Articles & Proceeding Papers", "Management & Business", "English").

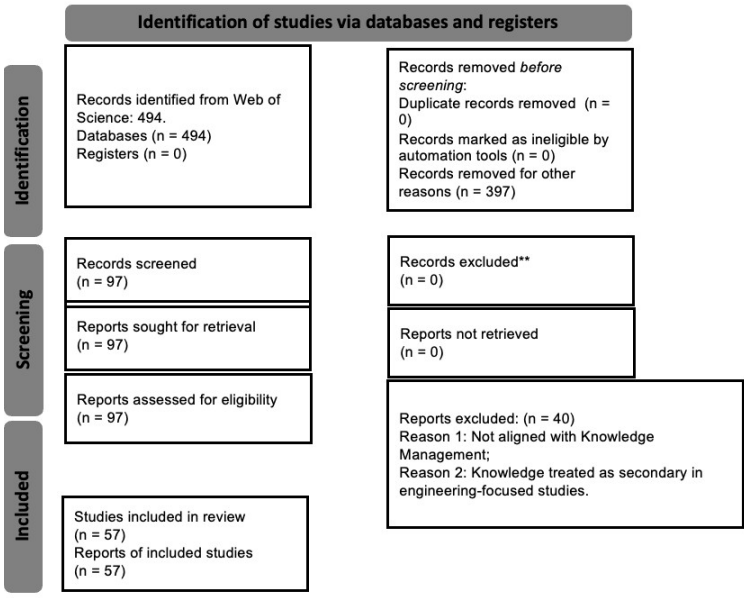

Figure 1. Identification of studies
Source: Page et al., 2021.

In methodological terms, the study follows the logic proposed by Snyder (2019), according to which literature reviews should not only collect prior evidence but also synthesize fragmented knowledge into clearer conceptual structures. In substantive terms, the coding framework draws on key contributions in the knowledge transfer literature. Argote et al. (2022) identify mechanisms and components that shape transfer processes, while Argote (2024) further highlights the importance of knowledge characteristics, motivation and recipients' consideration in explaining transfer outcomes. Battistella et al. (2016) provide an inter-organisational perspective centred on actors, object, channels, relationships and contextual conditions. In this study, "transfer" refers to knowledge flows from aerospace to non-aerospace sectors, while "implementation" captures the deployment or adaptation of knowledge within aerospace contexts or in closely related sectors whose practices may inform aerospace applications. The inclusion of implementation cases beyond direct aerospace transfer reflects an analytical choice aimed at capturing transferable knowledge practices from cognitively or industrially proximate sectors. These cases are not treated as direct spillovers, but as informative analogues that may support knowledge recombination within aerospace contexts.

4 Findings

The analytical framework was derived from the literature and further refined through the authors' interpretative synthesis. It was then used to systematically organise the findings emerging from the 57 reviewed papers across six analytical dimensions, including the three core dimensions of object, mechanism and sectoral proximity. These dimensions were defined in accordance with the research objectives and KM perspective. Specifically, each paper was examined through this pre-defined framework (Figure 2). Due to conference length constraints, the full article-by-article coding table derived from the analysis of the 57 reviewed studies is not reproduced in this version of the paper. In the extended manuscript, this material is reported through detailed appendix tables that systematically classify each contribution across the analytical dimensions adopted in this study. The findings discussed below therefore represent a synthetic cross-case interpretation grounded in that complete coding structure, rather than standalone descriptive observations. This choice was made to improve readability and focus the conference paper on the main patterns, theoretical implications and managerial relevance emerging from the review.

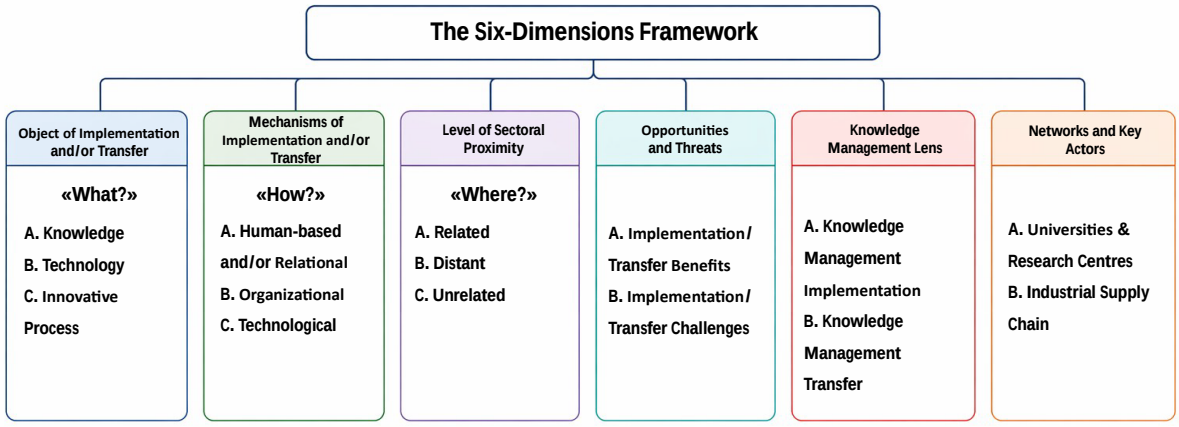

Figure 2. The six-dimensions framework
Source: Authors' own work.

4.1 Object of Implementation and/or Transfer

Across the analysed studies, three recurring categories emerge: knowledge, technology and innovative processes. Knowledge-related subjects include engineering expertise, managerial capabilities, market knowledge and organisational routines (e.g., Smith, 2013; Chirumalla, 2013; Philbin, 2010). Technological subjects involve, for instance, digital systems, hardware and software modules, monitoring infrastructures or Industry 4.0 technologies (e.g., Grubic & Peppard, 2016; Oshri & Newell, 2005; Dyba & De Marchi, 2022). Process-oriented subjects concern servitization models, collaborative innovation routines, new governance approaches and capability-development practices (e.g., Leoni, 2015; Buganza & Verganti, 2009; Johansson, 2014; Corallo et al., 2010). This suggests that cross-sector innovation is not limited to the movement of artefacts but also includes intangible and organisational assets.

Finding 1. The evidence suggests that what is transferred or implemented across sectors cannot be reduced to a single category resource. Rather, the analytical framework developed in this study, drawing on prior

literature and refined through the authors' interpretative synthesis, identifies three main objects: knowledge, technology and innovation processes. Knowledge includes: a) engineering knowledge (n = 15); b) organisational capabilities (n = 14); c) market-oriented understanding (n = 5). Technology refers to: a) digital systems, hardware, software modules, infrastructures and advanced technical solutions (n = 8). Innovation processes concern new ways of: a) organizing activities, coordinating actors, developing services (n = 32); b) applying technologies in novel settings (n = 4). The findings show that cross-sector transfer mainly concerns organizing, coordinating and service-development practices (n = 32), suggesting that innovation often derives from managerial and process reconfiguration rather than from isolated technologies. Engineering knowledge (n = 15) and organisational capabilities (n = 14) also emerge as complementary assets, indicating that technical expertise requires coordination and learning routines to create value. By contrast, standalone technologies (n = 8), market-oriented understanding (n = 5) and novel applications (n = 4) appear less frequent.

4.2 Mechanisms of Implementation and/or Transfer

The evidence suggests that implementation and transfer are enabled through multiple and often complementary mechanisms. Several papers emphasise human and relational mechanisms, such as specialised technicians, joint researchers, collaborative teams, and brokerage roles connecting otherwise separated actors (e.g., Israilidis et al., 2015; Holford, 2010). Others highlight organisational mechanisms, including open innovation agreements, R&D partnerships, university-industry collaboration and supply-chain coordination (e.g., Braziotis & Tannock, 2011; Ehret & Cooke, 2010; Esangbedo et al., 2024). A third group points to technological mechanisms, such as component sharing, digital platforms, Web-based systems, and advanced communication infrastructures (e.g., Oshri & Newell, 2005; Corallo et al., 2012; Grubic & Peppard, 2016).

Finding 2. Transfer and implementation processes do not occur through a single channel. Instead, the application of the framework to the reviewed studies highlights three recurrent mechanisms: human-based & relational, organisational and technological. These mechanisms explain how knowledge, technologies and innovation processes are mobilised, adapted and made operational across contexts. The numerical identifiers reported below indicate the studies associated with each mechanism: a) human-based and relational (n = 46); b) organisational (n = 37); c) technological (n = 29). Human-based and relational mechanisms are the most recurrent channel of transfer and implementation (n = 46), highlighting the centrality of collaboration, trust, mobility and network ties in knowledge circulation. Organisational mechanisms (n = 37) also play a key role through routines, governance and coordination practices that sustain transfer over time. Technological mechanisms are less frequent (n = 29), suggesting that technology alone is insufficient.

4.3 Level of Sectoral Proximity

The studies reveal heterogeneous patterns of sectoral proximity. Some transfers occur toward related sectors where technological and cognitive similarities reduce adaptation costs (e.g., Smith, 2013; Grubic & Peppard, 2016). Other contributions involve more distant or unrelated sectors, where aerospace-derived capabilities are recombined to generate novel applications (e.g., Su et al., 2007). In further cases, the papers do not describe an explicit intersectoral transfer but analyse implementation processes within other industries that may offer lessons transferable to aerospace contexts (e.g., Alberti & Pizzurno, 2015; Chang et al., 2012).

Finding 3. The findings show that sectoral proximity is not a binary condition but a continuum that depends on the nature of the knowledge involved, the recipient context and the KM lens adopted in the analysis. In some studies, the phenomenon concerns an effective transfer from the aerospace sector to non-aerospace domains. In other cases, the evidence refers to implementation processes rather than direct intersectoral transfer. Accordingly, sectoral proximity was used to distinguish between related, distant or unrelated sectors, while also capturing whether the observed contribution concerns transfer or implementation: a) related (n = 41); b) distant (n = 12), c) unrelated (n = 5). The literature is mainly concentrated in related sectors (n = 41), with fewer cases in distant (n = 12) and unrelated sectors (n = 5). This suggests that sectoral proximity facilitates transfer by reducing adaptation costs and easing collaboration through shared knowledge bases and similar requirements.

4.4 Opportunities and Threats

The literature highlights a dual dynamic in which opportunities and threats coexist. On the opportunity side, implementation and transfer processes are associated with stronger innovation capacity, access to new markets, efficiency gains, enhanced competitiveness and the creation of new collaborative ecosystems (e.g., Philbin, 2010; Smith, 2013; Leoni, 2015). For example, cluster strength, network embeddedness and cooperation with educational institutions are presented as important levers for value creation (e.g., Alberti & Pizzurno, 2015;

Esangbedo et al., 2024). On the threat side, authors report risks linked to imitation by competitors, weak coordination, communication barriers, organisational resistance, capability gaps and difficulties in integrating heterogeneous knowledge bases (e.g., Mey & McMahon, 2009; Jafari et al., 2011; Esangbedo et al., 2024).

Finding 4.

Macro-theme	Count	% on filled cells
Knowledge Management & Knowledge Flows	11	33.3
Technology Enablement	6	18.2
Networks, Clusters & Collaboration	5	15.2
Performance, Efficiency & Competitiveness	4	12.1
Innovation & New Development	2	6.1
Skills & Human Capital	2	6.1
Security & Defence Improvement	2	6.1
Risk, Learning & Resilience	1	3.0

Figure 3: Opportunity Macro-themes; n = 33 filled cells
Source: Authors' own work.

The main opportunities identified concern knowledge management and knowledge flows (33,3%), showing that transfer creates value by improving how knowledge is organised, shared and mobilised across boundaries. Other relevant opportunities involve technology enablement (18,2%) and networks, clusters and collaboration (15,2%), which support new applications and inter-organisational exchange. Additional benefits include higher performance, efficiency and competitiveness (12,1%), as well as innovation, skills development, resilience and long-term adaptive capacity.

Macro-theme	Count	% on filled cells
Cultural, Organizational & Communication Barriers	8	24.2
Monitoring, Cost & Managerial Burden	8	24.2
Security, Leakage & Information Protection	6	18.2
Adaptation & Compatibility Challenges	5	15.2
Knowledge Loss & Tacit Dependency	2	6.1
Risk, Safety & Operational Complexity	2	6.1
Training & Capability Gaps	1	3.0
Competitive Pressure	1	3.0

Figure 4: Threat Macro-themes; n = 33 filled cells
Source: Authors' own work.

The main threats concern cultural, organisational and communication barriers, as well as monitoring, cost and managerial burden (24,2% each), showing that transfer is often hindered by coordination problems and implementation complexity. Additional risks include security and knowledge leakage (18,2%), adaptation challenges (15,2%), tacit knowledge loss, operational risks, capability gaps and competitive pressure, all of which can weaken successful transfer outcomes.

4.5 Knowledge Management Lens

Most studies can be interpreted through two dominant KM perspectives: knowledge transfer and knowledge implementation. The first perspective is visible when the emphasis is placed on moving expertise, technologies or routines across organisational and sectoral boundaries (e.g., Smith, 2013; Corallo et al., 2016; Greco et al., 2025). The second emerges when the focus concerns internal dissemination, collaborative learning and the collective use of distributed knowledge (e.g., Davenport & Prusak, 1998; Grimaldi et al., 2015; Duffield & Whitty, 2015).

Finding 5. The findings show a prevalence of an internal KM perspective (n = 39) over an external one (n = 18). Here, the external lens refers to transfer processes, while the internal lens captures implementation

dynamics, including aerospace-to-aerospace cases or practices developed in other sector but potentially applicable to aerospace.

4.6 Networks and Key Actors

Finally, the synthesis confirms the centrality of networks and multi-actor configurations. Universities, research centres, industrial supply chains, startups, public institutions and intermediary organisations recurrently appear as pivotal actors in enabling implementation and transfer (e.g., Buganza & Verganti, 2009; Latino et al., 2016; Greco et al., 2025). Some studies explicitly stress the role of clusters as coordination platforms (e.g., Wu et al., 2015; Grimaldi et al., 2012), while others underline the importance of third-party brokers, strategic alliances or collaborative R&D programmes (e.g., Philbin, 2010; Alberti & Pizzurno, 2017).

Finding 6. The findings show that high relevance is mainly associated with the industrial supply chain (n = 17), followed by universities (n = 12) and research centres (n = 6). This suggests that knowledge transfer and implementation processes are primarily embedded in industrial networks, with academic and research actors playing a supportive but relevant role.

5 Discussion

The findings suggest that aerospace spillovers should not be interpreted as simple one-directional transfers of isolated technologies from one sector to another. Rather, they emerge as multidimensional and non-linear phenomena shaped by the interaction between different types of resources, transfer mechanisms, contextual conditions and actor configurations (Corallo et al., 2012; Smith, 2013; Parihar & Sidharth, 2025). The diffusion of knowledge, technologies and innovation processes depends on whether they can be translated, adapted, recombined and embedded in new organisational settings. This perspective moves beyond deterministic views of spillovers and supports a more systemic understanding of cross-sector innovation dynamics (Argote, 2024). A second theoretical implication concerns the relative importance of mechanisms over artefacts. While prior discussions often focus on what is transferred, the review indicates that successful outcomes depend more strongly on how transfer occurs. The same technological asset may generate very different results depending on the presence of collaborative routines, absorptive capabilities, inter-organisational trust, mobility of skilled personnel or structured interfaces between actors (Grimaldi et al., 2015; Pérez-Valls et al., 2019; Ferreira et al., 2022). The recurrent role of universities, research centres, industrial partners, startups, clusters and intermediaries highlights that aerospace spillovers are deeply embedded in networks rather than produced by isolated organisations. Startups often act as agile recombiners of existing technologies into new applications (Philbin, 2010; Alberti & Pizzurno, 2017; Dalmarco et al., 2019; Dyba & De Marchi, 2022). However, proximity should not be considered a sufficient or deterministic condition. Several studies indicate that distant sectors may generate significant innovation precisely because they combine aerospace knowledge with unrelated competences, needs and market logics (Grubic & Peppard, 2016).

6 Conclusion

This study contributes to the knowledge transfer and KM literature by developing an integrated framework based on object, mechanisms and sectoral proximity. The framework extends prior fragmented approaches by showing that aerospace spillovers are configurational phenomena shaped by the interaction among multiple dimensions rather than linear transfers of isolated technologies. In addition, the aerospace industry emerges as a valuable empirical setting for understanding how complex knowledge assets can be redeployed across sectoral boundaries. The framework, developed through a systematic literature review approach (Wittenborg et al., 2025; Snyder, 2019), will be validated through empirical cases designed to demonstrate both the robustness of the reported relationships and the replicability/generalizability of the proposed model (Fauri, 2025). In this sense, the framework is intended as an analytical device able to specify what has been transferred, how the transfer has occurred, between which actors, which empirical cases substantiate the process, and which forms of innovation and/or sectoral convergence have emerged because of transfer dynamics. These considerations also generate several managerial and policy implications. More broadly, the framework may be conceived as a set of guiding principles for good practices to be adopted by knowledge workers (Ferreira et al., 2022) and, more generally, by specialized intermediaries operating in knowledge and technology transfer processes, such as universities, research centres and consulting organisations (Greco et al., 2025; Esangbedo et al., 2024; Pereira et al., 2021). From a managerial and policy perspective, investments should not focus only on technological assets, but also on relational mechanisms, collaborative routines, intermediary actors and ecosystem architectures that enable knowledge diffusion. Firms may benefit from exploring both related and cognitively

distant sectors, while public institutions may foster cross-sector partnerships and broader socio-economic returns from aerospace capabilities. This study is limited by its reliance on secondary data and the exclusion of engineering and geopolitical contributions. Future research should extend the review and develop case studies to empirically test the proposed framework.

7 Ethics Declaration

This study is based exclusively on a systematic literature review of publicly available academic sources indexed in Web of Science. No human participants, personal data, interviews, surveys, experiments, or confidential organisational data were involved. Therefore, formal ethical clearance was not required for this research according to standard institutional procedures for secondary-source review studies.

8 AI Declaration

No AI tools were used to generate the submitted research content. The manuscript, including its conceptual development, literature analysis, interpretation of findings, and final written version, was independently developed and finalized by the authors.

Climate Change Adaptation and Mitigation through Digital Technologies in the Extra Virgin Olive Oil Supply Chain

Giulia Padovani, Dario Barberini, Maria Giovina Pasca, Gabriella Arcese
Niccolò Cusano University, Rome, Italy

Abstract

The study aims to analyse the role of digital technologies across the extra virgin olive oil (EVOO) supply chain, with particular reference to their contributions to climate change adaptation and mitigation. The research is developed through a systematic literature review, following the approach proposed by Tranfield et al. (2003), to examine the existing scientific literature on the topic in a structured manner. The analysis was conducted in January 2026 using the Scopus database, applying specific inclusion criteria for document type, language, and full-text availability. The final corpus consists of 20 articles, selected through a full-text screening and evaluation process conducted by two researchers.

The results focus on three main themes: I) digitalisation and operational optimisation in olive cultivation; II) predictive models based on artificial intelligence and digital twins; III) digital technologies for climate change adaptation and mitigation. The results highlight a clear prevalence of applications aimed at climate adaptation, especially in the upstream stages of the supply chain, through the use of IoT sensors, open-source platforms, GIS systems, remote sensing, drones, and AI models for monitoring water stress, forecasting yields, managing plant health, and optimising irrigation. The findings on climate change mitigation primarily focus on improving input efficiency, reducing the carbon footprint, and valorising by-products within a circular bioeconomy framework.

