Strategy, leadership and governance	Understand the value and challenges associated with the sustainability of digital transformation; Translate the values of digitalization into concrete actions; Be aware of technological developments and trends assessing associated opportunities and threats; Structure a governance model for digital transformation that includes guidelines for cybersecurity; Allocate human and financial resources to digitalization initiatives; Promote the use of digital technologies	Understand the value and challenges related to the digitalization of sustainability transformation; Translate the values of sustainability into concrete actions; Be knowledgeable about approaches and methods related to sustainability; Structure a governance model for sustainability transformation that includes guidelines for cybersecurity; Allocate human and financial resources to sustainability initiatives; Promote life cycle analysis of services and their associated economic, environmental, social, and territorial sustainability; Adopt tools for the planning, monitoring, and evaluation of public policies from a sustainability perspective	Develop a strategy that fosters sustainability, ethical, and inclusive development through innovation and digitalization in service of individuals, communities, and territories; Strengthen investments that jointly enable the achievement of digital and sustainability objectives; Establish a performance measurement system with indicators to monitor digitalization and sustainability in an integrated manner; Foster the advancement of the twin transformation through top management commitment; Develop long-term infrastructure innovation plans that take sustainability impact into account; Evaluate and identify opportunities and threats associated with the twin transformation; Perceive and recognize the needs of internal and external users to guide decision-making from a twin transformation perspective	Promote the implementation of transformation initiatives through (top) management; Reconfigure the value proposition and organizational identity to enhance efforts toward the twin transformation	Evaluate the achievement of twin transformation objectives and, where necessary, revise transformation strategies accordingly; Promote pathways of continuous process improvement; Evaluate the organization's digital and sustainability performance to inform the planning of future interventions
Culture and employees	Train human capital in relation to digital competencies; Encourage employees and promote a culture of innovation; Develop competencies related to the use of digital technologies within one's area of activity	Train human capital in relation to sustainability competencies; Encourage employees and promote a culture of innovation; Develop competencies related to the application of sustainability principles within one's area of activity	Foster creativity and self-fulfillment to stimulate digital and sustainability innovation; Strengthen and introduce principles and values capable of fostering cultural change aligned with a digital and sustainability vision; Facilitate the exchange of ideas regarding transformation through open discussions among managers; Create an environment that stimulates employees; Enhance leadership and supervisory competencies of managers	Train employees on administrative, digital, ecological, and social transformation topics; Redefine employee and (top) management incentive systems in relation to digital and sustainability performance; Enable new ways of working and new tools introduced as a result of the twin transformation; Improve coordination within the organization; Promote employee engagement on issues related to the twin transformation	Evaluate employee satisfaction with the training provided and their competencies in terms of sustainability and digitalization; Evaluate employee and (top) management incentive systems in relation to digital and sustainability performance

Capability dimension	1 Awareness of combining digitalization and sustainability (DT)	1 Awareness of combining digitalization and sustainability (ST)	2 Twin transformation development	3 Twin transformation implementation	4 True twin transformer
External ecosystem	Increase transparency in administrative decision-making through e-democracy tools; Interact with different stakeholders on the themes and implementation of digital transformation in the public administration; Organize moments of discussion with other public administrations aimed at monitoring compliance with digital transformation requirements	Foster dialogue with partners to share sustainability goals and practices; Interact with different stakeholders on the themes and implementation of sustainability transformation in the public administration; Organize moments of discussion with other public administrations aimed at monitoring compliance with sustainability transformation requirements	Co-design and co-plan with stakeholders to achieve joint projects; Define processes for the exchange of information and knowledge with stakeholders; Define mechanisms to identify priorities among the interventions emerging from stakeholder engagement	Integrate partners' knowledge and competencies on the twin transformation, developed through established dialogue; Implement processes for the exchange of information and knowledge with stakeholders; Initiate dialogue with stakeholders on potential issues arising from the implementation of twin transformation pathways	Contribute to the definition of standards and guidelines for the twin transformation through collaboration among the Government, central authorities, Regions, Autonomous Provinces, and local authorities
Public services	Promote the development of digital services; Promote projects aimed at making territories smart and digital (e.g., smart cities)	Promote the collection of environmental and social data through the creation of a (potentially digital) platform; Promote projects aimed at making territories sustainability	Redesign or develop services in accordance with the objectives of the twin transformation (e.g., sustainability procurement policies through digitalization); Reorganize service development teams by including specialists in sustainability and digitalization; Establish systems that facilitate knowledge management to develop and improve public services; Consider needs emerging from interactions with users to foster innovation in the development of new services and projects; Identify the economic and financial, social, and environmental benefits and sustainability of the services implemented	Implement services in accordance with the objectives of the twin transformation; Implement new processes and solutions, including through the use of emerging technologies and artificial intelligence, in an ethically conscious and sustainability manner; Implement systems that facilitate knowledge management to develop and improve public services	Assess economic, environmental, and social sustainability throughout the entire life cycle of services and projects implemented

Capability dimension	1 Awareness of combining digitalization and sustainability (DT)	1 Awareness of combining digitalization and sustainability (ST)	2 Twin transformation development	3 Twin transformation implementation	4 True twin transformer
Operations	Promote the use of integrated digital systems for information exchange and operational management; Design and implement transformation through the reengineering of processes using digital technologies; Establish routines to minimize waste in operational processes and improve sustainability performance (e.g., energy efficiency of public buildings)	Promote the introduction of criteria for digitally assessing the sustainability performance of operations; Design and implement transformation through the reengineering of processes, potentially also using digital technologies; Promote interdepartmental collaboration by encouraging the sharing of operational practices and information to achieve common results; Recognize the need to protect, maintain, and conserve resources supporting public infrastructures (e.g., managing resources through a green approach); Orient the selection towards the procurement of goods and services with environmental characteristics; Recognize the need to maintain and improve health quality	Design a real-time data collection and monitoring system (for sustainability data); Design new processes and advanced technologies oriented toward the twin transformation; Implement processes to continuously and effectively share information across the organization; Strengthen the capacity to acquire external funding in a twin transformation perspective; Plan, evaluate, and acquire new equipment to support operations from a twin transformation perspective	Implement new processes and advanced technologies oriented toward the twin transformation; Implement processes, IT resources, and services to improve their effectiveness in terms of sustainability	Evaluate advanced data analytics tools, including AI-based solutions, to continuously improve activities and operational performance related to the twin transformation; Monitor and improve systems that support the updating, sharing, and reorganization of knowledge within the organization
Technology	Establish data management mechanisms to support decision-making processes; Scouting and acquisition of digital technologies for the reengineering of processes; Promote awareness of sustainability within the IT unit (green IT / efficient IT); Pursue the modernization of infrastructures for the delivery of digital services that respond to users' needs	Establish data management mechanisms for sustainability/ESG-related data collection to ensure their usability in decision-making processes; Scouting and acquisition of digital technologies for the reengineering of processes from a sustainability perspective	Design technological solutions, including potentially AI-based systems, that are human-centric, reliable, secure, and sustainability; Design energy-efficient and economically sustainability digital infrastructures	Facilitate inter-organizational (inter-office) cooperation through the adoption of shared digital tools; Promote the use of advanced analytics in management dashboards to monitor the achievement of twin transformation objectives; Ensure the effective use of data and information analysis tools to enhance organizational knowledge assets and steer the organization toward a data-driven model	Continue to leverage the sustainability potential of emerging digital technologies, consolidating already implemented projects

4.2 Implications for research

The study has significant implications at the theoretical, practical, and societal levels. The theoretical contribution of the study is threefold. First, it contributes to the existing body of literature on twin

transformation, a field that has been predominantly explored within the private sector, by developing a twin transformation maturity model for local public administrations, thereby addressing a significant research gap. Second, the self-assessment instrument helps operationalize the maturity evaluation, bridging the gap between theory and practice. Third, the study informs theory by examining the application of dynamic capabilities to twin transformation in public administration.

At the practical level, the proposed model provides public managers with a self-assessment instrument based on multiple dimensions, capabilities, and maturity levels. Such an instrument enables the assessment of the current level of twin transformation maturity, highlighting the capabilities and, consequently, the strategic decisions, resources, and investments that need to be designed in order to advance toward twin transformation.

At the societal level, the study fosters dialogue and awareness of the concept of twin transformation in the public sector, thereby influencing public debate and promoting a more informed discussion of its implications.

5 Conclusion

The study adapts and refines an existing model to the context of local public administration by incorporating new dynamic capabilities and expanding its dimensions. The resulting maturity model is structured around six dimensions and 99 dynamic capabilities and helps organizations simultaneously measure their efforts in the digital and sustainability domains. The model is also accompanied by a self-assessment instrument that enables policymakers to independently evaluate their maturity, representing a novel feature compared to previous models. However, the study is not without limitations. At its current stage, the model is conceptual and is based on a framework originally developed for the private sector. Although significant adaptations were made, some underlying assumptions may not be fully transferable to public administrations. In the future, expert interviews and real-world case applications are planned to verify the model's full applicability and its alignment with the public administration sector.

6 Ethics declaration

Participants were informed about the purpose of the study and their contribution. The data, which did not contain sensitive information, was treated confidentially and anonymity was guaranteed.

7 AI declaration

No artificial intelligence tools were used in developing the paper.

Experiences of Knowledge-based Human Resources Management in the Finnish Public Sector

Sini Tenhovuori, Nina Helander
Tampere University, Tampere, Finland

Abstract

Knowledge-based human resource management (KHRM) functions as an enabler of sustainability by making visible the consequences of HR practices and by supporting evidence-informed decision-making that extends beyond financial indicators to incorporate human, social and environmental impacts. Accordingly, sustainable and strategic KHRM creates the conditions for balancing service effectiveness, employee well-being and long-term societal responsibility.
The purpose of this study is to explore how KHRM is implemented in Finnish public sector organisations through the experiences of employees involved in HRM. Aim is to identify the organisational, managerial, cultural and competence-related factors that either enable or hinder the implementation and development of strategic and sustainable KHRM. The empirical data was collected from 14 Finnish public sector organisations.
According to the findings of this study, the development and implementation of KHRM in Finnish public organisations are specifically promoted by a set of clearly identifiable enabling factors. The need to strengthen KHRM has been widely recognised, creating also a shared mandate for development. The integration of KHRM into organisational strategies, together with explicit support from top management, provides a strong structural and leadership foundation for its advancement. Furthermore, an organisational culture that is receptive to data-driven practices, the increasing interest in HR indicators, and a general orientation toward knowledge-based development all act as an important driver that actively facilitate and reinforce the implementation of KHRM. However, the study found many factors that hinder the development of KHRM. These included, for example, challenges in the availability of the HR data, quality of HR information as well as ambiguities related to HR concepts and indicators. In addition, the implementation of KHRM was weakened by deficiencies in the utilization of human resources, deficiencies in the processes of KHRM, manual reporting, fragmented data sources.
KHRM is slowly developing in Finnish public sector organisations. Identifying factors that are enabling or hindering the implementation and the development of KHRM helps organisations to strengthen the maturity of KHRM.

Keywords: Knowledge management, Human resources management, HR-analytics, public sector, management

Paper Type: Academic Research Paper

1 Introduction

Knowledge-based management has been recognised as a foundation for both strategic and sustainable human resources management, as it enables organisations to utilise data, information and knowledge in a more systematic and forward-looking manner (Partanen et al. 2023; Vakkuri et al. 2023). In the Finnish public sector, the provision services is fundamentally dependent on human resources. The availability of skilled, sufficient and well-being personnel is therefore a prerequisite for delivering high-quality and effective public services (Keva 2025; Laihonen & Kokko 2023). At the same time, personnel costs constitute a substantial share of the public sector expenditure (Kauhanen 2025).

From a KM perspective, the public sector represents particularly relevant research context due to its strong requirements for transparency, accountability and effectiveness, as well as its exposure to complex and often competing societal expectations (Partanen et al. 2023; Erkkilä 2020). Prior research has shown that KM in the public sector operates within a context characterised by institutional complexity, where multiple logics, actors and governance mechanisms shape how data and information are produced, interpreted and utilised (Laihonen & Kokko 2023). While earlier studies have emphasised the strategic importance of KM for public organisations, evidence from recent research suggests that knowledge-based practices are still unevenly implemented and significant gaps remain between strategic intentions and everyday managerial practices (Laihonen & Kokko 2023; Laihonen et al. 2024). Considering these findings there is a need to examine how KHRM is implemented and developed across broader service systems and institutional environments, particularly from the perspective of HRM and leadership practices.

The purpose of this study is to explore and analyse how KHRM is implemented in Finnish public sector organisations through the lived experiences of employees involved in human resource management and leadership. By focusing on these experiences, the study seeks to develop an in-depth understanding of the current state and maturity of KHRM and examine how prepared these organisations are to move towards sustainable and strategic KHRM.

More specifically, this study aims to identify the organisational, managerial, cultural and competence-related factors that either enable or hinder the implementation and development of strategic and sustainable KHRM. By adopting an experience-based perspective, the study contributes to a nuanced understanding of how knowledge, data and analytics are currently utilized in human resource management practices and decision-making, and what conditions are required to strengthen KHRM as a long-term strategic capability. The research question of this study is:

Which factors enable and which factors hinder the implementation and development of sustainable and strategic KHRM in public sector organisations?

2 Theoretical Background

2.1 Sustainable human resources management

Sustainable HRM refers to an approach in which HRM is deliberately designed to generate simultaneous economic, social and human value in both the short and long term. Rather than focusing solely on efficiency or performance outcomes, sustainable HRM emphasizes the preservation and development of human and social resources over time, acknowledging employees as a critical and finite organisational asset (Kramar 2022.) From this perspective, sustainability in HRM is not an add-on to strategic HRM, but an extension that broadens its temporal horizon, stakeholder orientation and evaluative criteria.

A core assumption in sustainable HRM is that organisations face inherent tensions and trade-offs between competing goals, such as short-term productivity, employee well-being and long-term capability development. These tensions are particularly salient in a complex and resource-constrained context, such as the public sector, where organisations are expected to deliver high-quality services while maintaining legitimacy, fairness and social responsibility. Sustainable HRM literature highlights that such tensions cannot be resolved through isolated HR practices but requires a systemic and reflective approach to people management that recognizes paradoxes rather than attempting to eliminate them (Kramar 2014).

Within this framework, sustainable HRM places strong emphasis on fairness, organisational support, job satisfaction and employee commitment, which are viewed as both ethical imperatives and prerequisites for long-term organisational functioning (Cugueró-Escofet et al. 2019). Empirical research suggests that when employees perceive HR practices as fair, transparent and supportive, they are more likely to remain engaged, resilient and willing to contribute to organisational goals over time. These align with the objectives of sustainable HRM, as they support continuity, adaptability and the maintenance of human capital rather than short-term exploitation. (Pimenta et al. 2024)

Consequently, sustainable HRM highlights the need for decision-making that goes beyond financial indicators and incorporates information on employee-experiences, well-being and long-term capability development. From this perspective, the systematic use of information becomes prerequisite for sustainability-oriented HRM as it enables organisations to recognize the consequences of HR decisions across different time horizons and stakeholder groups (Aust et al. 2020). This creates conceptual link between sustainable HRM, strategic HRM and knowledge-based approaches of HRM.

2.2 Strategic human resources management

Strategic human resource management (SHRM) refers to the deliberate alignment of HRM practices, processes and decision-making with an organisation's long-term strategic objectives, based on the recognition of personnel as the key strategic resource. SHRM is proactive, systematic, and context specific. However, SHRM is not a universal or uniform model; its content and underlying mechanisms that are inherently context-dependent and vary across organisational and institutional settings (Knies et al. 2024; Lepak et al. 2006). In public organisations, SHRM primarily emphasises strategic coherence and a long-term development orientation rather than short-term efficiency gains. The central objective of SHRM in public sector value creation, reflecting the broader societal mission of public organisations. (Demo et al. 2024)

In the Finnish public sector, SHRM carries particular significance due to the operating environment characterised by short legal regulation, high societal expectations and persistent resource constraints. These conditions intensify the need for transparent, equitable and data-informed HR-practices that support both organisational legitimacy and sustainable performance (Jarlström, Saru & Vanhala 2018). While SHRM can positively influence employee motivation, attitudes and organisational performance in public organisations, these effects do not primarily arise through economic incentives of efficiency-oriented reward system, as is often the case in the private sector. Instead, public sector performance is shaped by multiple, simultaneous and

sometimes competing objectives, such as service quality, equality, legitimacy and the creation of public value. Consequently, within public sector SHRM, particular emphasis is placed on HR practices that strengthen employee capabilities and enhance opportunities for participation, engagement and professional development (Demo et al. 2024)

2.3 Knowledge-based human resources management

KHRM refers to an approach in which HRM is systematically grounded in the collection, integration and use of data, information and organisational knowledge to support HR-related decision-making. Rather than relying primarily on intuition or isolated metrics, KHRM emphasizes the transformation of HR data into actionable knowledge that informs strategic decisions regarding workforce development, performance, and long-term organisational capability (Marler & Boudreau 2017; Patil & Priya 2024).

In the context of SHRM, KHRM provides a mechanism through which HRM can be more closely aligned with organisational strategy. Prior research has shown that the strategic contribution of HRM depends not only on the presence of HR practices, but on the organisation's ability to generate and interpret information about how these practices influence employee skills, motivation and opportunities to contribute (Lepak et al. 2006; Marler & Bourdeau 2007). KHRM supports this alignment by enabling evidence-based assessments of workforce-related risks, trade-offs and development needs, there by strengthening the strategic role of HRM beyond administrative or reporting functions.

At the same time, KHRM is closely connected to sustainable HRM. Sustainable HRM highlights the need to balance short-term efficiency with employee well-being and long-term capability development, a task that requires visibility into the human consequences of HR decisions over time. Such balancing cannot be achieved without systematic and transparent use of information, as sustainability-related tensions often remain invisible in traditional performance indicators (Ehnert 2009; Kramar 2022). From this perspective, KHRM functions as an enabling infrastructure that makes the effects of HR practices on engagement, learning and retention visible and discussable, thereby supporting sustainable HRM.

An increasingly important aspect of KHRM concerns its level of maturity. Prior studies indicate that maturity is not determined by technology alone, but by the integration of data governance, analytical competence, managerial interpretation and decision-making routines (Jääskeläinen et al. 2022; Tenhovuori 2024). Higher levels of KHRM maturity are associated with more coherent HR-strategies, stronger alignment between HRM and organisational goals, and an increased ability to address sustainability-related trade-offs in a deliberate manner (Tenhovuori & Helander 2025).

Taken together, KHRM can be understood as a connecting concept that operationalizes both strategic and sustainable HRM. While strategic HRM defines the alignment of HRM with organisational objectives and sustainable HRM emphasizes long-term and multi-stakeholder outcomes, KHRM provides base through which these orientations can be enacted in practice.

4 Methodology

4.1 The collection of the data

The data for this study was collected in connection with a broader survey on the maturity level of human resource management in November–December 2025. The data was collected with an electronic questionnaire. A link to the electronic questionnaire was distributed in a network operating under the Ministry of Finance, which includes experts working in tasks related to the knowledge-based management of human resources in municipalities and wellbeing services counties. The members of the network were also given the opportunity to distribute a cover letter with a survey link in their own organisations. At the questionnaire, there were a total of 5 open-ended questions, and they were divided into themes related to: strategy and organisation of KHRM, resources and competence, HR data and information needs, HR metrics and HR-analytics and utilization of HR data. In addition to the five open-ended questions, the respondents were asked about the organisation in which they work and their job title. The background questions selected were used to ensure that the respondents belonged to the target audience. This minimised the collection of sensitive and identifiable information about the respondents. To maintain anonymity, the respondents were given ID numbers.

A total of 94 experts responded to the questionnaire. Of them, 33 answered to one or more open ended questions. In total, the data comprised 75 open-ended responses. Some of the answers did not answer the set research question and were therefore omitted from the final data. The final material consisted of 70 responses

submitted by 30 different respondents. The respondents worked in a total of 14 different organisations. The research material consisted of a total of four A4-sized pages of text, covering a total of 2133 words.

4.2 Analysis of the data

In the analysis phase of the data, the themes were abandoned. This was done in order to get an overall picture of the material and to better perceive the connections between the themes. The analysis proceeded in accordance with the topics of qualitative inductive content analysis. Inductive content analysis is recommended for the use in situations where there is little previous research on the phenomenon and the researcher wants to form an in-depth preliminary understanding of the topic (Lyhne et al. 2025).

The analysis of the data began with getting acquainted with the data. The material was carefully read through. The descriptive data was imported into Excel file. A coding template was developed based on the research question. The unit of analysis was a set of ideas that contained one or more sentences. The originality of the context was preserved in the reduction phase, and encoding the analysis units corresponding to the research question and exporting them to an Excel file made it possible to return to them. The reductions (n=163) were grouped into subcategories, main categories and further themes based on content homogeneity. Although the content analysis was carried out with special care, there is always the possibility of error (Boselie et al, 2005).

5 Results

The implementation of KHRM is primarily affected by factors related to HR reporting, analytics and indicators, the collection, availability and storage of HR data, organisational roles, structures and responsibilities, resources and competence, strategic steering and organisational culture, information systems and technical prerequisites, and the utilisation of data in decision-making. In each of the identified main categories, factors that promote and weaken management with HR knowledge were found. The results of the study are described by theme for the main categories and subcategories in Figure 1.

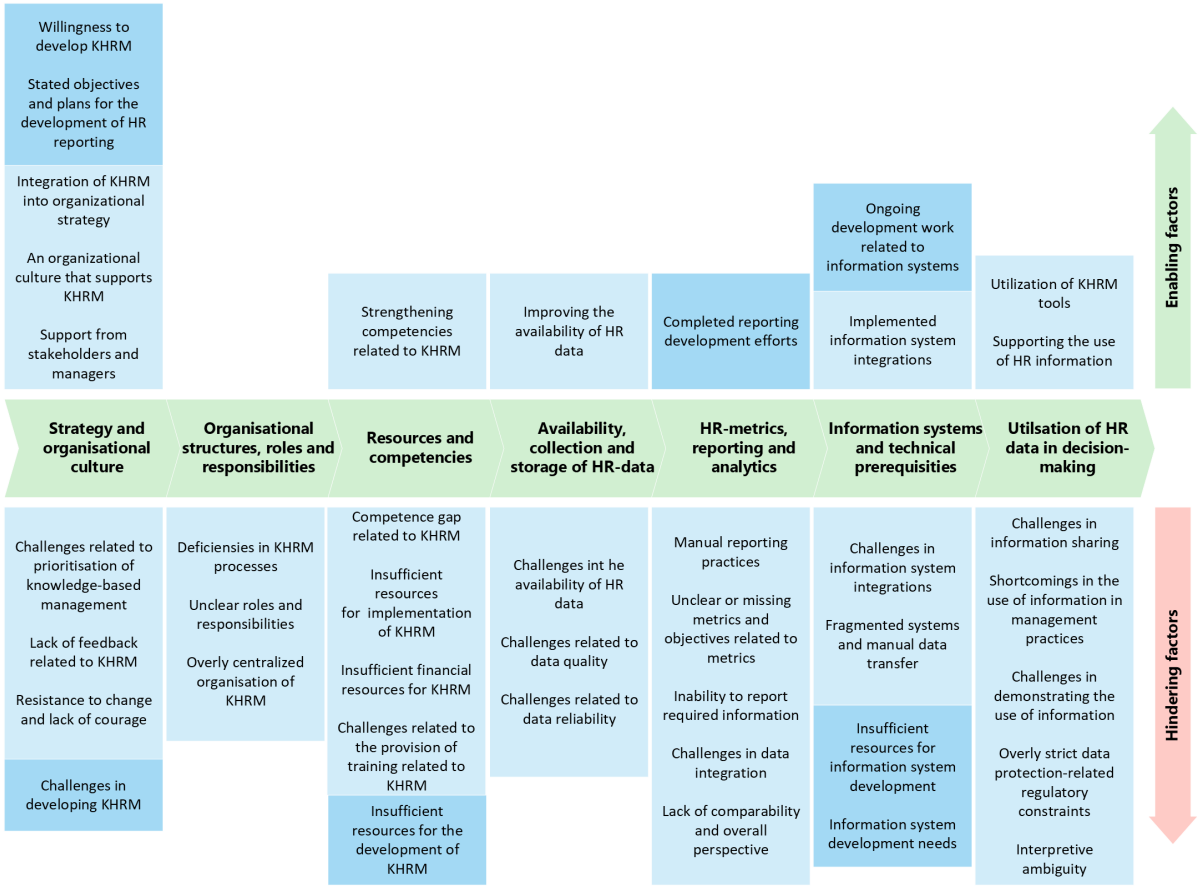

Figure 1: Themes, main categories and subcategories

5.1 Strategy and organisational culture

The development of KHRM is promoted by the goals and plans presented for the development of HR reporting (74, 25, 61, 89, 46) and the willingness to develop management based on HR information (88). The implementation of KHRM is promoted by the inclusion of KHRM in the organisation's strategy (25, 7, 55), the support received from senior management and supervisors (90) and the organisational culture that supports KHRM (88).

"KHRM is reflected in organisational strategy, and to some extent it is supported by organisational culture. There is a clear orientation towards monitoring HR indicators and using them to drive improvement."

The implementation of KHRM is weakened by resistance to change and lack of courage (43, 45, 61, 71, 74), prioritisation related to knowledge-based management (39, 43, 48, 68), challenges in developing KHRM (12, 27, 48, 78) as well as lack of feedback related to KHRM (78).

"Information is produced for the use of the field, but it remains unclear how this will be used in the field, or whether it will be used at all. We don't get feedback on whether the information produced is necessary, whether it is sufficient, or what we would like to see more of."

5.2 Organisational structures, roles and responsibilities

No factors promoting the implementation or development of KHRM were identified. On the other hand, deficiencies in KHRM processes (8, 68, 96), unclear roles and responsibilities (7, 8, 39, 40) and overly centralised organisation of KHRM were identified as factors hindering the implementation and development of KHRM (45).

"An overly centralised resource for knowledge-based management tends to forget the field where it should be used in everyday life."

5.3 Resources and competencies

The implementation of KHRM is constrained by insufficient organisational resources (10, 14, 19, 25, 27, 39, 43, 44, 88, 90), competence gaps related to KHRM knowledge (8, 35, 88), limited financial resources (46), and the challenges related to the provision of systematic training in KHRM (40, 88). Similarly, the further development of KHRM is hindered by the lack of resources for development of KHRM (40).

"The same human resources have many other tasks, which results in a lack of time to focus solely on the development of knowledge-based management."

5.4 Availability, collection and storage of HR-data

Improved availability of HR information strengthens the implementation of KHRM (25, 51). However, the effective implementation of KHRM is often constrained by challenges related to the reliability of HR data (21, 25, 88), limited availability of relevant HR data (27, 35) and challenges in the quality of HR data (68).

"More attention should be paid to the quality of data. It is directly proportional to the urgency of managerial work and the focus on HR matters."

5.5 HR-metrics, reporting and analytics

The implementation of KHRM is hindered by challenges related to HR reporting practices (34), the manual nature of HR-reporting processes (19, 39, 51), and the lack of clarity regarding HR metrics and the targets related to the metrics (12, 27, 35, 39, 40, 43, 51, 61, 96).

"There is a need for more shared discussion within organisation on KHRM, particularly regarding what is measured and for what purpose. At present, KHRM relies heavily on HR department, highlighting the need to make these practices more flexible and responsive to the information needs of the organisation. Strengthening organisation-wide engagement with HR-related data would support a more holistic and effective use of information in decision-making."

Additional challenges include difficulties in integrating HR data across systems (39, 40, 61), the lack of comparability and an overall holistic view of HR information (7, 88), as well as the need to further develop HR analytics capabilities (39, 49, 55) and predictive reporting practices (19, 39, 43, 49). At the same time, the development of KHRM is supported by prior development work already undertaken within the organisation (19).

"At present, there is a clear need to automate recurring HR reports. This would free up HR specialists' time for the meaningful use of HR-related information, such as examining patterns and conducting analysis, and would enable them to retrieve data from information systems for deeper, needs-based analysis when required."

5.6 Information systems and technical prerequisites

Completed integrations between information systems (25) and development work already carried out or currently underway in relation to HR information systems (25, 40, 46) support the implementation and further development of KHRM. However, implementation and further development of KHRM are hindered by insufficient resources allocated to information system development (35), challenges in system-to-system integrations (25, 68) as well as the fragmentation of information systems and the reliance on manual data transfer (27, 34, 40) and current development related needs related to HR information systems (12, 21, 27, 34, 40, 55).

"With the current systems, it is not possible to implement knowledge-based management as we would like without manual work."

5.7 Utilisation of HR data on decision-making

The implementation of KHRM is hindered by challenges related to knowledge sharing (12, 27, 40, 88, 90), data protection regulation (40, 88), the interpretative ambiguity of reports and analytics (88), insufficient integration of information use into managerial practices (43), and challenges related to verifying the actual use of information in decision-making (25, 40, 45, 51, 78).

"Senior management and those holding managerial positions utilise KM tools to support decision-making. However, the competence of middle management and frontline supervisors, as well as the implementation of decisions and the utilisation of information almost always require guidance from higher levels of management. Decisions may be made contrary to strong evidence or available information is simply not utilised. There is limited willingness to act differently from established practices. Frontline supervisors are particularly exposed to the influence of personnel. There is often an inability to justify decisions based on data, leading instead to reliance on established practices or the preferences of staff. Even when employees' views conflict with evidence derived from KM, decisions tend to follow previous practices or individual preferences."

In contrast, the implementation and further development of KHRM are supported by organisational efforts to actively promote the use of HR related information (25, 61) and the utilization of KHRM tools (45).

"At the moment, we are strengthening the foundation (availability of information, data quality, visualisation, up-to-date situational awareness for decision-making and support for the use of information) and resourcing in general to achieve the goals. At the end of 2026, the aim is to take big steps forward in this area in terms of the implementation of development measures."

6 Conclusions

This study set out to explore how KHRM is implemented and developed in Finnish public sector organisations through the experiences of employees involved in HRM and leadership. The study contributes empirical insights into practical realization of KHRM in context characterised by strong legal regulation, societal expectations and persistent resource constraints (Järlström, Saru & Vanhala, 2018).

This study identified several strategy-related factors that promote both the implementation and development of KHRM. Thus, the implementation and development of KHRM are strongly shaped by strategic and cultural factors. This supports the key assumptions of SHRM and sustainable HRM literature. In line with SHRM, the results highlight the importance of integrating KHRM into organisational strategies and the role of explicit stakeholder and manager support in creating legitimacy and direction for KHRM practices (Lepak et al. 2006; Knies et al. 2024). Furthermore, organisational cultures that are receptive to data-driven practices and oriented toward systematic development appear to function as enablers for KHRM, reinforcing the long-term development focus emphasised in sustainable HRM (Ehnert 2009; Kramar 2022). The results of this study reinforce prior research indicating that KM in public sector is inherently shaped by institutional complexity, where multiple logics, actors and governance mechanisms influence how information is produced, interpreted and utilised (Laihonen & Kokko 2023; Laihonen et al. 2024). In this context, the implementation of KHRM cannot be understood solely as a technical or organisational issue, but rather as a phenomenon deeply embedded in broader service systems, organisational culture and institutional conditions.

At the same time, the results reveal substantial barriers that hinder the maturation of KHRM. These barriers are not limited to technical challenges but extend to fragmented organisational structures, unclear roles and responsibilities, limited resources, competence gaps, and difficulties in embedding the use of HR information into everyday managerial practices. This finding is consistent with prior research on knowledge-based management and maturity models, which emphasise that maturity is determined by the alignment of data governance, analytical competence, organisational structures and decision-making routines rather than by

information systems alone (Jääskeläinen et al. 2022; Tenhovuori & Helander 2025). However, the study also points to persistent gap between strategic intent and operational reality, particularly in the utilisation, interpretation and verification of HR data in decision-making, which limits the realisation of strategic and sustainability-oriented HRM in practice.

None of the respondents of this study referred to the use of AI in HRM or knowledge-based management. This suggests that Finnish public sector organisations are largely situated at earlier stages of KHRM maturity, focusing on foundational capabilities such as data availability, data quality, information system integration and analytical competence. Several respondents explicitly highlighted current information system development needs or ongoing system renewal projects as factors hindering the effective implementation of KHRM, indicating that organisations are still engaged in strengthening basic technical and structural prerequisites. This observation supports the view that KHRM development should be understood as a staged, maturity-based process rather than as a technology-driven transformation (Marler & Boudreau 2017; Jääskeläinen et al 2022; Tenhovuori & Helander 2025). From a KHRM perspective, information systems and technical prerequisites form a critical foundation for effective use of HR data in decision-making, and limitations at this level constrain progress towards more advanced, analytics- or AI-enabled HRM practices (Tenhovuori 2024).

The findings related to resources further reinforce the previous literature on sustainable and strategic HRM. Consistent with sustainable HRM perspective, this study shows that insufficient organisational, financial and competence-related resources weaken the implementation and development of KHRM, despite widespread recognition of its strategic importance. This tension is particularly pronounced in the public sector, where service provision is fundamentally dependent on human resources and where personnel costs constitute a substantial share of organisational expenditure. Sustainable and strategic KHRM is expected to support the availability, capability and well-being of personnel to ensure the continuity, quality and effectiveness of public services. (Keva 2025) However, the results of this study indicate that limited resources, competing priorities and insufficient time allocated to systematic development undermine the realisation of these objectives in practice. This finding underscores a central paradox of sustainable HRM in public sector: while human resources are recognised as core enabler of public value creation, the resourcing of KHRM necessary to support this role remains insufficient.

7 Ethics Declaration

Ethics declaration was not required for this research. No personal data was collected in this study. Participation in the study was voluntary, and responding to the electronic questionnaire was considered as informed consent. In connection with the link to electronic questionnaire, the respondents were provided with cover letter. The respondents answered the electronic questionnaire anonymously. The research material is stored appropriately and carefully throughout the life cycle of the research project.

8 AI Declaration

Artificial intelligence tools (Microsoft Copilot) were used for language refinement only. All substantive content, analysis and conclusions were produced and validated by the authors.

Life Cycle Costing in Regenerative Systems: A Knowledge Integration Approach

Francesca Lerario, Achille Claudio Garavelli
(DMMM), Polytechnic University of Bari, Bari, Italy

Abstract

Post-extractive landscapes, such as abandoned quarries, represent complex socio-ecological systems in which environmental degradation, material flows, regulatory constraints, and local development dynamics intersect. Within this context, these environments can be interpreted as manifestations of a broader polycrisis, where multiple ecological, economic, and institutional pressures interact and reinforce one another. Regenerative approaches respond to this condition by moving beyond impact reduction toward restoration-oriented value creation processes that actively contribute to ecosystem and community recovery. At the same time, the implementation of regenerative systems requires lifecycle-oriented evaluation tools capable of supporting decision-making under conditions of uncertainty, long-term dynamics, and multi-stakeholder involvement. This paper develops an analytical framework, grounded in socio-ecological and regenerative system perspectives, for the application of Life Cycle Costing (LCC) to restoration systems based on circular materials and additive manufacturing. The proposed approach structures cost evaluation across lifecycle phases, including material processing, manufacturing, installation, monitoring, maintenance, and end-of-life, and considers alternative production configurations at different scales. The study highlights how lifecycle cost structures can support knowledge integration and stakeholder coordination, particularly in configurations where monitoring, maintenance, and data-driven activities play a central role. It also emphasizes the relevance of lifecycle-based analysis in capturing the temporal dimension of value creation and in supporting the alignment of technical and organizational decisions across system phases and improving transparency in complex, multi-actor restoration settings. Expected results suggest that LCC can enable the comparison of alternative restoration configurations and provide insights into the temporal distribution of activities and responsibilities across lifecycle phases. At the same time, the study acknowledges the limitations of LCC in capturing broader ecological and social value, pointing to the need for complementary evaluation approaches. The paper contributes to the literature on regenerative socio-ecological systems and lifecycle evaluation by proposing a structured framework that integrates economic analysis with knowledge-intensive and multi-stakeholder restoration processes.

Keywords: Regenerative approach; Life Cycle Costing; Knowledge Integration; Product-Service Systems; Polycrisis

Paper type: Academic Research

1 Introduction

Abandoned quarries are not merely degraded sites; rather, they can be interpreted as territorial manifestations of a slow-onset polycrisis: complex socio-ecological systems shaped by the interaction of environmental degradation, material flows, regulatory dynamics, and local development trajectories (Chenot, 2018; Legambiente, 2023; Legambiente, 2025). In recent years, such contexts have been increasingly interpreted within broader systemic perspectives that emphasize the interconnected nature of environmental, economic, and social challenges (Dirk Helbing, 2013; Lawrence et al., 2024). This framing highlights how post-extractive landscapes are embedded in multi-layered processes that require coordinated responses across multiple domains of expertise.

Within this perspective, quarry restoration represents not only an ecological or technical challenge, but also an organizational and coordination problem. Restoration processes typically involve a wide range of actors, including engineers, ecologists, material scientists, public authorities, and local stakeholders, whose knowledge bases, objectives, and time horizons may differ significantly. Research on socio-ecological systems emphasizes that outcomes in such contexts depend on the ability to manage interdependencies and coordinate heterogeneous forms of knowledge (Buckton et al., 2023). In practice, however, achieving such coordination remains difficult, particularly when restoration outcomes unfold over long timeframes and under conditions of uncertainty.

Recent contributions on regenerative business models (RBMs) further reinforce the need for systemic and coordinated approaches. This stream of literature moves beyond traditional sustainability and circular economy frameworks by focusing on value creation processes that aim to restore and enhance ecosystem health (Konietzko et al., 2023; Das & Bocken, 2024). Despite this conceptual advancement, empirical applications remain limited, especially in territorially embedded contexts such as post-extractive landscapes. Studies indicate

that organizations often face significant challenges in translating regenerative principles into operational practices, particularly when implementation requires coordination across multiple stakeholders and domains (Gualandris et al., 2023).

In parallel, Life Cycle Costing (LCC) has been widely adopted as a techno-economic tool for evaluating costs across the lifecycle of products and systems (European Commission, 2023; International Organization for Standardization, 2017). Within sustainability and circular economy contexts, LCC supports decision-making by enabling the comparison of alternative solutions based on their long-term cost implications (Kambanou & Lindahl, 2016; Kambanou & Sakao, 2020). However, the use of LCC remains primarily oriented toward economic evaluation, and its application in complex socio-ecological systems raises important limitations. In particular, LCC relies on assumptions regarding system boundaries, lifecycle duration, and future operating conditions, and it does not fully capture non-monetizable dimensions such as ecological functions or social value.

These limitations are especially relevant in quarry restoration contexts, where decision-making involves long-term ecological processes, uncertainty, and multiple interacting actors. At the same time, technological advances in additive manufacturing and circular materials, such as the use of PLA-based composites incorporating marble waste, demonstrate the technical feasibility of innovative restoration approaches (Fico et al., 2025; Romani et al., 2021). Nonetheless, existing studies tend to focus on material performance or process efficiency, often without integrating economic, ecological, and organizational dimensions within a unified analytical framework.

Against this background, this paper adopts Life Cycle Costing as an analytical tool to evaluate the economic performance of a regenerative restoration system for post-extractive environments. The study focuses on a restoration configuration based on additive manufacturing and circular materials, and aims to provide a structured comparison of lifecycle cost components across alternative system configurations. Accordingly, the paper addresses the following research question:

RQ: *How does Life Cycle Costing support the evaluation of economic performance in regenerative restoration systems for quarry sites?*

To answer this question, the paper evaluates: (1) evaluating the lifecycle costs of a regenerative restoration system based on additive manufacturing and circular materials; (2) comparing cost structures across different lifecycle phases; and (3) discussing the implications of cost distribution for decision-making processes, stakeholder coordination, and the understanding of dynamics in complex socio-ecological systems.

2 Theoretical Background

2.1 Regenerative socio-ecological systems and lifecycle-oriented value creation

While circular economy strategies primarily focus on resource efficiency and waste reduction, regenerative approaches emphasize the restoration and enhancement of ecological and social systems (Konietzko et al., 2023). Accordingly, regenerative business models aim not only to reduce negative impacts, but also to generate positive outcomes for ecosystems and communities (Das & Bocken, 2024). Recent literature conceptualizes regenerative systems as socio-ecological configurations characterized by the interdependence of ecological processes, social dynamics, economic activities, and institutional arrangements (Buckton et al., 2023). This perspective is particularly relevant for post-extractive landscapes, such as abandoned quarries, where environmental degradation is intertwined with land-use change, material flows, regulatory constraints, and local development trajectories.

This view is consistent with systemic perspectives on risk and polycrisis, which emphasize the interconnected nature of environmental and socio-economic challenges (Dirk Helbing, 2013; Lawrence et al., 2024). In this sense, quarry degradation can be understood as the outcome of interacting pressures across ecological, economic, and institutional domains, rather than as an isolated environmental issue. Empirical evidence further highlights the complexity of these contexts: reports on quarrying and circular economy in the construction sector point to persistent environmental and material management challenges (Legambiente, 2021, 2025), while studies on quarry degradation and pedogenesis identify specific ecological constraints affecting restoration processes (Chenot et al., 2018). Within such contexts, value creation cannot be reduced to a single intervention phase, but must be understood as distributed across the lifecycle of the system. Literature on Product-Service Systems and servitization supports this perspective by showing how value emerges from the integration of products, services, and ongoing activities over time (Kohtamäki et al., 2019). In digital and service-oriented configurations, value is increasingly generated through monitoring, maintenance, and data-driven interactions, rather than through the delivery of a physical artefact alone (Langley, 2022; Paiola et al., 2024). Accordingly,

regenerative restoration systems require lifecycle-oriented approaches capable of capturing both the temporal distribution of activities and the coordination of multiple actors.

2.2 Circular materials and additive manufacturing for regenerative restoration

Circular materials and additive manufacturing have been increasingly explored as approaches to reduce waste and enable new applications of secondary resources within production systems. In circular economy contexts, additive manufacturing allows the transformation of waste streams into new products through material reprocessing and localized production processes (Romani et al., 2021). In relation to post-extractive landscapes, recent studies have demonstrated the feasibility of using quarry waste as input material for additive manufacturing applications. Fico et al. (2025) show how marble waste can be processed into eco-friendly filament for 3D printing, supporting renaturalization processes in quarry environments. This approach connects material recovery with restoration interventions, linking circular economy strategies to regenerative practices.

Material performance represents a key constraint in the application of circular materials to restoration contexts. The behavior of biodegradable polymers, such as polylactic acid (PLA) and related composites, depends on thermal degradation, environmental conditions, and long-term stability (Ohkita & Lee, 2006; Urayama et al., 2002), which directly affects their suitability in environments exposed to natural processes.

However, existing contributions tend to focus on material and process performance, with limited attention to broader lifecycle implications. Economic costs, service requirements, and long-term operational activities are often not integrated into the analysis. This gap reinforces the relevance of lifecycle-oriented approaches, such as LCC, to complement technical assessments and support a more comprehensive evaluation of regenerative restoration solutions. These limitations highlight the need for lifecycle-oriented analytical approaches capable of integrating technical, economic, and operational dimensions, such as Life Cycle Costing.

2.3 Life Cycle Costing (LCC)

Life Cycle Costing (LCC) is a techno-economic method used to assess costs incurred throughout the lifecycle of a system, including acquisition, operation, maintenance, and end-of-life phases (European Commission, 2023; International Organization for Standardization, 2017). Its relevance lies in supporting decisions that extend beyond initial investment, particularly in contexts characterized by long-term cost implications. In Product-Service System contexts, LCC has been applied to analyze how costs are distributed across lifecycle phases, enabling the comparison of alternative configurations that combine products and services (Kambanou & Lindahl, 2016). Similarly, in circular economy applications, LCC supports the evaluation of different resource and design strategies by accounting for costs associated with use, maintenance, and end-of-life management (Kambanou & Sakao, 2020). Applied to regenerative restoration systems, LCC provides a structured framework to compare solutions that involve both material components and long-term service activities. This is particularly relevant when restoration interventions extend beyond installation and require ongoing monitoring, maintenance, and adaptation over time. In such contexts, system performance depends not only on technical and economic factors, but also on ecological processes that evolve over time and are not fully predictable (Chenot et al., 2018). Beyond its evaluative function, the application of LCC requires the integration of heterogeneous forms of knowledge. Lifecycle modelling depends on inputs related to ecological dynamics, material behavior, production processes, cost structures, and regulatory conditions, which are often distributed across different domains. According to the knowledge-based view, the integration of specialized knowledge is a key condition for effective decision-making in complex systems (Grant, 1996). Research on knowledge boundaries further highlights how differences in assumptions and interpretative frameworks can complicate the integration of such knowledge (Carlile, 2002, 2004). In this sense, developing an LCC model involves making explicit a set of assumptions and parameters that reflect contributions from multiple domains. As a result, LCC does not eliminate knowledge complexity, but requires it to be structured within a common analytical framework. Despite its usefulness, LCC remains limited to the economic dimension of system performance and does not fully capture ecological or social outcomes. It should therefore be understood as a partial evaluation tool that supports economic comparison within broader, multi-dimensional decision-making processes.

3 Methodology

3.1 Research design and approach

This study adopts a conceptual and analytical Life Cycle Costing (LCC) modelling approach aimed at structuring the evaluation of regenerative restoration systems at the design stage. The research is currently in progress, with data collection and model calibration ongoing.

The approach is consistent with LCC applications in early design phases, where cost modelling supports decision-making prior to system implementation (Asiedu & Gu, 1998; Kambanou & Lindahl, 2016; Rodríguez et al., 2020). In line with established LCC practices, the model considers the entire lifecycle of the system, from material acquisition to end-of-life, adopting a long-term perspective (Rebitzer & Hunkeler, 2003; Settanni et al., 2014).

Two alternative production configurations are defined to structure the analysis. Scenario A represents laboratory-scale production, while Scenario B represents a potential industrial-scale configuration. These scenarios provide a comparative framework for analysing how differences in scale and process organization may affect lifecycle cost structures.

3.2 Goal and scope definition

The functional unit is defined as **1m² of restored quarry over a six-year period**. This temporal boundary reflects the timeframe typically required for vegetation establishment and initial ecosystem recovery in degraded environments (Urayama et al., 2002; Ohkita et al., 2006). The system is conceptualized as a restoration configuration based on the deployment of biodegradable microhabitat devices designed to support substrate stabilization, moisture retention, and microclimate regulation. The number of devices per m² is defined as a modelling assumption based on spatial coverage and design parameters.

The system boundaries follow a cradle-to-grave perspective and include five lifecycle stages:

- materials extraction and processing;
- manufacturing;
- installation;
- use phase;
- end-of-life.

3.3 Life Cycle Costing model

The LCC model is structured to estimate cost components across lifecycle phases, enabling the comparison of alternative system configurations. Costs are organized into the categories defined in 4.2.

The total cost per device is expressed as:

$$C_{device} = C_{materials} + C_{preprocessing} + C_{manufacturing} + C_{installation} + C_{monitoring} + C_{EoL}$$

Costs are then normalized to the functional unit based on the number of devices per m².

The model adopts a deterministic structure, with explicit assumptions to ensure transparency and comparability across scenarios.

3.4 Data and assumptions

The model is based on a combination of literature data, technical parameters, and preliminary market-based estimates. Data collection is currently ongoing and aims to refine key cost components and operational assumptions.

Data inputs include:

- material and process parameters from additive manufacturing and circular materials literature (Fico et al., 2025)
- cost-related assumptions informed by sectoral data and market observations
- lifecycle assumptions related to system duration, maintenance requirements, and environmental conditions

Given the current stage of the research, the model should be interpreted as an evolving analytical framework. Further work will focus on data validation, parameter refinement, and empirical calibration.

4 Expected Results and Discussion

Based on the proposed Life Cycle Costing framework and the characteristics of regenerative restoration systems, it is expected that the distribution of costs across lifecycle phases will provide insights into how activities are organized and coordinated among stakeholders. In particular, cost structures are anticipated to reflect different coordination patterns depending on their temporal distribution. Higher upfront costs associated with design and production phases may indicate a concentration of coordination efforts in early project stages, while the presence of recurring costs related to maintenance, monitoring, and operational activities is expected to signal the need for ongoing coordination among multiple actors over time. These expected patterns are consistent with existing research on Product-Service Systems and servitization, which highlights how service-oriented configurations require continuous interaction and coordination across lifecycle phases (Kohtamäki et al., 2019; Kambanou & Lindahl, 2016). In the context of socio-ecological systems, such coordination is particularly critical due to the involvement of heterogeneous stakeholders and long-term system dynamics (Buckton et al., 2023).

4.1 Expected knowledge requirements and informational complexity

The development of the LCC model is expected to require the integration of multiple forms of knowledge, reflecting the inherent complexity of regenerative restoration systems. Specifically, it is anticipated that ecological knowledge (e.g., environmental dynamics), engineering and manufacturing knowledge (e.g., additive manufacturing processes), economic knowledge (e.g., cost structures and assumptions), and institutional knowledge (e.g., regulatory frameworks) will need to be combined within a single analytical framework. From a theoretical perspective, this aligns with the knowledge-based view of the firm, which emphasizes the importance of integrating distributed and specialized knowledge for effective decision-making (Grant, 1996). The LCC modelling process is therefore expected to make explicit the range of assumptions and inputs required, highlighting both the diversity of knowledge domains involved and the potential challenges in aligning them. Furthermore, it is expected that uncertainty associated with key parameters, such as lifecycle duration, maintenance needs, and environmental conditions, will play a significant role in shaping the results. This suggests that LCC outcomes should be interpreted as contingent on underlying assumptions and subject to revision as additional knowledge becomes available.

4.2 Expected implications for multi-capital value and decision-making

While the LCC analysis is expected to provide a structured assessment of economic performance, it is also anticipated that it will reveal important limitations in capturing the broader value generated by regenerative restoration systems. Ecological benefits, such as the restoration of ecosystem functions, and social impacts at the territorial level are unlikely to be fully reflected in monetary terms. This is consistent with literature on sustainability accounting, which highlights the challenges of representing multi-dimensional value through economic metrics alone (Bebbington et al., 2014). From this perspective, regenerative restoration processes can be understood as generating value across multiple forms of capital – natural, social, and produced – of which economic cost represents only one dimension. Accordingly, it is expected that decision-making in such contexts cannot rely exclusively on LCC results but should incorporate complementary qualitative and multi-dimensional evaluations. The role of LCC, in this sense, is anticipated to be that of providing a structured basis for economic comparison, while supporting broader discussions on value creation in complex socio-ecological systems.

5 Conclusions

This study addressed the need for lifecycle-oriented evaluation in regenerative restoration systems within post-extractive landscapes. By framing these contexts as complex socio-ecological systems shaped by polycrisis dynamics, the study highlighted the challenges of coordinating technical, ecological, and organizational dimensions over time.

An analytical framework based on Life Cycle Costing (LCC) was developed to structure cost evaluation across lifecycle phases in regenerative Product-Service Systems. The framework enables the comparison of alternative configurations and highlight. At the same time, the study acknowledges that LCC captures only the economic dimension of system performance and does not fully represent broader ecological and social value. This limitation points to the need for complementary approaches to support decision-making in complex socio-ecological systems.

From Unstructured Inputs to Structured Knowledge: A Modular LLM-Based Approach for Enterprise Knowledge Extraction

Umair Ali Khan, Dmitry Kudryavtsev, Janne Kauttonen, Akseli Leskinen, Jukka Remes
Haaga-Helia University of Applied Sciences, Helsinki, Finland

Abstract

Enterprises increasingly use generative AI to convert unstructured organizational knowledge into structured outputs that can support reporting, decision-making, analytics, and process automation. However, structured knowledge extraction in real enterprise settings remains difficult because input data often appears in fragmented forms such as speech transcripts, scanned documents, complex forms, and layout-rich business records. In addition, each use case usually requires its own fields, constraints, terminology, and output format, making tailored extraction pipelines costly to build and difficult to maintain.

This paper presents a modular, large language model (LLM)-based knowledge extraction component developed as part of the GAIK toolkit - a generative AI toolkit for supporting organizational knowledge processes. The component enables users to define extraction requirements in plain language, automatically generate a structured schema, and use that schema for the extraction of knowledge from parsed documents or transcribed speech using LLM. The approach is designed to reduce repetitive engineering work while improving consistency, reusability, and adaptability across different enterprise use cases.

The study follows a design science research approach. The artifact was designed, implemented, demonstrated, and evaluated through industry-oriented use cases, with a particular focus on incident reporting and construction site diary creation. The incident reporting case demonstrates how spoken safety observations can be converted into structured reports using a reusable audio-to-structured-data module that combines transcription, transcript enhancement, schema generation, and extraction. A pilot evaluation with 15 incident-reporting audio samples provides preliminary evidence of technical feasibility and shows how schema persistence, human review, and configurable semantic similarity thresholds can support adaptation when business requirements or field definitions change, while maintaining reusable knowledge extraction workflows across organizational contexts.

The paper presents a practical, reusable design for enterprise knowledge extraction using generative AI. It shows how plain-language requirements, dynamic schema generation, and schema-conformant extraction can be combined into configurable building blocks for knowledge capture.

Keywords: structured knowledge extraction, knowledge capture, dynamic schema generation, large language models, workflow automation, knowledge management

Paper type: Practical Paper

1 Introduction

Knowledge management focuses on how organizations capture, store, share, and reuse knowledge to support decisions, operations, and learning. Much of this knowledge is embedded in unstructured or semi-structured materials, such as meeting recordings, field notes, purchase orders, requests for proposals, inspection reports, and safety observations. When such content remains scattered across documents, systems, and individual employees, it is difficult to reuse, analyze, or integrate into business processes. Structured knowledge extraction addresses this problem by transforming organizational content into machine-readable records that support search, analytics, reporting, automation, and governance.

Generative AI, and especially LLMs, create new opportunities for supporting knowledge processes. Companies see especially high perceived usefulness of AI for knowledge acquisition and documentation, including eliciting personal knowledge from experts and extracting knowledge from discussions, meetings, and conversations. Recent work shows that LLMs can support a wide range of extraction tasks across domains (Ateia et al., 2025a). From a knowledge management perspective, this reflects a broader human-AI partnership, where humans define meaning, goals, context, and accountability, while AI helps scale knowledge capture, structuring, and reuse (Jarrahi et al., 2023).

However, applying LLMs to structured knowledge extraction in enterprises remains challenging. First, reliable extraction requires stable schemas with clear field names, data types, constraints, and optional fields. Without such schemas, LLM outputs may vary across runs and become difficult to validate or integrate. Second, enterprise inputs often include scanned documents, tables, forms, images, and speech transcripts. If these are

not parsed correctly, extraction quality decreases. Third, organizations need many extraction tasks across departments, each with its own terminology, fields, and reporting requirements. Building a separate solution for every use case is costly, hard to maintain, and poorly suited to SMEs with limited technical capacity.

These challenges are closely connected to the knowledge management idea of codification. Codification strategies aim to make knowledge explicit, reusable, and accessible through structured repositories and systems (Alavi and Leidner, 2001). In this paper, we argue that LLM-based structured extraction can support codification by converting tacit, fragmented, or document-bound knowledge into consistent records. This also raises a broader question: whether such systems enable new forms of organizational memory, understood as stored information from an organization's history that can inform present decisions (Walsh and Ungson, 1991). If spoken observations, field notes, reports, and business documents can be continuously converted into schema-conformant records, generative AI may expand how organizations capture and reuse memory from everyday work.

This paper addresses these issues through the design and evaluation of a modular LLM-based knowledge extraction component developed as part of the Generative AI Enhanced Knowledge Management (GAIK) toolkit (GAIK Project, 2026a). The component supports knowledge capture and codification by transforming fragmented workplace observations, speech records, and documents into reusable structured knowledge. The work is relevant to human-AI hybrid knowledge ecosystems, digital transformation of knowledge management practices, and generative AI for knowledge management.

GAIK is an open-source, business-oriented toolkit that organizes reusable GenAI building blocks around key knowledge processes, including knowledge capture, knowledge access, and knowledge synthesis (Kudryavtsev et al., 2025, 2024). The component presented in this paper focuses on knowledge capture. It allows users to describe extraction requirements in plain language, automatically converts them into type-safe schemas, and uses the generated schemas to guide schema-conformant extraction from parsed documents or speech transcripts.

The research is grounded in our experience from AI consultancy and industry-oriented development work, where structured knowledge extraction repeatedly appears as a bottleneck in early AI adoption. Common needs include extracting fields from purchase orders, invoices, and contracts; converting voice notes into structured reports; capturing observations from field work; and preparing consistent inputs for reporting, compliance review, or proposal generation. These recurring needs motivated reusable extraction building blocks rather than isolated use-case-specific scripts.

The paper is guided by the following research questions:

- *RQ1: How can plain-language extraction requirements be transformed into reusable schemas for structured enterprise knowledge extraction?*
- *RQ2: How can schema-guided LLM extraction be implemented as a modular building block for knowledge capture across documents and speech transcripts?*
- *RQ3: Can this approach support organizational memory by converting tacit and/or unstructured inputs into validated and reusable knowledge records?*

To answer these questions, the paper follows a design science research approach. We present the design of the extraction component, its integration into reusable software modules, and its demonstration through enterprise use cases, focusing on incident reporting and construction site diary creation. We also report an objective evaluation of the incident reporting use case, where spoken safety observations are transformed into structured reports through an audio-to-structured-data workflow.

2 Related Work

2.1 Academic work

(Xu et al., 2024a) conclude that LLMs can handle multiple extraction tasks in a unified format, with strong performance in zero-shot and few-shot settings. This generalization capacity is directly relevant to enterprise knowledge extraction, where extraction targets vary widely across departments and use cases, and annotated training data is rarely available at scale.

Within the same space, Ateia et al. (2025b) apply LLM for in-context learning to extract key concepts from scientific publications. Their approach requires few or no labelled examples to configure extraction for a new target field. This finding strengthens the case for plain-language, schema-driven extraction as a viable model for enterprise settings where requirements change frequently, and technical configuration capacity is limited.

Structured extraction from domain-specific text has also gained traction. Dagdelen et al. (2024a) demonstrate that LLMs can be fine-tuned for joint named entity recognition and relation extraction in materials

chemistry, producing structured records. Their work shows that LLMs can be directed to extract records consistently across sentences and paragraphs, and that the output format itself can be controlled through prompt design and schema specification.

A recurring challenge in LLM-based enterprise extraction is the accurate parsing of business documents. Zhang et al. (2024) note that VLM-based approaches offer stronger generalization, which is consistent with a recent study (Zhang et al., 2026). This forms the basis for one of our custom parsers (a multimodal parser) used in the software modules, where extraction is followed by parsing.

Schema-guided LLM-based extraction has emerged as a reliable method in production settings. When an LLM is guided to produce output conforming to an explicitly defined schema, the result is more consistent, easier to validate, and more directly integrable with downstream systems than free-form generation. Dagdelen et al. 2024b) and Xu et al., 2024b) both identify well-defined output schemas as critical for reliable, reproducible extraction, especially in settings where outputs must feed into reporting workflows, compliance systems, or databases.

The challenge that follows naturally from schema-guided extraction is schema generation itself. In enterprise settings, extraction requirements are often initially held as tacit knowledge, where a subject-matter expert knows what fields a report should contain. However, the mapping from that knowledge to a formal, machine-enforceable schema is a non-trivial step. If users must specify schemas manually in technical formats, the barrier to adoption rises significantly for organizations without strong AI or software engineering capability.

2.2 Industrial solutions

Many cloud platforms provide knowledge extraction services. Azure AI Document Intelligence (Microsoft Azure, 2026) extracts text, tables, document structure, and key-value pairs, and also supports custom models for structured, semi-structured, and unstructured documents. Google Document AI(Google Cloud, 2026) provides processors for parsing documents and extracting structured fields. Amazon Textract (Amazon Web Services, 2026) extracts text, handwriting, layout elements, forms, tables, and bounding-box information from scanned documents and images.

Current LLM APIs and developer frameworks increasingly support structured output generation. OpenAI Structured Outputs (OpenAI, 2026) are designed to make model responses adhere to a given schema. Azure OpenAI similarly describes structured outputs as a way to make a model follow a schema definition. Similarly, Anthropic(Anthropic, 2026) and LangChain(LangChain, 2026) also support structured outputs with a schema in various formats. These methods reduce the need to parse free-form LLM responses and make generated outputs easier to validate and integrate.

However, these industrial solutions do not fully address the problem studied in this paper. Document AI platforms are strong at document processing, but they are usually organized around predefined processors, custom models, or vendor-specific workflows. LLM structured-output APIs provide schema adherence, but they do not by themselves solve the broader enterprise problem of translating plain-language business requirements into reusable extraction schemas, selecting appropriate parsing or transcription routes, and embedding extraction into knowledge-management workflows. The contribution of this paper is therefore not another standalone extraction model, but a reusable design for configurable knowledge extraction as part of a broader GenAI toolkit for organizational knowledge capture.

3 Research Methodology

The research paper follows a design science research methodology (Peffers et al., 2007). Knowledge extraction components are part of the GAIK toolkit, and the overall methodology for toolkit development is presented in Kudryavtsev et al. (2026). Design and development of the required components were done in cooperation with companies in several iterations with a feedback loop. The knowledge extraction problem was identified through our AI consultancy in the Finnish AI Region project (Finnish AI Region, 2026) and research activities with organizations exploring generative AI adoption, where structured knowledge extraction appeared as a recurring problem. Based on this problem diagnosis, three design requirements were defined for the knowledge extraction solution: i) the artifact should provide business-level support, ii) it should ensure technical reuse, and iii) it should be designed for SMEs and organizations with low AI maturity, where users may not have the expertise to manually define schemas, validation rules, or complex LLM pipelines. The knowledge extraction solution design and development results are presented in Section 4. Demonstration and evaluation of the suggested artifact are presented in Section 5.

4 Knowledge Extraction Approach and Reusable Components

The resulting artifact is a modular knowledge extraction software component in GAIK's toolkit (GAIK extractor (GAIK Project, 2026b). The artifact consists of four main methodological steps (see Figure 1).

1. **Requirement parsing:** the user's natural-language specification is converted into an intermediate requirement representation. This representation defines the target fields, meanings, expected data types, required or optional status, and constraints such as enumerations or patterns.
2. **Structure detection:** the component determines whether the expected output is a flat record or a nested structure. A flat structure may involve extracting invoice-level fields such as invoice number, sender, receiver, date, subtotal, tax, and total. A nested structure may involve extracting repeated line items from a purchase order and linking each item to information from an accompanying bill of materials.
3. **Input preparation:** for documents, the input is first converted into a textual representation (called parsing). Simple documents are handled through standard parsers, while scanned, layout-rich, or visually complex documents are parsed with custom vision-based or multimodal parsers. This design is important because parsing quality directly affects extraction quality. If tables, charts, figures, or layout cues are incorrectly represented, the downstream extractor may receive incomplete or misleading input. Similarly, audio/video input is first converted into a textual format (called transcription).
4. **Schema generation and extraction:** extraction requirements are compiled into runtime validation models, enabling type checking, strict field control, and consistent output structures. The extractor then applies schema-guided extraction to the parsed input and returns schema-conformant structured records. This design follows recent work on LLM-based structured extraction, where schema constraints and structured outputs are used to reduce output drift and improve downstream integration (Dagdelen et al., 2024b; Xu et al., 2024b).

The artifact was operationalized through two reusable software modules in the GAIK toolkit. The first module, documents-to-structured-data, combines a document parser with the schema generator and extractor. It parses the input with a selected parser, generates or reuses an extraction schema from user requirements, and returns extracted fields, the generated schema, and the corresponding requirements. It also supports schema persistence, allowing organizations to generate a schema once and reuse it for repeated extraction tasks.

The second module, audio-to-structured-data, combines transcription with the same requirement-to-schema and schema-guided extraction pipeline. It accepts audio or video input, produces a raw transcript, applies transcript enhancement using our 2-pass transcript enhancement software component, and then passes the transcript to the extractor. The module returns extracted fields, a generated schema, and extraction requirements. The current transcriber component supports configurable transcription backends, including Whisper, GPT-4o-transcribe, and language-specific Whisper models. Figure 2 shows the two reusable knowledge extraction software modules using the knowledge extraction pipeline.

In the evaluation design, three validation dimensions were defined. First, functional validity assesses whether the component can transform plain-language requirements into schemas and produce schema-conformant outputs. Second, reusability and configurability assess whether the same component can support different extraction tasks by changing requirements, parser choices, or module configuration rather than rewriting the pipeline. Third, output quality assesses whether extracted fields match human-annotated ground truth. Exact fields, such as dates, names, and prices, are compared through normalized string or value matching, while semantic fields are compared through embedding-based cosine similarity. The performance metrics include precision, recall, F1 score, exact match rate, and semantic match rate.

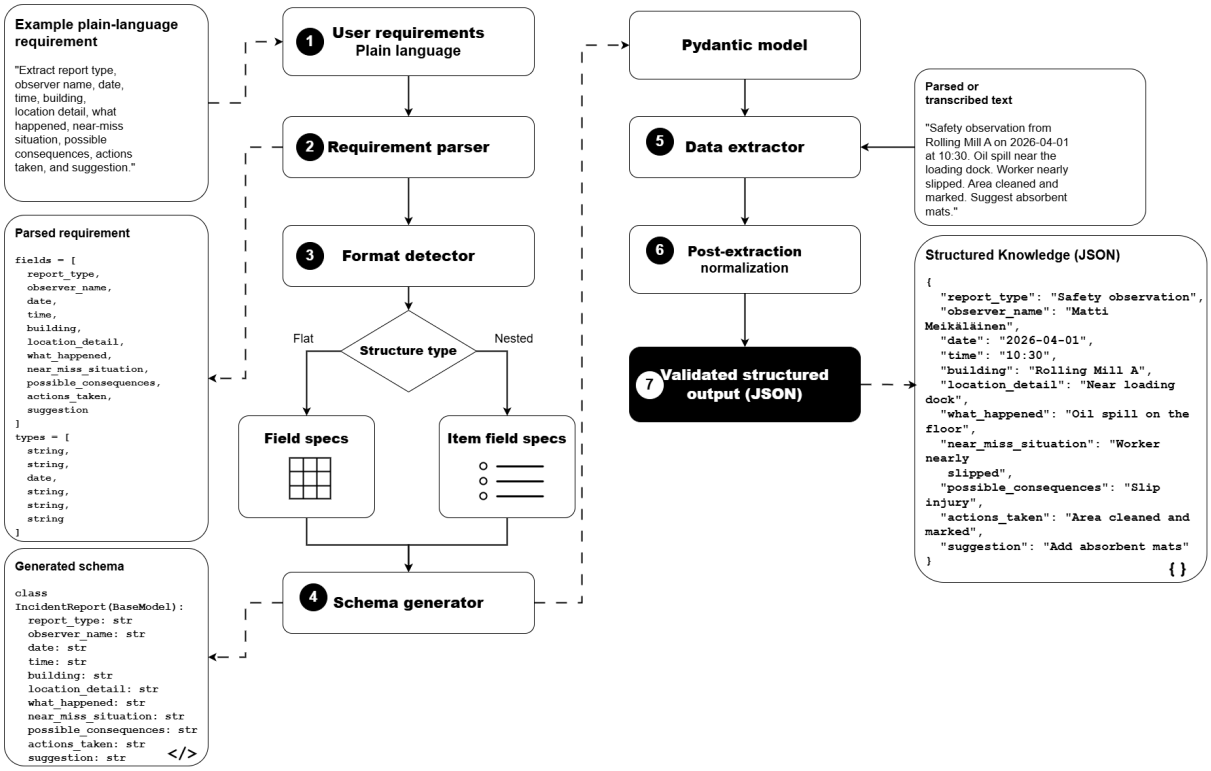

Figure 1: The main steps of the reusable knowledge extraction software component

5 Demonstration and Evaluation

5.1 Overview of use cases

The current implementation demonstrates end-to-end feasibility and reusability for several use cases, including incident report and safety observation in factories, construction site daily diary creation, construction site inspection report generation, and extracting data from purchase orders and bill of materials. The present focus is functional validation, modularity, and use case coverage rather than large-scale benchmarking.

Table 1: Two use cases for demonstration and evaluation

Use case name	Company	Problem	Solution
Incident reporting and safety observation	Manufacturing company	Reporting safety incidents is slow due to manual form-filling	Voice and image-based reporting with automatic structuring into reports
Construction site diary creation	Construction company	Difficult and time-consuming to document daily site activities	Converts voice notes, calls, and photos into structured daily diaries

5.2 Incident reporting and safety observations as one of the application areas for the extraction component

The incident reporting use case demonstrates how the knowledge extraction component can support structured knowledge capture from spoken workplace observations. In the partner company, employees are expected to report safety observations, near misses, and incidents such as spills, water leakage, broken equipment, or other hazards. The existing process requires employees to access a computer and complete a web form in the company's Impact system, which slows down reporting, especially when observations are made far from a workstation.

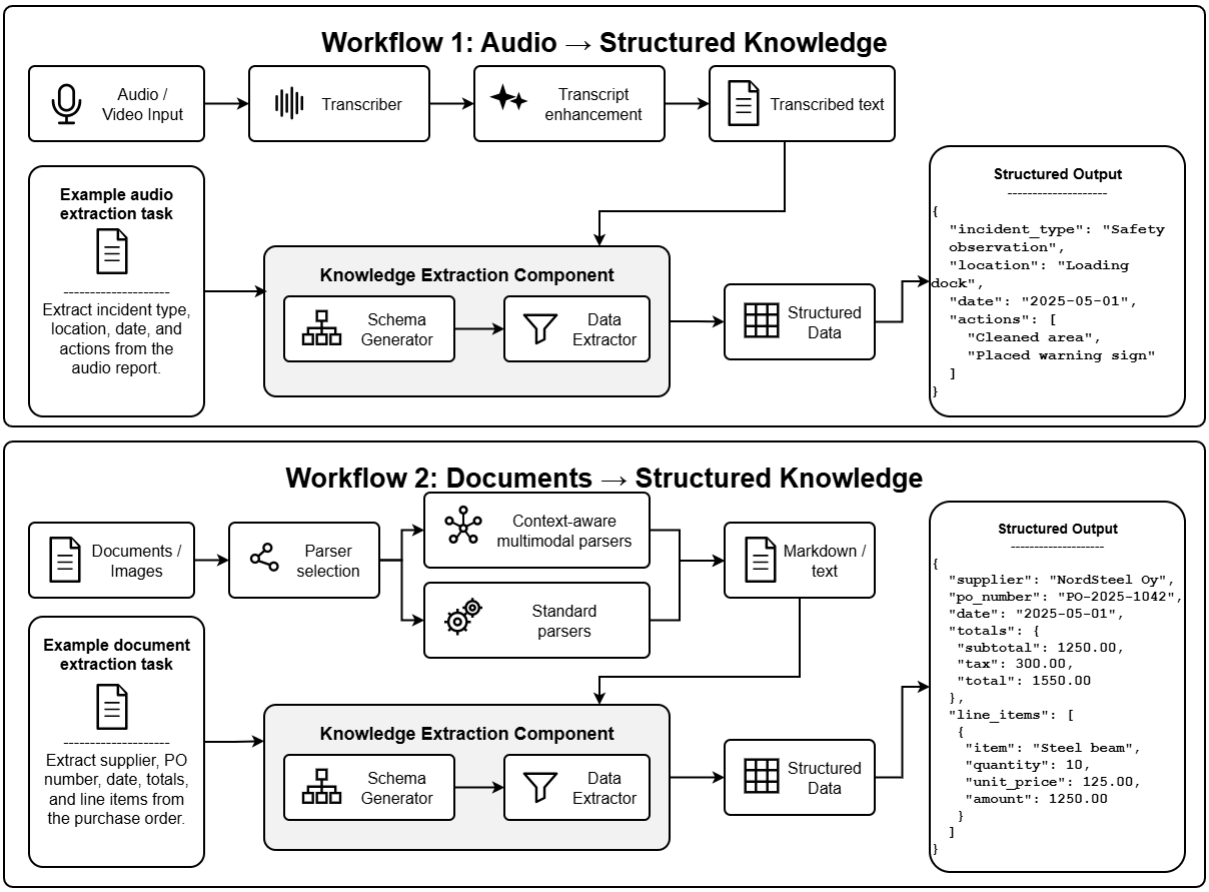

Figure 2: Depiction of the reusable knowledge extraction software modules using the knowledge extraction component

The designed AI-supported workflow enables employees to report incidents through voice input on a mobile device, with optional images when visual evidence is useful. The audio description is first transcribed by selecting a suitable transcription model, the transcript is enhanced using our 2-pass LLM-based enhancement method, and the extractor component then converts the description into the required structured fields of the incident report. The user reviews the extracted fields and modifies them as required. Subsequently, the generated report (raw and PDF converted) is transferred to the company's existing reporting system.

AI solution customization does not require technical skill. The schema generator helps convert natural-language requirements into a schema (e.g., an incident-reporting or safety-observation template). Once a schema is generated, it can be reused for the same extraction task. If, however, the task changes or some of the fields in the extraction task are modified, a new schema is generated and persisted. Figure 3 shows the solution implementation for incident reporting and safety observations.

5.3 Solution evaluation for incident reporting and safety observations

The evaluation of the incident reporting workflow mainly focused on the quality of the system output. Two other evaluation streams, system use and adoption evaluation, and business value evaluation, are in progress and will be conducted with the partner company after further piloting.

For the pilot evaluation, the partner company generated a dataset of 15 incident-reporting audio samples. Each audio described one incident, near miss, or safety observation. A blank structured schema (JSON) was prepared with company representatives to define the required report fields. This pilot primarily evaluated schema-guided extraction quality; systematic evaluation of automatic schema-generation accuracy remains future work. Company representatives listened to each audio sample and filled in the corresponding ground-truth values using this schema. This resulted in one ground-truth JSON file for each audio recording. Subsequently, the incident reporting AI workflow was applied to the same audio samples. The workflow transcribed the audio, enhanced the transcript, and used the approved schema and extractor to produce predicted JSON outputs.

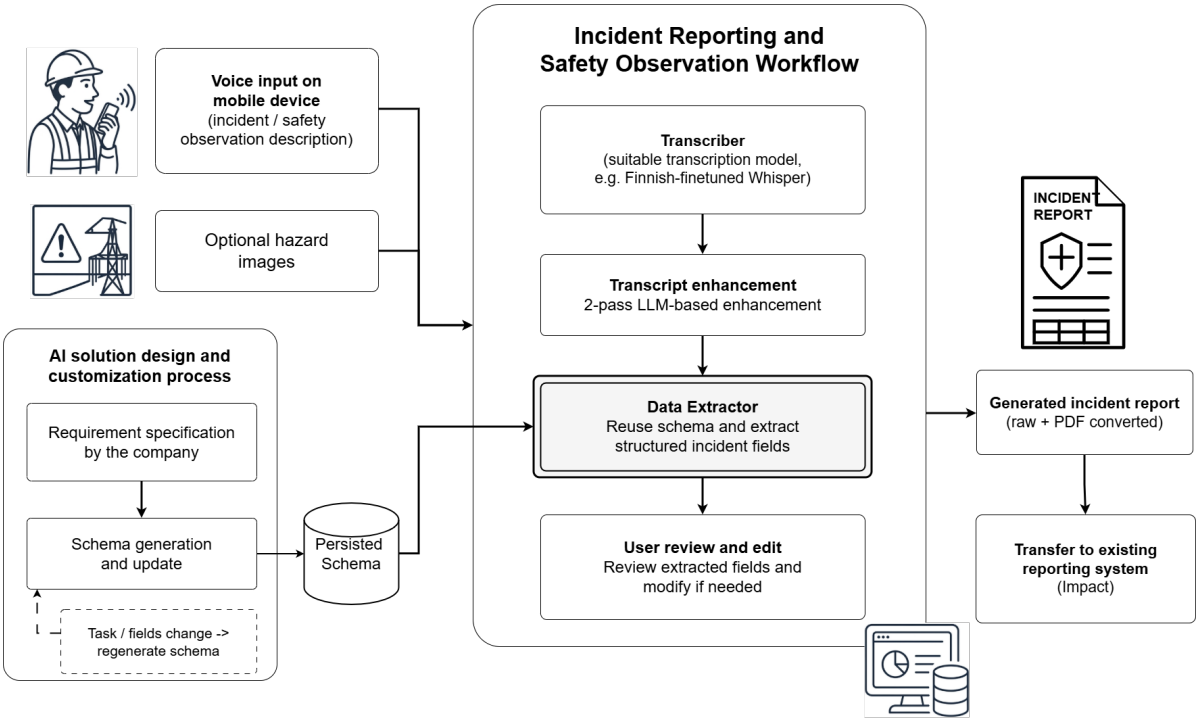

Figure 3: Solution implementation for incident reporting and Safety observations

The same ground-truth and predicted JSON files were then used for two types of system-output evaluation. In the subjective evaluation, members of the research team and company officials compared the predicted JSON outputs with the ground truth and used the feedback to refine the extraction task and prompt. In the objective evaluation, the predicted JSON outputs were compared against the ground-truth JSON files using field-level metrics.

The evaluation schema included two types of fields: i) those requiring exact agreement, such as report type, observer name, observer organization, date, time, etc., and ii) descriptive fields that may be correct even when expressed using slightly different wording, such as location detail, what happened, near-miss situation, possible consequences, actions taken, and suggestions. Exact fields were compared using normalized string or value matching. Semantic fields were compared using embedding-based cosine similarity with a threshold of 0.50. Fields scoring below 0.50 were classified as mismatches. This threshold was selected after analysis of several ground-truth and predicted pairs.

In comparison, a positive case means that a field has a non-empty ground-truth value. Therefore, a True Positive (TP) is counted only when the system correctly extracts a required non-empty value. If both the ground truth and prediction are empty, the comparison is counted as a True Negative (TN), not as a true positive, because no positive field value was present. If the ground truth is empty but the system produces a value, the comparison is counted as a False Positive (FP). If the ground truth contains a value but the system leaves the field empty, the comparison is counted as a False Negative (FN). If both contain values, but the values do not match, the comparison is counted as both a false positive and a false negative. This represents a strict field-level evaluation design where the system produced an incorrect value and, at the same time, failed to produce the correct ground-truth value.

Figure 4 shows an example of a field-level comparison of ground truth and AI-extracted JSONs. The objective evaluation was implemented using a Python script that iterated over matched ground-truth and prediction JSON files. Exact fields were normalized by lowercasing, collapsing whitespace, and stripping punctuation. Semantic fields were compared using OpenAI text-embedding-3-large embeddings and cosine similarity. The script produced field-level and aggregate results for the incident reporting extraction task.

The objective evaluation used five metrics: precision, recall, F1 score, exact match rate, and semantic match rate. Precision indicates the proportion of system-filled fields that were correct, while recall indicates the proportion of expected fields that the system successfully captured. The F1 score provides a combined view of precision and recall. The evaluation results are shown in Table 1.

The system captured most of the required information, with 90.00% precision, 87.10% recall, and an F1 score of 88.52%. This indicates that most system-filled fields were correct and that most fields that should have been captured were successfully extracted. The exact match rate of 90.67% shows strong performance on fields that

require normalized string or value matching. The semantic match rate of 87.78% shows strong performance on descriptive fields with the selected threshold of > 0.50.

The semantic match rate depends strongly on the selected similarity threshold. In this evaluation, a cosine similarity threshold of > 0.50 was used to classify semantic fields as matches. A higher threshold would be stricter and may reduce the number of accepted matches, especially when the system produces a correct but differently worded description. The threshold should therefore be selected based on the business use case. For low-risk applications, a lower threshold may be acceptable to capture more useful information. For safety-critical or compliance-related reporting, a stricter threshold may be preferable.

Table 2. Objective evaluation results for the incident-reporting workflow

Metric	Result	Interpretation
Precision	90.00%	Of all fields filled by the AI system, about 90% were correct.
Recall	87.10%	Of all fields that should have been filled, about 87.52% were captured.
F1 score	88.52%	Overall balance between precision and recall.
Exact match rate	90.67%	Strong performance on exact fields such as report type, observer name, date, and categorical values.
Semantic match rate (threshold > 0.50)	87.78%	Strong performance on descriptive fields where wording can vary.

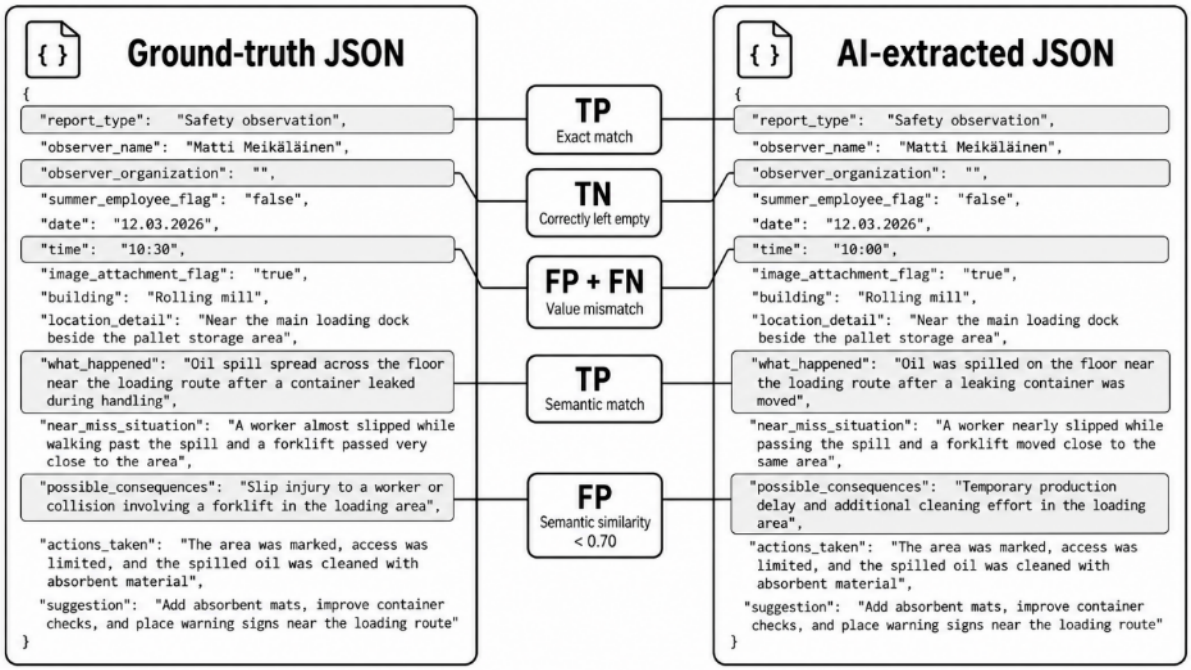

Figure 4: An example of a field-level comparison of ground truth and AI-extracted JSONs

5.4 Generalized publicly available and customisable knowledge extraction solutions

In addition to company-specific demonstrations and evaluations, we developed generalized and public demo solutions to show how the knowledge extraction component can be reused and customized across contexts. These demos are available through the GAIK demo portal: https://gaik-demo.2.rahtiapp.fi/.