The study highlights how digital technologies serve as a strategic lever to strengthen resilience, traceability, and competitiveness in the sector. At the same time, the findings underscore the need to develop more integrated approaches between adaptation and mitigation, as well as more advanced predictive and prescriptive models that systematically support decision-making processes and future climate reporting across the supply chain.

Keywords: climate change, digital technologies, extra virgin olive oil, olive production, systematic literature review

Paper type: Practical Paper

1 Introduction and Background

The extra virgin olive oil (EVOO) sector plays a strategic role in the European agri-food system, both nutritionally and economically, representing a key element of the Mediterranean cultural and landscape heritage (El Joumri et al., 2023). EVOO is widely recognised for its health benefits and high nutritional value. Within this framework, the European Union (EU) plays a central role in the global olive oil sector, accounting for approximately 65–70% of total production and generating an annual market value of approximately €7–8 billion, with EVOO being the segment with the highest added value (OIV, 2023). The EU also remains the world's leading exporter, with over 800,000 tonnes annually, primarily destined for the United States, China, and Japan. The sector also plays an important social role, involving more than 2.5 million producers and contributing to rural development and employment protection (Özdel et al., 2025).

However, the EVOO supply chain is increasingly exposed to the effects of climate change, including rising temperatures, prolonged droughts, greater climate variability, and extreme events, which directly impact olive tree physiology, yield stability, and oil quality (Kaniewski et al., 2023). Specifically, these phenomena lead to water stress, alterations in phenological phases, and the spread of plant diseases and pests, compromising both the quantity produced and the product's nutritional and sensory properties (Demissie et al., 2026). Furthermore, the high economic value of EVOO makes it vulnerable to fraud, which undermines consumer trust and producers' competitiveness (Parra-López et al., 2025).

In this context, digital technologies are emerging as strategic tools for developing resilient and efficient agri-food systems. The literature highlights the growing adoption of digital technologies across the supply chain, particularly in the upstream stages of cultivation and harvesting (Stillitano et al., 2019). Technologies such as remote sensing, Internet of Things (IoT)-based systems, artificial intelligence (AI), machine learning (ML), and decision support systems (DSS) enable monitoring of climate variables, assessing crop health, optimising irrigation, and supporting data-driven management (Lozano-Castellón et al., 2022), improving olive growers' adaptive capacity (Casado-Vara et al., 2018). Furthermore, tools such as blockchain enable traceability and authenticity throughout the supply chain, strengthening transparency and trust in the market (Salzano et al.,

2026; Parra-López et al., 2025). Despite this, the literature remains fragmented, with studies focusing on individual technologies or supply chain stages and limited integration between climate adaptation and mitigation objectives, underscoring the need for a systematic, structured analysis of the role of digital technologies in the EVOO sector (Violino et al., 2019).

In light of the identified gaps, this study proposes to analyse the role of digital technologies across the EVOO supply chain, with particular reference to their contributions to climate change mitigation and adaptation. From this perspective, the analysis, through a systematic literature review, examines how these technologies support resource efficiency and process improvement throughout the product life cycle, identifying the main research lines, existing gaps, and future research perspectives.

The study is structured as follows: Section 2 describes the methodology; Section 3 presents the results; and Section 4 presents the discussion and conclusions.

2 Methodology

The study, following the guidelines proposed by Tranfield et al. (2003), adopts a systematic literature review (SLR) methodology to analyse existing literature in a structured manner. The literature search was conducted on the Scopus database in January 2026, and studies were analysed by both author and conceptual content to extract relevant information (Webster and Watson, 2002).

The systematic literature review was guided by the following research questions:

- *(RQ1) What is the role of innovative digital technologies along the extra virgin olive oil supply chain?*
- *(RQ2) How do these technologies contribute to climate change mitigation and adaptation processes in terms of resource optimisation, process efficiency, and reduced environmental impacts?*

To answer the research questions, the study extracts, synthesises, and critically analyses the existing literature.

The Scopus database search was conducted using the following search term: (olive OR "olive oil sector" OR "edible oil" AND "climate change" OR "climate adaptation" OR "climate mitigation" AND "digital technologies" OR "artificial intelligence" OR "AI" OR "blockchain technology" OR Blockchain OR "Internet of Things" OR IoT). The following filters were applied to the database used: (i) document type: scientific articles, literature reviews, and conference proceedings; (ii) language: English; and (iii) full-text availability. The authors decided not to impose strict time constraints to capture the evolution of the literature on the topic.

The initial search identified 42 contributions. All records were screened by title and abstract. During this phase, 20 articles were excluded as they did not align with the research objectives. Therefore, 22 studies were eligible for full-text review.

During the eligibility phase, the full texts were analysed in detail, and two contributions were excluded because they did not fit the study's relevant disciplinary fields (Environmental Science, Computer Science, Business, Management and Accounting, Social Sciences, Economics, Econometrics, and Finance). After applying these criteria, the final literature corpus consisted of 20 articles included in the systematic review. The screening and selection process was conducted by two researchers to ensure the reliability of the review. In the event of disagreement, decisions were discussed until consensus was reached.

The full texts of the final literature were analysed to gather information on the scope, study approach, methodology, results, and suggestions for future research. This information was then organised into an Excel file.

In light of the research questions underlying the systematic literature review, the selected studies were examined using content analysis. The aim was to describe the bibliometric characteristics of the existing literature, identify the main areas of application, and analyse, for each area, the findings and future research perspectives.

The authors highlighted the bibliometric characteristics of the reviewed articles and subsequently presented the results of the three identified macro-thematic areas. Specifically, the analysis distinguished between: (i) digitalisation and new technologies for operational optimisation in olive growing; (ii) AI-based predictive models and Digital Twins for crop management; and (iii) climate change adaptation or mitigation.

3 Results

3.1 Bibliometric characteristics of the reviewed articles

The analysis shows that the publication years of the selected articles range from 2020 to 2026. Bibliometric analysis shows that between 2023 and 2025, there was a significant increase in publications on the role of

innovative digital technologies in climate change mitigation and adaptation processes along the extra-virgin olive oil supply chain, demonstrating that the topic has become more relevant to the scientific community. Specifically, one article was selected for 2020, while the authors analysed two studies for 2021. Four articles were selected for 2023, and five for 2024. 2025 was the year with the most selected contributions (eight). Finally, only one article was selected for 2026, as the literature review was conducted in January 2026, limiting the availability of contributions published that year. Regarding the typology, 14 are journal articles, 4 are conference proceedings, and 2 are reviews.

The methodologies adopted in the reviewed studies include 11 case studies, 5 conceptual analyses, and 2 systematic literature reviews.

For the empirical studies, the geographical contexts of application are distributed as follows: Italy (7 studies), Morocco (2), Portugal (2), Spain (1), Greece (1), Turkey (1), Cyprus (1), Algeria (1), Djibouti (1), and Nigeria (1).

3.2 Digitalisation and new technologies for operational optimisation in olive growing

The analysis highlights how integrating Agriculture 4.0 technologies in the olive sector has radically transformed the management of agronomic activities, promoting data-driven operational efficiency (Parra-López et al., 2025). Seven reviewed articles focus on operational optimisation in olive growing through the use of digital technologies. The analysis highlighted that the most commonly used technologies include smart sensors, IoT platforms, drones/UAVs, GIS systems, and remote sensing tools.

The review emphasises that the implementation of smart sensor networks forms the backbone of remote, continuous monitoring of olive grove conditions (Tzerakis et al., 2023). In particular, the effectiveness of LoRaWAN (Long Range Wide Area Network), a long-range, low-power communication protocol, makes it well-suited for large olive groves in remote areas where traditional network connectivity is limited (Varandas et al., 2020). These low-cost sensor networks enable real-time monitoring of vital parameters, including soil moisture, air temperature, and plant water status. In this sense, the use of internal and external sensors enables the assessment of plant temperature differences, providing crucial data to determine the actual need for pesticide treatments and to reduce chemical waste (Tzerakis et al., 2023; Varandas et al., 2020). The system's energy autonomy is often ensured by integrating photovoltaic panels, making the sensing nodes completely independent of the electricity grid and less polluting. The collected data is subsequently fed into open-source IoT platforms (such as ThingsBoard or Node-RED), which, through intuitive dashboards, inform farmers about irrigation needs and the risk of pest infestation, such as the olive fruit fly (Bactrocera oleae) (Tzerakis et al., 2023; Ammouri et al., 2019).

Among new technologies, the introduction of robotic systems and unmanned aerial vehicles (UAVs) is particularly important, as they aim to automate labour-intensive tasks and reduce labour costs. Unmanned aerial vehicles (UAVs) play a dual role: in addition to providing high-resolution mapping to identify water stress and nutrient deficiencies, they are used as autonomous sprayers. The latter allows for precise application of pesticides, drastically reducing water consumption, soil compaction, and airborne product drift (Demissie et al., 2026; Parra-López et al., 2025).

The use of precision agriculture, particularly the combined application of geographic information systems (GIS) and satellite remote sensing, enables site-specific management that optimises the use of production inputs such as water, fertilisers, and pesticides (Demissie et al., 2026; Granado-Díaz et al., 2024). Multispectral image analysis from satellites such as Sentinel-2, Landsat, and MODIS allows for large-scale tree health monitoring, facilitating the classification of phenological stages and accurate yield estimation (Demissie et al., 2026). GIS platforms support site-suitability assessments and the planning of optimal irrigation strategies, thereby improving the resilience of olive groves to climate change (Parra-López et al., 2025; Tzerakis et al., 2023). This data-driven approach ensures that each agronomic intervention is tailored to the actual needs of each specific plot of land, reducing environmental impact and preserving the quality of the final product (Parra-López et al., 2025; Demissie et al., 2026; Granado-Díaz et al., 2024).

3.3 AI-based predictive models and digital twins for crop management

Six reviewed articles analyse AI-based predictive models and digital twins for crop management, identifying relevant applications in yield estimation, water status monitoring, irrigation planning, and early detection of stress, disease, and plant diseases.

The application of Artificial Intelligence (AI) and advanced digital models in the olive sector is driving a paradigm shift toward data-driven management, enabling accurate forecasts and optimal resource coordination. These technologies offer sophisticated analytical tools for processing large volumes of agricultural

data, supporting olive growers in making strategic decisions such as yield estimation, disease detection, and quality control (Salzano et al., 2026; Preite et al., 2025).

Indeed, integrating AI techniques with remote sensing (RS) overcomes the limitations of traditional methods, improving the accuracy and scalability of growth parameter and crop yield estimation (Demissie et al., 2026). Machine learning algorithms, such as Random Forest (RF), are used to analyse vegetation indices derived from satellite or unmanned aerial vehicle (UAV) imagery to predict final yield. In particular, the use of convolutional neural networks (CNNs), such as the Mask R-CNN model applied to UAV imagery, enables tree canopy segmentation and biovolume estimation, facilitating accurate yield prediction at the individual plant level (Demissie et al., 2026; Parra-López et al., 2025). Similarly, AI supports the classification of phenological stages (based on the BBCH scale), achieving high reliability (F1 Scores up to 0.89 for olive trees), a key element in planning timely agronomic interventions. Furthermore, AI-based species distribution models predict significant shifts of suitable cultivation areas northward or to higher altitudes due to climate change-induced drought stress (Salzano et al., 2026; Özdel et al., 2025).

The creation of digital twins of the soil-plant-environment system allows modelling the complex flows and interactions between living and non-living entities. The integration of IoT sensors with neural networks, specifically Multi-Layer Perceptron (MLP), has demonstrated accuracy exceeding 97% in predicting soil water content (Preite et al., 2025). These models process continuous data on leaf temperature, stem size, and ambient humidity to provide data-driven irrigation recommendations that optimise water use and mitigate water stress. Advanced approaches that combine particle swarm optimisation (PSO) and neural networks (ANN) allow the system to dynamically learn from new datasets, automating irrigation and liquid fertilisation decisions without human intervention (Preite et al., 2025; Tawfeek et al., 2022).

Finally, the use of deep learning models has revolutionised plant health monitoring, enabling early detection of biotic and abiotic stresses. Convolutional neural networks (CNNs) are valuable tools for identifying and classifying images captured by IoT devices or drones, thereby facilitating automated diagnosis of leaf diseases (Salzano et al., 2026; Parra-López et al., 2025). The integration of remote sensing, AI, and UAVs is particularly effective for early, even pre-visual, detection of devastating pathogens such as Xylella fastidiosa and for monitoring traps for the olive fruit fly (Bactrocera oleae). Open-source IoT platforms can also generate automatic email alerts when climatic conditions (temperature between 15°C and 26°C and relative humidity >65%) favour the development of pest populations, allowing farmers to adopt targeted protective measures and reduce the indiscriminate use of pesticides (Salzano et al., 2026; Parra-López et al., 2025).

3.4 Adaptation or mitigation of climate change

The authors identified seven articles that analysed approaches to assessing climate change adaptation and mitigation using digital technologies.

The review results reveal a clear predominance of adaptation strategies over mitigation approaches. This trend reflects the urgency of responding to the immediate impacts of climate variability in the Mediterranean basin, where digital technologies are being used as primary tools to ensure resilience and yield stability under increasing environmental stress (Demissie et al., 2026).

Regarding adaptation, studies primarily focus on enhancing olive orchard resilience through monitoring and forecasting abiotic and biotic stresses. The integration of Artificial Intelligence (AI) and IoT sensors enables modelling of flows between living and non-living entities, predicting soil water content with greater than 97% accuracy, and providing irrigation recommendations crucial for drought mitigation (Preite et al., 2025). Advanced predictive models based on machine learning also highlight that climate change is causing northward shifts in areas suitable for cultivation and upward shifts to higher altitudes, influencing long-term strategic decisions in the planning of new plantations (Majikumna et al., 2024). In crop protection, digitalisation enables early warning systems for emerging adversities: algorithms based on climate rules send automatic notifications when conditions favour the proliferation of the olive fruit fly (Bactrocera oleae), while the use of mobile robots and drones facilitates the early identification of devastating pathogens such as Xylella fastidiosa (Tzerakis et al., 2023).

Conversely, the effects of climate change mitigation are addressed more indirectly and documented less quantitatively. Reducing greenhouse gas (GHG) emissions primarily involves optimising resource use (input efficiency): precise management of water, fertilisers, and pesticides, enabled by precision agriculture, reduces the overall carbon footprint of the production phase (Demissie et al., 2026). Furthermore, the literature identifies the potential of olive ecosystems to sequester carbon in biomass and soil, suggesting that advanced digital management could improve CO2 storage capacity (Majikumna et al., 2024; Granado-Díaz et al., 2024). A promising path to future sustainability is the circular bioeconomy, where digitalisation supports the valorisation

of by-products (olive oil mill wastewater, olive pomace, and pruning residues) for producing biofuels or bioactive compounds, thereby transforming residues into resources and reducing the environmental impact of the transformation phase. Although quantitative evidence remains limited, the integration of Industry 4.0 technologies with life cycle assessment (LCA) frameworks emerges as an enabler of future supply chain climate reporting (Parra-López et al., 2025).

4 Discussions and Conclusions

The study highlights an approach to integrating digital technologies into the EVOO supply chain, one that plays a central role, especially in the upstream phases, by supporting olive grove monitoring, crop management, yield forecasting, and the optimisation of agronomic practices. Specifically, the integration of IoT sensors, AI, remote sensing, UAVs, cloud platforms, and GIS systems enables more data-driven production management, improving operators' ability to promptly detect water stress, plant diseases, and changes in plant physiological conditions (Salzano et al., 2026; Demissie et al., 2026; Granado-Díaz et al., 2024).

The results show that the technologies adopted in the sector are primarily geared toward supporting climate change adaptation, strengthening the resilience of olive groves, and improving the efficient use of critical resources such as water, fertilisers, and pesticides. Specifically, the use of internal and external sensors, AI-based predictive models, and digital twins enables more accurate assessments of plant water and physiological status, thereby enabling more targeted and timely agronomic interventions (Preite et al., 2025; Tawfeek et al., 2022). At the same time, the study confirms a growing interest in more integrated climate mitigation approaches based on resource efficiency and the principles of the circular economy (Majikumna et al., 2024). In this context, digital technologies play an enabling role in the development of the bioeconomy, promoting the valorisation of olive mill byproducts, such as wastewater and pomace, for the extraction of high-value compounds or for the production of biofuels. This approach allows waste to be transformed into resources, thereby reducing the carbon footprint and environmental impacts associated with the transformation phase (Parra-López et al., 2025).

Furthermore, the findings highlight the opportunity to develop more structured digital governance systems, based on smart contracts and open-source cloud platforms, capable of connecting traditional agronomic practices with advanced technological tools and promoting more equitable access to innovation, even for small-scale producers (Salzano et al., 2026; Granado-Díaz et al., 2024). The creation of an integrated digital ecosystem, in which blockchain ensures data integrity, and AI provides high-precision predictive models (achieving accuracy levels above 97% for critical variables such as soil moisture), defines a new paradigm of "Traceability 4.0" (Parra-López et al., 2025). This integration not only protects EVOO against fraud and adulteration but also consolidates consumer trust and ensures the global competitiveness of Mediterranean olive cultivation, making it a resilient pillar in the face of pressing environmental and market challenges (Salzano et al., 2026; Demissie et al., 2026). Among the main managerial implications is the ability to forecast crop yields at the beginning of the year with an error margin of less than 20%, enabling advance economic planning and targeted crop management (Parra-López et al., 2025). Furthermore, the use of IoT platforms and AI models enables irrigation optimisation with an accuracy of over 97%, provides early warnings of pests such as the olive fruit fly, and drastically reduces pesticide use and operating costs (Preite et al., 2025; Tzerakis et al., 2023).

This systematic literature review has several limitations. First, the investigation was limited exclusively to the Scopus database, a choice motivated by the need to ensure full reproducibility and transparency of the search process. Although this approach ensures methodological rigour and consistency in the analysis, it may have excluded relevant contributions indexed in other databases. Furthermore, the decision to include only articles, reviews, and conference papers published in English may have further limited the inclusion of studies written in other languages. Consequently, the overall reconstruction of the digitalisation phenomenon in the EVOO sector may be only partially representative in terms of international coverage (Macke et al., 2019).

In light of the emerging evidence, one of the main directions for future research concerns the progressive shift towards increasingly predictive and prescriptive management models. Indeed, the synergistic integration of multi-scale data from heterogeneous platforms, such as satellite remote sensing, drones, and sensors, appears particularly promising for more accurately monitoring the physiological state of plants and optimising resource use (Demissie et al., 2026).

Furthermore, it will be crucial to develop phenology-aware AI models that incorporate the specific phenological phases of the olive tree to improve yield estimates and more effectively calibrate the use of production inputs (Demissie et al., 2026). Further expected developments include advances in automation and intelligent robotics, through the design of systems that support selective harvesting based on olive ripeness and

automated pruning. In this context, the use of autonomous sprayers and precision endotherapy techniques could also help combat vascular diseases, thereby significantly reducing chemical use (Parra-López et al., 2025).

These evolutionary trajectories outline relevant perspectives for the construction of an olive-growing sector more resilient to climate change, in which technology is configured not only as a lever for production efficiency, but also as a strategic factor for the competitiveness of the sector and the safeguarding of the cultural heritage connected to it (Granado-Díaz et al., 2024).

5 Ethics declaration

Ethical clearance was not required for this study, as it is based exclusively on a systematic literature review of publicly available sources.

6 AI declaration

The authors declare that no artificial intelligence tools were used in the analysis, processing and writing of this manuscript.

Abstract

The twin transition, combining circular economy and digital transformation, is reshaping the food industry and generating new skill requirements. While previous studies have examined circular and digital technologies in agri-food systems, limited attention has been paid to the employability skills needed to support their implementation. This study addresses this gap by profiling the skills required for the twin transition in the food processing phase of the agri-food supply chain. The research adopts a big-data-driven approach based on 6,473 job advertisements collected from major online recruitment platforms. Starting from ESCO occupations, relevant food processing job profiles were selected and integrated with keyword-based searches. The textual corpus was analysed through natural language processing, BERTopic, hierarchical clustering, machine learning and SHAP analysis. Skills were classified into three semantic topics - hard, soft and transversal skills - and three cognitive clusters: industry-specific, circular and digital competences. Findings show that labour demand is dominated by hard and industry-specific skills, especially production, quality management, safety standards and packaging. Circular competences are increasingly present, whereas digital skills remain comparatively underrepresented, despite their strategic role in traceability, monitoring and efficiency. Advanced traceability, LCA-guided eco-design and industrial symbiosis emerge as high-impact but still underdeveloped competence areas. The study contributes to the literature by framing employability skills as strategic assets for enabling the twin transition. It also provides practical implications for firms, policymakers and education providers, highlighting the need to invest in targeted skill portfolios able to translate circular and digital innovation into sustainable performance.

Keywords: twin transition; employability skills; circular economy; digital technologies; food industry

Paper type: Academic Research Paper

1 Introduction

The global economy is undergoing a profound transformation driven by the twin transition (TT), understood as the simultaneous and interconnected green and digital transition aimed at reducing companies' carbon footprint. Rather than representing a merely technological shift, TT constitutes a systemic transformation that affects industrial structures, governance mechanisms, and labour markets (Trevisan et al., 2024). It combines two complementary trajectories: digitalisation, based on data-driven technologies, automation, and artificial intelligence, and circularity, aimed at decoupling economic growth from resource depletion through reuse, recycling, and regenerative business models (Uhrenholt et al., 2022).

At the European level, these transitions are increasingly viewed as key levers for competitiveness, sustainability, and resilience (European Commission, 2020; Vitti et al., 2025). The European Green Deal and the Circular Economy Action Plan promote the path towards climate neutrality by 2050, while the European Skills Agenda stresses the need for upskilling and reskilling to prepare the workforce for the new demands generated by digitalisation and sustainability (Cavallini & Soldi, 2023).

Academic research has also paid growing attention to the relationship between circular economy (CE) and digital technologies (DT). Studies show that DT can support circularity by improving traceability, resource efficiency, and circular business models (Kristoffersen et al., 2020; Tabares et al., 2025). However, the integration between digital and circular transitions is still hindered by several barriers, including technological immaturity, financial constraints, fragmented governance, weak policy coordination, and, crucially, the lack of adequate skills (Sica et al., 2024; Trevisan et al., 2023).

The shortage of skilled professionals is therefore a central obstacle to the TT. Scholars emphasise that this transition requires not only advanced technical expertise, but also a combination of digital, circular, and transversal skills (Acerbi et al., 2022; Beducci et al., 2024; Trevisan et al., 2024). Skills represent the human dimension of transformation, enabling organisations to convert sustainability and digital challenges into opportunities for innovation and competitiveness (Trevisan et al., 2025). Existing studies have begun to classify and map the skills needed for circular and digital transitions, proposing different frameworks (Trevisan et al.,

2024; Beducci et al., 2024; Vitti et al., 2025). Nevertheless, much of this literature focuses on education, higher education, and vocational training, thus privileging the supply side of skills development.

By contrast, less attention has been devoted to the demand side, namely the skills actually required by employers and signalled by the labour market. This perspective is captured by the concept of employability skills (ES), which refers to the set of knowledge, competencies, attitudes, and experiences that allow individuals to obtain and maintain employment while contributing effectively to organisations (Fugate et al., 2004; Pool & Sewell, 2007; Smaldone et al., 2022). Unlike narrowly defined technical qualifications, ES include hard, soft, and transversal dimensions, offering a more comprehensive lens through which to interpret the labour market implications of TT (Smaldone et al., 2025).

Despite their relevance, ES remain underexplored in relation to both circular and digital transitions. Existing studies have examined ES either in circular contexts (Smaldone et al., 2025) or in digital contexts (Smaldone et al., 2022), but no research has systematically analysed their combined implications for the TT. This gap is particularly significant because the mismatch between educational provision and labour market demand may reinforce skill shortages and reduce firms' capacity to implement sustainable and digital innovations (Trevisan et al., 2025).

A further limitation concerns the sectoral focus of existing research. Most studies on TT-related skills have concentrated on manufacturing, examining competences linked to remanufacturing, recycling, design for circularity, and digital integration (Acerbi et al., 2022; Beducci et al., 2024; Trevisan et al., 2024). The food industry has received far less attention, despite being one of the most environmentally impactful sectors and, at the same time, one of the most promising contexts for circular and digital strategies. The sector contributes substantially to greenhouse gas emissions, waste generation, and resource inefficiency, but it also offers opportunities for by-product valorisation, blockchain-based traceability, eco-design, nutrient cycling, and digital platforms for waste reduction (Esposito et al., 2020; Scandurra et al., 2023; Myshko et al., 2024; Farace & Tarabella, 2024; Sica et al., 2024).

In the transformation phase of the agri-food supply chain, the TT can generate particularly relevant benefits. Digitalisation can improve monitoring, transparency, and efficiency, while circular approaches can reduce environmental pressures through resource recovery and more sustainable production models. However, existing studies on CE and DT in the agri-food sector have mainly examined technological implementation, without adequately considering the role of skills in enabling the transition (Guidani et al., 2024; Padthar et al., 2024; Esposito et al., 2025). As a result, no prior research has systematically profiled the ES required to support TT in the food industry.

Against this background, the present study addresses this gap by profiling the employability skills required for the TT in the food industry, with specific attention to the transformation phase of the agri-food supply chain. Adopting a big-data-driven methodology, the study analyses thousands of job advertisements collected from major recruitment platforms and applies text mining and topic modelling techniques to identify relevant ES. These skills are then classified into semantic topics, including hard, soft, and transversal skills, and into cognitive clusters, namely industry-specific, circular, and digital skills. In doing so, the study develops a comprehensive taxonomy of the ES required by the European labour market to support the circular and digital transformation of the food industry.

2 Research Methodology

The methodological design was developed to ensure both representativeness and alignment with an institutional framework. The analysis began with a systematic screening of occupations listed in the European Skills, Competences, Qualifications and Occupations (ESCO) database, following prior studies (Akyazi et al., 2023). The focus was restricted to the transformation phase of the food industry, defined as the industrial stage in which agricultural raw materials are converted into intermediate or final food products through processing, refinement, preservation, and packaging. This phase was selected because it represents a crucial interface between upstream production and downstream distribution, where CE practices and DT are particularly relevant. All ESCO occupations related to the agri-food sector were first identified, and only those directly connected to food transformation were retained. Occupations linked exclusively to upstream or downstream activities were excluded. To ensure reliability, two independent researchers coded an initial sample of 30 job profiles, and Krippendorff's alpha exceeded the accepted threshold of 0.8, confirming satisfactory intercoder agreement (Krippendorff, 1980). The remaining profiles were then screened by the researchers, while final inclusion required unanimous agreement. The selected occupations were also cross-checked on major recruitment platforms. Since ESCO may not fully capture rapidly evolving labour market needs (Akyazi et al., 2022, 2023), an additional keyword-based search was conducted using terms such as "food", "agri-food",

“agrifood”, “agrofood”, and related variants. Job advertisements were collected from leading online recruitment platforms between February and July 2025 through a custom R-based scraping protocol. Around 8,000 unique postings related to food processing were retrieved. After removing duplicates, incomplete entries, and advertisements lacking substantive descriptions, the final dataset included 6,473 job ads, enriched with metadata such as occupation title, country, date, sector, and stated requirements.

The textual corpus was then prepared through a multi-step natural language processing routine, including lowercasing, removal of punctuation and numerals, language detection, tokenisation, and lemmatisation. Food-industry-specific collocations were preserved to maintain domain accuracy (Smaldone et al., 2022). Semantic validation relied on a lexicon of 35 pre-identified skills relevant to food processing, covering technical, managerial, transversal, and soft categories. A stratified keyword-matching procedure was applied, and disagreements were resolved through consensus discussion to strengthen internal validity (Moore, 2017).

The validated dataset was analysed using advanced computational techniques. BERTopic, based on BERT embeddings, was used to identify latent semantic structures in the corpus (Devlin et al., 2019; Grootendorst, 2022). This produced three macro-topics consistent with employability literature: hard skills, soft skills, and transversal skills. In parallel, agglomerative hierarchical clustering with cosine distance generated three macro-clusters: industry-specific, circular, and digital. This dual structure provided complementary perspectives on the skill space. Further multivariate analyses, including Multiple Correspondence Analysis, Principal Component Analysis, and Linear Discriminant Analysis, were used to examine latent patterns and predictive strength. Chi-square tests confirmed a significant relationship between topics and clusters, while Gini and Theil indices highlighted inequalities in the distribution of skills.

Cognitive profiling was carried out through heatmaps, radar charts, and skill networks, revealing the semantic relationships and weighted interconnections among competences. Network analysis distinguished strong and weak ties, showing the centrality of digitalisation and circularity in shaping employability in food processing (Smaldone et al., 2025). The predictive stage applied supervised machine learning, treating each skill as an observation and using topics and clusters as prediction targets. Decision Trees, Random Forests, and Support Vector Machines were tested (Cortes & Vapnik, 1995), with SHAP values used to interpret model outputs (Lundberg & Lee, 2017). Models were trained on an 80/20 stratified split, and Random Forest classifiers showed the strongest robustness. SHAP analysis identified the most discriminative skills, including communication, quality management, energy efficiency, and traceability systems.

Finally, the prescriptive stage conceptualised skills as a competence portfolio to support managerial decision-making. The Opportunity Map combines impact and prevalence to distinguish strategic opportunities, established leverage skills, maintenance skills, and marginal competencies. ROI analysis estimates the expected return from increasing the presence of a skill, comparing predictive and distributional benefits with its current baseline prevalence. What-if and sensitivity analyses simulate the effects of increasing specific skills, showing potential gains, trade-offs, and leverage effects. Lastly, the Concentration Risk gauge uses the Herfindahl–Hirschman Index to assess whether reliance on a narrow set of competences creates systemic fragility, with lower post-portfolio values indicating a more diversified and resilient skill base.

3 Results and Discussions

Results provide a comprehensive overview of the employability skills landscape within the food processing phase, combining descriptive distributions, inequality measures, predictive modelling and prescriptive scenarios. Overall, the distribution of competences across topics and clusters appears relatively balanced, although some relevant asymmetries emerge. Hard skills dominate the landscape, with frequencies exceeding 3,000 postings at their peak, compared with approximately 2,000 postings for both soft and transversal skills. A similar pattern emerges at the cluster level: industry-specific competences record more than 3,000 mentions, whereas circular and digital competences stabilise closer to 2,000 mentions. However, no single topic or cluster exceeds 30% of the total distribution, suggesting a fragmented rather than uniform skill structure.

The strongest intersections occur between hard skills and industry-specific competences, with 13,653 occurrences, followed by transversal skills and circular competences, with 11,306 occurrences. This indicates that traditional technical competences still play a central role in food processing employability, particularly in relation to production, processing, quality, safety and packaging. At the same time, transversal skills appear especially relevant when circular practices are involved, suggesting that the circular transition requires not only specialised technical knowledge, but also broader capabilities such as adaptability, collaboration, problem-solving and systems thinking.

Hard skills account for nearly 40% of job advertisements, confirming their predominance in labour demand. Soft skills, including communication and teamwork, appear in lower but still significant proportions, while

transversal skills are less frequent but strategically important for managing change and innovation. From a cluster perspective, industry-specific and circular competences together represent more than 70% of total demand, whereas digital skills remain close to 20%. This result confirms a substantive digital gap in food processing and supports previous evidence identifying digital immaturity as a key bottleneck in agri-food systems (Sica et al., 2024). The findings also reflect a structural skills gap, whereby firms retain strong compliance and operational capabilities but invest less in the competences needed for innovation and resilience (Trevisan et al., 2023).

The inequality analysis further clarifies this picture. The Gini index reaches 0.15 and the Theil index is approximately 0.05, indicating a moderate but meaningful concentration of skills. A limited number of competences, particularly industrial processing, safety standards and quality management, account for a disproportionate share of labour market demand. Chi-square residuals confirm this imbalance: circular competences are significantly over-represented in the circular cluster, with a residual of +66.82 for transversal skills, whereas digital competences show under-representation, with a residual of –41.64 for soft skills. These disparities suggest that circular priorities are increasingly embedded in food processing job profiles, while digitalisation, contrary to initial expectations, remains less consolidated.

The analysis of skill relationships reinforces this interpretation. Central competences are still dominated by food packaging and safety standards, while emerging digital competences such as smart sensors and IoT remain peripheral, despite their recognised potential to improve transparency, traceability and efficiency (Pakseresht et al., 2023; Shrivastava et al., 2023; Zhao et al., 2025). This confirms a relevant paradox: although digital technologies offer significant opportunities for the twin transition, their practical adoption is constrained by limited absorptive capacity and insufficient human capital (Kumar et al., 2021; Annosi et al., 2020).

Predictive modelling provides further support for these results. Accuracy rates approach 75% for both topic and cluster classification, while precision is close to 80%, confirming the predictive validity of the skill dataset. Hard skills are classified with higher accuracy, with 13 correct predictions, whereas soft and transversal skills show greater overlap and are more frequently misclassified between Topics 1 and 2. This reflects both methodological complexity and labour market reality: industrial competences tend to be more codified, while transversal competences cut across different roles and occupational profiles.

The most influential skills for topic classification are communication skills, years of experience, production efficiency, quality management and traceability systems. By contrast, smart sensors, greenhouse gas emissions and ingredient traceability are the most decisive for cluster classification. These findings confirm that employability in food processing is multidimensional, combining technical, soft, transversal, circular and digital competences. They also support the view that hybrid profiles, able to integrate technical expertise with adaptability and digital literacy, are increasingly relevant for competitiveness in changing labour markets (Van Laar et al., 2017; Shakina et al., 2021; Xu et al., 2022).

The prescriptive analysis translates these findings into strategic indications for workforce development. Eco-design, industrial symbiosis and advanced traceability emerge as high-impact but underrepresented competences, offering substantial potential returns. The selected skill portfolio shows benefit–cost ratios above 1.05, indicating that investment in these competences could generate value greater than their current prevalence. Scenario analysis shows that a 20% increase in transversal and circular competences would increase their representation by almost 2% across topics and 1.5% across clusters, contributing to a more balanced skill ecosystem. Sensitivity analysis further confirms that modest increases of 10% in competences such as eco-design and ingredient traceability produce measurable effects, whereas further investment in already dominant hard skills generates negligible marginal returns.

Finally, the concentration risk assessment, based on the Herfindahl–Hirschman Index, places the current configuration at 0.130, indicating low but still observable concentration risk. After portfolio diversification, the index decreases to 0.031, showing a clear reduction in systemic fragility and a stronger stabilising effect produced by redistributing competences across categories. Overall, the results reveal a food processing sector that is more mature in circularity than in digitalisation. The decisive lever is not simply the adoption of more technologies, but the development of targeted skill bundles able to transform digital tools into circular performance.

4 Conclusions

This study profiled the employability skills required to support the TT in the food industry, focusing specifically on the transformation phase of the agri-food supply chain. Through big-data text mining and AI-driven modelling, the analysis examined the distribution of hard, soft, and transversal skills, while also assessing their predictive relevance, trade-offs, and role within broader competence portfolios. The findings clearly show

that employability skills are a decisive factor in enabling firms to manage the convergence between circularity and digitalisation. Without adequate and diversified skill sets, food firms risk remaining anchored to traditional industrial models and failing to exploit the full potential of the TT.

The study offers relevant theoretical and managerial contributions. From a theoretical perspective, it enriches the literature on circular and digital transitions by placing employability skills at the centre of the debate. Skills are not interpreted as fixed qualifications, but as dynamic and strategic assets that shape firms' absorptive capacity and their ability to transform sustainability and digital pressures into innovation and competitive advantage. From a managerial perspective, the findings suggest that human capital should be treated as a form of strategic infrastructure. A diversified skill portfolio can reduce concentration risks, strengthen organisational resilience, and generate higher returns when investments are directed towards underrepresented but high-impact competences.

The study also presents some limitations. First, although job advertisements provide valuable evidence of labour market demand, they mainly reflect employer signalling rather than the actual competencies possessed by workers. Future research should therefore triangulate these data with employee surveys, training outcomes, and longitudinal career paths. Second, the analysis focuses only on the transformation phase of the agri-food supply chain. Further studies could extend the investigation to upstream production and downstream distribution and consumption, enabling a more comprehensive understanding of skill complementarities across the whole chain. Third, despite the robustness of the methodological framework, the results remain influenced by the quality, language, and structure of online recruitment data, as well as by the rapid evolution of labour markets.

5 Ethics Declaration

No ethical clearance was required for this study, as it did not involve human participants, personal data, or sensitive information requiring ethical approval.

6 AI Declaration

The authors used DeepL only for language proofreading and stylistic refinement. The intellectual content, analysis, interpretation, and final responsibility for the manuscript remain entirely with the authors.

Abstract

Competence-based HRM reforms in public administrations often remain trapped in formal compliance because competence taxonomies, templates, and platform inscriptions must be translated into locally credible and administratively governable routines. This paper examines how inter-organisational knowledge brokering enables such translation in SKiLL-PA, a national, platform-mediated reform programme designed to institutionalise strategic, competency-based HRM and to connect competence modelling to workforce planning and development. We adopt a qualitative, process-oriented single-case study of UNI-1, a mid-sized public university in inland Southern Italy, drawing on interviews, documentary analysis, and direct observation. Findings show that implementation effectiveness hinged on a formally mandated academic coordinator acting as the primary knowledge broker across organisational interfaces and internal domains. Brokerage unfolded through a patterned repertoire of mechanisms: sense-giving and shared framing to reduce equivocality; translation and reframing of competence language to align behavioural competences with situated work; artefact-mediated alignment through versioned templates and traceable decision logs; cross-domain convening to integrate HR modelling with budgetary sustainability; negotiated bounded flexibility to reconcile standardisation with role hybridity; data management to secure informational integrity; legitimacy work with governance and social partners; and iterative learning routines that stabilised interpretations over time. The findings extend knowledge management research by showing how brokering work aligns interpretive, socio-technical, and institutional layers in platform-mediated competence reforms, framing inter-organisational knowledge transfer as negotiated translation rather than a top-down transmission.