The demo portal includes the standalone Knowledge Extraction Component, which allows users to define extraction requirements and test structured extraction directly. It also includes two reusable software modules that use the knowledge extraction component as a primary building block. The first module, Audio → Structured Data, transcribes audio and extracts structured data from the resulting transcript. The second module, Document → Structured Data, parses documents or images and extracts structured data from the parsed content.

Beyond these component-level and module-level demos, the portal also provides generalized business-level solutions built around knowledge extraction. The Incident Reporting demo allows users to report incidents through voice or text, after which AI extracts the required structured fields. The Construction Site Diary demo supports daily site documentation by allowing users to record activities through voice or text and convert them into structured diary entries.

These demos show that the proposed artifact is not limited to one partner-specific implementation. Instead, the same extraction logic can be exposed as a reusable component, embedded in software modules, and adapted into business-facing applications for different organizational needs.

6 Limitations

This study has some limitations. The evaluation is based on a small pilot dataset of 15 incident-reporting audio samples and one primary evaluated use case. The results, therefore, provide preliminary evidence of technical feasibility rather than generalizable performance across organizations, languages, document types, or reporting tasks. The evaluation also measures the end-to-end workflow and does not isolate errors from transcription, transcript enhancement, schema design, or extraction. In addition, the study does not include a baseline comparison or assess long-term adoption, business value, or actual reuse of extracted records as organizational memory. Future work should address these limitations through larger multi-case evaluations, baseline and ablation studies, and user-centered assessment of adoption, trust, and knowledge reuse.

7 Conclusion

This paper presented a modular LLM-based knowledge extraction component developed as part of the GAIK toolkit. The component addresses organizations' recurring problem of extracting structured knowledge from fragmented data. The proposed artifact allows users to describe extraction requirements in plain language, generate a reusable schema, and apply schema-guided extraction to documents or speech transcripts.

The study followed a design science research approach. The artifact was designed in response to practical needs identified through AI consultancy and industry collaboration, implemented as reusable software components, and demonstrated through company-specific and generalized public demos. The two reusable modules, audio-to-structured-data and document-to-structured-data, show how the same knowledge extraction component can be combined with transcription, transcript enhancement, document parsing, and multimodal parsing workflows.

The incident reporting evaluation provides initial evidence of technical feasibility and practical usefulness. From a knowledge management perspective, the artifact supports knowledge capture and codification by transforming fragmented organizational inputs into schema-conformant structured records. It can help make spoken observations, field notes, and documents easier to store, search, and reuse. However, this study does not evaluate long-term reuse or decision impact. Therefore, the approach should be understood as a human-AI knowledge-capture process rather than a fully autonomous replacement for human judgment in which AI performs the first structuring step, while humans review, correct, and approve outputs before integration into business systems.

Future work will expand testing across more companies, languages, document types, and extraction tasks; improve prompt and schema handling for sparse fields; explore alternative semantic thresholds; and evaluate system adoption, business value, and configuration effort for SMEs, low-AI-maturity organizations, and non-technical users. Further development will also focus on stronger validation, confidence scoring, complex multimodal documents, and closer integration with enterprise systems.

Behaviour as Knowledge: Neuro-Immersive AI Assessment in HRM

Laura Iacovone
University of Milan, Milan, Italy

Abstract

In contemporary organizations, Human Resource Management (HRM) increasingly relies on assessment processes to evaluate leadership potential, behavioural competences, and alignment with organizational values. However, traditional assessment tools—such as self-report questionnaires, structured interviews, and role-playing exercises—primarily capture deliberate and consciously controlled responses, leaving a significant portion of behaviour underexplored, particularly under conditions of ambiguity and time pressure.

This paper proposes a shift in perspective by conceptualizing assessment as a knowledge creation process, in which behaviour is interpreted as a form of tacit knowledge. Drawing on Knowledge Management (KM) theory, the study argues that many critical competences—such as ethical judgment, decision-making under pressure, and interpersonal sensitivity—emerge through action rather than articulation and therefore cannot be fully captured through conventional HR instruments. To address this limitation, the paper explores the role of neuro-immersive technologies, integrating Virtual Reality (VR) and Artificial Intelligence (AI), as assessment infrastructures capable of eliciting and capturing behavioural knowledge in context. Through immersive simulations enriched with behavioural triggers and AI-driven analytics, these systems allow organizations to observe spontaneous decision-making patterns and transform them into actionable knowledge.

Empirically, the study adopts a qualitative multiple-case approach, analysing two neuro-immersive assessment implementations conducted in large Italian organizations, involving approximately 200 participants. The first case focuses on value-based assessment, highlighting discrepancies between declared organizational values and actual behaviours. The second case examines behavioural potential assessment, revealing latent dimensions of individual performance and development needs.

The findings support a conceptual model in which simulation design variables activate cognitive-emotional processes, leading to observable behavioural outputs that can be externalized as organizational knowledge. The study contributes to KM and HRM literature by reframing assessment as a mechanism for knowledge generation and organizational alignment.

From a practical perspective, the paper provides insights into how immersive technologies can enhance HR practices while emphasizing the importance of ethical governance, transparency, and reflective feedback processes. Ultimately, the study argues that sustainable organizations depend not only on technological advancement but on their ability to transform behavioural evidence into shared knowledge.

Keywords: Organizational behaviour, Knowledge management, Tacit knowledge, Neuro-immersive technologies, HRM assessment

Paper type: Academic Research Paper

1 Introduction

In recent years, immersive technologies such as Virtual Reality (VR) and Artificial Intelligence (AI) have gained increasing relevance within organizational contexts. To date, most existing applications have focused on training and behavioural change, particularly in areas such as leadership development and DE&I, where they are mainly used to enhance experiential learning.

However, despite their growing adoption, their potential as *assessment infrastructures* remains underexplored. Recent studies on AI-driven HRM and algorithmic management further highlight the growing importance of behavioural data in organizational decision-making, while raising critical concerns related to transparency, bias, and governance (Bandara et al., 2025; Milanez et al., 2025).

This paper introduces a shift in perspective: rather than considering immersive technologies as tools for training and sensitization, it conceptualizes them as *mechanisms for capturing behavioural knowledge in action.*

This shift is particularly relevant in the context of Human Resource Management (HRM), where traditional assessment methods—such as structured interviews, self-report questionnaires, psychometric tests, and role-playing exercises—are inherently limited in their ability to capture spontaneous, context-dependent, and unconscious behavioural dynamics. These methods primarily rely on declared intentions and controlled responses, while many critical competences—such as ethical judgment, people orientation, and decision-making under pressure—emerge in real-time under conditions of pressure, ambiguity, and social interaction, often outside conscious awareness.

From a Knowledge Management (KM) perspective, this limitation reflects a deeper epistemological issue: organizations lack effective mechanisms to capture, externalize, and reuse *tacit behavioural knowledge* (Nonaka

& Takeuchi, 1995). Behaviour, particularly under conditions of stress, ambiguity, and social pressure, can be interpreted as situated knowledge that remains largely invisible within existing assessment systems.

This paper addresses this gap by proposing a *knowledge-based reconceptualization of assessment*, in which immersive neuro-technological environments enable the activation, observation, and interpretation of behavioural patterns. Through AI-driven analytics and structured feedback processes, these behavioural traces can be transformed into actionable organizational knowledge assets.

Empirically, the study is based on two neuro-immersive assessment implementations conducted in large Italian organizations, involving approximately 200 participants. These cases provide a unique opportunity to explore how immersive simulations can reveal discrepancies between declared values and enacted behaviours, as well as to identify latent dimensions of individual potential. The study proposes a conceptual model in which immersive simulation design elements activate behavioural responses through cognitive and emotional mediators, enabling the externalization of tacit knowledge in the form of observable decision patterns.

The paper contributes to the IFKAD 2026 theme by demonstrating how intelligent technologies can support the transformation of behavioural evidence into knowledge, thus enabling more sustainable and reflective organizational systems.

2 Theoretical Background

2.1 Behaviour as tacit knowledge

Knowledge Management literature has long distinguished between *explicit* and *tacit* knowledge, emphasising that a significant portion of what individuals know cannot be easily articulated or codified (Nonaka & Takeuchi, 1995). Tacit knowledge is deeply embedded in action, experience, and context, and is often revealed through practice rather than verbalisation.

Within organizational settings, many critical competences—such as leadership, decision-making, ethical judgement, and interpersonal sensitivity—are inherently tacit. These competences are not only difficult to formalise, but also highly dependent on situational dynamics, making them particularly challenging to assess through traditional HRM tools.

The process of knowledge creation, as described in the SECI model (Nonaka & Takeuchi, 1995), and further developed in studies on knowledge processes and organizational use of knowledge (Davenport & Prusak, 1998), highlights the importance of externalising tacit knowledge through interaction, reflection, and shared experience. However, while considerable attention has been devoted to how knowledge is created and shared, less emphasis has been placed on how tacit knowledge can be *captured and interpreted in real-time behavioural contexts.*

From this perspective, *behaviour* can be understood as a manifestation of *tacit knowledge in action*. Rather than being treated solely as an outcome to be evaluated, behaviour represents an observable expression of how individuals interpret situations, prioritise actions, and respond to environmental stimuli.

Organizational learning theory further supports this view by emphasising the role of action and reflection in the development of knowledge (Argyris & Schön, 1978; Davenport & Prusak, 1998). In particular, the distinction between espoused theories and theories-in-use suggests that what individuals claim to believe may differ from how they actually behave in practice. This gap is especially relevant in assessment contexts, where declared values and observed behaviours may not align.

Despite these theoretical insights, traditional assessment methods remain largely focused on explicit knowledge and self-reported information, limiting their ability to capture the tacit dimension of competences. As a result, organizations may base critical decisions on incomplete or biased representations of individual capabilities.

This limitation of traditional HRM assessment methods, which rely on verbalization and abstraction, calls for new approaches capable of accessing tacit knowledge through observation of behaviour in context. In this sense, immersive environments offer a promising avenue, as they enable the creation of realistic situations in which tacit knowledge can be enacted, observed, and subsequently interpreted.

This perspective provides the foundation for interpreting behaviour not merely as an outcome of action, but as a source of knowledge that can be systematically observed and analysed.

2.2 Decision-making and automatic behaviour

Understanding human behaviour in organizational contexts requires moving beyond purely rational models of decision-making. A substantial body of research in cognitive psychology and neuroscience has demonstrated

that individuals often rely on automatic, intuitive processes, particularly under conditions of uncertainty, time pressure, and emotional activation (Kahneman, 2011; Damasio, 2018).

According to dual-process theories, decision-making operates through two interacting systems: a fast, automatic, and intuitive system (System 1), and a slower, deliberate, and analytical system (System 2) (Kahneman, 2011). While traditional assessment methods tend to capture responses associated with deliberate reasoning, many critical behaviours in organizational settings are driven by automatic processes that emerge in real-time interactions.

These automatic responses are particularly relevant in contexts characterized by ambiguity, competing priorities, and social complexity, where individuals are required to make rapid decisions without the possibility of extended reflection. In such situations, behaviour reflects not only cognitive evaluation but also emotional states, prior experiences, and implicit assumptions, making it a rich source of tacit knowledge.

From an organizational perspective, this has important implications for assessment practices. If decision-making is significantly influenced by automatic processes, then methods based solely on self-report or structured evaluation may provide only a partial representation of individual competences. This limitation is especially critical when assessing soft skills such as leadership, responsibility, and interpersonal sensitivity, which are often enacted rather than explicitly articulated.

Immersive environments offer a unique opportunity to address this gap. By recreating realistic scenarios and introducing elements of unpredictability and pressure, they activate cognitive-emotional processes that are more likely to trigger spontaneous behavioural responses. In this sense, neuro-immersive simulations enable the observation of decision-making as it unfolds, providing access to behavioural dynamics that remain largely inaccessible in traditional assessment settings.

2.3 Immersive technologies and behavioural observation

While immersive technologies have been widely explored in training contexts, their application as assessment infrastructures remains limited, particularly in relation to behavioural data interpretation and knowledge generation.

Recent literature confirms that immersive technologies, particularly Virtual Reality, are increasingly used for soft-skill development and experiential learning, although primarily within training-oriented frameworks rather than assessment contexts (Dubiel et al., 2025).

At the same time, emerging research highlights the potential of immersive environments as platforms for behavioural measurement, enabling the capture of stress responses and decision-making dynamics in real time (Rah & Chen, 2025).

This evolution is particularly relevant in light of broader developments in AI-driven HRM and algorithmic management, which emphasise the growing role of behavioural data while also raising concerns related to bias, transparency, and ethical governance (Bandara et al., 2025; Milanez et al., 2025; Naoum et al., 2026).

Immersive environments enable the simulation of realistic contexts in which individuals interact naturally. When combined with AI-based analytics, these environments allow for the systematic observation of behavioural patterns, opening new possibilities for assessment. This reinforces the need to investigate how immersive environments may function not only as learning tools, but also as infrastructures for *behavioural observation* and *knowledge generation*.

3 Conceptual Framework

Building on the integration between Knowledge Management, organizational behaviour, and immersive technologies, this study proposes a conceptual model that explains how neuro-immersive environments enable the externalization of tacit behavioural knowledge and the transformation of behavioural evidence into organisational knowledge. Based on the proposed framework, the study advances the following propositions:

- **P1**: Simulation design variables positively influence cognitive-emotional activation.
- **P2**: Cognitive-emotional activation facilitates the emergence of spontaneous behavioural responses.
- **P3**: Behavioural responses can be captured and interpreted as forms of tacit knowledge.

The model is structured as a dynamic flow system consisting of four main dimensions, as illustrated in Figure 1:

1. **Simulation Design Variables (Input Layer)**
    - Scenario realism
    - Behavioural triggers (e.g., unexpected events, ambiguity, social tension)
    - AI-driven interaction (adaptive responses, conversational agents)

2. **Cognitive-Emotional Mediators (Process Layer)**
    - Emotional activation
    - Cognitive dissonance
    - Decision-making under pressure

These mediators play a crucial role in reducing conscious control and activating automatic behavioural responses (Kahneman, 2011; Damasio, 2018).

3. **Behavioural Knowledge Outputs (Output Layer)**
    - Observable behavioural patterns
    - Decision-making pathways
    - Tacit knowledge externalization
4. **Organizational Knowledge (Outcome Layer)**
    - Feedback
    - HR insights
    - KM integration

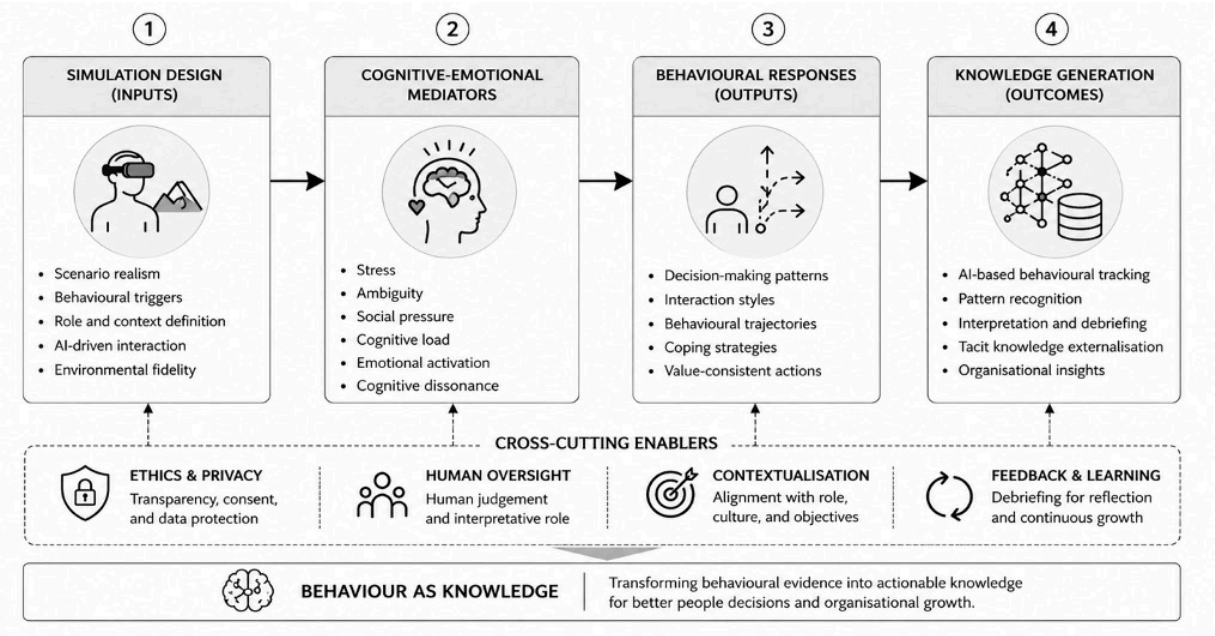

Figure 1. Neuro-Immersive Behavioural Knowledge Generation Model

The proposed model conceptualises neuro-immersive assessment as a process through which behavioural knowledge is generated and formalised. It is structured as a multi-layered system linking simulation design, cognitive-emotional activation, behavioural responses, and knowledge outcomes. Through AI-based tracking systems, these outputs are captured, structured, and interpreted, enabling their transformation into organizational knowledge.

At the *input level*, simulation design elements—such as scenario realism, behavioural triggers, and AI-driven interaction—create a controlled yet ecologically valid environment.

These elements activate a set of *cognitive-emotional mediators*, including stress, ambiguity, and social pressure, which are known to influence decision-making processes (Kahneman, 2011; Damasio, 2018).

These mediators reduce the extent of deliberate control and facilitate the emergence of spontaneous *behavioural responses*. Such responses manifest as observable decision-making patterns, interaction styles, and behavioural trajectories.

Finally, through AI-based tracking and structured feedback mechanisms, these behavioural outputs are captured, interpreted, and transformed into *organisational knowledge*, supporting learning and alignment. In this sense, the model positions assessment not as a static evaluation process, but as a dynamic system of knowledge generation and interpretation.

4 Methodology

This study adopts a qualitative multiple-case research design aimed at analytical generalisation (Eisenhardt, 1989; Yin, 2018), combined with an abductive research approach that iteratively connects empirical observations with theoretical constructs.

The empirical setting includes two neuro-immersive assessment implementations conducted in large Italian organisations operating in the consulting and financial services sectors, involving a total of approximately 200 participants (130 partners and senior managers, and 70 high-potential talents).

The selection of these cases follows a theoretical replication logic, as they represent distinct organisational contexts and assessment objectives—namely value alignment and behavioural potential evaluation—thereby enabling cross-case comparison and enhancing the robustness of analytical generalisation.

Data collection relied on a multi-source triangulation strategy, including direct observation of immersive sessions, behavioural data generated by AI-based decision-tracking systems, scenario design documentation and underlying algorithmic logic, individual feedback reports and aggregated analytics, debriefing sessions, and facilitated group discussions.

Data analysis was conducted through a three-stage qualitative coding process (open, axial, and selective coding), supported by behavioural analytics: a) *Open coding*, identifying recurring behavioural patterns and decision-making dynamics across scenarios; b) *Axial coding,* linking observed behaviours to contextual triggers (e.g., stress, ambiguity, social pressure); c) *Selective coding*, mapping behavioural patterns to higher-level constructs related to tacit knowledge and value alignment.

In parallel, the analysis also integrates *behavioural analytics outputs*, including decision sequences, interaction patterns, and response variability, to support interpretation and reduce reliance on self-reported data.

This approach enabled the identification of recurring behavioural patterns and their interpretation as forms of tacit knowledge, in relation to contextual triggers and higher-level constructs. To enhance robustness, cross-case analysis was performed to identify convergent and divergent behavioural dynamics across the two contexts.

Although participants were aware of being observed, the immersive and time-constrained nature of the simulations reduced the degree of deliberate control, allowing more spontaneous behavioural responses to emerge. Scenario standardisation ensured comparability across participants, while embedded unexpected events introduced sufficient variability to capture individual differences.

This methodological approach enables the systematic transformation of behavioural evidence into structured organisational knowledge, supporting the study's conceptualisation of assessment as a knowledge creation process.

5 Results

5.1 Case 1: Value-based assessment and behavioural alignment

The first case of neuro-immersive simulations focuses on the assessment of alignment between declared organizational values and actual managerial behaviour. Participants—all senior managers—were immersed in simulations reproducing a full working day, including both professional and relational situations. These scenarios encompassed interactions with colleagues, decision-making under time constraints, conflict management, and situations requiring prioritization between organizational goals and interpersonal considerations.

The design of the simulations intentionally introduced elements of ambiguity, competing priorities, and social tension, allowing participants to navigate situations in which no single "correct" answer was available. This structure made it possible to observe not only explicit decision outcomes, but also *how attention was distributed between people*, *tasks*, *and objectives*, both at a conscious and implicit level.

From a behavioural perspective, the presence of unexpected events and social tension acted as *triggers activating automatic responses*, often bypassing conscious control. These responses were captured through AI-based behavioural tracking, revealing recurring decision-making patterns across participants.

The analysis revealed a consistent gap between *declared values* (e.g., inclusivity, responsibility, collaboration) and *observed behavioural patterns* under pressure. While participants were generally able to articulate organizational values, their behaviour in immersive contexts often reflected alternative priorities, such as efficiency over listening, risk aversion over accountability, and goal achievement over relational sensitivity.

The results showed a high degree of variability across participants, leading to the identification of *distinct behavioural clusters*, characterised by different orientations toward people, performance, and responsibility. These clusters did not emerge from predefined categories, but from recurring behavioural patterns observed across scenarios.

Importantly, the structured debriefing process enabled participants to reflect on these discrepancies and patterns, transforming individual behavioural evidence into *shared insights* and *collective knowledge about organizational culture.*

5.2 Case 2: Behavioural potential assessment

The second case examines the assessment of behavioural potential within a financial institution, focusing on a group of high-potential talents identified for future leadership roles. Participants engaged in immersive simulations structured as a dynamic working-day narrative, including multiple decision points, time constraints, unexpected events, and evolving interpersonal interactions.

The simulations were designed to reflect both operational and relational dimensions of work, requiring participants to balance task execution, decision-making under pressure, and attention to colleagues and stakeholders. This holistic structure enabled the observation of behaviour across a range of contexts, rather than in isolated or artificial tasks.

The findings show that neuro-immersive environments are particularly effective in revealing *latent dimensions of behavioural potential*, which are not easily captured through traditional assessment methods.

The analysis highlighted the emergence of *distinct behavioural trajectories*, reflecting different ways of interpreting complexity and responding to uncertainty. AI-based analytics enabled the identification of recurring patterns, as well as the detection of inconsistencies between self-perception and observed behaviour.

Participants showed significant variation in their ability to manage pressure, prioritise effectively and responsibly, and maintain relational awareness (listening and interpersonal sensitivity) while pursuing performance objectives.

Notably, the analysis revealed that behavioural potential could not be reduced to a single dimension, but rather emerged as a combination of patterns, including adaptability to unexpected situations, consistency, and responsiveness to context. In several cases, discrepancies were observed between participants' self-perception and their actual behaviour in the simulations, providing valuable insights for development.

Similarly to the first case, the identification of recurring behavioural patterns enabled the classification of participants into *behavioural clusters*, reflecting different orientations toward leadership, decision-making under pressure, and interpersonal engagement.

The combination of immersive experience, behavioural feedback, and identified clusters allowed for a more nuanced understanding of individual potential, supporting HR processes such as talent development and succession planning.

5.3 Cross-case insights: from behavioural data to organizational knowledge

An important contribution of this study concerns the transformation of behavioural data into organizational knowledge. The findings suggest that the value of neuro-immersive assessment does not lie solely in the collection of behavioural data, but in the processes through which these data are interpreted, structured, and restituted within the organization.

Across both cases, immersive simulations generated rich behavioural evidence in the form of decision patterns, interaction styles, and response trajectories. Specifically, simulation design variables (such as realism, triggers, and AI interaction) consistently activated behavioural responses, while cognitive-emotional mediators—including stress, ambiguity, and social pressure—reduced conscious control and facilitated spontaneous actions. These dynamics resulted in behavioural outputs observable as recurring decision-making patterns.

Due to confidentiality constraints, company names and raw data are not disclosed; however, the consistency of behavioural patterns across participants supports the robustness of the findings.

These behavioural traces, when analysed systematically, revealed consistent differences among participants, enabling the identification of *distinct behavioural clusters*. Such clusters reflect different orientations toward key organizational dimensions, including the balance between task achievement and attention to people, as well as the ability to manage complexity and uncertainty.

The identification of these clusters represents a crucial step in transforming raw behavioural data into meaningful knowledge. Rather than focusing on isolated actions, the analysis highlights recurring patterns that can be interpreted as expressions of tacit knowledge in action. In this sense, behavioural data become *knowledge artefacts*, capturing how individuals actually interpret situations, prioritise objectives, and respond to contextual demands, enabling organizations to identify behavioural tendencies, detect misalignments between values and actions, and generate actionable insights for HRM.

This transformation process is further reinforced through structured feedback and debriefing activities, in which individual behavioural patterns are discussed, compared, and collectively interpreted. Through this process, personal experiences are translated into shared reflections, enabling the emergence of insights related to organizational culture, leadership styles, and development needs.

Importantly, this approach differentiates neuro-immersive assessment from forms of algorithmic management focused on monitoring and control. Rather than automating decisions, the system supports *human-mediated interpretation*, ensuring that behavioural data are used as a basis for reflection and learning. This is consistent with recent research highlighting the importance of transparency, ethical governance, and the responsible use of AI in HRM contexts (Bandara et al., 2025; Milanez et al., 2025).

Overall, the findings demonstrate that immersive assessment environments can act as *knowledge-generating systems*, enabling organizations to capture, interpret, and reuse behavioural evidence in a structured and meaningful way.

6 Discussion

They extend the literature by extending the conceptualisation of assessment from a *measurement-oriented activity* to a *knowledge-generative process* grounded in *behavioural evidence.*

6.1 Assessment as knowledge creation

From a Knowledge Management perspective, this shift is particularly relevant. The findings contribute to a reconceptualization of assessment within HRM. The results support the view that behaviour, especially when enacted under conditions of ambiguity and pressure, represents a form of tacit knowledge that cannot be fully captured through traditional assessment methods. By enabling the observation of behaviour in context, neuro-immersive environments provide access to dimensions of knowledge that would otherwise remain implicit and inaccessible. Rather than being limited to performance measurement, assessment can be understood as a *knowledge creation process*, in which *behavioural evidence is generated*, *interpreted*, *and reintegrated into organizational systems.*

This perspective aligns with KM theory, particularly the notion that tacit knowledge can be externalized through experience and reflection (Nonaka & Takeuchi, 1995). Neuro-immersive environments extend this process by providing structured contexts in which behaviour can be observed under realistic conditions, thus bridging the gap between knowing and doing.

This interpretation extends traditional Knowledge Management perspectives by integrating behavioural evidence into knowledge creation dynamics, reinforcing the role of action-based learning processes (Davenport & Prusak, 1998).

6.2 The Role of cognitive-emotional mediators

A central insight emerging from the analysis concerns the role of *cognitive-emotional mediators*. The simulations show that factors such as time pressure, social interaction, and uncertainty significantly influence how individuals act, often reducing the extent of deliberate control and activating automatic decision-making processes (Kahneman, 2011; Damasio, 2018). These mediators are critical, as they reduce the reliability of self-reported data, reveal behavioural patterns that remain hidden in controlled settings, and enable a more authentic assessment of soft skills.

This highlights the importance of designing assessment environments that are not only realistic, but also *intentionally disruptive*, in order to activate meaningful behavioural responses. This reinforces the idea that assessment environments should not aim to eliminate complexity, but rather to incorporate it as a necessary condition for revealing meaningful behavioural patterns.

The empirical evidence also highlights the importance of moving beyond isolated observations toward the identification of recurring behavioural configurations. The emergence of distinct behavioural clusters across participants suggests that individuals tend to adopt relatively stable orientations in the way they balance competing demands, such as task achievement and attention to people. These orientations, while not always consciously articulated, represent valuable insights into how individuals interpret and navigate organizational contexts.

6.3 From behavioural data to organizational knowledge

Another important contribution concerns the transformation of *behavioural data* into *organizational knowledge*. The study shows that the value of immersive assessment lies not only in data collection, but in the processes of interpretation and restitution that follow.

Through structured debriefing and collective reflection, individual behavioural patterns are translated into shared reflections, cultural insights and development pathways. This process transforms behavioural outputs into *knowledge assets*, contributing to organizational learning and alignment. In this sense, assessment becomes a mechanism through which organizations can make sense of their own behavioural dynamics.

At the same time, the increasing use of AI-driven systems in HRM raises important ethical considerations. As highlighted by recent research on algorithmic management, the use of behavioural data may lead to risks related to algorithmic bias, opacity, and unintended consequences of data-driven decision-making processes or forms of control (Floridi, 2021; Bandara et al., 2025; Milanez et al., 2025).

Importantly, the neuro-immersive approach proposed in this study emphasizes *reflection*, *transparency*, *and developmental use of data*. Behavioural evidence is *not used to automate decisions*, *but to support dialogue and learning*.

6.4 Implications for HRM and organizational development

From a managerial perspective, the findings suggest that neuro-immersive assessment can complement traditional HR tools by enabling organizations to enhance talent identification, support leadership development, identify gaps between organizational values and actual practices, and foster a more coherent organizational culture.

At the same time, the adoption of such systems requires careful attention to governance issues, including transparency of evaluation criteria, ethical use of behavioural data, and avoidance of bias in AI-based analytics.

Overall, the findings suggest that neuro-immersive assessment can play a key role in bridging the gap between *behaviour* and *knowledge*. By enabling the observation of how individuals act in complex situations, these environments support a more nuanced and dynamic understanding of competences, contributing to more informed and sustainable organizational practices.

7 Conclusion

This study has explored the potential of neuro-immersive technologies as assessment infrastructures capable of capturing and transforming behavioural knowledge within organizational contexts. By integrating insights from Knowledge Management, organizational behaviour, and emerging technologies, the paper has proposed a conceptual shift *from assessment as measurement* to *assessment as knowledge creation*.

The findings demonstrate that immersive environments enable the observation of behaviour under realistic conditions, revealing patterns that are often inaccessible through traditional assessment methods. In doing so, they provide a means of *externalising tacit knowledge*, contributing to a more comprehensive understanding of individual competences and organizational dynamics.

Importantly, the study highlights that the value of such approaches does not lie solely in technological innovation, but in the ability to interpret behavioural evidence and integrate it into organizational learning processes. In this sense, neuro-immersive assessment should not be understood as a replacement for existing tools, but as a complementary layer that enriches the understanding of behaviour in context.

From a practical perspective, the adoption of immersive assessment systems offers new opportunities for HRM, particularly in areas such as talent development, leadership evaluation, and cultural alignment. However, these opportunities must be balanced with careful attention to ethical considerations, including transparency, fairness, and the responsible use of behavioural data.

The study is not without limitations. The qualitative nature of the research and the limited number of cases constrain the generalizability of the findings. Furthermore, the interpretation of behavioural data remains dependent on contextual and organizational factors, requiring careful and informed analysis.

Future research could extend this work by exploring the application of the proposed model across different sectors (e.g., pharmacy counselling simulations), integrating quantitative behavioural metrics, and examining the long-term impact of immersive assessment on organizational culture and performance.

Ultimately, this paper argues that the sustainability of intelligent organizations depends not only on their ability to generate data, but on their capacity to transform behavioural evidence into meaningful knowledge. In this perspective, assessment becomes not merely a tool for evaluation, but a strategic process for understanding and shaping organizational behaviour.

The results therefore suggest that neuro-immersive assessment environments enable the *externalization of tacit knowledge*, supporting its integration into organizational learning processes.

8 Ethics Declaration

This study was conducted within private organizational contexts and did not involve the collection of sensitive personal data. All data were fully anonymized, and company names have been omitted to ensure confidentiality.

Given the nature of the study and the absence of sensitive data, vulnerable populations or experimental interventions, formal ethical approval was not required. However, the research was conducted in accordance with general ethical principles of academic research, including respect for participants, data confidentiality, and responsible data use.

9 AI Declaration

Generative AI (ChatGPT, OpenAI, April 2026 version) was used to support preliminary drafting in translation refinement, and the retrieval of non-academic sources (e.g., corporate case studies and reports). All content was subsequently verified, reviewed, and critically validated by the author.

Individual Intellectual Capital for Sustainability

Jonna Käpylä
Tampere University, Tampere, Finland

Abstract

Given the urgent need for radical sustainability transformation, all fields of research, including intellectual capital theory, must critically examine their underlying foci, points of departure, and assumptions. Previous research on sustainability and intellectual capital has primarily conceptualised sustainable or green intellectual capital at the organisational level, while largely neglecting the individual level and failing to specify the content of individual intellectual capital for sustainability. In response, this study addresses the research question of how individual intellectual capital for sustainability can be defined and conceptualised. The study develops a conceptualisation of individual intellectual capital for sustainability through an integrative review method, in which existing literature is synthesised to generate new theoretical knowledge. Drawing on individual intellectual capital theory as an organising framework, the review integrates insights from research on education for sustainable development, sustainability transformation, sustainability science, and sustainability leadership. The study makes two main contributions. First, it defines individual intellectual capital for sustainability as an asset encompassing the full range of individual cognitive, socio-emotional, and behavioural knowledge and knowing capabilities that contribute to the development of sustainability-oriented thinking, identity, and agency, and thereby promote sustainability transformation. Second, it delineates the core components of individual intellectual capital for sustainability. Individual intellectual capital for sustainability is conceptualised as a multidimensional asset comprising human, structural, and relational capital, each expressed through cognitive (thinking), socio-emotional (identity), and behavioural (agency) domains. Together, these dimensions capture how sustainability-related knowledge, values, relationships, and action capabilities are embodied in individuals in ways that enable sustainability transformation. For example, systems thinking, an ecologically grounded worldview, and a personal connection to sustainability are identified as key intangible assets for advancing sustainability. The resulting integrated framework provides a foundation for the operationalisation and measurement of individual intellectual capital for sustainability and offers guidance for human resource management aimed at advancing sustainability transformation.

Keywords: Individual intellectual capital, Sustainable development, Individual intellectual capital for sustainability, Sustainability competencies, Integrative review.

Paper type: Academic Research Paper

1 Introduction

Humanity is currently operating outside the safe planetary boundaries; six of the nine planetary boundaries, including biosphere integrity, climate change and novel entities, have already been crossed (Richardson et al., 2023; Stockholm Resilience Centre, 2026). This points to the need for radical sustainability transformation in societies, where existing worldviews and paradigms must be questioned and critically evaluated (Abson et al., 2017). Each field of research, including the theory of intellectual capital, must critically examine its own starting points and assumptions. Thus, the only yardstick of intellectual capital management cannot be profit and competitive advantage but also ecological and social value. Čabrilo, Užienė and Kianto (2025) call for better recognition of sustainability in intellectual capital research and aligning it with long-term value creation and societal impact rather than short-term performance. Intellectual capital, as representing the knowledge and knowing capability (Nahapiet and Ghoshal, 1998), has huge transformational potential in contributing to sustainable development. However, this requires that our knowledge and knowing capability serves sustainability and not the unsustainable development trajectories of previous decades, which have led to overconsumption and environmental degradation.

The traditional framework of intellectual capital understands sustainability as one of several intangible assets (Benevene et al., 2021) and not as an overarching theme that is integrated into the concept of intellectual capital. The discussion of the interrelationship between intellectual capital and sustainability has gained ground in recent years (Alvino et al., 2021) and the previous literature on sustainability and intellectual capital has defined and explicated sustainable or green intellectual capital at the organizational level (Chen, 2008) but not at an individual level and furthermore, not specifying the content of individual intellectual capital for sustainability. Therefore, this study addresses the research question of *how to define and conceptualise individual intellectual capital for sustainability.*

The study defines and conceptualises individual intellectual capital for sustainability by applying the method of integrative review where existing literature is used to create new knowledge (Torraco, 2005; 2016). The theory of intellectual capital (Martín-de-Castro et al., 2011) is used as a guiding theory to conceptually structure the topic and organise the synthesis. The critical analysis and synthesis of the key intangible assets for sustainability are conducted by enriching intellectual capital theory with new insights, concepts, and theoretical perspectives drawn from the fields of education for sustainable development, including transformative learning for sustainability (e.g. Rodríguez Aboytes and Barth, 2020) and sustainability competencies (e.g. Redman and Wiek, 2021); sustainability transformation and sustainability science (e.g. Amel et al., 2017); and sustainability leadership (e.g. Sajjad, Eweje and Raziq, 2024). Accordingly, this research aims to further develop the concept of individual intellectual capital by integrating perspectives from related disciplines in which the skills and competencies required for sustainability transformation have been extensively examined. For emerging research topics such as this, the integration of literature across multiple fields can offer novel and valuable perspectives (Torraco, 2016). Although individual-level intellectual capital has gained increasing scholarly attention in recent years (Wang et al., 2020; Khan et al., 2024; Kmieciak, 2024; Alppivuori and Kianto, 2025), research in this area remains limited.

2 Intellectual Capital Theory

2.1 Intellectual capital and sustainable intellectual capital

The concept of intellectual has developed in an organisational context, and many of the definitions of intellectual capital refer to the organisational context (Martín-de-Castro et al., 2011). Meso- and macro levels (i.e. organisations, networks, regions, nations) have dominated the literature on intellectual capital, rather than the micro level of individuals. Intellectual capital has been defined as “the knowledge and knowing capability of a social collectivity” and “a valuable resource and a capability for action based in knowledge and knowing” (Nahapiet and Ghoshal, 1998, p. 245) or “the sum of all knowledge firms utilise for competitive advantage” (Subramaniam and Youndt, 2005) thus emphasising its collective and instrumental nature. In the light of these definitions, intellectual capital can be characterised by three features: intangibility (i.e., knowledge-related assets), the ability to create value now and in the future, and its social or collective nature.

Intellectual capital has been divided into different dimensions the most established being the classification into human, structural and relational capital (Martín-de-Castro et al., 2011). Another well-known and partly similar categorisation is the classification into human, organisational and social capital (Subramaniam and Youndt, 2005; Kang and Snell, 2009). Each aspect accumulates and distributes knowledge differently: human capital through individuals, organisational capital through organisational structures, processes and systems, and social capital through relationships and networks (Subramaniam and Youndt, 2005).

Research on sustainable or green intellectual capital has only recently begun to gain traction. To date, the dominant focus of this body of research has been on examining the effects of green or sustainable intellectual capital on organisational performance (e.g. Yusliza et al., 2020). Alvino et al. (2021) link intellectual capital and sustainability through the notion of long-term value creation, while the review by Benevene et al. (2021) demonstrates that green intellectual capital contributes to enhanced organisational performance and competitive advantage. Although the existence of green intellectual capital at the individual level is acknowledged in the literature, it remains insufficiently elaborated. For example, Chen (2008, p. 277) defines green intellectual capital as “the total stocks of all kinds of intangible assets, knowledge, capabilities, and relationships, etc. about environmental protection or green innovation at the individual level and the organisational level within a company”.

2.2 Individual intellectual capital

While a small number of studies addressed individual-level intellectual capital prior to the 2020s (e.g. Arenas et al., 2013), it is only more recently that this line of research has begun to gain momentum. Despite growing scholarly interest, research on individual intellectual capital remains relatively scarce (Wang et al., 2020; Wang, Bu and Cai, 2021; Bu et al., 2023; Khan et al., 2024; Kmieciak, 2024; Hong, Chen, and Zhang, 2025; Alppivuori and Kianto, 2025). This limited development is well illustrated by search results from the Scopus database. A search for the term “intellectual capital” (in article titles, abstracts, and keywords) yielded approximately 9,200 results (as of 24 April 2026), whereas a search for “individual intellectual capital” returned only 25 results. Given the traditional definitions of intellectual capital, individual intellectual capital is somewhat of an oxymoron,

juxtaposing concepts with opposite meanings: analysing a phenomenon recognised as collective at the individual level.

Individual intellectual capital has been defined by Wang et al. (2020, p. 1107) as "the sum of knowledge and skills owned or controlled by individual employees". Furthermore, Wang, Bu and Cai (2021, p. 1206) emphasise that it "is accumulated through one's intellectual activity, and constitutes competitive advantage for the individual, as well as for his/her organisation". As with conceptualisations at the organisational level, definitions of intellectual capital at the individual level are thus closely linked to the notion of competitive advantage. In a similar vein, Alppivuori and Kianto (2025, p. 67), building on Wang et al. (2020), conceptualise individual intellectual capital as "the sum of knowledge, skills, and abilities held by an individual, which the individual uses to succeed in their work". Taken together, these definitions position individual intellectual capital primarily as an instrumental resource for achieving competitive advantage or success in the workplace.

Individual human capital, individual structural capital and individual relational capital are considered to be the three main sub-dimensions of individual intellectual capital (Wang et al., 2020; Wang, Bu and Cai, 2021). Individual human capital refers to the objective and tactical knowledge accumulated in the process of learning and working (Wang et al., 2020; Wang, Bu and Cai, 2021). It represents work experience, professional skills, academic ability, new ideas and knowledge or innovative consciousness, as operationalised in the measurement tools by Wang et al. (2020) and Wang, Bu and Cai (2021). Individual structural capital refers to the subjective knowledge that one acquires during the thinking and cognitive processes, including the individual's principles, standards, methods and knowledge of business routines (Wang et al., 2020; Wang, Bu and Cai, 2021). In the operationalisation, it represents, for example, ways of thinking, methodologies for dealing with problems, self-management, such as time management and attention to focus on important matters, decision logic and operation procedure (Wang et al., 2020; Wang, Bu and Cai, 2021). Individual relational capital represents an individual's ability to acquire knowledge from various stakeholders, collaborate, interact, communicate, learn from others and build relationships (Wang et al., 2020; Wang, Bu and Cai, 2021). These definitions provide a basis for analysing intellectual capital at the individual level in recent research on the subject (Bu et al. 2023; Khan et al., 2024; Kmieciak, 2024, Hong, Chen and Zhang, 2025). However, several conceptual ambiguities remain. In particular, it remains unclear what is meant by the distinction between objective and subjective knowledge, which is presented as the principal differentiating factor between human and structural intellectual capital. Nor is it evident how the three sub-dimensions differ at a more fundamental level in terms of their underlying knowledge dimensions.

Alppivuori and Kianto (2025) further develop the concept of individual intellectual capital by providing a more detailed structural framework and by specifying its components and sub-elements. They introduce two additional dimensions, emotional capital and renewal capital, and present a five-part model of individual intellectual capital comprising human, relational, structural, renewal, and emotional capital. They do not provide precise definitions of the individual dimensions of; instead, they describe them through their constituent components. For example, emotional capital consists of emotions, recognising emotions, managing emotions, and utilising emotions in action. Furthermore, the five dimensions of individual intellectual capital are classified along two analytical axes: rigid versus dynamic and inward versus outward orientation. In this 2 x 2 matrix, structural capital occupies an intermediate position, functioning as a platform for individual action that enables and supports the effective utilisation of the other components of individual intellectual capital.

Researchers therefore appear to be relatively consistent in their understanding of what is meant by individual intellectual capital. However, established definitions of its dimensions remain unspecific or lacking, and there is divergence among scholars regarding their interpretation. In particular, the definitions appear to leave the distinction between individual human capital and individual structural capital unclear. For example, Alppivuori and Kianto (2025) associate problem-solving skills and thinking methods with individual human capital, whereas Wang et al. (2020) classify them as part of individual structural capital.

2.3 Dimensions of individual intellectual capital: An organising framework

Because previous definitions of the individual dimensions of intellectual capital are either imprecise (Wang et al., 2020) or absent (Alppivuori and Kianto, 2025), and partly contradictory, there is a clear need for a proposal that both defines and specifies these dimensions. Such an elaboration is presented in Table 1. It draws in part on the earlier definitions of individual intellectual capital proposed by Wang et al. (2020), while further refining and specifying them. These definitions are subsequently employed as the organising framework for the review.

Table 1: Dimensions of individual intellectual capital

	Individual human capital	Individual structural capital	Individual relational capital
Definition	Knowledge and knowing capability embodied in an individual, encompassing knowledge, competencies, values, motivations, skills, and capacity for action.	Knowledge and knowing capability that are embedded in relatively stable knowledge structures, such as cognitive frames, mental models, habitual routines, methods, and professional practices, as well as more encompassing paradigms and worldviews.	Knowledge and knowing capability that arise from and are embedded in an individual's relationships, networks, and collaborative interactions.
Primary locus	Embodied in the individual	Embedded in relative stable knowledge structures that manifest as internalised patterns of thought and behaviour	Embedded in social relationships and co-created through interaction
Degree of stability	Dynamic and situational	Relatively stable and enduring over time	Dependent on quality and continuity of relationships

Drawing on the existing literature, this study conceptualises individual intellectual capital as the knowledge and knowing capacity embodied in an individual that can be mobilised to create value. Individual structural capital is understood to be relatively stable and enduring when compared with the more dynamic and context-dependent nature of individual human capital. As with organisational structural capital, changes to an individual's structural capital are generally more difficult to enact than changes to individual human capital.

Individual relational capital, by contrast, is embedded in an individual's social relationships and is co-created through ongoing interaction. Emotional and renewal capital, as identified by Alppivuori and Kianto (2025), are conceptualised as being subsumed within this tripartite framework, specifically within the dimensions of human and structural capital.

3 Methodology

This study employs the integrative review method (Torraco, 2005; 2016), which "reviews, critiques, and synthesises representative literature on a topic in an integrated manner such that new frameworks and perspectives on the topic are generated" (Torraco, 2005, p. 356). This approach is well suited to the aims of the study, as it facilitates the synthesis of perspectives and insights from multiple research fields and thereby supports the development of a novel conceptual framework of individual intellectual capital for sustainability. Integrative reviews often require a more creative approach to literature identification, as the researcher must weave together insights drawn from diverse bodies of research (Snyder, 2019). Accordingly, the study does not rely on systematic literature searches, but rather on the identification of relevant research domains from which seminal and foundational sources were sought.

Literature searches were conducted using the Scopus database and Google Scholar in order to identify highly cited sources within the following research domains: education for sustainable development—including transformative learning for sustainability and sustainability competences—sustainability leadership, sustainability transformation, and sustainability science. Highly cited articles were selected for analysis where they addressed forms of knowledge or knowing considered necessary for advancing sustainability. The final body of literature (n = 12) includes work on transformative learning for sustainability (Sipos, Battisti and Grimm, 2008; Sterling, 2011; Rodríguez Aboytes and Barth, 2020), sustainability competencies (Olsson et al., 2020; Brundiers et al., 2021; Redman and Wiek, 2021), sustainability leadership (Metcalf and Benn, 2013; Haney, Pope and Arden, 2020; Sajjad, Eweje and Raziq, 2024), as well as sustainability transformation and sustainability science (Amel et al., 2017; Abson et al., 2017; Wamsler et al., 2021).

Integrative literature reviews require conceptual structuring in order to clarify how the central concepts of a topic cohere into a unified whole (Torraco, 2005, 2016). In this study, the theory of individual intellectual capital is employed as a guiding theoretical framework to structure the topic conceptually and to organise the synthesis. Accordingly, the critical analysis and synthesis of key intangible assets for sustainability are undertaken by enriching the theory of individual intellectual capital with new insights, concepts, and theoretical perspectives drawn from the research fields of education for sustainable development, sustainability transformation, sustainability science, and sustainability leadership.

4 Sustainability Transformation through Individual Intellectual Capital

4.1 Individual human capital for sustainability

The role of critical, complexity, and systems thinking is widely recognised in the literature as a core sustainability competence (Metcalf and Benn, 2013; Rodríguez Aboytes and Barth, 2020; Brundiers et al., 2021; Redman and Wiek, 2021; Sajjad, Eweje and Raziq, 2024). The capacity to understand socio-ecological systems, engage with complexity and uncertainty, and reason through complex problems is regarded as crucial for advancing sustainability (Metcalf and Benn, 2013). In addition, futures thinking, values thinking, and strategic thinking are identified as important competencies for articulating sustainability visions, developing transition strategies, and applying, reconciling, and negotiating sustainability-related values.

However, the literature on individual human capital for sustainability does not focus solely on cognitive dimensions. The tripartite classification of learning domains into cognitive, social-emotional or affective, and behavioural or psychomotor domains is widely applied in education for sustainable development, and particularly within transformative learning theory for sustainability (Sipos et al., 2008; Rodríguez Aboytes and Barth, 2020). For example, Sipos et al. (2008) draw on the principles of 'Head' (engagement, cognitive), 'Hands' (enactment, psychomotor), and 'Heart' (enablement, affective) to facilitate transformative behavioural change towards sustainability. Accordingly, values and socio-emotional characteristics – such as empathy, compassion, collective concern, and non-materialistic and biospheric values – are emphasised as central components of sustainability learning (Rodríguez Aboytes and Barth, 2020; Wamsler et al., 2021). Sajjad, Eweje and Raziq (2024) argue that ethical values provide the foundation for sustainability leadership practice, while also highlighting the importance of mindfulness and resilience. Such personal wellbeing dimensions are emphasised in several other studies. Brundiers et al. (2021) and Redman and Wiek (2021), for instance, refer to intrapersonal competence, defined as the ability to maintain personal wellbeing and avoid adverse health impacts when engaging in sustainability-related work. Similarly, Metcalf and Benn (2013) stress the importance of emotional intelligence and the capacity to manage emotions.

In addition, a sense of agency, empowerment to act, and other action-oriented capabilities are highlighted across the literature (Haney, Pope and Arden, 2020; Olsson et al., 2020; Rodríguez Aboytes and Barth, 2020; Brundiers et al., 2021; Redman and Wiek, 2021). Olsson et al. (2020) conceptualise action competence for sustainability as comprising knowledge of action possibilities, confidence in one's own capacity to exert influence, and a willingness to act. Likewise, Brundiers et al. (2021) and Redman and Wiek (2021) identify implementation competence as a key sustainability competence, referring to the ability to put sustainability strategies into action in effective and efficient ways – that is, to engage in conscious, purposeful action.

4.2 Individual structural capital for sustainability

Many studies argue that sustainability transformations require changes at deeper levels, including shifts in worldviews and paradigms (Amel et al., 2017; Abson et al., 2017; Wamsler et al., 2021). Abson et al. (2017) point out to the need to change mindsets and ways of thinking, which are seen as the deep leverage points out of which the whole system arises (Abson et al. 2017). Amel et al. (2017) emphasise that leaders must think differently and internalise an ecologically grounded worldview. For example, in the context of food systems, such a worldview entails several assumptions that contrast with those of the modern-industrial worldview: Earth's regenerative capacity is limited (rather than abundant), socio-ecological systems must be circular (rather than linear "take-make-waste" systems that can continue indefinitely), even small manipulations of nature has system-wide consequences (rather than technology will fix our problems), and diversity maintains system integrity (rather than efficiency increases profits).

Alongside these more cognitively oriented worldview shifts, the literature highlights identity-based changes in individuals' relationships and connections with others, nature, and future generations (Amel et al., 2017; Abson et al., 2017; Wamsler et al., 2021). Haney, Pope and Arden (2020) emphasises the importance of personal connection to sustainability by allowing individuals to see and to feel the connections between themselves and particular sustainability issues, and between potential solutions to sustainability problems and their roles. Furthermore, Wamsler et al. (2021) emphasise agency as the capacity to recognise broader and deeper patterns and one's own role in the world, combined with the intention, optimism, and courage to act upon this understanding. Similarly, Amel et al. (2017) highlight the role of agency and individuals' influence on broader systems through ecologically compatible engagement and leadership. Individual structural capital for sustainability thus emerges across cognitive, identity-based, and agency-related dimensions.

Overall, individual structural capital appears to be emphasised through the knowledge and knowing capacities required to advance sustainability, as this perspective focuses on knowledge embedded in relatively

stable cognitive structures. Many authors stress the need to influence and transform these structures as deep leverage points for change (e.g. Sterling, 2011; Abson et al., 2017; Wamsler et al., 2021). The model of the levels of knowing by Sterling (2011) suggest that deeper perceptions and conceptions (related to metaphysics, paradigms and worldviews) inform, influence and help manifest beliefs, values, norms, and assumptions, which in turn influence more immediate ideas, theories and everyday thoughts and actions. Thus, individual structural capital forms the basis of individual intellectual capital, while intellectual capital manifests itself across different levels of knowing.

4.3 Individual relational capital for sustainability

Studies recognise the importance of interpersonal competence in advancing sustainability, as sustainability transformations require collaboration and the ability to engage others effectively (Amel et al., 2017; Rodríguez Aboytes and Barth, 2020; Brundiers et al., 2021; Redman and Wiek, 2021). Interpersonal competence refers to the capacity to work successfully in interdisciplinary and interprofessional teams, as well as to involve diverse stakeholders in meaningful and effective ways in advancing sustainability transformations (Redman and Wiek, 2021).

4.4 Individual intellectual capital for sustainability: A framework

Individual intellectual capital for sustainability is defined here as an asset encompassing the full range of individual cognitive, socio-emotional, and behavioural knowledge and knowing capabilities that contribute to the development of sustainability-oriented thinking, identity, and agency, and thereby support sustainability transformation. Table 3 illustrates the constituent elements of individual intellectual capital for sustainability. Each dimension of individual intellectual capital comprises the elements of thinking, identity, and agency, which together represent three interrelated domains of knowing.

Table 3. Individual intellectual capital for sustainability.

Individual intellectual capital for sustainability encompasses the cognitive, socio-emotional, and behavioural knowledge and knowing capabilities embodied in an individual that shape thinking, identity, and agency in ways that enable and advance sustainability transformation.			
	Individual human capital for sustainability	Individual structural capital for sustainability	Individual relational capital for sustainability
Sustainability thinking *(cognitive)*	Expertise and content knowledge of sustainability Systems, complex and critical thinking competencies, and reflexivity Futures, strategic and values thinking competencies	Ecologically grounded worldview	Relationships and networks to promote sustainability
Sustainability identity *(socio-emotional)*	Empathy, compassion, collective concerns, non-materialistic and biospheric values (ethical values) Intrapersonal competence, i.e., the ability to promote sustainability in self-caring ways, resilience, mindfulness and emotional intelligence	Interconnection with other people, society, and the more-than-human world Personal connection with sustainability	Collaborative capacity and will to promote sustainability in collaboration with others
Sustainability agency *(behavioural)*	Action and implementation competencies	Ecologically compatible engagement, agency and leadership	Interpersonal and integration competencies

Compared to conventional conceptualisations of individual intellectual capital, individual intellectual capital for sustainability foregrounds three interrelated aspects: a broad understanding of knowledge, the role of structural capital, and the importance of transformative competencies that enable change and action (for example, the ability to question and critique prevailing systems and institutions). A broad understanding of knowledge implies that individual human, structural, and relational capital each encompass the elements of

thinking, identity, and agency, rather than focusing exclusively on the cognitive aspects of knowledge. This broader conception also reflects the relevance of multiple levels of knowing, as emphasised by Sterling (2011).

The role of structural capital is particularly salient in the context of individual intellectual capital for sustainability. Previous studies have highlighted the fundamental importance of human capital. For instance, Wang, Bu and Cai (2021, p. 1206) argue that individual human capital constitutes the most important dimension, as it can generate the other two forms: "if individuals make efforts to study and learn objective knowledge, their professional skills and competence would increase, resulting in better individual structural capital and individual relational capital." However, when individual intellectual capital is considered from a sustainability perspective, the emphasis shifts away from the accumulation of objective knowledge towards the foundational role of structural capital. Ways of thinking and underlying worldviews are understood to form the basis for the meaningful application of more technical and specialised expertise in advancing sustainability.

Finally, the importance of transformative competencies is accentuated in conceptualisations of individual intellectual capital for sustainability. Intellectual capital for sustainability transformation is not limited to adopting efficient organisational routines; it also entails the capacity to challenge and transform existing practices, inspire others to engage in change processes, and reflectively learn from experience. Consequently, competencies such as systems thinking, critical thinking, strategic thinking, and futures thinking, along with reflection and implementation capacities, are particularly emphasised.

5 Conclusions

This study makes two contributions to intellectual capital theory. First, it conceptualises and defines individual intellectual capital for sustainability by synthesising insights from the literatures on sustainability leadership, sustainability science, sustainability competencies, and transformative learning for sustainability with intellectual capital theory. Individual intellectual capital for sustainability is defined as an asset encompassing the full range of individual cognitive, socio-emotional, and behavioural knowledge and knowing capabilities that contribute to the development of sustainability-oriented thinking, identity, and agency, and thereby promote sustainability transformation. In contrast to traditional definitions of intellectual capital, which primarily emphasise the creation of competitive advantage, this conceptualisation explicitly foregrounds the role of intellectual capital in enabling sustainability transformation. Research on individual intellectual capital remains limited. While sustainable intellectual capital have been conceptualised at the organisational level, they have not been systematically defined at the individual level. The proposed definition of individual intellectual capital for sustainability therefore addresses an important gap by emphasising a broader understanding of knowledge that extends beyond purely cognitive elements and immediate, concrete levels of knowing.

Second, the study specifies the content of individual intellectual capital for sustainability and develops a novel conceptual framework. Previous studies have operationalised individual intellectual capital through sets of measurable indicators (Wang et al., 2020; Alppivuori and Kianto, 2025), but without an explicit sustainability focus. Similarly, earlier work has conceptualised green intellectual capital in general terms (Chen, 2008), yet has not articulated its dimensions at the individual level. The framework presented in this study addresses these gaps by detailing the constituent elements of individual intellectual capital for sustainability.

The framework supports the management of human resources for sustainability transformation by identifying key intangible assets relevant to advancing sustainability. Moreover, the integrated framework offers a foundation for future research aimed at operationalising and measuring individual intellectual capital for sustainability. At present, there are few well-developed and widely accepted assessment methods for sustainability competencies or intellectual capital at the individual level. Research suggests that current practices for assessing students' sustainability competencies remain at an early stage of development (Redman et al., 2021), and that considerable ambiguity persists regarding the measurement scales employed (Annelin and Boström, 2023). Future studies could therefore focus on developing and validating robust measures of individual intellectual capital for sustainability, with potential benefits for both education and management research and practice.

From the perspective of education for sustainability, the intellectual capital lens highlights that sustainability competencies should be understood not only as learning outcomes, but also as manageable intangible assets that can be intentionally developed and mobilised to support sustainability transformation.

6 Ethics Declaration

The research referred to in this paper did not require ethical clearance, as no human subjects, personal data, or ethically sensitive materials were involved. Consequently, no formal ethical approval was sought or granted.

7 AI Declaration

Microsoft 365 Copilot Chat (Pro version with an organisational ID) was used to check the final text for grammatical errors. The tool was thus used for language improvement.

Dynamic Capabilities and Economies of Scale: An Optimization Perspective on Intelligent Knowledge Investments

László Kállay
Corvinus University of Budapest

Abstract

This paper develops an economic perspective on dynamic capabilities by conceptualizing them as investments in intelligent knowledge under uncertainty. The dynamic capabilities literature has made substantial progress in explaining how firms sense opportunities, seize them, and reconfigure resources, yet it has paid less systematic attention to the cost structure of capability development and to the possibility that organizations may invest either too little or too much in dynamic capabilities. Building on a formal transaction cost optimization model previously developed by the author, the paper argues that dynamic capability investment follows an analogous optimization logic: organizations incur direct and quasi-fixed costs in building sensing, seizing, and reconfiguring mechanisms, while these investments reduce the expected losses associated with misadaptation, missed opportunities, strategic errors, or delayed transformation. The central claim is that there is a scale-dependent optimum of dynamic capability investment. As organizational exposure increases - through size, volume, scope, technological interdependence, or ecosystem involvement - the potential losses from weak adaptation increase, making higher capability investment economically justified. However, the optimum remains bounded because excessive investment may generate coordination burdens, cognitive overload, bureaucratic routines, and declining flexibility. The paper contributes to dynamic capability theory by integrating economies and diseconomies of scale into the analysis of intelligent knowledge investments and by deriving propositions for SMEs, large firms, and sustainability-oriented innovation ecosystems.

Keywords: dynamic capabilities; economies of scale; intelligent knowledge; transaction costs; optimization; sustainability-oriented innovation

Paper type: Academic Research Paper

1 Introduction

Dynamic capabilities have become one of the central concepts of strategic management because they explain how organizations renew themselves under conditions of uncertainty, technological change, and competitive turbulence. Since Teece, Pisano, and Shuen (1997), dynamic capabilities have been understood as higher-order capacities that enable firms to integrate, build, and reconfigure internal and external competences. Later work refined this broad definition by distinguishing sensing, seizing, and reconfiguring as core classes of capability activity (Teece, 2007), while the microfoundations literature emphasized managerial cognition, routines, decision structures, governance mechanisms, and organizational learning as the building blocks of such capabilities.

A large part of this literature is concerned with why some firms adapt better than others. It explains differences in strategic renewal, innovation performance, and resilience by reference to heterogeneous capabilities accumulated through path-dependent learning. This is a powerful perspective, but it also leaves an important question underdeveloped: how much should an organization invest in dynamic capabilities? The literature often treats dynamic capabilities as desirable strategic assets, but it rarely treats them as costly investments with an optimum level. This omission matters because dynamic capabilities are not costless. They require environmental scanning, data systems, managerial attention, strategic forums, experimentation budgets, cross-functional coordination, change management routines, and governance mechanisms. These investments may improve adaptation, but they also consume resources and may themselves become a source of complexity.

This paper addresses this gap by developing an optimization perspective on dynamic capability investment. The argument is not that dynamic capabilities should be reduced to a simple cost item. Rather, the paper claims that the development and deployment of dynamic capabilities has a recognizable economic structure. Capability investments create direct and quasi-fixed costs, while reducing expected losses from uncertainty, misadaptation, delayed response, or missed opportunities. The relevant managerial problem is therefore not whether dynamic capabilities are valuable in general, but which level and architecture of dynamic capabilities are justified under given conditions of organizational scale, scope, and exposure.

The paper builds on a formal transaction cost optimization model previously developed by the author (Kállay, Takács, & Trautmann 2020). That model demonstrates that total cost under uncertainty can be represented as the sum of direct costs and expected losses, and that an optimum exists because higher direct expenditure reduces the probability of loss but with diminishing returns. The present paper adapts this logic to dynamic capabilities. In the proposed framework, investment in sensing, seizing, and reconfiguring reduces the expected loss associated with weak adaptation. However, as investment rises, marginal returns decline and coordination costs increase. The result is a scale-dependent optimum.

The main contribution of the paper is threefold. First, it integrates economies and diseconomies of scale into dynamic capability theory. Second, it conceptualizes intelligent knowledge as an economically constrained organizational infrastructure rather than merely as a knowledge stock. Third, it develops propositions linking organizational scale to optimal dynamic capability investment and to the risk of underinvestment or overinvestment. The framework is particularly relevant for sustainability-oriented innovation, where organizations must combine experimentation, adaptation, and diffusion at scale.

2 Literature Background

2.1 Dynamic capabilities and intelligent knowledge

Dynamic capabilities research starts from the observation that ordinary operational efficiency is insufficient when environments change. Operational capabilities allow firms to perform current activities effectively; dynamic capabilities allow them to modify the resource base and the activity system itself (Winter, 2003; Helfat & Winter, 2011). Teece (2007) distinguishes three broad groups of microfoundations: sensing opportunities and threats, seizing opportunities through investment and business model choices, and reconfiguring assets and organizational structures. These activities are knowledge-intensive. They depend on how organizations collect information, interpret signals, coordinate judgment, and implement change.

This is naturally linked to the notion of intelligent knowledge. In this paper, intelligent knowledge is not treated as a passive stock of information. It is defined as the capability-embedded ability of an organization to generate, integrate, interpret, and apply knowledge for purposeful adaptation. It is intelligent because it connects information to action; it is organizational because it is embedded in routines, governance structures, and decision processes; and it is dynamic because its value is realized under uncertainty, not merely under stable execution conditions.

The dynamic capabilities literature has strongly emphasized heterogeneity, path dependence, and context specificity. These are essential insights. However, the same emphasis has also made the literature less attentive to the cost and scalability of capability development. If capabilities are highly idiosyncratic and embedded, then replication and scaling are difficult. Yet many firms do in fact create shared innovation platforms, central analytics units, corporate venture functions, transformation offices, and standardized strategic review processes. These are attempts to make at least some parts of dynamic capability activity scalable.

2.2 Economies of scale in capability development

Economies of scale arise when average costs decline as output, volume, or scope increases. In the context of dynamic capabilities, the relevant output is not a physical product but the number and value of adaptive decisions, innovation initiatives, transformations, and strategic reallocations supported by the capability system. Many elements of dynamic capabilities have fixed or quasi-fixed costs. Examples include data infrastructure, strategic scanning systems, innovation governance, experimentation platforms, business intelligence routines, and specialized managerial expertise. Once created, these elements may serve multiple products, markets, business units, or ecosystem relationships.

The resource-based and capability literatures already contain partial support for this view. Penrose (1959) emphasized the role of managerial resources and the limits of firm growth, while also showing that unused productive services of resources may create opportunities for expansion. Zollo and Winter (2002) show that deliberate learning, articulation, and codification contribute to the evolution of capabilities. Winter and Szulanski (2001) discuss replication as a strategy, emphasizing that templates can reduce the cost of reproducing complex routines. These contributions imply that capability development can benefit from learning, codification, and reuse.

At the same time, dynamic capabilities are not automatically scalable. Szulanski (1996) shows that best practices are often sticky and difficult to transfer. Eisenhardt and Martin (2000) argue that dynamic capabilities differ across environmental conditions: in moderately dynamic markets they may be more structured and

analyzable, whereas in high-velocity environments they are more experiential and fragile. This implies that scalability depends on the balance between codification and contextual adaptation.

2.3 Diseconomies of scale and organizational limits

Scale also creates diseconomies. As organizations grow, coordination becomes more complex, communication channels multiply, and decision processes slow down. A larger organization may have more resources for sensing and seizing, but it may also suffer from internal fragmentation and cognitive overload. Helfat and Winter (2011) caution that the distinction between operational and dynamic capabilities is not always clear in practice, and that capabilities must be understood in relation to their actual use. More dynamic capability activity is not automatically better if it creates excessive deliberation, redundant committees, or rigid change programs.

The key theoretical implication is that dynamic capability investment should not be assumed to have monotonically positive returns. At low levels, investment may sharply reduce the risk of misadaptation. At higher levels, additional investment may yield smaller incremental reductions in expected loss while adding direct cost and complexity. The natural implication is an interior optimum: a level of investment at which the marginal cost of further capability development equals the marginal reduction in expected loss.

3 Conceptual Framework: Dynamic Capability Investment as Optimization

3.1 From transaction cost optimization to capability investment

The model used as a foundation in this paper defines total cost as the sum of direct costs and expected losses. In a transaction, actors may spend resources to reduce the probability of loss. The expected loss is the probability of loss multiplied by exposure. The total cost is minimized where the saving in expected loss from an additional unit of effort is equal to the additional direct cost. The model also shows that the optimum shifts when exposure changes: at low exposure, little effort may be optimal; at high exposure, more effort is justified.

This logic can be transferred to dynamic capabilities without claiming that dynamic capabilities are identical to transaction costs. The structural analogy is the important point. Organizations invest in dynamic capabilities to reduce the probability and consequences of strategic failure under uncertainty. Weak sensing may lead to missed opportunities. Weak seizing may lead to delayed or mistaken investment. Weak reconfiguring may lead to inertia, stranded assets, or failed transformation. These are expected losses. Dynamic capability investment reduces them, but only by incurring direct and quasi-fixed costs.

Table 1. Mapping the transaction cost model to dynamic capability investment

Transaction cost model	Dynamic capability interpretation	Illustrative examples
Direct cost of effort	Investment in sensing, seizing, and reconfiguring	Analytics systems, strategic forums, experimentation budgets, transformation offices
Probability of loss	Probability of misadaptation or missed opportunity	Wrong market entry, delayed innovation, failure to respond to regulation
Exposure	Organizational scale, scope, volume, or strategic stakes	Number of products, markets, transactions, customers, ecosystem links
Expected loss	Value at risk from weak adaptation	Lost revenue, technological lock-in, reputational damage, compliance risk
Cost sharing rule	Internal or inter-organizational allocation of capability costs and benefits	Business unit budgets, ecosystem governance, platform participation rules

Source: Author, building on (Kállay, Takács, & Trautmann 2020)) and the dynamic capabilities literature.

3.2 Formal representation

Let I denote the level of investment in dynamic capabilities and S denote organizational scale or exposure. Scale may refer to firm size, activity volume, product-market scope, technological complexity, or the value at stake in adaptation decisions. The organization chooses I to minimize total adaptation cost:

$$TC(I,S) = C(I) + L(I,S)$$

where C(I) is the direct and quasi-fixed cost of capability development, and L(I,S) is the expected loss associated with uncertainty and misadaptation. The cost function C(I) is increasing in I. The expected loss L(I,S) is decreasing in I, because stronger dynamic capabilities reduce the probability or magnitude of failure, but it is increasing in S, because larger organizations or broader activity systems face greater exposure.

The optimality condition is:

dC(I)/dI = - dL(I,S)/dI

This condition states that the organization should invest in dynamic capabilities up to the point where the marginal cost of additional capability development equals the marginal reduction in expected loss. If investment is lower than this point, the organization leaves avoidable losses unaddressed. If investment is higher, the organization spends more on capability infrastructure than the expected reduction in losses justifies.

3.3 Scale-dependent optimum

Figure 1 illustrates the central mechanism. Direct capability costs increase with investment, while expected losses decline as stronger dynamic capabilities reduce misadaptation. Total cost is therefore minimized at an interior optimum. When scale or exposure rises, the total cost curve shifts and the optimum moves to the right, implying a higher economically justified level of dynamic capability investment.

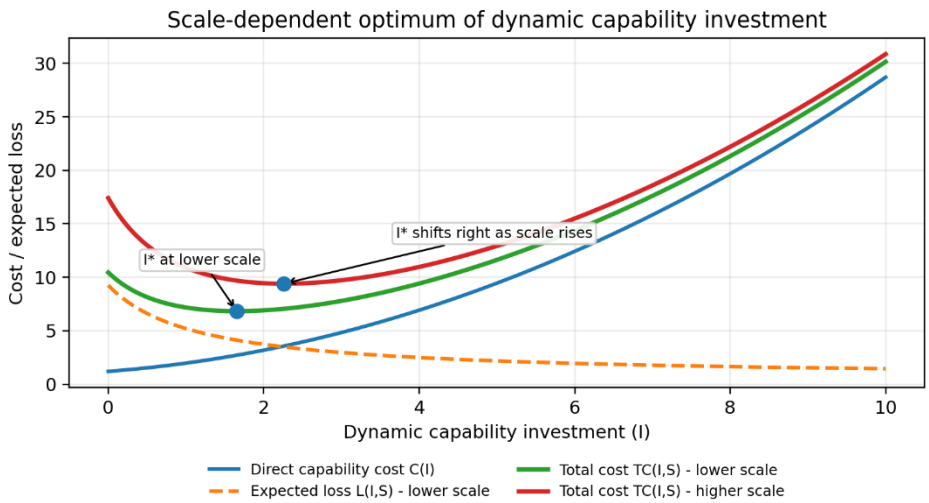

Figure 1. Scale-dependent optimum of dynamic capability investment. Source: Author.

4 Economies and Diseconomies of Scale in Dynamic Capabilities

4.1 Economies in development

Economies of scale in dynamic capability development arise when the average cost of capability infrastructure declines as the organization uses it across more decisions, projects, products, or units. A central market intelligence function may be expensive to create, but once it exists, it can inform many strategic choices. A data platform may require substantial investment, but its marginal cost of supporting an additional innovation project may be low. A corporate venture process or transformation office may be costly, but its templates and routines may be reused across multiple initiatives.

Learning economies are also central. Repeated engagement in innovation and transformation helps organizations learn how to search, experiment, evaluate, and reconfigure. Zollo and Winter (2002) emphasize deliberate learning mechanisms such as experience accumulation, knowledge articulation, and codification. These mechanisms reduce the cost of future capability deployment by transforming repeated experience into organizational routines. In this sense, dynamic capabilities become more efficient when they are used often enough to generate learning.

Replication economies are related but distinct. Winter and Szulanski (2001) show that replication requires a template and a process for transferring routines. Dynamic capabilities may be scalable when sensing dashboards, innovation stage-gates, portfolio review practices, or transformation playbooks can be transferred across units. However, replication is never purely mechanical. The local context matters, and excessive standardization may undermine the adaptive purpose of the capability.

4.2 Economies in deployment

Capability development and capability deployment should be distinguished. Development refers to building the knowledge infrastructure, routines, and governance mechanisms that make dynamic adaptation possible.

Deployment refers to applying these mechanisms in concrete contexts. Economies of scale may be stronger in development than in deployment. It may be efficient to build a common data infrastructure or strategic review process, but the interpretation of signals and the reconfiguration of resources may still require local judgment.

This distinction helps explain why large firms often develop formal systems for innovation and transformation, while still struggling to achieve agility. The common infrastructure creates economies, but deployment across heterogeneous business units may produce transfer frictions. Szulanski (1996) concept of internal stickiness is useful here: knowledge does not move automatically just because it is available. Motivation, absorptive capacity, causal ambiguity, and relationship quality affect transfer.

4.3 Diseconomies and the limits of capability investment

Diseconomies of scale appear when additional investment in dynamic capabilities creates more complexity than adaptive benefit. More scanning may generate information overload. More governance may slow down decisions. More formalization may reduce entrepreneurial initiative. More coordination may increase political bargaining inside the firm. These effects are especially relevant for large organizations, where dynamic capability systems can become bureaucratic.

The diseconomy argument is not a rejection of dynamic capabilities. It is a warning against treating them as unbounded goods. The same routines that support adaptation at one level may produce rigidity at another. A transformation office may accelerate resource reconfiguration when it clarifies priorities, but may hinder adaptation when it becomes a procedural bottleneck. A strategic planning system may help sense trends, but may create false confidence if it replaces experimentation with reporting.

5 Propositions

Proposition 1 - Optimization structure: Dynamic capability investment follows an optimization logic in which organizations balance the direct and quasi-fixed costs of capability development against the expected losses associated with uncertainty, misadaptation, and missed opportunities.

Proposition 2 - Scale-dependent optimum: The optimal level of dynamic capability investment increases with organizational scale, scope, and exposure, because larger or more complex organizations face higher expected losses from weak adaptation.

Proposition 3 - Bounded optimum: The optimal level of dynamic capability investment is finite and bounded because marginal returns decline and coordination costs increase at higher levels of investment.

Proposition 4 - Development-deployment asymmetry: Economies of scale are stronger in the development of dynamic capability infrastructure than in the deployment of dynamic capabilities across heterogeneous contexts.

Proposition 5 - Governance and cost allocation: The realized level of dynamic capability investment depends on how costs and benefits are allocated inside firms and across ecosystems. Misaligned internal cost-sharing rules may generate underinvestment, overinvestment, or fragmented investment.

Proposition 6 - Ecosystem scale effects: For sustainability-oriented innovation, the relevant scale of dynamic capability investment may be ecosystem-level rather than firm-level, because sensing, seizing, and reconfiguring often require inter-organizational coordination.

6 Illustrative Examples and Empirical Implications

6.1 SMEs

Small and medium-sized enterprises often face a structural disadvantage in dynamic capability investment. They need sensing, seizing, and reconfiguring capabilities no less than larger firms, but they have fewer opportunities to spread fixed costs. A professional market intelligence unit, data analytics system, or formal transformation office may be too expensive relative to the scale of the firm. Therefore, SMEs often rely on simpler, more informal, and more owner-manager centered forms of dynamic capability.

This does not mean that SMEs lack dynamic capabilities. Many SMEs are highly adaptive precisely because they are close to customers, have short communication lines, and can make quick decisions. Their problem is different: they may be unable to finance specialized knowledge infrastructure or to codify routines in a way that supports repeated scaling. The model predicts that the optimal level of formal DC investment is lower for SMEs, but also that underinvestment may occur when exposure grows faster than capability infrastructure.

6.2 Large firms and multinational corporations

Large firms can justify more extensive dynamic capability investments because the value at stake is higher. A mistake in technology strategy, regulatory response, sustainability transition, or platform positioning may affect many products and markets. Large firms can spread the cost of sensing systems, strategic analytics, corporate venture units, and reconfiguration routines across a broad activity base. This is the scale advantage emphasized by the model.

Yet large firms also face stronger diseconomies. Their dynamic capability systems may become too formal, too slow, or too politically mediated. Investment may continue beyond the optimum because managers prefer visible capability infrastructure, consultants, dashboards, and committees even when marginal adaptive value is low. Therefore, large firms face a double risk: they need more dynamic capability investment than SMEs, but they are also more exposed to overinvestment and bureaucratization.

6.3 Platform firms and digital ecosystems

Platform firms provide a clear example of scalable dynamic capability infrastructure. Digital platforms can use shared data, analytics, experimentation systems, and ecosystem governance to sense changes across many users and complementors. Once built, these systems may be deployed repeatedly at low marginal cost. A/B testing, automated monitoring, and algorithmic recommendation systems are examples of capability elements that can scale across very large volumes.

However, platform scale also increases exposure. A design error, governance failure, or regulatory misjudgment can have systemic consequences. Therefore, platform firms may require higher investment in sensing and governance than traditional firms, but they also face the risk that control systems become too centralized or insensitive to local ecosystem effects.

6.4 Sustainability-oriented innovation ecosystems

Sustainability transitions create especially strong reasons to analyze dynamic capabilities at the ecosystem level. Decarbonization, circular economy models, and inclusive innovation require coordinated changes among firms, public agencies, users, financiers, and knowledge institutions. No single organization fully controls the relevant resource base. Sensing must include technological, social, environmental, and regulatory signals. Seizing often requires joint investment. Reconfiguring may involve supply chains, standards, infrastructures, and institutions.

In such contexts, the optimal level of dynamic capability investment may not be determined at the level of the individual firm. A small firm may not be able to build advanced sensing capabilities alone, but a cluster, platform, or public-private partnership may create shared capability infrastructure. This creates collective economies of scale. At the same time, cost-sharing and governance problems become central. If some actors pay for shared sensing while others capture most of the benefits, investment may fall below the system-level optimum.

Table 2. Expected investment patterns by organizational context

Context	Scale effect	Main risk	Likely capability architecture
SMEs	Limited cost spreading	Underinvestment when exposure grows	Informal routines, owner-manager sensing, external networks
Large firms	Strong fixed-cost spreading	Overinvestment and bureaucracy	Formal analytics, governance, portfolio routines
Platform firms	Very strong deployment economies	Systemic failure and centralization	Data-driven sensing, scalable experimentation, ecosystem rules
Sustainability ecosystems	Collective economies beyond firm boundaries	Free-riding and weak cost sharing	Shared knowledge infrastructure, public-private governance

7 Discussion

7.1 Contribution to dynamic capability theory

The paper contributes to dynamic capability theory by shifting attention from the existence of capabilities to their economically justified level. This is not a minor change. If dynamic capabilities are costly investments, then their value depends not only on whether they exist, but also on whether their scale, architecture, and

governance match the organizational exposure. The concept of a scale-dependent optimum helps reconcile two strands of the literature: the view that dynamic capabilities are necessary for adaptation and the view that organizational complexity can undermine responsiveness.

The proposed framework also clarifies why empirical findings on dynamic capabilities and performance may be mixed. If the relationship is non-linear, then studies assuming a simple positive association may miss important effects. Firms with low dynamic capability investment may perform poorly because they fail to adapt. Firms with excessive investment may also perform poorly because they suffer from complexity and slow decision-making. The highest performance should be expected near the optimum, not necessarily at the highest observed level of capability investment.

7.2 Contribution to IFKAD: intelligent knowledge as investment

For the IFKAD theme, the paper offers a specific interpretation of intelligent knowledge. Intelligent knowledge is not only knowledge that is useful, actionable, or technology-enabled. It is also knowledge embedded in costly organizational mechanisms. Its value depends on whether the organization can generate, process, and apply it at an appropriate scale. Too little intelligent knowledge infrastructure leaves the organization exposed to uncertainty. Too much may create reporting burdens, attention dispersion, and procedural inertia.

This interpretation connects knowledge management with strategic economics. It suggests that organizations should ask not only how to create more knowledge, but also where knowledge investments reduce expected losses most effectively. In sustainability-oriented organizations, this question becomes especially important because the relevant uncertainty is multidimensional: technological, regulatory, social, environmental, and reputational.