Keywords: project; competences; public administration; knowledge brokering

Paper type: Academic Research Paper

1 Introduction

The expectation of new competences and responsibilities for public managers has long been a central concern in public administration scholarship and a recurring target of reform agendas aimed at strengthening administrative capacity (De Nito and Pezzillo Iacono, 2020). Yet competence-based reforms do not travel effortlessly. The knowledge infrastructures that underpin competence-centred public organisations (e.g. classification schemes, coordination mechanisms, professional standards, learning routines, and digital repositories) remain only partially integrated with HR policies and organisational design choices. The resulting misalignment sustains a persistent gap between strategic intent and operational capability, which is frequently addressed through short-term training initiatives or compliance-oriented workforce plans rather than through an organisation-wide redesign of competence architectures (Canonico et al., 2025). These implementation fragilities are well documented. Competency frameworks may be inadequately integrated with staffing, development, and reward systems; they may be confined within bureaucratic procedural compliance routines instead of serving as practical tools for managerial decision-making and learning; or they may be disputed as mechanisms of managerial control when they challenge established professional domains and evaluative norms (Horton et al., 2002). These dynamics become even more pronounced when competence frameworks are embedded in digital platforms that reconfigure what is made visible, how accountability is enacted, and how competence-related data are produced, standardised, and circulated (Nisio et al., 2023).

In complex public-sector organisational change projects initiated through top-down reform programmes, competence-based HRM reforms are not only "implemented" but *translated*: they require the circulation, reinterpretation, and stabilisation of categories and prescriptions as they travel across organisational tiers and disciplinary domains, from central programme designers and implementing partners to local administrations where the reform must be rendered workable. In practice, this translation entails aligning standardised competence artefacts with situated work arrangements, accountability expectations, and data infrastructures, through iterative negotiation among heterogeneous stakeholders and professional communities.

SKiLL-PA is a national reform initiative designed to develop an integrated approach to strategic HRM grounded in competency-based HRM, supported by a digital toolkit and an interoperability agenda across national platforms for recruitment, skills development, and integrated planning. The programme encompasses the mapping of innovative HRM practices, the co-design of a competency-based framework, and piloting and implementation in participating administrations. In this study, SKiLL-PA is treated as a sustainability-oriented competence-building project: it aims at durable competence development, institutional learning, and public value creation, while mobilising distributed expertise and coordinated action across organisational boundaries. As such, it provides a particularly informative empirical setting for examining how competence-based templates and digital artefacts are made locally workable in knowledge-intensive public organisations.

Instead of conceptualising adoption as the presence of favourable conditions, the paper examines the inter-organisational mechanisms that make the reform workable in practice, focusing on knowledge brokering activities that connect programme templates, organisational vocabularies, and operational constraints. Specifically, we focus on the role of a *knowledge broker*, an actor who connects heterogeneous communities and vocabularies, enabling knowledge transfer and translation across domains and organisations. Our objective is to explain how brokering is enacted in practice during the implementation of a competence-based, platform-mediated HR innovation: which mechanisms and practices allow the project's competence taxonomy and profiling rules to be interpreted, negotiated, adapted, and stabilised within a specific administration.

Accordingly, the paper addresses the following research question: *What mechanisms and practices do knowledge brokers mobilise to transfer and translate competence-related knowledge across organisational and disciplinary boundaries during the local customisation and implementation of SKiLL-PA?*

Empirically, we develop an in-depth case study of *UNI-1*, a mid-sized public university in inland Southern Italy, where competency-based HRM was co-designed through iterative translation into digital and procedural artefacts. Building on established conceptualisations of competence as a multidimensional construct (knowledge, skills, attitudes, and behaviours) and as a basis for competency modelling (Campion et al., 2011), we treat competence frameworks not merely as classificatory devices but as knowledge infrastructures that stabilise expectations, coordinate distributed expertise, and provide a shared language through which work design and HR decisions are negotiated across organisational boundaries.

2 Theoretical Framework: Knowledge Brokerage as Translation in Inter-organisational Projects

Collaboration between heterogeneous actors from different organisations involved in an inter-organizational change management project often involves complex knowledge transfer. All the partners have their own nomenclature, demands and expectations of innovation (Sandberg and Tsoukas, 2015). Partners have to adopt each other's perspectives and select a framework and words that can easily be understood by others.

To facilitate knowledge transfer, actors need to work together to overcome their individual and organisational interests and needs and collaborate to achieve a common goal (Canonico et al., 2025). Individuals use their own language and framework but are pushed to move from their "natural environment" (De Rond & Bouchikhi, 2004).

Specific forms of expertise play an important role in facilitating the coordination and transfer of knowledge across boundaries. According to Haas (2015) the concept of knowledge broker could be interpreted in different ways and is something different (even if with some overlap) from gatekeeper and boundary spanner. For example, knowledge brokers are intermediaries between unrelated groups or individuals geared toward knowledge gathering and dissemination. The main difference between gatekeepers and knowledge brokers is their position. Gatekeepers belong to one of the groups they link, but research presents knowledge brokers as "*liaisons*" linking two different groups without belonging to either or linking two individuals with no previous relation (Haas, 2015). On the contrary, boundary spanners could be defined as links between a unit and its environment (Cross and Prusak, 2002) who can play several different functions (Haas, 2015). In this sense when in a cross-disciplinary project academics act to put together people with different background and belonging to different organizations (or organizational units) could be typically considered as knowledge brokers more than gatekeepers or boundary spanners.

However, the concept of knowledge brokers is not unique and deserves a clarification. In a traditional perspective (Wenger, 2000) knowledge brokers are members of a community of practice who adopt different roles and practices, such as boundary spanners, roamers, outposts and pairs (Wenger, 2000) and act as brokers between communities (Ishiyama, 2016). This perspective suggests that the role of knowledge broker is critical. However, it is also a part of day-by-day work. It is therefore practiced within and outside communities and is influenced and socially constructed by the knowledge broker.

As reported by (Haas 2015 p. 1037), considering knowledge brokers as a bridge between different communities they do not belong, is very close to the role identified by Brown and Duguid's (1998) as the "translator". They are people who enable knowledge transfer across different organisational actors. They mediate between different disciplinary perspectives, facilitating communication, and creating a shared understanding of the problem or issue (Ishiyama, 2016). They act as liaison, gatekeepers, coordinators, representatives, and itinerant brokers. Recently this idea of translation has been applied in the knowledge management literature, trying to investigate the processes and tools that could help in translating knowledge (typically from a domain to another one). Donnelly (2014) has focused his attention on the role of design as a way to facilitate knowledge translation.

In our perspective, knowledge brokers should promote change, help to eliminate barriers and promote the creation of a shared language and culture. Chiambaretto et al. (2019, p. 585) stated: "*knowledge brokers are defined as actors who fulfil the role of an intermediary within the knowledge transfer process between disconnected parties (…) … They can take many forms, from consultancies to project managers*".

Perrin (2013) has investigated how knowledge brokers act to facilitate knowledge transfer inside an organization, focusing on two main aspects: the translation activities (especially related to the ability to create explicit knowledge for instance, through the generation of written documents) with concern about the capacity of filling a document creating explicit knowledge and the organizational activities (addressing the role of managers who are in charge of identifying knowledge and defining incentives to transfer knowledge and good practices inside the organization).

Our paper wants to go deeper in understanding what happens in an inter-organizational context, focusing on how knowledge brokers work to facilitate knowledge transfer. More specifically, in a cross-disciplinary project where people belong to different organizations but also to different domains. We identified the knowledge broker as someone not related to a specific community, but as someone who acts to connect people coming from different contexts, working "together" in a specific project.

3 Methodology

The study adopts a qualitative, process-oriented single-case design (Eisenhardt, 1989; Yin, 2018) aimed at explaining how knowledge is transferred and translated across organisational and disciplinary boundaries during the implementation of a competence-based, platform-mediated HR innovation. While the empirical setting is anchored in UNI-1, the analytical focus is not the organisation per se but the inter-organisational knowledge-brokering work through which SKiLL-PA's competence grammar, templates, and digital artefacts are rendered locally actionable. Accordingly, the unit of analysis is the set of brokering mechanisms and practices enacted at the interfaces among UNI-1, the programme owner (the Department), and the implementing partners (IPA and NIA), as well as across internal domains (HR/organisational development, finance, and administrative units).

In UNI-1, the academic coordinator functioned as the main knowledge broker and boundary spanner, translating the programme's competence grammar across organisational interfaces (Department/partners - University) and disciplinary domains (HRM, finance, and digital/data work).

UNI-1 was selected as an information-rich site for observing knowledge brokering in action. First, as a knowledge-intensive public organisation with structurally hybrid roles and limited slack, UNI-1 provides a context where translation work is not optional but constitutive of implementation: competence models must be adapted to multifunctional arrangements and to constrained data and governance infrastructures. Second, UNI-1's implementation architecture intentionally combined HR and finance within the core project team, increasing the likelihood of domain friction (HRM language, budgetary logics, digital/data requirements) and making the brokering function both visible and consequential.

Data collection follows a triangulation strategy combining interviews, documentary materials, and direct observation.

First, semi-structured interviews were conducted with (1) UNI-1 project-team members (HR/organisational development and finance), (2) internal governance and employee-representation actors involved in validation and sensemaking, and (3) programme counterparts where access was possible. Interviews reconstructed sequences of interactions and focused on how actors experienced translation challenges, how conflicts of interpretation were resolved, and what forms of mediation were considered legitimate.

Second, documentary analysis examined the artefacts through which knowledge was circulated, stabilised, and rendered governable. This included procedural guidance issued by the Department, templates and competence libraries provided by IPA and NIA, meeting minutes, internal communications, successive versions of UNI-1's competence-based professional system, and ancillary HR records used to validate contractual classifications and training histories.

Third, direct observation focused on the interactional settings in which brokering practices are performed: alignment meetings with programme counterparts, internal profiling and validation sessions, and workshops devoted to interpreting and refining competence descriptors. Two of the four authors acted as participant observers within the SKiLL-PA pathway, enabling access to the micro-processes of translation and mediation that are often under-specified in retrospective accounts. This included the practical work of making behavioural competences intelligible to administrative roles, reconciling HR language with budgetary constraints, and aligning toolkit affordances with established routines and data governance practices (Atkinson and Hammersley, 1995).

Confidentiality was ensured through systematic anonymisation: "SKiLL-PA" is used as a pseudonymic acronym, UNI-1 is a descriptive code, and potentially identifying institutional markers and platform labels were generalised where necessary to limit re-identification while preserving the organisational meaning of brokering mechanisms and enabling conditions.

4 SKiLL-PA as a Competence-Based HRM Reform: Aims, Design, and Toolkit Mechanisms

SKiLL-PA is embedded in Italy's National Recovery and Resilience Plan (PNRR) governance architecture and is tied to EU-facing milestones aimed at institutionalising an integrated, competence-centred approach to strategic HRM across public administrations. In this policy design, the move towards competence-based HRM is not framed as an isolated HR modernisation effort, but as a lever for strengthening administrative capacity and for enabling a more resilient public sector workforce model, whose progress must be monitored through periodic reporting obligations up to the PNRR deadline.

At its core, SKiLL-PA pursues the definition of a unitary and integrated HR strategy that re-design organisational systems towards a competency-based model shared across administrations, yet adaptable to different public-sector "comparti". This objective is operationalised through the construction of a competency-based framework, coupled with the support of an integrated data infrastructure intended to sustain comparability, aggregation, and evidence-based workforce planning. The plan logic explicitly responds to the limits of traditional job classification grounded in tasks and duties, promoting instead an HR system centred on competence typologies, professional profiles, recruitment and development pathways, and reward/career mechanisms that can be aligned with organisational redesign and strategic planning.

From an implementation standpoint, SKiLL-PA is delivered through a multi-actor arrangement led by the central public governance authority (the Department) and supported by an in-house implementation partner (*IPA*, *Implementation Partner Agency*) acting as the operational arm for project execution. In parallel, a second national-level partner (*NIA*, *National Investment Agency*) contributes to dissemination activities intended to expand uptake beyond early adopters. This division of labour is significant from an organisational perspective because it separates the design and piloting capacity required to craft a coherent competence management, from the scaling capacity required to diffuse templates, tools, and know-how across heterogeneous organisational contexts.

A distinctive feature of the programme's instrumentation is its coupling of design and diffusion with a formal monitoring regime based on KPI. The KPI reports function as a governance device through which implementation progress and reform effects are periodically assessed, enabling feedback, corrective actions, and (in the institutional framing of the PNRR) follow-up initiatives connected to integrated planning processes. The monitoring architecture is not merely evaluative: it also exerts structuring effects on participating organisations by stabilising what "counts" as progress and by shaping the reporting routines through which competence-based HRM becomes administratively actionable.

5 Implementing SKiLL-PA in UNI-1: coordination design and organisational enabling conditions

UNI-1, a mid-sized public university located in inland Southern Italy, joined SKiLL-PA after the programme's initial experimental wave involving approximately thirty public administrations. Entry into the initiative was not treated as the technical adoption of a "ready-to-use" HR toolkit. Rather, UNI-1 framed implementation as an organisational design challenge: how to render a competence-based, platform-mediated HR innovation actionable within a medium-to-small public administration characterised by limited slack resources, role hybridity, and recurrent task rotation and multifunctional teamwork.

The first implementation moves therefore concerned the architecture of coordination. UNI-1 constituted an inter-functional working group chaired by an academic with expertise in change management and HRM and composed of senior administrative representatives from the Personnel and Organisational Development area and the Financial Systems area. The inclusion of finance was consequential. It signalled that competence-based HRM was being assessed as a governance and sustainability issue, not as an HR-only reform: from the outset,

the working group sought to anticipate the cost implications of competence profiles for training investments, mobility options, career mechanisms, and internal resource allocation, thus reducing the risk that the model would later be delegitimised as fiscally unfeasible or organisationally "unfunded".

The working group operated at the intersection of intra-organisational alignment and inter-organisational coupling. Externally, it maintained structured interfaces with the Department (programme owner) and with the implementing partners (IPA and NIA), which provided procedural guidance, shared artefacts (templates, competence libraries, profiling logics), and standardisation requirements intended to preserve comparability across administrations. Internally, the group positioned itself as the translation locus where the programme's competence grammar could be rendered meaningful for the University's organisational language and work arrangements. This translation work unfolded through a staged implementation pathway, with distinct coordination mechanisms and a progressive tightening of the coupling between competence categories and certified personnel information.

During Phase 0 (approximately two months), UNI-1 prioritised onboarding and internal capability building. The core activity consisted of orientation meetings, internal training sessions supported by programme counterparts, and the stabilisation of decision rights and validation routines: who was authorised to curate personnel data, who could validate role labels, and how interpretive disagreements would be resolved. This phase also established a minimal coordination infrastructure. A restricted-access digital workspace was used to manage shared documentation, version control, and the traceability of modelling decisions—features that are particularly important where HR-related information is sensitive and where accountability demands are non-trivial. Regular virtual meetings, aligned with milestones and procedural requirements issued by the Department, created cadence and reduced equivocality, allowing the team to absorb the cognitive burden of the model without fragmenting responsibilities across organisational silos.

Phase 1 (approximately four months) marked the shift from familiarisation to modelling and implementation work. UNI-1 produced a local work plan by selecting among the methodological options offered by SKiLL-PA, thereby tailoring sequencing while remaining within the programme's core requirements. The working group then engaged in iterative cycles of data mobilisation, toolkit application, profiling, and validation as the competence framework was translated into a competence-based representation of UNI-1's professional system. In practice, this involved moving beyond the organigram as a purely structural depiction and constructing a professional system in which roles, bundles of competences, and pathways could be made comparable and usable for HR decision-making.

A pivotal operational decision concerned how to represent role plurality. Given the frequency of blended assignments and multifunctional teamwork in medium-to-small universities, the team implemented a "prevailing activity" criterion: each employee was profiled primarily against the activity that absorbed most of their time and responsibility, while secondary activities were recognised but not fully formalised in the model to avoid undermining interpretability and managerial tractability. This choice reflects a broader organisational design trade-off between descriptive completeness and governance usability. In competence-based HRM, frameworks that attempt exhaustive representation often become unwieldy and encourage compliance-driven documentation rather than operational uptake; conversely, a parsimonious representation can increase usability and the likelihood that competence profiles inform staffing, development priorities, and internal mobility discussions.

As modelling progressed, tensions emerged at the interface between standardisation and contextual fit. UNI-1 did not contest the competence-based premise; it questioned the adequacy of certain standard role labels for an organisational context in which rotation and cross-functional teamwork are routine responses to staffing constraints. Toward the end of Phase 1, internal actors requested the possibility to adapt selected elements of the general model to better represent UNI-1's division of labour. The response from programme counterparts proved enabling: rather than enforcing rigid uniformity, IPA and NIA supported a negotiated adaptation process that preserved the overarching grammar while allowing semantic adjustment of descriptors and labels. Over an additional month, an adaptation sprint, UNI-1 refined the pre-definition of its professional system within the Department's modelling framework, enhancing interpretability for local actors without compromising comparability. This episode illustrates a key enabling condition for sustainable implementation: bounded flexibility within a standardised reform, which allows local translation and reduces the risk of the model being bureaucratically contained as a short-lived compliance artefact.

The coordination regime underpinning this work combined complementary mechanisms. The restricted-access digital platform enabled distributed collaboration and auditability while protecting sensitive information flows; virtual meetings maintained inter-organisational alignment and ensured cadence; and periodic face-to-face sessions functioned as intensive translation arenas in which competence libraries were reconciled with situated knowledge of administrative work. Department-issued procedures anchored the process within

recognised institutional authority, reducing interpretive drift and providing a formal backbone for validation decisions. Within this regime, the academic chair performed a boundary-spanning and knowledge-brokering function: translating the competence grammar into locally legitimate categories, facilitating the internal legitimacy of behavioural and relational competences, and supporting communication with governance bodies and employee representatives when modelling choices required organisational endorsement.

Two enabling conditions were particularly salient in explaining why UNI-1 could complete the modelling phase within the expected timeframe and with limited resistance. The first concerns data access and informational integrity. Competence profiling required certified information on contractual profiles, role allocations, career trajectories, and training histories; involving actors with legitimate access to comprehensive personnel data reduced validation cycles and mitigated perceptions of arbitrariness. The second concerns expert boundary spanning. The academic coordinator's role strengthened coupling between programme expectations and local feasibility constraints, improved interpretive alignment when model properties were ambiguous, and enhanced legitimacy across organisational constituencies. Boundary spanning operated simultaneously as an epistemic mechanism (translation and knowledge transfer) and a political mechanism (legitimacy building and conflict mediation), which is crucial when competence-based innovations have latent implications for evaluation, mobility, and career trajectories.

By the end of Phase 1, UNI-1 produced a competence-based representation of its professional system that functioned as a new organisational artefact: it provided a shared language for discussing work, staffing, development priorities, and the alignment between HR practices and public value goals. This artefact constitutes the necessary substrate for the subsequent stage, engagement with internal governance bodies and social partners, through which the model can be institutionalised within HR routines rather than remaining confined to the project perimeter.

To consolidate the within-case analysis, Table 1 synthesises the mechanisms through which the academic coordinator enacted knowledge brokering across organisational and disciplinary boundaries during UNI-1's implementation pathway.