7.3 Managerial implications

Managers should treat dynamic capabilities as investments with explicit cost-benefit logic. This requires identifying the main organizational exposure: the value at risk from weak adaptation. For a small local firm, exposure may be modest and highly formal capability systems may be unnecessary. For a multinational firm, exposure may be large and underinvestment in sensing or reconfiguration may be extremely costly. For an ecosystem, exposure may be distributed, requiring shared governance and cost-sharing arrangements.

Managers should also distinguish between capability infrastructure and capability use. Building dashboards, offices, committees, and routines is not the same as improving adaptation. The relevant test is whether these investments reduce the probability or expected cost of strategic error. Finally, organizations should periodically reassess the optimum because both exposure and technology change. Digital tools may reduce the cost of sensing, while regulatory or sustainability pressures may increase the expected loss from weak adaptation.

8 Methodological Implications and Future Research

The framework suggests several empirical research paths. First, survey-based studies could measure dynamic capability investment, organizational scale, and performance outcomes, while testing for non-linear relationships. If the model is correct, the effect of investment should be positive up to a threshold and weaker or negative beyond it. Second, case studies could examine how firms decide on the size of sensing, innovation, and transformation functions. Such studies could identify whether managers explicitly consider exposure and expected loss or whether investment is driven by imitation and managerial fashion.

Third, comparative studies of SMEs and large firms could examine how fixed costs shape capability architecture. SMEs may substitute external networks and informal routines for internal systems, while large firms may rely on formalized processes. Fourth, ecosystem-level research could analyze cost-sharing rules in sustainability initiatives, clusters, and platforms. The transaction cost model suggests that inefficient cost-sharing may prevent the system from reaching the optimum even when the technical solution is known.

A useful empirical strategy would combine qualitative and quantitative elements. Qualitative case studies can identify the relevant capability investments and expected loss categories. Quantitative analysis can then examine whether investment intensity varies systematically with scale and whether performance follows an inverted-U pattern. Data envelopment analysis may also be relevant, because the original transaction cost model uses frontier logic to identify efficient combinations of direct costs and loss reduction. A similar approach could compare organizational units or firms as decision-making units using inputs such as DC investment and outputs such as innovation success, adaptation speed, or resilience.

9 Limitations

The paper is conceptual and does not provide direct empirical testing. Its purpose is to develop a theoretical framework that can guide subsequent empirical research. The formal representation is deliberately simple. It abstracts from multiple capability dimensions, uncertainty about the cost and benefit functions, and political processes inside organizations. These simplifications are useful for theory building, but future work should relax them.

Another limitation is that dynamic capabilities are difficult to measure. Investment in dynamic capabilities is not always visible in accounting data. It may be embedded in managerial attention, routines, culture, and informal networks. Therefore, empirical testing requires careful operationalization. Finally, the framework assumes that organizations can approximate the relationship between investment, expected loss, and scale. In practice, managers face imperfect information, and misperception of exposure may itself be a source of underinvestment or overinvestment.

10 Conclusion

This paper has developed an optimization perspective on dynamic capabilities and economies of scale. It argues that dynamic capabilities should be understood as costly investments in intelligent knowledge that reduce expected losses under uncertainty. Building on a formal transaction cost optimization model, the paper shows that the optimal level of dynamic capability investment depends on organizational scale or exposure. Larger organizations and broader ecosystems can justify higher investment because the value at risk from weak adaptation is larger. However, investment remains bounded because excessive capability infrastructure may generate coordination burdens, cognitive overload, and rigidity.

The paper contributes by integrating scale effects into dynamic capability theory, by conceptualizing intelligent knowledge as an economically constrained organizational infrastructure, and by deriving propositions for SMEs, large firms, platform organizations, and sustainability-oriented ecosystems. The central managerial implication is straightforward: organizations should not ask whether dynamic capabilities are good in general. They should ask what level, form, and governance of dynamic capability investment is optimal for their scale, exposure, and strategic uncertainty.

For future research, the framework opens a path toward empirical testing of non-linear capability-performance relationships and toward deeper analysis of cost-sharing rules in ecosystems. For practitioners, it provides a disciplined way to think about capability development: invest enough to reduce expected losses from uncertainty, but avoid building capability systems whose complexity exceeds their adaptive value.

Do Renewable Energy Communities Create Value? Evidence from a Systematic Literature Review

Fabrizio Rossi, Alessandro Sicali
Università degli studi di Trieste, Trieste, Italy

Abstract

This study aims to analyse the literature on the economic performance of Renewable Energy Communities (RECs). Specifically, the objective of this work is to identify how existing research assesses REC profitability and to shed light on whether they represent financially viable investment vehicles. The distribution mechanisms employed to allocate economic benefits among REC participants are also investigated. To address these questions, a systematic literature review was conducted following the PRISMA 2020 guidelines, based on a search of the Scopus database. A final sample of 40 peer-reviewed articles published between 2018 and 2026 was analysed. The findings show that capital budgeting tools, such as NPV, IRR, and Payback Period, are the most widely adopted instruments for assessing REC economic performance. The empirical evidence suggests that RECs generally represent profitable investments capable of generating positive returns. Italy emerges as the most extensively studied context, notably in the residential sector, driven by a robust incentive system that has proven decisive in sustaining profitability. Indeed, economic performance tends to deteriorate and NPV can turn negative where regulatory support is insufficiently developed. Furthermore, photovoltaic technology emerges as the primary renewable energy source, while alternative configurations show potential but remain financially constrained by high CAPEX. Public and private involvement consistently generates positive economic outcomes by leveraging the complementarity of energy demand profiles. Regarding benefit distribution, a delicate balance exists between prosumers and consumers that can lead to participant dropout when allocation mechanisms prove ineffective. Minimum return guarantees, fairness-based criteria, and technology-driven tools have been shown to improve distributional outcomes and community stability. This study adds to the existing literature by providing systematic evidence on the key drivers of REC profitability and benefit distribution, while stimulating future research to further examine RECs through a corporate finance lens. The insights suggest that participation by private citizens, SMEs, and public administrations represents both an economically sustainable choice and a positive contribution to the energy transition. At the same time, this study offers practical implications for policymakers, identifying incentive system as a key driver of REC development, and for REC managers, highlighting the role of advanced benefit distribution systems in preserving community cohesion.

Keywords: Renewable Energy Communities; sustainability; economic benefits; systematic literature review; project evaluation

Paper type: Academic Research Paper

1 Introduction

Renewable Energy Communities (RECs) are a key instrument in the European regulatory framework for combating climate change and advancing the energy transition (Basilico et al., 2025; Biancardi et al., 2026; Moretti & Stamponi, 2023). Formally defined under the Renewable Energy Directive (RED II, 2018/2001/EU), RECs are legal entities characterised by the voluntary and open participation of citizens, small and medium-sized enterprises (SMEs), and local authorities in the collective self-consumption of electricity from renewable sources. RECs embody a predominantly mutualistic nature, in which financial profit is explicitly secondary to the generation of environmental, economic, and social benefits for their members and the local areas in which they operate, reflecting the principles of stakeholder theory (Freeman, 1984).

Although profitability is not the primary objective of RECs, financial sustainability remains a prerequisite for these entities to fulfil their broader mission (Biancardi et al., 2026; Martiniello & Presciutti, 2024). Without adequate economic returns, members lack the incentive to participate, and communities struggle to attract the investment needed to develop and maintain renewable energy infrastructure (Chaudhry et al., 2022b; Imset et al., 2025). The literature on RECs is rich and multidisciplinary, encompassing legal, social, engineering, and economic perspectives. Adopting a corporate finance lens, this paper focuses specifically on the economic and financial dimension of RECs, a challenging field that remains fragmented and underexplored.

To bridge this gap, this systematic literature review addresses the following research questions (RQs):

- ***RQ1:*** *What quantitative approaches have been used to assess the financial profitability of REC investments?*
- ***RQ2****: Do REC investments generate economic value?*

- ***RQ3:*** *What distribution mechanisms are employed to allocate economic benefits among REC participants?*

2 Methodology

This study adopts a systematic literature review to organise existing contributions on the economic dimension of RECs into a coherent framework, addressing the RQs through a replicable process of mapping and synthesising the available evidence (Tranfield et al., 2003). In particular, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) guidelines (Page et al., 2021) were adopted. This model has gained widespread adoption in finance studies (Galletta et al., 2024), as it guarantees transparency and traceability across all phases of the review process: identification of records, screening of titles and abstracts, assessment of eligibility, and final inclusion of the sample.

In line with the PRISMA 2020 protocol, eligibility criteria were defined to ensure the relevance and quality of the review. The search strategy considered only original peer-reviewed articles written in English and published from 2018 onwards, the year of adoption of RED II (11 December 2018), while conference proceedings, book chapters, and grey literature were excluded. Articles were retrieved from Scopus, which was selected as the primary database following a preliminary search that revealed substantial overlap with Web of Science (WoS) results. The search query was structured in two steps based on keywords and Boolean operators.

The first step limits the studies to RECs. In the legal framework of the European Union, the term "energy communities" is used as an umbrella category that includes RECs, but also different configurations that are not within the scope of this research. For this reason, the search strategy includes both keywords "energy communit*" and "renewable energy communit*". A manual check was carried out during the screening phase to exclude articles referring to energy communities that do not present the characteristics required by RED II.

The second step included studies addressing the economic dimension of RECs, captured through keywords related to project evaluation metrics and profitability, such as "net present value", "internal rate of return", "discounted cash flow", "project financ*", "valuation methodolog*", "cash flow*", "payback period", "Public Private Partnership", "cost of equity", "scenario analys*", "sensitivity analys*", "discount rate", "cost of capital", "cost of debt", "capital structure", "leverage", and "corporate governance". Additional keywords related to economic benefits and their distribution among participants were also included, such as "financial benefit*", "economic benefit*", "revenue model*", "benefit sharing", and "benefit allocation". Studies addressing RECs exclusively from a technical, engineering, environmental, or social perspective, with no economic or financial dimension, were excluded.

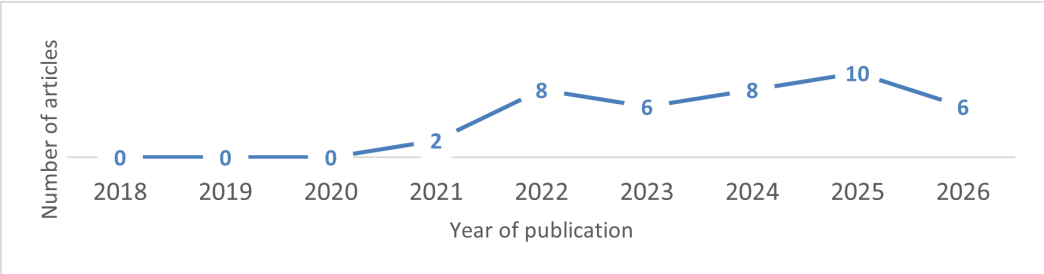

Fig. 1 Publication Trend.

The database search, finalised on 8 April 2026 following preliminary explorations, yielded 522 records. Upon the application of exclusion criteria based on peer review, language, and publication year, 292 articles underwent title and abstract screening, of which 53 proceeded to full-text review. Of these, 13 were excluded as their economic analysis proved marginal or absent. The final sample therefore consists of 40 articles, and Figure 1 illustrates the publication trend over the years. All phases of the review process, conducted in accordance with the PRISMA 2020 guidelines, are summarised in Figure 2.

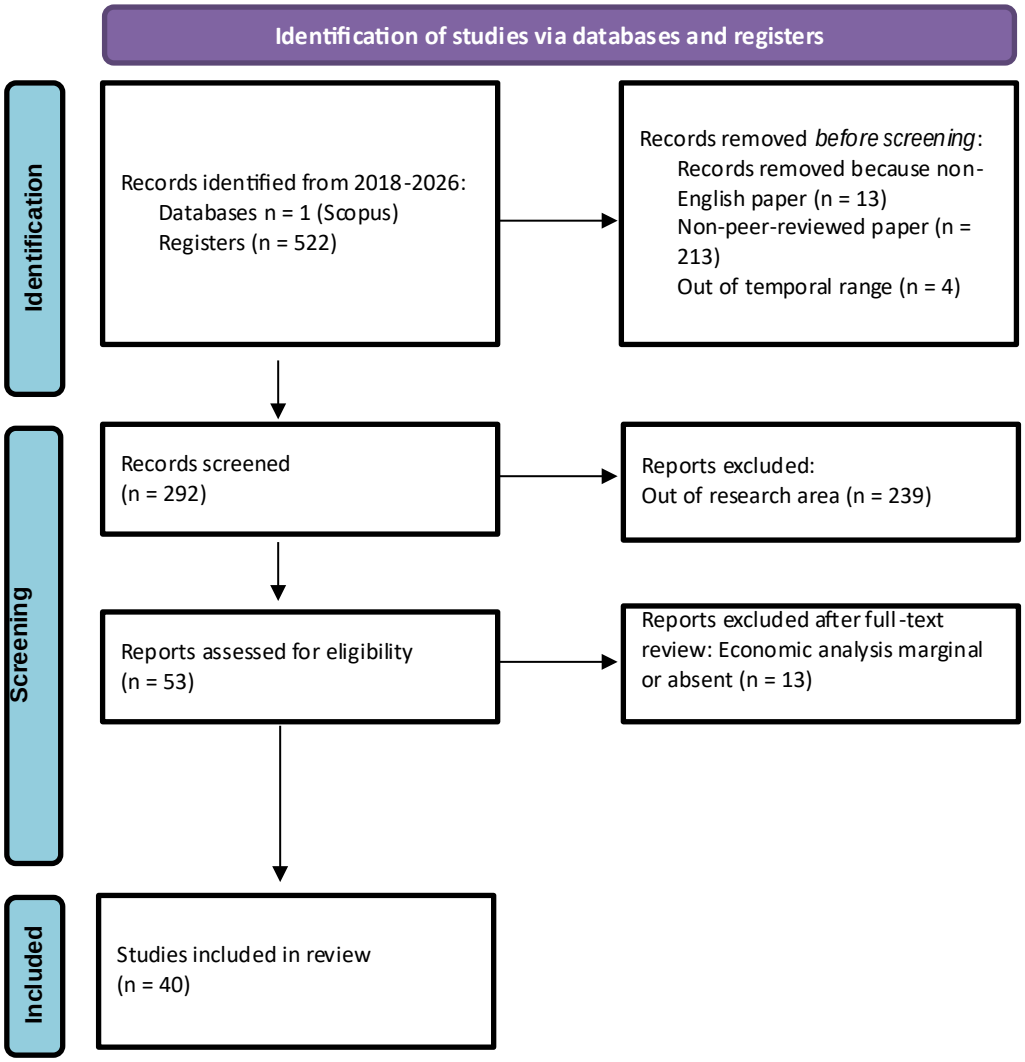

Fig. 2. PRISMA flow diagram for systematic literature reviews.

3 Results

3.1 Quantitative assessment of RECs economic performance

Regarding RQ1, most of the studies, about 60% included in this review, employ at least one capital budgeting technique, mainly based on on Net Present Value (NPV), Internal Rate of Return (IRR), and Payback Period (PBP). The empirical evidence addressing RQ2 is presented in the following sections.

3.1.1 Residential RECs

Among the various REC configurations studied in the literature, residential photovoltaic communities represent the most extensively investigated context, with private citizens as the primary participants. A significant share of this evidence draws on the Italian context, which has attracted considerable academic and investment interest owing to its advanced incentive system (Magni et al., 2025), consistently documenting positive economic returns.

Basilico et al. (2025) find that RECs generate positive NPV regardless of electricity price levels, confirming the robustness of returns across different market conditions. D'Adamo et al. (2023; 2024) corroborate these results, showing that NPV remains positive even under reduced incentive scenarios. Biancardi et al. (2026) show that economic sustainability holds even in the complete absence of public incentives, with positive NPV across all incentive scenarios. Sassone et al. (2025) document that profitability can be further enhanced by finding the optimal balance between prosumers and consumers, reducing the PBP.

Beyond the Italian context, the evidence on residential REC profitability is more mixed. Riquelme-Dominguez et al. (2025) find that forming a REC from scratch in Spain yields significantly higher collective savings and

increased NPV compared to individual self-consumption setups, driven by lower capital expenditure (CAPEX) and reduced maintenance costs. Meanwhile, Mutule et al. (2025) show that in Latvian RECs NPV can be negative due to high sensitivity to electricity market prices, concluding that without targeted incentives individual households face limited financial motivation to join a REC. In line with this evidence, Chaudhry et al. (2022a; 2022b) underline that over an extended investment horizon, a potential REC in Germany generates highly negative NPV values, driven by restrictive legislation and a structural revenue shortfall. This finding highlights the dependence of REC sustainability on public subsidies, a pattern further documented across multiple European regulatory contexts (Gjorgievski et al., 2023).

Overall, residential photovoltaic RECs prove to be profitable investments, though their financial viability remains dependent on public support. This dependence is more pronounced where regulatory frameworks are less developed, often requiring subsidies to remain financially attractive, while more advanced incentive systems such as the Italian one, which tailors support to plant size, geographical location, and market conditions, foster greater financial independence in the long term.

3.1.2 RECs with public and private involvement

Beyond the residential context, the literature observes that public and private involvement represent key drivers of value creation. Regarding mixed municipal and residential RECs in Italy, Ruggieri et al. (2023) report positive NPV over a 20-year horizon. Similarly, Moretti & Stamponi (2023) find significant positive NPV for a REC led by the municipality of Assisi, confirming that the inclusion of energy-intensive municipal facilities significantly amplifies economic returns. However, Cielo et al. (2021) document that mixed RECs present a positive investment potential that proves highly dependent on incentives. The authors show that in the presence of incentives the IRR exceeds the cost of capital, while in their absence it falls below it, rendering the investment financially unattractive.

Mari et al. (2025) extend this logic, highlighting that integrating commercial buildings into residential communities enhances NPV by exploiting the alignment between daytime commercial demand and solar energy production. This complementarity effect proves even more pronounced when REC composition is actively optimised. Blasuttigh et al. (2025) find that aggregating industrial firms based on load profile complementarity significantly increases NPV and reduces PBP, while Buonomano et al. (2024; 2026) confirm this approach in port and mixed urban configurations, achieving short PBP. Consistent results are documented in the Portuguese context, where Rego et al. (2025) find positive NPV for a mixed residential and private REC over a 25-year horizon.

Dujany et al. (2026) examine how governance configurations influence REC development in Italy, distinguishing between publicly and privately led initiatives. Their findings indicate that publicly led RECs pursue more inclusive and long-term oriented strategies, though their effectiveness is frequently constrained by bureaucratic complexity. Privately led RECs, by contrast, exhibit greater managerial flexibility and operational efficiency, but tend to prioritise short-term financial returns over the broader social objectives of the community. The authors consequently advocate for hybrid governance arrangements as these are best positioned to reconcile the social orientation of public leadership with the managerial agility of private actors. In line with this perspective, Martiniello & Presciutti (2024) examine Public-Private Partnership (PPP) models for RECs in Italy comparing two distinct configurations. The Cold model, where the public administration compensates the private concessionaire through an availability fee, generates a positive NPV. The Hot model, by contrast, struggles to reach financial equilibrium, as the private concessionaire assumes demand risk and requires substantial public capital contributions to remain viable. In both cases, once investment and management costs are absorbed, the residual economic benefits for individual community members remain minimal.

Taken together, these findings suggest that public and private participation consistently enhances REC economic performance through the complementarity of energy demand profiles. Furthermore, the governance model adopted plays a decisive role in determining REC development outcomes. However, the financial sustainability of these configurations remains dependent on public support.

3.1.3 RECs with mixed technology configurations

The literature also investigates RECs incorporating technologies beyond photovoltaics, showing that profitability is not uniformly achievable across all technological configurations. Ceglia et al. (2022) analyse a REC combining photovoltaic generation, biomass cogeneration, and hydroelectric power, finding that this integration reduces the PBP when favourable heat sale tariffs are in place. González et al. (2023) find that RECs based on local biomass district heating networks generate positive NPV only in the long term for urban configurations, contingent on a minimum community scale and high competing natural gas prices. In contrast to thermal

technologies, Marino et al. (2024) observe that the integration of battery storage slightly reduces NPV due to CAPEX and replacement costs, while substantially reducing energy withdrawals from the grid and thereby mitigating exposure to electricity price volatility. Consistent with these findings, Battaglia et al. (2024) find that electric vehicle recharging services systematically outperform standard REC. Meanwhile, Imset et al. (2025) underline that combining photovoltaics with battery storage and electric vehicles generates significant savings, though solar investments yield negative NPVs without balancing market revenues. Sousa et al. (2023) find that wind enhances REC profitability through temporal complementarity with photovoltaic. Moving to emerging technologies, Raimondi & Spazzafumo (2024) find that a hydrogen-based REC business model is not currently economically feasible, projecting sustainability only for large-scale configurations involving more than 3,000 people.

The literature indicates that alternative technology configurations hold potential for enhancing REC performance but remain financially constrained by high CAPEX. Further technological development is required before these solutions can be effectively integrated into REC business models, and future research should explore the conditions under which these configurations become financially sustainable.

3.2 Benefit redistribution mechanisms among REC participants

This section turns to RQ3, examining how the literature addresses the distribution of economic benefits among REC participants. Prosumers own the renewable energy installations and bear the upfront investment costs, while consumers benefit from energy sharing without owning any plant. Given these different roles, the two categories may develop diverging interests, in a dynamic analogous to the agency conflict between majority and minority shareholders (Jensen & Meckling, 1976). A flat distribution of costs and benefits is not optimal, as consumers could achieve greater financial benefits when energy is allocated based on their real time energy needs (Fina et al., 2022, Volpato et al., 2022), while maximising aggregate community benefits risks marginalising consumers in favour of prosumers (Volpato et al., 2024). This conflict becomes acute when the community composition changes, as new members with incompatible profiles can compromise existing members' returns, increasing the risk of participant dropout (Sousa et al., 2025).

A first response to this risk consists of mechanisms designed to ensure that every participant receives a minimum economic return from community membership. Manuel de Villena et al. (2022) address this through a centralised optimisation model that guarantee every participant a minimum share of locally produced energy and a minimum estimable financial return. Beraldi & Sener (2026) pursue a similar objective by introducing a safety net that guarantees each participant a minimum reduction in electricity bills of at least 8.17%, improving REC cohesion.

Other studies shift the focus from minimum return guarantees to the fairness of benefit distribution. Caferra et al. (2024) identify economic savings as the primary driver for REC participation, while Basilico et al. (2026) find that energy self-consumption is perceived as the fairest distribution criterion. Casalicchio et al. (2022a; 2022b) operationalise this notion through an optimal allocation method based on each participant's marginal contribution and a Fairness Index measuring distributional accuracy, which evaluates how closely a chosen business model aligns with the optimal allocation.

The literature also explores approaches to benefit distribution based on technology. Giudice et al. (2026) introduce a data driven mechanism that dynamically adjusts benefit allocation, rewarding members who align their behaviour with the community's energy objectives. Finally, Chantrel et al. (2021) develop a blockchain-based governance model for German RECs, enabling transparent and automated benefit redistribution among participants.

The distribution of economic benefits among REC members represents a governance challenge that communities must explicitly address, as the divergence of interests between prosumers and consumers can lead to participant dropout, undermining community stability. Flat allocation rules have proven insufficient to manage this complexity, and the literature has responded with mechanisms guaranteeing minimum returns, measuring distributional fairness, and leveraging technology for transparent benefit redistribution. However, identifying the optimal governance model requires further research, as the effectiveness of these mechanisms is likely to depend on broader contextual factors such as the regulatory and incentive framework in which RECs operate.

4 Discussion

This systematic review of the literature on RECs economic performance allows us to draw the following considerations.

First, given the multidisciplinary nature of RECs, disentangling the economic dimension from the technical one represents a methodological challenge. Nevertheless, the evidence reveals a clear dominance of NPV as the primary indicator for assessing REC profitability, complemented by IRR and PBP. Future studies should adopt a cost-benefit analysis as the primary evaluation tool, better capturing the environmental and social dimensions required under RED II.

Second, the empirical evidence reviewed suggests that RECs generally create value for private citizens, public administrations, and firms. However, the magnitude of returns varies considerably depending on several factors. The regulatory context emerges as one of the most impactful drivers: where incentive frameworks are insufficiently developed, profitability tends to decline significantly over time, while in supportive contexts such as Italy, RECs can remain viable even without public incentives. As the existing literature remains predominantly focused on single country analyses, future research should address this gap by conducting comparative studies across multiple countries with different regulatory frameworks.

Third, residential photovoltaic RECs represent the most extensively studied configuration in the literature, consistently documenting positive economic returns. The evidence further suggests that public and private involvement can significantly amplify these returns, leveraging the complementarity of energy demand profiles. Meanwhile, researchers should investigate the unexplored intersection between project finance and REC development.

Fourth, photovoltaic technology dominates REC configurations, though combining it with alternative technologies can potentially enhance community performance, despite these configurations not yet being fully profitable due to high CAPEX. Future studies should expand the literature on how public support can accelerate their deployment while fostering long-term financial independence.

Finally, the distribution of economic benefits among REC participants represents a governance challenge. The divergence of interests between prosumers and consumers can generate tensions leading to participant dropout. Flat allocation rules have proven insufficient, and for this reason further empirical research should explore how different distribution mechanisms perform over time, to identify the governance models most effective in preventing community attrition.

5 Conclusion and Implications

This paper presents a systematic review of the economic performance of RECs, based on a final sample of 40 articles. The evidence confirms that RECs generally represent financially viable investments, though their profitability is influenced by the regulatory framework and the technology adopted. Capital budgeting techniques dominate the literature, while the allocation of benefits between prosumers and consumers emerges as a critical governance challenge. These findings point to several implications for REC stakeholders.

From a practical standpoint, policymakers should design stable incentive schemes that gradually foster REC financial independence, as the regulatory context has proven a critical determinant of financial viability. Incentive frameworks should also be extended to cover alternative renewable technologies, supporting private citizens and firms in adopting energy solutions beyond photovoltaics. Finally, policymakers should consider developing a standardised evaluation methodology to make it immediately clear whether investing in a REC is worthwhile for potential participants.

From a managerial perspective, REC managers should invest in advanced benefit distribution systems and actively monitor member satisfaction, as flat benefit allocation rules have proven insufficient to prevent participant dropout and preserve community cohesion. PPP models represent a promising instrument for REC development, as hybrid arrangements have proven more effective than purely public or private configurations. Finally, private citizens, firms, and public administrations should consider joining RECs as economically sustainable investment vehicles, with mixed configurations proving particularly effective in generating significant economic value for all stakeholders.

Despite the potential limitations of this study, RECs are effectively contributing to the energy transition while generating value for their stakeholders.

Rethinking Product Data Management Through Digital Product Passports: Data Governance for Global Supply Chains

Martina De Giovanni, Antonella Marsano, Mariangela Lazoi
University of Salento, Lecce, Italy

Abstract

Increasing regulatory pressures and societal expectations have made digital transparency a critical requirement, positioning DPPs as key instruments to support traceability and supply chain-based decision-making. However, their effectiveness depends not only on technological infrastructure (e.g., blockchain, RFID, IoT sensors, and system integration), but also on robust data governance frameworks.

This study aims to explore the role of data in enabling the effective implementation of Digital Product Passports (DPPs) as strategic governance tools for transparency, accountability, and sustainable value creation in global supply chains. The research is based on a Systematic Literature Review (SLR) conducted through Scopus and Web of Science, focusing on the evolution of Product Data Management (PDM) and its transition toward the emergence of DPPs. While early PDM approaches emphasized manufacturer-controlled data for operational efficiency, more recent developments show a shift toward multi-actor data ecosystems incorporating environmental, social, and end-of-life information. This transition has been accelerated by European policy initiatives, particularly the Circular Economy Action Plan (CEAP) and the Ecodesign for Sustainable Products Regulation (ESPR), which are transforming DPPs from voluntary tools into mandatory regulatory instruments.

DPPs are especially relevant in high-impact sectors (e.g., electronics, textiles, construction), where they contribute to reducing environmental footprints and enhancing supply chain accountability.

The literature review identifies forty-two data typologies (referred to as factors) required for DPP implementation and organizes them into ten key data categories. The proposed data mapping framework is linked to the Environmental, Social, and Governance (ESG) criteria, emphasizing the integration of data into governance processes to support strategic decision-making. DPPs enable continuous monitoring and lifecycle traceability fostering alignment between circularity and sustainability practices. Moreover, they facilitate bidirectional information flows: consumers gain access to reliable product data, while their feedback can inform producers and regulators, promoting adaptive governance and collective learning.

Despite these opportunities, significant challenges remain, including data asymmetries, privacy concerns, lack of standardization, and unclear stakeholder responsibilities. Without well-defined governance structures, DPPs risk reinforcing existing power imbalances rather than enhancing transparency.

The study concludes that governance is a critical determinant of DPP success. It calls for the development of scalable, harmonized, and compliant data governance models capable of supporting DPP adoption across sectors while ensuring data continuity along the value chain. By framing governance as a strategic enabler, DPPs can evolve beyond compliance tools into foundational mechanisms for circular and sustainable value creation.

Keywords: Corporate Governance, Product Data Management, Digital Transparency, Sustainable Supply Chains

Paper type: Academic Research Paper

1 Introduction

The transition to sustainable and circular economic models is redefining data's role in global supply chains. Growing regulatory pressure, particularly from European initiatives like the Green Deal and the Circular Economy Action Plan (CEAP), requires companies to account for environmental and social impacts throughout the entire life cycle (Mollahassani et al., 2025; Papile et Del Curto, 2025).

In this landscape, the Digital Product Passports (DPPs) emerge as a key tools for traceability and transparency integrating value chain for stakeholders including companies, regulators, consumers, and recyclers (Gieß et Möller, 2025; Jeganathan et Szymkowiak, 2025). This reflects Product Data Management (PDM)'s evolution from company-centric systems to multi-stakeholder ecosystems supporting sustainability (Fares et al., 2025). DPP development followed a conceptual phase (2020–2022) followed by an implementation phase (from 2022 onward).

Existing studies focus on enabling technologies, such as blockchain, the Internet of Things (IoT), and systems integration (Kebede et al., 2024), while neglect data aligned with environmental, social, and governance (ESG) objectives (Jensen et al., 2024). This gap is particularly critical because the DPP effectiveness depends on structuring data across environmental (eco-design, LCA), social (due diligence, human rights), and governance (transparency, risk management) dimensions (Gieß et Möller, 2025; Kim et al., 2023). This approach enables the

integration of sustainability metrics into strategic decision-making processes and promotes alignment between circularity and sustainability practices (Ospital et al., 2023; Pracucci et Giovanardi, 2025). In this context, the study aims to investigate how product data can be structured and governed within DPP systems to effectively support traceability, sustainability, and life-cycle-based analyses. To address this objective, a systematic literature review (SLR) is conducted to identify the key data categories involved in DPP implementation and to develop a comprehensive framework for their classification and governance across the supply chain. This paper contributes to the literature by (i) bridging the gap between DPP technological architectures and ESG-oriented data governance, (ii) providing a structured mapping of product data across life cycle stages, and (iii) outlining the governance implications for the effective implementation of DPPs in complex, multi-stakeholder contexts.

2 Research Methodology

The objective of the paper is to understand how to structure data governance to make the DPP an effective tool for transparency, traceability and sustainability across supply chains.

Therefore, a Systematic Literature Review (SLR) is used as the research methodology to clarify the scientific body of knowledge through a replicable, scientific and transparent protocol that aims to minimize bias through an exhaustive literature search (Tranfield et al., 2003). The systematic approach provides a comprehensive, unbiased synthesis of many relevant studies of the literature (Egger et al., 2001).

Protocols include aspects related to the design and implementation of the review, in line with the definition of research questions, criteria for documents eligibility, search strategy, study selection, data extraction, contents assessment, synthesis and reporting. A protocol provides a step-by-step guide to carrying out the work in a clear and consistent way. Several procedures for outlining an effective review protocol have been identified in the literature and, although they are different, they have some commonalities.

The methodological SLR protocol used in this paper is based on (Corallo et al., 2023), which consists of four steps: (i) review planning, (ii) review execution, (iii) analysis and (iv) reporting. Each phase will be discussed in more detail in the following subsections and the procedure was summarized in Figure 1.

2.1 Review planning

In the initial phase of the research, it is essential to define a clear objective to guide the entire analysis. Therefore, in line with the objective of this study, the systematic literature review (SLR) aims to identify all relevant types of supply chain data enable to support DPP in all industrial sectors involved, with a focus on the evolution of PDM and its transition toward the emergence of DPPs.

Consequently, the research question (RQ) formulated for this study is: What product data must be managed and integrated into digital systems, such as the Digital Product Passport in manufacturing industries to support traceability and sustainability across supply chains?

The Scopus and Web of Science (WoS) databases were selected as reference sources for scientific contributions, thanks to their reliability and broad interdisciplinary coverage.

To facilitate the implementation of the review, some appropriate keywords were selected to ensure a comprehensive and targeted literature search.

In addition, eligibility criteria were established for the inclusion or exclusion of articles identified in the literature. Four inclusion criteria were selected for this study as reported in Figure 1. However, no time restrictions were applied.

Finally, a preliminary qualitative content analysis was adopted as mechanism for article selection to align the content with the analysis scope.

2.2 Review execution

This phase is based on the implementation of the SLR. Scopus and WoS have been interrogated in November 2025 by selecting keywords appropriately combined through Boolean operators The search query obtained is shown in Figure 1. Papers can be selected only if keywords are included within the title, abstract or the keywords of the paper. Specifically, as research field has been selected TIT-ABS-KEY in Scopus is, while topics (TS) in WoS that refers to the same fields. This formula ensured that the review captured a full range of interest within literature.

Moreover, the initial sample was refined by applying specific filters in accordance with the inclusion and exclusion criteria as detailed in Figure 1 together with the quantitative results of initial sample.

2.3 Analysis

The third step aims to a comprehensive analysis of the papers returned from the search. The quantitative advancement of the articles analyzed during the SLR procedure is reported in Figure 1.

A systematic qualitative content analysis was carried out by organizing and synthesizing the information gathered from the selected documents in a structured predefined excel matrix. The relevant information extracted referred to bibliometric information, the study's objective, main findings, and finally core contents such as data types processed in each study, technologies supporting DPP implementation and PDM background.

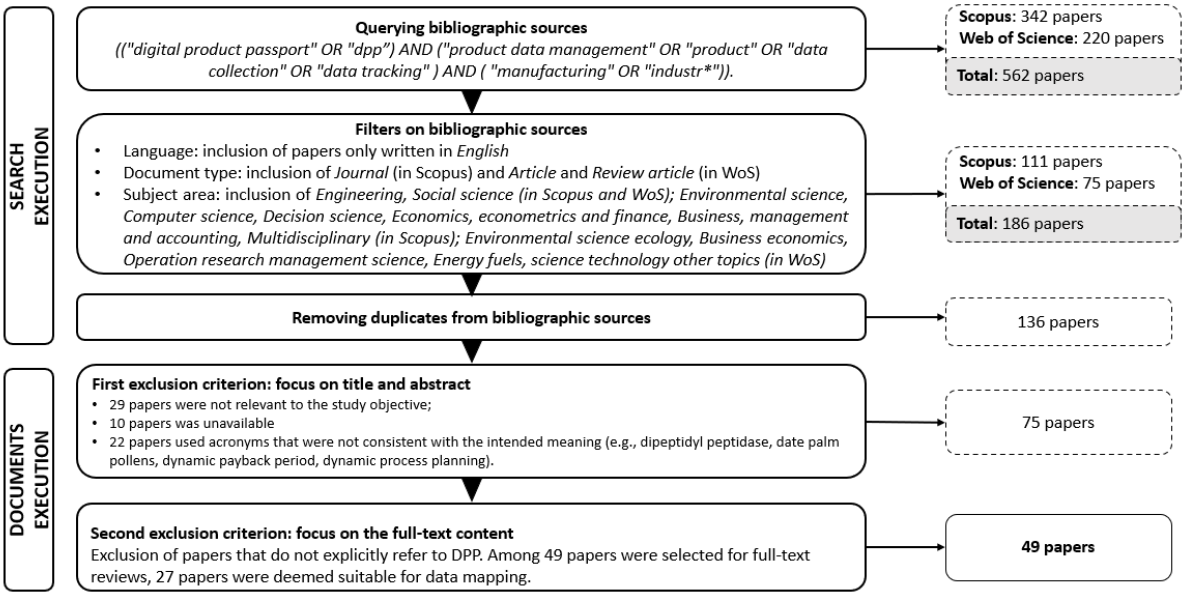

Figure 1. SLR procedure.

2.4 Reporting

This phase provides an overview about the most relevant findings emerged from the body of knowledge, highlighting key relationships and insights related to the research topic. The analysis content in Section 3 is mainly organized into two sections. The first one examines the evolution of PDM by identifying the key factors that have driven it with particular emphasis on enabling technologies. The second one develops a framework for mapping data to be included in the DPP, encompassing various sectors. Finally, such data was discussed about their implications from a governance perspective.

3 Content analysis

3.1 Evolution of product data management in digital product passport

Historically, PDM has been defined as a single repository of heterogeneous data related to the entire product lifecycle, with utility limited to the boundaries of the organization. In this context, data (such as CAD drawings, bills of materials, and analysis reports) served primarily to optimize the design and production phases (Do, 2017; Liu et al., 2021). However, this model led to the creation of information silos, where data remained trapped in fragmented ecosystems and a persistent reliance on paper-based documentation. All of this resulted in high interoperability costs between different systems, difficulties in traceability throughout the entire supply chain, and risks related to intellectual property (Mabkhot et al., 2025). To overcome fragmentation, research introduced the concepts of Digital Twin and Digital Thread. While the Digital Twin provides a synchronized virtual representation of the physical asset to monitor performance, the Digital Thread aims to link the data flow across all phases of the lifecycle. Despite this approach, however, these tools have often remained limited to ad hoc applications and focused on operational benefits for the manufacturer, with poor interoperability among different supply chain actors (Mabkhot et al., 2025). The introduction of the DPP, driven by European regulations such as the ESPR, marks the definitive evolution of the PDM into a tool for universal transparency (Langley et al., 2023). The DPP is no longer just an internal technical data sheet, but a 'digital identity card' that accompanies the product throughout its entire lifecycle (Gösken, 2025; Petrik et al., 2025). This evolution is driven by the need to bridge the information gaps that hinder the circular economy, making data actionable not only for businesses

but for all stakeholders (Kemmner et al., 2025; Mollahassani et al., 2025). The true transformation lies in expanding the user base; in fact, the DPP acts as a 'boundary object' that facilitates a common language among different actors (Gieß et Möller, 2025; Petrik et al., 2025). In particular, among these we can identify consumers, who, through the DPP, are able to make informed purchasing decisions based on verifiable data regarding environmental footprint, durability, and reparability (Gieß et Möller, 2025; Ruismäki et al., 2025); repairers and recyclers, who will have detailed instructions on disassembly and material composition—information essential for the recovery of raw materials (Carvalho et al., 2025); and authorities, for whom it enables verification of compliance with environmental and social regulations (Gösken, 2025; Langley et al., 2023) and for the supply chain, ensuring collaboration among suppliers and improving risk management and the traceability of raw materials (Abreu et al., 2025; Hakola et al., 2025).

Data management has thus evolved from a technical support activity into a strategic lever for social and environmental responsibility, where data becomes a digital common necessary to ensure global sustainability (Kemmner et al., 2025; Mollahassani et al., 2025). Therefore, among the key drivers of this evolution, we can certainly identify the European Union's legislative package related to the Green Deal and the CEAP. In particular, the ESPR regulation mandates the creation of the DPP as a mandatory requirement for placing products on the European market, starting with high-impact sectors such as electric batteries and textiles, requiring data that is not only collected but also accessible and verifiable (Jensen et al., 2024; Petrik et al., 2025; Saenz et al., 2024). In addition to regulatory requirements, the DPP was created to bridge the information gap across the supply chain by centralizing data from various stakeholders into a single digital identity, overcoming the fragmentation of the traditional model (Cruz et al., 2025; Kebede et al., 2024; Wan et Jiang, 2025). Furthermore, changing purchasing behaviour has required greater transparency regarding origin, working conditions, and carbon footprint to avoid greenwashing (King et al., 2023; Ospital et al., 2023; Papile et Del Curto, 2025; Ruismäki et al., 2025), as also demonstrated by empirical studies showing that consumers are willing to pay a premium of up to 17% for products bearing a label certifying their sustainability (Colasante et al., 2025; D'Adamo et al., 2025), serving as a bridge of trust between brands and the public (Alves et al., 2023; Carvalho et al., 2025; Jeganathan et Szymkowiak, 2025). As a further key aspect, it is impossible to implement circular economy strategies without precise technical data about product end-of-life (Mollahassani et al., 2025).

The literature also points to a shift from mere operational efficiency to a human-centric approach (Voulgaridis et al., 2024). The DPP has also been adopted to protect intellectual property (Gösken, 2025) and, through the use of blockchain, allows the product's history to be recorded in an immutable manner (Colasante et al., 2025; Jensen et al., 2023; Panza et al., 2023).

3.2 Technology architecture and digital pillars for data governance and transparency

The literature reviewed identifies an integrated technological architecture that serves as the cornerstone for the digital governance of the DPP. In particular, recent research highlights that the interaction between product data and advanced digital tools is essential for ensuring transparency, accountability, and sustainability in global supply chains (Abreu et al., 2025; De Diego et Gutiérrez-Aguero, 2025; Papile et Del Curto, 2025). Among the technologies playing a key role in data governance, blockchain stands out (Abreu et al., 2025). It is considered the technology of choice for establishing a 'digital chain of trust'; it provides a decentralized and immutable ledger where every transaction or product transformation is chronologically recorded, preventing tampering and fraud. Thanks to the use of Smart Contracts (Liu et al., 2021; Voulgaridis et al., 2024), it enables the automation of governance rules, verifying the identity of actors and managing access rights in a granular manner; meanwhile, integration with Self-Sovereign Identity (SSI) systems (De Diego et Gutiérrez-Aguero, 2025; Langley et al., 2023) ensures that companies retain control over their sensitive data, sharing only the information necessary for regulatory compliance. On the other hand, IoT enables the automated and continuous collection of data from the field through the use of smart sensors that monitor critical parameters—such as energy consumption—in real time, transforming the product passport from a static record into a dynamic document (De Diego et Gutiérrez-Aguero, 2025; Fares et al., 2025; Kemmner et al., 2025). Technologies such as RFID and NFC overcome the limitations of traditional barcodes, enabling the unique identification of individual garments or components and facilitating tracking throughout the entire lifecycle, from production to end-of-life (Hakola et al., 2025; Wan et Jiang, 2025). Furthermore, to avoid creating new silos, the DPP must be integrated with existing IT infrastructures, and the adoption of modular ontologies standardizes data formats, allowing heterogeneous systems (ERP, SCM) (Alves et al., 2023; Cruz et al., 2025; King et al., 2023) to communicate with one another without technical barriers. Integration with enterprise management systems reduces the administrative burden and the risk of human error resulting from manual data entry (Petrik et al., 2025).

4 Mapping Data Across the Supply Chain: A Proposed Framework for DPP

In this study, the analysis focused on identifying and organizing the data generated and exchanged throughout the supply chain, with particular attention to its potential contribution to the development of the DPP. This classification (shown in Figure 2) has made it possible to map the relevant data across the supply chain in a coherent and systematic manner, providing a solid foundation for the definition and implementation of the DPP. This analysis outlined the sectors affected by the introduction of the DPP are the following: constructions (Çetin et al., 2023; Kebede et al., 2024; Pracucci et Giovanardi, 2025; Ruismäki et al., 2025; Vergés et al., 2026), textile (Alves et al., 2023; Carvalho et al., 2025; Colasante et al., 2025; Cruz et al., 2025; D'Adamo et al., 2025; Domskienė et Gaidule, 2024; Gonçalves et al., 2025; Ospital et al., 2023; Papile et Del Curto, 2025; Won, Y.; Jang, S.; Kim, H.Y.; Lee, Y.원 et al., 2025), manufacturing (Jensen et al., 2023, 2024; Mollahassani et al., 2025; Panza et al., 2023), electronics (Saenz et al., 2024), energy (Boukhatmi et al., 2023), EV battery (Kim et al., 2023). Moreover, in some studies the resulting data are regarded as cross-sector since it serves multiple industries (De Diego et Gutiérrez-Aguero, 2025; Fares et al., 2025; Gieß et Möller, 2025; Kühn et al., 2025; Wan et Jiang, 2025).

A total of 42 information factors were identified and subsequently organized into 10 categories to facilitate the data interpretation and integration.

Moreover, such categories have been further linked to ESG criteria. The environmental (E) perspective encompasses five categories. The first category "Material & Composition" includes data regarding the nature of raw materials, including virgin and circular-origin materials, bio-based characteristics, as well as the product's composition with particular attention to the presence and quantity of chemicals and the bill of materials. On the other hand, End-of-Life (EoL) data which includes instructions for disassembly and disposal, the amount of waste generated, recovery strategies (R-strategies), and the product's residual economic value was included in the "EoL & Circularity" category. Then, "Environmental Performance" category involved indicators and impacts by considering emissions and liquid effluent volume according to a circular and non-renewable approach.

Some factors related to energy consumption during the manufacturing process as well as the energy consumption in service was considered respectively within "Production" category and "Use Phase & Performance" one. The rest of factors included in those categories were referred respectively to Governance (G) and Social (S) criteria.

Therefore, the Governance (G) perspective encompasses a total of five macro-categories. "Design & Technical" category collects information regarding the physical and technical properties of the product, including digital models (e.g., CAD, BIM). Another key area is "Product Identification", which encompasses all identifying information related to suppliers and manufacturers, including identity, ownership, product code, product category, and the location of the production site. On the other hand, the "Traceability" category focuses on the data related to packaging and information needed to ensure product traceability throughout its supply chain by considering both past-oriented information (tracing) as well as present & forward information (tracking). Finally, the "Deployment & Support" category includes product warranty factor, whereas the remaining factors support users and are therefore aligned with the Social (S) lens.

Finally, in addition to the abovementioned categories, the "Social Impact & Compliance" category was included from a Social (S) point of view too. It includes ethical and social responsibility aspects related to working conditions, hours worked, and corporate policies as well as certification standards.

Figure 2. Data Mapping Framework for DPP according to ESG criteria.

5 Discussion and Conclusions

Since the various stages of the value chain involve a multitude of stakeholders, each responsible for the production, management, or transmission of specific information, a holistic approach is necessary to capture the heterogeneity and distributed nature of these data flows. In this respect, the research highlights how the digitalization of information can translate regulatory requirements into concrete operational advantages, by structuring data according to the environmental, social, and governance (ESG) dimensions.

It is important to highlight that, when considering data mapping from a multi sector perspective, not all data categories hold the same level of relevance across industries. Some types of data emerge as broadly applicable, supporting several sectors with relatively standardized structures, while others are more tightly linked to specific industrial contexts and operational characteristics. This distinction reflects underlying structural and functional differences between industries, which influence both the relevance and the level of detail of product-related data throughout its supply chain. Specifically, among those data (factors) related to highly formalized digital design representations (e.g., CAD/BIM models) are predominantly relevant in sectors like construction or advanced manufacturing, where design processes rely heavily on standardized digital modeling. Similarly, data such as detailed bill of materials, production date, expected lifespan, operating and safety instructions, and installation or use instructions tend to be more prominent in sectors characterized by high levels of standardization, regulatory requirements, and product complexity. Their reduced presence in other sectors may reflect differences in production processes, documentation practices, and perceptions of product durability and use conditions. Among data concerning "Traceability" category, the highest relevance is addressed to packaging which can also vary significantly depending on the sector, influenced by factors such as logistics complexity, regulatory constraints, and its role along product value chains. Likewise, in the "Use phase & Performance" category, factors such as product installation and energy consumption in service are critical in some industries (e.g., energy-using products or technical equipment), while being marginal or not directly applicable in others. Moreover, from the analysis is emerged a clear emphasis on some factors that represent a converging baseline of product information requirements driven by sustainability regulations, circular economy objectives, and the need for greater transparency and traceability. Specifically, they include environmental impact data, certification standards, and information supporting circular economy R-strategies (e.g., reuse, repair, remanufacturing,

recycling). Strong attention is also given to disassembly and disposal instructions, product composition data, and the identification and quantification of hazardous (and non-hazardous) chemical substances.

Although the importance of sustainability aspects to be included within the DPP is growing, the existing literature highlights significant gaps in the lack of systematic and scalable methods to structure heterogeneous data for Environmental Product Declarations (Vergés et al., 2026). Furthermore, the effectiveness of circular models strongly depends on the adoption of eco-design principles, including repairability and the use of innovative materials such as bio-based fibers and recycled components. These aspects should be considered elements in an environmental impact assessment conducted through Life Cycle Assessment (LCA) analysis.

In addition, the social perspective of DPP must be considered to ensure social responsibility along the supply chain by including the previously mapped factors in line with the Corporate Sustainability Due Diligence Directive (CSDDD).

Data gaps do not merely represent sectoral limitations, but concrete opportunities for a systemic innovation. From a managerial perspective, companies should prioritize tailored approaches rather than one-size-fits-all models by integrating data on product documentation, use-phase impacts, and user interactions. By enhancing transparency and traceability, governance needs are addressed, ensuring verifiable information on product origin, material composition, and end-of-life management. Therefore, investing in digital infrastructures, data standardization, and enhanced supply chain collaborations will strengthen data management practices. The benefits are multiple: more accurate sustainability assessments, facilitated regulatory compliance, and support for informed decisions along the value chain. Ultimately, a strategic view of the DPP is essential: it not only provides structured information but empowers consumers for informed choices, recyclers for material recovery, regulators for standards enforcement, and generates new opportunities in traceability, resale, repair, and recycling.

It is also important to note that the analyzed literature reflects a relatively recent and rapidly evolving research field. Therefore, some identified gaps can be partially attributed to the early stage of DPP development as it is still evolving and will become progressively mandatory under upcoming regulatory requirements in the coming years.

Future research should investigate how sectoral specificities shape DPP data requirements, develop interoperable data models, and empirically validate the integration of missing data categories to measure their impact on sustainability performance.

Managing Sustainability in a Fashion Supply Chain: The Case of an Italian SME

Sara Ianniello, Livio Cricelli, Serena Strazzullo
University of Naples Federico II, Naples, Italy

Abstract

Sustainability regulations and voluntary standards are increasingly transforming fashion supply chains into information-intensive systems, in which firms are expected to document practices that extend beyond their organisational boundaries. This is particularly relevant in the fashion supply chain, where, although these requirements are usually defined by large focal firms, their implementation often depends on small and medium-sized enterprise (SME) suppliers that collect, interpret, and transmit sustainability information across multiple tiers. However, how SMEs manage sustainability information flows across organisational boundaries remains underexplored. To address this issue, the study draws on knowledge governance literature on supply chains and adopts a single case study based on semi-structured interviews, with an Italian SME operating in a fashion supply chain. Findings show that sustainability information management is mainly driven by customer requests and unfolds as a document-based process of acquisition, internal processing, and dissemination. The SME acts as an intermediary knowledge broker, translating external requirements into operational requests for suppliers, laboratories, and consultants, while sending documentary evidence back to customers. However, the process remains constrained by limited internal verification capabilities and strong dependence on third parties. The analysis identifies a hybrid governance configuration across the fashion supply chain, dominated by contract-based mechanisms, reinforced by market-based pressures, and supported by trust-based coordination, whereas reciprocity-based mechanisms appear marginal. The study contributes to knowledge governance and sustainable supply chain literature by showing how SMEs manage sustainability information under asymmetrical pressure and resource constraints, highlighting both their enabling role and organisational barriers to sustainability implementation. From a managerial perspective, the findings suggest that SMEs should strengthen internal management through simple procedures, clearer allocation of responsibilities, and shared tools for document collection and storage. At the same time, focal firms and policymakers should provide greater support, ensuring that standards, documentary obligations, and reporting tools do not become unsustainable administrative burdens.

Keywords: case study, fashion industry, SME, supply chain, sustainability.

Paper type: Academic Research Paper

1 Introduction

In recent years, sustainability regulations and voluntary standards have progressively expanded firms' responsibilities beyond their own organisational boundaries, requiring them to monitor, document, and report sustainability practices throughout their supply chains (European Commission, 2023). The European Union Corporate Sustainability Reporting Directive (CSRD) reinforces disclosure obligations across the entire value chain, significantly increasing the amount and complexity of sustainability-related information that companies are required to collect, process, and exchange.

At the same time, academic debate has shown a growing relevance of sustainability in global supply chains, encouraging extensive research across sustainability management, supply chain management, and corporate governance. Within this context, the knowledge management literature has conceptualised supply chains as knowledge systems in which competitive advantage depends on resource ownership but also on the ability to create, share, integrate, and apply knowledge across organisational boundaries (Foss & Mahoney, 2010; Zhao et al., 2021).

From this perspective, knowledge governance mechanisms have increasingly gained attention as a perspective for understanding how knowledge processes are structured and coordinated within and across organisations. It refers to the set of formal and informal rules that shape how knowledge is created, shared, accessed, and applied, thus influencing the effectiveness of knowledge-related activities (Foss & Mahoney, 2010; Zhao et al., 2021).

Empirical studies have demonstrated that such mechanisms influence knowledge sharing and integration, ultimately affecting organisational and supply chain performance.

While this distinction provides a useful starting point, it may be insufficient to fully capture the diversity of governance arrangements observed in complex inter-organisational contexts. For this reason, several scholars

propose a more granular classification of knowledge governance mechanisms into four main types of mechanisms (Zhao et al., 2021): trust, market, reciprocity, and contract-based.

However, this stream of research has largely focused on focal firms' innovation outcomes, with limited attention to sustainability enforcement along supply chain.

Only recently have scholars begun to acknowledge that implementing sustainability is inherently knowledge-intensive, requiring continuous interpretation, translation, and validation of heterogeneous information among multiple actors (Miandar et al., 2024). Gong et al. (2018) show that sustainability in multi-tier supply chains is learned through processes of resource orchestration involving focal firms and supply chain partners, and that it requires deliberate efforts to mobilise resources, coordinate actors, and support the acquisition and internalisation of sustainability. Similarly, Gualandris et al. (2015) suggest that sustainability in supply chains is not simply a matter of compliance, but also a matter of organising information in processes embedded in everyday organisational practices.

This issue is particularly significant in fashion supply chains, which are typically organised as multi-tier and geographically dispersed production networks. In the European fashion supply chain, apparel production is frequently supported by networks of specialised small and medium-sized enterprises (SMEs) involved in sourcing, processing, subcontracting, and manufacturing activities (European Commission, 2023). Specifically, the European fashion value chains rely on a dense base of Italian suppliers, while the broader textiles ecosystem is overwhelmingly composed of SMEs. Within this context, focal firms coordinate design, branding, and market access, while a wide range of manufacturing and sourcing activities are carried out by legally independent and often small actors (Arimany Serrat et al., 2025; Singhal, 2023). Thus, sustainability requirements are often operationalised by SMEs that must transmit them across the supply chain. Existing studies have shown that first-tier suppliers play an important coordinative and interpretive role in cascading sustainability demands along multi-tier supply chains (Jia et al., 2021); yet little is known about how SMEs manage sustainability and which governance mechanisms emerge with the other actors involved in processing it. From a theoretical perspective, this raises important questions for the knowledge governance literature. Prior studies on knowledge governance mechanisms have mainly examined how such mechanisms support knowledge exchange, integration and supply chain performance (Zhao et al., 2021). Less attention has been paid to how these mechanisms operate when SMEs are required to manage sustainability-related information under asymmetric customer pressure, limited internal resources and dependence on external actors (Abdul Basit et al., 2024; Nath et al., 2024). As a result, knowledge governance mechanisms may operate differently. Accordingly, this study contributes to the knowledge governance literature and addresses the following research questions:

- ***RQ1****: How does an SME operating in a European fashion supply chain manage the sustainability information?*
- ***RQ2****: How do knowledge governance mechanisms along the European fashion supply chain shape sustainability information management within an SME?*

To answer these research questions, the authors adopt an exploratory single case study approach based on semi-structured interviews, designed for an Italian SME operating in a European fashion supply chain. The aim is to understand how the SME manages sustainability information in response to external demands, how different governance mechanisms shape the process across the supply chain actors, and what drivers and barriers emerge in this process.

2 Theoretical Perspective

2.1 Knowledge governance mechanisms

Durst & Edvardsson (2012) define knowledge management as the set of processes and structures through which firms support knowledge-related activities such as transfer, storage, and creation. Within this broad stream, a more specific line of investigation has developed around knowledge governance. This perspective examines the mechanisms through which such processes are coordinated and regulated. As Zhao et al. (2021) explain, a common distinction in the literature differentiates between formal and informal knowledge governance mechanisms. Formal mechanisms rely on codified structures and managerial tools, such as performance evaluation systems, incentives, training programs, and reward schemes, which are designed to motivate individuals to engage in knowledge creation, sharing, and transfer activities. In contrast, informal mechanisms are rooted in social and relational dimensions, including trust, shared norms, and teamwork, which facilitate knowledge exchange through interpersonal relationships and mutual understanding.

Compared to the broader distinction between formal and informal mechanisms, there is another approach that divides mechanisms into four categories (Zhao et al., 2021):

1. Trust-based mechanisms emphasise the role of mutual confidence in enabling knowledge exchange. Trust reduces perceived risks associated with opportunistic behaviour and facilitates the transfer of tacit knowledge, which is often difficult to codify. Prior research highlights several factors that contribute to the development of trust, including prior relationships, third-party referrals, open communication, and geographical proximity.
2. Market-based mechanisms, on the other hand, rely on price signals and economic incentives to regulate knowledge exchange. In this case, knowledge is treated as a tradable resource, and its transfer occurs through market transactions based on supply and demand conditions.
3. Reciprocity-based mechanisms are grounded in mutual exchange relationships, where actors share knowledge with the expectation of future returns. Drawing on the notion of reciprocity as "giving and receiving according to need", this mechanism fosters stable and long-term relationships, which in turn facilitate the sharing of valuable knowledge and resources. Such relationships are particularly important in networked environments, where sustained interactions enhance collaboration and knowledge diffusion.
4. Contract-based mechanisms rely on formal agreements that define roles, responsibilities, and obligations among partners. Contracts function both as coordination tools and as safeguards against opportunistic behaviour and uncertainty. In addition, they allow adaptation to changing conditions and can support learning processes by structuring interactions and clarifying expectations.

This approach enables the identification of specific governance practices and their role in facilitating interactions among actors. For these reasons, it has been widely used to explain how knowledge exchange is regulated in inter-organisational contexts, particularly in supply chains characterised by distributed knowledge, heterogeneous actors, and coordination challenges (Foss & Mahoney, 2010). This is particularly relevant in the fashion supply chain, when lots of SMEs are required to process a wide range of information, with limited internal resources and high dependence on external actors (Sartori et al., 2020). Compared to large firms, SMEs typically rely on less formalised approaches, as financial, human, and technological constraints limit the adoption of structured systems and dedicated functions (Abdul Basit et al., 2024; Nath et al., 2024; Sartori et al., 2020). Related studies on fashion supply chains show that sustainability implementation depends on the ability to coordinate multiple actors across tiers. Karaosman et al. (2020) demonstrate that this coordination is built through a combination of formal and relational practices, including supplier engagement, long-term trading relationships, and the mobilisation of technical and relational resources. However, they also show that these practices do not automatically ensure full transparency, since end-to-end visibility remains difficult to achieve in fragmented fashion supply chains. Some scholars extend this view: sustainability-oriented innovation emerges through the ability of a focal SME to monitor its external environment, involve relevant partners, combine internal and external resources, and activate capabilities across the network (Ermini et al., 2024).

2.2 Conceptual model

In the Italian context, the fashion industry is characterised by a dense network of SMEs that operate within European supply chains. Within these networks, SMEs are increasingly required to align with the sustainability standards, reporting practices, and information requirements imposed by focal firms. This growing external pressure suggests that, even in traditionally informal organisational settings, SMEs may progressively adopt more structured and formalised governance mechanisms within the supply chain to manage sustainability information.

As a result, contract- and market-based mechanisms, which have generally been less visible, may become more relevant when considering the entire chain currently.

Building on this perspective, the present study adopts a knowledge governance approach as the main theoretical lens. While Zhao et al. (2021) examine knowledge governance mechanisms mainly in relation to supply chain performance, this study uses the same categorisation to investigate how sustainability information is managed across supply chain actors. In line with Gualandris et al. (2015), sustainability information management is conceptualised here as a process characterised by three sequential phases: acquisition, internal processing, and dissemination across the supply chain. From this perspective, the study investigates how different governance mechanisms between the SME and the other actors influence how an SME acquires, interprets, and shares sustainability-related information. Figure 1 presents the conceptual framework guiding the analysis.

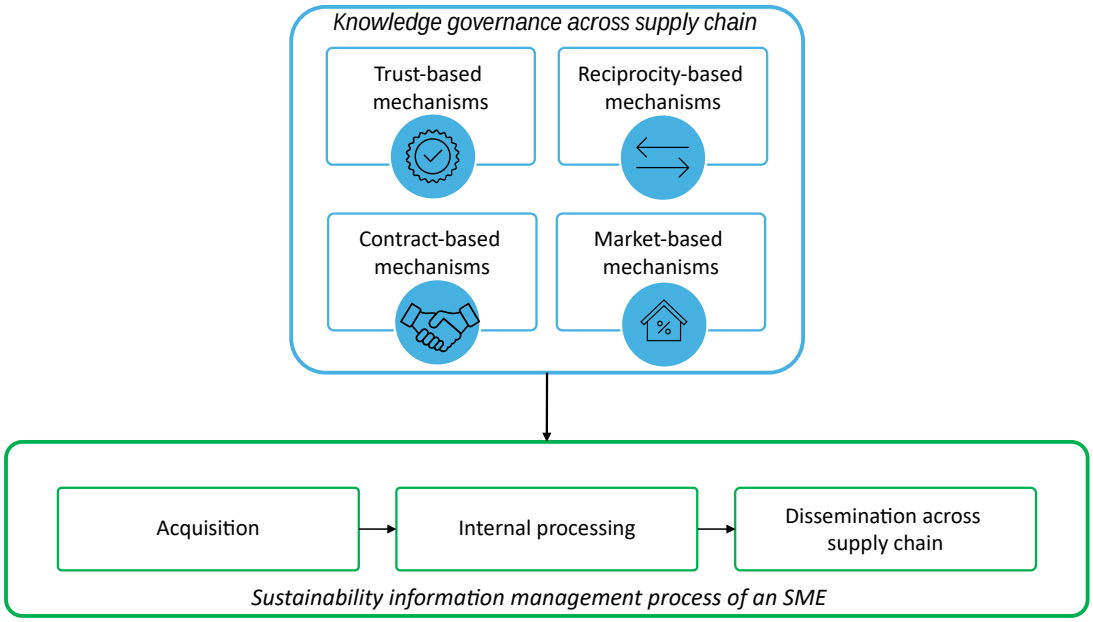

Figure 1: Conceptual framework adapted from Zhao et al. (2021).

3 Method

This study adopts an exploratory single case study, based on semi-structured interviews, widely recognised as an effective method for exploring knowledge processes and governance mechanisms. A single case study is particularly appropriate when the research aims to answer "how" and "why" questions and to explore contemporary phenomena within their natural context. Moreover, it allows for an in-depth investigation of organisational processes that are difficult to observe through large-scale quantitative methods.

Case selection

The study focuses on a single Italian SME operating within a European fashion supply chain. The firm was selected through purposeful sampling because it represents an information-intensive context. Specifically, the company coordinates relationships between international fashion brands and upstream suppliers in the manufacture of men's trousers. This positioning makes it a particularly suitable case for investigating how the sustainability information process is managed along the supply chain.

Data collection

The interviews involved 5 organisational actors whose expertise areas are detailed in the following Table 1:

Table 1: Characteristics of the interviewed experts.

Expert	Organizational role	Main expertise
1	Production	Materials, fabrics, product tests, supplier interaction, laboratory testing
2	Administration	Administrative documentation, contracts, supplier regularity, formal declarations
3	Ownership and commercial management	Client relationships, market pressures, supplier coordination, responsibility allocation
4	Commercial and customer interface	Client requests, traceability, certifications, supplier documentation, information flows
5	Commercial and operational support	Customer requests, supplier communication, product information

The interview protocol was designed to explore all the dimensions identified in the conceptual model:

1. how sustainability information is collected and received from external stakeholders;
2. how such information is internally processed, interpreted, and validated;
3. how it is shared and disseminated across supply chain actors;
4. what governance mechanisms are implemented along the supply chain;
5. relations between the process and the governance mechanisms adopted, complemented by a matrix;

3.1 Data analysis

First, the empirical material was analysed using a thematic analysis approach. Following Saldaña (2013), interview data were analysed through a two-step coding process. First, relevant extracts from the transcripts were condensed into brief descriptive labels, generating initial nodes and preliminary sub-themes. These were then reviewed and grouped according to conceptual similarity. The analysis followed three coding steps: open coding, to inductively identify categories emerging from participants' accounts; axial coding, to explore relationships among codes; and selective coding, to refine higher-order themes capturing the core patterns of the data. An example of the coding process is provided in Table 2.

Table 2: Example of the coding process.

Expert	Interviews sentences	Open code	Axial code	Selective code
1	*"Clients request certifications, chemical tests, fabric conformity documents and laboratory analyses, such as REACH, OEKO-TEX and product-specific tests"*	Documentary and technical sustainability requirements	External pressure and documentary formalization	Sustainability information management as externally driven compliance work

The second stage of the data analysis involved the expert-based construction of an impact matrix aimed at assessing the influence of each knowledge governance mechanism on the different phases of the sustainability information management process. Experts were asked to assign a score from 1 to 3, where 1 indicated a weak impact, 2 a moderate impact, and 3 a strong impact. A weak impact was assigned when the mechanism did not influence how sustainability information was managed. A moderate impact indicated that the mechanism was present only marginally or occasionally. A strong impact was assigned when the mechanism made a relevant contribution to the process.

4 Results

4.1 Thematic analysis

The coding process identified four main themes that explain how sustainability information management unfolds across internal activities and supply chain relationships. These themes are discussed below.

4.1.1 Sustainability information management process

Regarding the first research question, the empirical evidence shows that sustainability information management, rather than emerging as a fully internalised managerial process, takes the form of a reactive and document-based activity through which the SME receives, interprets, collects and transmits sustainability requests of downstream actors.

In particular, the company is positioned between downstream customers and upstream suppliers, laboratories, consultants and production partners. Its role consists of receiving customer requirements, translating them into operational and documentary requests, mobilising the relevant actors and transmitting the collected evidence back to customers. Although the process is analytically divided into acquisition, internal processing and dissemination, the empirical evidence shows that these phases are recursive rather than strictly sequential. Specifically, requirements are received from clients, usually through emails, order-related documents, specifications, questionnaires, or contractual documents. These requirements are not limited to environmental issues, nor do they only concern product certification. They include product-related tests, chemical compliance, material certifications, traceability information, supplier declarations, social and ethical commitments, administrative documents, contractual obligations and, in some cases, customer-specific insurance requirements. The type of information requested varies depending on the client, the product, and the extent to which the SME directly manages the supply of fabrics and accessories. When customers indicate already approved suppliers, the SME assumes that such suppliers are likely to possess the required certifications. The requirements identified through interviews have been grouped in Table 3:

Table 3: Main sustainability requirements and information that SME manages.

Category	SME sustainability requirements
Product safety, chemical and environmental compliance	REACH compliance for fabrics
	Oeko-Tex certification for fabrics/materials
	Tests on fabrics, accessories, dyes, prints or treatments
	PFAS tests
	Evidence of absence or limited presence of harmful substances
	Laboratory test reports issued by certified or recognized bodies
Durability and product-performance requirements	Cross-staining test
	Colour fastness test
	Light fastness test
	Anti-pilling test
	Antistatic treatment for synthetic fabrics
Materials and product origin	Information on raw material origin
	Information on materials used in garments
	Certificates of origin
	Information on upstream suppliers, sub-suppliers or raw material producers
	Traceability information on the production chain
Social and ethical requirements	Ethical commitments regarding outsourced production activities
	Commitments concerning workers' treatment and labour-related standards
	Evidence of compliance with customer-defined social standards
	Codes of conduct requested by customers
Supplier responsibility and documentary assurance	Updated supplier sustainability certifications
	Signed declarations by suppliers assuming responsibility for the truthfulness of sustainability-related information
	Declarations of conformity concerning materials, products or production standards
Audit and inspection requirements	Customer audits on supply-chain conduct or sustainability-related requirements
	Physical inspections at suppliers, laundries, "façoniste", or foreign production sites
	Evidence of production processes when required by customers for sustainability or traceability purposes

Following, the SME collects the required documents from suppliers, external laboratories, consultants, accountants or other supply chain actors. Importantly, the empirical evidence does not support the existence of a systematic internal verification phase. The SME does not usually have internal tools or dedicated competencies to technically verify the sustainability information received. Instead, the firm relies on external sources of assurance. Finally, the information is transmitted back to the client, generally through email, PEC or standard documentation.

4.1.2 Sustainability information management as externally driven compliance work

The second theme shows that sustainability does not emerge primarily as a personal strategy, but as a set of documentary and technical obligations imposed by downstream actors. Interviewees report that customers increasingly request evidence of compliance. The owner confirms that medium-high brands request several requirements, creating internal organisational work to respond to these demands. As a result, the SME is indirectly exposed to sustainability regulation through the imposition by focal firms, while remaining only marginally involved in the definition of the standards it is expected to implement. This creates a cascading accountability structure, in which the focal firm becomes responsible not only for its own practices, but also for demonstrating the compliance of suppliers, subcontractors and material providers. Such a dynamic is particularly challenging for a small firm, as it must respond to complex and evolving requirements without necessarily having the internal resources, expertise or bargaining power of larger organisations.

4.1.3 Hybrid governance: formal requirements managed through informal coordination

The interviews point to a hybrid form of governance in the management of sustainability information. Formal and market-based mechanisms have become increasingly relevant, as they exert pressure on the SME to comply with external expectations to maintain commercial relationships and access to important clients. However, formal mechanisms do not fully replace relational forms of governance. Trust-based relationships with long-standing clients and suppliers remain essential for facilitating communication, accelerating information

exchange and reducing uncertainty in situations where documentation is incomplete or difficult to obtain. This is especially problematic when information concerns upstream actors, indirect suppliers or the origin of materials, where transparency is more difficult to achieve. Moreover, since the SME lacks dedicated internal tools and technical competencies to produce and then verify this information directly, the internal processing phase remains dependent on third-party declarations and documentation.

Therefore, the sustainability information management process relies on the coexistence of contractual obligations, market pressures and relational trust. This hybridity reflects the practical need to combine formal compliance with informal coordination to manage complexity across the fashion supply chain.

4.1.4 Learning-by-doing under resource and capability constraints

The last theme captures the learning process through which the SME gradually develops practical knowledge about sustainability information management. Interviewees explain that certifications such as OEKO-TEX and REACH were initially difficult to understand; over time, however, the company learned which actors to contact, how to request documents and how to obtain information more quickly. This learning remains fragile because it depends on accumulated experience, external consultants, suppliers and a limited number of internal actors. The owner emphasises that a small firm would need legal, accounting and technical expertise to manage all customer requirements precisely, but such competences are mostly external and limited by time and cost. Overall, low competences, limited resources and lack of dedicated personnel remain key barriers.

4.2 Relational model

The thematic analysis was complemented through an expert-based matrix in which each interviewee assessed the perceived impact of four knowledge governance mechanisms, adopted along the supply chain, on the three phases of sustainability information management. The results show that contract-based mechanisms have the strongest overall impact, followed by market-based and trust-based mechanisms, while reciprocity-based mechanisms remain weak and marginal, consistent with the qualitative evidence. Average scores across experts were then synthesised into the relational model presented in Figure 2:

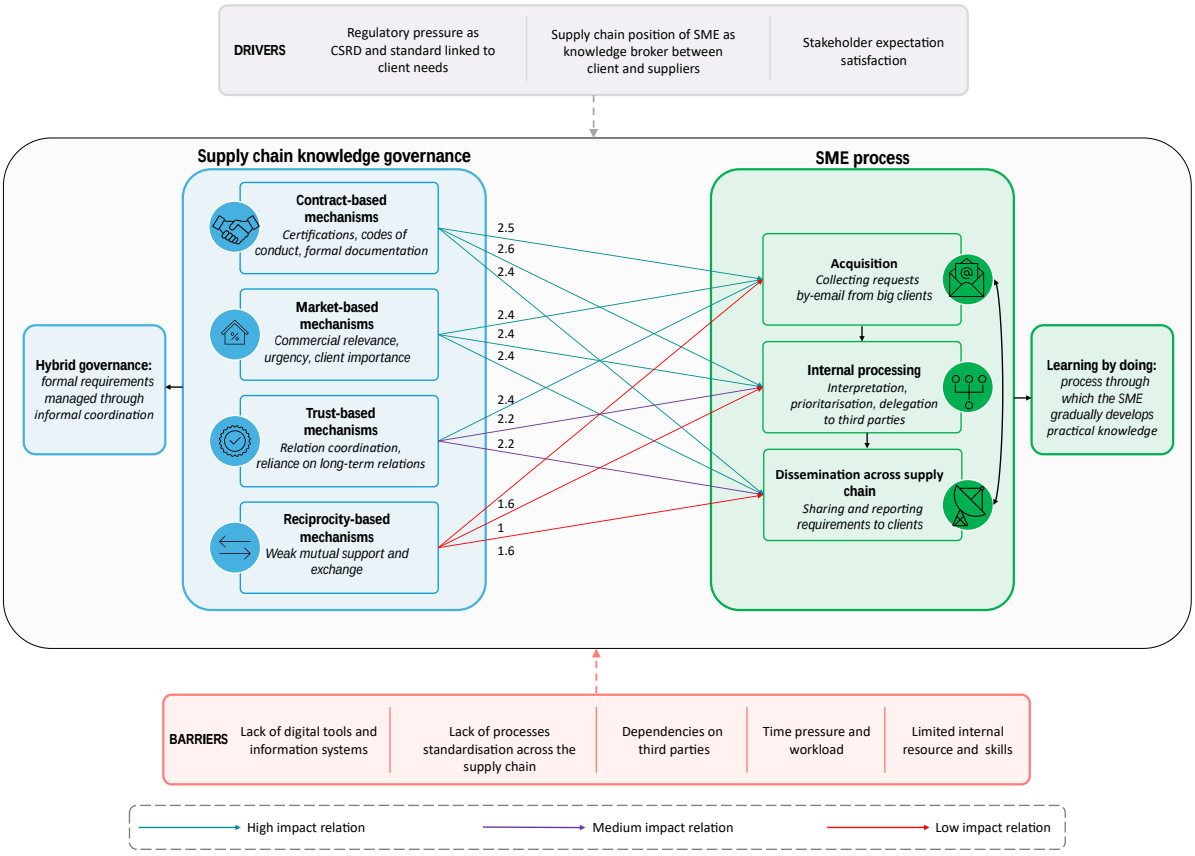

Figure 2: Relational model.

The model suggests that the sustainability information process is primarily activated by external drivers, including regulatory pressure, client requirements, and stakeholder expectations, consistent with Gualandris et al. (2015). The bidirectional arrow between acquisition and dissemination indicates that sustainability information management is not a linear process. According to the first theme, information circulates recursively from clients to the SME, from the SME to third parties, and back again to the SME and clients.

The central pattern emerging from the model is the hybrid governance configuration. Formal and informal mechanisms coexist, but they do not contribute equally to the process. Contract-based mechanisms structure what information must be collected, how it is validated, and how it is transmitted, through certifications, codes of conduct, test reports, supplier declarations, and client documentation. Market-based mechanisms further reinforce this formal orientation, as client importance, commercial urgency, and order relevance influence the prioritisation of sustainability requests.

Trust-based mechanisms play a supporting role: long-term relationships with clients and informal communication with suppliers help the SME obtain missing information, clarify ambiguous requests, and manage clients, but they do not replace formal documentation. Reciprocity-based mechanisms, instead, remain weak, suggesting that the process is more of a cascade of requests than a collaborative construction of knowledge.

Compared with studies that emphasise the informal nature of knowledge management in the fashion supply chain, informal practices are present (Ermini et al., 2024; Karaosman et al., 2020), but they are mainly activated to make formal requirements workable due to limited digital tools, incomplete procedures, uncertain supplier responses, time pressure, and resource constraints. This pattern is consistent with Ermini et al. (2024), who underline the importance of informal coordination mechanisms in sustainability implementation, but our findings add that these practices emerge as a pragmatic response to the incompleteness of formal systems. Over time, these constraints lead the SME to develop practical capabilities through learning by doing. In this sense, the role of knowledge governance differs from the innovation perspective often adopted in prior studies, such as Zhao et al. (2021): here, governance mechanisms aim to enable operational coordination, information reliability, and the circulation of sustainability knowledge across interdependent actors in the supply chain.

5 Conclusions

This study investigated how sustainability information is acquired, processed and disseminated within an Italian SME operating in a European fashion supply chain, and how knowledge governance mechanisms along the supply chain shape this process. Regarding the first research question, the findings show that sustainability information management is mainly activated by downstream customer requirements and unfolds as a document-based and recursive process. As a result, the SME performs an intermediary knowledge-brokering role, which interprets and coordinates heterogeneous sustainability requirements across multiple actors.

The research contributes to the knowledge governance literature by showing that, although sustainability information management within the SME remains partly informal and experience-based, its inter-organisational configuration is strongly shaped by contract-based and market-based mechanisms imposed along the supply chain. Thus, for the second research question, trust-based mechanisms do not replace formal requirements, but support their practical management when documentation is incomplete, ambiguous or difficult to obtain. Contract-based mechanisms define the documentary obligations, standards and responsibilities attached to sustainability requirements, while market-based mechanisms reinforce compliance through customer pressure, commercial urgency and the need to maintain access to valuable business relationships. By contrast, reciprocity-based mechanisms appear relatively weak, suggesting that sustainability information management is more of a cascading process of requirements, responsibilities and documentary evidence. These findings also extend the sustainable supply chain literature by highlighting the hidden organisational work performed by an SME in the implementation of sustainability standards. Therefore, the case shows that SME acts as critical but vulnerable nodes in sustainability governance: it absorbs administrative burdens, uncertainty and responsibility without always having adequate resources, expertise or digital tools.

From a managerial perspective, the findings suggest that the Italian SME should strengthen the internal organisation of sustainability information through simple but systematic practices, such as shared document repositories, standardised checklists, clearer responsibility allocation, and basic procedures for collecting, storing and verifying sustainability-related documents. These tools would not eliminate the need for external certifications or supplier declarations, but they could reduce dependence on individual experience and improve the reliability and traceability of information flows. At the same time, focal firms should recognise that sustainability requirements generate significant organisational work for SME suppliers. Similarly, policymakers

should consider the resource constraints of SMEs when designing reporting obligations and support mechanisms.

Finally, the study is subject to some limitations. First, it is based on a single case study and therefore does not aim at statistical generalisation. Second, the analysis focuses on the perspective of the SME, while future research could include clients, suppliers, laboratories and consultants to reconstruct the full multi-tier sustainability information flow. Third, the expert-based matrix captures perceived impacts of governance mechanisms and could be further developed or validated through comparative research. Moreover, future studies could examine how digital tools, shared platforms and standardised processes moderate the relationship between knowledge governance mechanisms and sustainability information management.

Competence Model for Collaborative Workplaces in Industry 5.0: Initial Insight

Tadej Crnjac[1], Robert Ojsteršek1, Marta Aranyossy[2], Zlatko Nedelko[1,2]
[1] University of Maribor, Maribor, Slovenia
[2] Corvinus University of Budapest, Budapest, Hungary

Abstract

Industry 5.0 emphasizes the synergy between humans and technology, where employees' competencies are critical for the effective implementation of collaborative workplaces. In this context, collaborative robots play a key role in modernizing organizational processes by increasing flexibility, usability, and reprogrammability (Segura et al., 2021; Ojsteršek et al., 2024). Research on human–robot collaboration (HRC), grounded in task analysis and ISO 10218-2 safety guidelines (International Organization for Standardization, 2011), highlights the need to align task requirements with human capabilities and competency profiles. Effective HRC requires not only technical knowledge but also cognitive and psychosocial competencies (Wilson & Salas, 2010; Villani et al., 2018; Salas and Rosen, 2020). Existing models typically distinguish four competency clusters: technical, safety, cognitive, and psychosocial. However, none provides a fully comprehensive framework for collaborative robotics (Werning et al., 2021; Simone et al., 2022; Wang et al., 2023; Potocan et al., 2024). This study addresses the gap by proposing a methodology for predicting competency weights, enabling structured learning approaches and supporting future empirical validation. Safety competencies are treated as embedded within technical, cognitive, and psychosocial dimensions, reflecting their integrative role in ISO-based HRC environments. The article develops an enhanced competency model based on task and job analysis aligned with ISO standards and applies the Analytic Hierarchy Process (AHP) to determine competency weights according to their impact on safety, efficiency, and work quality. The model integrates technical, cognitive, and psychosocial competencies, as well as ethical aspects, and emphasizes continuous professional development. To identify competencies, we combined a literature review with the Delphi method, collecting expert opinions through iterative rounds. This resulted in a comprehensive set of existing and additional competencies enabling safe and adaptive performance in collaborative environments. Employees were categorized into three groups: experts (Group A), students (Group B), and laypersons (Group C), reflecting different levels of prior knowledge and experience. Using ISO-based analysis, base competency weights were derived as follows: technical (0.30), cognitive (0.40), and psychosocial (0.30) (Romero et al., 2016; 2022). The model further combines AHP with TOPSIS, a robust multi-criteria decision-making approach (Opricovic & Tzeng, 2004). The main contribution lies in the methodological and normative development of a competency model for Industry 5.0 collaborative environments. The proposed framework establishes a foundation for empirical validation and practical application in personnel selection, training design, and task adaptation across different user groups.

Keywords: Competency Model, Industry 5.0, Human-Robot Collaboration, Human-Centered Manufacturing.

1 Introduction

The implementation of Industry 5.0 represents a major technological shift that transforms business environments and managerial paradigms (Richa Saxena & Arya, 2023). Within this context, collaborative robots play a central role by enhancing flexibility, usability, and reprogrammability in production systems (Segura et al., 2021; Ojsteršek et al., 2024). Their integration requires technical, cognitive, and psychosocial competencies to ensure safe and effective human–robot collaboration (Villani et al., 2018). However, literature highlights significant gaps in existing models. Several studies (Simone et al., 2022; Werning et al., 2021; Wang et al., 2023) emphasize insufficient attention to cognitive and psychosocial competencies, safety, ethical aspects, and continuous learning, as current approaches remain overly focused on technical skills (Potocan et al., 2024). This paper addresses this gap by proposing a methodology for predicting competency weights in collaborative workplaces, enabling structured learning design and supporting future empirical validation. The study develops an enhanced competency model that combines ISO-based task and job analysis with the Analytic Hierarchy Process (AHP) to determine the relative importance of technical, cognitive, and psychosocial competencies, including safety and ethical aspects, while emphasizing continuous professional development.

2 Existing and Additional Competencies

Through an in-depth analysis of competencies and requirements for the successful performance of defined tasks, while considering the work environment and safety standards in accordance with ISO 10218-2 guidelines (International Organization for Standardization, 2011), many publications on competency categorization in smart manufacturing (Frey & Osborne, 2017; Bughin et al., 2018) follow the study of Wilson and Salas (2010).

The authors identified four main competency clusters forming the basis of competency models in smart manufacturing: technical, safety, cognitive, and psychosocial competencies. The following chapters present the methodology for predicting the weights of technical, cognitive, and psychosocial competencies using the ISO analytical model, the AHP method, and the TOPSIS method (Technique for Order Preference by Similarity to Ideal Solution). The methodological framework begins with a theoretical review of competencies and the development of a comprehensive competency set. Competencies are then assigned to groups A, B, and C according to predefined criteria and importance. In the next phase, the AHP method is applied to determine competency weights through pairwise comparison, while the TOPSIS method is used to identify the optimal alternative based on the relative closeness index. Finally, the framework predicts the most suitable group for working with a collaborative robot and validates the model through the Delphi method and expert interviews.

2.1 Existing competencies

Existing competencies include the knowledge, skills, and abilities acquired through education and experience that enable individuals to manage complex systems and ensure safe and productive environments. Technical competencies remain the foundation of smart manufacturing and include knowledge of mechatronics, data analysis for production optimization and fault detection (Bahrin et al., 2016), and understanding of safety standards such as ISO 10218-1 (International Organization for Standardization, 2011). Alongside technical skills, cognitive competencies such as problem-solving, critical thinking, and adaptability are essential due to rapid technological change (Frank et al., 2019), while psychosocial competencies, including teamwork, communication, and stress resilience, are increasingly important in human-centered production environments (Spöttl & Windelband, 2021). Their integration, combined with continuous learning, is crucial for successful adaptation to digital transformation (Liu et al., 2024). Furthermore, traditional models often lack mechanisms for continuous competency development in rapidly evolving production systems (Liu et al., 2022).

2.2 Additional competencies

For the successful integration of collaborative robots into the production process, individuals must develop additional competencies to perform effectively in collaborative environments (Simone et al., 2022). In defining the key competencies of operators working with collaborative robots, this paper assumes that workplaces already include clearly defined tasks and focuses on the additional competencies required for safe and efficient human–robot interaction. Particular attention is given to ISO 10218-1, ISO 10218-2, and ISO/TS 15066 (International Organization for Standardization, 2016), which represent the main international standards in the field of collaborative robotics (Matheson et al., 2019). ISO 10218-1 defines safety requirements for the design and manufacture of industrial robots, including protective functions such as speed limitations, power and force monitoring, and emergency stop systems. ISO 10218-2 complements these requirements by focusing on the safe integration of robots into the work environment through protective barriers, safety sensors, and risk-reduction procedures. ISO/TS 15066 specifically addresses collaborative robots and safety in shared workspaces by defining threshold values for safe human–robot interaction and providing guidelines for risk assessment and permissible loads on different parts of the human body.

2.3 Assessment of additional competencies

To verify the validity of the proposed and additional competencies, we applied the Delphi method, systematically collecting expert opinions through multiple video-based rounds. This structured approach, based on iterative, anonymous surveys with feedback, is widely used to align expert views (Skulmoski et al., 2007) and is suitable for developing competency models in advanced technological contexts. The process included three rounds. In the first, experts were interviewed using a semi-structured questionnaire to evaluate technical, cognitive, and psychosocial competencies. Qualitative content analysis with thematic coding showed strong consensus on technical competencies (e.g., HMI, safety protocols) and cognitive competencies (e.g., problem-solving, spatial orientation), while psychosocial competencies (e.g., teamwork, stress resilience) were also identified as essential. Based on these findings, the second round introduced structured Likert-scale questions to assess competency relevance, identify gaps, and highlight challenges in human–robot collaboration, contributing to a more comprehensive validation of the model. In the third round, experts received group feedback and could revise their assessments, increasing consensus—especially for competencies with higher variability. Strong agreement was reached for most technical and cognitive competencies, while psychosocial competencies remained more diverse. The outcome was a validated list of key additional competencies, incorporated into the further development of the comprehensive competency model.

3 Comprehensive Competency Model

The process of integrating existing smart manufacturing competencies with additional competencies related to collaborative robots requires a systematic approach. This includes the analysis of production processes, assessment of job roles, consultation with experts, identification of additional competencies, and the integration of comprehensive competencies into a unified competency framework. The first step in this process is production analysis, where key processes in industrial environments—already using or planning to implement collaborative robots—are examined. This phase involves reviewing existing research, industry standards, and competency frameworks defined by ISO standards. It is followed by an analysis of job roles, technological requirements, and strategic objectives of the companies, focusing on how the introduction of collaborative robots affects task requirements. This phase includes a systematic evaluation of changes in technical knowledge, cognitive abilities, and psychosocial skills required by employees to work effectively in a collaborative robot environment (Dabić et al., 2021).

3.1 Formulation of comprehensive competencies

Existing and additional competencies together form a comprehensive framework enabling effective, safe, and adaptive work in collaborative environments. This study examines how technical, cognitive, and psychosocial competencies influence productivity in human–robot collaboration and their role in selecting suitable individuals. These dimensions must therefore be integrated into a unified competency profile to ensure successful performance (Welfare et al., 2019; Roychoudhury, 2023). Participants were divided into three groups: experts (A), students (B), and laypersons (C), reflecting different levels of prior knowledge and experience. Technical competencies were assessed differently across groups, while cognitive and psychosocial competencies were evaluated uniformly. Technical competencies represent the foundation for working with collaborative robots and include knowledge of programming, artificial intelligence, sensors, and automation (Huang & Wang, 2023). Experts require advanced understanding of robot operations (Siciliano & Khatib, 2016; Villani et al., 2018), whereas students possess mainly theoretical and basic practical knowledge (Smith & Peterson, 2019). Laypersons, in contrast, require only minimal technical skills. Cognitive competencies support problem-solving, decision-making, and adaptation in dynamic environments (Frank et al., 2019), while psychosocial competencies such as teamwork, communication, and stress management directly influence performance and safety in human-centered production systems (Le Blanc et al., 2020; Parker & Griffin, 2022).

3.2 Validation and generalization of the comprehensive competency model

The comprehensive competency model, integrating technical, cognitive, and psychosocial competencies, is designed to ensure effective, safe, and adaptable work in collaborative environments. Its scientific credibility was assessed through expert validation involving specialists in industrial robotics, ergonomics, work psychology, and human resource development. Following Thürer et al. (2022), the evaluation focused on the adequacy of competencies, clarity of definitions, and relevance for real industrial environments. Although primarily developed for collaborative robots, the model can be extended to other smart manufacturing systems. In Industry 5.0, employees increasingly work with technologies such as smart exoskeletons, digital twins, flexible manufacturing systems, AR/VR, and autonomous mobile robots (AMRs), all requiring varying combinations of technical, cognitive, and psychosocial competencies. The model's generalization is based on key factors, including the degree of human–machine interaction, collaboration requirements, technological complexity, and psychological resilience. Table 1 presents a comparative assessment of competency requirements across selected technologies.

Table 1: Comparative applicability of the competency model across smart technologies

Technology	Technical Competencies	Cognitive Competencies	Psychosocial Competencies
Collaborative robots	5	5	5
Smart exoskeletons	3	4	5
Digital twins	4	5	3
Flexible manufacturing systems	5	4	3
AR/VR support at work	3	4	4
Autonomous mobile robots	4	4	3

The results are consistent with prior research, highlighting high technical and cognitive demands in smart manufacturing (Thürer et al., 2022), the importance of psychosocial competencies in Industry 4.0 transitions

(Ergün and Cevickan, 2021), and the growing role of human adaptability in Industry 5.0 environments (Romero et al., 2021). The table is based on the analysis of technological complexity, competency clusters, relevant literature, and expert judgment, and represents a preliminary framework for further validation.

4 Theoretical Prediction of Competency Weights

In collaborative robotics, understanding the competencies of different user groups is essential for the successful implementation of new technologies. Before conducting the empirical study, it is important to predict the relative importance of competencies for each target group (experts, students, novices). Using standardized frameworks such as ISO 22156 (International Organization for Standardization, 2022), ISO 9241-210 (International Organization for Standardization, 2019), and ISO/TS 15066 (International Organization for Standardization, 2016), together with AHP and TOPSIS methods, enables the definition of competency significance in advance. Predefined weights improve methodological transparency and support empirical verification of competency assumptions across target groups (MacCoun, 2003). They also provide a basis for designing tasks and assessment tools aligned with the expected importance of competencies, supporting the development of suitable profiles for working with collaborative robots and identifying groups that require additional training or support.

4.1 Prediction of weights using the ISO analytical model

Using the ISO analytical model, we derived the weights of technical, cognitive, and psychosocial competencies through a methodological review and analysis of ISO standards (Romero et al., 2022). The weights were determined through the review of key standards, qualitative categorization and quantification of content, averaging of results across standards, and adjustment according to professional profiles and practical recommendations (Buhl et al., 2021). The identification of competencies was based on the relevance of each standard to human–robot interaction and assessed on a scale from 0 to 1 according to ISO/IEC 24773−1 (International Organization for Standardization & International Electrotechnical Commission, 2022). Each selected ISO standard was analyzed in terms of explicit and implicit requirements for the individual competency categories. The ratios were determined based on:

4.1.1 Qualitative Content Analysis:

- ISO 22156 (technical: 0.6, cognitive: 0.3, psychosocial: 0.1) focuses primarily on technical areas such as understanding robot operations, programming, and integration. The emphasis on technical competencies is rated at 0.6.
- ISO 9241-210 (cognitive: 0.6, psychosocial: 0.3, technical: 0.1) prioritizes user experience, perception, cognitive load, and decision-making processes, which aligns with the cognitive competency rating of 0.6.
- ISO/TS 15066 (psychosocial: 0.5, cognitive: 0.3, technical: 0.2) addresses human limits, risk, hazard perception, and teamwork, justifying the emphasis on psychosocial competencies with a rating of 0.5.

4.1.2 Consideration of the proportion of text related to each category:

For each standard, we analyzed the proportion of content (e.g., number of paragraphs, chapters, or sections) that directly or indirectly addresses a specific competency. Based on this, a weight was assigned on a scale from 0 to 1. For clarity, Table 2 presents a comparative analysis of the content distribution within each standard. For example, ISO 22156:2021 addresses technical aspects of human-robot collaboration (operating modes, safety systems, robot structure, etc.) in more than half of its content, which justifies assigning a weight of 0.6 to technical competencies. In contrast, ISO 9241-210:2019 focuses on the design of interactive systems from the user's perspective, frequently referencing cognitive load, decision-making, and information perception, which supports a weight of 0.6 for cognitive competencies. This approach ensures traceability and reproducibility of the assessment while providing a methodologically grounded basis for subjective judgment. Naturally, the credibility of the model could be further reinforced using a modified Delphi method as an alternative or enhancement.

Table 2: Comparative Analysis of Content Distribution in Each Standard

Standard	Percentage of Content on Technical Competencies	Percentage of Content on Cognitive Competencies	Percentage of Content on Psychosocial Competencies
ISO 22156:2021	60	30	10
ISO 9241−210:2019	10	60	30
ISO/TS 15066:2016	20	30	50

In the next step, based on the content analysis of the mentioned ISO standards, we determined the base weights of the three competency categories as the average emphasis across the individual sources: technical competencies: 0.30, cognitive competencies: 0.40, psychosocial competencies: 0.30.

4.1.3 Consistency with Other Normative and Applied Sources

The initial competency values did not fully reflect differences in prior knowledge and participant roles; therefore, they were additionally balanced according to real industrial requirements, where technical competencies often dominate (Buhl et al., 2021). This adjustment was supported by recommendations from the Fraunhofer Institute for Manufacturing Engineering and Automation and the ARENA2036 project, which combine ISO-based normative frameworks with advanced industrial practices in human–robot collaboration (Romero et al., 2022; ISO/IEC 24773−1:2022). In addition to ISO 10218−1, ISO 10218−2, and ISO/TS 15066, the balancing process considered ISO 12100 (International Organization for Standardization, 2010), ISO 22935 (International Organization for Standardization, 2009), ISO 45001 (International Organization for Standardization, 2018), and ISO/IEC 24773−1 (International Organization for Standardization, 2022), covering risk assessment, occupational safety, psychosocial factors, and operator competencies. Competency weights were then adjusted according to participant roles and industrial requirements: experts emphasized technical competencies, students a balanced combination of technical and cognitive competencies, and novices mainly safety and psychosocial factors.

Table 3: Balanced Weight Values

Group	Technical Competencies	Cognitive Competencies	Psychosocial Competencies
Experts	0.50	0.35	0.15
Students	0.30	0.40	0.30
Laypeople	0.20	0.35	0.45

Fraunhofer IPA (2020) emphasizes that balanced weights better reflect the characteristics of different target groups by considering their knowledge, robotics experience, and task requirements. Such weighting supports the development of targeted training programs and competency-based learning paths. Romero et al. (2020) further highlight those personalized approaches in digitalized manufacturing environments can improve motivation and reduce resistance to technological change.

4.2 Prediction of competency weights using the AHP method

For systematic prediction of weights, Multi-Criteria Decision Making (MCDM) methods can also be used, representing a structured approach for decision-making in situations where multiple, often conflicting criteria must be considered. One of the most widely used MCDM methods is the Analytic Hierarchy Process (AHP). The results are organized into a comparison matrix $\boldsymbol{A}$, where element a_{ij} represents the relative importance of criterion *i* compared to criterion *j*. The relative importance of criteria *i* and *j* is assessed using Saaty's scale, with values ranging from 1 to 9. The comparison matrix is reciprocally symmetric, meaning $a_{ij} = 1/a_{ji}$. Matrices comparing the importance of individual competencies for each target group are constructed based on expert evaluations and guidelines (Romero et al., 2020; Buhl et al., 2021; Liu et al., 2022; Huang & Wang, 2023). The criteria used for pairwise comparisons are technical (T), cognitive (C), and psychosocial (P) competencies. Prediction of Competency Weights for Experts:

	T	C	P
T	1	2	3
C	0.5	1	2
P	0.33	0.5	1

Working with collaborative robots requires a specific set of technical skills, as experts are expected to interact directly with the robot and actively contribute to the optimization of production processes. Prediction of Competency Weights for Students:

	T	C	P
T	1	0.5	2
C	2	1	2
P	0.5	0.5	1

In working with collaborative robots, expert opinion places the greatest emphasis on cognitive competencies, which enable students to effectively apply their understanding of technology, adapt to changing conditions, and solve complex problems in various situations. Prediction of Competency Weights for Laypersons:

	T	C	P
T	1	0.5	0.25
C	2	1	0.5
P	4	2	1

Expert opinion places the greatest emphasis on psychosocial competencies (e.g., communication, emotional stability) and considerably less on technical competencies, as laypersons lack technical knowledge and cannot actively operate in the world of collaborative robotics.

Table 4: AHP Weight Value

Group	Technical Competencies	Cognitive Competencies	Psychosocial Competencies
Experts	0.54 (0.50)	0.30 (0.35)	0.16 (0.15)
Students	0.31 (0.30)	0.49 (0.40)	0.20 (0.30)
Laypersons	0.14 (0.20)	0.29 (0.35)	0.57 (0.45)

Table 4 compares competency weights obtained with the AHP method and balanced ISO model values. Experts show the highest technical competency weights in both models, students are dominated by cognitive competencies, and laypersons by psychosocial competencies. Results from AHP and ISO-based weights show similar trends across all groups, confirming the stability of competency assessments.

4.3 TOPSIS procedure with AHP-derived weights

The combination of the AHP and TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) methods is considered one of the most effective approaches for multi-criteria decision-making (Opricovic & Tzeng, 2004). The AHP method determines criterion weights through pairwise comparisons, while TOPSIS identifies the optimal alternative according to its proximity to the ideal solution and distance from the worst solution. Their integration increases objectivity by combining systematic weight determination with quantitative ranking of alternatives (Sivalingam & Subramaniam, 2024; Tran et al., 2024). The procedure begins with defining the hierarchical structure of objectives, criteria, and alternatives. After determining weights with AHP, the TOPSIS method is applied through the construction of a decision matrix with normalized criteria values and assigned weights. The TOPSIS procedure then evaluates alternatives according to their distance from the ideal and worst solutions (Behzadian et al., 2012). In this study, the decision matrix of initial competency assessments (Table 5) contains hypothetical values based on expected group competencies and research assumptions from the literature (Fraunhofer IPA, 2020; ISO/TS 15066).

Table 5: Decision Matrix of Initial Competency Assessments

Group	Technical Competencies	Cognitive Competencies	Psychosocial Competencies
Experts	90	80	70
Students	70	75	65
Laypersons	50	60	80

Experts showed the highest technical competencies (90), followed by cognitive (80) and psychosocial competencies (70). Students relied most on cognitive competencies (75), while technical (70) and psychosocial competencies (65) were less emphasized because of limited practical experience. For laypersons, psychosocial competencies (80) were the most important, followed by cognitive (60), whereas technical competencies (50) represented the weakest area. The decision matrix was then normalized into a dimensionless form to ensure comparability between criteria (Behzadian et al., 2012).

Group	T	K	P
Experts	0.723	0.64	0.562
Students	0.562	0.6	0.522
Laypersons	0.402	0.48	0.643

The weighted normalized matrix $\boldsymbol{V} = [v_{ij}]$ is obtained by applying the criteria weights, multiplying the normalized matrix by the weight vector (Behzadian et al., 2012).

Group	T	K	P
Experts	0.2386	0.2304	0.1742
Students	0.1855	0.2160	0.1618
Laypersons	0.1326	0.1728	0.1993

Next comes the ranking step, aiming to identify the best alternative that satisfies all criteria, being closest to the ideal solution and farthest from the worst solution. The ideal solution A^+ includes the most favorable values for all criteria (higher values are better), while the worst solution A^- represents the least favorable values (lower values are worse) (Behzadian et al., 2012). Based on the weighted normalized matrix, the ideal and worst solutions are defined as follows: $A^+ = (0.2386,\ 0.2304,\ 0.1993)$ $A^- = (0.1326,\ 0.1728,\ 0.1618)$. The distance of each alternative from the ideal and worst solutions is then calculated, followed by the relative closeness index C_i, which enables the final ranking of alternatives (Behzadian et al., 2012). The results for experts, students, and laypersons are summarized in Table 6.

Table 6: The results of the calculations for experts, students, and laypersons are summarized

Group	S_i^+	S_i^-	C_i
Experts	0.0251	0.1212	0.828
Students	0.0644	0.0692	0.518
Laypersons	0.1170	0.0374	0.242

Experts achieved the highest score, confirming that strong technical and cognitive competencies provide the closest match to the ideal profile. Students ranked in the middle because of their theoretical foundation but limited practical experience, while laypersons were furthest from the ideal solution, indicating that psychosocial competencies alone cannot compensate for lower technical and cognitive abilities. Overall, the TOPSIS ranking confirms the validity of the AHP analysis and highlights the importance of balanced competency profiles in human–robot collaboration (Behzadian et al., 2012). Only minor differences were observed between AHP-derived and ISO-based weights, confirming the robustness of the model. Collaborative robots achieved the highest scores, followed by digital twins and autonomous mobile robots because of their technical and cognitive demands, whereas AR/VR systems and exoskeletons achieved lower scores due to their stronger psychosocial emphasis.

Table 7: TOPSIS Scores of Experts in Different Technologies

Technology	TOPSIS Score (AHP Weights)	TOPSIS Score (ISO Weights)
Collaborative Robots	1.0000	1.0000
Smart Exoskeletons	0.2292	0.2282
Digital Twins	0.4899	0.5038
Flexible Manufacturing Systems	0.7130	0.6887
AR/VR Work Support	0.1282	0.1276
Autonomous Mobile Robots	0.4379	0.4259

5 Conclusion

In this paper, we presented a theoretical framework to assess the key competencies required to work with collaborative robots. By analyzing job requirements and operators' tasks, we identified those with the greatest impact on safety, efficiency, and work quality. These tasks were then linked to the corresponding competencies, followed by a hierarchical ranking of competencies according to their importance. Using the multi-criteria decision-making methods AHP and TOPSIS, we systematically developed well-founded predictions that enable more targeted design of educational programs and the development of assessment tools tailored to the real needs of the work environment.

5.1 Results and discussion

The results of the study offer a structured approach to the development of a competency model and support decision-making in the design of training programs for work in modern smart factories. Theoretical predictions of competency weights contribute to a more deliberate design of practical tests used to assess the abilities of

candidates or employees. If certain competencies are identified in advance as more critical, the difficulty of tasks, required precision, and scope of responsibility can be adjusted accordingly. This is particularly relevant when comparing different target groups, such as experienced professionals, students with only theoretical knowledge, or laypersons without prior experience with robots. Such adjustments ensure greater relevance in the assessment of competency potential. Despite its many advantages, the proposed combination is not without limitations. Moreover, the model assumes static decision-making conditions, while in practice, the competency profiles of employees and technological requirements can change rapidly. Therefore, it would be reasonable for further research to focus on empirical validation of the model, for instance, by comparing its outcomes with the actual performance of individuals working with collaborative robots in real-world environments. Additionally, it would be useful to include a broader group of experts and conduct further consultations using the Delphi method to re-examine and validate the appropriateness of the selected criteria and their weights. A potential extension of the model involves the application of advanced methods such as fuzzy AHP or fuzzy TOPSIS, which allow for better handling of uncertainty and vagueness inherent in the subjective evaluation of competencies. Furthermore, future research could benefit from a comparative analysis with other multi-criteria decision-making methods, such as VIKOR, ELECTRE, or PROMETHEE, in order to test the robustness and broader applicability of the developed model across various contexts of industrial practice.

6 Ethics Declaration

The Commission for Research Ethics at Faculty of Economics and Business at University of Maribor establishes that the research titled Determining competencies for working with collaborative robots, proposed by Tadej Crnjac, falls under research with no risk to participants and issues a positive opinion regarding the ethical aspects of the research..

7 AI Declaration

Unveiling the Unseen: A Meta-Synthesis of Qualitative Informal Female Entrepreneurship Research

Simona Mormile, Roberta Romano, Gabriella Piscopo, Paola Adinolfi
University of Salerno, Fisciano, Italy

Abstract

Entrepreneurship is widely recognized as a key driver of economic growth, innovation, and social development. However, traditional entrepreneurship research has largely focused on formal business activities, often overlooking the experiences of women operating within the informal economy. Informal female entrepreneurship (IFE) represents a significant yet underexplored phenomenon, particularly in developing contexts where structural barriers, limited employment opportunities, and social norms constrain women's participation in the formal labour market. Despite its growing relevance, scholarly attention to IFE remains fragmented, and qualitative insights into women's lived entrepreneurial experiences are still limited.

This study aims to advance the understanding of informal female entrepreneurship by conducting a meta-synthesis of qualitative research. Specifically, the study seeks to identify the key factors influencing women's engagement in informal entrepreneurial activities and to explore how these factors shape their entrepreneurial trajectories across different socio-economic contexts. To achieve this objective, a qualitative meta-synthesis methodology was adopted. Following a systematic search across major academic databases, 15 peer-reviewed qualitative studies published between 2011 and 2023 were selected according to predefined inclusion criteria. Data were extracted and analyzed using an open coding approach, allowing for the identification of recurring themes and conceptual categories across the selected studies.

The findings highlight four main dimensions shaping informal female entrepreneurship. First, women's access to labour market resources and entrepreneurial opportunities plays a crucial role in motivating engagement in informal ventures, often driven by limited access to formal employment or financial capital. Second, cultural and social barriers—such as gender norms, domestic responsibilities, and institutional discrimination—significantly influence women's entrepreneurial choices and growth potential. Third, digital technologies emerge as important enablers, providing new opportunities for networking, market access, and business development. Finally, informal female entrepreneurship generates significant economic and social contributions, including household income generation, community development, and women's empowerment.

By synthesizing qualitative evidence, this study contributes to the entrepreneurship literature in two main ways. First, it broadens the conceptualization of entrepreneurship by highlighting the diversity of women's entrepreneurial experiences within informal economic systems. Second, it provides a comprehensive overview of qualitative research on IFE, offering deeper insights into the motivations, strategies, and challenges faced by informal female entrepreneurs. The findings also suggest important implications for policymakers and practitioners, emphasizing the need for supportive policies, access to financial resources, and targeted training programs aimed at fostering women's entrepreneurial potential and facilitating pathways from informal to formal economic participation.

Keywords: Informal Female Entrepreneurship; Informal Sector; Female; Meta-synthesis; Qualitative Study.

Paper type: Academic Research Paper

1 Introduction

Entrepreneurship is widely recognized as a key driver of economic growth, innovation, and social development (Holcombe, 1998; Valliere and Peterson, 2009). Traditional research on entrepreneurship has largely focused on formal business activities characterized by legal registration, regulatory compliance, and access to financial markets (Baumol, 1993). However, an important part of entrepreneurial activity occurs outside formal institutional frameworks.

One emerging yet understudied phenomenon is informal female entrepreneurship (IFE), which refers to women engaging in entrepreneurial activities within the informal economy without formal registration, taxation, or regulatory compliance (Spring, 2009; Thapa Karki et al., 2021). Informal female entrepreneurship is particularly widespread in developing countries, where women often face limited access to formal employment opportunities and financial resources (Rashid and Ratten, 2020).

IFE encompasses a wide range of micro and small-scale activities, including street vending, home-based businesses, and small-scale service provision (Muhammad et al., 2021). These ventures frequently emerge as strategies for income generation and economic survival in contexts characterized by structural inequalities and restricted labor market participation. Despite operating outside formal regulatory frameworks, informal female entrepreneurs contribute significantly to household income, local economies, and community development (Brush and Cooper, 2012).

Several factors may encourage women to engage in informal entrepreneurship. Limited access to formal employment, cultural expectations, and gender-related barriers often push women toward informal economic activities (Agarwal and Lenka, 2015; Naguib, 2024). At the same time, informal entrepreneurship may offer women flexibility, autonomy, and opportunities for financial independence (Agyemang, 2017).

Despite the growing relevance of the informal sector in global economies, the literature on informal female entrepreneurship remains fragmented and relatively limited (Rugina, 2019). Existing studies often focus on the broader informal economy without specifically examining the gendered dynamics shaping women's entrepreneurial experiences. Furthermore, many studies rely on quantitative approaches, leaving a gap in qualitative research that explores the lived experiences, motivations, and challenges faced by women entrepreneurs operating informally (Corrêa et al., 2022).

Understanding the drivers and implications of IFE is particularly important given its potential impact on women's economic empowerment and socio-economic development. Informal entrepreneurship may serve as both a survival strategy and a pathway to opportunity, depending on contextual conditions and individual motivations (Amorós and Bosma, 2014).

In response to these gaps, this study conducts a meta-synthesis of qualitative research on informal female entrepreneurship. By synthesizing findings from qualitative studies, the research aims to identify recurring themes and factors shaping women's entrepreneurial activities in informal contexts.

Specifically, the study addresses the following research questions:

- What factors influence informal female entrepreneurship?
- How do these factors shape women's entrepreneurial experiences across different contexts?

Through this analysis, the paper seeks to contribute to the entrepreneurship literature by offering a more comprehensive understanding of women's participation in the informal economy and highlighting the broader socio-economic implications of informal female entrepreneurship.

The remainder of the paper is structured as follows. The next section reviews the relevant literature on informal female entrepreneurship. This is followed by the methodology describing the meta-synthesis approach. Subsequently, the results are presented and discussed, highlighting the main themes emerging from the analysis. Finally, the paper concludes with theoretical and practical implications for research and policy.

2 Literature Review

Informal female entrepreneurship has gained increasing attention in recent years due to its economic and social relevance. The phenomenon refers to women who establish and manage businesses within the informal economy, typically without official registration or compliance with formal regulatory frameworks (Williams and Nadin, 2010). These activities range from home-based production to small-scale trade and service provision.

Several studies highlight the significant role women entrepreneurs play in economic development. Female entrepreneurship contributes to job creation, innovation, and income generation, particularly in developing economies (Brush et al., 2019). Within the informal economy, women often engage in entrepreneurial activities as a strategy to overcome barriers in formal labour markets.

IFE is characterized by several key features. First, informal enterprises typically operate without formal registration or licensing (Agarwal and Lenka, 2015). Second, women entrepreneurs in the informal sector often face limited access to financial resources, training, and business networks (Minniti and Naudé, 2010). Despite these constraints, informal female entrepreneurs frequently demonstrate high levels of adaptability and resilience, relying on creativity and social networks to sustain their businesses (Jennings and Brush, 2013).

Another important dimension concerns the motivations driving women to engage in informal entrepreneurship. Previous research suggests that both necessity and opportunity factors may influence entrepreneurial entry. For some women, informal entrepreneurship represents a response to unemployment, economic necessity, or lack of formal employment opportunities. For others, it provides opportunities for autonomy, flexibility, and work-life balance (Williams, 2009; Amorós and Bosma, 2014).

A substantial body of literature also highlights the barriers faced by women entrepreneurs in informal contexts. These barriers include cultural norms, gender discrimination, limited access to financial capital, and difficulties in balancing entrepreneurial activities with domestic responsibilities (Ahl, 2006; Hughes et al., 2012). In many societies, traditional gender roles restrict women's economic participation and limit their ability to access entrepreneurial resources.

In addition to economic barriers, institutional factors may also influence informal female entrepreneurship. Institutional theory suggests that both formal regulations and informal social norms shape entrepreneurial behavior (Kazumi and Kawai, 2017). In contexts where formal institutions provide limited support for women entrepreneurs, informal economic activities may become an accessible alternative.

Despite these challenges, research highlights the significant contributions of informal female entrepreneurs to household welfare and community development. Women's entrepreneurial activities often play a crucial role in supporting family income and improving living conditions (Brush and Cooper, 2012). Moreover, entrepreneurial engagement may enhance women's empowerment and social status within their communities (Amorós and Bosma, 2014).

In recent years, scholars have also begun to explore the role of policy interventions and support mechanisms in promoting women's entrepreneurship. Programs such as microfinance initiatives, entrepreneurial training, and regulatory reforms have been proposed to facilitate the growth and formalization of women-led businesses (Datta and Gailey, 2012).

However, despite the growing interest in the topic, several gaps remain in the literature. In particular, qualitative studies on informal female entrepreneurship remain relatively limited and fragmented. Qualitative approaches are particularly valuable for understanding the motivations, strategies, and lived experiences of women operating in informal contexts (Corrêa et al., 2022). By capturing context-specific dynamics and individual perspectives, qualitative research can provide deeper insights into the processes underlying informal entrepreneurship.

To address these gaps, the present study adopts a meta-synthesis approach to integrate findings from existing qualitative studies. This approach allows for the identification of common themes and patterns across different contexts, contributing to a more comprehensive understanding of informal female entrepreneurship.

3 Methodology

To explore the dynamics of informal female entrepreneurship (IFE), this study adopts a qualitative meta-synthesis approach, which allows the systematic integration and interpretation of findings from multiple qualitative studies (Hoon, 2013; Walsh and Downe, 2005). Unlike meta-analysis, which statistically aggregates quantitative data, meta-synthesis focuses on interpreting qualitative findings to identify common themes and theoretical insights across studies.

Our methodological approach was based on five sequential steps, represented graphically in Figure 1, and explained in detail in the following subsections, involving synthesizing qualitative arguments to create a model.

The objective was to explore the key factors influencing informal female entrepreneurship and to understand how these factors shape women's entrepreneurial experiences across different contexts.

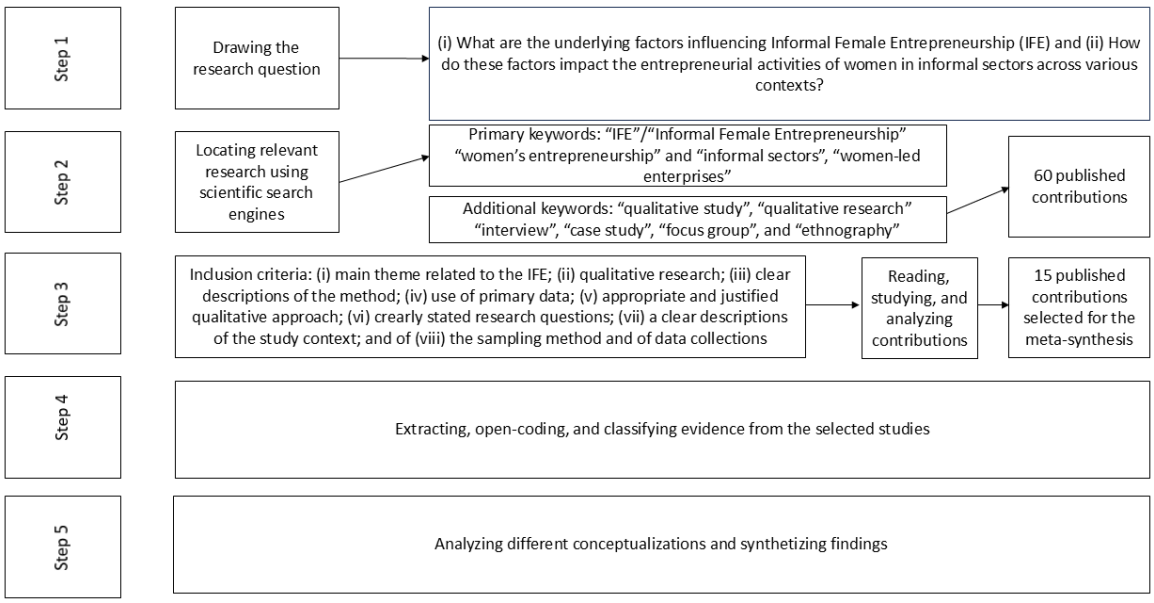

Figure 1 The five methodological steps of meta-synthesis

3.1 Research Design and Research Questions

The analysis was guided by two research questions:

- What factors influence informal female entrepreneurship?
- How do these factors shape women's entrepreneurial activities in informal sectors across different contexts?

These questions guided the identification and analysis of qualitative studies examining women's experiences in informal entrepreneurial activities.

3.2 Study Selection

Relevant studies were identified through a systematic search of major academic databases, including Scopus, Web of Science, EBSCOHost Business Source Complete, and Google Scholar. The search included keywords such as *informal female entrepreneurship*, *women's entrepreneurship*, *informal sector*, and *women-led enterprises*, combined with terms related to qualitative research (e.g., *interview*, *case study*, *focus group*, and *ethnography*).

The search was conducted between October 2023 and January 2024 and was complemented by manual searches of reference lists and relevant academic networks.

To ensure the relevance and quality of the selected studies, the following inclusion criteria were applied:

- focus on informal female entrepreneurship;
- use of a qualitative research design;
- primary data collection (e.g., interviews, observations, or focus groups).
- clear description of research context and methodology

The initial search identified 60 studies. After screening titles and abstracts and reviewing full texts, 15 qualitative studies published between 2011 and 2023 met the inclusion criteria and were included in the meta-synthesis (Table 1).

Table 1 Details of studies selected for meta-synthesis

3.3 Data Analysis

The selected studies were analyzed using an open coding approach to identify key themes and recurring concepts across the literature (Strauss and Corbin, 1998). The analysis focused primarily on the findings and discussion sections of the selected studies in order to capture the main insights generated by the original researchers.

Through an iterative analytical process, the identified codes were grouped into broader conceptual categories that reflected recurring patterns across the studies. This approach allowed the analysis to move from individual study findings to a cross-study interpretation, generating higher-level theoretical insights.

The final step of the analysis involved synthesizing the emerging categories into broader thematic dimensions that explain the main factors shaping informal female entrepreneurship. These dimensions form the basis of the findings presented in the following section.

4 Results

The meta-synthesis of the selected qualitative studies identifies several recurring themes that explain the dynamics of informal female entrepreneurship (IFE). The findings highlight four main dimensions: access to labour market resources, cultural and social barriers, the role of digital technologies, and the economic and social contributions of informal female entrepreneurs.

4.1 Access to Labor Market Resources and Opportunities

Female entrepreneurship represents an important pathway toward economic independence and empowerment in many contexts. Several studies highlight that women engage in informal entrepreneurship as a response to limited access to formal employment and financial resources.

Research on informal entrepreneurs in Ghana and Ethiopia shows how women demonstrate strong resilience and creativity in overcoming structural constraints. In many cases, women intentionally pursue informal entrepreneurship as a strategic choice to improve their economic conditions rather than merely as a survival strategy.

Education and professional training also play a crucial role in enabling women to develop entrepreneurial skills and expand their opportunities. However, access to financial capital remains a persistent challenge. Studies conducted in Uganda and India show that women entrepreneurs frequently encounter difficulties obtaining credit and financial support due to institutional barriers and gender biases.

In addition to financial constraints, limited access to markets, networks, and mentorship opportunities further restricts the growth potential of women-led informal businesses. These findings highlight the importance of developing more inclusive support systems and entrepreneurial infrastructures.

4.2 Cultural and Social Barriers

Cultural norms and traditional gender roles represent significant barriers to women's entrepreneurial activities. In many contexts, social expectations regarding women's domestic responsibilities limit their participation in economic activities and restrict their access to entrepreneurial resources.

Studies conducted in the MENA region and Sub-Saharan Africa demonstrate how gender norms influence women's entrepreneurial opportunities and constrain their business development. Women entrepreneurs often face discrimination, limited access to financial services, and additional pressures related to family responsibilities.

These structural barriers are frequently reinforced by institutional and societal dynamics that limit women's participation in economic life. Addressing these challenges requires not only economic support measures but also broader cultural and social interventions aimed at promoting gender equality and changing societal perceptions regarding women's entrepreneurship.

4.3 Digital Technologies as Enablers of Informal Female Entrepreneurship

Digital technologies increasingly play an important role in supporting women entrepreneurs operating in informal sectors. Online platforms and digital tools allow women to expand their market access, develop professional networks, and improve business operations.

Evidence from studies conducted in Jordan and Ghana highlights how digital technologies can help women overcome physical and social barriers that limit traditional business opportunities. Through digital platforms, entrepreneurs can access new customers, acquire information, and develop innovative business strategies.

These findings suggest that digital literacy and technological access represent important factors in supporting the growth and sustainability of informal female entrepreneurship.

4.4 Economic and Social Contributions

Despite operating outside formal regulatory frameworks, informal female entrepreneurs contribute significantly to economic and social development. Informal enterprises generate income for households, create employment opportunities, and support local economic systems.

Studies conducted in India, Bangladesh, and Nigeria demonstrate that women's informal entrepreneurial activities often contribute to family welfare, community development, and social cohesion. In addition to their economic contributions, women entrepreneurs frequently play important roles in supporting family education, community networks, and cultural preservation.

Overall, the findings highlight the importance of recognizing informal female entrepreneurship as a significant component of economic activity and a potential driver of women's empowerment and social inclusion.

5 Discussion and Conclusions

The purpose of this study was to explore the dynamics of informal female entrepreneurship through a meta-synthesis of qualitative research. By analyzing fifteen qualitative studies, this research identifies key factors shaping women's entrepreneurial activities within informal economic contexts.

The findings highlight the complex interplay between structural constraints and individual agency in shaping informal female entrepreneurship. Limited access to labor market opportunities and financial resources often encourages women to pursue informal entrepreneurial activities. At the same time, cultural norms and gender-related barriers continue to restrict women's access to entrepreneurial resources and opportunities.

Despite these challenges, the study highlights the resilience and adaptability of women entrepreneurs operating in informal contexts. Many women strategically leverage available resources, social networks, and digital technologies to develop sustainable entrepreneurial activities.

Digital technologies, in particular, emerge as important tools for overcoming traditional barriers to entrepreneurship. By facilitating access to information, markets, and professional networks, digital platforms provide new opportunities for women entrepreneurs to expand their businesses and enhance their economic participation.

In addition to their individual benefits, informal female entrepreneurs contribute significantly to broader socio-economic development. Their activities support household income, promote community welfare, and enhance women's empowerment in contexts where formal employment opportunities remain limited.

This study contributes to the literature on entrepreneurship in two main ways. First, it advances understanding of informal female entrepreneurship by synthesizing qualitative evidence on the factors shaping women's entrepreneurial activities in informal contexts. In doing so, it extends traditional entrepreneurship research, which has often focused primarily on formal business environments.

Second, the study highlights the value of qualitative research in capturing the lived experiences and motivations of women entrepreneurs. By integrating insights from multiple qualitative studies, this research provides a more comprehensive and nuanced understanding of informal female entrepreneurship.

The findings of this study have several implications for policymakers, educators, and practitioners. Policymakers should develop policies that recognize the unique characteristics of informal female entrepreneurship and facilitate access to financial resources, training programs, and entrepreneurial support services.

Educational institutions can also play a key role by promoting entrepreneurship education and digital skills development, particularly among women. Strengthening entrepreneurial competencies may help women transition from informal to formal economic activities.

Finally, women entrepreneurs themselves may benefit from expanding their use of digital technologies and professional networks to overcome traditional barriers and access broader market opportunities.

This study has several limitations. The meta-synthesis focuses exclusively on published qualitative studies, which may exclude relevant insights from grey literature and policy reports. Additionally, the studies included in the analysis are primarily concentrated in developing countries, potentially limiting the generalizability of the findings.

Future research could adopt mixed method approaches to combine qualitative insights with quantitative evidence, providing a more comprehensive understanding of informal female entrepreneurship. Longitudinal studies may also offer valuable insights into the evolution and sustainability of women-led informal businesses over time.

Further research should also explore the processes through which informal entrepreneurial activities transition into formal business ventures, as this transition represents an important pathway for economic development and women's empowerment.

Mapping Energy Innovation and ESG: A Bibliometric Review

Giovanni Spatola, Stefania D'Aprile, Antonio Capasso, Maria Zifaro, Andrea Presciutti
Mercatorum University, Rome, Italy

Abstract

The global energy sector is currently undergoing a profound "twin transition", characterized by the simultaneous pursuit of digital transformation and environmental sustainability. This dual trajectory is reshaping not only the technological infrastructure of energy production and distribution, but also the strategic, financial, and organizational logics governing utilities, independent producers, grid operators, and the wide ecosystem of stakeholders revolving around them. In this context, the integration between technological innovation and Environmental, Social, and Governance (ESG) considerations has emerged as a central axis around which contemporary academic and managerial debate revolves. The present study provides a comprehensive bibliometric analysis of the intersection between the energy sector, technological and organizational innovation, and performance metrics, specifically ESG factors, social acceptance, and profitability. The choice of a bibliometric approach is motivated by the need to overcome the fragmentation that historically characterizes this literature, where engineering, financial, managerial, and policy contributions tend to coexist without systematic integration. Using the Web of Science (WoS) Core Collection, a final dataset of 395 articles published between 2015 and 2026 was extracted, following a rigorous selection process inspired by the PRISMA protocol. The temporal window was deliberately set to coincide with the signing of the Paris Agreement and the adoption of the United Nations 2030 Agenda, two milestones that catalyzed academic attention and corporate strategic reorientation toward sustainability. Through the R package Bibliometrix and its graphical interface Biblioshiny, the research maps the intellectual structure, evolutionary trends, and collaboration networks underpinning the field, combining performance metrics, keyword co-occurrence networks, co-citation analysis, and historiographic mapping.

The results show an annual growth rate of 8.28% and an average of 26.31 citations per document, indicating a particularly dynamic and high-impact research field. The study identifies a clear thematic shift: from initial technical challenges to systemic themes (smart grids, regulatory policy), up to the recent emphasis on ESG metrics. Two main intellectual domains emerge: innovation systems for socio-technical transitions and sustainable business models based on the circular economy. Geographically, China leads in volume while Europe—particularly Italy and the United Kingdom—drives qualitative excellence, supported by Switzerland's disproportionately high citation impact. The paper concludes by outlining future research trajectories addressing the social dimension of ESG, Scope 3 emissions, and greenwashing detection.

Keywords: Circular Economy, Renewable Energy, ESG, Smart Grid, Bibliometrics.

Paper type: Academic Research Paper

1 Introduction

In recent decades, the global economic and industrial landscape has undergone radical transformations, but no sector has been subjected to as much pressure and profound change as the energy sector. Currently, the energy sector is at the center of what scholars and policymakers define as the "twin transition," a dual transition that combines digital transformation with the imperative need for environmental sustainability. This convergence represents not just a technological upgrade, but a true paradigm shift that redefines business models, value chains, and interactions with stakeholders. The implications cut across multiple dimensions: from the architecture of energy infrastructures to the design of regulatory frameworks, from capital allocation decisions to the renegotiation of the social contract between energy producers and the communities they serve.

The urgency to mitigate climate change, combined with the United Nations Sustainable Development Goals (SDGs) and international agreements like the Paris Agreement, has pushed energy companies, utilities, and governments to invest heavily in renewable energy, energy efficiency, and smart grids. However, technological innovation alone is not sufficient to ensure a successful transition. The need to integrate organizational and managerial innovation has strongly emerged, measuring results not only in terms of financial profit but also through holistic metrics. In this context, ESG (Environmental, Social, and Governance) criteria have become the gold standard for evaluating corporate sustainability performance, influencing access to capital, social acceptance, and institutional legitimacy. The financial system itself is being reshaped: green bonds, sustainability-linked loans, and ESG-screened investment funds have grown exponentially, channeling capital toward firms that can credibly demonstrate alignment with sustainability principles.

Despite growing academic and managerial interest in the intersection of energy innovation and ESG factors, the literature in this field appears fragmented. Studies tend to focus on disciplinary silos: some purely analyze the engineering aspects of smart grids or renewable energy, others focus on policy dynamics, while still others explore the financial impact of ESG metrics in isolation. There is a lack of a comprehensive overview that synthesizes how these research streams are merging and what the future trajectories are. Moreover, the rapid pace at which new contributions appear makes it increasingly difficult for both scholars and practitioners to navigate this body of knowledge without a structured cartographic tool.

To fill this gap, the present study aims to conduct a systematic and comprehensive bibliometric review. Bibliometrics, supported by powerful data analysis tools, allows for the deciphering of large volumes of scientific publications, identifying hidden networks, emerging themes, and the intellectual structure of a given research field. Unlike narrative reviews, bibliometric analyses minimize subjective biases and provide replicable, quantitatively grounded insights.

The Research Questions (RQ) guiding this study are as follows:

- *RQ1: What are the main publication trends, most prolific authors, leading countries, and highest-impact sources in the field of energy innovation and ESG?*
- *RQ2: How has the thematic structure of the research evolved over time, and what are the emerging, niche, and foundational themes?*
- *RQ3: What are the intellectual foundations (co-citation networks), and how are collaboration networks structured among researchers and institutions globally?*

By answering these questions, the paper offers a significant contribution to the literature, providing a conceptual map that will help future researchers position their studies and managers understand the evolutionary dynamics of the sector. Furthermore, the analysis is intended to serve policymakers seeking evidence-based orientation in the design of incentives, regulations, and standards capable of accelerating an authentic and inclusive energy transition.

2 Theoretical Background

To fully understand the results of the bibliometric analysis, it is necessary to outline the theoretical boundaries of the key concepts guiding this research: innovation in the energy sector, the circular economy, and the emerging role of ESG metrics. These three domains, while traditionally treated separately, have increasingly converged in both academic discourse and corporate practice, generating new hybrid frameworks that this study aims to map.

2.1 Innovation in the energy sector and socio-technical transitions

Innovation in the energy sector does not follow linear paths. It is best described through the lens of socio-technical transitions theory (Geels, 2002). According to this perspective, system changes (such as the shift from fossil fuels to renewable energy) occur through the interaction of three levels: "niches" (where radical innovations emerge), "regimes" (dominant practices, rules, and technologies), and the "landscape" (exogenous macro-trends like climate change or geopolitical crises). The interplay among these three levels explains why technological breakthroughs alone rarely translate into systemic change, and why successful transitions require coordinated alignment of technologies, institutions, user practices, and cultural meanings.

The introduction of technologies such as smart grids, energy storage systems, and distributed generation represents a direct challenge to traditional centralized energy regimes. Furthermore, the Technological Innovation Systems (TIS) approach (Bergek et al., 2008) emphasizes that the success of a new energy technology depends not only on its technical performance but also on the creation of actor networks, resource mobilization, guidance of the search, and institutional legitimation. Social acceptance, both at the local community level (e.g., for the installation of wind or biogas plants) and at the market level, thus becomes a critical success factor (Markard et al., 2016). Recent contributions have further enriched this framework by incorporating notions of justice, inclusion, and procedural legitimacy, recognizing that transitions inevitably generate winners and losers and that failure to address distributional impacts can stall or reverse otherwise promising trajectories.

2.2 Circular Economy and Sustainable Business Models

Parallel to technological innovation, the energy sector is experiencing profound innovation in business models, driven by the principles of the Circular Economy (CE). The circular economy aims to overcome the linear "take-make-dispose" model, aiming to close, slow, and narrow resource loops (Geissdoerfer et al., 2017). In the energy context, this translates into practices such as waste heat recovery, biomethane production from

agricultural waste (Cucchiella et al., 2018), recycling of solar panels and lithium batteries, and the integration of green supply chain management practices (Ghosh, 2022). These practices are no longer marginal experiments but increasingly form the backbone of competitive strategies in mature renewable industries.

From a strategic management perspective, the adoption of circular and sustainable business models can be interpreted through the Resource-Based View (RBV) (Barney, 1991). According to the RBV, companies that develop unique, rare, and inimitable capabilities in sustainable resource management and green innovation can achieve a sustainable competitive advantage. Sustainability ceases to be a mere regulatory compliance cost and becomes a driver of value creation. The dynamic capabilities perspective further extends this view, emphasizing the importance of sensing, seizing, and reconfiguring resources in response to rapidly evolving sustainability challenges.

2.3 The role of ESG metrics and performance measurement

The third theoretical pillar of this study concerns performance measurement through ESG criteria. While in the past the evaluation of energy companies was based almost exclusively on financial metrics (ROI, ROE, cash flows), today investors, regulators, and consumers demand transparency on environmental impacts (e.g., CO2 emissions, water management), social impacts (e.g., worker health and safety, impact on local communities), and governance (e.g., board diversity, corporate ethics, risk management).

Recent literature has begun to explore the link between ESG performance and firm value. Numerous studies suggest that strong ESG performance reduces the cost of capital, mitigates operational and reputational risks, and improves the long-term resilience of the firm. In the energy sector, which is highly exposed to regulatory and environmental risks, the integration of ESG criteria into decision-making and innovation processes has become an essential condition for survival and growth. The recent surge of mandatory disclosure regulations—such as the European Corporate Sustainability Reporting Directive (CSRD) and the EU Taxonomy—has further institutionalized ESG metrics, transforming them from voluntary signals into binding obligations that profoundly affect corporate strategy and reporting infrastructures.

3 Methodology

To rigorously and objectively map the intersection of energy innovation, circular economy, and ESG factors, this study adopts an approach based on quantitative bibliometrics. Bibliometrics allows for the analysis of large volumes of scientific literature, reducing the subjective biases typical of narrative reviews and providing a visual and statistical representation of the intellectual structure of a research field. The combination of performance analysis, science mapping, and network analysis offers a robust methodological foundation for capturing both the breadth and the depth of the literature.

3.1 Data Collection and Search Strategy

Data were extracted from the Web of Science (WoS) Core Collection database. The choice of WoS is motivated by its high quality, the rigorous selection of indexed journals, and the reliability of the provided metadata (such as cited bibliographies), which are essential for co-citation analyses.

The search strategy was constructed using a complex Boolean query, structured to intercept three conceptual macro-areas:

- Reference Sector: terms related to the energy context (e.g., "Energy sector", "Utilities", "Renewable Energy", "Power generation").
- Innovation and Transition: terms related to technological and process changes (e.g., "Smart Grid", "Circular Economy", "Digitalization", "Technological Innovation").
- Performance and Outcomes: terms associated with impact measurement and acceptance (e.g., "ESG", "Environmental Social Governance", "Firm Value", "Social Acceptance", "Sustainability Performance").

The search period was set from January 1, 2015, to January 31, 2026. The starting year, 2015, was strategically chosen as it coincides with two global milestones: the signing of the Paris Agreement on climate and the adoption of the 2030 Agenda for Sustainable Development by the United Nations, events that catalyzed academic and corporate attention on energy sustainability issues. The end of the period (January 2026) ensures the inclusion of the most recent and cutting-edge publications, capturing the latest evolutions in regulatory frameworks, technological breakthroughs, and managerial practices.

3.2 Selection and Filtering (PRISMA Protocol)

The selection process followed a logic similar to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol. The initial extraction produced a total of 468 documents. Subsequently, rigorous inclusion and exclusion criteria were applied:

- Document Type: Only original research articles (articles) and literature reviews (reviews) were included, excluding editorials, book chapters, and conference proceedings to ensure the highest quality and the completion of the peer-review process.
- Language: The search was limited to documents written in English, considered the lingua franca of international scientific communication.

Following this refinement process, the final dataset under analysis stabilized at 395 documents. Each record was downloaded in plain-text BibTeX-compatible format, including full metadata such as authors, affiliations, abstracts, keywords (both authors' and KeyWords Plus), references, and citation counts.

3.3 Analysis Tools

The bibliometric analysis was conducted using Bibliometrix, an open-source package developed in the R programming environment, and its graphical interface Biblioshiny. This tool was selected for its versatility, transparency, and comprehensiveness. The techniques employed include:

- Performance analysis: to evaluate the productivity of authors, countries, and journals, alongside their citation impact.
- Keyword co-occurrence analysis: to map the conceptual structure and thematic evolution of the field.
- Co-citation analysis and historiographic mapping: to reconstruct the intellectual roots and evolutionary paths of the literature, identifying both seminal works and turning points.
- Collaboration network analysis: to visualize patterns of cooperation among authors, institutions, and countries.

4 Descriptive Results

The descriptive analysis of the dataset provides a fundamental overview of the health, size, and demographics of research in this domain.

4.1 Scientific Production and Growth Rate

The results reveal that the research field at the intersection of energy, innovation, and ESG is extremely dynamic. The annual growth rate of scientific production stands at 8.28%. This upward trend reflects the growing regulatory pressure (such as the European directives on sustainability reporting) and the interest of institutional investors in green finance. It also signals the maturation of a research community that increasingly sees the field as a legitimate and rewarding venue for academic contribution.

A particularly relevant finding concerns the impact of the research: the average number of citations per document is 26.31. This is an exceptionally high value, especially considering that the average age of the analyzed documents is only 3.7 years. This indicates that the articles published in this area are quickly read, recognized, and cited by the scientific community, confirming the "freshness" and urgency of the debate on sustainable energy transitions.

4.2 Source Analysis (Scientific Journals)

The profoundly interdisciplinary nature of this line of research is confirmed by the analysis of publication sources. The most relevant journals do not belong to a single sector (e.g., only engineering or only finance) but cover a broad spectrum of disciplines that combine environmental sciences, management, and technology.

The top three journals by number of publications are:

- Sustainability (43 articles): An open-access journal that serves as a main platform for cross-cutting studies on economic, environmental, and social sustainability.
- Energies (36 articles): Focused more on techno-economic aspects, energy technologies, and policies.
- Journal of Cleaner Production (22 articles): A very high-impact journal, historically linked to environmental engineering, circular economy, and sustainable production practices.

The concentration of articles in these three journals (about 25% of the total dataset) suggests the existence of a consolidated core of publications that drive the academic discourse on sustainable energy innovation. At the same time, the long tail of less concentrated venues confirms the field's multidisciplinary nature, where

contributions appear in journals as diverse as Renewable and Sustainable Energy Reviews, Business Strategy and the Environment, and Research Policy.

4.3 Geographical Distribution and Global Impact

The geographical analysis of scientific production shows a clear polarization, largely reflecting the global geopolitical and economic dynamics related to energy.

China absolutely dominates the research landscape, both in terms of production volume (262 articles) and in terms of impact (1,752 total citations). This primacy is not accidental but is a direct reflection of massive Chinese state policies aimed at dominating the supply chains of renewable energies (solar, wind, batteries) and managing the complex transition from coal to a low-carbon economy.

Italy ranks second, with 101 articles and 774 citations. This excellent result can be attributed to Italy's historical leadership in Europe in the field of smart grids (thanks to the early roll-out of smart meters) and a strong academic tradition in circular economy and waste management studies.

Following are India (84 articles) and the United Kingdom (82 articles). An anomalous and interesting finding emerges when analyzing Switzerland: although not in the top 4 for the number of publications, it ranks third globally for the number of citations (638). This indicates that the research produced in Switzerland, while quantitatively lower, possesses a disproportionately high quality and influence, likely due to the presence of excellent research institutes and international organizations based in Geneva and Zurich, which often act as bridges between academia, policy circles, and global governance bodies.

4.4 Author Profile and Collaboration Dynamics

The complexity of the energy "twin transition" requires skills that a single researcher rarely possesses. This is clearly reflected in the collaboration metrics. The dataset involves a total of 1,581 authors, with a very high collaboration index of 4.14 co-authors per document.

Furthermore, 38.23% of the documents feature forms of international co-authorship. Research on energy and ESG is therefore an intrinsically collective and global enterprise. Materials scientists, electrical engineers, environmental economists, and management scholars increasingly find themselves having to join forces to address systemic challenges, from the technical feasibility of a biogas plant to its acceptance by the local community and its impact on the ESG rating of the financing company. This trend mirrors the broader recognition that sustainability problems are by their nature "wicked," requiring interdisciplinary teams and methodological pluralism to be adequately addressed.

5 Conceptual Structure and Thematic Evolution

To understand what the scientific literature concretely discusses and how these topics have evolved over time, an analysis based on keywords (both Author Keywords and database-generated Keywords Plus) was conducted.

5.1 Keyword Co-occurrence Analysis

The co-occurrence network maps the keywords that jointly appear in the same articles, revealing the main thematic clusters. The analysis identified three fundamental macro-clusters:

- Strategic-Financial Cluster (ESG and Corporate Value): Dominated by terms such as "ESG performance", "Corporate Governance", "Financial performance", and "Firm value". This cluster highlights how the energy transition is now framed not only as an ethical or regulatory obligation but as a critical factor for mitigating financial risk and attracting capital.
- Technological-Operational Cluster (Innovation and Efficiency): Characterized by keywords such as "Renewable energy", "Smart grids", "Digitalization", "Artificial Intelligence", and "Energy efficiency". Here emerges the enabling role of digital technologies (the so-called Twin Transition, digital and green) in optimizing power grids and integrating intermittent renewable sources.
- Systemic-Environmental Cluster (Circular Economy and Decarbonization): Centered on "Circular economy", "Carbon neutrality", "Life cycle assessment (LCA)", and "Waste management". This group reflects the shift from a linear approach to circular business models within the utilities sector.

5.2 Thematic Map and Evolutionary Dynamics (2015-2026)

Using the Thematic Map (which positions themes on two axes: centrality/relevance and density/development), it is possible to trace the evolution of the debate:

- Motor Themes (High centrality and high density): The integration between "ESG" and "Financial Performance" remains the driving force of current research. Energy companies are the main testing ground to demonstrate that sustainability generates economic value.
- Basic Themes (High centrality, low density): "Renewable energy" and "Corporate Social Responsibility (CSR)" are positioned here. They are foundational but now mature concepts; CSR, in particular, is being progressively replaced by the ESG acronym, which offers more quantifiable metrics.
- Emerging Themes (Low centrality, low density): In the last three years (2023-2026), themes related to "Digital twin technology", "Green Hydrogen", and "Scope 3 emissions" have strongly emerged. This indicates that the research frontier is shifting towards measuring emissions along the entire value chain and using virtual simulations to optimize energy assets.

6 Intellectual Structure

The analysis of the intellectual structure allows us to identify the theoretical "roots" upon which today's research is founded, through the study of co-citations (two documents cited together by a third document).

6.1 Co-citation Analysis

The author co-citation network reveals that current literature relies on two distinct theoretical pillars that are merging:

On one hand, theorists of Institutional Economics and Stakeholder Theory (e.g., Freeman, Porter), used to explain the regulatory and social pressures driving energy companies to adopt ESG practices. On the other hand, scholars of Innovation Systems and Socio-Technical Transitions (e.g., Geels, Schot), fundamental for understanding how new technologies (e.g., smart grids, advanced storage) manage to overcome the barriers of the traditional fossil fuel market. The progressive convergence of these two streams reflects the recognition that technological feasibility and institutional acceptability are inseparable dimensions of any successful energy transition.

6.2 Historiographic Mapping

The historiographic analysis shows a clear turning point around 2019-2020. Before this two-year period, literature on energy innovation and sustainable finance traveled on parallel tracks. Starting in 2020, with the acceleration of the European Green Deal and the growing awareness of post-pandemic climate risks, a "merging" of citation paths is noted: technological articles begin to heavily cite financial studies and vice versa, sanctioning the birth of a truly interdisciplinary field of study. This convergence is also visible at the methodological level, with quantitative econometric techniques increasingly applied alongside qualitative case studies and engineering simulations.

7 Collaboration Networks

As anticipated in the descriptive results, the high complexity of the topic requires strong teamwork at a global level. The analysis of Collaboration Networks provides interesting details on how researchers interact.

7.1 Country Collaborations

The map of international collaborations is dominated by a strong China-United States and China-Europe (particularly the UK and Italy) axis. Despite global geopolitical tensions in the energy sector, academic cooperation remains solid. China, a leader in the production of hardware technologies (solar panels, batteries), collaborates intensely with European and North American institutions, which bring advanced expertise in circular business models, ESG regulatory frameworks, and climate finance. This pattern of complementarity helps explain why scientific cooperation has remained relatively resilient even during phases of trade tension and political friction.

7.2 Institutional Collaborations

At the institutional level, polytechnic universities (e.g., Politecnico di Milano, Tsinghua University, MIT) act as central "hubs" in the network. It is interesting to note a growing presence of co-authorships between universities and corporate research centers or international institutions (such as the World Bank or the International Energy Agency). This phenomenon of academic Open Innovation demonstrates that research in this field is strongly oriented towards practical application and supporting policy-making, blurring the traditional boundaries between scientific inquiry and operational decision-making.

8 Managerial and Policy Implications

The results emerging from this bibliometric analysis offer concrete insights for both corporate decision-makers and policy makers involved in the energy transition.

8.1 Managerial Implications

ESG as a strategic lever, not just compliance: The literature clearly demonstrates that ESG performance is closely correlated with corporate value and a reduction in the cost of capital. Managers of utilities and energy companies must integrate ESG criteria directly into technological innovation processes, shifting from a reactive approach (based on mere reporting) to a proactive one (based on sustainable design or eco-design). This shift requires a corresponding evolution in performance management systems, with executive incentives increasingly tied to ESG outcomes alongside financial targets.

Adoption of Circular Economy models: The integration of circularity into energy supply chains (for example, the recycling of lithium batteries or the reuse of materials from decommissioned wind turbine blades) emerges as a fundamental strategy to mitigate risks associated with the price volatility of critical raw materials. In a geopolitical environment characterized by supply chain disruptions and resource nationalism, circular strategies represent a form of strategic insurance.

Leveraging the "Twin Transition": The thematic analysis highlights the crucial importance of digitalization. Managers should invest in technologies such as Artificial Intelligence, IoT, and Digital Twins not only to optimize the operational efficiency of grids but also to transparently track and report environmental and social data in real-time. The credibility of ESG disclosures will increasingly hinge on the robustness of the underlying data infrastructure.

8.2 Policy Implications

Harmonization of metrics: The proliferation of different ESG standards creates confusion and favors greenwashing. Governments and regulatory bodies must accelerate towards a global standardization of sustainability metrics, making data comparable and verifiable. International cooperation among standard-setters such as the ISSB, EFRAG, and the SEC is essential to avoid regulatory fragmentation.

Incentivizing systemic innovation: Public policies should not be limited to subsidizing a single technology (e.g., solar panels) but should incentivize the entire circular ecosystem, promoting industrial symbiosis and collaboration across different sectors. Cross-sectoral incentives, public-private partnerships, and innovation procurement can play a significant role in stimulating systemic transformation.

9 Conclusions

This study explored the evolution and intellectual structure of scientific research at the intersection of energy innovation, circular economy, and ESG factors, analyzing 395 documents published between 2015 and 2026.

The results confirm that we are facing a highly dynamic field of study (with an annual growth rate exceeding 8%) with a high impact. The analysis revealed a progressive shift in academic focus: while in the early years the debate was dominated by theoretical concepts related to Corporate Social Responsibility (CSR), today research is strongly oriented towards quantitative metrics (ESG), enabling technologies (digitalization), and transformative business models (circular economy).

Geographically, research is led by China (by volume) and Europe (with Italy and the UK at the forefront of systemic innovation), supported by solid international collaboration networks that withstand geopolitical fragmentation. From an intellectual perspective, we are witnessing the merging of two historically separate streams: the engineering of socio-technical transitions and sustainable corporate finance. This convergence not only enriches the conceptual depth of the field but also enhances its practical relevance, providing decision-makers with integrated frameworks rather than isolated technical or financial perspectives.

10 Limitations of the Study and Future Research Agenda

Like any research, this study has limitations. First, the analysis is based exclusively on the Web of Science database and English-language documents; the inclusion of other databases (such as Scopus or Dimensions) or "grey" literature (institutional reports, white papers, and industry analyses) could further enrich the picture. Second, bibliometric analysis provides a quantitative map, which always needs to be integrated with qualitative reviews to capture the methodological nuances of individual articles. Third, the keyword-based approach inevitably depends on authors' tagging choices, which may be inconsistent across journals and disciplines.

Based on the gaps identified in the thematic map, we propose the following agenda for future research:

The role of the "S" (Social) in ESG: Currently, the literature is heavily skewed towards the environmental and governance dimensions. Future studies are needed to investigate the social impact of the energy transition, such as the creation of "green jobs," the social acceptability of new infrastructures, and the fight against energy poverty (the so-called Just Transition).

Measurement of Scope 3 Emissions: With the evolution of regulations, the real challenge for energy companies will be measuring and reducing indirect emissions across the entire value chain (Scope 3). Research will need to develop models and frameworks to facilitate this complex reporting.

Impact of Artificial Intelligence on ESG: Although AI is an efficiency enabler, training models requires enormous amounts of energy. It will be crucial to investigate the paradox between the benefits of AI for smart grid management and its own environmental impact (the digital carbon footprint).

Detecting Greenwashing: With the growing financial pressure linked to ESG ratings, there is an urgent need for empirical studies that develop advanced methodologies to identify and measure greenwashing and circularwashing practices in the energy sector. The development of natural-language-processing tools, sentiment analysis algorithms, and forensic accounting techniques will be central in equipping investors, regulators, and civil society with reliable instruments to discriminate between substantive and rhetorical sustainability commitments.

11 Ethics declaration

This study is based on publicly available bibliographic information retrieved from indexed scientific databases and does not involve, at any stage, the participation of human subjects, animals, or personally identifiable information. As the research relies exclusively on secondary data drawn from peer-reviewed publications and metadata, prior approval from an institutional ethics review board was not required, in line with prevailing guidelines for desk-based bibliometric studies. The authors adhered to the general principles of research integrity, including reliability of the analysis, honesty in the reporting of methods and results, accurate citation of prior scholarship, and accountability for the entire research process. All sources have been duly acknowledged, no data have been fabricated or selectively omitted, and no conflict of interest exists that could have influenced the design or interpretation of the study. Should future extensions of this research involve the collection of primary data, the authors commit to obtaining the necessary ethical clearances from the competent committees, ensuring informed consent, voluntary participation, and full compliance with applicable data-protection regulations.

12 AI declaration

In the preparation of this manuscript, generative Artificial Intelligence tools were used only as auxiliary instruments for minor tasks such as linguistic refinement, grammatical checking, and the formal organization of references. Every output produced with AI assistance was critically reviewed and validated by the authors before inclusion in the final text.

Contextual–RFM (C-RFM): a Multimodal Framework for the Fusion of Transactional and Semantic Data Through LLMs for Interactive Customer Segmentation

Davide Madonna, Simone Malacaria, Andrea De Mauro
Luiss University, Rome, Italy

Abstract

This study examines the evolution of customer segmentation from rule-based systems to multimodal AI architectures, emphasizing the necessity for transparent and context-aware CRM strategies. Despite the widespread adoption of RFM models, organizations often struggle to synthesize transactional metrics with multifaceted qualitative feedback, creating a numerical paradox that this research addresses by capturing the authentic voice of the customer within high-dimensional analytical spaces. This paper presents the Contextual-RFM (C-RFM) framework, an innovative multimodal architecture aimed at bridging the representational divergence between quantitative metrics and qualitative feedback.

The research operationalizes a comprehensive five-phase pipeline to ensure methodological transparency and replicability: (1) establishment of a statistical baseline, (2) narrative synthesis for tabular serialization, (3) multimodal vectorization utilizing advanced embeddings, (4) semantic analysis through Latent Dirichlet Allocation (LDA) and (5) implementation of the C-RFM Expert chatbot. This entire workflow is implemented using KNIME Analytics and Langflow, providing a robust and replicable process for both scholars and practitioners. A key distinction of the framework is its early-fusion approach. Unlike traditional late-fusion models that integrate data streams only at the final analysis stage, early-fusion retains critical cross-modal correlations during the initial processing phase, effectively addressing the semantic opacity common in traditional numerical-only datasets.

Empirical findings indicate that the C-RFM framework adeptly organizes linguistic complexity, evidenced by a significant improvement in structural validity when transitioning from purely transactional environments to topic-validated contexts. Moreover, this study introduces the Discrepancy Detection Rate (DDR) as a novel performance metric to quantify the misalignment between transactional behaviour and qualitative feedback, thereby identifying critical churn risks that conventional quantitative analyses often overlook.

The primary contribution of this research lies in the synergy achieved between human expertise and Artificial Intelligence. By deploying dynamic persona chatbots grounded in Retrieval-Augmented Generation (RAG), the framework facilitates a shift from opaque analytical outputs to actionable, customized recovery strategies. This glass-box methodology transforms intricate numerical complexities into auditable business narratives, empowering decision-makers to transcend statistical constructs and foster a deeper, dialogue-based understanding of consumers. The C-RFM framework represents a significant advancement in human-centred AI, promoting strategic marketing intelligence that is not only transparent but also finely tuned to the authentic voices of real-world consumer archetypes, thereby paving the way for the next generation of customer-centric strategies.

Keywords: C-RFM Framework, Large Language Models, Explainable AI, Multimodal Data Fusion, Human-Centred CRM

Paper type: Academic Research Paper

1 Introduction

Artificial Intelligence is fundamentally transforming the Customer Relationship Management (CRM) landscape by enabling a significant shift from standardized marketing approaches to highly personalized interactions (Naderipour and Hosseini Nasabian, 2025; Bukhari et al., 2022; Kandi and Basani, 2024). In this evolving framework, segmentation continues to play a crucial role, allowing organizations to effectively manage market density by identifying and isolating specific behavioural groups (Syahra, Fadlil and Yuliansyah, 2025; Akande, Asani and Dautare, 2024). Historically, the theoretical foundation of this field has been the Recency, Frequency, and Monetary (RFM) model. However, its evolution from rule-based systems to unsupervised machine learning, notably K-means clustering, has exposed a persistent numerical paradox: a reliance on purely transactional data that lacks the contextual depth necessary to capture the multifaceted nuances of the modern consumer journey (Lewaa, 2023; Gopakumar et al., 2021).

The technical roots of this limitation lie in traditional One-Hot Encoding (OHE), which often suffers from the dimensionality curse and statistical instability (Chung, 2024). More critically, OHE induces a condition of semantic opacity within datasets. As Bayrak (2022) and Liang (2025) highlight, by treating all categories as mathematically independent, this method fails to recognize latent behavioural similarities between consumer

actions. Contemporary analytical frameworks are transitioning toward deep semantic embeddings to resolve these structural flaws. Smutek et al. (2024) utilize encoder-decoder structures to compress high-dimensional inputs into dense vectors where numerical proximity reflects semantic relationships. Validating these learned representations presents a significant challenge: while the Silhouette score is traditionally utilized as the primary metric for cluster validation, assessing structural quality by measuring both intra-cluster cohesion and inter-cluster separation (Gagolewski, Bartoszuk and Cena, 2021; Shutaywi and Kachouie, 2021), its effectiveness is often diminished in embedding spaces. The dimensionality curse and latent space sparsity make data points appear nearly equidistant, rendering traditional distance-based validation unreliable (Simpson et al., 2025). Researchers have increasingly adopted Latent Dirichlet Allocation (LDA) as a robust alternative to overcome these geometric limitations, thereby overcoming geometric limitations while demonstrating remarkable stability even when semantic relationships are intricate or data is sparse (Sidek and Ahmad, 2026).

Treating transactional data as a linguistic structure (Woltmann, Thiele and Lehner, 2018) positions Large Language Models (LLMs) as the next transformative frontier, leveraging their emergent abilities for data synthesis and optimization-based feature engineering (Nam et al., 2024). Despite this potential, LLM integration into analytical workflows faces a significant numerical paradox, where standard Byte-Pair Encoding (BPE) tokenizers fragment digits into subunits without inherent meaning, which, as Penttala (2025) states, strips numerical values of their quantitative significance. Hegselmann et al. (2023) demonstrate that serializing tabular data into natural language strings allows models to leverage their extensive prior knowledge to mitigate these errors, effectively interpreting transactional records as coherent behavioural narratives. This trajectory culminates in multimodal fusion strategies, which merge structured metrics with unstructured insights through sophisticated transformer-based architectures to capture cross-modal interactions and improve predictive transparency (Hangloo and Arora, 2025). Yet, even as these models enhance analytical depth, the transition from opaque outputs to actionable managerial trust remains a critical hurdle. This difficulty is primarily driven by the inherent lack of transparency in high-dimensional clustering, which frequently generates skepticism among strategic decision-makers (Wang and Ding, 2024). In critical CRM contexts, Explainable AI (XAI) offers a vital methodological framework for converting opaque computations into narratives that are comprehensible to humans (Patil, 2024). Beyond merely achieving predictive accuracy, XAI employs post-hoc tools such as SHAP and counterfactual analysis to uncover behavioural drivers, thereby bridging the gap between statistical constructs and strategic marketing intelligence while ensuring ethical and accountable insights (Almtrf, 2025). This integration is exemplified in dynamic persona chatbots, which transform the interaction between decision-makers and consumer archetypes from static descriptions to engaging, real-time dialogues (Salminen et al., 2026). By leveraging text embeddings models and direct LLM prompting to create persona chatbots, these agents accurately simulate consumer preferences, fostering a trust-based synergy between humans and AI to address complex marketing challenges (Li, Liu and Yu, 2025; Huang, Markovitch and Stough, 2024). This paper introduces the Contextual-RFM (C-RFM) framework to reconcile quantitative rigor with semantic interpretation. In addressing the heterogeneity gap that arises when comparing distinct representation spaces (Hangloo and Arora, 2025), C-RFM employs an early-fusion approach. By integrating transactional and semantic data during the initial preprocessing phase, the framework produces robust embeddings that overcome both the semantic limitations of traditional models and the numerical paradox associated with tokenization (Avnat et al., 2024). This methodology equips LLMs with a deeper contextual understanding while alleviating the information loss and managerial distrust often linked to high-dimensional clustering. By combining XAI with interactive chatbots, C-RFM enables an interactive data interpretation, addressing the following research questions:

- *RQ1: Which methodological approaches prove most effective for validating the multimodal segmentation of integrated transactional and semantic data?*
- *RQ2: How can an LLM-embedding framework, implemented through Explainable AI and interactive persona chatbots, effectively bridge the divide between opaque analytical outputs and actionable, transparent strategies?*

2 Methodology

The C-RFM framework is operationalized through a comprehensive five-phase pipeline, which serves as a procedural structure for converting the theoretical early-fusion strategy into a replicable analytical process.

2.1 Phase 1: Statistical baseline

This phase establishes a quantitative benchmark utilizing the Olist Brazilian E-Commerce dataset. A refined sample of 4,783 profiles was processed in KNIME Analytics, incorporating relational data from customers, orders, payments, and reviews. Procedural filters were applied to remove low-density reviews, while stratified sampling

was employed to maintain variance within high-value segments. A baseline RFM analysis was performed using K-means clustering, optimized through a two-stage methodology, which identified three segments as the optimal configuration. Cluster validation was carried out using the Silhouette score, resulting in a mean coefficient of 0.474. Although this outcome is considered acceptable, it highlights the structural ambiguities and boundary overlaps present in raw transactional data.

2.2 Phase 2: Narrative synthesis

The limitations of traditional tokenization are mitigated by replacing statistical grouping with row-level textual representations. The dimensions of RFM were redefined through quantile binning into semantic categories, transforming numerical variance into contextually significant data for LLMs. As suggested by Hegselmann et al. (2023), this serialization enables models to utilize extensive prior knowledge to interpret transactional records as coherent behavioural narratives. By integrating these categories with the verified customer perspective, the framework preserves cross-modal correlations prior to high-dimensional processing.

2.3 Phase 3: Multimodal vectorization

This phase implements the early-fusion strategy by embedding synthesized narratives into a high-dimensional space using the OpenAI *text-embedding-3-small* model. To avoid data leakage and facilitate the identification of new latent relationships, narratives were cleansed of Phase 1 RFM labels. Dimensionality was managed through Principal Component Analysis (PCA), which retained 100 components, accounting for 76% of the variance, followed by K-means clustering with three clusters to ensure stable segmentation. The analysis indicated a notable transition between transactional and semantic profiles. As illustrated in the migration matrix (Figure 1), RFM clusters are predominantly aligned with embedding cluster 0, an occurrence attributed to the specific feedback distributions found within the Olist dataset. Despite this skewness, cross-tabulation analysis revealed a p-value of 0.001, indicating that high-value transactional segments are distributed across diverse semantic contexts. This finding highlights the limitations of relying solely on raw numerical data and emphasizes the need for enhanced semantic depth (Li, Liu and Yu, 2025).

Frequency Row Percent	0	1	2	Total
At-Risk Customers	998	314	533	1.845
	54,0921%	17,019%	28,8889%	
Lost Customers	1.096	386	531	2.013
	54,4461%	19,1754%	26,3785%	
Top Customers	449	166	310	925
	48,5405%	17,9459%	33,5135%	
Total	2.543	866	1.374	4.783

Figure 1 – Migration matrix of RFM and embeddings clusters.

2.4 Phase 4: Semantic analysis

Topic modelling using LDA revealed behavioural communities within the high-dimensional vector space. Following a text mining workflow designed to minimize linguistic noise and an evaluation of the perplexity index, three distinct themes emerged. Labels for these topics were assigned based on the semantic relevance of the most representative terms identified during the modelling process (Figure 2). Topic 0 was labelled as *delivery excellence and reliability*, indicating positive logistical experiences; topic 1 was characterized as *product discrepancy and material quality*, which highlighted concerns regarding the physical attributes of products; and topic 2 was designated as *logistic and administrative friction*, focusing on post-sale and bureaucratic challenges.

Topic id String	Concatenate(Term) String
topic_0	recommend, quality, ahead, packaged, price, earlier, expectations, quickly, advertised, correct
topic_1	quality, missing, box, photo, material, original, watch, bad, little, fit
topic_2	delay, invoice, wrong, response, email, requested, day, refund, address, exchange

Figure 2 – Representative terms extracted for each topic

The assignment of narrative identities to the embedding clusters was informed by their distribution across these themes (Figure 3). As a result, cluster 0 was classified as *effortless brand ambassadors*, cluster 1 as *quality-focused skeptics*, and cluster 2 as *administrative hostages*. The structural integrity of these segments was further substantiated through unigram and bigram validation, culminating in the development of a high-fidelity customer narrative.