Table 1. Mechanisms of Brokerage in the UNI-1 SKiLL-PA Implementation Pathway

Brokerage mechanism	Core practice enacted by the broker	Boundary/interface bridged	Contribution to implementation	Where
SENSE-GIVING AND SHARED FRAMING	Established a shared interpretive frame for competence-based HRM and clarified decision rights, expectations, and milestones with internal actors and programme counterparts.	UNI-1 internal domains ↔ Department and partners	Reduced equivocality; aligned meanings and responsibilities before technical work started.	P0
TRANSLATION AND REFRAMING OF COMPETENCE LANGUAGE	Reframed behavioural and relational competences through concrete administrative episodes (interdependencies, stakeholder interactions, service continuity) to increase local intelligibility and legitimacy.	Competence grammar ↔ situated work practices	Enabled uptake of the competence library beyond formal labels; supported credible profiling.	P1
ARTEFACT-MEDIATED ALIGNMENT	Used templates, competence libraries, versioned documents, and a traceable decision log to stabilise interpretations and coordinate iterative revisions.	People ↔ artefacts across organisational boundaries	Turned discussions into auditable outputs; reduced interpretive drift and rework.	P0–P1
CONVENING CROSS-DOMAIN COORDINATION	Designed structured interactions among HR/organisation, finance, and administrative units; synchronised internal work with external procedural guidance.	HR ↔ finance ↔ operations	Integrated feasibility (budget/sustainability) with competence modelling; strengthened implementability.	P1
NEGOTIATED BOUNDED FLEXIBILITY	Brokered a negotiated adaptation of role labels/descriptors to fit hybrid work patterns while preserving the programme's core grammar and comparability requirements.	Standardisation ↔ contextual fit	Avoided bureaucratic containment; increased local usability without abandoning coherence.	P0-P1
DATA MANAGEMENT	Mobilised certified personnel data (contractual profiles, training histories, role allocations) and coordinated validation to prevent arbitrary or contested classifications.	Data governance ↔ modelling work	Shortened validation cycles; reduced resistance by grounding profiles in trusted data.	P1

Brokerage mechanism	Core practice enacted by the broker	Boundary/interface bridged	Contribution to implementation	Where
LEGITIMACY AND STAKEHOLDER MEDIATION	Translated modelling choices into governance-relevant implications (fairness, careers, development priorities) in interactions with senior leadership and employee representation.	Technical model ↔ institutional arenas	Built endorsement pathways; protected implementation from political/legitimacy shocks.	P1 end
ITERATIVE LEARNING AND FEEDBACK LOOPS	Maintained reflective routines (check-ins, issue logs, recap notes) that supported incremental refinement and learning across cycles.	Project cycles ↔ organisational learning	Sustained momentum; enabled continuous improvement of descriptors and mappings.	P0–P1

Legend: P0 = onboarding and internal capacity-building; P1 = modelling and translation work

Building on these empirically grounded mechanisms, the discussion interprets UNI-1's implementation dynamics through the paper's theoretical framework on inter-organisational knowledge transfer and brokerage.

6 Discussion and Conclusion

The SKiLL-PA case suggests that implementation hinges less on the provision of codified HR artefacts (e.g., competence libraries, profiling logics, procedural scripts, and platform features) than on an organisation's capacity to translate them into a coherent system of structures, practices, and routines, one that is forged through a complex process of negotiation and adaptation among the public administration's key stakeholders as the reform is enacted.

What crosses organisational boundaries, therefore, is not "knowledge" as an abstract object, but a bundle of categories, representations, and prescriptions that becomes consequential only once it is anchored in situated routines, accountability relations, and data infrastructures. In this sense, knowledge transfer is better understood as a socio-organisational accomplishment, produced through interpretive alignment and boundary work, rather than as a linear act of transfer (Yih-Tong Sun & Scott, 2005).

At project level, SKiLL-PA intentionally couples standardisation and customization. Tools, templates, competence taxonomies, procedural milestones, KPI-driven reporting, and a dedicated digital environment collectively provide a shared grammar meant to stabilise comparability across administrations. Yet the same grammar can intensify interpretive and political tensions when it encounters organisations whose division of labour is structurally fluid.

In UNI-1, the potential for misfit was amplified by role hybridity, task rotation, and multifunctional teamwork, features that sit uneasily with the implicit assumption, often built into competence models, that roles can be discretely bounded and consistently labelled over time. This is precisely the cross-domain condition in which actors carry distinct criteria of legitimacy, and where "making knowledge travel" depends on negotiation and translation rather than dissemination alone (Sandberg and Tsoukas, 2015). Collaboration, in turn, requires participants to step outside habitual frames and co-construct a vocabulary that can be shared and operationalised, overcoming domain-specific interests and interpretive inertia (Canonico et al., 2020).

In UNI-1, this translation burden was addressed through a formally mandated brokerage role. The academic coordinator, an internal faculty member appointed through a rectoral directive, was empowered to convene units, access required organisational information through legitimate channels and represent the University in inter-organisational alignment with the Department and programme partners. The role operated across HR, finance, and the programme interface, bridging domains whose assumptions about work, data, and legitimacy only partially overlap. This configuration aligns with accounts that conceptualise knowledge brokers as intermediaries who enable knowledge gathering and dissemination across partially disconnected groups and interpretive communities (Haas, 2015), and with the broader notion of boundary spanning as linking internal units to external environments in ways that enable coordination and knowledge flow (Cross and Prusak, 2002).

The UNI-1 implementation narrative indicates that brokering was enacted through a combination of interactional, artefactual, and institutional mechanisms, activated at critical episodes where standardisation encountered contextual constraints. First, the broker performed translation and reframing to render the competence grammar locally intelligible. In several profiling sessions, administrative staff initially treated behavioural competences as generic managerial rhetoric, peripheral to "real" administrative tasks. The coordinator re-specified these competences by anchoring them to concrete work situations (such as cross-office coordination, managing interdependencies under time pressure, and handling stakeholder expectations) thereby making them legitimate and actionable. This resembles the "translator" role emphasised in organisational knowledge accounts, whereby brokers mediate disciplinary perspectives and enable shared

understanding by reframing content into locally meaningful categories (Ishiyama, 2016). It also echoes the argument that brokering across communities of practice involves connecting practices and meanings rather than merely transmitting information (Wenger, 2000).

Second, the broker mobilised artefacts as coordination devices to stabilise meaning across interactions. The restricted-access digital workspace, versioned templates, and traceable decision logs did more than store documentation; they provided reference points that disciplined discussion, surfaced disagreements, and allowed interpretive closures to be fixed into successive artefact versions. This is consistent with the idea that boundary-crossing mechanisms rely on pragmatic infrastructures that support communication and the construction of a common collaborative framework (Rajalo and Vadi, 2017). In UNI-1, artefact mediation reduced the likelihood that the competence model would remain an episodic discourse and increased its chances of becoming a governable organisational object.

Third, brokerage became decisive when UNI-1 confronted the tension between standard labels and local work reality. A composite vignette (consistent with observed dynamics) illustrates the point. During Phase 1, the team attempted to profile a cluster of staff whose work blended procurement, digital support, and process coordination across departments. The programme template required assignment to a single standard role label that presupposed stable functional boundaries. HR staff argued that any single label would misrepresent work and generate perceived inequities; finance warned that misclassification could distort training and development priorities. The coordinator convened a "profiling clinic" with IPA/NIA counterparts and the Department's procedural referent, using three artefacts to structure negotiation: the programme role taxonomy, UNI-1 internal job descriptions and workload evidence, and a draft mapping note proposing retention of the prevailing-activity rule alongside a controlled annotation field for secondary responsibilities. The outcome was a bounded adaptation: UNI-1 preserved the programme's core profiling logic (to protect comparability) while refining descriptors and embedding a limited mechanism to represent role plurality without proliferating idiosyncratic labels. This episode illuminates a central brokerage mechanism - negotiated flexibility under a shared grammar - through which the broker converted prospective resistance into a jointly authorised adjustment, sustaining both local credibility and programme alignment. From a knowledge translation standpoint, this aligns with the view that design work can function as a translation mechanism by shaping representations so that knowledge can travel across contexts while retaining usability (Donnelly, 2014).

Fourth, the broker performed institutional and legitimacy work to protect implementation from bureaucratic containment. The formal mandate enabled early engagement with internal governance bodies and employee representatives, translating technical modelling decisions into organisationally salient stakes: recognisability of roles, perceived fairness, implications for development pathways, and the sustainability of resource commitments. This legitimacy work is consistent with definitions of knowledge brokers as intermediaries who remove barriers and foster shared language and culture in transfer processes (Chiambaretto et al., 2019). It also clarifies why UNI-1's inclusion of finance in the core team was enabling: it reduced the likelihood that the competence system would be dismissed as aspirational yet "unfunded," strengthening the credibility of the emerging professional system as a basis for managerial decisions.

Overall, the case refines the paper's argument by specifying that inter-organisational knowledge transfer in competence-based, platform-mediated reforms depends on brokerage that aligns three layers simultaneously: interpretive alignment across domains (what competences mean for local work and how they are recognised as legitimate), socio-technical alignment (how the competence grammar is inscribed into digital and documentary artefacts with attention to data integrity and traceability), and institutional alignment (how the competence system is authorised, defended, and made negotiable with internal constituencies).

The knowledge broker's dynamic role involved interdependent and overlapping functions. We identified three main functions. The first was facilitating the alignment of different languages and lenses using different brokerage mechanisms (sense-giving, translation of competence language, artefact-mediated alignment, convening cross-domain coordination, negotiated bounded flexibility, data governance, iterative learning and feedback loop, i.e. table 1). The second was connecting separated know-how, needs, and practices by managing interactions, which involved managing interactions and negotiating relationships between different stakeholders to connect knowledge, needs, and practices, and increase the permeability of boundaries between team members. The third function was sustaining engagement in HR change project by building coordination and communication mechanisms in a bottom-up approach that involved participation, involvement, and cooperation between different organisational actors.

7 Ethics Declaration

Ethical clearance was not required for this study under the authors' institutional procedures, as the research involved no interventions, no collection of special category personal data, and no foreseeable risks beyond those encountered in routine organisational activities.

8 AI Declaration

The authors used AI-based tools solely to support language editing and proofreading (e.g., improving clarity, style consistency, and correcting typographical or grammatical errors). No AI tool was used to generate, fabricate, or modify empirical data, results, or interpretations. The authors explicitly confirm that they carefully reviewed, verified, and accepted all AI-assisted edits and that they take full responsibility for the final content of the manuscript.

Evaluating the Acceptance of GenAI in Italian Academies of Fine Arts

Francesco Filippo, Francesco Paolo Lagrasta, Barbara Scozzi
Politecnico di Bari - (DMMM), Bari, Italy

Abstract

Generative Artificial Intelligence (GenAI) is increasingly entering higher education, offering new opportunities for teaching, learning, content generation and creative experimentation. In artistic and design-oriented education, however, the acceptance of GenAI cannot be explained only through traditional efficiency-based criteria. Within Italian Academies of Fine Arts (AFAM), creative work is closely linked to identity, authorship, aesthetic judgment, expressive autonomy and cultural meaning. For this reason, understanding the factors that shape students' and educators' intention to use GenAI requires a contextualized extension of established technology acceptance models.

This paper investigates the acceptance of GenAI in Italian Academies of Fine Arts by developing and preliminarily validating a survey instrument grounded in the Technology Acceptance Model (TAM) and enriched with constructs specific to creative contexts. The study builds on a systematic literature review conducted on Scopus, which identified 274 articles at the intersection of artificial intelligence, creativity and technology adoption. A core dataset of 31 studies was then examined to identify recurrent theoretical frameworks, constructs and measurement items. Based on this analysis, TAM was selected as the reference model and extended with four context-specific constructs: trust in GenAI systems, aesthetic satisfaction, creative autonomy and subjective norm. The methodological design combines literature-based construct development, questionnaire design and qualitative validation through a cognitive interviewing approach. The questionnaire is structured around a seven-point Likert scale and includes items adapted from prior acceptance studies and reformulated for GenAI-enabled creative practices. A preliminary validation phase was conducted with participants familiar with artistic and creative domains, to assess semantic clarity, item interpretability, cognitive load and potential response biases. The paper contributes to the literature by proposing a TAM-based model tailored to creative higher education. It also offers practical implications for AFAM institutions, educators and curriculum designers interested in supporting responsible and context-sensitive GenAI integration. The findings suggest that GenAI acceptance in artistic education depends not only on usefulness and ease of use, but also on trust, perceived control over the creative process and satisfaction with the aesthetic quality of AI-generated outputs.

Keywords: Generative Artificial Intelligence; Higher Education; Technology Acceptance Model; Creative Autonomy; Academy of Fine Arts

Paper type: Academic Research Paper

1 Introduction

Generative Artificial Intelligence (GenAI) is transforming the ways in which digital content is conceived, produced and revised. Through natural language prompts, sketches or iterative interactions, users can now generate texts, images, videos, layouts and other creative outputs with unprecedented speed and accessibility. These technologies are increasingly embedded in educational environments and creative software ecosystems, where they are presented as tools for supporting ideation, experimentation, personalization and productivity (Kim, 2025; Kanont et al., 2024).

In higher education, the diffusion of GenAI has raised strategic, pedagogical and ethical questions. Institutions are required to understand how students and teachers perceive these tools, which factors influence their intention to use them, and how curricula and institutional practices should evolve in response. The relevance of this issue is reflected in the Special Track on the Acceptance of Generative Artificial Intelligence in Higher Education, which explicitly calls for studies on influencing factors of AI adoption, technology acceptance, institutional preparedness, curriculum innovation and the regulation or support of AI use in higher education. The track also highlights the relevance of models such as TAM, UTAUT, CFA and SEM-based approaches for studying these phenomena.

The acceptance of GenAI in artistic and creative higher education deserves specific attention. In Italian Academies of Fine Arts, hereafter referred to as AFAM institutions, creative production is not merely a technical activity. It is connected to identity, authorship, expressive autonomy, cultural sensitivity and aesthetic judgment. Unlike the adoption of traditional information systems, the adoption of GenAI in this context does not only depend on whether the technology is useful or easy to use. It also depends on whether students and educators

trust the system, perceive that it preserves their creative agency, and consider the generated outputs aesthetically meaningful and aligned with their intentions.

This study addresses this issue by developing a model for evaluating GenAI acceptance in AFAM institutions. The research builds on previous work on GenAI adoption in creative contexts and on a systematic literature review focused on the intersection between artificial intelligence, creativity and technology adoption. The literature review identified a corpus of 274 articles through a Scopus query and selected a core dataset of 31 papers for deeper semantic and methodological analysis. This review showed that established models such as TAM, UTAUT and TPB remain central in the study of technology adoption, but also that their application to GenAI in creative domains requires contextual adaptation.

The paper responds to a dual gap. First, technology acceptance models have often been applied to organizational, business, healthcare or general educational settings, while creative higher education remains underexplored (Cabero-Almenara et al., 2024; Zhang and Hou, 2024). Second, traditional acceptance constructs may not fully capture the symbolic, emotional and aesthetic dimensions of GenAI use in artistic practice. For example, perceived usefulness may explain whether a student believes that GenAI improves performance, but it does not fully explain whether the student feels creatively in control. Similarly, output quality may be relevant in technical contexts, but in artistic domains it is necessary to consider aesthetic satisfaction and cultural alignment.

The objective of this paper is therefore to develop and preliminarily validate a survey instrument for evaluating the acceptance of GenAI in Italian Academies of Fine Arts. The study adopts the Technology Acceptance Model as its theoretical foundation (Davis, 1989), while integrating additional constructs derived from the literature and from the specific characteristics of creative work. The model includes perceived usefulness, perceived ease of use, attitude toward use and behavioral intention, together with trust, aesthetic satisfaction, creative autonomy, facilitating conditions and subjective norm.

The main research question guiding the study is:

RQ: Which factors influence the behavioral intention to use GenAI in Italian Academies of Fine Arts, and how do creative-context constructs extend traditional technology acceptance models?

2 Relevance of the Research

The relevance of this research lies in the increasing need to understand the acceptance of GenAI in higher education and, more specifically, in creative and artistic institutions. The rapid diffusion of GenAI tools requires universities and academies to make decisions about curriculum design, student support, academic integrity, creative practice and institutional regulation. These decisions should not be based only on technological enthusiasm or fear, but on empirical knowledge about how users perceive and evaluate GenAI.

The AFAM sector represents a particularly meaningful context for this investigation. Italian Academies of Fine Arts are part of the national Higher Artistic and Musical Education system and provide first- and second-cycle degrees in fields such as painting, sculpture, scenography, design, multimedia arts and related creative disciplines. These institutions train future artists, designers, educators and creative professionals. As a consequence, their response to GenAI may influence not only current educational practices, but also future norms within creative industries.

Existing research on GenAI adoption in higher education has often focused on students' general attitudes, pedagogical beliefs, perceived usefulness, academic writing or technology readiness (Cabero-Almenara et al., 2024; Kanont et al., 2024; Mourtajji and Arts-Chiss, 2024). These contributions are important, but they rarely address the specificities of artistic education. In creative contexts, users evaluate GenAI not only as a tool that may increase efficiency, but also as an actor that can influence authorship, autonomy, originality, aesthetic coherence and emotional resonance. For this reason, a context-sensitive model is needed.

The research is also relevant from a theoretical perspective. TAM and UTAUT have provided robust frameworks for explaining technology acceptance across different settings (Davis, 1989; Venkatesh et al., 2003; Venkatesh et al., 2012). However, GenAI differs from traditional software because its outputs are probabilistic, partially unpredictable and often difficult to evaluate through purely functional criteria. In creative work, the value of an output is not simply determined by accuracy or efficiency, but by meaning, style, originality and alignment with the user's expressive goals. This makes it necessary to integrate constructs such as trust, aesthetic satisfaction and creative autonomy.

The research is also relevant for practice. Educators and institutional decision makers need tools to understand whether GenAI is perceived as a support for learning and creativity or as a threat to authorship, competence and artistic identity. A validated questionnaire can help AFAM institutions identify barriers to adoption, differences between students and educators, and areas where training, guidelines or technological

support are needed. It can also inform software designers and providers interested in developing GenAI tools that are more aligned with the needs of creative learners.

3 Contribution

This study contributes to the literature on GenAI acceptance by proposing a contextualized extension of the Technology Acceptance Model for creative higher education. Rather than replacing established acceptance frameworks, the paper builds on them and adapts them to the specific characteristics of GenAI-mediated creative practice.

3.1 Theoretical contribution

The theoretical contribution of the paper is threefold.

First, the study extends TAM to the context of GenAI in artistic education. TAM traditionally explains technology acceptance through perceived usefulness and perceived ease of use, which influence attitude toward use and behavioral intention (Davis, 1989). These constructs remain relevant, but they do not fully capture the experiential, symbolic and aesthetic dimensions of GenAI use in creative domains. By incorporating creative autonomy, aesthetic satisfaction and trust, the proposed model offers a more suitable lens for studying GenAI acceptance in AFAM institutions.

Second, the study clarifies the conceptual distinction among constructs that may otherwise overlap. For example, perceived usefulness refers to the extent to which GenAI is expected to improve creative or educational performance. Aesthetic satisfaction refers to users' evaluation of the artistic, stylistic and cultural adequacy of generated outputs. Creative autonomy refers to the perceived preservation of control, authorship and intentionality during the creative process. Trust refers to confidence in the reliability, transparency and appropriateness of GenAI systems. These distinctions respond to the need to avoid conceptual ambiguity among constructs.

Third, the paper contributes to the literature by combining literature-based item selection with qualitative validation. The questionnaire was not designed only by adapting generic TAM items, but by building a structured database of items and constructs extracted from previous studies. This database included approximately 600 items retrieved from the analyzed literature and enabled the comparison of different operationalizations of the same variables. The final items were then adapted to the language and experience of creative users.

3.2 Practical implications

From a practical perspective, the study provides a tool that can support AFAM institutions in evaluating how students and educators perceive GenAI. The questionnaire can help identify whether adoption is mainly driven by perceived usefulness, ease of use, social pressure, trust, creative autonomy or aesthetic satisfaction. This information can support targeted interventions.