Semantic Cluster String	Delivery Excellence & Reliability... Number (Integer)	Logistic & Administrative Friction... Number (Integer)	Product Discrepancy & Material Quality Number (Integer)
Administrative Hostages	411	805	158
Effortless Brand Ambassadors	2096	234	213
Quality-Focused Skeptics	165	130	571

Figure 3 – Distribution of embeddings clusters across semantic topics

This format serves as the foundational contextual input for the persona chatbot, integrating transactional data, experience scores, and semantic analysis into a cohesive behavioural profile (Figure 4).

```
"CUSTOMER PROFILE: This user is a '", $RFM Cluster$, "' (categorized as: ", $Recency Label$, ", ", $Frequency Label$, ", and ", $Monetary Value Label$, "). ",
"TRANSACTIONAL DATA: Last purchase: ", string($Recency$), " days ago. Total activity: ", string($Frequency$),
" orders with a total lifetime value of ", string($Monetary Value$), " Reais. ",
"EXPERIENCE DATA: Review Score: ", string($Review Score$), "/5 stars. Feedback: '", $Review Text$, "'. ",
"SEMANTIC ANALYSIS: Cluster: '", $Semantic Cluster$, "'. Topic: '", $Topic Name$, "'. ",
"CONTEXTUAL KEYWORDS: ", $Topic Keywords$, ". "
```

Figure 4 – Prompt engineering template for customer stories

2.5 Phase 5: Implementation of the C-RFM Expert

The final phase focuses upon the deployment of the C-RFM Expert through a RAG architecture, which serves as the primary interface for narrative explainable AI. The implementation is structured around three core processes: knowledge base construction, orchestration via Langflow, and agentic deployment.

The construction of the knowledge base began with 1,000 representative vectorized narratives. A distributed processing approach utilizing a LLMs was employed to conduct a discrepancy analysis, aligning transactional metrics with sentiments derived from qualitative feedback. This methodology facilitates the categorization of customers into semantic clusters and the development of recovery plans that are specifically tailored to the unique behavioural nuances identified within each profile narrative.

System orchestration was executed in Langflow, utilizing Chroma DB for long-term multidimensional storage and a *gpt-4o-mini* agent to independently search the vector store. The resulting C-RFM Expert persona operates under a system prompt designed to identify friction points and rationalize strategic interventions. This approach guarantees that strategic recommendations are both auditable and grounded in empirical customer narratives, effectively converting numerical complexity into actionable business intelligence.

3 Results and Discussion

The following sections outline the empirical findings of the C-RFM framework, emphasizing the validation of the multimodal approach and its strategic advantages compared to conventional transactional models. By integrating quantitative metrics with generative insights, the results illustrate how the numerical paradox can be effectively addressed through both structural and semantic alignment.

3.1 Quantitative performance and validation

The validation of the C-RFM framework employed a multi-faceted statistical approach, incorporating the Silhouette score to assess segment cohesion, the Adjusted Rand Index (ARI) to measure model novelty, and the Discrepancy Detection Rate (DDR), a novel metric specifically developed and implemented through this study, to quantify the business value of uncovering latent attrition risks.

3.1.1 Multimodal structural validation

A significant finding emerged when traditional RFM clusters were projected onto the PCA-derived semantic space, resulting in a Silhouette score of 0.000. This outcome suggests that transactional segments are statistically indistinguishable from random noise when assessed through customer feedback, thereby providing empirical evidence that purely quantitative models lack semantic richness. Within this conventional framework, RFM categories do not share a unified linguistic or experiential narrative, highlighting that high spending does not necessarily equate to customer satisfaction and that transactional loyalty can often obscure underlying administrative challenges. In contrast, the C-RFM framework effectively organized this linguistic complexity. As illustrated Table 1, the transition from raw PCA space to probabilistic topic distributions significantly improved structural validity.

Table 1 – Comparative analysis of Silhouette scores across multimodal analytical spaces

Model/Space	Silhouette score	Interpretation
RFM clusters on PCA space	0.000	Total semantic opacity
C-RFM clusters on PCA space	0.161	Emergence of latent structure
C-RFM on topic matrix (LDA)	0.249	Probabilistic consolidation

3.1.2 Innovation and risk: ARI and DDR

The scientific novelty of the model was evaluated by calculating the Adjusted Rand Index (ARI) between the RFM clusters from Phase 1 and the semantic clusters from Phase 4. The primary aim of the ARI analysis was to assess the degree of similarity, or lack thereof, and potential redundancy between the established transactional model and the proposed multimodal framework (Sundqvist, Chiquet and Rigaill, 2023).

The computed ARI of 0.005 represents a significant finding, indicating that the two partitioning methods are stochastically independent. This near-zero value underscores a phenomenon of semantic opacity, suggesting an almost non-existent correlation between a customer's spending behaviour and their qualitative experiences. While an ARI close to 1 would indicate redundancy, this outcome confirms that the C-RFM framework reveals distinct behavioural dimensions, demonstrating its capacity to provide a non-redundant and unique strategic perspective.

Additionally, the framework presents the DDR as an innovative performance metric, which is established through the statistical cross-validation of transactional RFM segments and semantic topic clusters. This metric is defined by the following ratio:

$$DDR = \frac{|\{c \in Starget : \omega(c) \in Crisk\}|}{|Starget|}$$

- Starget: this refers to the group of customers identified within the highest transactional value segment.
- Crisk: this denotes the subset of semantic clusters that highlight critical friction points.
- ω(c): this is the semantic mapping function that assigns a customer, denoted as c, to a specific cluster based on their textual feedback.
- |·|: this operator indicates cardinality, representing the total number of individuals within the specified set.

Derived from the empirical values within the dataset, the computed DDR of 0.515 exposes a significant latent churn crisis, indicating that 51.5% of the company's most valuable customers are classified within high-risk clusters. This underlying threat underscores the fundamental limitations of conventional RFM analysis, which often fails to identify these critical churn risks (Lewaa, 2023). LDA topic modelling validates the internal differentiation within traditional RFM clusters, proving that customers are not a homogeneous entity but are instead fragmented across diverse experiential themes.

3.2 Managerial interpretability

The evolution from abstract clusters to persona chatbots signifies the peak of Human-Computer Interaction (HCI) (Salminen et al., 2026). By transforming statistical groupings into strategic archetypes, the framework effectively connects data science with actionable marketing strategies. The deployment of the C-RFM Expert agent illustrates that LLMs, when supported by a RAG vectorized knowledge base, can conduct discrepancy analysis and generate prescriptive strategies with high accuracy.

This interpretability is implemented within the Langflow playground, where the agent enables interactive segmentation. Unlike conventional dashboards that present static data lists, the agent empowers managers to query the database using context-sensitive criteria. A pertinent example of this functionality is illustrated by the following strategic inquiry:

"Identify a high-value customer in the database who had a negative experience with the last purchase and provide a brief report specifying their exact numerical Recency, Frequency, and Monetary values, their Semantic Cluster name, a quote of their actual Review Text, and a concise 3-step recovery plan to resolve the discrepancy between their high transactional value and negative feedback".

As demonstrated in Figure 5, the agent successfully retrieved a high-value profile, accompanied by feedback expressing significant frustration with delivery failures.

High-Value Customer Report

Customer Profile:

- **Recency:** 192 days since last purchase
- **Frequency:** 18 orders
- **Monetary Value:** 181.86 Reais
- **Semantic Cluster Name:** Administrative Hostages

Review Feedback:

- **Rating:** 1.0/5 stars
- **Quote:** "The delivery was severely lacking, leading to frustration and dissatisfaction."

Recovery Plan

1. **Immediate Resolution:**
   - Contact the customer to provide an update on their delivery status. If the product is confirmed lost or significantly delayed, offer a prompt refund or replacement. Ensure clear communication about the steps being taken to resolve the issue.
2. **Compensation Offer:**
   - As a gesture of goodwill, offer free expedited shipping on their next order and a 20% discount on their next purchase. This acknowledges their loyalty and addresses the logistical issues they faced.
3. **Follow-Up Communication:**
   - After resolving the issue, follow up with the customer to ensure their satisfaction with the resolution and to reinforce the commitment to improving their experience. This can help rebuild trust and encourage future purchases.

Figure 5 – C-RFM Expert prescriptive response

The output generated by the C-RFM agent represents a significant shift in analytical detail and segmentation effectiveness. While traditional RFM clustering provides a purely quantitative perspective on consumer value, remaining semantically opaque regarding the underlying causes of attrition, the C-RFM framework leverages the agent's ability to integrate transactional significance with detailed linguistic feedback.

By following the agent's reasoning, managers could obtain an auditable and evidence-based understanding of the proposed strategy. This glass-box methodology ensures that each recommendation is underpinned by a clear rationale, enabling decision-makers to transition from descriptive insights to prescriptive interventions in real-time (Patil, 2024). Such transparency effectively alleviates the managerial skepticism commonly associated with black-box automated systems (Wang & Ding, 2024).

3.3 Academic and practical implications

The results of this study provide a dual-layered contribution, connecting advanced data science with strategic marketing management.

3.3.1 Academic implications

This research resolves the numerical paradox by demonstrating that early-fusion textualization enables LLMs to preserve and interpret cross-modal correlations. The shift from a Silhouette score of 0.000 to 0.249 illustrates that semantic signals can be mathematically structured to enhance transactional data.

However, it is important to acknowledge the absolute value of these structural metrics. Although this transition signifies a measurable improvement, scores remain lower than traditional RFM baselines, aligning with literature on the dimensionality curse in high-dimensional embedding spaces. This structural compression arises because the Silhouette score on Euclidean distance, which often fails to capture true proximity within high-dimensional contexts where latent space sparsity complicates rigid partitioning (Simpson et al., 2025). The framework addresses this challenge by shifting from geometric rigidity to the probabilistic logic of LDA, supplemented by the ARI and DDR metrics. While ARI provides empirical proof of the framework's novelty by confirming the stochastic independence of transactional and semantic spaces, the DDR offers a non-geometric validation of the model's strategic utility. By modelling the relationship between documents and topics as a distribution, the framework navigates the inherent ambiguity and polysemy of natural language more effectively than traditional distance metrics. Thus, the observed spatial overlap should not be interpreted as a failure of the model, but rather as a reflection of the fuzzy and continuous nature of semantic meanings (Petukhova et al., 2024).

3.3.2 Practical implications

The C-RFM framework effectively addresses hidden customer attrition by shifting from aggregate, retrospective segmentation to proactive, hyper-personalized recovery strategies. While traditional RFM models often lack insight into the emotional and logistical challenges that accompany high-value transactions, this framework functions as a scalable tool that converts passive data points into dynamic, conversational intelligence.

Organizations can implement interventions that are both semantically and economically tailored by automating the identification of strategic archetypes. Such a transformation ensures that recovery efforts directly address the root causes of dissatisfaction, tackling specific friction points that numerical metrics alone may overlook. Additionally, the introduction of an agentic interface effectively mitigates the managerial skepticism. The framework establishes AI as an advanced strategic partner by integrating complex multidimensional insights into actionable and verifiable business narratives, thereby ensuring a human-centred and evidence-based response.

4 Conclusions and Future Research

The C-RFM framework operationalized in this study effectively reconciles the quantitative inconsistencies inherent in traditional segmentation methods with a transparent model of XAI through the implementation of an early-fusion architecture. Its primary contribution lies in the practical validation of this early-fusion approach, which minimizes information loss and generates integrated semantic embeddings, thereby preserving semantic richness.

In addressing RQ1, the study illustrates that a comprehensive validation strategy is crucial for effective integrated multimodal segmentation. By merging structured narrative synthesis with LDA topic modelling and structural metrics, the framework identifies behavioural segments that are both statistically robust and semantically distinct. This methodology ensures that the resulting clusters transcend mere mathematical constructs, representing meaningful and interpretable consumer archetypes.

Concerning RQ2, the framework bridges the divide between opaque analytical outputs and actionable strategies through an agentic RAG architecture. The C-RFM Expert persona exemplifies how interactive chatbots, rooted in validated narratives, can automate discrepancy assessments and generate customized recovery plans. This shift from static categorizations to dynamic dialogue guarantees that marketing strategies are contextually transparent, data-driven, and auditable by human stakeholders.

Additionally, the introduction of the DDR signifies a foundational innovation for identifying latent customer attrition. As a novel metric, it serves as a crucial starting point for iterative development, facilitating further refinement as it is applied across various organizational contexts to quantify the misalignment between transactional value and consumer sentiment.

Future research could enhance the C-RFM framework by tackling current challenges related to data acquisition and the computational demands associated with commercial LLM interface. By incorporating socio-demographic variables, subsequent studies can further enrich the depth and detail of customer narratives, yielding more comprehensive contextual insights. This framework can also serve as a significant advancement

in human-centred CRM, fostering a more ethical and accountable approach that aligns data-driven accuracy with the complex realities of human behaviour.

5 Ethics Declaration

No ethical approval was required for this study.

6 AI Declaration

LLMs including Notebook LM were employed for content extraction, while Gemini was employed for linguistic refinement. Gemini specifically assisted in proofreading, structural clarification, and the formalization of the DDR formula, which is firmly grounded in the author's conceptual framework and empirical data. All substantive content, interpretations, and analytical contributions remain the author's original work. These tools provided purely editorial and formalization support, without influencing the intellectual or methodological foundations of the research.

Perturbation-First Robustness Evaluation of Automated Short Answer Grading

Ferdinando Sasso, Andrea De Mauro
LUISS Guido Carli University, Rome, Italy

Abstract

Automated Short Answer Grading (ASAG) is increasingly deployed in high-stakes educational contexts, yet the dominant evaluation paradigm focuses primarily on agreement with human raters, overlooking robustness as a complementary quality dimension. Robustness, defined as the consistency of grading behaviour under controlled, meaning-aware input transformations, bears directly on construct validity, the degree to which an assessment measures what it claims to measure, and conditions the trustworthiness of automated decisions in education.

We propose a perturbation-first evaluation framework that assesses robustness across three validity-theoretic dimensions: invariance to construct-irrelevant variation, sensitivity to meaning-altering changes, and resistance to adversarial gaming. The framework combines rule-based perturbation generators, two-gate quality validation, and self-referential metrics that compare the grader against its own output rather than against gold labels, isolating robustness from accuracy. A dual-protocol design contrasts within-question evaluation, the optimistic scenario typically reported in the literature, with cross-question evaluation, the realistic deployment scenario, capturing how trained graders degrade under distribution shift.

We apply the framework to a benchmark ASAG dataset of science short answers and compare a trained machine-learning baseline with zero-shot Large Language Model (LLM) graders evaluated at two prompting levels, with and without access to a reference answer. Three findings emerge. First, trained graders exhibit substantial robustness degradation under realistic cross-question evaluation, suggesting that standard within-question benchmarks overestimate operational reliability. Second, zero-shot LLM graders exhibit stronger robustness on invariance and sensitivity dimensions while remaining comparatively less vulnerable to adversarial manipulation, although residual sensitivity failures display a stable hierarchy across perturbation types. Finally, providing reference answers introduces a subtle trade-off, with improved consistency on meaning-preserving variations but increased susceptibility to keyword-based gaming, which is invisible to single-metric evaluation.

We argue that multi-dimensional robustness evaluation should complement accuracy-based metrics in ASAG systems intended for high-stakes educational use, and we release an open-source framework that operationalises the approach and is freely available to the research community.

Keywords: Automated Short Answer Grading; Robustness Evaluation; Perturbation Testing; Large Language Models; Construct Validity

Paper type: Academic Research Paper

1 Introduction

Automated Short Answer Grading (ASAG) systems assign grades to free-text student responses by comparison with reference answers. The dominant evaluation paradigm, which relies on accuracy or Quadratic Weighted Kappa against gold labels, reveals an important blind spot: a grader may agree with human raters on clean test data yet behave erratically when inputs vary in superficial, meaning-preserving ways. Such inconsistency violates construct validity and undermines the pedagogical purpose of assessment (Messick, 1989; Williamson et al., 2012). Operational ASAG systems are also vulnerable to simple adversarial inputs (Ding et al., 2020; Kumar et al., 2020; Filighera et al., 2024), yet such vulnerabilities remain largely absent from standard benchmarking.

We argue that robustness should be evaluated alongside accuracy as a first-class quality dimension and propose a perturbation-first framework built on three families targeting distinct validity threats: invariance (construct-irrelevant variance), sensitivity (construct underrepresentation), and gaming (adversarial manipulation). Four metrics compare the grader against itself rather than against gold labels, isolating robustness from accuracy, and a dual-protocol design (Leave-One-Question-Out vs. within-question 80/20 split) quantifies how much consistency a trained grader loses beyond its training distribution.

We apply this framework to the SemEval 2013 Beetle dataset (5,199 answers, 42 questions), evaluating a hybrid ML baseline and a Large Language Model (LLM) grader (GPT-5.4 mini) at two prompting levels. The contributions of this work are threefold: a perturbation-first evaluation framework grounded in validity theory; a dual-protocol design that exposes the extent to which within-question evaluations overestimate operational

reliability; and a cross-paradigm comparison that documents a structured sensitivity-blindness gradient and an unexpected gaming trade-off introduced by reference-answer prompting.

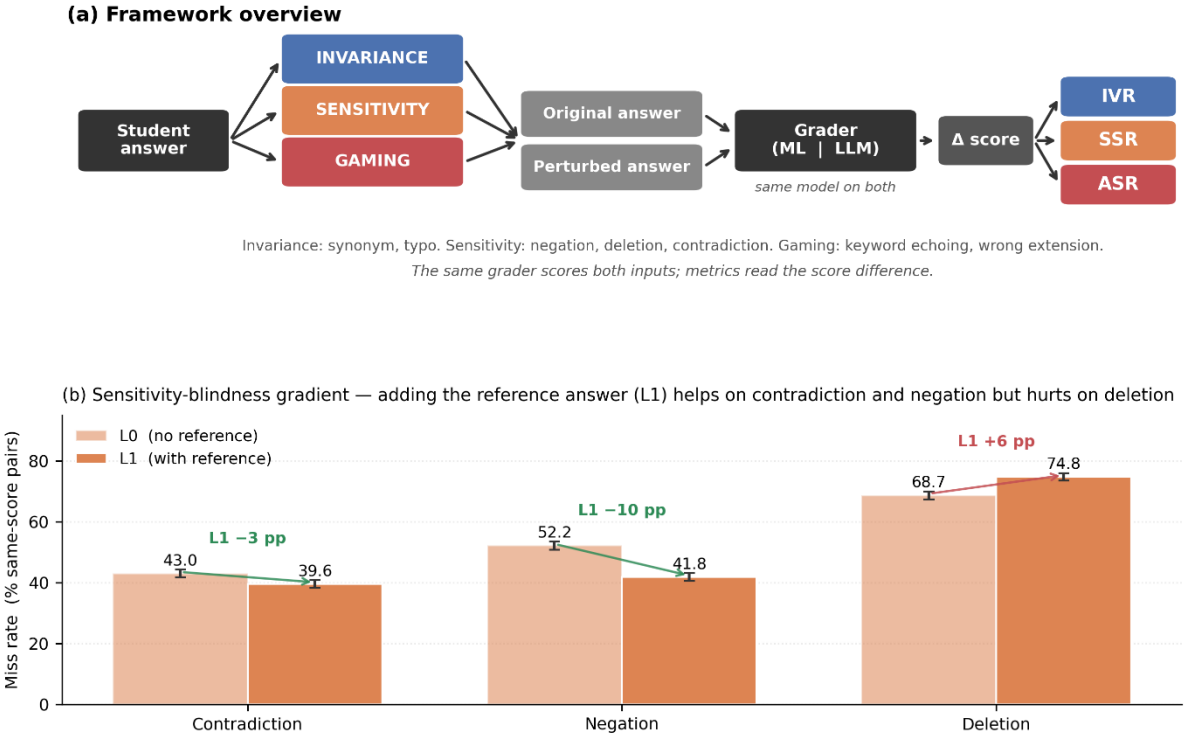

Figure 1: Framework overview and headline finding. (a) Pipeline: seven generators across three perturbation families produce paired (original, perturbed) inputs to the grader; three self-referential metrics — Invariance Violation Rate (IVR), Sensitivity Success Rate (SSR), and Adversarial Success Rate (ASR) — compare it against itself. (b) Sensitivity-blindness gradient in GPT-5.4 mini with 95% bootstrap confidence intervals. Reference prompting (L1) reduces missing on negation and contradiction but increases it on deletion: the L1 paradox.

2 Theoretical Background

The ASAG literature spans nearly two decades of methodological progress, from lexical and dependency-based approaches (Mohler et al., 2011; Burrows et al., 2015) to transformer-based models (Sung et al., 2019; Condor et al., 2021). Across this trajectory, evaluation has predominantly reported agreement with human raters via accuracy, Quadratic Weighted Kappa, or correlation, while the gap between in-distribution agreement scores and operational reliability has long been a concern of the educational measurement community (Heilman and Madnani, 2015; Williamson et al., 2012; Deane, 2013).

The limits of agreement-based evaluation are best understood through construct validity, that is, the degree to which an assessment measures what it claims to measure (Messick, 1989; Kane, 2006). Messick's framework identifies two principal threats: *construct-irrelevant variance* (scores influenced by factors unrelated to the construct, e.g. a grader penalising a correct answer for a typo) and *construct underrepresentation* (the assessment fails to capture meaningful aspects of the construct, e.g. a grader missing a negation that inverts meaning). To these, the literature on automated scoring has added a third threat specific to algorithmic systems, *adversarial gaming*, in which surface manipulations such as keyword stuffing artificially inflate scores (Williamson et al., 2012; Ferrara and Qunbar, 2022).

Perturbation-based evaluation is a standard methodology for assessing NLP model robustness. Ribeiro et al. (2020) introduced CheckList, a behavioural testing framework that systematically probes model capabilities through invariance, directional, and minimum-functionality tests. The general adversarial-NLP literature provides a wide toolkit of attack strategies, surveyed in Wang et al. (2022).

Within automated scoring, adversarial vulnerabilities have been documented but not systematically addressed. Ding et al. (2020) showed that content scoring systems could be fooled by random character strings, Kumar et al. (2020) attacked essay scoring with simple perturbations, and Filighera et al. (2024) extended this work to ASAG via adversarial adjectives and adverbs. Each focuses on a single attack family, and none proposes a unified, multi-dimensional framework anchored to validity theory.

The emergence of large language models has introduced new scoring paradigms that range from zero-shot or few-shot prompting (Mizumoto and Eguchi, 2023; Naismith et al., 2023) to lightweight fine-tuning (Latif and Zhai, 2024). These studies report encouraging accuracy figures but do not characterise robustness. Two questions are pressing: whether the cross-question robustness drop documented for trained models also affects zero-shot LLM graders, and whether prompting interventions (e.g. supplying a reference answer) interact uniformly with all validity dimensions or produce trade-offs invisible to accuracy alone.

3 Methodology

The evaluation framework follows a unidirectional pipeline (Figure 1a): data loading, perturbation generation, grading, metric computation, and cross-protocol comparison. All data flows through validated immutable models (questions, answers, perturbations, grade results) to ensure reproducibility. The framework is implemented in Python and released as an open-source pip-installable package (asag-perturbation) with a public API and command-line interface; source code, evaluation scripts, and the analyses reported in this paper are available at https://github.com/NNSS666/asag-perturbation-framework.

3.1 Perturbation Generation and Quality Validation

Seven rule-based generators produce up to ten perturbation variants per student answer, organised into three families.

Invariance family. Synonym substitution replaces content words with WordNet synonyms, producing up to two variants per answer (selected deterministically for reproducibility); typo insertion introduces a single character-level modification (swap, deletion, or duplication) into one content word.

Sensitivity family. Negation insertion adds "not" after auxiliary verbs or prepends "It is not true that" as a fallback. Key concept deletion removes one domain-relevant content word selected via seeded random sampling. Semantic contradiction replaces domain terms with curated antonyms (e.g., "open" → "closed", "series" → "parallel") drawn from a 40-pair dictionary covering physics and biology vocabulary.

Gaming family. Rubric keyword echoing appends reference-answer keywords absent from the student response, simulating keyword stuffing; fluent wrong extension appends a confident but factually incorrect domain statement from a curated pool of plausible-sounding misconceptions.

Illustrative examples for each perturbation type are reported below, with the perturbation marked in italics:

- *Synonym (invariance):* "the *bulb* lights up" → "the *lamp* lights up"
- *Negation (sensitivity):* "the terminals are connected" → "the terminals are *not* connected"
- *Deletion (sensitivity):* "the battery is in *a closed path*" → "the battery is in *a path*"
- *Contradiction (sensitivity):* "switches connected in *series*" → "switches connected in *parallel*"
- *Gaming:* "the bulb stays on" → "the bulb stays on *because voltage flows backwards*"

Invariance perturbations undergo two validation gates before acceptance. Gate 1 applies only to synonym substitution: candidate texts must achieve cosine similarity of at least 0.85 with the original, measured via sentence-BERT embeddings (all-MiniLM-L6-v2). Gate 2 applies to all invariance types: candidates introducing new negation markers or antonyms not present in the original are rejected. Rejected candidates are not regenerated, and the rejection rate is reported as a research result. The gates encode the *perturbation-level* ground truth (whether a candidate variant preserves meaning as intended), as distinguished from the *answer-level* gold labels supplied by the dataset (Section 4), which encode whether the original student answer is correct.

3.2 Robustness Metrics

All metrics compare the grader's score on the original answer against its score on the perturbed answer, isolating robustness from accuracy.

- *IVR_flip* (Invariance Violation Rate, binary): the proportion of invariance pairs where the score changed at all; lower is better.
- *IVR_absdelta* (Invariance Violation Rate, continuous): the mean absolute score difference across invariance pairs, capturing violation magnitude.
- *SSR_directional* (Sensitivity Success Rate): the proportion of sensitivity pairs where the perturbed score strictly decreased; higher is better, and no-change counts as a failure to detect the modification.
- *ASR_thresholded* (Adversarial Success Rate): the proportion of gaming pairs where the score crossed from below the passing threshold (0.5) to at or above it. Already-passing answers that increase further are excluded.

The four metrics are reported on their canonical scales rather than aggregated into a composite index, which preserves continuity with the validity-theoretic constructs each metric targets and avoids the arbitrariness of weighting heterogeneous dimensions whose practical importance varies by deployment context. Joint reading across the three dimensions, illustrated in Section 5.1, surfaces the trade-offs that single-metric evaluation hides.

3.3 Dual-Protocol Evaluation

The dual-protocol design targets trained graders and quantifies how much robustness they lose on unseen questions. Protocol A (Leave-One-Question-Out) implements cross-question evaluation: for each of 42 questions the grader is trained on answers from all other questions and tested on the held-out one, with a leakage diagnostic verifying that no held-out question text appears in training. This is the realistic deployment scenario. Protocol B (within-question 80/20) implements in-distribution evaluation: for each question independently, answers are split 80/20 with stratified sampling on gold labels and the grader is trained and tested on the same question. This is the optimistic scenario typically reported in the literature.

The *robustness drop* is the difference between A and B aggregate metrics, macro-averaged across questions. Zero-shot LLM graders receive an identical prompt regardless of split, so their A and B results are equivalent up to sampling noise, and we evaluate them on absolute metrics and compare against the trained baseline's Protocol A, the most demanding condition.

4 Experimental Setup

We use the SemEval 2013 Task 7 Beetle dataset (Dzikovska et al., 2013), comprising 5,199 student answers to 42 science questions about electrical circuits. Answers are labelled on a five-way scale (correct, partially_correct_incomplete, contradictory, non_domain, irrelevant) and normalised to a continuous [0, 1] scale (correct = 1.0, partial = 0.5, others = 0.0) following the ASAG2024 benchmark convention. These dataset-supplied labels constitute the *answer-level* ground truth used to interpret robustness results; the *perturbation-level* ground truth is enforced by the two-gate validation of Section 3.1 and by the rule-based construction of each perturbation type. The robustness metrics themselves do not consult either ground truth, since they compare the grader against itself.

4.1 Graders

Hybrid ML baseline. A logistic regression classifier trained on 388-dimensional feature vectors: four handcrafted linguistic features (lexical overlap, length ratio, negation flag, reference-token recall) concatenated with 384-dimensional sentence-BERT embeddings (all-MiniLM-L6-v2; Reimers and Gurevych, 2019). Class weights are balanced to handle label imbalance. This configuration is broadly representative of strong feature-based ASAG baselines (Sung et al., 2019; Condor et al., 2021).

LLM grader. Zero-shot prompting of GPT-5.4 mini at two information levels. Level 0 supplies the question and the student answer only; Level 1 additionally supplies the reference answer and instructs the model to compare the student response against it. Temperature is set to 0.0 for near-deterministic output, with a fixed seed for reproducibility, and the model outputs a JSON object with a label and a confidence score mapped to the same [0, 1] scale as the gold labels. Because the model operates in a zero-shot regime, the dual-protocol distinction does not alter its input, and it is evaluated once against the HybridGrader's Protocol A.

4.2 Perturbation Statistics

The perturbation engine generated 41,444 perturbations across all seven types from 5,199 source answers, averaging 8.0 perturbations per answer (theoretical maximum 10). Gate 1 rejected 40.3% of synonym substitution candidates, indicating that nearly half of WordNet synonym replacements produce semantically divergent texts in the science domain; Gate 2 provided additional filtering for meaning-inverting substitutions. The rejection rate is reported as a research result, since it quantifies the inherent difficulty of producing valid invariance perturbations in technical domains and motivates the two-gate design.

5 Results

Results are organised in four blocks: a dual-protocol analysis of the trained HybridGrader; a cross-paradigm comparison with the zero-shot LLM, including reference-answer availability (Section 5.1); score-distribution

artefacts and the floor effect (Section 5.2); and the structured sensitivity-blindness gradient (Section 5.3). We begin with the dual-protocol analysis.

Table 1 reports the HybridGrader's aggregate robustness metrics under both evaluation protocols.

Table 1: HybridGrader robustness metrics by evaluation protocol.

Metric	Protocol B (in-distribution)	Protocol A (cross-question)	Drop (A – B)
IVR_flip (↓)	0.179	0.337	+0.158
IVR_absdelta (↓)	0.125	0.242	+0.118
SSR_directional (↑)	0.120	0.140	+0.020
ASR_thresholded (↓)	0.115	0.188	+0.074

Invariance violations nearly double from Protocol B to A (IVR_flip 0.179 → 0.337): the grader changes its score on meaning-preserving perturbations 33.7% of the time on unseen questions, versus 17.9% on familiar ones. Gaming vulnerability follows the same pattern (ASR 0.115 → 0.188), with adversarial inputs 64% more effective on novel questions. Sensitivity detection remains low under both protocols (SSR ≈ 0.13), indicating that the HybridGrader's failure to detect meaning-altering perturbations is a structural limitation of feature-based scoring rather than a distribution-shift effect. The +15.8 pp IVR_flip and +7.4 pp ASR drops quantify the extent to which within-question evaluations overestimate operational robustness.

5.1 Cross-Paradigm Comparison: Trained ML vs. Zero-Shot LLM

Table 2 reports the zero-shot LLM's absolute robustness metrics, compared against the HybridGrader's Protocol A results.

Table 2: Cross-paradigm robustness comparison (HybridGrader at Protocol A; LLM zero-shot, single-run).

Metric	HybridGrader (A)	GPT-5.4 mini L0	GPT-5.4 mini L1
IVR_flip (↓)	0.337	0.243	0.134
IVR_absdelta (↓)	0.242	0.126	0.071
SSR_directional (↑)	0.140	0.420	0.461
ASR_thresholded (↓)	0.188	0.067	0.118

Four observations can be drawn from the comparison. *First, the LLM is more robust to surface variation.* GPT-5.4 mini Level 0 achieves IVR_flip of 0.243 versus 0.337 for the HybridGrader under Protocol A (a 28% relative reduction); with the reference answer available (Level 1) invariance violations fall to 0.134, a 60% reduction over the baseline. The reference appears to act as a semantic anchor against which meaning-preserving variations are recognised.

Second, the LLM detects meaning-altering perturbations more effectively. SSR_directional rises from 0.140 for the HybridGrader to 0.420 at Level 0 and 0.461 at Level 1, an approximately threefold improvement. The HybridGrader misses 86% of negations, deletions and contradictions, whereas the LLM at Level 1 misses 54%. Adding the reference answer yields only a modest additional gain (+4 pp), indicating that the sensitivity advantage arises predominantly from semantic processing rather than from the comparison target.

Third, reference-answer availability introduces an unexpected gaming trade-off. Providing the reference answer (Level 1) increases gaming susceptibility by 76% relative to Level 0 (ASR 0.118 vs 0.067). The prompt instructs the model to compare the student answer against the reference, so any token overlap becomes evidence of correctness, and when a gaming perturbation injects reference keywords into a wrong response the model registers them as partial understanding. The reference functions as a checklist from which an adversarial student can copy, whereas Level 0, lacking this anchor, must judge the answer on its overall coherence and is correspondingly harder to game.

Fourth, multi-metric evaluation reveals trade-offs invisible to any single metric. On invariance alone, Level 1 dominates Level 0; on gaming alone, Level 0 dominates Level 1; on sensitivity alone, the two are comparable. The same point applies to the trained baseline: under Protocol B its IVR_flip of 0.179 looks reasonable, yet SSR_directional of 0.120 reveals that this stability partly reflects indiscrimination, with the grader rarely changing its score even when it should.

5.2 Score Distribution Effects

To rule out the possibility that the lower IVR is an artefact of score compression, we examined the LLM's label distribution. At Level 0, GPT-5.4 mini exhibits a conservative scoring pattern: 54.3% of answers receive the partially_correct_incomplete label (score 0.5), against 23.1% in the gold distribution. Compression toward the midpoint mechanically reduces IVR, since scores at 0.5 have less room to flip. At Level 1, the distribution becomes substantially more discriminative, closer to the gold distribution, yet IVR_flip continues to fall (0.243 → 0.134). This rules out the score-compression explanation, and the invariance robustness observed reflects genuine semantic stability rather than a statistical artefact.

A symmetric artefact affects SSR_directional: answers already scored 0.0 cannot decrease further under sensitivity perturbations, mechanically producing SSR = 0% on those pairs regardless of grader quality. We term this the floor effect. Table 3 reports SSR with and without floor-affected pairs.

Table 3: SSR floor-effect analysis — overall vs. restricted to answers with original score > 0.

Configuration	Pairs	Floor pairs (orig=0)	SSR overall	SSR non-floor (orig>0)	Delta
GPT-5.4 mini L0	13,155	3,012 (22.9%)	0.423	0.549	+12.6 pp
GPT-5.4 mini L1	12,309	4,219 (34.3%)	0.480	0.731	+25.0 pp

The floor effect is larger for Level 1 because the reference answer makes the grader more discriminative, increasing the proportion of untestable pairs. After correction Level 1 detects 73.1% of meaning-altering perturbations on testable pairs, against 48.0% uncorrected.

5.3 Sensitivity Blindness Gradient

Disaggregating SSR by perturbation type reveals that the LLM's sensitivity failures follow a stable hierarchy (Figure 1b, Table 4): the grader is blindest to deletions, intermediate on negations, and least blind on outright contradictions, and the pattern holds for both prompting levels.

Table 4: Per-type miss rates (% same-score pairs) with 95% bootstrap CI (10k resamples).

Grader	Deletion	Negation	Contradiction
L0	68.7 [67.4, 70.0]	52.2 [50.8, 53.5]	43.0 [41.7, 44.3]
L1	74.8 [73.6, 76.0]	41.8 [40.5, 43.2]	39.6 [38.3, 40.9]

Pairwise McNemar tests confirm that the gradient is significant (all six within-grader comparisons $p < 0.001$). A further side-effect emerges between graders: adding the reference answer (L1) reduces the miss rate on negation (−10 pp) and contradiction (−3 pp) but *increases* it on deletion (+6 pp), a paradox confirmed by paired McNemar on the same answer set ($\chi^2 = 51$, $p < 0.0001$). Floor adjustment (Section 5.2) lowers all three rates uniformly without changing the ordering, and even at the bottom (~40% on contradiction in L1) the failure rate constitutes a substantive deployment risk.

A manual review of 30 random missed deletions characterises the mechanism. Of 17 cases involving deletion of a domain concept (terminal, battery, circuit, voltage, open/closed), 16 materially degraded or inverted answer meaning, while connective deletions ("because", "between") were correctly tolerated as benign. The grader systematically fails on content-bearing words. A representative inverted case is "the battery is in *a closed path*" → "the battery is in *a path*" (gold = correct, score 1.0 → 1.0): the closed/open distinction is the central conceptual axis of Beetle, and the Level 1 grader treats the two versions as equivalent.

6 Discussion, Implications, and Limitations

In this section we discuss the results of the study, distill implications for practitioners and researchers, and outline opportunities for further investigation.

The most consequential methodological finding is that within-question evaluations systematically overestimate the robustness of trained ASAG graders. The HybridGrader's invariance violation rate nearly doubles between the in-distribution and cross-question protocols, and its gaming susceptibility rises by roughly two-thirds, effects large enough to materially affect deployment. Published ASAG evaluations should therefore include cross-question results alongside in-distribution ones, and report the gap explicitly as a robustness drop.

The advantage that the zero-shot LLM exhibits on invariance and sensitivity arises from a form of semantic processing that feature-based scoring lacks. The HybridGrader relies on lexical overlap that shifts with surface

form, whereas the LLM processes the answer as language: a negation, deletion or antonym leaves surface features intact while shifting meaning, defeating feature-based scoring yet remaining at least partially visible to a semantic processor. The residual weaknesses in Section 5.3 refine rather than undermine this conclusion, showing that semantic processing handles meaning-preserving variation more reliably than meaning-altering omission.

Adding the reference answer is an intervention practitioners commonly expect to improve grading uniformly. It does so for invariance and sensitivity, but for gaming it nearly doubles vulnerability. The mechanism generalises beyond the particular prompt employed here: when the model is instructed to compare the student answer against a reference, any token overlap becomes evidence of correctness, which an adversarial student can exploit. The same checklist mechanism plausibly explains the deletion paradox of Section 5.3: when a domain concept is removed, the reference has no token to compare against while surrounding tokens still match, so the grader reads continued overlap as continued correctness and tolerates the omission. Reference-anchored prompting therefore fails on the same axis on which it succeeds, since token-level matching detects substitutions and negations but cannot detect what is no longer present. Prompt engineering and coherence-first instructions are plausible mitigations, yet such trade-offs remain invisible to single-metric evaluation.

As an outcome of the study, several implications can be drawn for practitioners and researchers. Practitioners should conduct perturbation evaluation across the three validity dimensions before placing a grader in consequential use, and should compare alternative prompting strategies on all dimensions rather than on accuracy alone, since gains in agreement with human raters can mask increased gaming exposure. Cross-question performance should be treated as the realistic baseline against which deployment decisions are made. From a research standpoint, the present findings position robustness alongside fairness as a precondition for responsible automated scoring (Loukina et al., 2019), and motivate further investigation of prompt designs capable of mitigating the trade-offs documented here.

We acknowledge several limitations that could be object of further research. First, the empirical evidence is restricted to a single dataset (Beetle) covering one science domain, and replication on additional ASAG corpora is necessary to establish the generality of the patterns reported. Second, the corpus lacks structured per-question rubrics, so the contrast between Level 0 and Level 1 prompting serves as a proxy for how additional grading information shapes robustness. Third, the LLM evaluation relies on a single model (GPT-5.4 mini), and cross-vendor as well as frontier-model comparisons are deferred to follow-up work. Finally, perturbations are produced by rule-based generators, and complementary human validation through inter-annotator agreement is a natural extension for the journal version.

7 Conclusions

We presented a perturbation-first evaluation framework for ASAG that quantifies robustness along three validity dimensions from Messick's taxonomy: invariance, sensitivity, and gaming. The framework combines seven rule-based generators, two-gate quality validation, four self-referential metrics, and a dual-protocol design that quantifies how trained graders degrade under cross-question generalisation.

Applied to the SemEval 2013 Beetle corpus, three findings stand out. The trained ML baseline exhibits a substantial robustness drop under cross-question evaluation (+15.8 pp IVR_flip; +7.4 pp ASR), confirming that within-question benchmarks overestimate operational reliability. The zero-shot LLM grader is markedly more robust on invariance and sensitivity, and less vulnerable to gaming. Adding the reference answer trades a 45% reduction in invariance violations for a 76% increase in gaming susceptibility, a subtle trade-off invisible to any single metric. We argue that robustness should be evaluated alongside accuracy as a first-class quality dimension for any ASAG system intended for high-stakes use, and that such evaluation should be multi-dimensional and grounded in validity theory.

8 Ethics Declaration

This study uses publicly available data from the SemEval 2013 Task 7 Beetle benchmark, which contains anonymised student responses released by the dataset authors for research purposes (Dzikovska et al., 2013). No primary data collection involving human participants was carried out for the present study, and no ethical clearance was required.

9 AI Declaration

Artificial intelligence tools were used in two ways. First, OpenAI's GPT-5.4 mini was the object of evaluation as one of the graders studied; its prompting configuration, decoding parameters, and access conditions are

documented in Section 4.1, and the resulting outputs are reported without modification. Second, general-purpose LLMs (Anthropic Claude and OpenAI GPT) were employed as writing assistants during manuscript preparation, specifically for grammar and style proof-reading, terminology consistency checks, and rephrasing suggestions on author-drafted text. All scientific content, research design, analyses, results, and interpretations are the authors' own. AI-generated wording was reviewed, edited, and retained only where consistent with the authors' intent and with the underlying empirical evidence.

Artificial Intelligence Applications in Biogas Systems: A Systematic Literature Review

Vincenzo Fiengo, Renato Passaro, Ivana Quinto
University "Parthenope", Naples, Italy

Abstract

The increasing importance of renewable energy and circular economy approaches has made biogas an important technology in sustainable energy generation and waste management (Uddin and Wright, 2023). In this respect, the application of artificial intelligence (AI) and machine learning (ML) in improving the efficiency and management of anaerobic digesters has become increasingly popular (Ananda et al., 2025). While there has been considerable research activity in this field, a systematic understanding of its progress has not yet been achieved. This research aims to fill this gap by performing a systematic literature review (SLR) based on PRISMA criteria (Page et al., 2021). A total of 131 articles has been selected from Scopus and Web of Science databases for analysis during the period 2010–2025. This paper presents a comprehensive overview of the literature using a combination of bibliometric and thematic analysis. Findings indicate a significant increase in the number of publications in recent years, confirming the growing scientific and practical interest in the topic. Moreover, there is a dominance of technical or engineering studies with a multidisciplinary yet fragmented body of literature, highlighting the evolving nature of the research field. From the thematic analysis, three major groups of studies were identified, which include: i) strategic and sustainability-oriented applications, focusing on techno-economic and environmental assessment; ii) operational optimisation, where AI is used to improve process efficiency, prediction, and control; iii) advanced computational modelling, centred on the development of hybrid and data-driven algorithms. The findings highlight that AI and ML are primarily used to enhance predictive accuracy and operational performance, while their potential as decision-support tools at strategic and organisational levels remains underexplored. Accordingly, the study proposes a research agenda emphasising the need to integrate AI into decision-making processes, improve data-driven management practices, and develop more holistic and interdisciplinary approaches to biogas system management.

Keywords: Anaerobic digestion, Artificial intelligence, Biogas production, Circular economies, Digital technologies.

Paper type: Academic Research Paper

1 Introduction

Over the past decades, growing issues over climate change, environmental pollution, and rising energy demand have determined a global shift from fossil fuels toward renewable energy sources (Overland, Juraev and Vakulchuk, 2022). In this context, biogas has emerged as a valuable renewable energy source, produced from biomass and organic waste, where its development driven by the expansion of agricultural and waste management activities (Salehian, 2013). The core process to enable biogas production is Anaerobic Digestion (AD). AD is a biological process where microorganisms decompose organic matter in the absence of oxygen, producing biogas mainly composed of methane and carbon dioxide. The process takes place in closed reactors, and the generated biogas is used primarily for heat and electricity production. From a circular economy perspective, anaerobic digestion contributes to closing material and energy loops by converting organic waste into renewable energy and nutrient-rich digestate, thereby reducing waste disposal and fossil energy dependence (Uddin and Wright, 2023).

In recent years, AI and ML have been increasingly applied to improve process efficiency, support techno-economic analysis (TEA) (Dominic and Baidurah, 2025), and assess environmental impacts in energy and biogas systems (Ranieri et al.,2023). Considering the growing interesting, in recent years biogas production and AD have been addressed from different but complementary perspectives. On one hand, some studies have mainly focused on the technological and process-related aspects of biogas production (Uranga-Valencia et al., 2025), while on the other hand recent papers have investigated the integration of automation, AI and ML in biomass and bioenergy systems, highlighting the potential of data-driven methods for process monitoring, prediction, and optimisation (Ananda, Sujeeth and Archana, 2025). Despite the growing number of papers focusing on A /ML applications in biogas production and AD, to our knowledge, it is still lacking studies able to properly investigate these topics in a systematic and reproducible way. Put differently, a comprehensive and rigorous analysis of the research landscape is still missing, including structured analyses of publication trends, influential contributions, and thematic development over time. This is particularly relevant given the fragmented and

multidisciplinary nature of the field, where a quantitative mapping of the interconnections between biogas research and digital technologies is essential to identify structural patterns, emerging themes, and existing knowledge gaps. In line with this, the main aim of this paper is to provide a comprehensive and systematic review of the literature on AI and ML applications in biogas and AD systems, with a particular focus on their economic, environmental, and operational implications.

Therefore, the study aims to address the following research questions:

- *RQ1: How is the literature about the applications of AI and Machine Learning in biogas systems developing?*
- *RQ2: What are the main research themes emerging from the literature on AI and machine learning in biogas systems?*
- *RQ3: Which artificial intelligence and machine learning techniques are most applied and for which operational purposes (e.g., prediction, optimization, monitoring)?*
- *RQ4: What economic, environmental, and operational benefits are associated with the adoption of AI and machine learning in biogas plants?*
- *RQ5: What are the implications and future research directions related to the adoption of AI and machine learning in biogas systems?*

2 Methodology

This study performs a systematic literature review conducted in accordance with the PRISMA guidelines (Page et al., 2021). The adopted approach is consistent with established frameworks for conducting literature reviews in management and interdisciplinary research (Snyder, 2019), ensuring transparency, rigor, and reproducibility in the identification, selection, and analysis of the relevant studies.

Anaerobic digestion-based biogas systems are considered not only as technical systems but also as organizational entities, whose performance depends on technological, managerial, and operational factors. In this context, data-driven technologies can support decision-making, process optimization, monitoring, and sustainability evaluation. To collect the required data, two recognized databases have been used: 1. Scopus; and 2. Web of Science. The search timeframe spanned from January 1, 2010, to December 31, 2025, with the objective of compiling all articles published during that time. The necessary articles were collected through a keyword search in English, using a combination of Boolean operators. The keywords used were the following:

(TITLE-ABS-KEY (biodigester) OR TITLE-ABS-KEY ("biogas production technology") OR TITLE-ABS-KEY ("biogas production plant") OR TITLE-ABS-KEY ("biogas production firm")) AND (TITLE-ABS-KEY ("machine learning") OR TITLE-ABS-KEY ("artificial intelligence")).*

Within the framework of this research, specific inclusion criteria were defined, considering the following aspects: i) types of samples: studies focusing on biogas production through AD were included; ii) digital technologies: articles addressing the application of ML and/or AI to biogas production systems were considered; iii) language of articles: only articles written in English were included; iv) nature of articles: the review focused on peer-reviewed journal articles, including both original research and review papers, published in scientific journals and indexed in the selected databases; v) period of publication: only articles published between January 1, 2010, to December 31, 2025, were considered. Three reviewers independently conducted the data extraction process, evaluating all selected articles according to the predefined inclusion and exclusion criteria. To ensure consistency and reproducibility, a structured data extraction form was developed using Microsoft Excel. For each selected article, a structured data extraction process was conducted. The following information was collected: I) authors' names; ii) year of publication; iii) journal of publication; iv) geographic origin of the study; v) objective of the study; vi) type of biogas system analyzed; vii) AI/ML techniques applied; viii) purpose of the application; ix) input variables and output indicators; x) model performance metrics; xi) main findings. A descriptive and content analysis was then performed by computing certain variables (distributions per year, citation indexes, etc.) and by in-depth analysis of selected papers. Finally, a critical analysis and discussion of the results obtained was carried out. The descriptive analysis involved a comprehensive overview of the selected articles. To investigate relational networks such as co-authorship and bibliographic coupling the software VOSviewer was used. Bibliometric analysis was performed following recognized approaches (Donthu et al., 2021; Aria & Cuccurullo, 2017), while content analysis was conducted based on established qualitative frameworks (Krippendorff, 2018; Mayring, 2014).

3 Results

Articles were collected in a database that was interrogated through Vos Viewer to obtain bibliometrics and visualisations. The results of the SLR are organised and presented into the following sections:

1. Corpus overview and bibliometrics
   - 1.1 Temporal trend
   - 1.2 Papers per source
   - 1.3 Citations per years and top-cited papers
   - 1.4 Most influential authors and cited papers
   - 1.5 Subject area distribution
   - 1.6 Co-authorship map
   - 1.7 Common keywords
2. Content analysis of the sources

3.1 Corpus overview and bibliometrics

The final corpus consists of 131 articles, for which a bibliometric analysis was conducted to provide a general overview of the investigated topic.

The selection process is summarized in the PRISMA flow diagram. During the systematic review, a total of 218 documents were identified in the Scopus and Web of Science databases. Subsequently, 25 duplicate records were removed. After screening the abstracts of the remaining 193 papers, 45 articles were excluded. A further 17 papers were deemed not relevant following full-text assessment. Ultimately, 131 articles were included in the final sample.

The temporal distribution of publications highlights a clear increase in research activity over time. Between 2010 and 2019, the number of contributions remained limited, ranging from 0 to 3 publications per year. From 2020 onwards, a significant growth is observed, reaching a peak in 2025 with 37 publications. This trend indicates a rapidly growing interest in the field, particularly in recent years.

As reported in Table 1, the publications in the sample appear to be highly multidisciplinary and published in a variety of journals. Bioresource Technology is the main contributor with 11 papers, followed by energies for which 6 articles collected.

Table 1: Top 10 journal

Journal	N° papers
Bioresource Technology	11
Energies	6
Fuel	5
Journal Of Environmental Management	5
Science Of the Total Environment	5
Biomass & Bioenergy	4
Journal Of Cleaner Production	4
Waste Management	4
Biomass Conversion And Biorefinery	3
Chemosphere	3

Reporting the number of citations per year, Table 2 shows that the highest number of citations is observed in 2023. A marked increase in citations is evident during the period 2020–2024, confirming a growing scientific impact of the research topic.

Table 2: Trend of citations and number of articles per year

Year	Number of articles	Citations
2010	1	196
2011	0	0
2012	0	0
2013	0	0
2014	0	0
2015	1	66
2016	2	143
2017	3	76
2018	3	196

Year	Number of articles	Citations
2019	3	164
2020	6	618
2021	9	541
2022	13	664
2023	24	734
2024	26	442
2025	37	149

The top 10 most cited articles are summarized in Table 3. Cruz et al. (2022) is the most cited paper with 211 citations and the highest CPY. Bioresource Technology plays a key role, with several contributions represented in the sample. Most of top-cited papers focus on the application of machine learning techniques, such as artificial neural networks, genetic algorithms, and hybrid models, for predicting and optimizing biogas production processes. This last finding clearly suggest that the research field is evolving towards the integration of machine learning methods for improving the performance and understanding of anaerobic digestion systems.

Table 3: Most influential authors and cited papers

Using functionalities provided by the SCImago Journal Rank (SJR) platform, fifty-three journal subject areas have been identified. Two main aspects emerge from the subject distribution. First, the topic is primarily covered by technical and engineering disciplines such as energy, environmental science, and chemistry, while socio-economic areas play a more marginal role. Second, the presence of many subject categories indicates a high degree of fragmentation, suggesting that the research field is still evolving. Third, the publication distribution pattern across many different subjects demonstrates the multidisciplinary character of the field. The multidisciplinary composition not only reflects the multifaceted of biogas systems that need to be optimized technologically and evaluated as whole systems, but it also suggests poor integration of technical and socio-economic considerations.

Fig.1 presents the co-authorship map obtained using the software VOSviewer, whereby nodes are the authors. 429 out of 753 meet the thresholds: a minimum number of one document for an author, and a minimum number of one citation for an author. From the network visualization, several distinct clusters are recognizable, each corresponding to research groups or established collaborations between scholars. In each cluster there is a dense connection, indicating strong scientific cooperation between authors belonging to the same group. Despite the lack of cooperation among the various groups, some authors such as Lim Jun Wei and Chan Yi Jing act as key connectors within the network, linking different clusters and facilitating knowledge exchange across research groups.

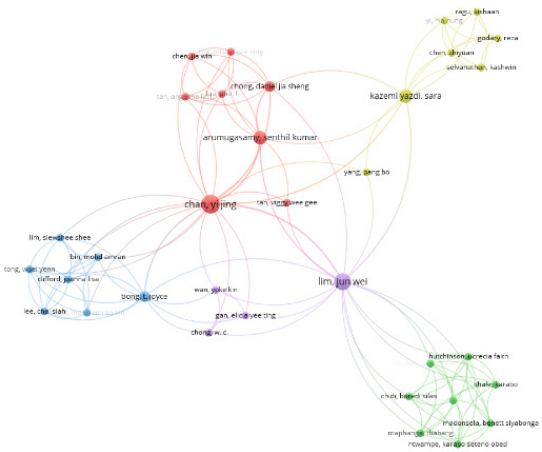

Fig.1: Co-authorship map

Using the same approach, a keyword co-occurrence analysis was conducted with VOSviewer to explore the main research themes in the field (Figure 2). 1600 keywords were obtained that met of the threshold of a minimum number of occurrences set equal to five. The map highlights a highly interconnected structure, with some central concepts acting as the hub of the entire network. “biogas” and “machine learning” emerge as the most relevant nodes, suggesting that the literature analysed focuses mainly on the application of ML techniques in the field of biogas production and optimization.

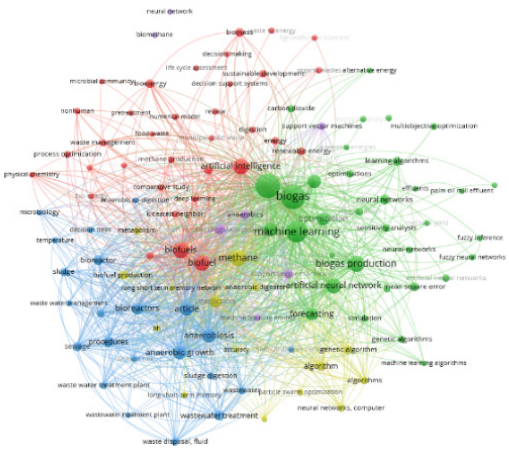

Figure 2: Co-occurrence keyword map

3.2 Content analysis

Content analysis recognises the importance of understanding the context in which an investigated item appears (Bryman, 2004). Based on the content analysis, the selected 131 papers are grouped in three main area, which we defined as “clusters”.

The first cluster focuses on strategic, environmental, and economic impacts of the adoption of AI in biodigester. Investigating how AI supports sustainability assessment and TEA, enabling scenario evaluation, environmental impact modelling, and performance benchmarking.

The second cluster represents the technical-operational core of this study. Here, the biodigester is conceptualised as a company that must forecast output, optimise yields, reduce operational uncertainty, and improve overall performance.

Finally, the third cluster focuses on the development and refinement of advanced algorithmic tools that enable predictive modelling and optimisation in biogas systems. The main contributions in this cluster include deal with optimisation strategies, development of hybrid modelling architectures and complex simulations and scenarios analysis to improve decision robustness.

In the following sections, the three clusters are analysed and discussed.

3.2.1. Strategic and Sustainability-Oriented AI Applications

Cluster 1 focuses on the strategic, environmental, and economic positioning of the biogas plant within complex territorial and energy systems. The cluster includes 27 contributions, almost equally divided between empirical studies and review papers.

About review papers, Heiker et al. (2021) provide a systematic overview of modelling approaches for biogas production, showing the complementarity between top-down and bottom-up models. Top-down models offer an aggregated perspective, used to analyse energy supply-demand dynamics, regional potential, and emissions, while bottom-up models provide a detailed representation of technical processes, allowing to capture the dynamic behaviour of anaerobic digestion and enabling operational optimisation. Similarly, Ananda et al. (2025) review the integration of automation and AI in biomass conversion systems, focusing on data-driven approaches for optimisation and decision support.

Among the key empirical studies, Dominic and Baidurah (2025) focus on techno-economic analysis, estimating key economic indicators and assess the feasibility of palm oil mill waste treatment systems. While Matheri et al. (2018) combine technical design considerations with decision-support methodologies for biodigester selection. But instead, Ouderji et al. (2023) provide a different prospective, integrating ML models with thermodynamic analysis and life cycle assessment, enabling the comparison of alternative energy configurations based on overall environmental performance and supporting decision-making processes through the identification of trade-offs between energy production, consumption, and environmental impact. Similarly, Selvanathan et al. (2023) apply ML techniques to predict methane emissions from palm oil mill effluent treatment systems, using real operational data to support environmental monitoring and emission reduction strategies. Despite the increasing use of AI in environmental assessment, economic feasibility remains a critical aspect in the evaluation of biogas systems. Among the few empirical contributions addressing this aspect, Vondra et al. (2019) propose a framework combining cost analysis and revenue modelling, to evaluate different operational scenarios and identifying the most influential variables. Overall, this cluster frames AI as a decision-

support tool at the strategic and system level, enabling the integration of environmental, economic, and operational dimensions.

3.2.2 Cluster 2- AI Applications for Biogas System Optimization

This research line is made up of 76 papers divided into 68 practical and 8 reviews papers. This cluster focuses on the use of AI to improve the operational performance of biogas systems. Cinar et al. (2021) highlight the significance of incorporating AI into biogas plants to facilitate sophisticated monitoring, prediction, and stabilization of processes. Likewise, Swami et al. (2023) propose an integrated framework for merging anaerobic digestion with data-driven technologies to optimize key operational parameters and enhance automation and real-time decision-making. Meanwhile, Cruz et al. (2022) examine the incorporation of ML algorithms into the modelling of anaerobic digestion processes and prove their efficiency in predicting biogas production. Practical research is mainly oriented towards the application of AI methods for estimating and optimizing biogas production. For instance, De Clercq et al. (2020) use algorithms such as the random forest and XGBoost models to analyze industrial-scale data and demonstrate their applicability and predictive accuracy. Salehi et al. (2022) create data-driven models relying on k-nearest neighbours and support vector machine techniques, which effectively predict biogas production and do not require specific kinetic information about the process. Moreover, Gonçalves Neto et al. (2021) implement artificial neural networks to estimate biogas production based on different organic substrates and evaluate the effect of temperature and other significant parameters. These studies confirm that AI-based models are effective tools for capturing the non-linear behavior of anaerobic digestion and improving process prediction and performance.

3.2.3 Cluster 3 - Advanced Computational Modelling and Optimization

Third stream contains 28 papers divided into 21 practical and 7 reviews papers. It focuses on the development and refinement of advanced algorithmic tools that enable predictive modelling and optimisation in biogas systems. Several review papers in this cluster focus on advanced computational and optimisation methods for modelling biogas systems. Ling et al. (2024) provide a comprehensive overview of ML algorithms, highlighting the benefits of hybrid models for improving prediction accuracy and process optimisation. Enitan et al. (2016) emphasise the role of evolutionary algorithms in solving complex, non-linear optimisation problems in anaerobic digestion systems. Wang et al. (2024) extend this perspective to the broader bioenergy sector, underlining the potential of algorithms for modelling, optimisation, and decision-making, while also addressing key challenges such as data limitations and model interpretability.

In addition to review studies, several practical contributions in this group of studies demonstrate the implementation of advanced computational techniques for modelling and optimisation of biogas systems. Gueguim Kana et al. (2012) combine artificial neural networks (ANN) with genetic algorithms (GA) to model and optimise co-substrate mixtures, achieving improved biogas yield and earlier production onset. Similarly, Abu Qdais et al. (2010) apply ANN and GA to real plant data, successfully predicting methane production and identifying optimal operating conditions. In addition, Kazemi et al. (2021) develop a data-driven framework based on soft sensors and ML models for fault detection, enhancing process monitoring and operational reliability.

4 Research Agenda/Future Research

Drawing upon the results from the content analysis, further research is outlined based on the three clusters (Table 4). Regarding the strategy-related and sustainable cluster, previous research focuses on utilizing AI for TEA and environmental assessment. While past literature predominantly applies an analytical view to the topic, there are no clear insights into how such information could be implemented in strategic decision-making. Hence, future research should concentrate on applying AI-based TEA in decision-making under uncertainty, focusing on investment decisions, scenario analysis, and strategic considerations. Furthermore, little is known about translating data-driven findings into decisions and their impact on decision quality and strategic behaviour in biogas facilities. In other words, further research should be undertaken to find out how the implementation of AI technologies changes decision-making processes to achieve more data and knowledge-driven decision-making. In the case of operational optimisation, most of the literature seems to focus on prediction and process efficiency. However, this view does not consider how AI can change the very nature of operational decision making in terms of its underlying logic. As such, future research will have to address the impact of AI integration into decision-making processes of anaerobic digestions and how it changes it. In particular, the issue needs to be explored as regards to whether AI allows for shifting from reactive operations into proactive ones and how this transformation is influenced by actual data availability and quality.

Lastly, regarding the advanced computational modelling stream, considerable progress has been achieved in terms of creating new modelling algorithms, but still the research area appears fragmented and rather performance oriented. Future research will have to move away from purely empirical and practical concerns towards integrative and theoretical ones and consider how advanced modelling techniques influence the way AD is represented and studied. Future research should explore whether hybrid and interlinked modelling frameworks allow for multi-level analysis of anaerobic digestion processes and how computational models help in generating knowledge and making decisions in digitalized

Table 4: Future research agenda on AI/ML application on biogas production.

Cluster	Open Research Questions
Cluster 1 – Strategic and Sustainability-Oriented AI Applications	· How can AI-driven TEA support investment decisions? · How are insights translated into decisions? · What is the role of AI in strategic planning?
Cluster 2 – Artificial Intelligence Applications for Biogas System Optimization	· How does the integration of AI reshape the decision-making logic of AD processes beyond traditional control systems? · To what extent does the adoption of AI shift biogas systems from reactive to predictive and proactive operational paradigms? · How do data availability and quality influence the effectiveness of AI-driven optimisation in real-world biogas plants?
Cluster 3 – Advanced Computational Modelling and Optimization	· How do advanced modelling approaches reshape the representation of AD processes, moving from mechanistic to data-driven system understanding? · To what extent can hybrid and integrated modelling frameworks enable a systemic and multi-level understanding of biogas systems? · How can computational models be designed not only for prediction, but also for supporting knowledge generation and decision-making in digitalised biogas systems?

5 Conclusions

This study introduces the notion that biogas can be considered as an energy company, in which digital technologies have significant influence on decision-making processes and performance achievements. From the perspective of managers, the results imply that implementation of AI in the production of biogas should not be restricted to enhancing the predictive precision or the efficiency of operations. Instead, AI should be used as a management tool to aid decision-making. In this sense, AI-powered techno-economic analysis will help make decisions and evaluate scenarios under conditions of uncertainty, while data-driven solutions will facilitate moving from a responsive to a more anticipatory and predictive mode of management. On the other hand, proper use of AI necessitates the formation of organisational competencies in data management and AI-human interaction. In terms of policymaking, the results show the necessity of enhancing institutional efforts to ensure digital transformation in the field of bioenergy. The government must take a critical role in supporting the use of innovative technology and developing AI tools, particularly in case of small-scale operations producing biogas. In addition, investments in modern digitalized technologies must be made to ensure effective implementation of the proposed technologies. It is also essential to mention that the digitalisation of biogas operations demands new skills, so training programs and knowledge transfer initiatives become crucial. Finally, the growing use of data driven tools brings up the issues associated with data protection and reliability of algorithms, so the development of corresponding regulatory policies is needed. Thus, there are several policy recommendations related to supporting digitalisation of biogas processes. First, it is necessary to design special incentives and offer funding programs for introducing innovations into practice. In addition, it is crucial to invest in modern digital technologies and develop regulations about data management and algorithm reliability.

Although this study makes certain contributions, it also has some limitations. Firstly, the literature analysis was based on Scopus and Web of Science. It is likely that other databases and sources contained papers which were also relevant for the topic and could have been included in the analysis. Secondly, even though the search string was carefully formulated, there might be other studies which could have been relevant but have not been captured due to the limited scope of the search strategy. In future studies, these limitations need to be addressed by analysing more databases and fine-tuning the search strategy. Additionally, more research is required to explore how the adoption of AI affects organisations, economies, and policies in practice and whether the conceptualization of biogas systems as digitalized energy enterprises can be validated empirically.

7 Ethics Declaration

The authors declare that no ethical approval was required for this research.

8 AI Declaration

In the preparation of this paper, AI tools, specifically ChatGPT and Gemini, were used solely to refine the English language and check grammar. These tools were not used to generate original content, ideas, or analysis. All intellectual work, arguments, and conclusions presented in this paper are the authors' own.

Servant Leadership as a Relational Resource: Initial Insights from Qualitative Case Studies in Saudi Higher Education

Hayam Mohammed A Jabali[1], Ashish Malik[2], Philip J. Rosenberger III[1], Cathy Ying Xu[1]

[1] Newcastle Business School, University of Newcastle, Newcastle, Australia

[2] School of Business, UNSW Canberra, Canberra, Australia

Abstract

This study explores how servant leadership functions as a relational resource within resource-constrained higher education environments in Saudi Arabia. Drawing on the Job Demands–Resources (JD–R) framework, the research examines how leadership behaviours influence employees' experiences of high job demands, including workload pressures, administrative responsibilities, and institutional constraints. Using a qualitative multiple case study approach, data were collected through semi-structured interviews with leaders and followers across two cases – academic departments within a Saudi public university.

The study specifically focuses on how leadership is enacted and experienced in real-life organisational contexts, providing a nuanced understanding of how employees interpret leadership behaviours under conditions of sustained pressure and limited resources. This approach allows for the exploration of both leader and follower perspectives, offering a more comprehensive view of leadership dynamics within higher education settings.

The findings indicate that servant leadership does not reduce structural job demands but instead plays a critical role in buffering their negative effects by strengthening relational and social job resources such as trust, psychological safety and collaboration. Leadership behaviours including empathy, consultation and support were consistently identified as essential in helping employees cope with demanding work environments.

These behaviours were particularly significant in contexts where formal resources were limited, highlighting the role of leadership in compensating for structural constraints through relational support and interpersonal engagement. Employees reported that such leadership practices contributed to a more positive work environment, even in the presence of ongoing institutional challenges.

The study also highlights the importance of cultural context, demonstrating how leadership effectiveness is shaped by expectations related to hierarchy, respect and fairness.

These cultural dimensions influence not only how leadership behaviours are perceived but also how they are enacted. This requires leaders to balance authority with relational sensitivity to maintain credibility and trust within their teams.

Furthermore, social learning processes emerged as an important outcome, with employees relying on informal interactions and peer collaboration as key mechanisms for knowledge sharing. This finding underscores the importance of relational environments in facilitating learning and adaptation, particularly in settings where formal training opportunities may be limited. Leadership plays a central role in enabling these processes by fostering a culture of openness, collaboration and mutual support.

Overall, the findings contribute to the JD–R literature by positioning leadership as a central relational resource and provide contextually grounded insights into servant leadership within Saudi higher education.

Keywords: Servant leadership, Job Demands–Resources model, Saudi higher education, Qualitative case study, employee wellbeing.

Paper type: Academic Research Paper

1 Introduction

Leadership plays an important role in shaping how employees experience and respond to challenging work environments, particularly in higher education systems undergoing rapid transformation (Bakker & Demerouti, 2017). In Saudi Arabia, the higher education sector is facing increasing pressures associated with Vision 2030, including growing student numbers, accreditation requirements and heightened expectations for performance and quality (Al-shahrani, 2022). These pressures have significantly intensified job demands for both academic and administrative staff, often without a corresponding increase in resources (Akbar et al., 2023). Within this context, servant leadership has been proposed as an effective leadership approach due to its emphasis on support, empowerment and follower wellbeing (Eva et al., 2019). However, empirical research examining how servant leadership is enacted in practice within Saudi higher education, particularly through a Job Demands–Resources (JD–R) lens, remains limited (Gonaim, 2019). Preliminary insights from a localised, contextual and

cultural setting of Saudi Arabia highlight and offer a nuanced explanation of how servant leadership is enacted and how the key tenets of JD-R play out in this setting.

In addition to these structural pressures, recent developments in higher education have introduced increased expectations for research productivity, international collaboration and quality assurance processes, further intensifying the complexity of academic roles (Den Hartog & De Hoogh, 2024). These evolving expectations require employees to continuously adapt to changing institutional priorities, often under conditions of uncertainty and limited organisational support (Bakker et al., 2023). This highlights the growing importance of leadership approaches that can effectively support employees in navigating these challenges while maintaining wellbeing and performance (Eva et al., 2019).

Furthermore, examining servant leadership within the Saudi context provides an opportunity to better understand how leadership behaviours are shaped by cultural norms, organisational structures and institutional constraints. This is particularly important in high power-distance environments, where leadership expectations differ significantly from Western contexts (Shafai, 2020). Therefore, this study contributes to both theory and practice by offering contextually grounded insights into leadership within Saudi higher education (Den Hartog & De Hoogh, 2024).

This paper presents initial insights from an in-depth qualitative case study drawing on two cases (academic departments) to explore leadership, job demands, and job resources within resource-constrained higher education contexts. By examining servant leadership under high job demands, this study contributes to the IFKAD track on Leadership, Competencies and Culture for Intelligent Knowledge Management.

2 Methodology

The study adopts a qualitative case study approach grounded in an interpretive research paradigm (Bell et al., 2022). While the broader research project is based on a larger number of cases within Saudi higher education, this paper reports preliminary findings from two completed cases. Each case focuses on an academic department within a public university and draws on semi-structured interviews with four participants representing different organisational roles: faculty members, department chair and administrative staff. Across the two cases, the academic department served as the unit of analysis, enabling comparison of leadership practices and employee experiences under similar systemic pressures (Yin, 2018). Interview data were analysed using thematic analysis with the support of NVivo software to identify patterns related to leadership behaviours, job demands, job resources and employee experiences (Bell et al., 2022).

The use of qualitative case studies allows for a deeper exploration of how leadership is experienced within its real-life context, rather than assuming uniform effects across settings (Yin, 2018). This approach is particularly valuable in leadership research, where context plays a critical role in shaping behaviours and outcomes (Bell et al., 2022). Additionally, the inclusion of both leaders and followers ensures a more comprehensive understanding of leadership dynamics, reducing bias associated with single-perspective studies (Eva et al., 2019).

3 Findings

The findings indicate that both departments operate under extreme and sustained job demands. Participants consistently described high teaching loads, severe staff shortages, increasing administrative responsibilities and continuous accreditation pressures. Such demands align with previous research highlighting intensifying workloads and resource scarcity in higher education institutions (Mudrak et al., 2017). These pressures were further exacerbated by bureaucratic systems and institutional procedures that limited access to financial, human and developmental resources, increasing the risk of employee strain and burnout (Bakker et al., 2023).

Across both cases, participants repeatedly emphasised that these demands were not temporary or cyclical, but rather ongoing and embedded within the structure of the departments. One participant described the situation as "*constant pressure with no real break*," while another noted that "*the workload keeps increasing, but the number of staff does not change*." These reflections highlight the sustained nature of job demands and reinforce the perception that employees are operating in persistently resource-constrained environments.

A more detailed analysis shows that these demands are not isolated but interconnected, requiring employees to simultaneously manage teaching, administrative and research responsibilities under constrained conditions (Bakker et al., 2023). Faculty members described emotional exhaustion and reduced capacity for research engagement, with one participant noting that "*the most exhausting thing is the pressure combined with the lack of basic resources*", while administrative staff highlighted procedural rigidity and workload accumulation as key stressors (Akbar et al., 2023).

Importantly, the interconnected nature of these demands was experienced differently across the two cases. In one department, participants described a more acute sense of overload, where multiple responsibilities had

to be managed simultaneously with minimal support, leading to what one participant referred to as *"a feeling of always being behind."* In contrast, while the second department also experienced high demands, participants described a relatively more manageable environment, where some level of coordination and informal support helped mitigate the intensity of these pressures, as one participant noted that *"the level of cooperation is really high and everyone really does everything for the department"*. This suggests that while both cases share structural similarities, the experience of job demands varies in degree rather than in kind.

From a follower perspective, faculty members reported emotional and physical exhaustion, particularly when expected to maintain high standards of teaching and performance without adequate support or basic resources. Administrative staff similarly experienced pressure arising from rigid systems that prioritised compliance over employee wellbeing (Akbar et al., 2023). While the specific sources and intensity of pressure varied between the two departments, the persistence of high job demands emerged as a shared structural feature across both cases.

Participants further described how these pressures affected not only their performance but also their motivation and sense of professional fulfilment. One faculty member explained that *"you want to do good research, but you just don't have the time or energy,"* while another highlighted that *"most of the work becomes about meeting requirements, not improving quality."* These insights demonstrate how sustained job demands can shift employees' focus from meaningful engagement to task completion, reinforcing the strain associated with high-pressure environments.

Within this highly constrained and structured environment, servant leadership emerged as a critical relational resource rather than a mechanism for reducing objective workload. From the perspective of followers, participants described the department chair's leadership as respectful, consultative and supportive attributes they associated with servant leadership. Leadership behaviours, such as consulting staff before assigning tasks, offering emotional support and providing clarity around expectations, were perceived as essential in helping employees cope with overwhelming demands. These behaviours contributed to psychological safety, trust and commitment, as reflected in participants' experiences.

Participants provided concrete examples of how these leadership behaviours were enacted in practice. For instance, one participant noted that *"before assigning extra work, the chair always asks if we can manage it,"* while another highlighted that *"even when things are stressful, the chair explains clearly what is expected, which makes it easier to handle."* These examples illustrate how leadership behaviours are experienced directly by employees and how they influence day-to-day work experiences.

However, the effectiveness of these behaviours varied slightly across the two cases. In the more resource-constrained department, leadership was often described as a "buffer" that helped employees cope with stress, even when structural issues remained unresolved. In contrast, in the second department, leadership was perceived not only as supportive but also as enabling a more positive and collaborative work environment. This distinction suggests that servant leadership operates differently depending on the intensity of contextual constraints.

Across both cases, leadership behaviours were interpreted as meaningful forms of support, particularly when they addressed individual needs and acknowledged contextual constraints. Employees emphasised the importance of being heard, respected and involved in decision-making processes, highlighting the relational dimension of leadership as central to their work experience (Eva et al., 2019).

Participants frequently linked these relational practices to their sense of value and belonging within the department. As one participant expressed, *"when you feel that your opinion matters, it changes how you approach your work,"* while another noted that *"being included in decisions makes the workload feel more manageable."* These responses highlight the importance of relational dynamics in shaping not only how work is performed but also how it is experienced emotionally and psychologically.

Importantly, within this cultural context, these relational leadership practices serve as key leadership competencies through which leaders shaped a supportive and developmental culture that enabled informal knowledge sharing, peer problem-solving and context-specific learning practices. In this way, servant leadership contributed to the development of a local culture for effective knowledge management (Klein et al., 2013; Pellegrini et al., 2020).

The data further suggest that such practices were particularly important in contexts where formal systems and resources were limited. In both cases, employees relied heavily on peer support and informal communication to solve problems and share knowledge. One participant explained that *"we learn from each other more than from formal training,"* while another highlighted that *"most of the time, solutions come from discussions with colleagues."* These findings indicate that relational leadership not only supports individuals but also facilitates collective learning processes.

The findings also indicate that social learning processes were primarily informal, occurring through daily interactions, collaboration and shared experiences rather than structured training programs (Yang et al., 2023). This highlights the role of leadership in enabling environments where knowledge sharing and learning can emerge organically.

Across the two cases, these informal learning processes were consistently described as essential for navigating complex and changing work demands. However, the extent to which these processes were embedded varied. In one case, informal learning appeared as a necessity due to the absence of formal structures, whereas in the other, it was experienced as a complementary and valued aspect of the work environment. This again reflects variation in how similar dynamics are experienced across different contexts.

In sum, the findings demonstrate that while leadership does not eliminate structural constraints, it plays a critical role in shaping how these constraints are experienced by employees. By enhancing relational resources such as trust, support, and collaboration, leadership enables employees to better cope with high job demands and maintain engagement under pressure. Across both cases, leadership was consistently described as influencing the experience of workload rather than reducing the workload itself. Importantly, the two cases collectively illustrate that the impact of leadership is context-dependent, varying according to the intensity of job demands and the availability of resources, while still maintaining a consistent relational foundation across both settings.

4 Discussion

The findings extend the JD–R model by highlighting leadership as a central relational resource that shapes how employees experience job demands (Bakker et al., 2023). While traditional JD–R research focuses on job characteristics, this study demonstrates that leadership behaviours play a critical role in influencing employee wellbeing and engagement (Bakker & Demerouti, 2017).

More specifically, the findings suggest that leadership should not be viewed as an external factor within the JD–R framework, but rather as an embedded and dynamic resource that interacts directly with both job demands and job resources. This perspective contributes to extending the JD–R model by positioning leadership behaviours as an active mechanism that shapes how employees interpret, respond to and cope with workplace pressures (Bakker et al., 2023).

Servant leadership appears to function as a buffering mechanism that mitigates the negative effects of high job demands by enhancing relational resources such as trust, support and collaboration (Eva et al., 2019). Rather than directly reducing objective workload, these findings suggest that leadership influences the subjective experience of job demands, reinforcing the distinction between objective and perceived demands within the JD–R framework. This reinforces the importance of interpersonal dynamics in shaping employee experiences in demanding environments.

In this study, the buffering effect of servant leadership is particularly evident in situations where structural constraints cannot be altered. In such contexts, leadership behaviours do not reduce workload directly, but instead influence how workload is experienced by employees, making it more manageable and less psychologically taxing. This further supports the argument that relational resources play a critical role in sustaining employee functioning under pressure, extending existing JD–R assumptions about how resources operate in high-demand environments. This highlights the distinction between objective job demands and perceived job demands, with leadership playing a critical role in shaping the latter (Bakker & Demerouti, 2017).

Furthermore, the findings demonstrate that relational resources generated through servant leadership, such as psychological safety and trust, contribute to sustaining employee motivation and commitment even under prolonged pressure. This aligns with prior research, suggesting that social and relational factors are essential for maintaining engagement in high-demand environments (Eva et al., 2019).

The study also highlights the importance of cultural context in shaping leadership effectiveness. In Saudi higher education, leadership behaviours are interpreted through cultural expectations related to respect, hierarchy and fairness, which influence how employees evaluate leadership practices (Shafai, 2020).

Importantly, these cultural expectations do not merely influence perceptions of leadership but actively shape how leadership is enacted in practice. Leaders are required to navigate complex relational dynamics, including hierarchical sensitivity, age-related expectations and norms of respect, which influence their ability to exercise authority while maintaining positive relationships (Den Hartog & De Hoogh, 2024).

This suggests that servant leadership in this context is not a fixed or universal model, but rather an adaptive and contextually embedded practice that evolves in response to cultural and organisational constraints. As such, the effectiveness of servant leadership depends not only on the behaviours themselves but also on how well they align with the broader cultural and institutional environment(Shafai, 2020).

5 Practical Implications

The findings suggest that leadership development programs should focus on relational competencies, such as empathy, communication and support (Pellegrini et al., 2020). Additionally, institutions should create environments that encourage collaboration and informal learning processes (Yang et al., 2023).

From a practical perspective, these findings highlight the need for leadership training programs that move beyond technical and administrative skills to emphasise relational and interpersonal competencies. Developing leaders' ability to listen, communicate effectively and provide context-sensitive support is critical in environments characterised by high job demands and limited resources (Eva et al., 2019).

Moreover, higher education institutions should recognise the importance of informal learning and knowledge-sharing practices, which were found to play a central role in supporting employees. Creating spaces for collaboration, peer interaction and shared problem-solving can enhance organisational resilience and improve overall performance (Pellegrini et al., 2020).

At an organisational level, there is also a need to address structural barriers that limit leadership effectiveness. Policies and procedures that restrict flexibility, decision-making and resource allocation should be reviewed to enable leaders to provide more meaningful support to their teams (Akbar et al., 2023).

6 Limitations and Future Research

This study is based on two case studies, which may limit generalisability (Yin, 2018). Future research should expand the number of cases and could also look to incorporate quantitative approaches to validate the findings (Bell et al., 2022).

In addition to the limited number of cases, this study focuses on a specific institutional and national context, which may influence the transferability of the findings to other settings. While the insights provide valuable understanding of servant leadership in Saudi higher education, caution should be exercised when generalising these results to different cultural or organisational environments (Den Hartog & De Hoogh, 2024).

Future research could therefore use comparative studies across different cultural contexts to examine how servant leadership is interpreted and enacted in diverse environments. This would provide a more comprehensive understanding of the role of culture in shaping leadership effectiveness (Shafai, 2020).

Furthermore, integrating quantitative measures with qualitative insights could strengthen the validity of the findings and provide a more robust understanding of the relationship between leadership, job demands and employee outcomes (Bell et al., 2022).

7 Conclusion

Servant leadership acts as a relational resource within resource-constrained academic environments, supporting employees in managing high job demands. Rather than reducing workload, it enhances employees' capacity to cope through strengthening social and psychological resources (Bakker et al., 2023).

This study demonstrates that the value of servant leadership lies not in its ability to eliminate structural challenges, but in its capacity to reshape how these challenges are experienced by employees. By fostering trust, collaboration, and psychological safety, servant leadership enables employees to sustain engagement and performance despite ongoing pressures (Eva et al., 2019).

Overall, the findings contribute to a more nuanced understanding of leadership within the JD–R framework by emphasising the importance of relational dynamics, cultural context, and organisational constraints. This highlights the need for future research to further explore the intersection of leadership, culture, and employee wellbeing in complex organisational environments (Bakker et al., 2023).

8 Acknowledgements

The lead author would like to express sincere appreciation to her supervisors at the University of Newcastle for their continuous guidance, constructive feedback, and academic support throughout this research. The author also extends her gratitude to the co-supervisor from the University of Canberra (UNSW) for their valuable insights and contributions to the development of this study. In addition, the author is grateful to all participants who generously shared their time and experiences, which were essential to the completion of this research and significantly enhanced the quality and depth of the findings presented in this paper.

9 Ethics Declaration

This study adhered to ethical research standards and received approval by the university's Human Research Ethics Committee (approval number: H-2024-0357).

10 AI Declaration

AI tools were used in a limited and selective manner to support language refinement, editing and structuring of the manuscript. No AI tools were used in the conceptualisation, research design, data collection, data analysis or interpretation of the findings. Full responsibility is taken for the accuracy, validity and integrity of all content presented in this paper. All AI-assisted outputs were carefully reviewed, verified, and revised to ensure their appropriateness and alignment with the research objectives. The limitations of AI tools, including potential bias, inaccuracies and gaps in knowledge, are acknowledged, and it is confirmed that all final decisions and interpretations are entirely the author's own.

Retrieval-Augmented Generation in Business Applications: A Systematic Literature Review and Taxonomy

Beren Çay, Mario Miozza, Andrea De Mauro
Luiss Guido Carli University, Rome, Italy

Abstract

Retrieval-Augmented Generation (RAG) has become one of the most visible mechanisms for grounding large language model outputs in organizational knowledge sources. While the technical literature on RAG architectures is substantial, the evidence on how RAG is deployed inside organizations, and on the organizational consequences of those deployments, has not been systematically synthesized. This paper addresses that gap by treating RAG as a hybrid knowledge capability pairing a generative model with curated organizational knowledge and human oversight. The study reports a systematic literature review of peer-reviewed work on RAG in business and organizational contexts published between 2023 and 23 February 2026, covering Scopus and Web of Science in line with the PRISMA 2020 reporting framework. From 727 records after database-side filtering, 513 were screened and 41 retained. The studies were synthesized through the empirical-to-conceptual taxonomy development method of Nickerson, Varshney and Muntermann (2013) into a three-dimensional framework linking business application contexts, RAG architectures, and reported organizational consequences. Three findings stand out. First, adoption concentrates in knowledge-intensive support functions: enterprise knowledge retrieval, document intelligence, and decision support together account for around seventy percent of the corpus. Second, Classic RAG remains the most frequent single configuration, while Advanced and Agentic variants together appear in 18 studies and concentrate in deployments with more demanding task structures. Third, the most consistent finding is not a benefit but a limitation: residual output quality issues appear in 26 of 41 studies and recur across every architectural category and every application context, while data-quality dependence is the most frequent implementation challenge. The paper contributes a business-oriented taxonomy empirically distinct from architecture-first surveys, positioning RAG as a socio-technical capability whose organizational value depends on the surrounding data, governance, and oversight infrastructure. For practitioners, it supports deliberate decisions about where RAG delivers value, which architecture fits which task, and which conditions enable successful deployment.

Keywords: Retrieval-Augmented Generation, Artificial Intelligence, Knowledge Management, Business Applications, Systematic Literature Review

Paper type: Academic Research Paper

1 Introduction

Large language models (LLMs) have moved from a research topic to a routine component of organizational work, embedded in tasks from internal knowledge search to customer support and analytical decision assistance (Dwivedi et al., 2023). The operational difficulty is documented: LLMs generate fluent but unverifiable outputs — hallucination — and rely on a parametric memory fixed at training time, providing no clear provenance for its claims (Ji et al., 2023; Huang et al., 2025). In knowledge-intensive work where outputs feed decisions, are communicated externally, or are subject to audit, these are operational liabilities, not peripheral concerns.

Retrieval-Augmented Generation (RAG) was introduced by Lewis et al. (2020) for conditioning generation on retrieved external evidence rather than parametric memory alone. From a knowledge-management standpoint, the re-design matters less for benchmark performance than for the relationship between model and knowledge: the knowledge moves to an external store the organization can update, govern, inspect, and restrict (Gao et al., 2023; Fan et al., 2024). RAG sits inside the conceptual frame of Alavi and Leidner (2001) — knowledge management systems supporting creation, storage and retrieval, transfer, and application of organizational knowledge — most directly at retrieval and application stages.

The existing review literature is dominated by architecture-first technical surveys (Gao et al., 2023; Fan et al., 2024), where applications appear as illustrations rather than objects of analysis. Practitioner-oriented evidence on engineering challenges is more concrete (Barnett et al., 2024) but reported through software-engineering case studies rather than structured organizational synthesis. No business-oriented synthesis was identified that maps where RAG is used, which architectures are adopted, and what organizational benefits, limitations, and challenges are reported.

This paper provides that synthesis. Three research questions guide the review. RQ1: In which business functions and decision contexts is RAG applied? RQ2: What architectures are employed? RQ3: What benefits, limitations, and challenges are reported organizationally? The contribution is a three-dimensional taxonomy,

derived empirically from 41 peer-reviewed studies, linking application context, architectural configuration, and organizational consequence. It treats RAG as a hybrid-knowledge capability combining retrieval and generation with human oversight and curated organizational knowledge. Unlike architecture-first surveys (Gao et al., 2023; Fan et al., 2024), its primary axis is the organizational application context, not the technical pipeline; architectures and outcomes are read off that axis.

2 Theoretical Background

Three streams of literature are relevant. The first is the knowledge-management view that systems supporting organizational knowledge work must address the cycle of creation, storage and retrieval, transfer, and application (Alavi and Leidner, 2001). In knowledge-asset terms, RAG converts dispersed, weakly indexed organizational knowledge into a contextually retrievable, query-conditioned resource — without changing the underlying stock, but altering how it can be deployed. It functions at retrieval and application stages: not producing new organizational knowledge, but making existing knowledge accessible at the moment a question is asked. Dwivedi et al. (2023) argue that the impact of generative conversational AI depends on integration into work systems rather than capability alone.

The second stream concerns the technical anatomy of RAG. Parametric memory in a sequence-to-sequence model is paired with non-parametric memory accessed through a neural retriever; retrieved passages are incorporated into generation, producing more specific and factual outputs on knowledge-intensive tasks (Lewis et al., 2020). Gao et al. (2023) describe a progression from Naive RAG, through Advanced RAG (pre- and post-retrieval stages), to Modular RAG. Fan et al. (2024) document architectural diversification. Edge et al. (2024) introduce graph-based retrieval for sensemaking that requires reasoning over relational structure. The present paper organizes the architectural landscape into five categories recurring in the corpus: Classic RAG (Gao et al.'s Naive RAG), Advanced RAG, Agentic RAG, Hybrid RAG, Graph-Based RAG. The categories are structural alternatives whose suitability depends on task and underlying knowledge, not an ascending hierarchy.

The third stream is the still-thin organizational literature on RAG. Practitioner work has identified seven recurring failure points in engineered RAG systems and concluded that validation is meaningful only in operation, not in isolation (Barnett et al., 2024). Survey work on hallucination has shown that retrieval imprecision, irrelevant content, and failures to integrate retrieved evidence with generation can reintroduce the problems RAG was meant to address (Huang et al., 2025). What these contributions do not provide is a structured mapping of business contexts, architectures, and organizational consequences. That gap is the object of the present review.

3 Methodology

The study follows a systematic literature review methodology (Tranfield, Denyer and Smart, 2003), with reporting aligned to PRISMA 2020 (Page et al., 2021). The review was not pre-registered; the search strategy, eligibility criteria, screening, and extraction procedure are reported here to support replicability.

The literature search covered Scopus and Web of Science. The Boolean query — ("retrieval-augmented generation" OR "retrieval augmented generation" OR RAG) AND (business OR enterprise* OR organization*) — was applied to title, abstract and keyword fields in Scopus and to the Topic field in Web of Science. Business-side terms were kept broad to capture organizational applications across industries without biasing the corpus toward a single sector. The final search was conducted on 23 February 2026.

Scopus initially returned 912 records and Web of Science 469. After database-side filters for years (2023–2026), document types (articles, reviews, conference papers), and language (English), 494 Scopus and 233 Web of Science records were retained, giving 727 before deduplication. The 2023–2026 window was selected because organizational applications of RAG emerged after the broader diffusion of LLM-based systems. Records were exported to Rayyan, where 214 duplicates were removed, leaving 513 for screening.

Inclusion criteria, defined before screening, retained studies that (i) explicitly addressed RAG or closely related retrieval-augmented architectures, (ii) reported a concrete application, framework, prototype, case study, or empirical evaluation in an organizational or business context, and (iii) were peer-reviewed journal or conference papers. Exclusion criteria removed (i) exclusively technical studies with no organizational application, (ii) papers on generative AI or LLMs with a small or absent RAG component, (iii) non-academic publications, and (iv) secondary reviews without a substantive business-oriented case, framework, or application analysis.

Title-and-abstract screening reduced the corpus to 237 reports for full-text retrieval. Full texts were sought through the author's institutional subscriptions and Google Scholar; reports unavailable through either channel were classified as unretrieved, and the resulting accessibility bias is acknowledged in §5. Of these, 108 could not be retrieved. The remaining 129 were assessed in detail; 88 were excluded (3 not focused on RAG; 83 lacking

organizational contexts; 1 not a primary research study; 1 not peer-reviewed) and 41 retained. The full PRISMA 2020 flow is presented in Figure 1.

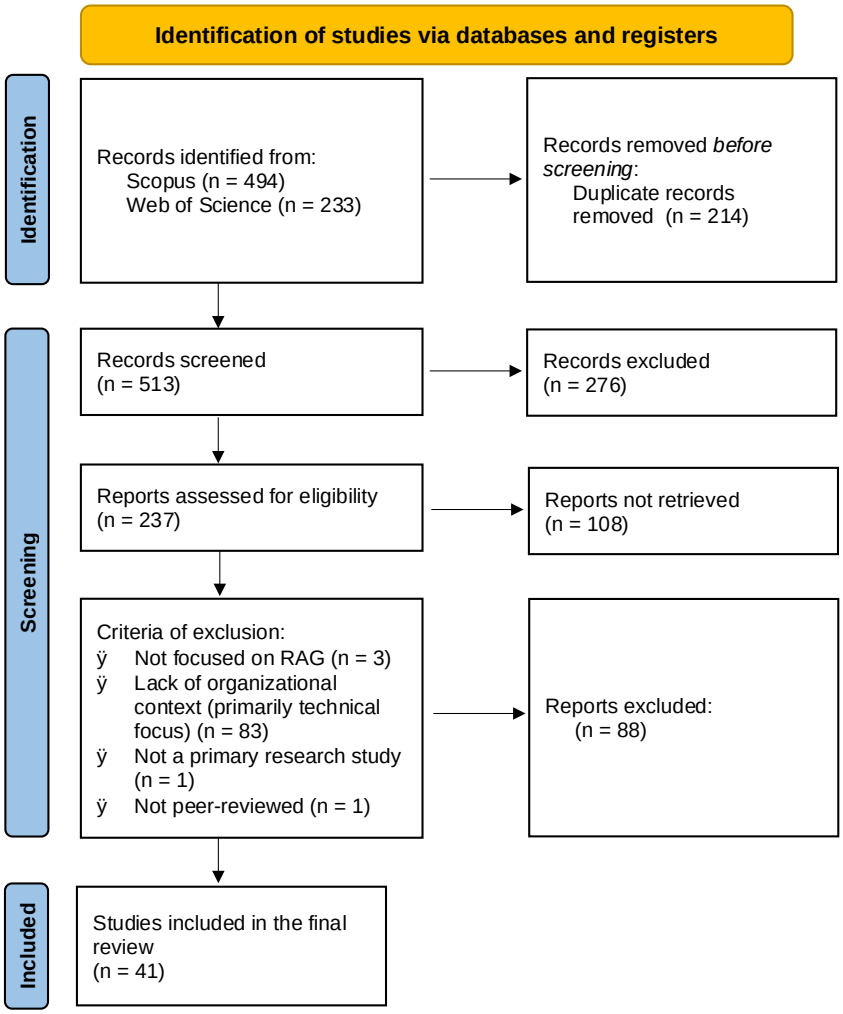

Figure 1: PRISMA 2020 flow diagram for the systematic literature search and screening process.

A formal quality appraisal was not performed: the corpus is heterogeneous in study type, and a single instrument would not apply evenly. Evaluation strength was recorded as a coded category at extraction (limitation *Weak or Missing Empirical Evaluation*, identified in 9 of the 41 studies and reported in §4.3) rather than aggregate scores. Coding and extraction were performed by a single reviewer; this and the absence of formal appraisal are acknowledged as methodological limitations. Each paper was reviewed using a purpose-built extraction instrument capturing sector, business application, RAG architecture, and reported organizational consequences. The taxonomy was developed following Nickerson, Varshney and Muntermann (2013), with the meta-characteristic defined as organisational use of RAG in business contexts.

4 Findings

The taxonomy is presented in Figure 2 and synthesized in Table 1.

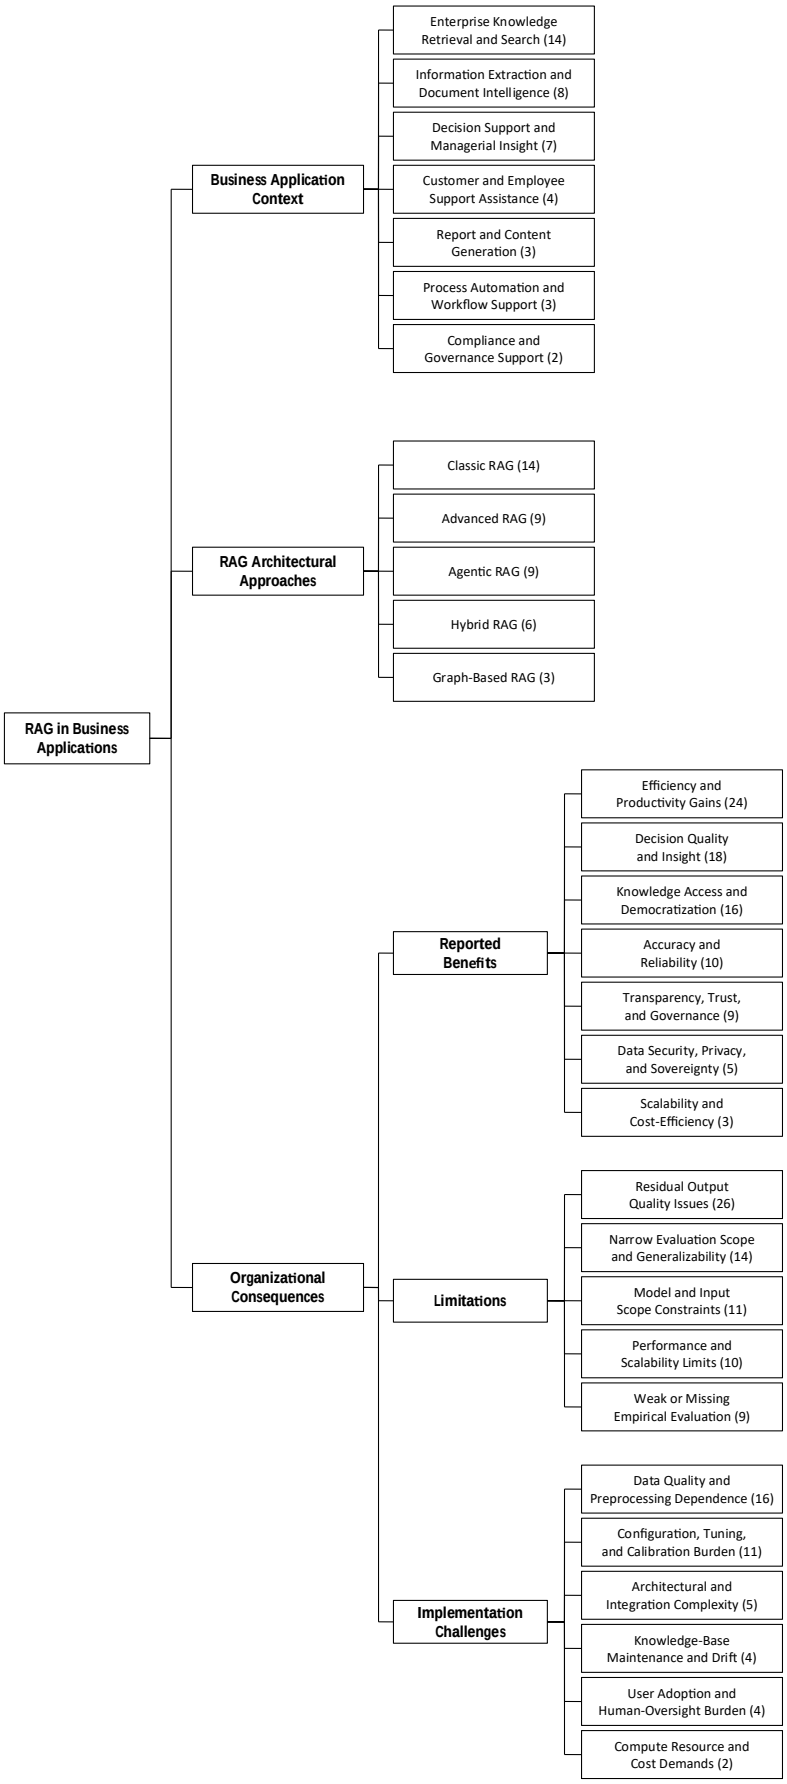

Figure 2: Three-dimensional taxonomy of Retrieval-Augmented Generation in business applications. Numbers in parentheses denote study counts within each category (n = 41 studies).

Table 1: Cross-dimensional synthesis of application context, observed architectures, and reported organizational consequences (n = 41 studies)

Business application context (n)	**Architectures observed (paper count)**	**Most frequently reported benefits**	**Most frequently reported limitations**	**Most frequently reported organizational challenges**	**Representative studies**
Enterprise Knowledge Retrieval and Search (14)	Hybrid (5); Advanced (3); Agentic (2); Classic (2); Graph-Based (2) — *all five architectures present*	Knowledge Access and Democratization (10); Efficiency and Productivity Gains (8); Accuracy and Reliability (4)	Residual Output Quality Issues (13); Model and Input Scope Constraints (4); Performance and Scalability Limits (3)	Data Quality and Preprocessing Dependence (7); Configuration, Tuning, and Calibration Burden (4)	Bordino et al. (2025); Choi et al. (2025); Eckroth et al. (2025); Tyndall et al. (2025); Viswanathan and Sasaki (2025)
Information Extraction and Document Intelligence (8)	Classic (4); Advanced (2); Agentic (2)	Efficiency and Productivity Gains (8); Decision Quality and Insight (7)	Narrow Evaluation Scope and Generalizability (5); Model and Input Scope Constraints (3); Performance and Scalability Limits (3); Weak or Missing Empirical Evaluation (3)	Data Quality and Preprocessing Dependence (4)	Arslan and Cruz (2024); Lin and Dang (2026); Vignesh et al. (2025)
Decision Support and Managerial Insight (7)	Classic (3); Advanced (2); Agentic (2)	Transparency, Trust, and Governance (4); Knowledge Access and Democratization (3); Decision Quality and Insight (3)	Narrow Evaluation Scope and Generalizability (4); Residual Output Quality Issues (3)	Data Quality and Preprocessing Dependence (4); Architectural and Integration Complexity (2)	Bi et al. (2025); Bernardi et al. (2024); Pitkäranta and Pitkäranta (2026); Colesanti Senni et al. (2025)
Customer and Employee Support Assistance (4)	Classic (3); Advanced (1)	Efficiency and Productivity Gains (2); Accuracy and Reliability (2); Knowledge Access and Democratization (2)	Residual Output Quality Issues (3); Weak or Missing Empirical Evaluation (2)	Configuration, Tuning, and Calibration Burden (2)	Della Sala (2025); Kruk, Herath and Choudhury (2025); Packowski et al. (2024); Orlowski, Knauff and Marquardt (2025)
Report and Content Generation (3)	Classic (1); Advanced (1); Hybrid (1)	Efficiency and Productivity Gains (2)	Narrow Evaluation Scope and Generalizability (2)	Configuration, Tuning, and Calibration Burden (2)	Alboaneen et al. (2025); Guan et al. (2025); Byun et al. (2025)
Process Automation and Workflow Support (3)	Agentic (2); Classic (1)	Efficiency and Productivity Gains (2)	Residual Output Quality Issues (3)	Configuration, Tuning, and Calibration Burden (1); User Adoption and Human-Oversight Burden (1)	Meddeb, Batti and Fathallah (2026) — Agentic; Rao et al. (2025) — Agentic; Cherednichenko and Maliarenko (2026) — Classic
Compliance and Governance Support (2)	Graph-Based (1); Agentic (1)	Decision Quality and Insight (2); Transparency, Trust, and Governance (2)	Each limitation reported once (n too low to identify dominant pattern)	Each challenge reported once (n too low to identify dominant pattern)	Sun, Luo and Li (2025) — Graph-Based; Pitkäranta and Pitkäranta (2024) — Agentic

Note. Architecture counts sum to row n and reflect dominant primary architecture coding. Benefits, limitations, and challenges are multi-coded per study; within-row counts may exceed n.

4.1 Dimension 1: Business application context

Across the 41 studies, seven contexts emerged. Enterprise Knowledge Retrieval and Search (14) is most frequent: banking knowledge bases (Bordino et al., 2025); automotive proprietary documentation (Choi et al., 2025); oil-and-gas community-of-practice assistants (Eckroth et al., 2025); enterprise resource planning (Viswanathan and Sasaki, 2025); privacy-preserving public-sector configurations (Tyndall et al., 2025). Information Extraction and Document Intelligence (8) synthesizes unstructured documents — manufacturing specifications (Lin and Dang, 2026); supply-chain mapping from financial filings (Jackson et al., 2026). Decision Support and Managerial Insight (7) foregrounds analytical orientation — climate-disclosure assessment (Colesanti Senni et al., 2025); human-aligned AI governance in banking (Pitkäranta and Pitkäranta, 2026). Together these account for around seventy percent of the corpus, indicating concentration in knowledge-intensive support functions rather than autonomous high-stakes settings. The remaining four — Customer and Employee Support (4), Report and Content Generation (3), Process Automation and Workflow Support (3), Compliance and Governance Support (2) — are present but limited.

4.2 Dimension 2: RAG architectural approaches

Five architectural categories appeared. Classic RAG, where a query triggers retrieval and retrieved content is added to the prompt (Lewis et al., 2020), is most frequent (14 of 41). Advanced RAG and Agentic RAG share second place (9 each). Advanced RAG extends the pipeline through re-ranking, validation, and self-reflective refinement, for tasks demanding greater precision or verifiability — bill-of-materials digitization (Lin and Dang, 2026); supply-chain mapping (Jackson et al., 2026). Agentic RAG embeds RAG in agent-based loops for planning, tool use, multi-step execution (Meddeb, Batti and Fathallah, 2026; Pitkäranta and Pitkäranta, 2024, 2026). Hybrid RAG (6) combines dense semantic with lexical or structured retrieval for heterogeneous enterprise knowledge bases. Graph-Based RAG (3) uses an explicit knowledge graph (Edge et al., 2024) for relational domains: regulatory compliance (Sun, Luo and Li, 2025); physical-internet logistics (Naganawa, Hirata and Yamada, 2025); ERP ontology (Viswanathan and Sasaki, 2025). The categories are not hierarchical: the prevalence of Classic RAG suggests substantial value (knowledge access, response grounding, reduced hallucination risk) is achievable through direct configurations. Architectural-selection rationale is rarely explicit; the distribution reflects outcomes.

4.3 Dimension 3: Organizational consequences

Nine of 41 studies did not explicitly report implementation challenges (coded as *Not explicitly reported*); categorical counts use the remaining 32, multi-coded. The most frequently reported benefit is Efficiency and Productivity Gains (24 studies): a 12.5× speedup in manufacturing document processing (Lin and Dang, 2026); 85% reduction in supply-chain rule-modification time (Meddeb, Batti and Fathallah, 2026); 20–30% latency improvement in enterprise retrieval (Khaliq and Adebayo, 2026). Decision Quality and Insight (18) and Knowledge Access and Democratization (16) follow, the latter where deployments reduce dependence on senior expertise (Eckroth et al., 2025). Accuracy and Reliability (10) and Transparency, Trust, and Governance (9) are secondary but consequential, the governance cluster appearing in regulated and high-accountability settings (Sun, Luo and Li, 2025; Pitkäranta and Pitkäranta, 2024; Alboaneen et al., 2025; Colesanti Senni et al., 2025). Data Security, Privacy, and Sovereignty (5) and Scalability and Cost-Efficiency (3) are least frequent.

The most frequently reported limitation is Residual Output Quality Issues, in 26 of 41 studies. This captures incomplete, vague, inconsistent, or insufficiently grounded outputs persisting even when generation is augmented by retrieval — hallucinations surviving RAG (Cherednichenko and Maliarenko, 2026); long-context handling difficulties (Choi et al., 2025); retrieval imprecision (Bordino et al., 2025). Its near-universal appearance across all five architectural categories and seven application contexts is the single most consistent finding. Narrow Evaluation Scope and Generalizability (14), Model and Input Scope Constraints (11), Performance and Scalability Limits (10), and Weak or Missing Empirical Evaluation (9) round out the limitations.

The most frequently reported implementation challenge is Data Quality and Preprocessing Dependence (16), capturing the degree to which RAG performance depends on the cleanliness, completeness, and structure of the underlying knowledge base. Configuration, Tuning, and Calibration Burden (11) is the effort to select embedding models, set retrieval thresholds, refine prompts, tune re-ranking, and adapt per domain. Architectural and Integration Complexity (5), Knowledge-Base Maintenance and Drift (4), User Adoption and Human-Oversight Burden (4), and Compute Resource and Cost Demands (2) complete the dimension.

4.4 Cross-dimensional observations

Two patterns are organizationally consequential. First, Residual Output Quality Issues appear across every architectural category and every application context — sophistication does not, in this evidence, eliminate them. This is hard to reconcile with the assumption that elaborate configurations (agentic, graph-based, hybrid) automatically resolve quality failures. Second, Data Quality and Preprocessing Dependence appears across all architectural categories, more frequent in elaborate ones (5 of 9 Advanced, 4 of 9 Agentic, against 3 of 14 Classic). Bin sizes are small and the pattern suggestive, but consistent with deployment success sitting outside the architecture, in surrounding organizational and data infrastructure. A third pattern: Graph-Based RAG appears in domains with explicit relational structure rather than a distinctive application category, illustrating architectural choice following knowledge-domain structure rather than a general upgrade path.

5 Discussion

Read against the research questions, the taxonomy supports reading RAG as a hybrid knowledge capability, not a self-contained technical artefact. For RQ1, adoption concentrates in the knowledge-management problem space — inaccessibility of dispersed institutional knowledge, processing of unstructured text, grounding judgements in traceable sources — consistent with the observation that re-use of dispersed knowledge is a main bottleneck in knowledge work (Alavi and Leidner, 2001). For RQ2, the prominence of Classic RAG alongside meaningful shares for Advanced and Agentic configurations in more demanding tasks suggests that, at this stage of adoption, the simplest fit-for-purpose configuration tends to win. For RQ3, the persistence of residual quality issues, together with data-quality dependence, supports a socio-technical reading: RAG's value depends on surrounding infrastructure rather than residing in the model.

For organizations in regulated and sustainability-relevant settings, the corpus offers a specific signal. Transparency, Trust, and Governance concentrates in compliance, governance, and disclosure-assessment applications (Sun, Luo and Li, 2025; Colesanti Senni et al., 2025; Alboaneen et al., 2025). The case for RAG is context-dependent: in operations-intensive settings the argument is efficiency; in regulated and ESG-relevant settings, grounded and auditable reasoning. Framing RAG only as hallucination reduction fails to capture where its value concentrates in practice.

For practitioners, three implications follow. First, data readiness is the primary adoption prerequisite, and its importance persists — perhaps intensifies — as architectural sophistication grows: a well-maintained knowledge base enables more reliable outcomes from a modest configuration than an elaborate architecture on poorly prepared documentation. Second, architecture should follow task structure: an Agentic system for a use case adequately served by Classic RAG adds configuration and governance burden without proportionate benefit. Third, human review and governance are operating requirements, not safeguards.

The study has methodological limitations. Coding was performed by a single reviewer; the absence of inter-rater reliability testing means classification reflects interpretive judgement. The review was not pre-registered. The search was restricted to two databases (Scopus and Web of Science), to peer-reviewed journal and conference papers, and to publications in English. 108 reports could not be retrieved and may have introduced accessibility bias. No formal quality appraisal was performed. The 2023–2026 window captures the active period of organizational RAG adoption but is short.

6 Conclusion

This paper reviews the RAG literature in business and organizational contexts and develops a three-dimensional taxonomy linking application context, architectural approach, and organizational consequence. Adoption concentrates in knowledge-intensive support functions; Classic RAG dominates while Advanced and Agentic configurations cluster in demanding deployments; benefits coexist with a persistent residual-quality limitation regardless of architecture, and with data-infrastructure dependence at least as strong in elaborate as in simple architectures. RAG is positioned as a hybrid knowledge capability whose value depends on surrounding data, governance, and oversight infrastructure. The next research step is comparative, longitudinal, governance-focused evidence from real deployments. For practice, the taxonomy supports decisions about where RAG delivers value, which architecture fits which task, and which conditions enable deployment.

7 Ethics declaration

This study did not require ethical clearance. No human or animal subjects were involved, and no personal or sensitive data were collected, processed, or analyzed.

8 AI declaration

The author used AI-assisted tools during the preparation of this paper. Generative AI was used to support language editing and structural refinement in selected sections. All conceptual work, methodological decisions, screening, coding, taxonomy development, interpretation of findings, and final wording were carried out by the author, who reviewed and verified all AI-assisted text and takes full responsibility for the content.

Abstract

Contemporary crises, ranging from pandemics and climate-related disasters to geopolitical conflicts, are increasingly interconnected and transboundary, giving rise to *polycrises* characterised by cascading effects, high uncertainty, and fragmented information. These dynamics challenge traditional crisis management and call for coordination mechanisms capable of aligning heterogeneous stakeholders under time pressure and asymmetric knowledge. Although Artificial Intelligence (AI), particularly generative AI, is gaining prominence in crisis management, it is still predominantly framed as a tool for prediction or automation. This paper argues that such a view overlooks AI's broader potential as a socio-technical coordination mechanism that augments human capabilities by supporting shared sensemaking and knowledge integration across organisational and institutional boundaries. Adopting a design science research approach combined with conceptual development, this paper proposes a reference framework that conceptualises AI as an embedded coordination infrastructure. The framework integrates three interrelated components. First, it specifies five AI-enabled coordination roles (Sentinel, Broker, Verifier, Orchestrator, and Scribe) aligned with core knowledge management processes (sensing, integration, validation, application, retention). These roles are derived by linking coordination dependencies (flow, fit, share) to knowledge processes that become critical during polycrises and are conceived as overlapping mechanisms embedded in human-AI interaction and organisational practices. Second, it proposes a four-layer architecture that operationalises these roles across heterogeneous environments, spanning data/provenance, knowledge processing, coordination enablement, and governance and learning. Third, the study introduces the construct of AI-enhanced regenerative coordination capacity, articulated through three pillars of crisis readiness: dependency visibility, coordination mechanism agility, and collective learning and institutionalisation. To make the concepts concrete without claiming empirical validation, the framework is examined through structured vignettes derived from recurring crisis patterns and assessed via an analytical, vignette-based evaluation. A common specification template supports traceability from roles to layers to outputs and enables assessment of coverage, governability (provenance, contestability, bounded authority), and explanatory usefulness. Practically, the framework informs the design of interoperable, transparent, and adaptive crisis coordination systems that strengthen informed trust, organisational learning, and cross-boundary collaboration in polycrisis settings.

Paper type: Academic Research Paper

1 Introduction and Problem Statement

Contemporary crises, such as pandemics, climate-related disasters and geopolitical conflicts, are increasingly characterised by their interconnected and transboundary nature. These events unfold across organisational, institutional, and territorial boundaries, creating a complex web of interdependencies. As a result, disruptions propagate across systems, generating cascading effects that amplify their impact and duration. Such dynamics challenge the effectiveness of traditional crisis management approaches, which are typically designed for more linear, predictable, and bounded scenarios (e.g., Comes et al., 2020; Reichstein et al., 2025).

These evolving conditions are often described as "polycrises," emphasising the interaction of multiple, overlapping disruptions. In such contexts, the challenge extends beyond responding to a single event to coordinating multiple actors operating under different institutional logics, priorities, and information regimes. Decision-makers must navigate radical uncertainty, where the nature of the problem may be unclear, while dealing with fragmented and rapidly evolving information. Time pressure further intensifies these constraints, requiring timely yet informed decisions despite incomplete knowledge. Consequently, effective crisis response increasingly depends on coordination mechanisms capable of aligning distributed actors, supporting shared understanding, and enabling continuous adaptation as situations evolve (Margherita et al., 2024).

In recent years, Artificial Intelligence (AI), particularly generative AI, has emerged as a promising resource in crisis management due to its ability to process large volumes of heterogeneous data and support decision-

making in real time (Otal et al., 2024; Pantiris et al., 2025). However, existing research largely frames AI in terms of automation and predictive accuracy. While valuable, this perspective underestimates its potential in complex, multi-actor environments, where the primary challenge lies not only in prediction but in coordination (Domfeh & Dancy, 2025).

Specifically, this prevailing view overlooks AI's capacity to function as a collaborative coordination mechanism that augments, instead of replacing, human capabilities. In crisis settings, where knowledge is distributed and continuously evolving, fostering shared understanding becomes critical. AI systems can support this process by integrating diverse data sources, translating information across domains, and making interdependencies more visible, thereby enabling more effective knowledge sharing and alignment among stakeholders (Li et al., 2025; Rai et al., 2025).

Building on this perspective, this paper reconceptualises AI as a socio-technical coordination mechanism embedded within organisational and inter-organisational processes. While AI is often treated as a passive tool, it is conceptualised as an active component that structures relational complexity, shapes how actors interpret information, and supports collective sensemaking during crises. Drawing on coordination theory, the study emphasises the management of interdependencies among activities and actors, as well as the role of shared knowledge in enabling coordinated action (Nespeca et al., 2020; Okhuysen & Bechky, 2009).

By positioning AI within this broader socio-technical framework, the paper addresses the following research question:

How can AI facilitate coordination in highly complex and uncertain environments?

In this view, the research develops a design-oriented perspective that explains how AI can enhance the capacity of organisations and networks to collectively respond to, learn from, and adapt to crises.

2 Background

The analysis developed in this study focuses on crises in which neither human intelligence nor artificial intelligence alone is sufficient to ensure effective decision-making and coordination. Instead, these contexts call for human–AI collaboration, where complementary strengths are combined to achieve superior outcomes (Li et al., 2025; Rai et al., 2025). Human actors contribute contextual understanding, ethical judgment, and the ability to interpret ambiguity, while AI systems provide scalability and the capacity to process heterogeneous data streams in near real time (Pantiris et al., 2025; Otal et al., 2024). The value of these complementarities is amplified in polycrisis settings, where knowledge is distributed in multiple sources and across organisations, and must be continuously integrated and updated (Nespeca et al., 2020).

Such settings are typically characterised by interrelated conditions that intensify coordination complexity. First, severe time pressure constrains deliberation and increases the need for rapid sensemaking and timely action (Margherita et al., 2024). Second, information is fragmented and asymmetrically distributed across stakeholders operating under different institutional logics, technological infrastructures, and governance regimes, often producing inconsistent situational interpretations (Comes et al., 2020; Nespeca et al., 2020). Third, task, resource, and information interdependencies evolve dynamically, making it difficult to anticipate how local decisions propagate across the system (Okhuysen & Bechky, 2009). Finally, crisis decisions are high-stakes and consequential, raising the premium on reliable, adaptive, and cross-boundary coordination (Reichstein et al., 2025).

A core implication of these conditions is that crisis coordination requires not only pattern detection but also interpretable reasoning about event chains and cascading effects. Purely correlation-driven analytics may identify regularities yet remain fragile when the crisis departs from historical patterns or when spurious relationships drive misleading signals (Pearl & Mackenzie, 2018). In this respect, causal reasoning approaches can strengthen crisis decision-making by supporting counterfactual thinking and scenario exploration, helping stakeholders distinguish plausible mechanisms from coincidental associations and better anticipate the consequences of alternative interventions (Pearl & Mackenzie, 2018; Li et al., 2025). However, the practical value of such reasoning depends on how it is embedded into collaborative processes that support shared interpretation and coordinated action across organisational boundaries (Rai et al., 2025; Margherita et al., 2024).

Within this broader perspective, generative AI (and large language models in particular) is increasingly relevant for crisis coordination because it can function both as an enabling infrastructure and as an active coordination mechanism. As infrastructure, it supports cross-domain translation and synthesis of heterogeneous inputs, and it can generate coordination artefacts such as situation reports, task assignments, and protocol recommendations. As a coordination mechanism, it can contribute to monitoring evolving conditions, highlighting emerging interdependencies, routing information to relevant actors, and supporting the production of shared representations needed for collective sensemaking. These capabilities align with recent surveys on

LLMs for coordination and cooperation tasks (Zhu et al., 2024), and complement work in crisis management information systems and actor-centred coordination (Nespeca et al., 2020; Benaben et al., 2020).

At the same time, applying generative AI in crisis contexts raises constraints that are not peripheral but architectural. LLMs can hallucinate and generate plausible yet incorrect outputs (Sandvik, 2025), a risk that is magnified under time pressure and cognitive bias (Comes, 2016). They can also be brittle under novelty, when crises deviate from patterns represented in training data (Comes, 2026), and their performance is strongly dependent on the quality, timeliness, and governance of underlying data. These limitations motivate human-centred design requirements, such as human-in-the-loop and override mechanisms, provenance and auditability of recommendations, explicit uncertainty communication, and governance arrangements that preserve accountability and legitimacy in high-stakes decisions (Shneiderman, 2020; SAPEA, 2025; Comes, 2024).

Overall, this background supports the need to move beyond viewing AI as an isolated decision-support tool and instead conceptualise it as part of a socio-technical system in which coordination quality depends on how human and artificial capabilities are integrated within workflows, knowledge processes, and governance structures (Hevner et al., 2004; Gregor & Hevner, 2013). Existing research on AI in crisis management still predominantly frames AI in terms of automation, prediction, or isolated decision support, under-specifying its role in managing interdependencies and shaping cross-boundary sensemaking and knowledge integration (Harika et al., 2024; Karinshak, 2024; Piller, 2024). This study addresses this gap by reconceptualising generative AI as an embedded coordination infrastructure and by developing a design-oriented framework that links coordination roles, architectural layers, and regenerative readiness in polycrisis contexts.

3 Framework of AI-Enabled Coordination in Crisis Management

3.1 Research approach

This study adopts a design-oriented approach that combines Design Science Research (DSR) (Hevner et al., 2004; Gregor & Hevner, 2013) with conceptual development (Jaakkola, 2020). This positioning reflects the exploratory nature of the work, which aims to advance theoretical understanding while proposing a structured way to think about AI-enabled coordination in crisis contexts, instead of delivering a fully validated prescriptive solution. The primary outcome of the study is a conceptual artefact in the form of a reference framework for AI-enabled coordination. The framework integrates three interrelated components: (i) a set of AI-enabled coordination roles aligned with key knowledge management processes (sensing, integration, validation, application, and retention), (ii) a layered architecture describing how these roles can be enacted across heterogeneous actors and systems, and (iii) a set of design-oriented considerations that clarify how such configurations may support coordination under conditions of uncertainty and interdependence.

The development of the artefact is informed by an iterative process of conceptual synthesis. Specifically, insights from coordination theory, knowledge management, human–AI collaboration, and crisis management literature are combined to identify and relate core constructs, such as interdependencies, distributed sensemaking, and AI-supported knowledge processes. As opposed to following a fully formalized build–evaluate cycle, the approach emphasises the gradual refinement and internal coherence of the framework through theory integration. Evaluation is limited and primarily analytical in nature. The framework is examined in terms of its internal consistency and its ability to capture salient characteristics of polycrisis contexts, including fragmented information, dynamic interdependencies, and high uncertainty. Scenario construction and evaluation are detailed in the next section.

3.1.1 Scenario construction and analytical evaluation

The operationalisation of the framework consists of structured scenario vignettes represented in Figure 1 and based on recurring crisis patterns (e.g., pandemics, climate-related disruptions, infrastructural failures), which are not used as empirical validation but as heuristic illustrations. Each scenario follows a common specification template: (1) *context and threat dynamics* (including escalation and cascading effects); (2) *stakeholder constellation and institutional logics* (public agencies, operators, NGOs, communities); (3) *salient flow–fit–share dependencies* (task, resource, and information interdependencies); (4) *information conditions* (fragmentation, latency, and asymmetry); (5) *expected coordination breakdown risks* (e.g., overload, misalignment, coordination-information bubbles); and (6) *candidate role–layer interventions and coordination artifacts* (e.g., dependency maps, shared situation reports, escalation triggers).

Scenarios are selected to ensure cross-boundary coordination demands across at least two domains (e.g., health and infrastructure), explicit cascading effects, high-stakes decision-making under time pressure, and informational asymmetry.

Evaluation is analytical and scenario-based: it is assessed whether the framework (a) covers the core polycrisis conditions, (b) supports traceability from roles to layers to outputs, (c) renders dependencies explicit and actionable, (d) remains governable through provenance, contestability, and bounded authority, and (e) provides explanatory usefulness for identifying where coordination value is generated and where breakdowns are likely to occur.

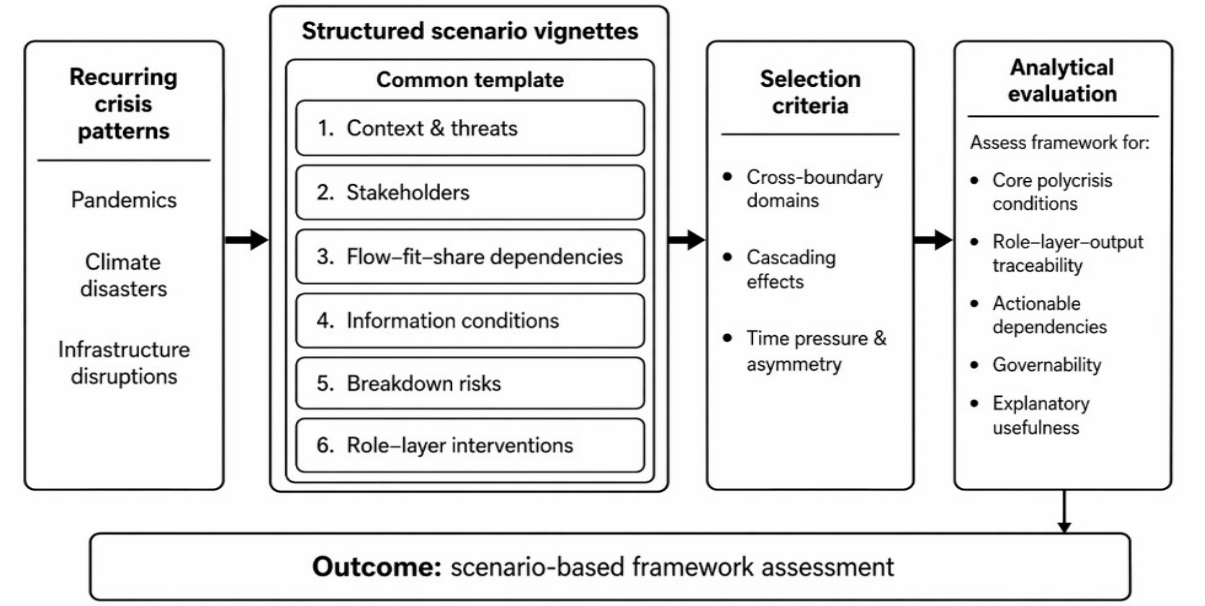

Figure 1. Scenario construction and evaluation process

3.2 AI-enabled coordination roles

This study specifies five AI-enabled coordination roles as the functional core of the proposed framework. The roles are derived by linking coordination dependencies (flow, fit, and share) to five knowledge management processes that become critical under polycrisis conditions—sensing, integration, validation, application, and retention. In this view, AI contributes to coordination by supporting the acquisition, transformation, and use of distributed knowledge across heterogeneous actors, thereby shaping how interdependencies are perceived and managed during crises. Given the dynamic nature of roles and responsibilities in crises (Turoff et al., 2004), the roles are not conceived as discrete or sequential stages; rather, they operate as overlapping and mutually reinforcing mechanisms embedded in human–AI interaction and organisational practices. Table 1 summarises the five roles, their coordination function, and illustrative applications in crisis management. By structuring AI-enabled coordination around knowledge processes, the framework provides a parsimonious way to link technical capabilities with organisational needs. The table offers a synthetic representation of these roles, their coordination functions, and illustrative applications in crisis and emergency management settings.

Table 1. Synopsis of AI-enabled Coordination Roles, related KM processes and Examples.

AI-Enabled Coordination Role	Knowledge Management Process	Description (Coordination Function)	Illustrative Example in Crisis/Emergency Management
Sentinel (Signal Detection & Monitoring)	Sensing	Identify and aggregate signals from heterogeneous data sources to support shared situational awareness, in line with distributed sensemaking and information processing (e.g. Comes et al., 2020).	*Real-time aggregation of satellite data, social media posts, and emergency calls to detect emerging flood zones or wildfire spread.*
Broker (Knowledge Integration & Translation)	Integration	Generate synthetic data and combine or translate distributed information across actors and domains, enabling shared representations and coordination across boundaries (e.g. Okhuysen & Bechky, 2009; Nespeca et al., 2020).	*Filling data gaps and integration of hospital capacity data, mobility patterns, and public health reports during a pandemic to create a unified operational picture.*

AI-Enabled Coordination Role	Knowledge Management Process	Description (Coordination Function)	Illustrative Example in Crisis/Emergency Management
Verifier (Consistency Checking & Causal Assessment)	Validation	Assess reliability, reconcile inconsistencies, and support causal reasoning to distinguish robust signals from spurious correlations (e.g. Rai et al., 2025).	*Cross-validation of field reports and sensor data to confirm infrastructure damage, or use of causal models to assess whether a supply shortage is driven by logistics disruption or demand spikes.*
Orchestrator (Decision Support & Coordination Enablement)	Application	Support decision-making and alignment of interdependent actions under uncertainty, consistent with coordination as the management of dependencies (e.g. Margherita et al., 2024).	*Scenario-based allocation of emergency resources (e.g., ambulances, shelters) and coordination of evacuation plans across agencies.*
Scribe (Learning & Knowledge Institutionalisation)	Retention	Capture and codify knowledge to enable organisational learning and the adaptation of coordination practices over time (e.g. Pimentel & Veliz, 2025).	*Post-crisis analysis of response actions to update emergency protocols, improve preparedness plans, and train future responders.*

3.3 Layered digital architecture for coordination

While the coordination roles defined in Section 3.2 clarify what AI-enabled systems do to support crisis coordination, an operating architecture is needed to explain how these functions are enacted across heterogeneous socio-technical environments. Building on a conceptual synthesis of research on digital infrastructures, multi-level coordination, and AI-enabled ecosystems (Nespeca et al., 2020; Cui et al., 2024), we propose four interdependent layers: (a) Data & Signal, (b) Knowledge Processing, (c) Coordination Enablement, and (d) Governance & Learning. The design logic is that coordination in polycrisis settings requires the progressive transformation of raw signals into validated and actionable knowledge, coupled with feedback and accountability mechanisms that sustain trust and adaptation over time.

The *Data & Signal Layer* provides the foundation of the architecture by acquiring and preparing heterogeneous inputs (e.g., sensor networks, satellite feeds, social media streams, institutional databases, and field reports) for downstream processing. At this level, AI-enabled functions primarily support the *Sentinel* role through ingestion, normalisation, time-stamping, aggregation, and initial relevance filtering. Core outputs include curated signal streams, basic quality indicators, and provenance metadata required for subsequent integration and validation. A central design constraint concerns data reliability under crisis conditions as well as the identification and bridge of data gaps, especially in polycrisis contexts, where sources may be delayed, incomplete, contradictory, or strategically manipulated, which makes uncertainty tagging and provenance preservation necessary at the point of capture.

The *Knowledge Processing Layer* transforms aggregated signals into integrated and contextually meaningful representations that can be shared across heterogeneous actors. It operationalises the *Broker and Verifier* roles by supporting cross-domain translation, semantic/ontological alignment, and consistency checking, including causal assessment when appropriate. The primary output is a validated, multi-perspectival situational knowledge base, accompanied by uncertainty and provenance cues, which enables shared interpretation and provides a reliable input to the coordination enablement functions in the upper layer.

The *Coordination Enablement Layer* translates validated knowledge into coordinated action. It operationalises the *Orchestrator* role by generating coordination artefacts such as situational summaries, resource allocation options, protocol recommendations, dependency alerts, and escalation triggers. This layer also manages dependency tracking: it maintains a continuously updated model of task, resource, and information interdependencies among actors, which allows it to identify coordination gaps, flag bottlenecks, and trigger adaptive responses when conditions change. A key architectural feature at this level is the presence of explicit human-in-the-loop mechanisms. Given the high-stakes nature of crisis decisions and the known limitations of AI systems with respect to hallucination and brittleness under novel conditions (Sandvik, 2025), the layer is designed to present options and recommendations instead of autonomous decisions.

The *Governance & Learning Layer* operates as the meta-level of the architecture. It operationalises the *Scribe* role in the Retention Process by performing three distinct functions. First, it monitors the quality and coherence of outputs generated by the lower layers, flagging inconsistencies or deviations from established protocols. Second, it captures and codifies knowledge generated during crisis episodes, structuring it into reusable artefacts such as updated response templates, revised causal models, and annotated case repositories. Third, it

manages access, accountability, and transparency across the system, including audit of AI-generated recommendations and compliance with applicable governance frameworks.

The four layers are linked by two interface mechanisms. Upward flows carry progressively abstracted knowledge, from raw signals to actionable coordination outputs. Downward flows carry feedback from higher layers to recalibrate lower-layer operations (e.g. when governance monitoring identifies a systematic bias in the signal detection function or when learning outputs update the ontologies used in knowledge integration). Figure 2 provides a synoptic representation of the architecture.

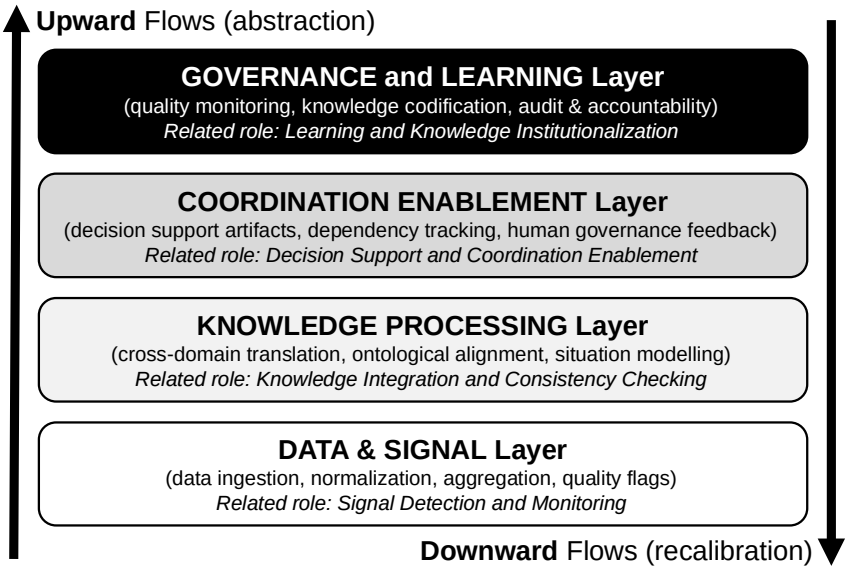

Figure 2. Structure of Layered Architecture

3.4 AI-enhanced coordination capacity

AI actively shapes collective sensemaking processes by influencing what information becomes visible, how it is interpreted, and how it circulates across actors (Comes, 2026). We introduce the concept of AI-enhanced regenerative coordination capacity as a conceptual extension of a higher-level theoretical abstraction of the impact of coordination roles and architecture on organisational readiness.

This capacity is defined along three interrelated pillars: a) dependency visibility, b) coordination mechanism agility, and c) collective learning and institutionalisation. *Dependency visibility* refers to the ability to make interdependencies observable and interpretable across distributed actors. In polycrisis contexts, the failure to perceive dependencies (between organisations, resources, information systems, and decision processes) is a primary source of coordination breakdowns. AI systems, particularly those operating at the Data & Signal and Knowledge Processing layers of the architecture, enhance this visibility by continuously mapping and updating dependency structures in near-real time, making latent interdependencies explicit and presenting them in formats that support human interpretation and action.

Coordination mechanism agility captures the capacity to dynamically reconfigure coordination structures in response to evolving conditions. Static coordination plans are inherently brittle in polycrisis environments where the nature and boundaries of the problem shift rapidly. AI-enabled systems contribute to agility by monitoring changes in dependency structures, identifying misalignments between existing coordination arrangements and emerging operational realities, and supporting the rapid adaptation of protocols, resource allocations, and communication flows. This pillar is most directly operationalised through the Coordination Enablement Layer and the Decision Support role.

Collective learning and institutionalisation emphasise the role of AI in supporting knowledge accumulation and adaptation over time. Crisis response does not end with the resolution of an immediate event; its value also lies in the organisational learning it generates. The Governance & Learning Layer operationalises this pillar by structuring the capture, validation, and codification of knowledge produced during crisis episodes into reusable organisational resources that enhance future preparedness.

Together, these three dimensions frame crisis readiness as a dynamic and regenerative capability, as opposed to a static condition, one that is continuously rebuilt through the interaction of AI-enabled functions,

human judgment, and institutional processes. Figure 3 provides a synoptic representation of the three pillars and their relationships.

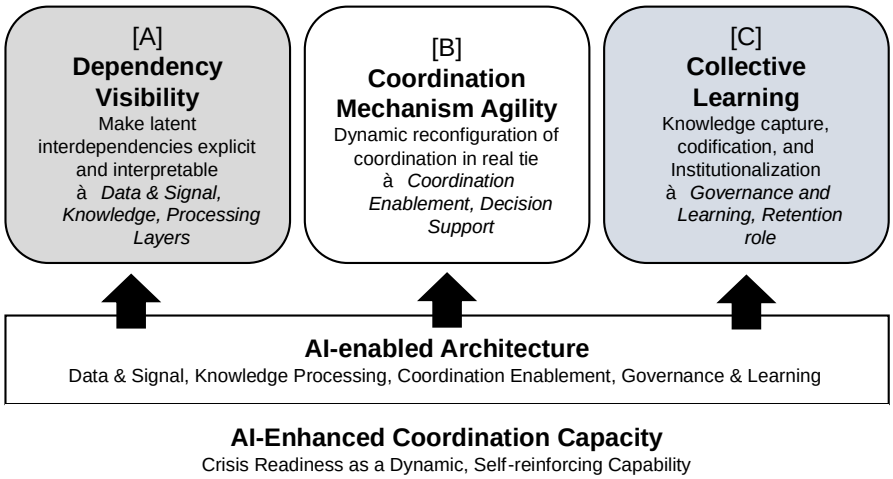

Figure 3. Coordination Capacity Pillars

4 Discussion and Implications

4.1 Academic implications

This study contributes to coordination and crisis management research by specifying how AI-enabled systems can be theorised as coordination mechanisms in polycrisis settings. Moving beyond considering AI as an external decision-support tool, the framework clarifies where and how coordination value is produced through the coupling of functional roles (Sentinel, Broker, Verifier, Orchestrator, Scribe) and architectural layers. This specification supports a testable and design-relevant account of human–AI collaboration in crisis coordination, with particular relevance for knowledge-intensive, cross-boundary settings.

A first contribution lies in extending research on AI-enabled systems and digital infrastructures. Existing approaches often emphasise performance improvements within bounded organisational settings, whereas this study conceptualises AI as an infrastructural layer that operates across organisational and institutional boundaries. By proposing a reference framework tailored to polycrisis contexts, the paper highlights how AI can structure interactions among heterogeneous stakeholders, enabling alignment despite fragmented information and divergent institutional logics. This perspective moves beyond system-centric views and contributes to an emerging stream of research on ecosystem-level coordination and AI-enabled socio-technical architectures.

Second, the paper advances coordination science by introducing a mechanism-based taxonomy of AI-enabled coordination roles. Unlike traditional coordination models, which treat technology as an external support, this framework positions AI as an active participant in the management of interdependencies. By linking coordination roles to knowledge management processes and to flow–fit–share dependencies, the study provides a more granular and operationalizable account of how coordination unfolds in hybrid human–AI environments. This represents a meaningful extension of coordination theory, particularly in contexts characterised by uncertainty, distributed knowledge, and dynamic interdependencies.

Third, the study contributes by integrating functional, structural, and dynamic perspectives into a unified framework. The combination of coordination roles (functional dimension), layered architecture (structural dimension), and regenerative coordination capacity (dynamic dimension) offers a multi-level analytical lens that is largely absent in existing models. This integration enables a more comprehensive understanding of how coordination mechanisms are designed, how they operate in practice, and how they evolve.

Finally, the paper links roles and architecture to AI-enhanced regenerative coordination capacity, articulated through dependency visibility, coordination agility, and collective learning and institutionalisation. The scenario-based analytical evaluation in Section 3.1.1 supports this linkage by tracing role–layer mechanisms to coordination outputs and readiness pillars, enabling comparative designs and evaluation beyond technical performance.

4.2 Practitioner implications

For practitioners in crisis management, the framework suggests that effective adoption of AI requires designing coordination infrastructures, not isolated analytics tools. A practical priority is interoperability by design: data and signal ingestion must be paired with shared semantic standards and dependency representations that can be interpreted across organisations. This implies investing not only in technical integration but also in shared vocabularies, role definitions, and accountability arrangements that allow information to travel without losing meaning or legitimacy.

A second implication concerns decision support under bounded authority. In high-stakes environments, AI should be configured to produce structured options, trade-offs, and escalation triggers (rather than autonomous decisions) while making assumptions and uncertainty explicit. Human-in-the-loop mechanisms should therefore be treated as architectural features, coupled with provenance and audit trails that support post hoc accountability and learning.

A third implication concerns organisational learning as a design target. Governance and learning mechanisms should capture crisis episodes as reusable knowledge assets (e.g., updated playbooks, annotated cases, revised ontologies) linked to decision provenance, enabling institutionalisation through training and standard updates. The scenario template in Section 3.1.1 can be used to stress-test designs ex ante by specifying stakeholders, dependencies, information conditions, and breakdown risks.

5 Conclusions

This paper highlights that the value of Artificial Intelligence (AI) in crisis and polycrisis contexts lies fundamentally in its ability to support regenerative coordination outcomes. These outcomes include enhanced adaptability, continuous learning, and the progressive strengthening of collective crisis response capabilities over time. By enabling the integration of distributed knowledge, the alignment of heterogeneous actors, and the dynamic reconfiguration of coordination mechanisms, we presented an integrated framework of AI-enabled coordination as an evolving process and a foundational element in the development of resilient socio-technical systems capable of evolving through disruption and uncertainty. This perspective shifts the focus of crisis management from reactive response toward the cultivation of long-term adaptive capacity embedded within coordination infrastructures.

The study acknowledges some limitations. The proposed framework has been analytically developed and validated through conceptual reasoning and scenario-based demonstration, but it has not been empirically tested. Moreover, the illustrative scenarios, while useful for demonstrating internal coherence and applicability, do not capture the full complexity and variability of real-world crises. As such, the findings should be interpreted as design-oriented and exploratory and not as conclusive.

Future research should therefore focus on empirical validation of the proposed framework through case studies, simulations, or experimental approaches, as well as on comparative analyses across different crisis domains and governance contexts. In addition, further investigation is needed to better understand the potential risks and unintended consequences associated with AI-enabled coordination, including issues related to bias, opacity, over-reliance on automated systems, and the governance of human–AI interaction in high-stakes environments. Addressing these challenges will be critical to ensuring that AI-enabled coordination infrastructures remain not only effective but also trustworthy, accountable, and aligned with broader societal objectives.

Artificial Intelligence in Pharmaceutical R&D: Evidence on Trial

Mattia Vincenzo Olive, Maria Pinelli, Chiara Sgarbossa, Luca Gastaldi, Emanuele Lettieri
Politecnico di Milano, Milan (Italy)

Abstract

Pharmaceutical Research and Development (R&D) is characterised by exceptional complexity, high costs, and pervasive uncertainty, with drug development typically spanning more than a decade and requiring investments that routinely exceed several billion dollars. Artificial Intelligence (AI) has attracted growing attention as a means of improving efficiency, accelerating early prioritisation, and reducing costly late-stage failures. Yet AI integration is far from straightforward: AI outputs are probabilistic and model-based, they lack causal explanations, and their reliability depends on data quality and modelling assumptions that are difficult to validate through conventional experimental protocols. These characteristics introduce epistemic uncertainty that intersects with the stringent accountability requirements governing pharmaceutical innovation.

This paper examines how a large pharmaceutical company integrates AI into its R&D processes, focusing on the governance mechanisms that enable firms to manage AI-introduced uncertainty while meeting regulatory standards of traceability and accountability. Drawing on the Technology–Organisation–Environment (TOE) framework, we structure the analysis across three dimensions: AI output characteristics (Technology), internal decision-making and governance arrangements (Organisation), and external regulatory expectations (Environment). Data were collected through an in-depth qualitative case study comprising twelve semi-structured interviews with senior leaders, AI specialists, and R&D managers, supported by document analysis and data triangulation.

Three main findings emerge. First, the company systematically frames AI as decision support rather than decision authority: outputs are treated as signals that can focus attention and narrow options, but are not accepted as sufficient grounds for resource commitment without human review, preserving regulatory legibility and clear accountability. Second, the value attributed to AI is inseparable from documentation and traceability practices. Teams invest in decision records that connect AI inputs to subsequent validation steps, making the reasoning behind key R&D choices auditable over time. Third, AI reshapes rather than eliminates uncertainty by shifting its locus upstream in the pipeline. The company responds by embedding AI within staged decision processes defined by explicit evidence thresholds, so that the technology is most influential in early phases and progressively less decisive as development approaches regulatory-facing milestones.

Theoretically, these findings show that governance practices mediate between AI's technical potential and pharmaceutical regulation's accountability requirements, and that AI redistributes uncertainty rather than removing it, shifting its character from experimental to epistemic. Practically, the study offers guidance for firms seeking to translate AI capabilities into sustained operational value through appropriate governance infrastructure, cross-functional coordination, and clear decision responsibilities.

Keywords: Pharmaceutical R&D; Artificial Intelligence; Pharmaceutical Industry; TOE framework; Healthcare Innovation

Paper type: Academic Research Paper

1 Background

Pharmaceutical Research and Development (R&D) is widely recognised as one of the most costly, time-consuming and uncertain innovation processes in contemporary industry (DiMasi et al., 2016; Pisano, 2006; Wouters et al., 2020). On average, developing a new drug takes more than ten years and requires investments that often reach several billion dollars, while only a small share of candidate compounds eventually obtain regulatory approval (DiMasi et al., 2016; Hay et al., 2014; Schuhmacher et al., 2016). Many projects are discontinued as they move from early research to clinical testing, meaning that resources are often committed long before the final outcome is known (Kaitin and DiMasi, 2011). For this reason, early decisions about which targets, compounds and development pathways to pursue have long-term consequences on resource allocation.

In this context, Artificial Intelligence (AI) has gained increasing attention in pharmaceutical R&D. Over the past decade, AI-based systems have been introduced to support activities such as target identification, compound screening, molecular design and clinical trial planning (Mak and Pichika, 2019; Paul et al., 2021; Vamathevan et al., 2019). By processing large and diverse datasets, these systems are expected to improve early prioritisation and support earlier go or no-go decisions, with the aim of reducing costly failures at later stages of development (Schneider et al., 2020).

At the same time, AI contributes to decision-making in ways that differ from established experimental and clinical practices. AI systems typically produce rankings, scores or predictions based on statistical patterns in historical data. These outputs are probabilistic and model-based, they rarely offer causal explanations, and they cannot be validated through standard experimental protocols when they are generated (Beam and Kohane, 2018; Lipton, 2018). Their reliability depends on data quality, modelling choices and assumptions that are often difficult to fully inspect or keep stable over time (Bender et al., 2021; Leonelli and Tempini, 2020). As a result, AI does not simply speed up existing R&D activities, but also changes what counts as usable evidence at early stages of innovation.

This creates a key trade-off in pharmaceutical R&D. AI makes it possible to move prioritisation and investment decisions earlier in the development process but, at the same time, it generates new forms of uncertainty in decision-making and evidence generation. This trade-off is particularly important since pharmaceutical innovation is characterised by strong regulatory oversight and public scrutiny. To obtain marketing authorisation, firms must document how decisions were made and how evidence was produced, in forms that remain traceable and open to review by regulatory authorities over time (Abraham, 2002; Davis and Abraham, 2011). In this setting, AI-related uncertainty concerns not only accuracy, but also explainability, accountability and alignment with established scientific and regulatory standards (Topol, 2019).

Despite the growing interest in AI for pharmaceutical R&D, there is still limited empirical evidence on how companies manage this trade-off in practice. Most existing studies focus either on technical applications or on high-level ethical and regulatory discussions, offering little insight into how AI is integrated into everyday R&D processes (Floridi et al., 2018; Morley et al., 2020).

To address this gap, this working paper adopts the Technology–Organisation–Environment (TOE) (Baker, 2012; Tornatzky et al., 1990) framework as an analytical scaffold to structure the analysis across the characteristics of AI outputs (Technology), internal decision and governance arrangements (Organisation), and external expectations of accountability and reviewability (Environment).

Thus, our guiding research question is: How do technological, organisational, and environmental factors shape the integration of AI into pharmaceutical R&D, and what governance practices enable firms to translate technical potential into sustained operational and strategic value?

2 Methodology

This study is based on an in-depth qualitative case study of a large pharmaceutical company's R&D department, hereafter referred to as Company S., to examine how the uncertainty introduced by AI outputs is handled in practice.

We explore AI adoption in a real-world context, examining the strategies, challenges, and organisational dynamics of integration across development stages (Siggelkow, 2007; Yin, 2009). A single-case design provides depth and contextual specificity, capturing the regulatory, data management, and organisational barriers that condition effective implementation.

Semi-structured interviews, described by Yin (2009) as "both versatile and flexible", were used to explore how AI integration unfolds across R&D decision contexts. To ensure the validity of the study we have followed a protocol for conducting interviews, a data analysis through NVivo software and data triangulation from multiple sources (official website, internal documents and reports).

The choice of Company S. reflects the company's substantial and well-documented investments in AI across R&D functions, including collaborations with external partners spanning drug discovery, clinical trials, and operations. This breadth of AI integration makes it a suitable case for examining how the technology is adopted and governed across the full development spectrum.

Data were gathered through semi-structured interviews with 12 actors involved in AI development, data governance and R&D decision-making. The choice of participants was made to cover various roles within Company S., ensuring a holistic view of AI's organisational impact within R&D. The diversified interview sample includes senior leadership, AI specialists, and R&D managers. Over three months (February to April 2024), 12 key informants were interviewed via Zoom by at least two authors of this manuscript to increase the reliability of the notes. Each session lasted 45 to 75 minutes and was audio-recorded with prior consent. The key topics addressed during the interview included: (i) the role of AI in R&D processes; (ii) challenges and barriers encountered during implementation; (iii) ethical and regulatory issues; and (iv) organisational strategies for integrating AI into workflows. The protocol included 20 questions organised into six thematic areas: background and role, AI in drug discovery, open innovation, business model impacts, challenges and barriers, and implementation benefits.

Clean verbatim transcription ensured accurate representation of the interviews for subsequent analysis (McGrath et al., 2019). The data analysis was conducted through an inductive thematic analysis (Braun and Clarke, 2006) using NVivo 11 software, which enabled the creation of nodes to represent emerging themes, allowing for a more structured approach to data management, synthesis, and visualisation.

3 Results

3.1 Technological context

Interviewees describe AI integration as spanning multiple R&D stages, with adoption intensity varying by activity and data maturity. One informant summarised the pipeline scope and heterogeneity of Machine Learning (ML) usage as follows: "There are two major parts in the discovery… the first is drug development… and the second is, in the clinical part. Adopting ML tools varies dramatically between these areas." (Head of R&D Data and Computational Science; Interviewee 12).

In early discovery, AI is framed as a capability to explore highly complex search spaces and accelerate target identification. As the Global Head of AI/ML for R&D reported: "Starting from the very, very beginning… we call it Target ID." (Interviewee 6). By exploring vast molecular spaces, AI helps Company S. pinpoint viable drug candidates, a task otherwise unattainable without advanced algorithms. As reported by the Head of AI for Large Molecule Research, "When you look at this molecular space, it's something like 10 to the power of 60 different possibilities, and most of them are not good." (Interviewee 4). AI is thus positioned as a filtering and prioritisation layer to reduce the search space and improve precision.

Company S. integrates AI not only in early drug discovery but also in clinical activities, where AI supports cohort identification and recruitment by linking real-world information to protocol constraints. The Head of Clinical Innovation Strategy highlighted that "Looking at patient records, understanding opportunities for patient recruitment, where patients match protocol criteria is important." (Interviewee 3). This indicates that value is not limited to discovery but extends to operationally relevant clinical processes.

AI facilitates resource optimisation at Company S., enhancing both efficiency and adaptability. The Head of AI for Large Molecule Research highlighted time-saving as a critical advantage: "You can reduce the time from the target to the market, or from the target identification to the preclinical phase." (Interviewee 4). By reducing clinical trial failure rates and streamlining processes, AI improves return on investment, which is especially critical in an industry where development costs often exceed $1 billion per drug.

Data foundations emerge as the core enabling substrate. Company S.'s approach emphasises central standards and governance to enable reuse and interoperability. The Global Head of the R&D Data Office stated: "Building the data strategy, putting together the standards, data management, and data governance… allows us to build this end-to-end data ecosystem." (Interviewee 9). This technological context also aligns with a hybrid sourcing strategy: the company selects "best-in-breed" tools from multiple providers to ensure flexibility and interoperability across platforms and R&D needs.

3.2 Organisational context

Organisational readiness strongly conditions whether AI tools become embedded capabilities rather than isolated pilots. Integrating AI into resource allocation processes demands a shift in organisational culture and structure. As the Global Head of the R&D Data Office stressed: "It's the whole organisational level of upskilling that needs to happen." (Interviewee 9). This indicates that adoption is constrained not only by the availability of data scientists but by the broader ability of scientific and operational teams to interpret, trust, and appropriately use AI outputs.

AI integration also requires cross-functional routines that connect data governance, scientific validation, and business decision processes. Interviewees repeatedly framed AI as augmenting human expertise rather than displacing accountability-bearing decisions. This boundary is expressed clearly in the following statement: "AI can assist but not completely replace human decision-making processes." (Head of AI for Large Molecule Research; Interviewee 4). The implication is that workflow design must specify where AI informs decisions, how outputs are checked, and who remains responsible for final judgement.

Change management and internal communication are highlighted as central levers to reduce resistance and enable adoption across functions. One informant described an anticipatory approach: "AI in Company S.… we anticipate the forthcoming changes, and there is clear communication about the impact that these new tools will have." (Head of AI for Large Molecule Research; Interviewee 4). This suggests that scaling depends on aligning expectations, clarifying role implications, and providing time and support for workflow adaptation.

Finally, organisational structure and culture shape integration pace. In the words of one interviewee: "The pharma companies are very traditional, very hierarchical… but technology is growing fast." (Head of Molecular and Digital Histopathology; Interviewee 7). This tension, between the speed of technological change and the inertia of established structures, helps explain why even technically promising tools may face slow institutionalisation unless governance and incentives evolve accordingly.

3.3 Environmental context

The external environment affects AI integration through regulation, partnership ecosystems, and intellectual property constraints. Regulatory scrutiny is a foundational element shaping internal governance practices. The demand for explainability and traceability is both an internal trust requirement and an external compliance expectation, as indicated by the need to "explain to the FDA and the authorities exactly how you generated the data." (Head of Molecular and Digital Histopathology; Interviewee 7). This raises the bar for documentation, validation, and accountability.

A second environmental factor is the role of external collaboration as a pathway to access talent, tools, and scientific advances. Company S.'s AI strategy is described as strongly collaborative: "Collaboration is key… there is a lot that we do in-house, but much more is happening outside of Company S." (VP Global Head of Precision Medicine and Computational Biology; Interviewee 11). Another informant quantified this orientation: "At least 25 percent of our projects are in collaboration with external partners." (Executive Director of Data Science; Interviewee 10). Collaboration is nonetheless selective: the company opens specific capabilities to partners while protecting proprietary data and core scientific assets.

Third, intellectual property and patent uncertainty influences how firms share and use data with partners. The Global Head of the Data Science Organisation emphasised the need for caution: "We need to find the right balance of using external data and sharing our internal data… at least until we have defined a proper patent framework to protect our IP." (Interviewee 8). This environmental condition shapes partnership governance, data-sharing boundaries, and strategic choices about "make or buy" approaches to AI tool development.

4 Discussion and Conclusion

Across the three analytical dimensions of the TOE framework, the case reveals a consistent pattern: AI adoption in pharmaceutical R&D is primarily a governance challenge, not a technical one. The three findings below each map onto one face of this challenge — defining the boundary of AI authority, anchoring its outputs in documentation, and structuring decisions around explicit evidence thresholds — before their combined implications are drawn out. Findings show, first, that the R&D department systematically frames AI as decision support rather than decision authority. In practice, AI outputs are treated as signals that can trigger attention, open new options or help narrow down choices, but they are not accepted as sufficient grounds for committing resources on their own. Keeping formal decision rights with human actors and committees functions as a core accountability device that, on the one hand, anchors responsibility in identifiable roles and, on the other, preserves a decision rationale explainable in ways that remain compatible with regulatory expectations (Abraham, 2002; Davis and Abraham, 2011).

Second, the case highlights that the "value" of AI is closely linked to documentation practices and to the ability to reconstruct decisions over time. Because AI outputs are model-based and depend on data provenance and modelling assumptions (Bender et al., 2021; Leonelli and Tempini, 2020), teams invest in practices that make these outputs traceable and discussable, rather than treating them as black-box recommendations. The empirical material shows increased attention to "decision records" that connect AI inputs to subsequent validation steps, including why particular molecules were advanced, deprioritised or stopped in the R&D process.

Third, the analysis shows that AI reshapes uncertainty by moving it earlier and changing its form. AI supports earlier prioritisation, but this also means that critical decisions are taken at a point when experimental confirmation is still partial. Rather than removing uncertainty, AI shifts the main governance challenge from "managing failure later" to "making early decisions acceptable". The company responds by embedding AI use in staged decision processes with explicit thresholds for what counts as sufficiently robust evidence at each stage. In this arrangement, AI is most influential in the early phases, where it helps focus scarce attention, but it becomes progressively less decisive as development moves closer to regulatory-facing milestones, where evidence must be based on established experimental and clinical standards (Beam and Kohane, 2018; Topol, 2019).

The study shows that AI redistributes uncertainty over time in R&D processes and changes the kind of evidence that supports decisions in early R&D phases. The organisational decisions and arrangements to manage this process are therefore a key determinant of AI's ability to reduce R&D costs and generate societal value.

Taken together, these three mechanisms — framing AI as decision support, anchoring its value in traceability, and embedding its use within staged processes with explicit evidence thresholds — constitute the governance infrastructure through which technical potential is translated into sustained operational value. Their interdependence is significant: traceability without staged gatekeeping leaves documentation disconnected from decisions, while staged decisions without clear human accountability create gaps in regulatory legibility.

From a practical perspective, this paper contributes to understanding how pharmaceutical firms can manage operations and decision-making processes in R&D when integrating AI. Specifically, it shows that capturing value from AI requires not only technical capability, but also appropriate governance mechanisms, cross-functional coordination, and clear decision responsibilities.

Theoretically, this paper contributes to the literature on AI adoption in regulated industries in two ways. First, where existing work tends to address either technical feasibility (Paul et al., 2021; Vamathevan et al., 2019) or normative principles of explainability and accountability (Floridi et al., 2018; Morley et al., 2020), this case shows how governance practices mediate between the two — translating abstract requirements into concrete workflow arrangements. Second, while prior work has largely framed uncertainty as something AI reduces, the evidence here suggests that AI redistributes uncertainty rather than eliminates it, shifting its locus upstream and changing its character from experimental to epistemic. This distinction has implications for how firms design validation processes and structure their interactions with regulators.

This study has some limitations. First, it is based on a single qualitative case study, which provides depth but limits the generalisability of the findings across firms, therapeutic areas, and institutional contexts. Second, the analysis relies primarily on interview-based evidence collected within one company and therefore reflects managerial and organisational perceptions of AI integration more than direct performance measurement. Finally, the study captures AI adoption at a specific point in time, while many of its effects on R&D outcomes may emerge only over a longer period. The rapidly evolving regulatory environment — including the EU AI Act and emerging FDA guidance on AI-assisted drug development — and the development of foundation models with capabilities substantially different from those documented here suggest that both governance practices and their organisational implications are likely to shift. Longitudinal work would be needed to track how the arrangements observed are maintained, adapted, or replaced as the technology and its regulatory context mature.

Future research could address these limitations by examining whether different organisational models lead to different patterns of AI integration and governance. Longitudinal studies would also be valuable to understand how AI-related routines, capabilities, and trust evolve over time. In addition, further work could explore how specific governance mechanisms, such as model documentation, validation practices, and human oversight, influence the ability of firms to convert AI-based insights into accepted and sustainable R&D decisions.

5 Ethics declaration

All participants provided informed consent for audio recording and subsequent analysis. Data were anonymised to protect participant confidentiality, and the participating organisation is referred to throughout as Company S.

6 AI declaration

Artificial intelligence tools (OpenAI ChatGPT and Anthropic Claude) were employed exclusively for proofreading purposes.

HRM Strategies for Diversity and Inclusion: A Bibliometric Analysis

Roberta Romano, Simona Mormile, Gabriella Piscopo, Paola Adinolfi
University of Salerno, Fisciano, Italy

Abstract

This paper systematically examines how Human Resource Management (HRM) strategies have been employed to promote diversity and inclusion (D&I) in organizations, with the aim of identifying the main themes, trends, and strategic approaches through which inclusive workplaces are fostered. Adopting a bibliometric approach, the study analyzes a curated dataset of 870 peer-reviewed, open-access journal articles published between 2012 and 2025. Data were retrieved from Scopus and examined using the Bibliometrix package in R. The analysis combines performance analysis, country-level production analysis, trend topic analysis, and conceptual structure mapping to investigate the temporal evolution, geographical distribution, and thematic clusters characterizing the literature.

The findings reveal a steady increase in academic interest in HRM strategies for D&I, with marked acceleration from 2019 onward and a peak in 2024. This growth reflects the influence of global sociopolitical movements, regulatory initiatives, ESG pressures, and changing expectations regarding equity, representation, and inclusive work environments. Geographical analysis shows a strong concentration of publications in Anglo-speaking and industrialized countries, together with growing contributions from emerging economies. Thematic analysis identifies well-developed clusters around gender identity, ethnicity, career development, workplace psychology, and job satisfaction, while also highlighting foundational themes such as sustainability, innovation, organizational culture, gender disparity, and women's status. Emerging areas include inclusive leadership, disability inclusion, diversity in top management teams, decision-making, and artificial intelligence in HR processes. The study also identifies gaps in intersectional theorizing, systemic approaches to inclusion, and the long-term effects of D&I policies.

The value of this paper lies in its comprehensive bibliometric synthesis of the HRM and D&I literature, which maps the field's conceptual, intellectual, and social structure. Its implications are relevant for scholars, practitioners, and policymakers seeking to advance inclusive HRM practices. By uncovering the "bright side" of diversity, the study reframes D&I not as a compliance obligation but as a strategic and cultural transformation imperative.

Keywords: human resource management, diversity management, organizational strategy, bibliometric analysis, innovation.

Paper type: Academic Research Paper

1 Introduction and Literature Review

In an increasingly globalized and interconnected world, diversity and inclusion (D&I) have become strategic priorities for organizations seeking competitiveness, innovation, and social responsibility. This attention reflects demographic, social, regulatory, and institutional transformations that have reshaped organizational expectations (Mor Barak, 2015). No longer confined to compliance or corporate social responsibility, D&I are recognized as levers for innovation, employee engagement, and organizational sustainability (Shore, 2011; Roberson, 2019). Organizations are therefore required to manage diversity as a knowledge-intensive process, in which heterogeneous perspectives enhance learning, creativity, and adaptive capacity.

In organizational studies, diversity and inclusion have evolved from legal compliance frameworks toward strategic approaches shaping organizational culture and performance (Shore et al., 2018). Early workplace diversity research focused on discrimination prevention and representational equity, especially after civil rights legislation in the United States (Edelman et al., 2001). Over time, diversity has been reconceptualized as a multidimensional construct referring to visible characteristics, such as gender, ethnicity, age, and disability, and less visible dimensions, including cognitive diversity, educational background, and sexual orientation (Shore, 2011; Van Knippenberg and Mell, 2016). Inclusion refers to the extent to which individuals feel valued, respected, accepted, and able to contribute meaningfully (Nishii, 2013; Ferdman and Deane, 2014). While diversity describes workforce composition, inclusion depends on organizational practices fostering belonging, voice, and psychological safety. These dynamics are central to knowledge creation, as inclusive environments enable tacit and explicit knowledge exchange across organizational boundaries.