For educators, the model can inform teaching strategies. If students perceive GenAI as useful but threatening to autonomy, educators may need to design activities that emphasize human control, critical selection and reflective use. If students report low trust, institutions may need to provide guidance on data sources, copyright, transparency and limitations of AI-generated outputs. If aesthetic satisfaction is low, training may focus on prompt refinement, iterative experimentation and evaluation of AI-generated alternatives.

For curriculum designers and technology providers, the model highlights the need to address GenAI not as a generic digital tool, but as a technology whose acceptance depends on usability, creative control, ethical awareness, aesthetic judgment and alignment with artistic identity.

4 Method

The study adopts a mixed and exploratory research design that combines systematic literature review, construct development, questionnaire design and qualitative validation. The methodology responds directly to the reviewers' request for a more detailed specification of the empirical strategy, sampling procedure and construct definition.

4.1 Literature review and item database

The first phase consisted of a structured Scopus review designed to capture the intersection between GenAI, creativity and technology adoption. The search was limited to English journal articles in subject areas relevant

to social sciences, computer science, business, engineering, arts, decision sciences, psychology and multidisciplinary research.

The search identified an initial corpus of 274 scientific articles. This corpus was analyzed at two levels. First, a bibliometric analysis was conducted to map temporal trends, geographical distribution, keyword co-occurrences and thematic clusters. Second, a core dataset of 31 papers was selected for deeper semantic and methodological analysis. The purpose of this second level was to identify theoretical frameworks, constructs, items, samples and methods used in the literature.

A structured item database was then created. The database collected approximately 600 measurement items from the analyzed papers, including information on the original construct, theoretical model, source and possible model extension. This database supported the identification of recurring constructs and allowed the research team to compare how similar variables were operationalized across different studies.

4.2 Selection of the reference model

The Technology Acceptance Model was selected as the reference theoretical framework because of its parsimony, clarity and suitability for studying individual-level adoption (Davis, 1989). Compared with broader models such as UTAUT and UTAUT2, TAM offers a more linear structure and allows the researcher to isolate the core drivers of acceptance: perceived usefulness, perceived ease of use, attitude toward use and behavioral intention.

However, TAM was not adopted without modification. The literature review and the specific characteristics of creative contexts suggested that the basic model should be extended. GenAI is not a deterministic tool that simply supports predefined tasks. It generates outputs that may be unpredictable, aesthetically variable and culturally sensitive. For this reason, users' acceptance may depend on additional constructs related to trust, autonomy and aesthetic evaluation.

UTAUT and UTAUT2 were also considered because they include relevant constructs such as social influence and facilitating conditions (Venkatesh et al., 2003; Venkatesh et al., 2012). In the proposed model, these dimensions are retained through subjective norm and facilitating conditions, but the overall model remains TAM-based in order to preserve parsimony and focus.

4.3 Sampling and recruitment strategy

The target population of the study consists of students and educators from Italian Academies of Fine Arts and related AFAM institutions. The empirical strategy distinguishes between two phases: a qualitative pilot validation phase and a broader quantitative survey phase.

The pilot validation phase is designed to assess the clarity, interpretability and contextual adequacy of the questionnaire. It involves participants familiar with creative and artistic practices, including students, doctoral candidates, educators or practitioners in artistic and humanistic disciplines. The purpose of this phase is not to statistically validate the factor structure of the model, but to identify semantic ambiguities, cognitive load, response difficulties and potential biases before broader administration.

The broader survey phase will target a larger sample of students and educators across multiple AFAM institutions. The recruitment strategy will follow a purposive and institutional logic. Institutions will be selected to ensure variation in geographical location, public or private status, and disciplinary orientation, including visual arts, design, multimedia arts and scenography. Within each institution, both students and educators will be invited to participate in order to compare perceptions across user profiles.

The pilot sample is therefore used only for qualitative validation and cognitive pretesting, while the broader survey will require a larger sample suitable for reliability assessment, factor analysis and, where possible, structural equation modeling.

4.4 Questionnaire design

The questionnaire is structured into two main sections. The first section collects demographic and control variables, including gender, age, educational level, role, creative discipline, previous experience with GenAI and frequency of use. These variables are important because prior experience and disciplinary background may influence perceived ease of use, trust and behavioral intention.

The second section measures the constructs included in the proposed model. Items are formulated as statements and assessed on a seven-point Likert scale, where 1 corresponds to "strongly disagree" and 7 corresponds to "strongly agree". The use of a seven-point scale is consistent with prior studies on technology acceptance and allows respondents to express nuanced levels of agreement.

The items were adapted from prior literature and reformulated for GenAI-enabled creative practice. For example, items measuring perceived usefulness refer to whether GenAI can improve the quality, speed or effectiveness of creative work. Items measuring creative autonomy refer to whether users feel that they remain in control of the creative process when using GenAI. Items measuring aesthetic satisfaction refer to whether generated outputs are perceived as aesthetically coherent and aligned with the user's expectations.

4.5 Qualitative validation through cognitive interviewing

The questionnaire was preliminarily validated through a qualitative protocol inspired by cognitive interviewing. Cognitive interviewing is used to identify sources of measurement error by investigating how respondents understand, retrieve information, judge and answer questionnaire items (Tourangeau et al., 2000; Willis, 2005; Beatty and Willis, 2007).

After completing the questionnaire, participants were invited to discuss the clarity of items, the meaning of key terms, the difficulty of answering, and the perceived adequacy of the constructs. The validation focused on four dimensions: semantic clarity, cognitive load, social desirability bias and construct completeness.

This phase allowed the research team to identify whether terms such as "creative autonomy", "aesthetic satisfaction", "trust" or "GenAI-generated output" were interpreted consistently by participants. It also helped assess whether the questionnaire language was appropriate for creative education and whether some items required reformulation.

Table 1: Research design and methodological steps

Step	Description	Output
Step 1 – Literature review	Scopus-based review on GenAI, creativity and technology adoption	Corpus of 274 articles
Step 2 – Core dataset analysis	Semantic and methodological analysis of selected studies	Core dataset of 31 papers
Step 3 – Item database construction	Extraction and classification of measurement items	Database of approximately 600 items
Step 4 – Model selection	Comparison of TAM, UTAUT and TPB	TAM selected as reference model
Step 5 – Model extension	Addition of creative-context constructs	Trust, aesthetic satisfaction, creative autonomy and subjective norm
Step 6 – Questionnaire design	Adaptation of items to GenAI and creative education	Seven-point Likert questionnaire
Step 7 – Pilot validation	Cognitive interviewing and qualitative feedback	Refined instrument for broader survey
Step 8 – Future quantitative analysis	Reliability, factor analysis, SEM or regression	Empirical validation of the model

5 Proposed Model and Preliminary Validation

5.1 Construct definitions and theoretical origin

The proposed model includes nine constructs. Four constructs derive directly from TAM: perceived usefulness, perceived ease of use, attitude toward use and behavioral intention. Two constructs are incorporated from broader acceptance frameworks: subjective norm and facilitating conditions. Three constructs are introduced or adapted for the creative GenAI context: trust, aesthetic satisfaction and creative autonomy.

Table 2: Constructs for evaluating GenAI acceptance in AFAM institutions

Construct	Definition	Theoretical origin
Perceived usefulness (PU)	The degree to which users believe that GenAI improves the effectiveness, quality or productivity of their creative work	TAM
Perceived ease of use (PEOU)	The degree to which users believe that GenAI tools are easy to learn and use	TAM
Attitude toward use (ATU)	The user's positive or negative evaluation of using GenAI in creative practice	TAM
Behavioral intention (BI)	The intention to use GenAI tools in future creative or educational activities	TAM / UTAUT

Construct	Definition	Theoretical origin
Subjective norm (SN)	The perceived social pressure from teachers, peers, institutions or creative communities to use or avoid GenAI	TAM2 / TPB / UTAUT
Facilitating conditions (FC)	The perceived availability of technical, organizational and educational support for using GenAI	UTAUT
Trust (TR)	Confidence in the reliability, transparency and appropriateness of GenAI outputs and system behavior	TAM extensions / GenAI literature
Aesthetic satisfaction (AS)	Satisfaction with the aesthetic, stylistic and cultural adequacy of AI-generated outputs	Creative-context extension
Creative autonomy (CA)	The perception of maintaining control, authorship and intentionality when using GenAI	Creative-context extension

5.2 Hypotheses and structural relationships

The conceptual model assumes that GenAI acceptance in creative education is shaped by both classical acceptance factors and creative-specific constructs. Trust is expected to influence perceived usefulness and perceived ease of use because users are more likely to consider GenAI useful and manageable when they perceive it as reliable and predictable. Aesthetic satisfaction is expected to influence perceived usefulness because creative users evaluate usefulness partly through the quality and coherence of outputs. Creative autonomy is expected to influence attitude toward use because users may develop a more favorable attitude when they feel that GenAI supports rather than replaces their creative agency.

Subjective norm is expected to influence both attitude and behavioral intention, especially in educational contexts where teachers, peers and institutional guidelines shape technology-related behavior. Facilitating conditions may influence perceived ease of use and behavioral intention by reducing technical barriers and uncertainty. Finally, perceived usefulness and perceived ease of use are expected to influence attitude toward use and behavioral intention, consistently with TAM.

Table 3: Hypothesized relationships among constructs

Hypothesis	Relationship	Rationale
H1a	Trust → Perceived usefulness	Users who trust GenAI are more likely to perceive it as useful
H1b	Trust → Perceived ease of use	Trust reduces uncertainty and supports perceived manageability
H2	Aesthetic satisfaction → Perceived usefulness	In creative contexts, usefulness depends on aesthetic adequacy
H3	Creative autonomy → Attitude toward use	Users are more favorable when GenAI preserves creative control
H4a	Subjective norm → Attitude toward use	Peer, teacher and institutional expectations shape user attitudes
H4b	Subjective norm → Behavioral intention	Social pressure may directly affect intention to use
H5a	Facilitating conditions → Perceived ease of use	Technical and educational support reduces perceived effort
H5b	Facilitating conditions → Behavioral intention	Supportive environments increase willingness to adopt
H6	Perceived ease of use → Perceived usefulness	Easier tools are more likely to be perceived as useful
H7	Perceived usefulness → Attitude toward use	Usefulness supports favorable evaluations of GenAI
H8	Perceived ease of use → Attitude toward use	Ease of use contributes to positive attitudes
H9	Attitude toward use → Behavioral intention	Favorable attitudes increase intention to use

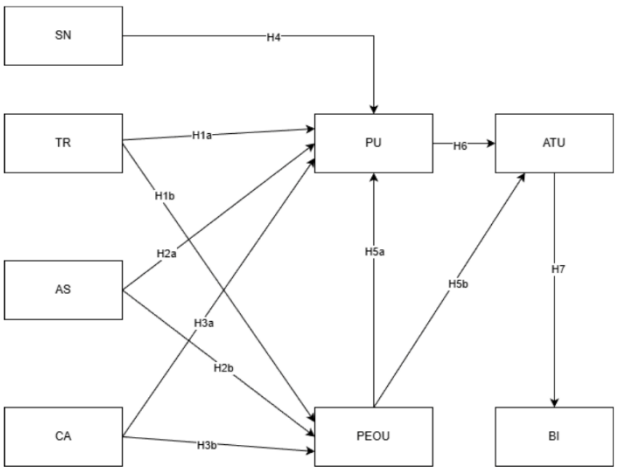

Figure 1: Proposed TAM-based model for GenAI acceptance in AFAM institutions

5.3 Questionnaire structure

The questionnaire translates the constructs into measurable items. Items were selected by comparing prior operationalizations in the item database and then adapting them to GenAI-enabled creative practice. The questionnaire includes two sections.

The first section collects demographic and contextual information. Respondents are asked to indicate their role, age, gender, educational level, creative discipline, previous experience with GenAI tools and frequency of use. These variables will be used as control variables in subsequent analysis.

The second section measures the constructs of the model through Likert-scale statements. Respondents are asked to evaluate their level of agreement with statements concerning usefulness, ease of use, trust, creative autonomy, aesthetic satisfaction, subjective norm, facilitating conditions, attitude and behavioral intention.

Table 4: Questionnaire structure and examples of item content

Section	Content	Example of measured dimension
Respondent profile	Role, age, gender, education, discipline	Student/educator profile and creative domain
GenAI experience	Prior use and frequency of use	Familiarity with text, image or video generation tools
Perceived usefulness	Impact of GenAI on creative performance	Improvement of ideation, productivity or output quality
Perceived ease of use	Effort required to learn and use GenAI	Clarity, accessibility and ease of interaction
Trust	Reliability and appropriateness of GenAI outputs	Confidence in outputs and system behavior
Aesthetic satisfaction	Alignment with aesthetic expectations	Stylistic, expressive and cultural coherence
Creative autonomy	Perceived control over the creative process	Preservation of authorship and intentionality
Subjective norm	Influence of peers, teachers and institutions	Social and educational pressure toward adoption
Facilitating conditions	Availability of support and infrastructure	Training, access to tools, institutional guidance
Attitude and intention	Overall evaluation and future use	Willingness to use GenAI in creative projects

5.4 Preliminary validation findings

The qualitative validation phase provided useful insights into the adequacy of the questionnaire. Overall, the instrument was considered relevant and aligned with the experience of creative users. Participants recognized the importance of constructs such as trust, creative autonomy and aesthetic satisfaction, confirming that GenAI acceptance in artistic contexts cannot be reduced to usefulness and ease of use.

The validation also revealed some critical issues. First, several terms required clarification. Concepts such as “GenAI”, “creative autonomy” and “aesthetic satisfaction” may be interpreted differently depending on the respondent’s background. This suggests that the questionnaire should include short preliminary definitions and examples of GenAI tools before the item section.

Second, the validation highlighted the importance of contextualizing items. Generic technology acceptance statements may be too abstract for AFAM respondents. Items should refer explicitly to creative work, artistic projects, design outputs, visual experimentation or educational activities.

Third, participants indicated that the degree of prior experience with GenAI may strongly affect responses. For this reason, previous use and frequency of use should be included as control variables. Respondents with no experience may answer based on expectations or fears, while experienced users may evaluate the technology based on actual interaction.

Fourth, the validation confirmed the risk of social desirability bias. In educational contexts, respondents may feel pressure to present themselves either as open to innovation or as protective of human creativity. For this reason, the questionnaire should emphasize anonymity and clarify that there are no right or wrong answers.

Table 5: Main insights from the qualitative validation phase

Validation area	Main issue identified	Implication for the questionnaire
Semantic clarity	Some key terms may be interpreted differently	Add short definitions and examples
Contextual relevance	Generic acceptance items may be too abstract	Reformulate items around creative and educational practices
Cognitive load	Some constructs may appear conceptually close	Clarify distinctions among usefulness, aesthetic satisfaction and autonomy
Prior experience	Users with different levels of experience may answer differently	Include previous use and frequency as control variables
Social desirability	Respondents may answer according to perceived expectations	Emphasize anonymity and neutrality
Construct completeness	TAM alone does not fully capture creative experience	Retain creative autonomy, aesthetic satisfaction and trust

5.5 Expected quantitative analysis

The refined questionnaire will be administered to a broader sample of AFAM students and educators. The quantitative analysis will first use descriptive statistics to profile respondents and summarize construct distributions. Reliability will then be assessed through Cronbach's alpha or composite reliability. Depending on the final sample size, exploratory factor analysis, confirmatory factor analysis or structural equation modeling will be used to test the measurement and structural model. If the sample is not sufficient for full SEM, hierarchical regression will be adopted to estimate the incremental explanatory power of creative-context constructs beyond traditional TAM variables. This strategy is consistent with the special track's interest in PLS-SEM, CB-SEM, CFA and technology acceptance models, while remaining appropriate for the exploratory nature of the study.

6 Discussion and Implications

The proposed model suggests that GenAI acceptance in AFAM institutions is shaped by both traditional and creative-specific factors. Perceived usefulness and perceived ease of use remain important because users are more likely to adopt technologies that support their activities and are easy to learn. However, in creative higher education these constructs are insufficient on their own.

Trust is central because GenAI systems are often perceived as opaque, probabilistic and difficult to control. Users may hesitate to rely on outputs whose sources, training data or decision logic are unclear. This is particularly relevant in artistic education, where originality and authorship are essential.

Aesthetic satisfaction is also critical. In creative contexts, users do not evaluate outputs only in terms of functionality. They assess whether outputs are stylistically coherent, expressive and aligned with their intentions. A tool may be useful in a technical sense but still rejected if its outputs are perceived as aesthetically generic or culturally misaligned. This is also consistent with responsible AI approaches that emphasize transparency, human oversight and contextual risk management (OECD, 2022; NIST, 2024).

Creative autonomy is perhaps the most distinctive construct. GenAI can be perceived as empowering when it supports exploration and expands creative possibilities. At the same time, it can be perceived as intrusive when it reduces user control or homogenizes creative expression. Therefore, acceptance depends on whether users feel that GenAI strengthens or weakens their role as authors.

7 Conclusion

This paper developed a model for evaluating the acceptance of GenAI in Italian Academies of Fine Arts. Building on TAM and related technology acceptance frameworks, the study proposed an extended model that integrates constructs specific to creative education: trust, aesthetic satisfaction and creative autonomy.

The study also responds to the need for more context-sensitive evidence on GenAI in higher education. Rather than assuming that acceptance factors are universal, it shows that local institutional settings and disciplinary cultures matter. In AFAM institutions, GenAI adoption is not only a question of performance and usability, but also of trust, control, aesthetic alignment and professional identity.

The study has limitations. The qualitative validation phase provides preliminary insights but does not yet constitute statistical validation of the full model. Future research should administer the questionnaire to a larger sample of AFAM students and educators, allowing reliability analysis, factor validation and structural model testing. Further studies may compare public and private academies, different artistic disciplines and different levels of GenAI experience.

Future developments may also support the construction of a maturity model for GenAI acceptance in creative higher education. Such a model could help institutions identify their level of readiness, design appropriate training interventions and develop policies for the responsible integration of GenAI into artistic and design education.

8 Ethics Declaration

The research design involves the administration of a questionnaire and qualitative validation activities with participants from higher education and creative contexts. Participation will be voluntary and based on informed consent. No sensitive personal data will be collected beyond information strictly necessary for the purposes of the study. Where required by the authors' institution, ethical clearance will be requested before broader data collection. Data will be anonymized and used only for academic research purposes.

9 AI Declaration

No AI tool was used to develop the paper.