Human resource management (HRM) plays a central role in translating D&I principles into practices. HRM systems can either enable or constrain D&I goals (Sabharwal, 2014). Organizations may promote inclusion through recruitment and selection processes that reduce bias and widen access for underrepresented groups (Konrad, 2003), bias-aware performance management and promotion systems (Castilla, 2008), diversity training

and inclusive leadership development (Randel et al., 2018), and mentoring programs or employee resource groups supporting marginalized employees (Dobbin and Kalev, 2016). However, such initiatives should not remain isolated interventions; rather, they should be aligned with strategic HRM frameworks and embedded across the employee lifecycle (Özbilgin et al., 2011). Inclusion requires cultures that reinforce fairness, respect, and voice, making D&I a systemic rather than merely programmatic concern (Nishii, 2013; Shore et al., 2018).

Despite their relevance, HRM strategies for D&I still face significant challenges. Scholars have criticized symbolic or performative initiatives lacking structural change (Ahmed, 2012), resistance from dominant groups when inclusion threatens established hierarchies (Dobbin and Kalev, 2016), and standardized approaches that overlook contextual specificities (Tatli and Özbilgin, 2012). These critiques have encouraged context-sensitive, intersectional, and reflexive perspectives attentive to power relations, organizational politics, and marginalized employees' lived experiences (Nkomo et al., 2019). In parallel, AI adoption in HRM introduces challenges concerning the validity, transparency, and ethical use of algorithmically generated knowledge, raising concerns about bias, accountability, and governance.

Although the D&I-HRM literature has expanded, it remains fragmented across business ethics, organizational behavior, public administration, psychology, and related fields, making overarching trends, conceptual convergences, and dominant paradigms difficult to identify. Most reviews are narrative or conceptual, lacking the systematic rigor needed to map the field's evolution and structure (Zupic and Čater, 2015). Bibliometric analysis addresses these limitations by enabling quantitative assessment of temporal developments, thematic patterns, and knowledge structures (Donthu et al., 2021).

To address this gap, this paper maps academic research at the intersection of HRM and D&I, focusing on the "bright side" of diversity. It conducts a bibliometric analysis of 870 peer-reviewed, open-access journal articles published between 2012 and 2025 using Bibliometrix in R (Aria and Cuccurullo, 2017). The study asks: how scientific production on HRM strategies for D&I has evolved; which thematic areas characterize the field; and which countries have contributed most to knowledge development.

The study contributes by providing a quantitative synthesis of more than a decade of research, tracing the field's maturation and internationalization; identifying key topics and trends; and mapping the domain's conceptual and social structures to highlight research gaps and future directions, especially in underrepresented contexts and populations.

2 Methodology

This study adopts bibliometric analysis to examine the literature on promoting diversity in organizations through HRM strategies. Bibliometric analysis is a quantitative method for describing, evaluating, and monitoring academic research through bibliographic data (Garfield, 2004; White and McCain, 1998). It allows the identification of research trends, influential areas, and conceptual structures.

The analysis was conducted using Bibliometrix in R (Aria and Cuccurullo, 2017), which supports the import and analysis of bibliographic data and the construction of networks revealing conceptual, intellectual, and social structures. Biblioshiny, its web interface, further improves accessibility and usability (Moral-Muñoz *et al*., 2020). The research process included two main phases: data collection and bibliometric analysis.

3.1 Data collection

Data were retrieved from Scopus, one of the most widely used databases for scientific research (Singh *et al*., 2021). The search was conducted on September 25, 2025, using terms related to diversity and HRM. The following search string was applied to titles, abstracts, and keywords: ("Diversity management" OR "Diversity and inclusion" OR "Workplace diversity") AND ("Human resource management" OR "HRM" OR "HR strategies").

The initial query returned 12,875 documents. Several exclusion criteria were then applied. First, the analysis was limited to the period 2012–2025, reflecting the increased relevance of diversity in organizational HRM strategies from 2012 onward. Second, only English-language, published, open-access journal articles were included. Third, unrelated subject areas, such as mathematics, medicine, and energy, were excluded, while business, management and accounting, social sciences, decision sciences, and psychology were retained. After data cleaning, duplicate removal, and exclusion of irrelevant contributions, the final corpus included 870 articles uploaded to Bibliometrix in CSV format.

3.2 Data analysis

Scientific output was analyzed through annual production and country-level contributions. Annual production highlighted the temporal evolution of the topic, while country-specific production showed the geographical diffusion and relevance of the field.

Trend topic analysis was used to identify HRM strategies and diversity-related concepts over time. Keywords were extracted, and their temporal distribution was calculated. For each keyword, the median year, first quartile, and third quartile were identified. Results were visualized through a scatter plot in which each bubble represented a term, its size reflected frequency, and its position indicated the median year of use. The conceptual structure was analyzed through co-word analysis, based on the assumption that keyword co-occurrence reflects the conceptual content of documents (Callon *et al*., 1991). Keywords appearing together were connected in a network, and the Louvain clustering algorithm was used to identify thematic areas. The resulting thematic map was organized according to Callon centrality and density, distinguishing motor themes, basic themes, emerging or declining themes, and niche themes (Courtial, 1994; Coulter *et al*., 1998).

3 Findings and Discussion

4.1 Research performance

The analysis of the annual evolution of scientific production (Figure 1) reveals a steadily increasing trend, marked by several particularly significant phases. Between 2012 and 2015, the literature on the topic remained limited and marginal, with fewer than twenty publications per year. Starting from 2016, a gradual increase is observed, reflecting an initial consolidation of scholarly interest in the link between diversity management and HRM practices. A more marked turning point, however, occurs during the 2019–2021 period, when the number of publications doubles, reaching approximately 125 articles per year. This surge can be attributed to the intensification of public and academic discourse on inclusion, equity, and representation, further stimulated by global social movements and growing regulatory and reputational pressures on organizations (Özbilgin, 2019).

In particular, movements such as #MeToo have brought public attention to racial and gender inequalities, urging concrete responses from the world of work (Kirton and Greene, 2021).

Simultaneously, there has been increased visibility of advocacy for *LGBTQIA+* rights, neurodiversity, and disability inclusion, thereby expanding the very notion of diversity (Fontana, 2020; Gupta and Priyadarshi, 2020). At the regulatory level, the European Union has reinforced its commitment through initiatives such as the *Gender Equality Strategy 2020–2025* (Debusscher, 2023; Muñoz; 2022). Moreover, pressures from ESG investors, international certifications (such as *EDGE* and the *Diversity & Inclusion Index*), and the expectations of new generations of workers have made diversity a central element in talent attraction strategies (Kirton and Greene, 2021; Clementi *et al*., 2019; Ng *et al*., 2021). Until 2024, there was exponential growth in research, and 2024 marked a peak in scientific output, with almost 180 articles published, signaling a phase of greater academic attention to the role of human resources as drivers of cultural and organizational change (Qurniawan *et al*., 2024; Poulose *et al*., 2024; Ezeafulukwe *et al.*, 2024).

Data for 2025 show a decline, with a lower number of publications compared to the previous year. This decrease, however, may be due to incomplete data collection, as the year is still ongoing at the time of analysis. Overall, the observed trend suggests a gradual scientific maturation of the field, with growing attention to the management of diversity within organizations.

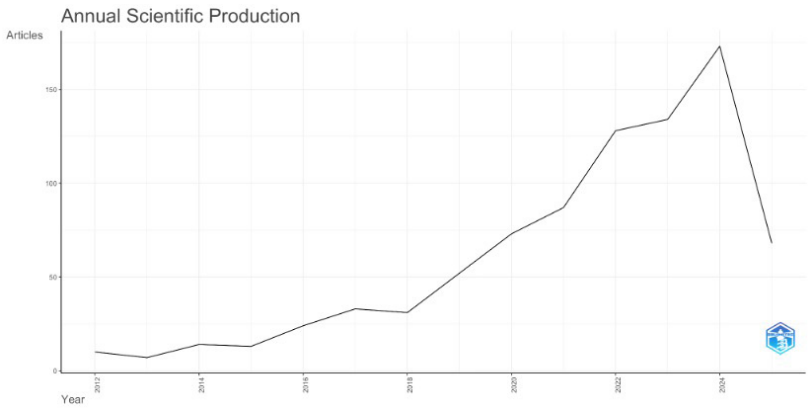

Figure 1. Annual scientific production

The geographical distribution of publications reveals a strong concentration in Anglo-speaking and industrialized countries. The United States is among the leading contributors, reflecting long-standing debates on equity, representation, and civil rights, supported by a university system strongly oriented toward empirical research (Kirton and Greene, 2021). The United Kingdom also shows substantial scientific output, consistent with a political and academic tradition that integrated diversity principles into public policies and organizational evaluation systems (Köllen, 2021).

Canada and Australia follow with significant contributions, reflecting their multicultural profiles and policies focused on ethnic, linguistic, and Indigenous inclusion (Yadav and Lenka, 2020). Among European countries, Germany, France, the Netherlands, and Italy contribute actively to diversity management research. The Italian case is developing in light of recent regulatory reforms and growing interest in the role of public administrations and firms in promoting gender equality and inclusion (Romano and Petruccioli, 2020). Law No. 162/2021, for example, introduced obligations for companies to monitor and report gender parity conditions.

Emerging countries, particularly China, India, South Korea, Brazil, Mexico, Chile, South Africa, Nigeria, and Kenya, also show growing scientific production. In these contexts, organizational diversity is often linked to economic development, institutional modernization, and corporate social responsibility (Kharroubi, 2021). Overall, the findings suggest progressive internationalization of D&I research and increasing recognition of diversity as a strategic factor for organizational competitiveness and sustainability.

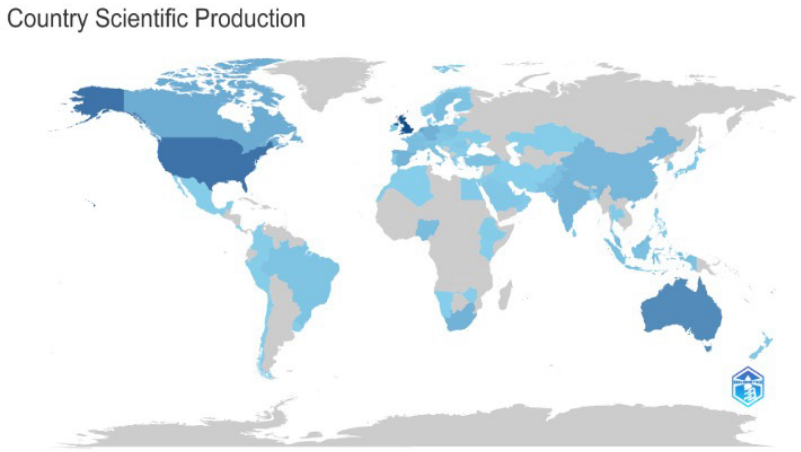

Figure 2. Country scientific production

4.2 Key themes and topics

Trend topic analysis reveals the evolution of research interests over time and indicates increasing theoretical sophistication. Recent and recurrent topics focus on the intersection between diversity and new work dynamics, especially leadership, workplace, employees, working conditions, and artificial intelligence, which have gained relevance since 2020. These terms suggest a broadening of diversity management toward employee well-being, hybrid work, and digitalization (Köllen, 2022; Dwivedi, 2025; Kamasak *et al.*, 2023).

The presence of terms such as female, male, employment, and middle-aged highlights attention to inequalities related to gender, age, and labor market access. Gender-related research appears to be moving from binary categories toward broader reflections on historically marginalized groups, including LGBTQIA+ individuals and people with migratory backgrounds, although the latter remain less prominent (Fontana, 2020; Köllen, 2021).

The growing relevance of perception indicates greater attention to qualitative and organizational-psychological approaches, focused on employees' subjective experiences of inclusive policies and practices (Yadav and Lenka, 2020). Similarly, terms related to sustainability and learning show the expansion of the field toward systemic and long-term approaches linking social equity and sustainable performance (Köllen, 2022; Dzhengiz, 2020). This development aligns with ESG criteria and governance transformations that encourage organizations to make diversity commitments visible as part of their strategic identity.

Organizational culture and cultural diversity remain central, confirming that effective HR practices depend not only on formal policies but also on cultural assumptions that are often difficult to transform (Ince, 2023; Park, 2020). The emergence of artificial intelligence is particularly relevant, as it marks growing scholarly interest in how digital technologies may promote or distort organizational diversity. Research is beginning to examine

whether algorithms used in recruitment, evaluation, and development processes introduce bias or support more equitable and transparent criteria (Rathore *et al*., 2022; Shams *et al*., 2025).

Finally, terms such as racism, satisfaction, career, and attitude indicate that the literature has also explored connections between diversity and job satisfaction, career aspirations, attitudes toward inclusion, and systemic inequalities, although these areas remain less developed (Van Knippenberg *et al.*, 2020; Maji *et al*., 2024).

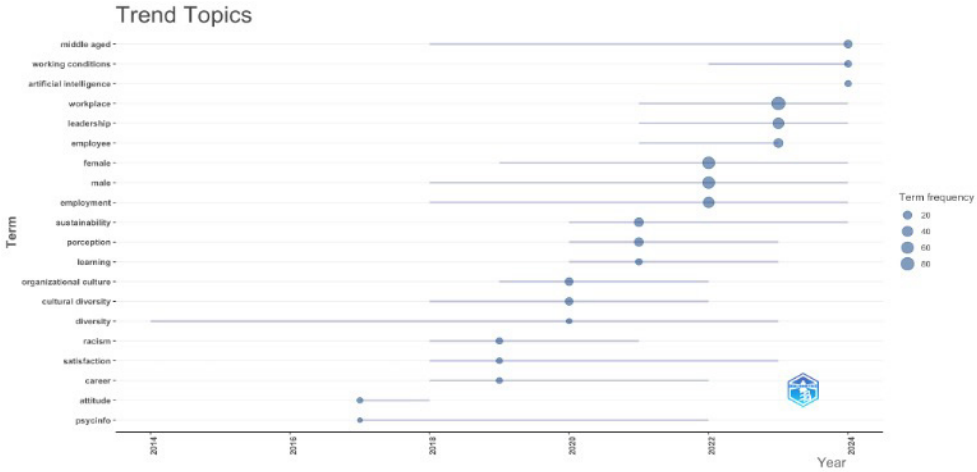

Figure 3. Trend topics analysis

The thematic map provides a visual representation of the conceptual structure of the literature, organizing themes according to development and centrality. Motor themes, located in the upper-right quadrant, are the most developed and central. These include ethnicity, gender identity, and career, which represent core pillars of the academic debate and indicate consolidated interest in identity dynamics and career trajectories in relation to diversity policies.

From an HRM perspective, these findings suggest the importance of ethnic and cultural inclusion, equitable career development, and recognition of gender identities (Morfaki and Morfaki, 2024; Yadav and Lenka, 2020). Relevant practices include mentoring for underrepresented groups and inclusive career pathways (Van Knippenberg *et al*., 2020; Williams *et al.*, 2023). The same area includes workplace, psychology, and job satisfaction, pointing to an integrated approach between inclusive HRM and psychosocial well-being (Köllen, 2022). HR strategies may therefore involve psychologically safe environments, employee support services, and systematic monitoring of organizational climate (Dwivedi, 2025; Kamasak *et al*., 2023).

Basic themes, positioned at the center of the map, are essential but still developing. The cluster composed of sustainability, innovation, and organizational framework represents the theoretical-practical infrastructure of the field, showing increasing attention to sustainability and social innovation as enabling contexts for inclusion. HRM strategies in this area may include diversity measurement in sustainability reports, integration of inclusive goals into organizational missions, and cross-functional task forces for social innovation (Walker *et al*., 2023; Naciti *et al.*, 2022).

Another central cluster includes organizational culture, gender disparity, and women's status, revealing that structural inequalities remain critical. HR practices should therefore transform organizational culture through targeted training, revision of decision-making processes, and promotion of female leadership across organizational levels (Triana *et al*., 2021; Aktepe, 2020).

Emerging or declining themes, located in the lower-left quadrant, include leadership, perception, decision-making, disability, and top management teams. Although currently less developed or marginal, these themes have significant potential, especially from a strategic HRM perspective. They represent opportunities for future research on inclusive leadership, representation at senior levels, disability inclusion, and diversity criteria in executive decision-making (Ince, 2023; Ezeafulukwe, 2024). These areas have important implications for HR innovation and organizational transformation.

Finally, niche themes in the upper-left quadrant include minority group, racism, and emotion. These themes are internally developed but less central to the broader discourse. Nevertheless, they raise important questions concerning systemic inequalities and the emotional dimensions of inclusion. HRM strategies may include training on emotional intelligence and implicit bias, listening tools for organizational minorities, and anti-discrimination policies that are experienced as credible and authentic by employees (Ogbonna, 2025; Nweiser and Dajnoki, 2022).

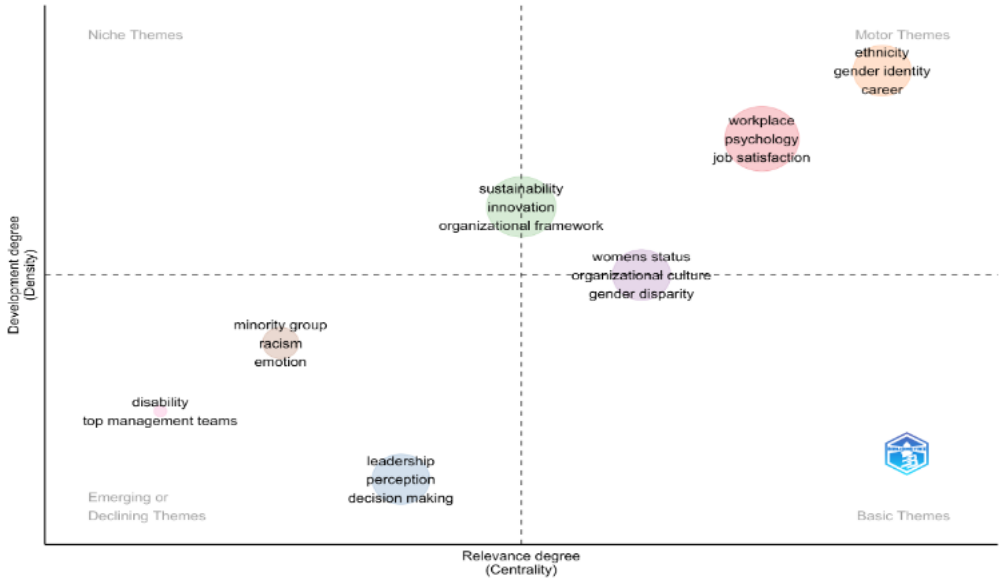

Figure 4. Thematic analysis

4 Conclusions

This study explored how the scientific literature has addressed the promotion of diversity in organizations through HRM strategies by conducting a bibliometric analysis of 870 articles published between 2012 and 2025. The aim was to identify key trends, conceptual developments, and the geographical distribution of publications, offering a systematic overview of the field.

The findings show a steadily growing body of research, with a significant acceleration from 2019 onward. This growth coincides with intensified public debates, regulatory pressures, and organizational attention to inclusion. Trend topic analysis highlights the emergence of inclusive leadership, workplace well-being, artificial intelligence, and working conditions, suggesting that diversity management is increasingly intertwined with technological, cultural, and organizational transformations. These developments indicate a shift toward hybrid knowledge ecosystems, where human judgment, relational intelligence, and AI-driven analytical capabilities may jointly support inclusive and sustainable decision-making.

The thematic map distinguishes established areas, such as gender identity and ethnicity; foundational but developing themes, such as sustainability and organizational culture; and promising emerging areas, including disability, inclusive decision-making, and diversity within top management teams.

Theoretically, the study contributes to mapping the D&I-HRM field, highlighting the transition from normative and compliance-oriented approaches to more systemic, intersectional, and strategic perspectives. However, relevant gaps remain. The literature still lacks an integrated theorization of diversity as a driver of organizational and social innovation. Further development is also needed on the relationship between diversity, organizational power structures, and the long-term effects of inclusion policies. Intersectional approaches remain underexamined, while the symbolic role of diversity in shaping organizational identity is still marginal.

Practically, the findings suggest several implications for HR professionals, public institutions, and organizational leaders. Organizations should implement structured mentoring programs for underrepresented employees, with clear objectives, accountability mechanisms, and career advancement pathways. Such programs may also serve as mechanisms for transferring tacit knowledge, strengthening relational learning, and supporting inclusive knowledge-sharing processes. D&I objectives should also be embedded in corporate missions, strategic plans, measurable KPIs, and executive evaluations. Moreover, robust D&I reporting frameworks are needed to monitor gender and ethnicity representation, pay equity, promotion rates, and hierarchical distribution.

Training on unconscious bias, inclusive behaviors, and emotional intelligence should be implemented as part of continuous learning strategies rather than isolated initiatives. Inclusive leadership models should move beyond symbolic representation and involve investment in cultural intelligence, empathic communication, and participatory decision-making. Diverse leadership should also be reflected in boards, C-suite positions, and key decision-making bodies.

Finally, organizations should critically assess artificial intelligence in HRM, especially in recruitment, performance evaluation, and promotion. AI tools may reduce human bias and enhance transparency when

properly designed, but they can also reproduce inequalities if trained on biased historical data. Their development should therefore follow inclusive design principles, involve cross-functional oversight, and include periodic bias audits to ensure fairness and accountability.

This study has limitations. The dataset is based only on Scopus and English-language publications, which may underrepresent relevant contributions from other databases and non-English-speaking contexts. Future research should expand the dataset to include sources such as Web of Science and non-English publications. Qualitative and mixed-method studies could also deepen understanding of the meanings and practices associated with diversity. Longitudinal research should examine the long-term impact of inclusive HRM strategies, while comparative studies across sectors and national contexts could clarify how cultural, institutional, and regulatory conditions influence policy effectiveness. Finally, marginal topics such as neurodiversity, algorithmic decision-making, and the emotional, symbolic, and value-laden dimensions of diversity should be explored more systematically. Advancing these directions may consolidate a transformative approach to diversity management, improving organizational relationships, internal equity, and the social sustainability of work.

5 Ethics Declaration

This study did not require ethical clearance, as it is based exclusively on bibliometric analysis of publicly available, peer-reviewed journal articles. No human participants, personal data, interviews, surveys, experiments, or sensitive information were involved in the research process.

6 AI Declaration

AI tools, specifically ChatGPT, were used exclusively for language editing, improving clarity, and refining the academic style of the manuscript.

[2]Luiss Guido Carli University, Rome, Italy

Abstract

This paper explores the use of Large Language Model (LLM)-based agents as tools for supporting knowledge creation from Environmental, Social and Governance (ESG) data, with a specific focus on the social dimension. Despite the growing availability of ESG data, organisations still face substantial challenges in transforming quantitative indicators into actionable insights that can effectively support strategic decision-making. Current reporting tools mainly provide descriptive outputs, while more advanced AI-based solutions often require technical expertise that limits their practical adoption. This study addresses that gap by proposing an accessible, low-cost decision support system built on open-source technologies. The research adopts a Design Science Research (DSR) approach and develops a conversational ESG advisory agent built on Langflow, an open-source low-code platform, and Llama 4 Scout 17B, a large language model served free of charge via Groq. The agent receives structured ESG indicators through a guided conversational interface, computes relevant metrics, compares them against sector benchmarks derived from principal component analysis and cluster analysis of real energy-sector data, and produces a qualitative assessment report including an improvement roadmap aligned with Global Reporting Initiative (GRI) 401-406, European Sustainability Reporting Standards (ESRS) S1-S2, and Sustainable Development Goals (SDGs) 3, 5, and 10. Evaluation on a synthetic dataset of 40 fictitious energy companies shows that the agent achieves 98.1% value accuracy and 93.2% judgment accuracy on eight of the eleven variables tested. The remaining three variables, specifically the Gender Pay Gap and the two Cultural Diversity indicators, show significantly lower accuracy ranging from 33% to 45%, attributable to the model's limited capacity to handle competing instructions and maintain parallel reasoning tracks. Through iterative DSR testing, the study finds that restructuring the input to eliminate ambiguity is a more reliable corrective strategy than refining the prompt, suggesting a broader design principle for low-code AI systems based on mid-sized models. The paper contributes to the emerging literature on AI-driven sustainability analytics by proposing and evaluating a replicable, low-cost system that bridges the gap between quantitative ESG reporting and qualitative organisational insight. From a practical standpoint, the findings demonstrate that accessible AI architectures can support meaningful ESG knowledge creation even in resource-constrained organisational settings, acting as a cognitive support tool for human decision-makers rather than replacing them.

Keywords: Hybrid Knowledge creation; ESG performance; Artificial Intelligence; Decision support system; Social sustainability

Paper type: Academic Research Paper

1 Introduction

In recent years, Environmental, Social and Governance (ESG) criteria have become a key reference for evaluating the sustainability and responsibility of organisations. Their relevance has increased significantly due to growing pressure from investors, regulators, and a wide range of stakeholders (Sierdovski et al., 2022; Censi et al., 2025). As a result, companies are producing an increasing amount of ESG-related data, supported by the diffusion of reporting standards and digital tools for data collection and analysis.

Despite this growth in data availability, organisations still face substantial challenges in transforming ESG data into actionable knowledge that can effectively support strategic decision-making. This issue is particularly evident in the social dimension of ESG, which includes complex and multidimensional aspects such as employee well-being, diversity and inclusion, workplace safety, and stakeholder relationships (Cui, 2024; Govindan et al., 2025). These elements are difficult to capture through purely quantitative indicators, as they often require contextual interpretation and qualitative assessment.

Current ESG reporting practices and analytics tools mainly focus on numerical indicators, aggregated scores, and descriptive dashboards (Nielsen, 2023). While these tools are useful for monitoring performance, they provide limited support for understanding causal relationships, identifying critical variables, and defining improvement strategies. At the same time, more advanced solutions based on Artificial Intelligence (AI) often require high levels of technical expertise, which reduces their accessibility and limits their adoption within organisations (Mustafa et al., 2025). In this context, recent developments in Large Language Models (LLMs), a

class of AI systems capable of processing and generating natural language, open new opportunities for enhancing the interpretation of ESG data. These models can support the transformation of structured data into qualitative insights, contributing to knowledge creation processes and organisational sensemaking (Rahmani et al., 2025; Engstrom et al., 2024). However, their integration into decision support systems remains an emerging area, especially in relation to accessible and low-code solutions.

Low-code approaches refer to development environments that allow users to design and implement applications with minimal programming effort. These approaches can reduce barriers to the adoption of AI technologies, enabling a broader range of users to interact with advanced analytical tools. In the ESG domain, combining low-code platforms with LLMs may provide a practical way to bridge the gap between quantitative data and qualitative interpretation. Based on these considerations, this study aims to explore the use of LLM-based agents as tools for supporting knowledge creation from ESG data, with a specific focus on the social dimension. The research adopts a Design Science Research (DSR) approach (Verschuren & Hartog, 2005; Delport et al., 2024) and develops a technological artefact capable of receiving structured ESG indicators as input and producing qualitative assessments and strategic recommendations as output. The proposed system is designed using a low-code architecture, integrating data analytics and language models within a single workflow.

The paper contributes to both theory and practice. From a theoretical perspective, it extends existing studies on the role of AI in knowledge creation and organisational decision-making, particularly in the context of sustainability (Gandia et al., 2025). From a practical perspective, it proposes a replicable and accessible model for building decision support systems that go beyond descriptive reporting and support a more interpretative and strategic use of ESG data.

2 Theoretical Background

The increasing relevance of ESG criteria has stimulated a growing body of research on how organisations collect, analyse, and use sustainability-related data. Three main streams of literature are particularly relevant: ESG measurement and social sustainability; knowledge creation and organisational sensemaking; and the role of AI in decision support systems.

2.1 ESG measurement and social sustainability

ESG frameworks are widely used to assess corporate sustainability performance, integrating environmental, social, and governance dimensions into a unified perspective (Sierdovski et al., 2022). Among these, the social dimension presents specific challenges due to its qualitative and context-dependent nature. It includes aspects such as employee well-being, diversity and inclusion, labour conditions, and relationships with stakeholders and communities (Govindan et al., 2025). While the availability of ESG data has increased significantly, much of the existing literature highlights the limitations of current measurement practices. ESG reporting systems often rely on standardised indicators and aggregated scores, which facilitate comparison across firms but may oversimplify complex social phenomena (Nielsen, 2023). As a result, important nuances and contextual factors are often lost, limiting the ability of organisations to derive meaningful insights from the data. Recent studies have also emphasised the role of digital transformation in improving ESG performance, suggesting that data-driven approaches can support more effective sustainability strategies (Cui, 2024). However, the challenge remains not only to collect and analyse data, but also to interpret it in a way that supports decision-making, especially when dealing with multidimensional and interrelated variables.

2.2 Knowledge creation and organisational sensemaking

The difficulty in interpreting ESG data can be understood through the lens of knowledge creation and sensemaking. Knowledge creation refers to the process through which data and information are transformed into meaningful insights that can guide action. In organisational contexts, this process often involves interpreting complex and ambiguous information, identifying patterns, and constructing shared understanding. Recent research has highlighted how AI technologies can support these processes by assisting in the interpretation and contextualisation of data (Engstrom et al., 2024). In particular, AI systems can contribute to sensemaking by generating narratives, identifying relationships between variables, and offering alternative perspectives on organisational performance. The role of AI is not limited to prediction or automation. Instead, it can act as a cognitive support tool that enhances human decision-making by providing structured interpretations and suggestions (Qin, 2024). This perspective is particularly relevant for ESG analysis, where decision-makers must deal with incomplete information, qualitative judgements, and multiple stakeholder perspectives.

2.3 Artificial Intelligence and low-code decision support systems

The application of AI to ESG analytics has attracted increasing attention in recent years. Studies have shown that AI can improve the quality, reliability, and relevance of non-financial reporting, supporting both internal decision-making and external communication (Majekodunmi, 2025; Mustafa et al., 2025). However, many AI-based solutions remain complex and require specialised technical skills, limiting their practical adoption.

LLMs represent a recent development in AI that can address some of these limitations. LLMs are capable of processing both structured and unstructured data and generating natural language outputs, making them suitable for tasks that involve interpretation and explanation (Rahmani et al., 2025). Their ability to translate quantitative inputs into qualitative insights makes them particularly relevant for ESG contexts. At the same time, the emergence of low-code platforms has made it easier to design and deploy AI-based applications. Low-code environments allow users to build data pipelines and integrate different components, such as data analytics tools and language models, with limited programming effort. This reduces barriers to entry and enables a wider range of organisations to experiment with AI-driven solutions. From a decision support perspective, this combination aligns with the concept of Decision Support Systems (DSS), which are designed to assist rather than replace human decision-makers. Early work on DSS highlights the importance of integrating data, models, and user interaction in a coherent system that supports problem understanding and solution development (Poch et al., 2004). Building on these insights, recent research has started to explore the role of AI as a tool for enhancing knowledge and supporting sustainability-oriented decision-making (Gandia et al., 2025). The integration of LLMs within low-code architectures can thus be seen as a promising approach to bridge the gap between data availability and knowledge creation, particularly in complex domains such as social sustainability.

3 Methodology

3.1 Data and empirical setting

The empirical foundation of the agent is based on data collected from the LPSG dataset, focusing on the energy sector over the period 2020-2024. The dataset includes 16 variables for a total of 66 firms and is used to derive sector benchmarks and support the analytical components embedded in the agent.

A thorough data cleaning and preprocessing phase was conducted to ensure suitability for econometric modeling. Out of the initial 16 variables, 9 were retained based on data completeness and temporal consistency, ensuring sufficient observations across the four-year period.

The correlation analysis reveals a generally low level of dependence among variables, suggesting limited multicollinearity within the dataset. The only notable exception is the strong correlation between the Social Pillar Score and the ESG Score (0.82), which is expected given that the social dimension is a core component of the overall ESG metric.

From an economic perspective, several meaningful relationships emerge. Firm size, proxied by the number of employees, is positively associated with both ESG performance and the Social Pillar Score, indicating that larger firms tend to adopt more advanced sustainability practices. Furthermore, governance and diversity-related variables exhibit moderate correlations with ESG performance, highlighting a consistent relationship between the quality of governance structures and attention to sustainability issues.

In contrast, financial variables such as Return on Equity (ROE) and dividend yield show weak correlations with ESG indicators, suggesting the absence of a strong direct association within the analyzed sample. Similarly, the time variable does not display significant trends, indicating that the observed differences are primarily cross-sectional rather than driven by temporal dynamics.

The Principal Component Analysis (PCA) indicates that the variables contributing most to total variance (28%) are the number of employees, board diversity, and executive members' gender diversity.

Overall, these findings define the empirical structure underpinning the agent, informing both the construction of sector benchmarks and the representation of the decision environment in which the agent operates.

3.2 Agent architecture

The agent runs on Langflow, an open-source platform that lets users assemble LLM-based pipelines visually, without writing code (Taulli & Deshmukh, 2025). Four nodes make up the pipeline: (1) a Chat Input node that captures the user's messages; (2) a Prompt Template node where all domain knowledge resides, variable definitions, formulas, sector benchmarks, PCA results, and cluster profiles; (3) a Chat Memory node that tracks

conversation history across multiple turns; and (4) an LLM node that sends the assembled prompt to the language model and returns the response.

The model selected is Llama 4 Scout 17B, served free of charge via Groq. The choice was deliberate: the study set out to assess what is possible when the entire stack, platform, model, and API, costs nothing. A commercial model such as GPT-4o would almost certainly perform better on harder reasoning tasks; however, selecting it would have bypassed the central research question. The trade-off was built into the evaluation design so that its consequences would be visible.

The conversation is organised into five thematic blocks: governance and board composition; workforce and gender; pay equity; ethnic diversity; and SDG disclosure. For each block, the agent collects raw figures from the user, computes the relevant percentages, and proceeds to the next block. Once all five blocks are complete, it presents a summary table for user confirmation and generates a structured report containing: an overall assessment assigning the firm to one of three performance clusters; a variable-by-variable comparison against sector benchmarks; an improvement plan with concrete targets and references to GRI 401-406, ESRS S1-S2, and SDGs 3, 5, and 10; a prioritised roadmap by time horizon; and a note on limitations. A batch mode is also available: if the user provides all data at once, the agent skips the dialogue and proceeds directly to the summary and report. Table 1 summarises the eleven variables processed by the agent, grouped by thematic block.

Table 1: Variables processed by the ESG advisory agent, grouped by thematic block.

Variable Group	Variables	Data Type	Benchmark Source
Board Composition	Board Gender Diversity, Executive Gender Diversity	Percentage (%)	Sector ESG cluster analysis
Workforce & Gender	Women Employees, Women Managers	Percentage (%)	Sector ESG cluster analysis
Pay Equity	Gender Pay Gap (index)	Index (0-100)	Provided pre-calculated index
Ethnic Diversity	Board, Executive & Workforce Ethnic Minorities	Percentage (%)	Sector ESG cluster analysis
Sustainability Disclosure	SDG Disclosure Score, Overall ESG Score	Score (0-100)	Sector ESG cluster analysis

3.3 Evaluation protocol

To evaluate the agent, a synthetic dataset of 40 fictitious energy companies was constructed. The firms are distributed across eight scenarios (five companies each), designed to stress-test different aspects of the agent's reasoning. Additional scenarios target specific edge cases, such as firms where board diversity is high but executive diversity is not, or vice versa. Each firm carries realistic values for all variables; crucially, the dataset includes both pre-calculated percentages and the raw figures from which those percentages were derived.

Two performance dimensions were measured. Value accuracy assesses whether the figure reported by the agent matches the dataset value within a tolerance of two percentage points. Judgment accuracy assesses whether the agent correctly identifies the direction of performance, that is, whether it accurately classifies a value as above or below the sector average.

4 Results

4.1 Overall accuracy

The results present a sharply divided picture. On eight of the eleven variables, Board Gender Diversity, Executive Gender Diversity, Women Employees, Women Managers, the three Ethnic Minorities indicators, and the Overall ESG Score, the agent achieves 98.1% value accuracy and 93.2% judgment accuracy. For a 17-billion-parameter model running on free infrastructure, these are strong results. The agent clearly understands what the variables mean, performs the required calculations correctly, and reliably compares results against benchmarks.

The remaining three variables tell a different story. Gender Pay Gap reaches only 33% value accuracy and 44% judgment accuracy. Board Cultural Diversity and Executive Cultural Diversity hover at approximately 42-45% on values. Something goes systematically wrong on these specific indicators; understanding why is

important both for improving the agent and for drawing broader conclusions about low-code AI systems. Table 2 presents the full accuracy results across all eleven variables.

Table 2: Value accuracy and judgment accuracy by variable.

Variable	Value Accuracy	Judgment Accuracy	Notes
Board Gender Diversity	98.1%	93.2%	Core variable - high performance
Executive Gender Diversity	98.1%	93.2%	Core variable - high performance
Women Employees	98.1%	93.2%	Core variable - high performance
Women Managers	98.1%	93.2%	Core variable - high performance
Ethnic Minorities (3 indicators)	98.1%	93.2%	Core variable - high performance
Overall ESG Score	98.1%	93.2%	Core variable - high performance
Gender Pay Gap	33%	44%	Conflict between raw data and index
Board Cultural Diversity	~42%	~44%	Confusion between similar variable populations
Executive Cultural Diversity	~45%	~44%	Confusion between similar variable populations

4.2 What went wrong, and why the model is responsible

The errors are not random. They follow two distinct patterns, both traceable to the same root cause: the model cannot reliably handle situations where the input contains competing signals that require prioritisation.

Consider the Gender Pay Gap. The test dataset provides the agent with two pieces of information: raw salary figures for women and men, and a pre-calculated index. The system prompt contains a general instruction, always compute percentages from raw numbers alongside a specific exception, for the Pay Gap, use the provided index. The model ignores the exception in every case and recalculates from raw salaries. Because the raw salaries and the index in the synthetic dataset were generated independently and do not perfectly correspond, the recalculated values diverge from the expected ones by as much as 78 percentage points.

Critically, this is not a prompt-writing problem. The instruction is present, clear, and unambiguous. The model simply cannot execute it. Recent work on instruction density by Jaroslawicz et al. (2025) explains why: the study identifies three degradation patterns as instruction complexity increases. Reasoning-oriented models maintain near-perfect adherence until reaching a threshold, then drop sharply. Mid-range models decline linearly. Llama 4 Scout specifically exhibits exponential decay, performance collapses rapidly once instruction complexity exceeds a modest level. The prompt used in this study, with its layered rules, benchmarks, formulas, and conversational flow structure, clearly crosses that threshold. Li et al. (2024), working on instruction-following robustness, reach a complementary conclusion: models with weaker contextual understanding tend to fixate on the most prominent instruction in the prompt rather than weighing competing directives against each other. In this case, the instruction to calculate from raw data is dominant; the exception for the Pay Gap is treated as noise.

The Cultural Diversity mix-ups fit the same explanation. Board Cultural Diversity and Executive Cultural Diversity use similar formulas but refer to different populations, board members versus executives respectively. Keeping them distinct requires the model to maintain two parallel variable tracks in working memory and route each raw figure to the correct denominator. This is precisely the kind of selective-attention task that mid-sized models struggle with when the prompt is already dense with other demands.

The 98.1% accuracy on core variables provides confidence that the architecture and prompt are not fundamentally at fault. The agent handles the same cognitive operations, percentage computation, benchmark comparison, qualitative labelling, almost flawlessly when the input is unambiguous. Failures are confined to cases requiring disambiguation or exception-handling: capacities that scale with model size.

4.3 Two attempts at fixing the Pay Gap

Two corrective strategies were tested on a subsample of six firms: three with large Pay Gap errors, two with moderate errors, and one control firm where the original output was already correct. Both strategies are consistent with the iterative logic of DSR.

Prompt-level fix: an explicit, prominent instruction was added: if both the index and the salary figures are present, always use the index and recalculate only when the index is missing. Result: one out of six firms was corrected. The model continued to recalculate from salaries in the remaining five cases. This is consistent with the Jaroslawicz et al. (2025) findings: adding instructions to an already overloaded prompt does not help a model past its instruction-following ceiling; if anything, it adds further complexity.

Input restructuring: instead of modifying the instruction, the source of conflict was removed. Raw salary figures were stripped from the input, leaving only the pre-calculated index. With no alternative figures available, the model had no opportunity to apply the wrong rule. Accuracy rose to 100% across all six firms. Table 3 summarises the two corrective attempts and their outcomes.

Table 3: Comparison of corrective strategies tested for the Gender Pay Gap variable.

Fix Attempt	Success Rate	Outcome	Interpretation
Prompt-level instruction added	1/6 firms	Largely failed	Model past its instruction-following ceiling; added instructions increase complexity without improving disambiguation
Input restructuring (raw salaries removed)	6/6 firms	100% accuracy	Eliminating the competing signal is more reliable than instructing the model to resolve it

The practical implication is clear. When working with a mid-sized open-source model, rewriting the prompt to resolve a conflict is often futile: the model lacks the reasoning depth to adjudicate between competing instructions regardless of how they are worded. Restructuring the input so that the conflict never arises is a more reliable strategy. For LLM-based tools intended to run on accessible, free infrastructure, the clarity of the input matters at least as much as the sophistication of the prompt.

5 Discussion and Conclusions

The results of this study provide several insights into the use of LLMs as tools for supporting knowledge creation from ESG data, particularly within low-code and accessible environments. The findings confirm that an ESG advisory agent built on a fully open and zero-cost infrastructure can produce structured and largely accurate outputs. The high value accuracy observed across most variables suggests that even mid-sized models are capable of performing basic analytical tasks, computing percentages, comparing values against sector benchmarks, with a high degree of reliability.

However, the results also highlight important limitations. The errors observed in specific variables, such as the Gender Pay Gap and Cultural Diversity indicators, reveal that the model struggles when the input contains competing signals or requires the application of exceptions to general rules. In these cases, the model tends to prioritise the most prominent instruction and ignore secondary ones, leading to systematic inaccuracies. This behaviour is consistent with recent studies on instruction-following limitations in LLMs, which show that model performance can degrade as instruction count and complexity increase (Jaroslawicz et al., 2025; Li et al., 2024).

From a theoretical perspective, these findings contribute to the literature on AI as a tool for knowledge creation and organisational sensemaking. While previous studies have emphasised the potential of AI to support interpretation and decision-making (Engstrom et al., 2024; Qin, 2024), this work shows that such potential is strongly dependent on the interaction between model capabilities, input structure, and system design. LLMs can effectively support the transformation of quantitative ESG data into qualitative insights when the analytical context is clear and unambiguous. Their contribution becomes less reliable when interpretation requires resolving conflicts, managing exceptions, or maintaining multiple parallel reasoning paths.

An important contribution of this study lies in the design implications emerging from the iterative DSR process. The comparison between the two corrective attempts for the Pay Gap issue shows that modifying the prompt is not always an effective strategy, especially when the model operates near its instruction-processing limits. Restructuring the input to eliminate ambiguity proved to be a more robust solution. This finding suggests a general design principle for low-code AI systems based on mid-sized models: reducing complexity at the input level is more effective than increasing complexity at the instruction level.

From a practical perspective, the study demonstrates that it is possible to develop accessible and configurable DSSs for ESG analysis using low-code tools and open-source models. This has important implications for organisations that lack the resources or technical expertise required to adopt more advanced AI solutions. The proposed approach allows users to combine quantitative data analysis with qualitative interpretation in a single workflow, supporting a more strategic use of ESG information. In this sense, the agent does not replace human decision-makers but acts as a support tool that enhances their ability to interpret data and identify potential improvement actions, in line with the traditional role of DSS (Poch et al., 2004).

The study acknowledges several limitations. First, the evaluation relies on a synthetic dataset which, although designed to be realistic, cannot fully capture the complexity of real-world organisational data. Second, the use of a mid-sized model (17 billion parameters) constrains the system's ability to handle complex reasoning tasks, particularly those involving ambiguity or conflicting information. Third, the quality of outputs remains

dependent on the quality and consistency of the input data, highlighting the importance of data preparation and validation.

Future research can build on these findings in several directions. First, the use of larger and more advanced models may improve performance in tasks requiring complex reasoning and exception handling. Second, testing the proposed system on real-world datasets would allow its applicability in organisational contexts to be assessed. Finally, further research could explore the extension of this approach to other ESG dimensions and the integration of additional data sources and analytical techniques.

In conclusion, this study shows that LLM-based agents, when integrated into low-code architectures, can play a valuable role in bridging the gap between quantitative ESG data and qualitative knowledge. While important limitations remain, particularly in relation to model capabilities and input design, the results highlight the potential of accessible AI solutions to support more informed and meaningful decision-making processes in the field of sustainability.

6 Ethics Declaration

The present research did not require the approval of an ethics committee, as it does not involve human subjects, sensitive personal data or experimentation on living beings. All the information used comes from publicly accessible sources and scientific literature.

7 AI Declaration

Generative Artificial Intelligence tools have not been used for the drafting or processing of the contents of this document. All sections of the paper were developed independently by the authors, without the aid of generative AI applications.

Can Ethics Become Isomorphic? Informational Power in GenAI Governance

Marco Di Giovanni
University G. d'Annunzio, Pescara, Italy

Abstract

The rapid diffusion of Generative AI (GenAI) across organizational contexts is transforming not only knowledge work and creative practices, but also the way ethical questions are defined, structured, and legitimized at the field level. Despite the growing scholarly attention devoted to AI ethics, relatively little is known about how the moral boundaries of GenAI are stabilized and diffused across dominant providers. This paper argues that the publicly available governance artifacts produced by leading GenAI providers — including usage policies, safety frameworks, transparency statements, and model documentation — can be understood as moral ordering infrastructures that shape what is permitted, what is prohibited, which harms are foregrounded, and how responsibility is framed.

Drawing on Information Ethics and the concept of the infosphere, the paper proposes that those who govern the infrastructures of generative intelligence exercise a form of informational power capable of orienting the moral grammar through which organizations interpret and manage ethical questions. Integrating this perspective with neo-institutional theory, the paper introduces the concept of ethical isomorphism: a process through which coercive, mimetic, and normative pressures, combined with the concentration of informational power, foster convergence in ethical governance scripts across dominant providers.

The paper develops this conceptual argument through a focused comparative reading of ten publicly available governance documents produced by five leading providers — OpenAI, Anthropic, Google, Microsoft, and Meta. The comparison uses a structured analytical template covering ethical principles, harm taxonomies, stakeholder framing, trade-offs, and enforcement and accountability mechanisms. This approach allows the paper to examine how abstract AI ethics principles are translated into observable governance scripts across the GenAI provider field.

The comparative analysis reveals a pattern of partial but meaningful convergence. The strongest alignment emerges in harm taxonomies, prohibited-use structures, and governance architectures, while the main divergences concern governance style, the breadth of stakeholder framing, and the degree to which moral trade-offs are explicitly acknowledged. The paper concludes that the public governance artifacts of leading providers make visible an emerging form of ethical isomorphism — not as full normative identity, but as a progressive standardization of the way ethics is operationalized and institutionalized. Such convergence may narrow the ethical pluralism available to adopting organizations, which may find themselves importing preconfigured moral assumptions alongside GenAI tools. The paper offers relevant implications for research, organizations, and AI governance policy.

Keywords: Generative AI governance; ethical isomorphism; informational power; algorithmic governance; ethical pluralism

Paper type: Academic Research Paper

1 Introduction

The rapid diffusion of Generative AI (GenAI) is reshaping organizational knowledge practices, creative work, and decision-making processes, while simultaneously intensifying ethical concerns related to bias, opacity, privacy, misuse, and accountability. Recent studies show that GenAI is increasingly embedded in knowledge-intensive work and human–AI collaboration, making it far more than a peripheral technological tool (Anthony et al., 2023; Benbya et al., 2024; Brynjolfsson et al., 2025). Yet the problem is not only that GenAI creates new ethical risks. It is also that the infrastructures through which these systems are governed are becoming increasingly central to how organizations define what counts as acceptable use, relevant harm, and legitimate control. In digitally mediated organizational environments, information is not merely an input to action, but a constitutive element of socio-economic life and inter-organizational relations (Vaccaro & Madsen, 2009). This makes the governance of GenAI inseparable from the governance of the informational environment in which organizations operate.

Despite the rapid expansion of the AI ethics literature, much of the debate has focused on the proliferation of principles and on the gap between ethical aspiration and practical implementation (Jobin et al., 2019; Morley et al., 2021). What remains less understood is how the ethical boundaries of GenAI are stabilized at field level by the actors who control its most influential infrastructures. In practice, these boundaries are increasingly articulated through provider-produced governance artifacts—such as usage policies, safety frameworks,

transparency statements, and model documentation—that specify what is allowed, what is prohibited, which harms matter, and how responsibility is framed. These artifacts can be understood as institutional devices that help structure the moral and epistemic boundaries of the field, much like ethical codes can operate as scripts that standardize organizational understandings of legitimacy and responsibility (Novis-Deutsch et al., 2022).

This paper approaches that issue through the lens of Information Ethics and the concept of the infosphere. The infosphere can be understood as the broader informational environment within which human and technological agents produce, exchange, and transform information (Floridi, 2009, 2010, 2013). In this view, organizations are informational actors embedded in a socio-digital environment whose structure shapes knowledge, judgment, and governance. This perspective expands the ethical focus from the use of technology to the governance of informational infrastructures. When information becomes constitutive of organizational reality, governing informational infrastructures also means shaping the conditions under which harms are classified, values are prioritized, and moral judgments become legitimate. In this sense, informational power is not only technical or economic; it is also moral and epistemic. GenAI is especially significant because it does not merely operate within the infosphere, but actively contributes to organizing it. Under conditions of provider concentration, those who govern generative infrastructures may also shape the moral grammar through which organizations interpret and manage ethical questions.

This concern becomes sharper when viewed through a neo-institutional lens. Organizational fields do not converge only because actors share technologies; they also converge through coercive, mimetic, and normative pressures that stabilize legitimate vocabularies, categories, and governance practices (DiMaggio & Powell, 1983; Boxenbaum & Jonsson, 2008). In the GenAI provider field, this raises a more specific question: do public governance artifacts progressively standardize moral categories, stakeholder framings, enforcement logics, and acceptable trade-offs? This paper refers to that possibility as ethical isomorphism: a process through which concentrated informational power and institutional pressures foster convergence in ethical governance scripts across dominant providers. Such convergence matters because it may reduce ethical pluralism, that is, the diversity of moral perspectives through which organizations and stakeholders can engage in reflexive and legitimate ethical deliberation (Buchholz & Rosenthal, 1996; Greenwood & Freeman, 2011). If ethics becomes increasingly procedural, standardized, and weakly contestable, organizations may end up importing preconfigured moral assumptions together with GenAI tools.

The paper develops this argument through three related conceptual and exploratory questions: (RQ1) How can ethical isomorphism be theorized at the intersection of Information Ethics and neo-institutional theory? (RQ2) How are ethical governance scripts articulated across the public governance artifacts of leading GenAI providers? (RQ3) How does convergence in these scripts reshape the space for ethical pluralism in organizational GenAI adoption? To address these questions, the paper combines conceptual theory-building with a focused comparative reading of public governance artifacts produced by leading GenAI providers. By comparing how providers define principles, prioritize harms, frame stakeholders, and construct enforcement and accountability, the paper examines how abstract AI ethics principles are translated into observable governance scripts. In doing so, it contributes to the literature in three ways. First, it reframes GenAI ethics as a field-level institutional outcome rather than merely a set of abstract principles. Second, it integrates Information Ethics and neo-institutional theory to explain how informational power may translate into convergent ethical governance. Third, it highlights the practical and policy relevance of preserving ethical pluralism in an increasingly concentrated GenAI landscape.

2 Theoretical Background

2.1 Information ethics and the infosphere

To understand why GenAI governance matters ethically, it is useful to begin from the perspective of Information Ethics. Rather than treating information as a neutral input or as a mere technical resource, Information Ethics conceives it as a constitutive element of contemporary socio-digital reality (Floridi, 2009, 2010, 2013). This broader informational environment can be described as the infosphere: the relational space in which human and technological agents continuously generate, exchange, process, and transform information. In this view, organizations are not external observers of the digital world; they are informational actors embedded in it, whose practices, decisions, and governance arrangements are increasingly shaped by informational infrastructures. Ethical questions, therefore, do not arise only at the level of individual conduct or technological malfunction, but at the level of how informational environments are structured, maintained, and legitimized.

This perspective implies that ethics is not simply a matter of applying abstract normative principles after technological systems have been developed. Rather, ethics becomes a structural issue concerning the integrity, quality, and sustainability of informational relations. Preserving the integrity of the infosphere means preserving the conditions under which knowledge can be produced, shared, and contested without being excessively distorted, monopolized, or procedurally narrowed (Floridi, 2009). From this standpoint, the governance of information is also a governance of moral possibility: actors who shape informational conditions indirectly shape what becomes visible, legitimate, and actionable in organizational life. This is precisely why the rise of GenAI deserves attention not only as an innovation in productivity or creativity, but also as a transformation in the moral architecture of the informational environment itself.

2.2 Informational power and the rise of generative AI

The relevance of this perspective has become especially clear with the rapid diffusion of Generative AI across organizational contexts. GenAI systems are now increasingly involved in creative work, decision support, communication, and knowledge-intensive practices (Anthony et al., 2023; Benbya et al., 2024; Brynjolfsson et al., 2025). Their significance, however, exceeds mere adoption rates. GenAI systems are trained on vast informational corpora, operate by processing and recombining information at scale, and continuously influence how information is retrieved, framed, and redistributed. In this sense, GenAI does not simply function within the infosphere; it contributes to organizing it. The more such systems mediate everyday organizational knowledge work, the more they participate in shaping the epistemic and moral conditions under which actors interpret problems, define harms, and judge acceptable conduct.

This leads to the notion of informational power. Following Floridi (2009, 2010, 2013), informational power can be understood as the capacity to shape moral and epistemic boundaries through control over informational flows and over the conditions of their production and circulation. Such power is not merely technical. It is also epistemic, because it influences what counts as relevant or credible knowledge, and moral, because it affects the classification of risks, acceptable uses, prohibited practices, and legitimate trade-offs. In the GenAI field, this power is concentrated in a relatively small set of dominant providers whose models, interfaces, safety policies, and usage rules increasingly function as infrastructural conditions for adoption. As a result, provider governance does not only regulate products; it may also shape the broader “space of the thinkable” available to organizations using those products.

2.3 Institutional mechanisms, ethical isomorphism, and ethical pluralism

While Information Ethics helps explain why control over informational infrastructures matters, neo-institutional theory helps explain how convergence may emerge across actors operating in the same field. Classic institutional theory shows that organizations tend to become similar through coercive, mimetic, and normative pressures (DiMaggio & Powell, 1983; Boxenbaum & Jonsson, 2008). Coercive pressures stem from formal and informal obligations, including regulatory expectations and compliance demands. Mimetic pressures arise under uncertainty, when actors imitate highly legitimate models. Normative pressures emerge through professional standards, expert communities, auditing practices, and shared vocabularies of appropriateness. In highly visible and contested technological fields, these pressures may not only shape organizational structures, but also the categories through which ethical legitimacy is articulated and defended.

Applied to GenAI governance, this suggests that providers may progressively align not only on technical safeguards but also on the ethical language embedded in their public artifacts. Governance documents can standardize what counts as harm, which stakeholders are rendered visible, how accountability is framed, and which ethical trade-offs are treated as legitimate or unavoidable. This paper refers to such a process as ethical isomorphism: the alignment of moral logics and governance scripts across actors within the infosphere under conditions of concentrated informational power and institutional pressure. Importantly, the object of convergence here is not formal organizational structure alone, but the institutionalization of “ethical alignment” itself as a field-level governance script (Wijen, 2014; Islam & Greenwood, 2024). In other words, ethics may become standardized not because moral dilemmas have been resolved, but because certain templates of responsible conduct become widely diffused and difficult to contest.

This theoretical possibility foregrounds a final construct: ethical pluralism. Ethical pluralism refers to the coexistence of multiple moral perspectives that enable reflexive deliberation, stakeholder responsiveness, and legitimate organizational judgment (Buchholz & Rosenthal, 1996; Greenwood & Freeman, 2011). In heterogeneous organizational environments, pluralism is not a weakness but a necessary condition for addressing complex ethical trade-offs. If dominant GenAI providers converge on a narrow moral grammar—particularly one that becomes increasingly procedural, compliance-oriented, and weakly reflexive—then ethical

pluralism may erode even as ethics discourse expands. The problem is therefore not simply whether providers use ethics language, but whether the concentration of informational power contributes to reducing the diversity of moral frameworks through which organizations can interpret and govern GenAI. This is the theoretical basis on which the present study investigates public governance artifacts of leading providers.

3 Method

This paper adopts a conceptual theory-building approach supported by a focused comparative analysis of public governance artifacts produced by leading Generative AI providers. The aim is to develop the concept of ethical isomorphism and to examine how providers define, justify, and operationalize the ethical boundaries of their systems in publicly available documents. Ethics is treated here as an institutionalized form of governance, expressed through principles, harms, stakeholder framings, trade-offs, and accountability mechanisms.

The empirical corpus consists of ten publicly available governance documents produced by five dominant providers: OpenAI, Anthropic, Google, Microsoft, and Meta. The sample was selected on the basis of field relevance, organizational visibility, and the availability of comparable public governance documentation. The corpus includes the following documents: for OpenAI, *Usage Policies* and *Model Spec*; for Anthropic, *Transparency Hub* and *Responsible Scaling Policy Version 3.0*; for Google, *Gemini for Google Cloud and Responsible AI* and the *Generative AI Prohibited Use Policy*; for Microsoft, *Responsible AI: Ethical policies and practices* and the *Transparency Note for Microsoft Copilot*; and for Meta, the *Responsible Use Guide* and the *Llama 4 Acceptable Use Policy*.

Each document was treated as a governance artifact, and each provider as a comparative case. The analysis followed a structured analytical template covering: document type, stated purpose, explicit ethical principles, prioritized harms, marginal or weakly articulated harms, stakeholder visibility, trade-offs, enforcement and accountability mechanisms, degree of operationalization, compliance language, references to standards or evaluation practices, and indicators of ethical openness or closure. Cross-case comparison focused on five dimensions: (1) ethical principles and their operationalization; (2) harm taxonomies; (3) stakeholder framing; (4) trade-offs between safety, openness, access, and responsibility; and (5) enforcement and accountability. This comparative structure supports the distinction between rhetorical similarity and more substantive alignment across providers.

The analytical process combined author-led document reading with AI-assisted comparative synthesis. The documents were read and interpreted by the author, while ChatGPT was used to support the identification of cross-case patterns of convergence, divergence, and ethical pluralism. The AI-assisted outputs were used as interpretive inputs within the author's analytical process and were reviewed, refined, and integrated through direct engagement with the original documents.

The analysis is theory-driven. Recurring similarities across provider artifacts are interpreted through neo-institutional theory as indicators of coercive, mimetic, and normative pressures within a concentrated provider field. Divergences across providers are analyzed as important variations in governance style, stakeholder framing, and ethical openness. This approach allows the paper to assess how public governance discourse makes ethical isomorphism visible as an emerging pattern in the GenAI provider field, and how such convergence may reshape ethical pluralism in the infosphere.

4 Findings

The comparative analysis reveals a visible pattern of partial convergence across the public governance artifacts of leading GenAI providers. Across the corpus, ethics is consistently framed through a shared vocabulary centered on safety, transparency, accountability, privacy, and responsible use. This convergence is visible not only at the level of declared principles, but also in the way providers classify harms, define prohibited uses, and operationalize governance through safeguards, monitoring, and restrictions. This convergence remains partial: providers differ in governance style, in the explicit treatment of trade-offs, and in the breadth of stakeholder framing. Table 1 summarizes the principal areas of cross-provider convergence and divergence emerging from the comparative analysis.

Table 1: Main cross-provider convergences and divergences in ethical governance

Dimension	Main convergence	Main divergence	Analytical implication
Ethical principles	All providers invoke safety, transparency, accountability, privacy, and responsible use.	OpenAI emphasizes model behavior; Anthropic emphasizes frontier safety; Microsoft emphasizes institutional governance; Meta emphasizes developer responsibility and open innovation; Google emphasizes prohibited use and risk control.	Strong rhetorical convergence with differentiated governance styles.
Harm taxonomy	Broad overlap on illegal use, child safety, self-harm, privacy misuse, cyber misuse, and harmful content.	Anthropic gives more weight to catastrophic risks; Google is especially explicit on restricted high-impact uses.	Strongest area of substantive convergence.
Trade-offs	Utility and risk control are salient across all cases.	OpenAI and Meta articulate trade-offs more explicitly; Microsoft, Google, and Anthropic frame them more procedurally.	Ethical pluralism is present, but unevenly articulated.
Enforcement and accountability	All providers rely on some mix of restrictions, safeguards, filtering, evaluation, or monitoring.	Enforcement architectures differ: behavioral hierarchy (OpenAI), scaling safeguards (Anthropic), whole-system governance (Microsoft), developer-layered controls (Meta), prohibited-use closure (Google).	Strong procedural convergence despite organizational variation.
Stakeholder framing	Users and developers are visible in all cases.	Microsoft offers the broadest stakeholder view; Meta gives more discretion to developers; participatory stakeholder voice remains weak across the corpus.	Managed stakeholder visibility is common; strong stakeholder agency is rare.
Ethical pluralism	Ethics is present across the field.	Most documents proceduralize ethics into safety and compliance rather than opening sustained space for contestation.	The field shows partial ethical closure rather than rich pluralism.

4.1 Convergence in ethical principles and harm framings

The strongest cross-case convergence appears in the articulation of ethical principles and harm categories. All five providers frame ethics through a common responsible-AI vocabulary and repeatedly prioritize a similar core of harms: illegal use, child sexual exploitation, self-harm, privacy and data misuse, cybersecurity abuse, and harmful or unsafe content. Google's prohibited-use policy is especially explicit in codifying restrictions, particularly in high-impact contexts. Microsoft's transparency note operationalizes risks through concrete mitigation logic. Meta's responsible-use materials connect harms to layered safeguards and developer controls. OpenAI combines policy prohibitions with model behavior rules, while Anthropic extends the harm horizon toward frontier and catastrophic risk. The analytical implication is that providers are not only using similar language, but are stabilizing a comparable moral core of what must be prevented, restricted, or controlled.

4.2 Convergence in governance architecture

A second clear pattern is that ethics is translated into governance architecture rather than left at the level of principle statements. Across the corpus, providers operationalize ethics through recurring devices: prohibited-use lists, behavior specifications, evaluations, safeguards, monitoring, reporting channels, and access restrictions. Here, convergence becomes operational. Microsoft uses a whole-system governance logic with product-level transparency and risk controls. Anthropic links capability development to escalating safeguards and transparency commitments. Meta adopts a layered mitigation approach that spans model-level and system-level controls. OpenAI structures governance through a behavioral hierarchy and refusal logic. Google relies most visibly on prohibition and human-supervision requirements. These architectures differ in form, but they perform a similar function: they convert ethics into actionable control.

4.3 Divergence in trade-offs, stakeholder framing, and pluralism

The main divergences concern how providers frame stakeholders and how explicitly they acknowledge moral trade-offs. Microsoft offers the broadest stakeholder formulation by including affected people and deployment context. Meta assigns greater responsibility to developers and downstream builders. OpenAI centers users and developers, while Anthropic gives more visibility to expert communities and society-wide risk. Google's materials frame stakeholders mainly through protection and oversight. Trade-offs are also unevenly articulated: OpenAI and Meta are the clearest in acknowledging tensions between usefulness and safety, or alignment and

helpfulness, whereas Anthropic, Microsoft, and Google frame these tensions more procedurally through risk management and compliance. The overall result is a condition of limited ethical pluralism. Ethics is visible across the corpus, but it is largely expressed through a standardized governance grammar centered on safety, mitigation, and control, with less space for explicit moral contestation or competing ethical perspectives.

5 Discussion

The comparative analysis substantiates the core argument of the paper: the ethics of GenAI is increasingly institutionalized through provider-produced governance artifacts that define the moral and operational boundaries of use. Across the five providers, ethics is translated into a relatively stable governance grammar organized around safety, transparency, accountability, privacy, harm prevention, and controlled use. Provider documents therefore operate as infrastructures of ethical ordering within the infosphere, shaping what becomes permissible, risky, contestable, or prohibited in organizational use of GenAI.

From a neo-institutional perspective, the pattern observed can be interpreted as partial ethical isomorphism. The providers do not present identical moral frameworks; rather, they converge on a common procedural architecture of governance. The strongest alignment appears in harm taxonomies, prohibited-use structures, and enforcement logics, while divergence remains more visible in governance style, stakeholder breadth, and the explicit treatment of trade-offs. This means that convergence in the field is primarily a matter of increasingly similar ways of operationalizing ethics through recurring categories, safeguards, and control mechanisms. In that sense, the field is becoming more alike because providers are stabilizing a common model of what responsible GenAI governance should look like.

This result is especially important when interpreted through the lens of Information Ethics. As GenAI providers increasingly mediate how information is generated, filtered, and distributed, their governance scripts also shape the moral boundaries of the infosphere. The concentration of informational power in a limited number of providers therefore has ethical significance beyond product design or compliance. It affects which harms are foregrounded, which stakeholders are rendered visible, which trade-offs are normalized, and which forms of conduct are treated as legitimate or unacceptable. The analysis suggests that this power operates through standardized governance templates that consolidate ethics into a portable grammar of responsible AI.

The findings also clarify the paper's position on ethical pluralism. Ethics is highly visible across the corpus, but its dominant form is procedural, safety-centered, and compliance-compatible. Stakeholders are usually framed as subjects of protection rather than as actors with strong voice in governance. Trade-offs are acknowledged unevenly, and explicit moral contestation remains limited. The current governance landscape therefore reflects a condition of compressed pluralism: variation remains, but it is increasingly contained within a shared procedural grammar that may narrow the range of ethical frameworks available to organizational adopters.

For organizations, this has a direct implication. Adopting GenAI means adopting technical systems together with provider-defined governance scripts. These scripts can increase safety and standardization, while also shaping the ethical categories through which organizations interpret responsibility, risk, and acceptable use. For researchers and policymakers, the implication is equally clear: the analysis of GenAI ethics should move beyond lists of principles and focus more closely on how ethical governance is concretely structured, diffused, and normalized across the provider field.

6 Conclusion

This paper has shown that the ethics of GenAI is increasingly articulated through provider-produced governance artifacts that define what counts as acceptable use, relevant harm, legitimate control, and responsible deployment. Across the five providers, the analysis identifies a condition of partial but meaningful convergence. The strongest alignment appears in ethical vocabulary, harm taxonomies, and governance mechanisms, while divergence remains more visible in governance style, stakeholder breadth, and the explicit treatment of trade-offs. The main conclusion is therefore that the public governance artifacts of leading providers make visible an emerging form of ethical isomorphism: not full normative identity, but a growing convergence in the way ethics is operationalized and institutionalized across dominant GenAI providers.

The contribution of the paper is twofold. First, it shifts the analysis of GenAI ethics from abstract principles to public governance scripts, showing that ethics is structured through operational categories, restrictions, safeguards, and accountability devices. Second, it connects Information Ethics and neo-institutional theory to show how concentrated informational power can help stabilize a shared procedural moral grammar in the infosphere. In this sense, the paper suggests that the central issue is no longer only whether providers adopt

ethical principles, but how a small number of influential actors increasingly shape the boundaries of what becomes ethically thinkable and governable for organizations adopting GenAI.

The study also opens a research agenda on the relationship between public governance scripts, organizational adoption, and actual enforcement practices. Future research can extend the analysis through interviews, internal governance evidence, external audits, and enforcement cases in order to examine how public ethical scripts are translated into organizational practice and whether the convergence observed here deepens over time. Preserving ethical pluralism in GenAI governance is therefore a central challenge for organizations, policymakers, and researchers concerned with the future of knowledge work in an increasingly provider-mediated infosphere.

7 Ethics declaration

This study is based exclusively on the analysis of publicly available documents produced by GenAI providers. It does not involve human participants, personal data, interviews, experiments, or other procedures requiring formal ethical approval. Accordingly, no institutional ethics review was required.

8 AI declaration

AI tools were used during manuscript preparation to support document comparison, the coding of cross-case similarities and differences, and the refinement of language. In particular, ChatGPT was used to assist the analysis of convergence, divergence, and ethical pluralism across provider governance documents. All AI-assisted outputs were reviewed, checked against the original sources, and validated by the author, who takes full responsibility for the final analysis, interpretations, and wording of the paper.

A Regenerative Framework for Socio-Ecological Resilience: The Case of Armani's Apulia Regenerative Cotton Project

Marta Menegoli[1], Luigi Jesus Basile[2], Roberto Mauriello[3]
[1] University of Salento, Lecce, Italy
[2] LITEM, Institut Mines-Telecom Business School, Paris, France
[3] Pegaso University, Naples, Italy

Abstract

In recent years, increasing stress on socio-ecological systems has highlighted the limits of traditional sustainability approaches, fostering growing interest in regenerative perspectives aimed at restoring natural assets and supporting long-term resilience. These approaches may be particularly relevant for the fashion industry, given the environmental pressures associated with production activities and the complexity of global supply chains. However, regenerative approaches are still nascent in the fashion industry, and the literature offers limited insight into how such models emerge and consolidate over time. To address this gap, this study analyses the development of a regenerative initiative in the fashion industry through the lens of Institutional Theory. This perspective is particularly suitable to examine how coercive, normative, and mimetic pressures affect the different actors involved and how these pressures are interpreted and translated into practices over time, contributing to the institutionalization of new business models based on regenerative approaches.

From a methodological perspective, the study builds on a longitudinal single embedded case study of the Apulian Regenerative Cotton Project promoted by Armani, a leading luxury fashion brand. The analysis considers the key actors involved in the initiative, including the focal firm, scientific partners, and local agricultural firms across the supply chain, following the project from its inception to garment production. The findings suggest that normative pressures play a central role in orienting actors' behaviours and in defining appropriate practices throughout the initiative. Mimetic pressures emerge as the initiative gains visibility, while coercive pressures remain relatively limited, although potentially evolving in connection with emerging regulatory frameworks. Overall, the institutionalization process appears as gradual and non-linear, shaped by the continuous interpretation and translation of multiple pressures into concrete practices through the interaction among actors. Overall, this study contributes to the literature by providing an empirical analysis of a regenerative initiative in the fashion industry through the lens of Institutional Theory, showing how regenerative business models may emerge and diffuse. From a practical perspective, the findings highlight the importance of recognising and managing multiple institutional pressures, as well as supporting coordination among heterogeneous actors involved in the development of such initiatives.

Keywords: Regenerative approaches; Socio-ecological systems; Institutional Theory; Fashion industry; Regenerative business models

Paper type: Academic Research Paper

1 Introduction

In recent years, the urgency of addressing systemic stress in socio-ecological systems has become increasingly evident (Gualandris et al., 2024). Climate change and the degradation of natural resources increased the exposure of socio-ecological systems to risks and disruptions, while also revealing structural vulnerabilities that require moving beyond traditional approaches to sustainability (Erzurumlu et al., 2023). In this context, regenerative approaches, grounded in the need to restore natural assets, protect diversity, and foster distributed forms of governance, are attracting growing attention from both policymakers and scholars (Gugganig, 2025). In the EU, recent regulatory developments started to explicitly recognize regenerative practices. The European Regulation 2024/3012 introduces the Carbon Removals Certification Framework (CRCF), establishing a formal basis for certifying carbon removal activities. The delegated acts adopted in 2026 further specify technical standards for carbon farming, identifying core practices, and measures for certification. On a broader perspective, the EU Nature Restoration Law, as well as consolidated frameworks like the Task Force on Nature-related Financial Disclosures (TNFD) and the Global Reporting Initiative (GRI), while primarily focused on biodiversity and sustainability reporting, highlight the central role of restoration interventions, specifying relevant domains, metrics, and interventions.

On this other hand, recent studies examine how regenerative agriculture and restoration approaches are articulated into sets of practices aimed at improving soil health, enhancing biodiversity, and supporting the long-term resilience of socio-ecological systems (Beacham et al., 2023). Thus, diversification, reduced input intensity, and soil regeneration are increasingly discussed as key components of more sustainable and adaptive agricultural systems (Shennan-Farpón et al., 2025). These approaches are also associated with the

reconfiguration of production systems that support sustainability through adaptive and resilient practices, and are increasingly framed as part of broader transitions toward more system-oriented models of agricultural production (Shahmohamadloo et al., 2021).

These approaches may be particularly relevant for the fashion industry, given the environmental stress that production activities impose on local territories, and the delicate social issues affecting global fashion supply chains (Colasante et al., 2025; Peter John and Mishra, 2023). In this context, regenerative approaches may be instrumental in enabling the shift towards more sustainable and responsible business practices.

Despite this, the application of regenerative approaches in the fashion industry remains limited and the literature is still in early stages. Available studies, however, suggest the potential of sustainability-oriented sourcing practices and production systems for the fashion industry, particularly in relation to natural fibres and circular production processes (Brydges, 2021; Oliveira Duarte et al., 2022). Such initiatives involve multiple actors, including farmers, manufacturers, and supporting institutions, and require strong coordination across the supply chain to develop shared business models and align diverse objectives.

In this scenario, this study aims to contribute by providing a longitudinal analysis of one of the most recent and relevant applications of regenerative agricultural approaches in the fashion industry, namely the Apulian Regenerative Cotton Project, coordinated by Armani, a leading luxury fashion brand. To do so, the study adopts Institutional Theory as a theoretical lens. This is particularly suitable to examine coercive, normative, and mimetic pressures to which the different actors involved in the initiative are exposed across the different phases of the project (DiMaggio and Powell, 1983). From this perspective, the Institutional Theory can help explain how each actor interprets and responds to coercive pressures, arising from formal rules and regulatory requirements, normative pressures, related to shared norms and expectations, and mimetic pressures, to achieve and maintain legitimacy at each stage of the project. Moreover, this perspective allows us to understand how actors contribute to the institutionalization of practices and novel regenerative business models in a continuously evolving context (Zucker, 1987). In doing so, it provides insights into how such practices can be progressively established and diffuse, becoming a reference point for similar initiatives within the industry. Consistently, the study addresses the following research questions:

- *RQ1) What types of institutional pressures affect the different actors involved in regenerative initiatives within the fashion industry?*
- *RQ2) How do these actors interpret and respond to such pressures across the different phases of the initiative?*

To address these questions, the study adopts a qualitative single case study design. The Apulian Regenerative Cotton Project represents a particularly suitable case, as one of the first and most relevant applications of regenerative approaches in the fashion industry. The study follows an embedded design and thus considers multiple units of analysis, including the leading firm, Armani, as well as the other key actors involved in the initiative namely scientific partners, local farmers, suppliers, and certification bodies. This allows to capture the different pressures experienced and enacted by the various actors across the supply chain. Moreover, the study adopts a longitudinal perspective, analysing the initiative across its key phases, to investigate how pressures develop over time and how practices are institutionalised by the partners to carry forward the project. Data collection is based on secondary sources and semi-structured interviews conducted with key actors involved in the project, covering the different stages of the initiative.

This study contributes to the literature by analysing an innovative, regenerative project in the fashion industry through the lens of Institutional Theory. In doing this, the study helps to explain how institutional pressures, including coercive, normative, and mimetic, affect key actors across the supply chain and shape their behaviour throughout the different phases of the initiative. Furthermore, the study shows how these pressures are interpreted and translated into practices that are progressively institutionalized over time, thus showing how regenerative business models can emerge and diffuse within the fashion industry, offering a grounded reference for similar initiatives. From a practical perspective, the findings highlight the importance of recognising and managing the multiple pressures affecting different actors, as well as the need to support coordination and align diverse objectives. In this sense, the study provides actionable insights for practitioners involved in the design and implementation of regenerative initiatives, supporting the development and scaling of such models within the industry.

The remainder of the paper is structured as follows. Section 2 establishes the theoretical framework, integrating Institutional Theory with the concept of socio-ecological regeneration to examine how isomorphic pressures drive organizational legitimacy. Section 3 details the research methodology, outlining the exploratory qualitative approach and the longitudinal single embedded case study design focused on the Apulian Regenerative Cotton Project. Section 4 presents the results and discussions, tracing the initiative through four key phases, initiation, experimentation, structuring, and diffusion, and mapping the evolution of institutional

pressures throughout this process. Section 5 explores the theoretical and practical implications, offering a narrative on institutional entrepreneurship and a blueprint for supply chain coordination. Finally, Section 6 provides the conclusions, summarizes the study's contributions, and addresses its limitations while suggesting directions for future research.

2 Theoretical Framework: Institutional Theory and Regeneration

To understand how regenerative practices gain legitimacy and diffuse across industries, this study employs Institutional Theory (DiMaggio and Powell, 1983). Organizations adopt new practices not only for efficiency but to seek social and cultural legitimacy (Pasamar et al., 2025). The transition to regeneration can be analysed through institutional entrepreneurship lens, where powerful actors like the Armani Group challenge existing industrial norms to establish new "rules of the game". According to (Roszkowska-Menkes, 2023), this process is driven by three main isomorphic pressures:

- Coercive Pressures: Emerging environmental regulations and international climate agreements (e.g., the EU Green Deal) force companies to adopt regenerative standards to avoid legal and reputational risks (Pasamar et al., 2025).
- Normative Pressures: These arise from professionalization and the setting of new industry standards. As regenerative agriculture becomes defined by scientific and professional bodies, it creates a "logic of appropriateness" that influences corporate behavior (Gualandris et al., 2024).
- Mimetic Pressures: In environments of high uncertainty, such as the current climate crisis, organizations tend to model themselves after successful peers. By pioneering regenerative cotton in Apulia, Armani acts as a "template" for other luxury brands to follow (DiMaggio and Powell, 1983).

By integrating Institutional Theory with socio-ecological resilience, this paper argues that regeneration is more than a technical fix; it is a systemic shift that requires the alignment of institutional logics with ecological boundaries to foster long-term survival of both the industry and the territory (Gualandris and Madonna, 2025).

3 Methodology

This study adopts an exploratory qualitative case study methodology, drawing on established approaches in case study research (Eisenhardt, 1989; Stake, 2000; Yin, 2018). It focuses on Armani's Apulia Regenerative Cotton Project as a single, in-depth case. The research is designed as a single embedded case study, allowing for the analysis of multiple units of inquiry within the case. The single-case design is justified by the project's status as a critical, information-rich instance in which regenerative agricultural practices are implemented within a highly stressed socio-ecological context under the leadership of a globally influential corporate actor. Data collection relies on a triangulated approach combining (i) desk-based analysis and (ii) semi-structured interviews. Desk research involves systematically reviewing publicly available sources, including corporate reports, sustainability disclosures, institutional communications, and media coverage. This is complemented by primary data gathered through interviews with diverse stakeholders directly involved in the project, including farmers, local institutions, company representatives, and non-governmental organisations, enabling the exploration of multiple embedded perspectives within the case. The integration of secondary and primary data ensures methodological triangulation, enhancing the robustness and credibility of findings. This approach supports a comprehensive understanding of the initiative's governance, implementation dynamics, and local impacts, while enabling the development of a framework that is both theoretically grounded and empirically informed, with potential practical applicability beyond the case under study.

4 Results and Discussions

The Apulian Regenerative Cotton Project originated as a collaborative initiative involving multiple actors, including the Armani Group, the European Forest Institute (EFI), and the Italian Council for Agricultural Research and Economics (CREA), with the aim of exploring the feasibility of regenerative cotton production in Italy. The project was launched in 2023 as a pilot initiative designed to test agroforestry practices applied to cotton cultivation in a context characterized by environmental stress and declining soil quality. In the inception of the initiative, normative pressures played a central role, reflecting the growing expectations associated with sustainable production practices within the fashion industry. These pressures are also reflected in the involvement of scientific and institutional partners, which supported Armani in defining and legitimizing the business model through the adoption of regenerative agriculture practices. On the other hand, given the absence of established regenerative-based models in the fashion industry, mimetic pressures appear to be less relevant in the initial phase. Rather, the initiative led by Armani, as a leading player in the luxury fashion industry,

can be interpreted as an attempt to explore and define new business models in this field. Overall, in its early stage, the initiative can be seen as an attempt to translate emerging expectations into concrete actions, laying the foundations for the subsequent development and potential institutionalization of regenerative practices within the fashion industry. Following its initial configuration, the project moved into an implementation phase focused on the experimental application of regenerative agricultural practices. This phase was centred on the development of an agroforestry-based cotton production system, combining cotton cultivation with different tree species and applying regenerative techniques aimed at improving soil health, biodiversity, and water efficiency. The initiative was described by the partners as a "living laboratory", where scientific experimentation and practical implementation could progress simultaneously. This phase is characterized by the translation of pressures into concrete actions. Normative pressures continued to play a key role, as scientific partners contributed to defining appropriate methods for regenerative approaches. At the same time, coercive pressures may have played an indirect role, as recent frameworks and initiatives, such as TNFD and GRI, provide guidance and best practices for the implementation and disclosure of restoration-oriented initiatives. In this phase, the involvement of local agricultural firms also contributes to the emergence of new pressures, while at the same time laying the foundations for the institutionalization of the business model through the engagement of local actors. This highlights how practices are not simply adopted but actively constructed through interaction among different actors. In this regard, the introduction of monitoring activities serves to reinforce the legitimacy of the initiative by providing measurable outcomes for all partners. Overall, the implementation phase represents a critical step in the institutionalization process, as it allows emerging practices to be tested, refined, and gradually shaped into potentially replicable production practices. As the project progressed, the focus moved beyond the experimental phase toward the structuring of the supply chain for the use of regenerative cotton in garment production. This required Armani to involve suppliers and partners in defining production processes and packaging solutions. A central element of this phase is the introduction of certification and traceability mechanisms, which play a crucial role in supporting the credibility of the initiative. In particular, the project relies on the Regenagri certification scheme, which verifies the adoption of regenerative practices across the entire supply chain and ensures traceability from raw material to final product. The certification process involves the auditing of suppliers and production stages, requiring compliance with specific criteria related to soil health, biodiversity, and resource use. From an institutional theory perspective, this phase is primarily shaped by normative pressures. In the absence of fully established regulatory frameworks for regenerative agriculture, voluntary standards and certification schemes provide reference points that define what constitutes appropriate and legitimate practices. At the same time, certification and traceability mechanisms contribute to addressing the expectations of final consumers regarding product quality and origin. In this sense, the introduction of tools such as the digital product passport also responds to, and anticipates, emerging regulatory developments, suggesting the presence of potential coercive pressures. Overall, this phase represents a critical step in the institutionalization process, contributing to the establishment of mechanisms for communicating the initiative to external audiences and beginning to define shared standards and recognizable practices, which are essential for achieving legitimacy and enabling wider diffusion. Ultimately, the project led to the commercialization of the first batch of T-shirts made from regenerative cotton, distributed through selected Armani channels. This step demonstrated the technical and business viability of the initiative for Armani and its supply chain partners, potentially contributing in a decisive way to the legitimization and diffusion of business models based on regenerative approaches within the fashion industry. In this sense, the visibility of the project, supported by communication activities and the positioning of Armani as a leading luxury brand, increases the potential to trigger mimetic pressures among competitors. Due to the novelty of such initiatives, the Apulian Regenerative Cotton Project may become a reference point for other luxury fashion brands interested in developing business models based on regenerative approaches. The combination of scientific validation, engagement of local firms, and certification contributes to shaping a model that may be observed and potentially replicated by competitors or even lay the foundations for the institutionalization of regenerative practices. At the same time, this phase also highlights some limitations and challenges associated with the initiative. In particular, the positioning of the products within the luxury segment and the relatively small scale of production raise questions about the scalability of regenerative models. In addition, the leading role of Armani within the initiative and its position as a first mover raise questions regarding its role in defining normative pressures for partners and setting standards that may later be reinforced through mimetic isomorphism. Moreover, the lack of widely recognized regulatory frameworks highlights the current absence of strong formal coercive pressures and the prevalence of implicit ones, a condition that may evolve as these models become more widespread.