Artificial Intelligence and Soft Skills Development in Organizations: A Systematic Literature Review

Antonio Lorena, Anna Maria Correale, Alessia Talarico, Rocco Reina
University Magna Graecia, Catanzaro, Italy

Abstract

The rapid integration of Artificial Intelligence (AI) into organizational contexts is progressively reshaping how knowledge and skills are developed and managed (Kaplan & Haenlein, 2019; Dwivedi et al., 2021). While AI-driven automation has transformed processes and decision-making, its implications for people's learning, particularly about soft skills, remain an area of growing scholarly and managerial interest. The current evidence base is still fragmented, and recent contributions have explicitly called for systematic reviews to clarify how AI supports (or constrains) soft skills (Deming, 2017; Heckman & Kautz, 2012; Balcar, 2016). Against this background, the present study adopts a Systematic Literature Review (SLR) methodology guided by the PRISMA 2020 framework (Page et al., 2021; Tranfield et al., 2003). The review focuses on peer-reviewed articles published in English, covering all available years up to February 2026. This inclusive temporal scope was adopted to provide a comprehensive view of the evolution of research on AI and soft skills development, while also incorporating the most recent contributions in the field. The search is conducted across three important academic databases: Scopus, Web of Science, and ProQuest, using the core query "Artificial Intelligence" AND "soft skills", adapted through wildcards to reflect database-specific syntax. The selection procedure follows a multi-stage screening protocol and includes a quality appraisal of the eligible studies. The review is guided by the following research question: How is Artificial Intelligence shaping the landscape of soft skills development in organizations? The synthesis is likely to highlight recurring patterns, and at the same time, expected to systematize evidence on relevant challenges such as algorithmic bias, data privacy, and the risk of dehumanizing learning contexts (Morandini et al., 2023). Overall, the study contributes by mapping the existing literature in a structured and transparent manner, while also offering actionable implications for professionals, educators, and policymakers seeking to harness AI in support of a future-ready workforce.

Keywords: Artificial Intelligence; Soft Skills; Upskilling; Reskilling; Organizational Learning

Paper type: Academic Research Paper

1 Introduction

In the contemporary organizational landscape, the rapid integration of Artificial Intelligence (AI) is transforming not only how tasks are executed, but also how knowledge and capabilities are generated, mobilised, and renewed within organizations (Kaplan et al., 2019; Dwivedi et al., 2021). AI-driven systems are increasingly embedded in decision-making, processes of communication, coordination, and learning thereby reshaping the broader architecture of work and capability development. While this transformation has been widely discussed, its implications for people's learning - particularly for the development of soft skills - remain comparatively underexplored. This is a significant gap, since soft skills such as communication, critical thinking, adaptability, and empathy are widely recognized as central to individual effectiveness, organizational resilience, and long-term employability (Heckman et al., 2012; Deming, 2017). The spread of AI appears to increase, rather than diminish, the strategic importance of these transversal capabilities. As intelligent systems become more deeply embedded in organizational routines, human actors are required not only to use new technologies, but also to interpret, contextualise, and govern their application within organizations. In this sense, soft skills are increasingly emerging as a constitutive dimension of human capital in AI-mediated workplaces. However, despite growing scholarly and managerial attention, the available evidence remains fragmented across disciplines, contexts, and methodological approaches. Recent contributions have therefore called for more systematic efforts to clarify how AI supports, reshapes, or constrains the development of soft skills across different domains of knowledge and practice (Alvarado-Bravo et al., 2024). Against this background, the present study examines the critical intersection between AI and soft skills development in organizational settings through a Systematic Literature Review (SLR) guided by the PRISMA 2020 framework (Page et al., 2021) and informed by the evidence-based review tradition in management research (Tranfield et al., 2003). By synthesizing the existing literature in a structured and transparent manner, the study aims to clarify the current state of knowledge, identify the main thematic patterns emerging from the field, and provide a stronger conceptual basis for understanding how AI is reshaping workforce development and organizational learning.

2 Methodological Design

This study adopts a SLR to consolidate and critically organize the emerging body of knowledge on the relationship between Artificial Intelligence (AI) and soft skills development in organizational settings. A systematic literature review (SLR) is highly appropriate as the research field is still fragmented and rapidly evolving, because it enables a transparent, replicable, and cumulative synthesis of the evidence (Tranfield et al., 2003; Lorena, 2018; Xiao and Watson, 2019). In line with this logic, the review was designed according to the PRISMA 2020 framework, which provides a robust protocol for study identification, screening, eligibility assessment, and final inclusion (Page et al., 2021). The review addresses the following research question: How is Artificial Intelligence shaping the landscape of soft skills development in organizations?

2.1 Research STRATEGY

The literature search was conducted in Web of Science, Scopus, and ProQuest, selected because of their breadth, multidisciplinary coverage, and relevance for management and organizational research. The search was based on the core query *"artificial intelligence"* AND *"soft skills"*, applied consistently across the three databases with minor syntax adaptations where required by each platform. To ensure comparability and methodological consistency, the search was restricted to peer-reviewed journal articles published in English, covering all available years up covering all available years up to February 2026. Detailed search settings for each database are reported below.

Table 1 - Search Strategy and Retrieval Parameters Across Databases

Database	Search options
Web of Science	Search: topic Document type: article Language: English Date range: all years to February 2026 Citation indexes: available Web of Science export set
Scopus	Search: article title, abstract, keywords Document type: article Language: English Date range: all years to February 2026
ProQuest	Search: title, abstract, and subject terms Document type: article Source type: scholarly journals Language: English Date range: all years to February 2026

2.2 Inclusion and exclusion criteria

Explicit inclusion and exclusion criteria were defined in advance to ensure relevance and analytical consistency. Studies were included published in peer-reviewed scientific journals, written in English, that addressed the relationship between AI and soft skills as their main topic, and that provided empirical, conceptual, or review-based insights relevant to organizational, work, and educational contexts. We excluded studies that did not examine the interaction between AI and soft skills, that were not part of organizational contexts, and that were not deemed sufficiently relevant after evaluating the title, abstract, or full text. Contributions developed in educational settings were retained only when they offered mechanisms, technologies, or developmental insights transferable to organizational learning and workforce development.

2.3 Data collection, extraction and synthesis

The study selection process followed the logic of the PRISMA 2020 workflow, moving from identification to screening, eligibility assessment, and final inclusion (Page et al., 2021). After retrieval from the three databases, records were checked for duplication and screened through titles and abstracts. Potentially relevant studies were then assessed in full text against the predefined eligibility criteria, leading to a final corpus of 33 articles.

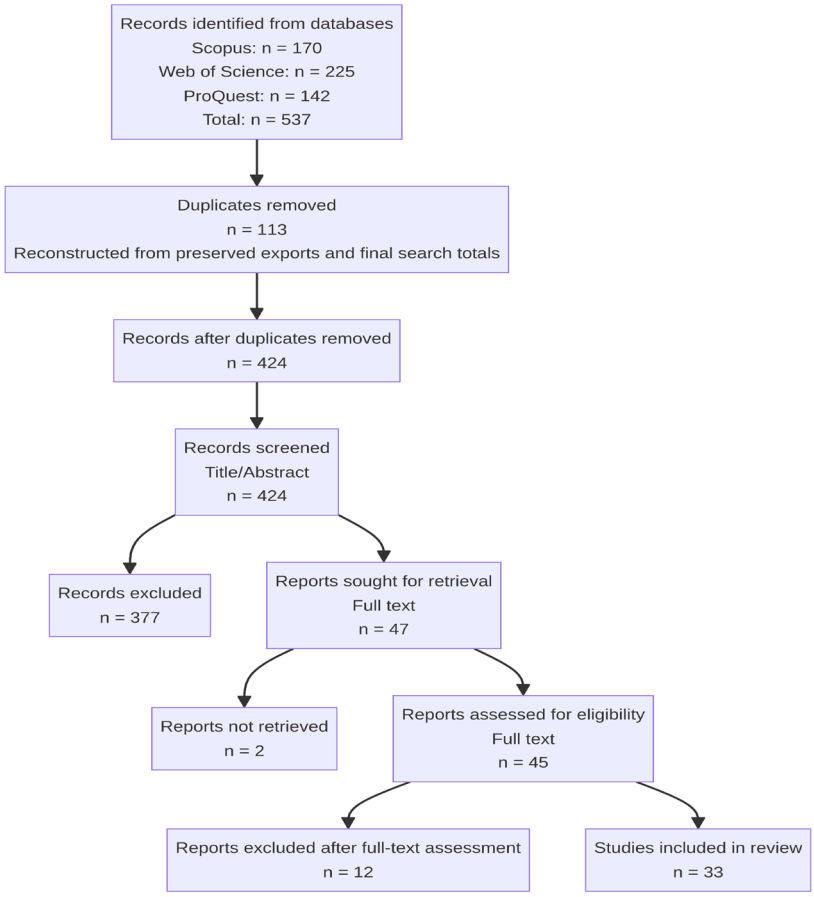

Figure 1 - PRISMA 2020 Flow Diagram of the Study Selection Process

Once the final set of studies had been identified, a structured data extraction process was conducted for each article. The extracted information included research focus, AI technologies or systems, soft skills addressed, methodological approach, principal findings, and organizational implications. The evidence was then synthesized through two complementary stages. First, a descriptive analysis was conducted to map the temporal distribution and internal composition of the corpus. Second, a thematic synthesis was developed to identify the main recurring dimensions across the reviewed studies. In line with the research objective, the synthesis was organized around three macro-areas:

- AI tools and systems used to support soft skills development;
- reported soft skills and learning outcomes;
- organizational strategies and enabling conditions, and barriers associated with AI-supported workforce development.

3 Descriptive Analysis

This section provides a concise descriptive overview of the 33 studies included in the review. Its purpose is to map the empirical structure of the corpus and highlight the main descriptive regularities, without anticipating the more interpretive discussion developed in the following section.

3.1 Publications per year

The temporal distribution of publications shows that research on AI and soft skills development in organizational and workforce-related settings is still relatively recent but has expanded markedly in the last two years of the observation period. While the earliest contributions in the final corpus appear only sporadically, the literature becomes much more concentrated from 2024 onward, with a clear acceleration in 2025. This pattern suggests that the topic has moved from a peripheral concern to a more recognizable research area, likely reflecting both the broader diffusion of AI across work contexts and the growing interest in its implications for human capability development.

Figure 2 – Annual Distribution of the Reviewed Publications (N = 33)

3.2- Main thematic synthesis aligned with the review objective

To organize the corpus descriptively, the reviewed studies were grouped into three broad thematic dimensions aligned with the review objective. The first concerns AI tools and systems used to support soft skills development and includes contributions focusing on machine learning, generative AI, chatbots, virtual and extended reality, natural language processing, and profiling systems used for training, coaching, learning support, or assessment. The second concerns learning outcomes related to soft skills. Among the most frequently mentioned in the corpus are communication, leadership, problem solving, critical thinking, empathy, adaptability, and collaboration. The third concerns organizational strategies, enabling conditions, and barriers, including reskilling projects, training design, privacy, bias, transparency, and broader implementation challenges.

Table 2 – Thematic Synthesis of the Reviewed Literature

Synthesis dimension	**Core analytical focus**	**Main recurrent elements in the dataset**	**Representative studies**
AI tools and systems used to support soft skills development	Identification and categorization of the AI technologies and system types described in the corpus.	Recurring technologies include machine learning and predictive analytics, generative AI and large language models, chatbots, natural language and speech-based systems, virtual and extended reality solutions, robotics and automation, and profiling or psychometric systems. Across the dataset, these tools are used mainly for training, coaching, learning support, decision support, assessment, evaluation, testing, and personalization.	Bartolome et al. (2025); Budnarowski et al. (2025); Ciaschi et al. (2024); Ebert et al. (2024); Tusquellas et al. (2025)
Reported soft skills and learning outcomes	Analysis of the competencies most frequently targeted and of the outcomes associated with AI-supported interventions.	The corpus recurrently refers to communication, leadership, problem solving, critical thinking, creativity, empathy, adaptability, collaboration, teamwork, negotiation, active listening, emotional intelligence, and time or stress management. Reported outcomes include personalized feedback, repeated practice, immersive or scenario-based learning, self-reflection, perceived preparedness, knowledge retention, and behavioral improvement in specific training environments.	AlAfnan et al. (2024); Bhargava et al. (2021); Budnarowski et al. (2025); Gonzalez-Rico et al. (2024); Luo et al. (2021)

Synthesis dimension	Core analytical focus	Main recurrent elements in the dataset	Representative studies
Organizational strategies, enabling conditions, and barriers	Synthesis of the organizational conditions that support or constrain the integration of AI into workforce development initiatives.	The reviewed studies recurrently associate implementation with reskilling and upskilling programs, on-the-job mentoring and coaching, human oversight, context-specific training design, and structured feedback loops. The synthesis also foregrounds challenges emphasized in the review framing, including algorithmic bias, data privacy, transparency, measurement validity, and the risk of de-humanizing learning contexts when AI-mediated development is not balanced with human interaction. Underexplored areas include longitudinal evidence, governance arrangements, and the organizational conditions under which AI-supported soft skills development can be both scalable and context-sensitive.	Bhargava et al. (2021); Bobitan et al. (2024); Bukartaite et al. (2023); Gafni et al. (2024); Sposato (2025)

Overall, this descriptive structure shows that the literature is not organized solely around the technological promise of AI, but also around the conditions under which its use in soft skills development becomes credible, scalable, and relevant for organizations.

3.3 Descriptive patterns across themes

Two broad descriptive patterns emerge from the corpus. First, the literature is strongly oriented toward the technological and developmental uses of AI, with a particular concentration on simulation, coaching and assessment. Second, the studies do not focus only on benefits, but also frequently emphasize organizational conditions and implementation challenges. As a result, the corpus is structured not merely around what AI can do, but also around the conditions under which its use in soft-skills development becomes credible and relevant for organizations.

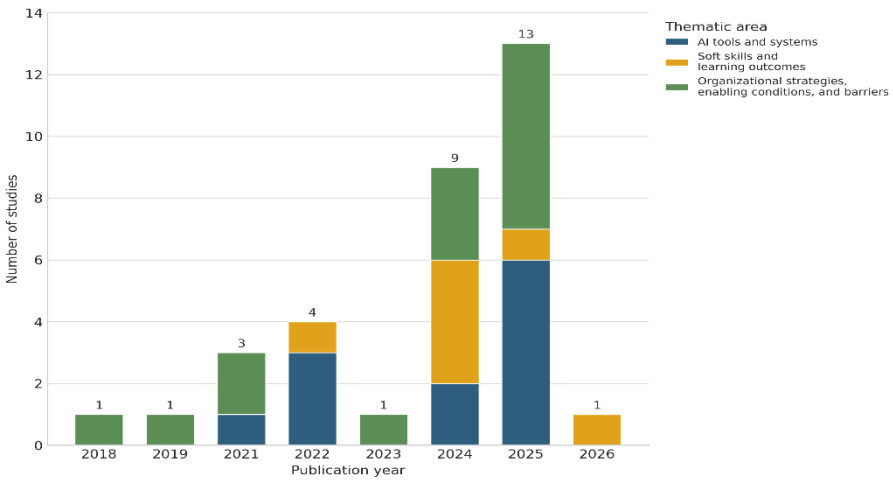

Figure 3 – Annual Distribution of Studies by Thematic Area (N = 33)

4 Results, Findings, and Discussion

The 33 studies reviewed here suggest that the literature on AI and soft-skills development is moving beyond a generic concern with technological adoption and toward a more analytically relevant question: how AI reshapes the organizational conditions through which human capabilities are developed, enacted, assessed, and governed. The descriptive analysis showed that the corpus clusters around three connected dimensions: the AI tools and systems used to support soft-skills development, the soft skills and learning outcomes most frequently addressed, and the organizational conditions that enable or constrain implementation. Building on that foundation, this section identifies three recurring and interrelated findings. First, AI is increasingly seen as a development infrastructure, not simply a technology. Second, the spread of AI appears to intensify, rather than

diminish, the strategic importance of purely human soft skills. Third, the development value of AI-based systems remains tied to organization, trust, and human-centred governance. Taken together, these patterns indicate that AI is not simply being added to existing training systems; it is contributing to a broader reconfiguration of how organizations identify, cultivate, evaluate, and legitimate human capability in hybrid work settings.

4.1 AI as a developmental infrastructure

A first major finding is that a substantial part of the literature no longer treats AI simply as a background driver of skill change or as a generic digital aid to training. Many studies frame AI as a sociotechnical infrastructure that organizes the conditions under which soft skills development occurs. From this perspective, AI plays a developmental role by diagnosing skill gaps, personalizing learning paths, providing iterative feedback, and monitoring progress over time. This infrastructural role is especially explicit in studies on AI-enabled coaching, profiling, assessment, and adaptive learning systems, where AI is placed within the architecture of development itself rather. (Luo et al., 2021; Gafni et al., 2024; Tusquellas et al., 2025).

4.1.1 Recurrent developmental functions

This first pattern becomes clearer when one examines the recurring developmental functions attributed to AI across the corpus. First, personalized developmental pathing emerges as a key function, through which AI identifies gaps, profiles learners or employees, and recommends differentiated developmental routes rather than standardized interventions. Second, coaching and feedback represent another recurring function, with AI-supported systems providing immediate and context-sensitive guidance during or immediately after performance episodes (Budnarowski et al., 2025; Luo et al., 2021; Balachandran, 2025). Third, immersive simulation and scenario-based practice appear prominently, especially in studies showing how AI-enhanced virtual or mixed environments can be used to rehearse communication, empathy, conflict resolution, or cross-cultural interaction in safe and repeatable settings (Budnarowski et al., 2025; Carvalho et al., 2025; Budnarowski et al., 2025). Finally, continuous assessment and diagnostic profiling emerge as an important infrastructural layer, particularly in studies where behavioural, linguistic, or interactional signals are translated into developmental information that can inform tailored interventions (Celsi et al., 2022; Ciaschi & Barone, 2024; Gafni et al., 2024). Across these studies, AI is valuable because it makes development more programmable, adaptive, scalable, and data-informed.

4.1.2 Conceptual significance and boundary conditions

This pattern is stronger than the claim that AI merely supports training. In the strongest studies, AI helps determine who needs what, under which conditions, and through which sequence of practice, feedback, and monitoring developmental progress can be sustained over time. This interpretation resonates with broader scholarship on organizational learning and knowledge processes, which has long emphasized that learning is processual and distributed by the infrastructures through which knowledge is created, shared, and applied (Nonaka, 1994; Tsoukas, 2009; Jarrahi et al., 2023). At the same time, some studies offer direct evidence from work contexts, while others illustrate transferable mechanisms without fully demonstrating long-term organizational effects (Bartolomé et al., 2025; Jung & Suh, 2024; Ottaviano, 2026). The literature therefore supports the claim that AI is increasingly framed as developmental infrastructure, but it also suggests that the conceptual maturity of this logic still runs somewhat ahead of its longitudinal validation.

4.2 The strategic revaluation of human soft skills

A second important finding emerging from the reviewed literature is that the spread of AI increases the strategic importance of capabilities that remain relational, interpretive, context-sensitive, and normatively oriented. This pattern is visible in conceptual, across foresight-oriented and organizational studies, which converge on the view that communication, empathy, collaboration, creativity and critical thinking continuous reskilling become even more important as AI and automation reshape work systems (Ghislieri et al., 2018; Bhargava et al., 2021; Bobitan et al., 2024). Related insights appear in studies of future skills, which consistently treat soft skills not as residual traits left untouched by technology but as capabilities that become more valuable precisely because AI is entering organizational processes (Bukartaite & Hooper, 2023; Depoo et al., 2025; Woods & Jones, 2025).

4.2.1 Core capabilities emphasized in the corpus

The reviewed studies recurrently refer to communication, leadership, problem solving, critical thinking, creativity, empathy, adaptability, collaboration, teamwork, negotiation, emotional intelligence, active listening, and time or stress management. These capabilities appear not only in papers focused on changing skill demand or workforce transition, but also in studies examining AI-enabled developmental interventions more directly, including work on mentoring, coaching, communication support, simulation-based learning, and managerial development (Luo et al., 2021; AlAfnan et al., 2024; González-Rico & Lluch Sintes, 2024). In this sense, the literature points not simply to the persistence of soft skills, but to their strategic revaluation.

4.2.2 Human–AI complementarity

This pattern aligns with a growing body of work on human–AI complementarity. Rather than framing organizational intelligence as a zero-sum contest between humans and machines, recent scholarship has emphasized the value of hybrid intelligence and human–AI symbiosis, in which analytical speed is combined with human judgment, contextual understanding, and social sensemaking (Jarrahi et al., 2023; Dellermann et al., 2019). The review findings are consistent with this perspective. Communication is important because AI outputs must be translated and made meaningful within organizational interaction. Critical thinking is important because AI-generated suggestions require evaluation rather than passive acceptance. Adaptability, empathy and collaboration are important because hybrid work systems continue to depend on affective understanding and coordinated action. The reviewed corpus therefore suggests that soft skills are becoming less peripheral and more constitutive of organizational capability in AI-mediated settings.

4.3 Organizational mediation, trust, and human-centred governance

A third finding, and arguably the one that prevents the review from sliding into technological optimism, is that the developmental potential of AI remains heavily conditioned by organizational mediation, trust, and governance. Across the corpus, the strongest interventions are rarely those in which AI replaces human developmental roles outright. Instead, they are typically hybrid arrangements in which AI complements coaching, mentoring, leadership judgment, or human interpretation. This pattern is especially clear in studies showing that AI-enabled development is most effective when embedded in broader systems of guidance and support rather than treated as an autonomous solution (Luo et al., 2021; Sposato & Dittmar, 2025; Woods & Jones, 2025). The same logic is reinforced by organizational studies emphasizing that human oversight, contextual sensitivity, and emotional attunement remain essential when AI enters capability development and workforce transformation (Ghislieri et al., 2018; Bhargava et al., 2021; Bhargava et a., 2021).

4.3.1 Governance pressures

The importance of mediation is closely tied to the governance burdens created by AI-enabled development systems. The same features that make AI attractive for people development, also make these systems governance intensive. Across the corpus, recurring concerns include privacy, bias, fairness, transparency, monitoring, trust, and the risk of dehumanizing (Bhargava et al., 2021; Ciaschi & Barone, 2024; Gafni et al., 2024). Also, olther studies on immersive and simulation-based environments, which point to additional barriers related to cost, usability, implementation, and ethical acceptability (Carvalho et al., 2025; Tutu et al., 2025; Balachandran, 2025). The broader literature on trust in AI show that successful integration depends not only on technical performance, but also on reliability, transparency, and the perceived legitimacy of the socio-technical system in which AI is embedded (Gafni et al., 2024).

4.3.2 Measurement and interpretive risk

A further issue concerns measurement. Several studies rely on behavioural proxies or inferred representations of soft skills, that enhance visibility, comparability, and scalability, yet they also risk reducing relational, judgment-based, and context-sensitive capabilities to what can be captured computationally. This tension is visible in studies on stealth assessment and NLP-based inference, where the analytical power of AI is evident but the possibility of over-instrumentalizing soft skills remains unresolved (Celsi et al., 2022; Bartolomé et al., 2025; Tutu et al., 2025). For this reason, the review does not support an understanding of AI as an autonomous answer to soft-skills development. Rather, it suggests that AI if combining structured practice, developmental analytics, human interpretation, and ethically robust governance.

4.3.3 Integrative interpretation

These findings suggest that the literature is converging around a coherent, though still maturing, understanding of AI and soft-skills development. First, AI is increasingly treated as developmental infrastructure rather than as a mere background technology. Second, this infrastructural transformation appears to revalue human soft skills by making more central to organizational performance and adaptation. Third, the developmental value of AI remains contingent on organizational mediation, trust, and governance. Read together, these findings say: AI shapes soft-skills development in organizations through the infrastructuring of development, the strategic revaluation of human capabilities, and the governance of hybrid developmental systems. All of this constitutes the main contribution of the review.

5 Conclusions and Future Research

This review set out to examine how AI is shaping soft-skills development in organizations. The evidence synthesized across the 33 reviewed studies suggests that AI should not be understood merely as a support technology for training, nor as a force that simply displaces human capability. Rather, the literature points to a more complex transformation. AI is increasingly functioning as a developmental infrastructure that reorganizes learning conditions through personalization, feedback, simulation, and analytics; at the same time, its diffusion appears to increase the strategic relevance of distinctively human capabilities such as communication, judgment, empathy, collaboration, and adaptability. Yet these potentials do not unfold automatically. Their developmental value depends on organizational mediation, hybrid human–AI arrangements, and governance mechanisms capable of preserving trust, legitimacy, and contextual sensitivity.

5.1 Main contribution

The review makes three contributions. First, it systematizes a fragmented literature by identifying a coherent set of developmental functions through which AI operates in relation to soft skills. Second, it shows that the rise of AI has been accompanied by a revaluation of human capabilities, rather than by their straightforward marginalization. Third, it clarifies that the effective integration of AI into soft-skills development is a socio-technical and governance challenge. In this sense, the review contributes to current debates on organizational learning, reskilling, and HR transformation by offering an integrative perspective that connects technological infrastructures, human capabilities, and working conditions.

5.2 Future research directions

The review points to important directions for future research. More longitudinal studies are needed to assess whether AI-enabled developmental gains persist over time rather than remaining short-term or context-bound. Additional research should examine sectoral variation, since the organizational conditions under which AI supports soft-skills development may differ substantially across industries, professions, and institutional environments. Finally, Future scholarship must shift from merely asking if AI supports soft-skills development to exploring when and how it does so effectively. Ultimately, research should focus on the specific organizational conditions that ensure AI-driven growth remains both impactful and meaningfully human.

Ethics declaration

This study is based exclusively on a systematic literature review of published sources and did not involve human participants, personal data, or confidential organizational data. Therefore, no formal ethical clearance was required.

AI declaration

AI tools were used only for language enhancement and editorial support.

Abstract

Digital transformation and sustainability transformation originate as different domains and have often been treated separately in both the public and private sectors. In recent years, their potential synergies, referred to as twin transformation, have begun to emerge. In this new field of research, initial contributions have primarily focused on the private sector, where a maturity model has also been developed. However, despite these early contributions, research on twin transformation remains limited, with little consideration of the public sector, and particularly local public administration. To date, the scientific literature has not identified any maturity model that specifically measures the maturity of both transformations simultaneously in public administration. To address this gap, the study adopts a design science research protocol to adapt a maturity model originally developed for the private sector to the context of local public administration. The research process includes a literature review and the design and development of the model. The results consist of a capability maturity model encompassing six capability dimensions, four maturity levels, and 99 dynamic capabilities. The model is complemented by a self-assessment instrument that enables policymakers to independently evaluate their level of twin transformation maturity. Although preliminary, these findings contribute to a more integrated understanding of digital and sustainability transformations within public administrations. By doing so, the study extends prior research on twin transformation by identifying the dynamic capabilities required to progress along the twin transformation journey.

Keywords: twin transformation, maturity assessment, public administration, dynamic capabilities.

Paper type: Academic Research Paper

1 Introduction

In recent years, the synergistic potential between digital transformation and sustainability transformation has gained increasing attention (European Commission 2022; Christmann et al., 2024), opening up a new field of research that warrants further investigation (Ologeanu-Taddei et al., 2025). To harness such potential, Christmann et al. (2024) align the digital and sustainability perspectives by defining twin transformation as "a value-adding interplay between digital and sustainability transformation efforts that improve an organization by leveraging digital technologies for enabling sustainability and leveraging sustainability for guiding digital progress" (p.495). The study further demonstrates the importance of dynamic capabilities for the implementation of twin transformation, thereby identifying 16 specific twin dynamic capabilities. Building on this foundation, Breiter et al. (2024) developed and validated the Twin Transformation Capability Maturity Model (TTCMM), a maturity model tailored to the private sector. Despite this contribution, limited attention has been devoted to the public sector, and more specifically to local public administrations. To date, the extant body of literature in this sector has proposed only a few maturity models, and these have treated the two transformations separately (Iannacci et al., 2025; Liu et al., 2022). Against this backdrop, the objective of this study is to develop a twin transformation maturity model tailored to the context of local public administrations.

To address the research objective, the study adapts a model originally designed for the business context (Breiter et al., 2024) to the public administration sector and designs and develops a self-assessment instrument that allows public administrations to measure their digital and sustainability transformation efforts in an integrated way. To achieve this, the study employs a design science research protocol following the guidelines proposed in Peffers et al. (2007). Such methodology is suitable for the development and adaptation of artifacts, especially in the case of a maturity model (Pöppelbuß and Röglinger, 2011).

2 Background

This section discusses the applicability of dynamic capabilities to the public administration sector and presents the reference model for the study.

2.1 Dynamic capabilities in public administration

Dynamic capabilities are the organizational and strategic routines through which firms achieve new configurations of resources in the market (Eisenhardt and Martin, 2000). These capabilities drive the creation, evolution, and recombination of resources into new sources of competitive advantage (Henderson and Cockburn, 1994; Teece et al., 1997). The concept of dynamic capabilities was originally developed for the private sector; however, the academic debate on the role of these capabilities has also been extended to the public sector (Panagiotopoulos et al., 2023). Public sector organizations adopt processes similar to those of private firms. These processes include the dissemination of best practices and the use of organizational resources and routines aimed at implementing policy initiatives and delivering services (Bryson et al., 2007; Pablo et al., 2007). Examples of dynamic capabilities in public administration include the ability to learn new practices, information gathering and evaluation, information-sharing systems, intellectual capital, and performance management routines (Vignieri and Zeinali, 2023).

Although in the private sector Christmann et al. (2024) have only recently identified sixteen twin transformation dynamic capabilities, there is still limited evidence in the public sector, and more specifically in the public administration. At present, dynamic capabilities in public administration are addressed in the literature mainly in relation to digital transformation and sustainability transformation as separate domains (Vignieri and Zeinali, 2023; Bhatia et al., 2025).

2.2 Reference model

Breiter et al. (2024) developed, evaluated, and demonstrated the Twin Transformation Capability Maturity Model. The model encompasses six dimensions, namely strategy and leadership, culture and employees, ecosystem and partnerships, products and services, operations, and technology, and four maturity levels: (1) awareness of combining digitalization and sustainability, (2) twin transformation development, (3) twin transformation implementation, and (4) true twin transformer. Developed for the business sector, the model is considered the starting point for the development of a twin transformation maturity model specifically tailored to the public administration context. It is regarded suitable for achieving the research objective. In particular, among its strengths, it assigns equal importance to both transformations and acknowledges that organizations may possess varying levels of capabilities related to both digital transformation and sustainability transformation.

3 Methodology

The design science research methodology was adopted to address the research questions, following the seven steps proposed by Peffers et al. (2007), as illustrated below.

Step 1: Identification and motivation of the problem. The first step was to identify and justify the problem. To this end, the literature was analyzed in order to identify the scientific contributions related to the development and application of maturity models in the digital and/or sustainability domains in public organizations. No model was identified that specifically measured the maturity of both transformations simultaneously in the public administration. Furthermore, given the limitations of existing maturity models in public administrations (e.g., published in non-indexed journals and lack of validation in real-world contexts), it was deemed appropriate to extend the analysis to the private sector. To this end, the only model identified (Breiter et al., 2024) that measured the maturity of twin transformation was selected. Based on the results of the analysis, the lack of twin maturity models specifically tailored for public administration was identified as a problem. Such a problem was confirmed by discussions with staff and the director of a local public administration in Italy.

Step 2: Defining the objectives of a solution. Defining the objectives of the solution represented a crucial step in guiding the adaptation and development of the artifact (Peffers et al., 2007). To address the problem, an existing maturity model developed for the private context (Breiter et al., 2024) was adapted to align with the specific characteristics of public administrations. Specifically, three solution objectives were outlined.

Solution objective 1. To adapt the maturity model originally conceived for the private sector to the specificities of public administration.

Solution objective 2. To redefine the dimensions and capabilities of the model from a public value perspective.

Solution objective 3. To develop the maturity measurement instrument, in line with the recommendation of Breiter et al. (2024), in order to provide a self-assessment instrument accompanying the model.

In light of the differences between the private sector and public administration, primarily in terms of objectives and the capabilities intended to be developed, we identified the first two solution objectives. Their achievement required an analysis of the characteristics of the public administration context, its purposes, the regulatory framework, and governance logic, in order to ensure relevance and full applicability. The third solution objective was linked to a limitation of the original model (de Bruin et al., 2005). Although it was demonstrated in a real context, the maturity assessment was guided by the authors. The model lacked a self-assessment tool that would enable organizations to independently carry out a maturity evaluation.

Step 3: Design and development. After identifying the problem and defining the objectives, the artifact was designed and developed. We began the design of the maturity model by mapping the capability dimensions and subsequently the dynamic capabilities, both in relation to the dimensions and the maturity levels. The details of the design are reported below.

Regarding capability dimensions, culture and employees, operations and technology remained unchanged. Human resources, technological resources and culture were all essential elements for public administration, particularly within the domain of digital transformation (Vignieri and Zeinali, 2023; Aras and Büyüközkan, 2023). The culture and employees dimension was understood as the study of the effects of the change generated by the digital transformation process on the existing culture (Aras and Büyüközkan, 2023) and the presence of appropriate skills and capabilities within the organization (Vignieri and Zeinali, 2023). For the operations dimension, the value creation processes through design techniques remained valid in the context of public administration. In particular, value creation was understood as a collaborative and multi-actor process through which different stakeholders participate in the design, delivery, and evaluation of services, generating benefits that are not limited to the individual experience but also include social, economic, and institutional outcomes (Osborne et al., 2022). The technology dimension was defined as the availability of technological infrastructures enabling people to adopt methods and tools to collect, analyze, and use data in support of decision-making processes (Vignieri and Zeinali, 2023). The other three capability dimensions of the original model underwent some adjustments. The strategy and leadership dimension was expanded to include the concept of governance. Governance was identified as a fundamental aspect in the public sector in order to ensure the successful implementation of digital transformation and its sustainability (Aras and Büyüközkan, 2023). The ecosystem and partnership dimension was renamed external ecosystem and refers to the management of external interactions and how such interactions were transformed into value. The product and service dimension was renamed public services, which play a central role for public administration, also in relation to sustainability and digital transformation (Gudmundsdottir et al., 2024; Ly, 2025).

Digital and sustainability dynamic capabilities were identified in the literature with reference to the public sector. The literature resulted in 164 dynamic capabilities, which were then compared with those proposed in the model by Breiter et al. (2024). Points of overlap were identified, such as the need to equip employees with new capabilities to face digital and sustainability transformations, and the importance of establishing partnerships to facilitate the exchange of information and the achievement transformation objectives. The overlapping capabilities remained almost unchanged in meaning and were slightly improved in form. Other capabilities were adapted more extensively. For instance, the original capability influencing legislators on twin transformation standards was expanded to the following: contributing to the definition of standards and guidelines for twin transformation through collaboration among the government, central agencies, regional authorities, autonomous provinces, and local administrations. Another example is the original capability focus on cradle-to-cradle approaches, which was adapted to focus on the entire life cycle of services and their economic, environmental, and social sustainability.

The discussion on the capabilities to be adapted, added, and removed was conducted among the authors until consensus was reached. All adaptations in terms of dimensions and capabilities with respect to the original model were systematically considered and documented. The comparison and adaptation process was also complemented by meetings with officials of an Italian public administration.

A self-assessment instrument was designed and developed to accompany the model. This instrument allowed public organizations to independently assess their maturity and was based on a four-point scale: Fully Implemented (FI), Largely Implemented (LI), Partially Implemented (PI), and Non Implemented (NI). Using scales for these purposes improved the reliability and consistency of responses and map outcomes to different levels of maturity (de Bruin et al., 2005). To design the instrument, each capability of the model was transformed into an interrogative statement. Respondents were asked to rate each statement on a scale from FI to NI. The maturity level was measured as a function of the number of capabilities that have been implemented. To reach a level, all statements must be evaluated as FI or LI. A level was not considered achieved if even a single statement within that level was assessed as PI or NI (DOE, 2022). For example, to attain level 3, all statements

related to levels 1, 2, and 3 had to be evaluated as FI or LI. The maturity level achieved was displayed through seven graphs.

Step 4&5: Evaluation and demonstration. The evaluation phase is ongoing. At present, ten experts have been selected and have been contacted by e-mail through the authors' contacts. Some of the experts were selected for their knowledge of the public administration sector, others for their relevance in the field of academic research, especially related to the development of maturity models. A first meeting was conducted, and two additional meetings were planned. To carry out the evaluation, following the meeting participants were asked to complete a questionnaire designed to gather quantitative and qualitative data. The questionnaire is structured into two sections. The first section included questions based on a 5-point Likert scale, for which "1" represents "strongly disagree" and "5" represents "strongly agree," to assess the model and instrument in terms of fidelity with real world phenomena, completeness, level of detail, internal consistency, ease of use, and usefulness (Davis, 1989; March and Smith, 1995). The second section included open-ended questions aimed at collecting feedback and suggestions for improving the maturity model. Based on the evaluation, the model will be refined as necessary. Subsequently, the model will be applied in a real-world setting.

Step 6: Communication. The design process of a maturity model will be documented and communicated in a way understandable for academics, public managers and practitioners (Becker et al., 2009; de Bruin et al., 2005).

4 Discussion

In this section, the preliminary results of the study are presented and discussed, and their implications are outlined.

4.1 Twin transformation capability maturity model

The model is grounded in the need, identified in the literature and through engagement with public administration staff, to assess the concurrent efforts undertaken by public administrations in both the digital and sustainability domains. Existing maturity models do not address these two domains simultaneously and are often developed for the private sector. This study extends prior research by adapting a private-sector model to the public administration sector, thereby providing an understanding of the capabilities required to progress toward a twin transformation journey. At the current stage of the study, the result is a theoretical model, developed through a rigorous design process, which provides insights into the evolution of dynamic capabilities for twin transformation. Although preliminary, these results suggest a possible integration of the two transformations also for public administrations, which are thus beginning to manage the twin transformation by leveraging the mutual benefits of digitalization and sustainability, in line with Christmann et al. (2024).

The proposed maturity model comprises six dimensions, namely strategy, leadership and governance, culture and employees, external ecosystems, public services, operations and technology. Each dimension encompasses a specific set of dynamic capabilities, which are organized across the four maturity levels, as listed in Table 1. At the first level, organizations are fully developed in one of the two domains and begin to develop awareness of the other domain. This initial level is characterized by capabilities related to a single transformation (digital or sustainability), as well as capabilities that enable the initial experimentation of integrated digitalization and sustainability initiatives. The second level of maturity assumes that organizations have embarked on a path toward the integration of the two domains; accordingly, they start to design capabilities that enable a joint consideration of both domains. For example, they develop a transformation strategy that incorporates both sustainability and digitalization, consider their opportunities and threats, and invest in twin projects that jointly enable the achievement of digital and sustainability objectives. At the third level, organizations operationalize the twin transformation strategy for organization-wide implementation. This is achieved, for example, through the implementation of new processes and services and the provision of training to employees. At the fourth level, organizations incorporate the principles of twin transformation into decision-making processes and are committed to continuously optimizing and aligning the two transformation objectives, also beyond organizational boundaries, by establishing dialogue with other local authorities.

Table 1: Twin Transformation Maturity Model: dimensions, capabilities and levels.

Capability dimension	1 Awareness of combining digitalization and sustainability (DT)	1 Awareness of combining digitalization and sustainability (ST)	2 Twin transformation development	3 Twin transformation implementation	4 True twin transformer