Overall, the longitudinal analysis of the Apulian Regenerative Cotton Project highlights a gradual process through which regenerative practices are progressively institutionalized both within the actors involved in the supply chain and toward the broader external environment. From an institutional perspective, the project shows

how multiple and interacting pressures contribute to shaping this process. Normative pressures, associated with scientific knowledge, voluntary standards, and sustainability expectations, play a central role in orienting actors' behaviours and practices. Mimetic pressures may emerge as the initiative gains visibility and begins to act as a reference point within the field, while coercive pressures remain largely limited to voluntary certification schemes, but may become more relevant as regulatory frameworks evolve. At the same time, the findings highlight that institutionalization is not a linear or automatic process. Rather, it depends on how actors interpret, negotiate, and translate institutional pressures into concrete practices within a specific context.

5 Implications

The journey of the Apulian Regenerative Cotton Project serves as more than just a corporate case study; it acts as a narrative of institutional transformation. By weaving together the threads of high fashion and soil science, this initiative reveals deep-seated implications for how we understand the future of the industry. From a theoretical standpoint, this research breathes new life into Institutional Theory by moving beyond the traditional view of companies as passive recipients of regulatory commands. Instead, we see the emergence of the brand as an institutional entrepreneur. In the absence of rigid laws, Armani does not wait for a mandate but collaborates with scientific pioneers to co-create a new logic of appropriateness. This suggests that in the early stages of systemic change, normative pressures, he shared belief in what is right or scientifically sound, are far more potent than formal rules. The project demonstrates that institutionalization is a social construction: by building a living laboratory, the actors involved are not just growing cotton; they are cultivating the very standards that will likely govern the fashion industry in the decade to come. The study thus proves that mimetic isomorphism is the final act of a successful pilot, where once the template is proven, the outlier becomes the benchmark for the entire field. For practitioners, the project offers a pragmatic blueprint for navigating the green transition while shattering the illusion that sustainability can be achieved through top-down directives alone. The primary takeaway for managers is that regenerative models live or die by their coordination. Success was not found in a simple purchase order, but in a deep, horizontal alignment between farmers, scientists, and certification bodies that bridged the gap between raw material and luxury product. Furthermore, by integrating tools like the Digital Product Passport and Regenagri certification today, firms can build a strategic regulatory buffer that allows them to stay ahead of looming EU mandates like the Carbon Removals Certification Framework. Perhaps the most vital practical lesson lies in the tension between luxury and volume. While the Armani model works for high-end garments, the true test for the industry will be translating these artisanal, territory-specific successes into global supply chain realities. Ultimately, the implications suggest that the future of fashion lies in radical transparency, where brands must become as invested in the health of the soil as they are in the aesthetics of the final garment.

6 Conclusions

The longitudinal analysis of the Apulian Regenerative Cotton Project provides a comprehensive understanding of how regenerative practices are nurtured, validated, and eventually institutionalized within the complex ecosystem of the luxury fashion industry. By applying Institutional Theory, this study clarifies that the transition to a regenerative business model is not merely a technical shift in agricultural inputs, but a profound social and organizational process. In the absence of mature regulatory frameworks, the interplay between normative expectations from scientific partners and the proactive entrepreneurship of a lead firm like Armani creates a new "logic of appropriateness". This logic serves as a precursor to broader industry standards, suggesting that institutionalization in fashion is increasingly a bottom-up phenomenon, fueled by cross-sector collaborations that bridge the gap between ecological restoration and commercial viability. From a practical standpoint, the study underscores that successful regenerative initiatives depend on the ability of a leading brand to act as a central coordinator. For firms aiming to remain competitive, the integration of certification schemes like Regenagri and traceability tools such as the Digital Product Passport is no longer optional but a strategic necessity to anticipate the risks of forthcoming European regulations. However, this research is not without its limitations. As an exploratory study centered on a single case in Southern Italy, the findings are inherently contextual. The "Armani model" may not be directly generalizable to smaller brands with less institutional weight or to different geographical regions with varying agricultural traditions. Furthermore, while we have mapped the early stages of institutionalization, it remains to be seen whether these practices will become deeply embedded industry norms or remain peripheral to the mass market. Future research should look toward comparative analyses across different market segments, such as fast fashion or outdoor apparel, to see how regenerative models survive under different price sensitivities. Additionally, as the regulatory environment evolves with the full implementation of the EU Carbon Removals Certification Framework, longitudinal studies

will be essential to assess the shift from voluntary to coercive pressures. There is also a significant opportunity to integrate quantitative data, such as Life Cycle Assessments, to evaluate if these “logics of appropriateness” translate into measurable ecological recovery and improved livelihoods for local farming communities.

Integrating ESG Principles into Production Processes for Shaping Sustainable Industry

Mattia Arcuti, Vito Del Vecchio, Mariangela Lazoi, Giorgia Specchia
University of Salento, Lecce, Italy

Abstract

The integration of Environmental, Social, and Governance (ESG) principles into organizational processes has become a critical challenge for firms seeking to align sustainability commitments with operational decision-making, regulatory compliance, and long-term value creation. Although Enterprise Resource Planning (ERP) systems represent core infrastructures for data integration, process standardization, and organizational memory, their role in supporting ESG integration remains fragmented and underexplored. This paper investigates how ESG principles and data can be integrated into ERP systems from a knowledge management perspective, with particular attention to the management of green knowledge. The study adopts a Systematic Literature Review (SLR), performed on Scopus, and collect 507 results. The findings, based on the final resulting 29 papers, show that ESG–ERP integration address specific technologies, indicators, sectors, or implementation issues, while limited attention is paid to how ESG-related data, practices, and responsibilities are transformed into structured, reusable, and actionable green knowledge within ERP systems. To address this gap, the paper proposes a research agenda organized around three dimensions: human, technological, and organizational. The paper also develops a set of best practices for knowledge-based ESG–ERP integration. These practices suggest that organizations should start from existing ERP processes, define shared ESG data meanings, embed ESG controls into workflows and decision-making, and support users through training, communication, and continuous learning. The study contributes to the literature by reframing ESG–ERP integration as a knowledge management process and provides practical guidance for organizations seeking to integrate sustainability principles into ERP systems in a gradual, coherent, and non-disruptive way.

Keywords: ESG; ERP systems; Knowledge Management; Green Knowledge, ESG-ERP Integration.

Paper type: Academic Research Paper

1 Introduction

On July 24, 2025, humanity reached Earth Overshoot Day, the date on which global demand for ecological resources and services exceeded what the Earth can regenerate within the same year. From that day onward, humanity operated in a state of ecological deficit, drawing on natural capital and accumulating environmental pressure. Since the early 1970s, Earth Overshoot Day has generally occurred earlier in the calendar year, reflecting the growing imbalance between human demand and the planet's regenerative capacity. (*Earth Overshoot Day Home - #MoveTheDate*, n.d.).

Mitigating this crisis requires the involvement of multiple actors, including firms. In recent years, the United Nations 2030 Agenda and the articulation of the 17 Sustainable Development Goals (SDGs) have encouraged organizations to expand the scope of their organizational knowledge by systematically incorporating sustainability principles. Environmental, Social, and Governance (ESG) criteria have emerged as a key framework for disciplining and assessing corporate sustainability, risk exposure, and long-term value creation (Wang et al., 2024). As a result, companies are increasingly required to acquire, develop, and manage what can be defined as green knowledge (Sahoo et al., 2023). This concept does not refer to a narrow or standalone category, but rather to environment-related knowledge (data, skills, know-how, and ideas) that is acquired, stored, shared, applied, and created inside organizations to improve environmental performance, support green innovation, and advance sustainability goals (Ulhaq et al., 2024).

This perspective is consistent with the Knowledge-Based Theory proposed by (Grant, 1996), which conceptualizes the organization as a system for knowledge integration, in which technologies, as embodiments of knowledge, human interactions, and organizational routines jointly contribute to value creation. If knowledge is inherently distributed and dynamic, its effective management requires technological infrastructures that spread beyond information storage and can support integration, coordination, and organizational memory (Duffy, 2000). In this context, Enterprise Resource Planning (ERP) systems emerge as potential enablers of organizational knowledge (Saide & Mahendrawathi, 2015). ERP systems can be interpreted as repositories of organizational knowledge (Palanisamy, 2008), as they enable firms to store and institutionalize so-called canonical organizational processes (Vandaie, 2008). Through process codification, ERP systems embed a

significant portion of organizational memory, making knowledge accessible, replicable, and governable over time (Vandaie, 2008).

The integration of ESG principles into ERP systems, however, raises specific knowledge management challenges. Drawing on Nonaka's theoretical framework, a distinction can be made between tacit and explicit knowledge (Nonaka & Takeuchi, 1995), ESG integration can be understood as a knowledge conversion process through which dispersed, heterogeneous, and often tacit sustainability-related knowledge must be transformed into explicit, structured, and reusable organizational knowledge. At the operational level, this process is particularly complex because firms deal with a heterogeneous mix of data, information, practices, regulatory requirements, and expertise that is difficult to disentangle and standardize (Vandaie, 2008).

This misalignment between the strategic relevance of ESG and its operational integration also emerge from preliminary focus groups conducted with C-level executives from a global IT consulting company. The discussions highlighted that, although digital technologies and sustainability are widely acknowledged as strategic levers, the integration of ESG data and principles into ERP systems remains fragmented, underexplored, and often deprioritized in implementation projects.

Against this background, the present study aims to investigate how ESG principles can be integrated into ERP systems from a knowledge management perspective. More specifically, the paper addresses the following research question: *How can ESG principles and data be integrated into ERP systems to support the management of green knowledge?*

To answer this question, the study adopts a qualitative and exploratory research design based on a Systematic Literature Review (SLR) conducted according to the consolidated protocol proposed by (Corallo et al., 2023). The findings of the study are articulated around two main contributions. First, the paper proposes a research agenda aimed at guiding future investigations on the integration of sustainability, ERP systems, and knowledge management. Second, it identifies a set of guiding principles intended to support organizations in the integration of ESG data into ERP systems.

The remainder of the paper is organized as follows. Section 2 describes the research methodology and the SLR protocol. Section 3 presents the findings of the literature review. Section 4 outlines the research agenda and proposes a set of best practices. Finally, Section 5 concludes the paper by summarizing its theoretical and managerial implications, limitations, and future research opportunities.

2 Methodology

This study adopts a qualitative and exploratory research design based on a Systematic Literature Review (SLR). The review was conducted following the protocol proposed by Corallo et al. (2023), which structures the process into four main phases: review planning, search execution, documents analysis, and results reporting. This approach was selected because it provides a transparent and replicable procedure for identifying, selecting, and synthesizing scientific contributions on an emerging and interdisciplinary topic (Tranfield et al., 2003).

In the review planning phase, the research objective was defined in line with the research question of the study. The search strategy was developed to capture interdisciplinary contributions. The query combined four groups of keywords. The first group referred to ERP systems, including both the full expression "Enterprise Resource Planning" and the acronym "ERP". The second group captured ESG and sustainability-related concepts, including "ESG", "Environmental Social Governance", "sustainab*", "sustainable reporting", "sustainability reporting", and "green ERP". The third group focused on data and information systems, including "data", "data management", "data architecture", "data model*", and "information system*". Finally, the fourth group included terms related to implementation and managerial processes, namely "integrat*", "implement*", "report*", and "monitor*". The final search string was applied to titles, abstracts, and keywords as follows:

TITLE-ABS-KEY(("Enterprise Resource Planning" OR ERP) AND (ESG OR "Environmental Social Governance" OR sustainab OR "sustainable reporting" OR "sustainability reporting" OR "green ERP") AND ("data" OR "data management" OR "data architecture" OR "data model*" OR "information system*") AND (integrat* OR implement* OR report* OR monitor*)).*

In the search execution phase, the bibliographic search was conducted in Scopus in October 2025. Scopus was selected because of its broad coverage of peer-reviewed academic literature. The initial search returned 507 documents. The results were then refined by limiting the sample to English-language publications, open-access documents, and journal articles or conference papers. The open-access filter was applied to ensure the full availability of papers for complete reading and analysis, while the document-type filter was used to include both consolidated academic contributions and emerging research trends. After these refinements, the resulting sample consisted of 105 papers.

Table 1: Screening process.

Initial Scopus results	English papers	Document type refinement	Open-access refinement	Title-abstract reading	Full-text reading
507	501	402	105	75	29

In the documents analysis phase, the titles and abstracts of the 105 papers were screened to assess their relevance to the research objective. This screening led to the exclusion of 30 papers that were not aligned with the focus of the study, leaving 75 papers for full-text assessment. The full-text analysis was conducted using one inclusion criterion and three exclusion criteria, defined ex ante. The inclusion criterion was:

- IC1: the paper addresses the relationship between ERP systems and the integration of ESG reporting data or sustainability-related data.

The exclusion criteria were:

- EC2: the paper does not address either ERP systems or ESG/sustainability reporting criteria;
- EC3: the paper focuses only on ERP or enterprise technologies, without considering ESG or sustainability-related data integration;
- EC4: the paper focuses only on ESG or sustainability issues, without considering their connection with ERP systems or enterprise information systems.

In Table 1 is resume the entire screening process, while in the Table 2 is reported the distribution of the paper according to the inclusion and exclusion criteria.

Table 2: Distribution of papers within the inclusion and exclusion criteria.

Papers IC1	Papers EC2	Papers EC3	Papers EC4
29	24	21	1

In the results reporting phase, the selected contributions were synthesized through a thematic and comparative analysis. This process made it possible to identify recurring patterns, operational barriers, methodological differences, and research gaps in the literature. Particular attention was paid to how ERP systems are conceptualized as infrastructures for data integration, process codification, sustainability reporting, regulatory compliance, and knowledge-based decision-making. The emerging themes provided the basis for developing the guiding principles for ESG integration into ERP systems and the research agenda presented in the following sections.

3 State of Art

Overall, the reviewed literature converges in recognizing that ERP systems are increasingly evolving beyond their traditional role of supporting resource planning and transactional processes. They are progressively conceptualized as integrated platforms for monitoring, measuring, and reporting sustainability performance. This evolution is consistent with the emerging notion of Sustainable ERP (S-ERP), according to which enterprise information systems should embed ESG-related metrics, data flows, and processes within core organizational routines rather than treating sustainability as an external reporting activity (Adriansyah et al., 2022; Alzahmi et al., 2025)

A first stream of contributions emphasizes the role of ERP systems as infrastructures for ESG data integration across business functions and supply chains. From this perspective, ERP systems support the collection, standardization, and sharing of sustainability-related data, enabling organizations to connect environmental and social indicators with operational processes. Empirical studies on ERP and Green Supply Chain Management show that this integration can improve both operational and environmental performance by supporting green procurement, environmental monitoring, production optimization, and the reduction of waste, energy consumption, and emissions (Rizki et al., 2022). Similarly, other studies highlight that ERP-enabled sustainability practices may contribute simultaneously to economic growth and environmental improvement, suggesting that ERP systems can act as mediating infrastructures between business efficiency and sustainability objectives (Anaya et al., 2023; Anaya & Qutaishat, 2022).

A second trajectory concerns the integration of ESG data along the product and supply chain life cycle. In this area, the literature highlights the need to connect ERP systems with Product Lifecycle Management (PLM), Life Cycle Assessment (LCA) tools, Warehouse Management Systems (WMS), and Manufacturing Execution Systems (MES). Such integration is considered essential to overcome data fragmentation, improve the completeness and reliability of sustainability information, and support more accurate ESG reporting (Felder et al., 2025; Loy et al., 2024; Rosich et al., 2013; Tong et al., 2023). This stream of research shows that ESG–ERP integration cannot be

reduced to the inclusion of additional reporting fields within ERP modules. Rather, it requires the alignment of multiple operational systems and the construction of consistent data flows across the entire value chain.

A third group of studies focuses on the measurement and evaluation of sustainability performance through indicators, KPIs, and decision-support models. These contributions address the methodological complexity of selecting, weighting, and operationalizing ESG indicators within enterprise systems. Approaches based on multi-criteria decision-making methods, such as Fuzzy Delphi, Analytic Hierarchy Process (AHP), ANP, TOPSIS, and MCGP, are used to support the selection of ESG indicators, suppliers, strategies, and knowledge-transfer mechanisms (Cano et al., 2025a, 2025b; Cosma et al., 2024; Lacurezeanu et al., 2021; Patalas-Maliszewska et al., 2022; Susanto et al., 2023). These studies suggest that ESG integration into ERP systems requires not only data availability, but also structured evaluation logics capable of translating sustainability goals into measurable and comparable decision criteria.

Another relevant line of research investigates the relationship between sustainability and economic efficiency, particularly in complex and resource-intensive sectors such as construction and manufacturing. In these contexts, ERP systems are presented as tools for integrating cost control, resource allocation, planning, and environmental performance. The literature shows that ERP-enabled sustainability management can support the balancing of economic and environmental objectives by improving visibility over resource use, process inefficiencies, and operational trade-offs (Mandičák et al., 2022; Tsai, 2023). This perspective reinforces the idea that ESG–ERP integration is not only a compliance-oriented activity, but also a mechanism for improving organizational efficiency and strategic decision-making.

From a technological standpoint, the literature also points to the increasing automation and intelligence of ESG-related ERP processes. Process mining has been proposed as a means to support automated ESG compliance control, while digital reporting tools and operational-data reinterpretation approaches contribute to transforming sustainability reporting from a manual and retrospective activity into a more continuous and data-driven process (Anjaria, 2024; Dudek & Kulej-Dudek, 2024; Schreiber, 2020). These contributions indicate a shift from static ESG reporting toward dynamic monitoring, where ERP systems interact with analytics, automation, and intelligent technologies to improve transparency, traceability, and responsiveness.

Alongside technological aspects, the literature stresses the relevance of organizational and human factors. ESG-ERP integration depends on the alignment between technical systems, organizational structures, governance mechanisms, data quality, and user acceptance. Studies on ERP implementation and sustainability-oriented information systems show that strategic alignment, top management support, process ownership, and data governance are critical conditions for effective integration (Hadi et al., 2018; Huang et al., 2019). Moreover, technology acceptance models highlight that perceived usefulness, user expectations, and behavioral intention influence the extent to which ERP systems are effectively adopted and used to generate sustainability-related value (Junaidi et al., 2024; Marsintauli & Sari, 2023).

A final and particularly relevant stream concerns the knowledge management dimension of ESG-ERP integration. From this perspective, ERP systems are not only repositories of sustainability data, but infrastructures that support the codification, transfer, and reuse of green knowledge. Knowledge Management strengthens the role of ERP systems in supporting sustainable decision-making, especially when sustainability-related information is dispersed across departments, processes, and external stakeholders (Yahya & Khalefa, 2021). More advanced approaches, such as the integration of ERP systems with intelligent systems, digital twins, and hybrid knowledge-based systems, further show how data, models, and expert knowledge can be combined to support more effective and sustainable decisions within Industry 5.0 contexts (Traini et al., 2024). This stream is particularly important for the present study because it reframes ESG-ERP integration as a process of transforming fragmented sustainability knowledge into structured, accessible, and actionable organizational knowledge.

Taken together, the reviewed literature shows that ESG–ERP integration is evolving from a reporting-oriented and technical issue into a broader socio-technical challenge involving data integration, process codification, sustainability measurement, governance, and knowledge management. However, the field remains fragmented: existing studies often focus on specific technologies, indicators, sectors, or implementation issues, while limited attention is paid to how dispersed ESG-related data and practices are transformed into structured, reusable, and actionable green knowledge within ERP systems.

4 Best Practices and Research Agenda

The gap, highlighted in reviewing analysis, suggests that ESG-ERP integration should be understood as a knowledge management process through which organizations codify sustainability knowledge, assign responsibilities, ensure data quality and traceability, and embed ESG principles into operational and strategic

decision-making. This supports the need to identify guiding principles for ESG–ERP integration and to define a research agenda capable of connecting sustainability, enterprise systems, and green knowledge management. The fragmentation of the studies suggests that future research should move beyond the technical question of how ESG indicators can be added to ERP platforms and investigate the human, technological, and organizational conditions that enable ESG-ERP integration as a knowledge management process. Accordingly, the following research questions are proposed.

Table 3: Proposed research agenda.

Dimensions	Research questions
Human	RQ1. Which green skills, competencies, and behaviors enable the effective integration of ESG principles into ERP systems?
	RQ2. How does green knowledge influence the interpretation and use of information generated by ERP systems?
	RQ3. How is the green transition of ERP systems perceived by different organizational actors, such as top management, middle managers, and operational users?
Technological	RQ4. Does the green transition of ERP systems require a radical redesign of existing platforms, or can it be achieved through incremental adaptation?
	RQ5. How can ERP systems remain aligned with the continuous evolution of ESG requirements, regulations, and indicators?
	RQ6. How can ERP systems integrate external, heterogeneous, and often unstructured ESG data while ensuring reliability, traceability, and timely updating?
Organizational	RQ7. Can Sustainable ERP systems be introduced as substitutes for traditional ERP systems, or do they require structured change management processes?
	RQ8. How can ESG-ERP integration support the transformation of green knowledge into ordinary organizational knowledge and routines?
	RQ9. What are the short-, medium-, and long-term effects of ESG–ERP integration on organizational performance, costs, resource allocation, compliance, and decision-making?

From an organizational point of view, firms need actionable best practices to translate ESG objectives into ERP-enabled processes. In the knowledge management perspective, the objective is not only to add ESG indicators to existing ERP modules, but to transform dispersed sustainability-related data, practices, and expertise into codified, shared, and actionable green knowledge. To reduce organizational disruption and support adoption, the following best practices are proposed.

- **BP1. Start from existing ERP systems and define shared ESG data meanings:** ESG integration should begin by mapping current ERP workflows and identifying where ESG data are already generated or used. Organizations should then translate tacit and dispersed ESG knowledge into shared data definitions, KPI meanings, and responsibilities. Linking ESG requirements to existing processes, supported by data dictionaries and common glossaries, reduces duplication, avoids parallel reporting systems, limits ambiguity, and supports user acceptance across functions.
- **BP2. Embed ESG controls into workflows and decision-making:** ESG controls should be integrated into daily ERP routines through predefined fields, alerts, approval rules, automated data capture, and audit trails. At the same time, ERP dashboards, reports, and budgeting tools should connect ESG indicators to operational and strategic decisions. This makes ESG knowledge traceable and actionable without creating an additional bureaucratic layer.
- **BP3. Support users and institutionalize continuous learning:** Users should understand both how to manage ESG data in ERP systems and why these data matter. Training, communication, workshops, and feedback loops can improve adoption, usability, and the capture of new tacit knowledge. At the same time, ERP systems should support the periodic revision of ESG indicators, procedures, responsibilities, and reporting structures, allowing integration to evolve with regulations, standards, technologies, and stakeholder expectations.

5 Discussions and Conclusions

This study contributes to the literature by reframing ESG–ERP integration as a knowledge management challenge rather than as a merely technical or reporting-oriented issue. The systematic literature review shows that existing research has mainly addressed ESG–ERP integration through specific lenses, such as sustainability reporting, data integration, KPI measurement, supply chain monitoring, compliance automation, or digital transformation. While these perspectives provide valuable insights, they often remain fragmented and do not

fully explain how ESG-related data, practices, responsibilities, and expertise can be transformed into structured, reusable, and actionable green knowledge within ERP systems. By adopting a knowledge management perspective, this paper highlights that ERP systems can act not only as repositories of organizational data, but also as infrastructures for codifying, sharing, and institutionalizing sustainability-related knowledge across organizational functions.

From a theoretical standpoint, the paper advances the debate on ERP systems, ESG integration, and knowledge management in three ways. First, it connects the literature on enterprise systems with the concept of green knowledge, showing that sustainability integration requires the transformation of dispersed and often tacit ESG knowledge into explicit and systematized organizational knowledge. Second, it extends the interpretation of ERP systems beyond their transactional and process-standardization role, emphasizing their potential contribution to organizational learning, ESG traceability, accountability, and decision-making. Third, it proposes a research agenda organized around the human, technological, and organizational dimensions of ESG–ERP integration. This agenda helps structure future research by identifying open questions related to green skills and user perceptions, the technological adaptability of ERP platforms, the integration of external and unstructured ESG data, and the organizational conditions required to embed sustainability into ordinary routines.

The managerial implications are equally relevant. The findings suggest that organizations should not approach ESG–ERP integration as the simple addition of sustainability indicators to existing modules. Instead, they should manage it as a gradual socio-technical transformation. This approach can reduce human resistance, avoid technological disruption, and prevent the creation of parallel reporting systems. It also helps managers clarify data ownership, improve data quality, and connect ESG information to operational and strategic decisions. In practical terms, ERP systems can support environmental management by linking resource consumption and emissions to production, logistics, and procurement processes; social sustainability by integrating workforce, safety, and supplier-related indicators; and governance by embedding compliance controls, ESG-related cost centers, audit trails, and accountability mechanisms into daily routines. The study also provides implications for consultants, ERP vendors, and sustainability managers. Consultants can use the proposed best practices as a roadmap for designing ESG–ERP integration projects that are less disruptive and more aligned with organizational knowledge flows. ERP vendors can benefit from developing functionalities that support ESG data governance, interoperability with external sources, traceability, and dynamic updating of sustainability indicators. Sustainability managers, on the other hand, can use ERP systems to move ESG management from a periodic reporting activity to an embedded decision-support process. In this sense, the integration of ESG principles into ERP systems may help organizations shift from compliance-oriented sustainability to knowledge-based sustainability management.

This study is subject to some limitations due to its exploratory and conceptual nature. First, the proposed research agenda and best practices are derived from the literature and from preliminary insights used to frame the research problem, but they require further empirical validation. Future research could test them through case studies, surveys, Delphi studies, or action research involving firms implementing ESG functionalities within ERP systems. Second, the study treats ESG-ERP integration as a general organizational challenge, while the relevance of specific ESG indicators, data flows, and regulatory requirements may vary significantly across industries. Future research could therefore investigate sector-specific configurations, for example in manufacturing, logistics, construction, energy, or services. Finally, the proposed best practices provide a general roadmap, but they do not define a maturity model or implementation sequence. Future studies could develop staged models to assess how organizations progressively move from fragmented ESG reporting to fully embedded, knowledge-based ESG management within ERP systems.

Explainable Artificial Intelligence as an Organisational Learning Lever: A Theoretical-Methodological Framework for Professional Upskilling in AI-Augmented Workplaces

Raimondo Fanale
Universitas Mercatorum, Rome, Italy

Abstract

The integration of Artificial Intelligence (AI) into professional practice is reshaping how knowledge is created, validated, and transmitted within organisations. While AI-driven decision support systems offer considerable analytical power, many rely on deep learning architectures that operate as black boxes, producing outputs that are difficult for human users to understand or critically evaluate. Explainable Artificial Intelligence (XAI) has emerged as a response to this opacity, yet its role has been framed predominantly in terms of technical transparency and user trust, underexploring its potential as a lever for professional development and organisational learning. This paper makes a theoretical-methodological contribution by introducing the XAI-OLL (Explainable Artificial Intelligence as an Organisational Learning Lever) framework, which reconceptualises XAI-generated explanations not merely as transparency mechanisms but as cognitive and organisational artefacts capable of activating processes of professional upskilling and knowledge integration. The framework proposes a sequential cognitive mechanism in which exposure to XAI explanations stimulates reflective reasoning — the deliberate comparison between algorithmic outputs and one's own judgment — which in turn fosters interpretive competence, defined as the capacity to critically engage with AI-generated evidence. This pathway is conditioned by explanation quality: imperfect or misleading explanations can attenuate or reverse the effect on calibrated trust. Interpretive competence enables calibrated trust, a proportionate form of reliance grounded in evidence quality rather than automation deference. Calibrated trust, in turn, facilitates the integration of AI-derived insights into shared professional knowledge, supporting organisational learning at the collective level. The XAI-OLL framework generates five testable propositions, operationalised through a pilot quasi-experimental protocol in AI-supported histopathology decision-making. The paper contributes to knowledge management, organisational learning, and HR transformation literature by positioning AI interpretive literacy — the competence to engage critically with XAI outputs — as a new dimension of professional capability in AI-augmented workplaces. Practical implications address HR professionals as active designers of XAI-enabled upskilling pathways, governance conditions, and organisational learning infrastructures.

Keywords: Explainable AI; organisational learning; professional upskilling; calibrated trust; XAI-OLL; HR transformation; knowledge management

Paper type: Theoretical and Methodological Contribution

1 Introduction

Artificial Intelligence (AI) is increasingly embedded in complex professional decision-making contexts, from medical diagnosis to financial risk assessment and industrial inspection. In these domains, deep learning systems generate predictions that carry significant epistemic weight, yet their internal logic remains largely opaque to the humans who rely on them. This opacity creates a fundamental tension for organisational learning: scholarship in this field has long linked individual and collective knowledge development to cycles of sense-making, deliberate reflection, and knowledge sharing (Nonaka and Takeuchi, 1995; Schön, 1983). When AI outputs arrive as unexplained predictions, they disrupt these cycles — users cannot reflect on criteria, compare interpretations, or integrate new insights into shared professional knowledge frameworks.

Explainable Artificial Intelligence (XAI) — the field of methods designed to make algorithmic decisions interpretable by human users (Arrieta et al., 2020) — has emerged as a direct response to this challenge. Yet despite rapid technical progress, the organisational and learning dimensions of XAI remain empirically underdeveloped. A systematic review of the XAI literature reveals that fewer than 0.7% of published papers validate explanations with human participants in real-world tasks (Chromik and Schubert, 2025). This gap is not merely a methodological shortcoming: it reflects a conceptual blind spot in which XAI is treated as a problem of output generation rather than a question of how professionals learn, adapt, and create knowledge in the presence of AI.

The central research question of this paper is: through what cognitive and organisational mechanisms do XAI explanations activate professional learning and upskilling, and what conditions determine whether those mechanisms succeed or fail? This is explicitly a question of professional development — not merely individual

decision accuracy — and it requires a framework that spans cognitive, organisational, and HR transformation perspectives.

This paper addresses that gap by proposing XAI-OLL (Explainable Artificial Intelligence as an Organisational Learning Lever), a theoretical-methodological framework that repositions AI-generated explanations as cognitive and organisational artefacts capable of triggering professional upskilling and collective knowledge integration. Drawing on dual-process theory (Kahneman, 2011), reflective practice (Schön, 1983), XAI metacognition research (von Zahn et al., 2024), trust calibration (Lee and See, 2004; Parasuraman et al., 1997), and the SECI model (Nonaka and Takeuchi, 1995), XAI-OLL proposes a sequential cognitive mechanism through which explainability activates reflective reasoning, builds interpretive competence, calibrates trust, and ultimately facilitates organisational knowledge integration. The framework is accompanied by a pilot quasi-experimental protocol designed to operationalise and validate its constructs in AI-supported histopathology decision-making.

2 Literature Review

2.1 Explainable Artificial Intelligence: Scope and Limitations

XAI encompasses methods designed to render the decisions of machine learning models interpretable by human users (Doshi-Velez and Kim, 2017). Arrieta et al. (2020) provide the foundational taxonomy, distinguishing intrinsically interpretable models from post-hoc explanation methods applied to opaque architectures. Post-hoc methods include local attribution techniques — LIME (Ribeiro et al., 2016) and SHAP (Lundberg and Lee, 2017) — that estimate feature contributions to individual predictions, and visual attribution methods — Grad-CAM (Selvaraju et al., 2017) and saliency maps — that highlight image regions most influential to a model's output. Longo et al. (2024) identify the human-centred and organisational dimensions of XAI as a priority research frontier, arguing for a shift from explanation as a technical property to explanation as a social and cognitive event.

However, empirical evidence on whether XAI explanations actually improve human decision-making and learning is mixed and frequently negative. Humer et al. (2024) demonstrate that saliency map explanations produced null or adverse effects on decision quality, particularly when explanations were imperfect or participants lacked the competence to assess them critically. Poursabzi-Sangdeh et al. (2021) show that explanations can create an illusion of understanding — users feel more confident without becoming more accurate — and may amplify cognitive biases by anchoring attention on highlighted features regardless of their diagnostic relevance. Von Zahn et al. (2024) further show that XAI's effects on metacognition depend strongly on cognitive engagement and explanation fidelity. These critiques impose important boundary conditions on the XAI-OLL framework: the sequential mechanism from XAI exposure to knowledge integration is not automatic. Corcoles-Jiménez et al. (2025) show that XAI disrupts traditional knowledge management, motivating the XAI-OLL framework.

2.2 Human-AI Collaboration and Trust Calibration

Effective human-AI collaboration requires that users neither over-rely on AI recommendations (automation bias) nor systematically reject them (algorithm aversion) (Dellermann et al., 2019). Lee and See (2004) define calibrated trust as a form of reliance proportionate to the system's actual reliability, updated dynamically through experience. Parasuraman et al. (1997) demonstrated that transparency-enhancing interventions reduce both over- and under-trust relative to opaque systems.

2.3 Knowledge Management, Organisational Learning, and GRAI Logics

Knowledge management scholarship has long investigated how organisations create, share, and apply knowledge across individual and collective levels (Nonaka and Takeuchi, 1995; Davenport and Prusak, 1998). The SECI model describes knowledge creation as a spiral involving four conversion modes: Socialisation (tacit-to-tacit), Externalisation (tacit-to-explicit), Combination (explicit-to-explicit), and Internalisation (explicit-to-tacit). AI systems are reshaping these dynamics. Jarrahi et al. (2023) argue that AI functions as an active knowledge partner, reshaping how professionals build expertise. Böhm and Durst (2025) propose that generative AI introduces new GRAI (Generative and Reflective AI Integration) logics of knowledge creation, extending the SECI spiral by positioning algorithmically generated knowledge as a distinct epistemic contribution.

2.4 Reskilling, Upskilling, and HR Transformation

The proliferation of AI in professional contexts is generating intense interest in workforce transformation. Morandini et al. (2023) identify the need for adaptive competencies in AI-augmented workplaces; Santana and Díaz-Fernández (2023) emphasise that technological progress demands higher-order capabilities such as critical judgment and interpretive competence. If XAI explanations systematically develop these competences, they represent an underutilised resource for embedded upskilling — delivered through the daily workflow rather than separate training. This reframes the HR professional's role from passive recipient to active designer of the conditions under which XAI-enabled learning can occur.

2.5 Reflective Practice and Dual-Process Reasoning

The cognitive mechanism proposed in XAI-OLL integrates two complementary traditions. Schön's (1983) theory of reflective practice posits that professional learning occurs through iterative cycles of action, observation, and reflection-on-action: moments in which practitioners consciously examine their own reasoning and assumptions in the light of new evidence. Kahneman's (2011) dual-process theory distinguishes between fast, heuristic cognition (System 1) and slow, deliberative reasoning (System 2). XAI explanations thus serve as an explicit analytical intermediary that may shift users from System 1 toward System 2, Together, these frameworks provide the micro-level cognitive foundation for the XAI-OLL sequential mechanism, augmented by von Zahn et al.'s (2024) demonstration that XAI exposure modulates metacognitive monitoring — an effect conditioned by explanation quality and the user's prior capacity for critical engagement.

3 The XAI-OLL Framework

3.1 Framework Overview

XAI-OLL (Explainable Artificial Intelligence as an Organisational Learning Lever) proposes that AI-generated explanations function not merely as transparency mechanisms but as cognitive and organisational levers that activate professional learning and knowledge integration. The framework positions XAI explainability as the antecedent of a sequential process comprising four constructs: Reflective Reasoning (RR), Interpretive Competence (IC), Calibrated Trust (CT), and Organisational Knowledge Integration (OKI). The model and its hypotheses are illustrated in Figure 1.

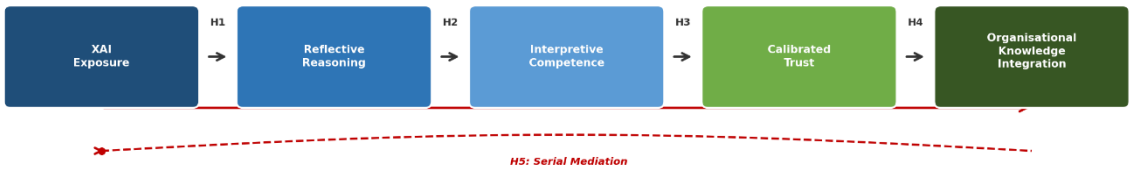

Figure 1. The XAI-OLL Sequential Model. Boxes represent latent constructs; labelled arrows indicate hypothesised causal paths (H1–H4); the dashed arc represents the serial mediation hypothesis (H5).

The framework articulates a specific relationship with the SECI model (Nonaka and Takeuchi, 1995) that requires careful conceptual specification. XAI explanations do not directly externalise the tacit knowledge of the human professional; rather, they make visible the tacit criteria embedded in the model's learned representations — a form of algorithmic externalisation. This visualisation of algorithmic logic then acts as a stimulus: confronted with an explicit representation of the model's reasoning, professionals are prompted to surface and articulate their own tacit interpretive criteria — the genuine Externalisation move in SECI terms. Through collaborative discussion of those explanations, teams subsequently synthesise individual explicit interpretations into shared diagnostic frameworks (Combination). The XAI-OLL framework thus provides the cognitive engine that GRAI logics (Böhm and Durst, 2025) describe at a structural level. Figure 2 illustrates the mapping between XAI-OLL and the SECI phases.

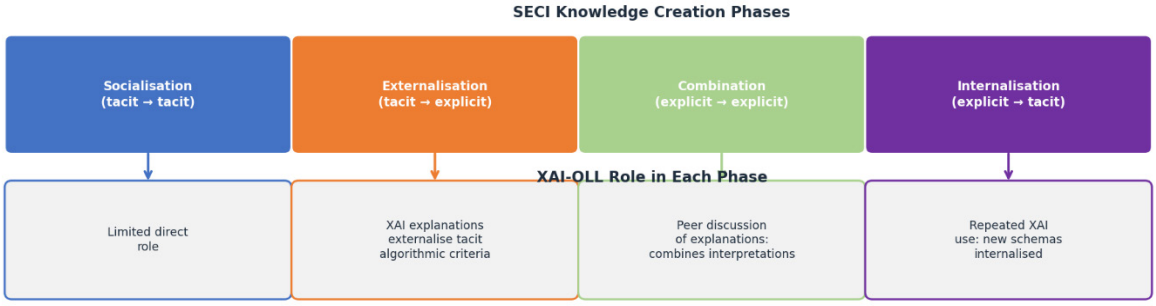

Figure 2. XAI-OLL within the SECI Knowledge Creation Framework. Upper row: SECI phases (Nonaka and Takeuchi, 1995); lower row: the corresponding role of XAI explanations in each phase.

3.2 Constructs and Formal Hypotheses

Reflective Reasoning (RR) is defined as the degree to which users engage in deliberate, comparative reasoning when examining XAI outputs — explicitly contrasting the model's rationale with their own prior assessment. The presence of a visual explanation disrupts heuristic acceptance (System 1) and creates an explicit cognitive reference point that invites comparison (System 2), enacting Schön's (1983) reflection-in-action:

H1: Exposure to XAI explanations positively activates reflective reasoning compared to prediction-only conditions.

Interpretive Competence (IC) is conceptually distinct from RR: whereas RR is an in-the-moment cognitive process (the deliberate comparison triggered by a specific explanation), IC is an acquired transferable skill — the durable capacity to critically engage with any AI-generated evidence across contexts, identifying relevant features, recognising model limitations, and discovering previously unnoticed patterns. IC accumulates through repeated reflective episodes and, once developed, persists beyond the immediate interaction — consistent with Ericsson et al.'s (1993) account of skill acquisition through deliberate practice and with Cheng et al.'s (2019) finding that XAI-based training transfers to new, unseen cases. Von Zahn et al. (2024) further demonstrate that XAI exposure stimulates metacognitive monitoring, supporting IC development — though conditioned by explanation fidelity. This aligns with the SECI Externalisation phase, where articulating one's tacit criteria in response to the algorithmic stimulus constitutes a genuine knowledge conversion event:

H2: Higher reflective reasoning positively predicts the development of interpretive competence.

Calibrated Trust (CT) represents proportionate reliance grounded in evidence quality rather than automation deference. Users with higher IC are better positioned to assess when AI recommendations are well-founded (Lee and See, 2004; Parasuraman et al., 1997). However, this relationship is conditional: Humer et al. (2024) show that imperfect explanations can attenuate or reverse the IC→CT effect by anchoring users on non-diagnostic features. XAI quality is therefore treated as a boundary condition moderating H3:

H3: Higher interpretive competence positively predicts calibrated trust (moderated by XAI explanation quality).

Organisational Knowledge Integration (OKI) captures the degree to which AI-derived insights contribute to shared professional knowledge through peer discussions, formalisation of criteria, and incorporation into practice. In this pilot, OKI is measured at team level (dyadic interaction), providing a proximal behavioural indicator; upward inference to the organisational level requires longitudinal team-based designs. OKI aligns with the Combination and Internalisation phases of SECI and with GRAI logics (Böhm and Durst, 2025):

H4: Higher calibrated trust positively predicts organisational knowledge integration.

H5: The effect of XAI explanations on organisational knowledge integration is serially mediated by reflective reasoning, interpretive competence, and calibrated trust.

In the pilot, H5 is treated as exploratory; confirmatory testing requires the full-scale study.

The path model implied by H1–H5 can be formally specified as a system of structural equations. Let $XAI_i \in \{0,1\}$ denote condition assignment; $Q_i \in [0,1]$ denote explanation quality; and RR_i, IC_i, CT_i, OKI_i denote the latent construct scores for participant i. The structural equations are: $RR_i = \beta_1 \cdot XAI_i + \zeta_1{}_i$ (H1); $IC_i = \beta_2 \cdot RR_i + \zeta_2{}_i$ (H2); $CT_i = \beta_3 \cdot IC_i + \beta_4 \cdot (IC_i \times Q_i) + \zeta_3{}_i$ (H3); $OKI_i = \beta_5 \cdot CT_i + \zeta_4{}_i$ (H4). The total indirect effect for H5 is $\delta = \beta_1\beta_2\beta_3\beta_5$, estimated via bootstrapped mediation analysis.

Table 1 summarises the five hypotheses alongside their theoretical bases. H3 is specified as a conditional relationship, with XAI explanation quality as an explicit moderator.

Table 1. XAI-OLL Hypotheses: Constructs, Theoretical Bases, and Expected Directions.

Hyp.	Relationship	Theoretical Basis	Direction
H1	XAI exposure → Reflective Reasoning	Kahneman (2011) dual-process; Schön (1983) reflective practice	Positive
H2	Reflective Reasoning → Interpretive Competence	Schön (1983); Hoffman et al. (2018); von Zahn et al. (2024); SECI Externalisation	Positive
H3	Interpretive Competence → Calibrated Trust (moderated by XAI quality)	Lee & See (2004); Parasuraman et al. (1997); Humer et al. (2024); Cai et al. (2024)	Positive (conditional)
H4	Calibrated Trust → Organisational Knowledge Integration	Nonaka & Takeuchi (1995); Jarrahi et al. (2023); GRAI logics	Positive
H5	XAI → OKI (serial mediation via RR, IC, CT)	Dual-process theory; XAI-OLL sequential mechanism	Positive indirect

4 Methodology

4.1 Research Design

This paper presents a theoretical-methodological contribution: the XAI-OLL framework and an associated pilot quasi-experimental protocol designed to operationalise its constructs and assess whether the hypothesised relationships are detectable before proceeding to full-scale validation. The pilot study is not yet executed; it constitutes the next planned step in this research programme. Participants will be randomly assigned to one of two between-subjects conditions:

Condition A (AI only): participants receive the model's probabilistic prediction (malignant/benign classification) without any explanation.

Condition B (AI + XAI): participants receive both the prediction and a visual explanation — a saliency map and Grad-CAM activation overlay — highlighting the image regions that drove the classification.

This two-condition design isolates the effect of explainability on the XAI-OLL constructs while controlling for all other aspects of the AI interaction, and provides a direct test of whether XAI is a necessary ingredient or merely one of several possible reflective stimuli. Independent assessment before AI exposure (Phase 1) allows measurement of decision revision as a behavioural indicator of cognitive engagement. Explanation quality will be operationalised as a moderator of H3 by stratifying cases into high- and low-fidelity subconditions. Crucially, the multi-phase design allows distinguishing perceived competence (self-report) from actual performance improvement (accuracy on transfer cases), strengthening the construct validity of IC.

4.2 Context and Participants

The experimental context is the interpretation of histopathology slide images, a domain in which deep learning models achieve diagnostic accuracy comparable to specialist pathologists and in which XAI visualisation techniques are technically mature. The domain is characterised by high epistemic stakes, well-defined interpretive criteria, and professional communities accustomed to collaborative case review — making it an ideal setting for studying learning dynamics in human-AI interaction.

The pilot sample will consist of approximately N = 50 participants from medical and biomedical communities: pathologists, resident physicians, biomedical researchers, and advanced medical students. Variation in professional background allows exploration of expertise-level moderation effects (Parasuraman et al., 1997). This size is appropriate for PLS-SEM pilot analysis; a subsequent study will target N ≥ 200 for covariance-based SEM (Hair et al., 2019).

4.3 Procedure and Measures

The procedure will unfold in four sequential phases. In Phase 1 (Independent Assessment), participants observe histopathology images and record their diagnostic judgment and confidence on a seven-point scale, without AI assistance. In Phase 2 (AI Exposure), the system's output is presented according to condition; participants may revise their diagnosis. Behavioural data — interaction time, decision revision rate, and accuracy against ground-truth labels — are logged automatically, providing objective performance indicators alongside self-report. Calibration error (the difference between stated confidence and actual accuracy) is computed per participant as an objective CT proxy, following Bansal et al. (2021). In Phase 3 (Reflective Task), participants provide a written justification and complete three unseen transfer cases without AI assistance — providing a behavioural IC measure (actual accuracy improvement) that complements Likert self-report and allows distinguishing perceived from actual competence. In Phase 4 (OKI Group Task), dyads discuss one shared case

and reach a joint diagnosis, providing a behavioural proxy for team-level knowledge integration beyond individual perception.

The four XAI-OLL constructs are operationalised as seven-point Likert scales. Table 2 presents sample items and sources.

Table 2. XAI-OLL Constructs: Sample Measurement Items and Theoretical Sources.

Construct	Sample Measurement Items (7-pt Likert)	Key Sources
Reflective Reasoning (RR)	"I consciously compared my interpretation with the AI-highlighted features"; "Viewing the explanation caused me to revisit my initial assessment"	Schön (1983); Kahneman (2011)
Interpretive Competence (IC)	"The explanation drew my attention to features I had not previously considered"; "I can now better identify diagnostically relevant image regions"	Hoffman et al. (2018); von Zahn et al. (2024); Arrieta et al. (2020)
Calibrated Trust (CT)	"I evaluated the AI's prediction critically rather than accepting it automatically"; "I could identify cases where the AI's reasoning seemed unreliable"	Lee & See (2004); Cai et al. (2024); Humer et al. (2024)
Organisational Knowledge Integration (OKI)	"The AI explanation would be useful to discuss with colleagues"; "This type of explanation could improve our team's shared diagnostic criteria"	Nonaka & Takeuchi (1995); Star & Griesemer (1989)

4.4 Analysis Strategy

Quantitative data will be analysed using PLS-SEM, well-suited to small pilot samples and exploratory model testing (Hair et al., 2019). Measurement quality will be assessed via Cronbach's alpha, composite reliability, AVE, and HTMT discriminant validity. The structural model will be evaluated through path coefficients and bootstrapped indirect effects (5,000 resamples) for H5. To address common method bias, self-reported constructs will be triangulated with objective behavioural indicators: accuracy improvement (Phase 1 vs. Phase 2 against ground-truth labels) as an IC proxy, and calibration error as a CT proxy. The moderation of H3 will be tested through subgroup analysis across high- and low-fidelity explanation conditions. Qualitative texts from Phase 3 and dyadic interaction data from Phase 4 will be coded using thematic analysis to contextualise quantitative findings.

5 Anticipated Propositions and Theoretical Discussion

5.1 Anticipated Empirical Patterns

On the basis of the theoretical model and existing literature, we formulate the following anticipated patterns to guide empirical interpretation. Regarding H1, participants in Condition B (XAI present) are expected to report significantly higher Reflective Reasoning scores than those in Condition A. Visual explanations disrupt heuristic acceptance and invite deliberate comparison — activating Kahneman's (2011) System 2 and enacting Schön's (1983) reflection-in-action. Regarding H2, IC is anticipated to emerge as users verbalise their diagnostic reasoning against XAI-highlighted features, externalising and refining interpretive schemas — enacting the SECI Externalisation mode, consistent with von Zahn et al. (2024).

Regarding H3, the IC→CT relationship is anticipated to be positive but conditional on explanation quality. Where Grad-CAM overlays faithfully reflect diagnostically relevant regions, users should demonstrate more accurate trust calibration, avoiding automation bias and algorithm aversion (Lee and See, 2004). Consistent with Humer et al. (2024), low-fidelity conditions are expected to attenuate or reverse this effect — a critical warning for organisations deploying XAI without quality assurance.

Regarding H4 and H5, Calibrated Trust is anticipated to predict OKI, and the serial mediation (H5) constitutes the XAI-OLL's most theoretically original proposition: that XAI affects organisational learning through a sequential cognitive chain, not a single mechanism — formalising conceptually what GRAI logics (Böhm and Durst, 2025) describe at a structural level.

5.2 XAI Explanations as Boundary Objects and Learning Levers

A key theoretical implication of the XAI-OLL framework concerns the social and collective dimensions of AI-generated explanations. Activation maps and local attribution outputs — particularly in visual domains such as histopathology — make visible what would otherwise remain tacit algorithmic knowledge, creating cognitive stimuli that prompt professionals to surface and articulate their own tacit interpretive criteria. In peer review

settings, these artefacts become objects of collective scrutiny: clinicians compare highlighted regions, challenge each other's interpretations, and arrive at shared diagnostic criteria — a Combination dynamic in the SECI spiral. Through repeated use, new interpretive schemas become internalised into professional practice (Internalisation). XAI explanations thus function as boundary objects (Star and Griesemer, 1989), bridging the epistemic gap between algorithmic and human knowledge communities, enabling the knowledge co-construction that GRAI logics theorise at the structural level.

6 Organisational Conditions for XAI-Enabled Upskilling

The XAI-OLL framework does not predict that XAI explanations will automatically generate organisational learning. The evidence reviewed — particularly Humer et al. (2024) and von Zahn et al. (2024) — indicates that the pathway from XAI exposure to knowledge integration depends on enabling conditions that organisations must actively design.

Designing for interpretive competence development. Professional training that incorporates XAI explanations as case-based learning materials is a prerequisite for activating the XAI-OLL mechanism. HR professionals must incorporate interpretive competence — not merely operational fluency with AI interfaces — as a core AI literacy dimension (Morandini et al., 2023; Santana and Díaz-Fernández, 2023), redesigning development pathways to include structured practice with XAI tools.

Governance and quality assurance of XAI tools. Because H3 is conditioned by explanation quality, organisations must establish governance standards: protocols for vetting explanation fidelity, regular audits against domain benchmarks, and counter-anchoring training that encourages independent assessment before AI exposure.

Creating knowledge integration infrastructure. OKI requires formalised channels for moving individual AI-assisted insights into collective knowledge: regular review sessions, structured processes for updating practice guidelines, and communities of practice in which professionals share interpretive experiences with AI tools. This 'learning in the flow of work' dynamic (Jarrahi et al., 2023) is organisationally designed, not spontaneous.

7 Theoretical Contributions and Limitations

This paper makes three theoretical contributions. First, it presents the first formal sequential cognitive-organisational model of how XAI explainability generates professional learning and organisational knowledge integration, specifying a testable sequential pathway (H1–H5) and incorporating boundary conditions on H3, engaging with the contradictory empirical literature (Humer et al., 2024; von Zahn et al., 2024). Second, the paper extends the SECI model with a precise specification: XAI functions as an algorithmic externalisation stimulus that provokes professional Externalisation rather than constituting it directly — clarifying a conceptual ambiguity in prior AI-knowledge management research. Third, the paper situates XAI within the HR transformation literature, positioning AI interpretive literacy as a new professional competence dimension, and HR professionals as active designers of AI-enabled upskilling conditions (Morandini et al., 2023).

The framework is currently theoretical: no empirical data have yet been collected. The pilot, once executed, will be constrained by small sample size and single-domain focus (histopathology), limiting causal inference and generalisability. Future research should pursue longitudinal designs, larger samples ($N \geq 200$), and cross-domain comparative studies.

8 Conclusions

The XAI-OLL framework proposes a theoretically grounded and empirically operationalisable account of how XAI explanations function as organisational learning levers rather than mere transparency tools. By specifying a sequential cognitive-organisational mechanism — XAI Exposure → Reflective Reasoning → Interpretive Competence → Calibrated Trust → Organisational Knowledge Integration — the framework generates five testable propositions grounded in knowledge management theory and operationalised through a formal SEM specification and a pilot quasi-experimental protocol. The framework makes three interconnected contributions: it advances mechanism-level theory of XAI-driven learning; it extends the SECI model into human-AI collaboration with conceptual precision; and it repositions HR professionals as active architects of AI-enabled upskilling environments. Critically, the framework does not assume that XAI automatically generates learning — it identifies the boundary conditions under which the pathway holds and the organisational investments required to activate it. As AI decision support becomes pervasive across professional domains, understanding how organisations can harness explanatory outputs as learning infrastructure represents a critical frontier for knowledge management theory and HR practice alike.

9 Ethics Declaration

The planned empirical study involves human participants. Informed consent will be obtained from all participants prior to data collection. No clinical patient data will be used; images will be drawn exclusively from publicly available, anonymised histopathology datasets. Participation will be voluntary, anonymous, and may be withdrawn at any time without consequence. Ethical approval will be sought from the relevant institutional review board prior to data collection.

10 AI Declaration

AI tools were used to support literature identification, drafting, and editing during the preparation of this paper. All theoretical constructs, framework design, hypotheses, and interpretations are the original work of the author. Full responsibility for the content rests with the author.

Tacit Knowledge Loss (TKL) from an Intelligent Knowledge-Based View (IKBV)

Joachim Lorenz
Reykjavik University, Reykjavik, Iceland

Abstract

Tacit knowledge loss (TKL) poses a critical challenge to an organization's competitiveness, especially when experienced experts retire. This challenge is exacerbated by the high cost of regenerating lost knowledge within organizations. Using an Intelligent Knowledge-Based View (IKBV) framework that integrates human and artificial intelligence, this paper explores how strategic approaches to knowledge retention, supported by generative AI (GenAI), can effectively mitigate TKL. A scoping review was conducted for the study using Scopus as the database. A total of 5 studies were identified to address the three research questions. This study suggests that strategic approaches to knowledge retention, such as capture, storage, and retrieval mechanisms, can be combined with GenAI methods to capture and synthesize the knowledge of mobile experts (RQ1). The resulting AI-supported knowledge retention mechanisms can be strategically complemented with an intelligence-based perspective (RQ2) to identify the critical types of knowledge and the mobile experts who need to be involved in knowledge retention. The IKBV framework resulting from the study (RQ3) can be understood as an intelligent knowledge retention strategy framework that incorporates all both research questions (RQ1; RQ2). The paper expands the theoretical understanding of knowledge loss research by proposing that future research investigate intelligent knowledge retention mechanisms to further test their effectiveness in mitigating knowledge loss. Furthermore, the study revealed that the mobile term "expert" needs to be more precisely defined so that researchers can specify the target group in their empirical studies. This is where a doctoral thesis could begin exploring how the concept of an expert can be defined and differentiated within an organization, enabling sustainable prioritization within an intelligent knowledge retention strategy. The findings show that a knowledge retention strategy requires not only technological implementation, but also human expertise and intelligent technological interaction. The knowledge retention strategy should be prioritized in organizations where the loss of intellectual capital due to the departure of experts can become a risk to innovation. This paper contributes to the theory of knowledge management by showing how the IKBV framework can bridge the gap between human expert knowledge and artificial intelligence capabilities, thus promoting sustainable organizational learning.

Keywords: Tacit Knowledge Loss, Knowledge Retention, Intelligent Knowledge-Based View, Generative Artificial Intelligence, Mobile Experts

Paper type: Academic Research Paper

1 Introduction

The loss of tacit knowledge is one of the most significant, but underestimated, organizational risks in the modern knowledge economy.

As Polanyi (1966) put it: “we know more than we can tell” (p. 4), capturing the essence of why tacit knowledge is so difficult to transmit, document, and preserve. This fundamental challenge becomes crucial when experienced employees leave an organization, taking with them years of accumulated experience, contextual understanding, and implicit expertise that cannot be easily replicated through documentation or training programs.

1.1 Problem statement

The literature on knowledge management has long recognized that organizational competitive advantage increasingly comes from intangible assets, especially human capital and organizational knowledge (Eisenhardt and Santos, 2012; Nonaka and von Krogh, 2009).

In this context, the tacit loss of knowledge (TKL) – the departure of critical knowledge when experts leave the organization – threatens organizational performance and innovation. Research by Massingham (2018) shows that the regeneration of lost tacit knowledge requires significant financial and time investments, as new knowledge must be created through costly interactions with social actors and organizational learning processes (Nonaka and Takeuchi, 1995).

Recent developments in generative artificial intelligence (GenAI) have created unprecedented opportunities for practice in knowledge management. Alavi et al. (2024) argue that GenAI technologies enable novel approaches to capture, synthesize, and mobilize organizational knowledge.

Despite this technological promise, a theoretical problem is that there is limited research on how strategic approaches can effectively leverage intelligent systems to mitigate TKL, especially in the context of departing experts.

1.2 Purpose statement

This paper approaches this research problem by presenting intelligent mechanisms to address TKL. The resulting Intelligent Knowledge-Based View (IKBV) is primarily intended to help researchers examine AI-supported knowledge retention mechanisms so that organizations can effectively counter the threat of knowledge loss. The IKBV expands the traditional knowledge-based view (KBV) by recognizing that intelligent knowledge retention requires not only human-centered or technology-centered approaches, but rather hybrid systems that leverage the strengths of both (Kaczorowska-Spychalska *et al.*, 2024; Lichtenthaler, 2019).

Furthermore, the IKBV includes the Knowledge Retention Cycle by Levallet and Chan (2019) and expands it with an intelligent, knowledge-based perspective to counter the problems identified that increase the risk of knowledge loss. The focus of the consideration should be on individual experiential knowledge, i.e. the knowledge that the organization needs to maintain its innovative strength.

The author of this study, following Levallet and Chan (2019), defines this knowledge as mobile expert knowledge and loss of knowledge as a result when this mobile expert knowledge is lost due to the departure of mobile experts.

Consequently, the central research question (RQ) is: Which intelligent knowledge retention mechanisms can counteract the loss of mobile expert knowledge?

The following sub-questions are to be answered:

- *RQ1: What role does GenAI play within a knowledge retention strategy?*
- *RQ2: Which model can be employed for the expansion of the Knowledge-Based View (KBV)?*
- *RQ3: How can an intelligent knowledge retention strategy framework be designed that incorporates all two research questions?*

2 Background

2.1 The knowledge-based view

The Knowledge-Based View (KBV) of strategic management states that organizational knowledge and skills are the primary sources of competitive advantage (Eisenhardt and Santos, 2012). Within the KBV framework, knowledge retention (KR) emerges as a critical strategic capability – the ability to retain and use existing tacit knowledge from departing experts to maintain a competitive position and support organizational continuity.

2.2 Tacit knowledge and organizational value

Tacit knowledge—the experiential, context-dependent understanding that individuals develop through practice and social interaction—makes up a significant portion of organizational knowledge. Unlike explicit knowledge, which can be codified in documents, databases, or manuals, tacit knowledge remains embedded in human cognitive and behavioral patterns. Nonaka and Takeuchi (1995) point out that tacit knowledge encompasses mental models, beliefs, perspectives, and expertise developed through experience and practice.

The strategic importance of tacit knowledge stems from its difficulty of imitation and its central importance for competitive advantage (Eisenhardt and Santos, 2012; Zack, 1999). Experienced engineers, managers, craftsmen, and long-term professionals accumulate tacit knowledge that shapes organizational practices, decision-making processes, and innovation skills.

When experts retire, organizations face the immediate challenge of knowledge loss and the long-term costs of reconstructing that knowledge. Massingham (2008) empirically shows that knowledge loss affects organizational performance and innovation. Research shows that regenerating lost tacit knowledge requires significant organizational investment, as knowledge creation is inherently a social process that involves interaction, dialogue, and learning.

This finding underscores the strategic need for proactive knowledge retention strategies that capture expert knowledge before departure.

2.3 Knowledge retention cycle

The core consideration of the present study is based on the Revised Knowledge Retention (KR) Cycle by Levallet and Chan (2019). The original KR Cycle (p. 179) includes three phases: Knowledge Capture, Knowledge Storage, and Knowledge Retrieval. The loss of knowledge is presented here as a phenomenon that results from an inability to record and store the individual knowledge of mobile experts for the organization.

The extended KR Cycle (p. 192) distinguishes between individual and social knowledge. The model can be used to explain how the individual knowledge of a mobile, or more precisely, retired expert, can be transformed into an organizational asset. The authors argue for knowledge transfer mechanisms that enable transformation into social knowledge, which should also be recorded, stored, and made available.

Here, an inability to transform implicit individual knowledge (automatic knowledge) into social knowledge can increase the risk of knowledge loss. This cyclical model provides a framework for understanding how organizations can systematically address knowledge retention and the risks of not having this capability. One limitation of the model is that it does not show how emerging technologies, especially generative AI, can support each stage of the retention cycle.

3 Methodology

This research uses a scoping review methodology to synthesize existing literature on strategic approaches to tacit knowledge loss and the role of intelligent knowledge systems. A scoping review provides a systematic approach to identifying, analyzing, and synthesizing evidence across a broad thematic area (Westphaln *et al.*, 2021).

To answer the research questions, Scopus was selected as the database, and the following search string was used as the search strategy:

TITLE-ABS-KEY(("generative artificial intelligence" OR "generative AI" OR "GenAI")
AND ("knowledge management" OR "knowledge retention" OR "tacit knowledge"))

This identified 547 studies. For the sake of consolidation and due to the limited scope of this conference paper, the corpus has been reduced: business, management and accounting (n = 100); article (n = 192); English (n = 540); journal (n = 217); Journal of Knowledge Management (n = 9) and VINE Journal of Information and Knowledge Management System (n = 3). Only one source could be included: Böhm and Durst (2025). The backward citation searching has yielded four additional sources; see Table 1.

Table 1**:** Included Studies

Scoping Review & Backward Citation Searching		
Author	Year	Title
Alavi et al.	2024	A Knowledge Management Perspective of Generative Artificial Intelligence
Böhm and Durst	2025	Knowledge management in the age of generative artificial intelligence – from SECI to GRAI
Ismail Al-Alawi and Al-Ahmed	2025	Integration of AI in Capturing Tacit Knowledge of Employees Leading to Innovation in Organizational Learning: A Literature Review
Rezaei	2025	Artificial intelligence in knowledge management: Identifying and addressing the key implementation challenges
Lichtenthaler	2019	An Intelligence-Based View of Firm Performance: Profiting from Artificial Intelligence

4 Findings

4.1 RQ1: What role does GenAI play within a knowledge retention strategy?

Generative artificial intelligence represents a technological paradigm shift in knowledge management. Alavi et al. (2024) argue that GenAI enables novel approaches to knowledge synthesis, availability, and application. Unlike traditional knowledge management systems, which mainly store and retrieve existing knowledge, GenAI systems can generate new synthetic knowledge by combining multiple sources of information and applying sophisticated pattern recognition.

Böhm and Durst (2025) propose a model that evolves from the Nonaka-Takeuchi SECI (Socialization, Externalization, Combination, Internalization) framework to a GRAI framework that integrates generative AI thinking and intelligence. This development recognizes that GenAI can facilitate knowledge externalization by

helping experts articulate tacit knowledge through dialogue, enhance combination by synthesizing dispersed knowledge sources, and support internalization through personalized learning experiences.

Ismail Al-Alawi and Al-Ahmed (2025) empirically demonstrate that AI-powered systems can improve organizational decision-making by leveraging predictive analytics to capture and apply employee knowledge. Her research highlights that transparent methods for capturing and synthesizing knowledge – instead of "black-box" AI implementations – create organizational conditions for sustainable knowledge cultures.

Rezaei (2025) shows how knowledge storage (KST) can be understood conceptually. Thus, KST is understood "the intricate processes and technological infrastructure employed for capturing, preserving, organising, and retrieving knowledge within an organisation" (p. 3). The KST aims to ensure that knowledge is easily accessible and usable. According to the author, KST primarily refers to an IT-supported form, which can be implemented using a data warehouse, for example. This involves collecting large amounts of data, cataloging them, and generating knowledge.

4.1.1 Intelligent knowledge capture

GenAI systems can facilitate knowledge capture by involving experts in a dialogue that increasingly externalizes tacit knowledge. Large language models can conduct interviews, ask clarifying questions, and help experts formulate an implicit understanding.

Alavi et al. (2024) discuss the potential of GenAI to enable the organization to generate new knowledge from external sources or by automatically capturing meeting notes.

Böhm and Durst (2025) point out that this dialogue-based externalization overcomes the limitations of traditional documentation approaches by creating dynamic, contextual representations of knowledge. The authors discuss the potential of GenAI as semantic intelligence that can support the organization in capturing tacit knowledge, for example, by linking data or identifying relationships.

Rezaei (2025) also understands this possibility of capturing new knowledge by accessing various sources.

Ismail Al-Alawi and Al-Ahmed (2025) postulate the existence of knowledge management systems capable of capturing tacit knowledge.

4.1.2 Intelligent knowledge storage

GenAI enables combining knowledge from multiple experts, disparate documents, and disparate organizational sources to create synthetic knowledge artifacts that transcend any single source. Alavi et al. (2024) emphasize that GenAI can synthesize patterns, best practices, and integrated insights from dispersed knowledge sources, thus creating comprehensive organizational knowledge that represents collective rather than individual expertise. Rezaei (2025) discusses, among other things, algorithms that can clean the database, freeing up more storage space.

4.1.3 Intelligent knowledge retrieval

GenAI systems can support the knowledge queries and applications via conversational interfaces, recommender systems, and decision support tools. These technologies can help organizational members quickly acquire relevant knowledge and receive contextual guidance for specific situations and decisions.

Böhm and Durst (2025) discuss the retrieval-augmented generation (RAG) functionality, which enables AI to access an externalized document collection. This makes it easier to call up information. Ismail Al-Alawi and Al-Ahmed (2025) show that AI-powered predictive analytics can facilitate proactive knowledge application in decision-making contexts. According to Rezaei (2025), search experiences can also be personalized. In this case, the AI model learns the user's preferences and behavior patterns.

4.2 RQ2: Which model can be employed for the expansion of the Knowledge-Based View (KBV)?

Lichtenthaler (2019) suggests that contemporary organizations need an 'intelligence-based view' that integrates perspectives from multiple forms of intelligence – human, organizational, and artificial. This framework recognizes that modern competitive advantage increasingly stems from the ability to combine human expertise with artificial intelligence in complementary ways.

Building on this conceptual foundation, the Intelligent Knowledge-Based View (IKBV) framework extends the traditional P/B ratio by explicitly integrating hybrid human-AI knowledge systems into the theory of competitive advantage. The IKBV assumes that sustainable competitive advantage increasingly results from the ability of organizations to:

Identify, codify, and retain the tacit knowledge of experts through human-centered knowledge gathering processes.

Aggregate captured knowledge into organizational assets through GenAI-assisted analysis and synthesis.

Deploy hybrid systems that mobilize both human judgment and AI-powered decision support to apply knowledge in organizational contexts.

5 RQ3: How can an intelligent knowledge retention strategy framework be designed that incorporates both research questions?

The research results suggest that AI-supported KR mechanisms have already been established alongside traditional knowledge management methods. With the help of the scoping review, three technological approaches were identified for the three primary approaches to KR, according to (Levallet and Chan, 2019): knowledge capture, knowledge storage, and knowledge retrieval: semantic intelligence, algorithm, and RAG. While semantic intelligence can combine existing and external knowledge, algorithms aim to prepare this knowledge so it can be retrieved via a RAG.

However, this represents a purely technical view of knowledge retention and requires human control mechanisms, as GenAI tends to be biased by data (Alavi *et al.*, 2024). There is also the question of the extent to which these AI-supported mechanisms can identify mobile expert knowledge when it is scattered or not yet codified. Consequently, human mechanisms and thus classical methods are also needed as part of a knowledge retention strategy, so that mobile expert knowledge can be recorded and retained through interviews (Ismail Al-Alawi and Al-Ahmed, 2025).

Finally, in addition to intelligent KR mechanisms and classical methods, there is also a view of which types of knowledge should be retained. This study cannot answer this question. Also, the question of how an expert can be defined or even identified. The IKBV must therefore be expanded to include these issues. In the figure below, the author proposes an IKBV framework.

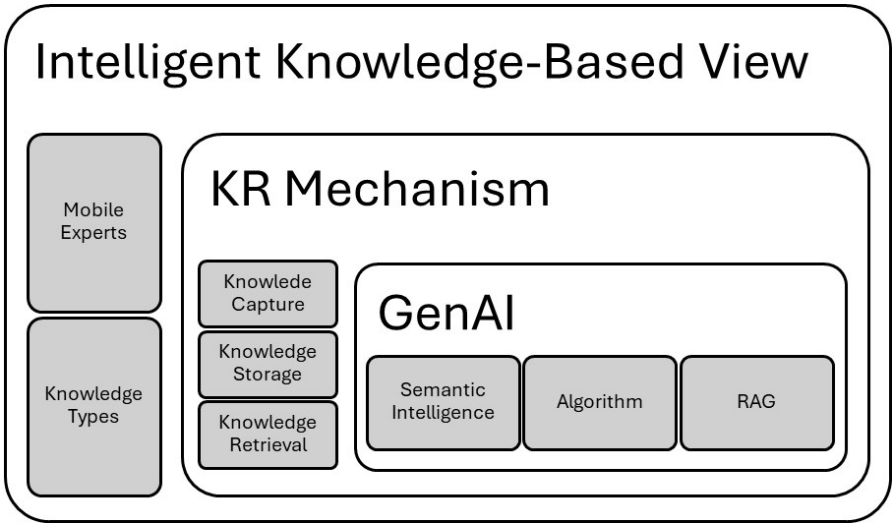

Figure 1: The Intelligent Knowledge-Based View (IKBV)

6 Implications

6.1 Implications for knowledge management theory

The IKBV framework contributes to knowledge management theory by extending the traditional knowledge-based view to include artificial intelligence as a strategic organizational capability. Rather than treating technology as a peripheral support function, the framework recognizes that GenAI-powered systems are increasingly central strategic assets for knowledge management in the modern organization.

This framework integrates GenAI into a coherent strategic approach to KR. Instead of viewing GenAI as a replacement for human knowledge management, the IKBV positions itself as a complementary capability that enhances organizational KR throughout the entire KR cycle. The results also support the development of human-centered SECI knowledge creation models towards integrated human-AI knowledge models, as proposed by Böhm and Durst (2025).

6.2 Practical implications for organizations

Organizations that want to mitigate the tacit loss of knowledge should adopt integrated approaches that combine human-centered and AI-powered strategies. Specifically, effective knowledge retention strategies should:

Knowledge capture: The use of semantic intelligence to unlock and link different knowledge bases so that mobile expert knowledge can be intelligently captured.

Knowledge Storage: The use of algorithms so that this knowledge base can be organized and intelligently structured.

Knowledge retrieval: The use of a RAG so that knowledge can be retrieved intelligently.

7 Conclusion and Future Research Directions

The loss of tacit knowledge is a critical organizational challenge in knowledge-intensive industries and sectors. The mobile expert phenomenon threatens organizational knowledge, competitive advantage, and innovation potential. Traditional approaches to knowledge storage partially address this challenge, but struggle with the inherently tacit, contextual, and embodied nature of mobile expert knowledge.

In this study, the research interest was in identifying which intelligent knowledge retention mechanisms can counteract the loss of mobile expert knowledge. Due to data scarcity, this question can only be answered to a limited extent. The study proposes to include two models in this consideration. On the one hand, the KR Cycle by Levallet and Chan (2019) offers a framework for differentiating KR into three parts: knowledge capture, knowledge storage, and knowledge retrieval. For the knowledge-based lens, Lichtenthaler's (2019) IBV can be used to expand the KBV.

The IKBV developed as part of this study uses these two models and gives an impression of how an intelligent view of knowledge retention can be designed. As organizations increasingly compete for knowledge and innovation, the ability to retain mobile expert knowledge is proving to be a critical strategic skill.

The IKBV framework provides a theoretical foundation and practical guidance for organizations seeking to protect knowledge assets, support organizational continuity, and secure a competitive advantage amid inevitable expert departures. Future research that validates this framework in different organizational contexts will further consolidate the usefulness of IKBV for the practice and theory of knowledge management.

Mixed-methods designs could be used in future research designs to assess the effectiveness of IKBV-oriented interventions in reducing knowledge loss and supporting organizational performance. Second, important questions remain about data management, knowledge ownership, and the ethical implications of using GenAI for knowledge capture and synthesis. Especially in contexts where the knowledge of mobile experts is captured, organizations need to address issues of consent, intellectual property, and fair use of synthetic knowledge resources. Third, the integration of IKBV approaches must go beyond sharing expert knowledge and address broader organizational learning, innovation, and knowledge sharing.

Future research should explore how IKBV frameworks support organizational capabilities beyond knowledge retention, such as in identifying critical mobile expertise.

8 Acknowledgements

The author acknowledges the support from the University of Reykjavík's research infrastructure, as well as the valuable feedback from the author's supervisor, Dr. Susanne Durst, and colleagues in the knowledge management research community.

9 Ethics Declaration

This research was limited to a theoretical review of scientific literature and did not include human subjects, data collection from individuals, or sensitive personal information. Therefore, ethical approval by an institutional review panel was not required. The research adheres to established academic standards for literature review and synthesis.

10 AI Declaration

Claude (Haiku Sonnet 4.5) was used to critically reflect on the paper's structure. Grammarly was used to improve spelling and expression.

Collective and Artificial Intelligence in the Challenge of Happy Degrowth

Marianna Mancino, Maria Zifaro, Giuseppe Ambrosio, Giovanni Spatola, Stefania D'Aprile
Mercatorum University, Rome, Italy

Abstract

The current context is marked by systemic, ecological, social, and economic crises. These are accompanied by an increasing acceleration of technological change. In this scenario, the urgent need emerges to rethink development models based on unlimited economic growth. The degrowth paradigm proposes an alternative orientation centered on principles of sufficiency, equity, and collective well-being. It challenges dominant productivist logics and promotes new forms of social organization. At the same time, artificial intelligence is emerging as a powerful infrastructure capable of influencing organizational and decision-making processes in contemporary societies, reshaping the relationship between technology, work, and society in significant and long-term ways. This contribution explores the joint role of collective intelligence (CI) and artificial intelligence (AI) in supporting scenarios of convivial degrowth. It adopts a theoretical-exploratory and interdisciplinary approach based on the analysis of existing literature and documented case studies. The findings show that AI, if designed and governed according to ethical, inclusive, and democratic principles, can facilitate distributed coordination of activities, knowledge sharing, and collective participation in decision-making processes, thus strengthening local resilience and cooperation. Within this perspective, CI emerges as the cognitive engine of community cooperation and co-creation. Time is understood as a fundamental resource that must be redistributed to enable non-market social practices such as care, volunteering, and participatory deliberation. The paper proposes the Cooperative Socio-Technical Regeneration Model (CSTRM), a theoretical framework that integrates CI, AI, time, and sufficiency as key elements of a socio-ecological transformation oriented toward collective well-being and long-term sustainability. The model highlights that the relationship between AI and degrowth is not automatic. Rather, it is deeply mediated by design, institutional, and cultural choices. The contribution aims to enrich the debate on socio-ecological transition pathways, while acknowledging the limitations related to the theoretical nature of the analysis and the need for future empirical validation, as well as further comparative research across different territorial contexts.

Paper type: Academic Research Paper

1 Introduction

Contemporary transformations, marked by ecological, social, and economic crises, challenge the centrality of growth as the organizing principle of modern societies (Hickel, 2020; Kallis et al., 2018). The degrowth paradigm proposes a reconfiguration of socio-economic systems oriented toward sufficiency, quality of life, and the regeneration of socio-ecological systems (Latouche, 2014; Raworth, 2018; Sachs, 2024). At the same time, artificial intelligence is emerging as a socio-technical infrastructure capable of shaping decision-making and organizational processes, whose impact depends on development contexts and governance logics (Elish and Boyd, 2018; Floridi et al., 2018).

Within this framework, the paper addresses the following research question: how can the interaction between collective intelligence (CI) and artificial intelligence (AI) enable degrowth-oriented pathways, and what are the implications for community structures?

The aim is to develop an integrated understanding of CI and AI as cognitive and socio-technical infrastructures serving an economy of sufficiency. The article adopts a theoretical-exploratory and interdisciplinary approach, based on a narrative literature review and qualitative case study analysis, in order to interpret the relationships between technology and social cooperation.

The main outcome is the Cooperative Socio-Technical Regeneration Model (CSTRM), which conceptualizes CI as the cognitive driver of cooperation, AI as a supporting infrastructure, time as a political resource, and sufficiency as a normative principle. The originality lies in integrating CI, AI, and degrowth within a unified framework, offering an alternative perspective on technological innovation as a lever for collective well-being. Limitations include the theoretical nature of the analysis and the limited generalizability of the cases. Managerial implications concern the design of digital systems oriented toward cooperation, transparency, and participation.

2 Theoretical Background

2.1 Collective Intelligence

Collective intelligence (CI) can be broadly defined as the emergent capacity of a group to produce solutions, decisions, or knowledge that are qualitatively superior to those generated by individuals alone (Wechsler, 1971). It arises from dynamic processes of interaction, communication, and knowledge sharing, rather than from individual attributes.

Lévy conceptualizes CI as "a form of universally distributed intelligence, constantly enhanced, coordinated in real time, and resulting in the effective mobilization of skills" (Lévy, 1997/1994, pp. 13–15). From this perspective, intelligence becomes an expression of the ability of social and organizational contexts to recognize and activate it.

Converging evidence from the "wisdom of crowds" literature shows that heterogeneous groups can outperform individuals when diversity, independence, and decentralization are preserved (Surowiecki, 2005). Similarly, Woolley et al. (2010) identify a collective intelligence factor (c), linked to social sensitivity and balanced participation within groups.

Nevertheless, aggregation alone does not guarantee the emergence of CI. As highlighted by Le Bon (1900), unstructured crowds may produce irrational and unreflective outcomes. CI instead develops within contexts characterized by coordination, structured interaction, and trust. In this regard, cooperation and cognitive diversity are key determinants. High-performing groups are those able to dynamically regulate diversity in relation to task demands, expanding it during exploratory phases and narrowing it during coordination phases, while maintaining internal coherence (Lix et al., 2022; Karadzhov et al., 2024). This dynamic explains the strong association between CI and processes of co-creation and social innovation, where active community involvement plays a crucial role in addressing complex challenges (Mulgan, 2006; Manzini, 2015).

Furthermore, the effectiveness of CI depends on enabling conditions. Technological and organizational infrastructures support coordination, information flows, and the integration of contributions. The "collective intelligence genome" framework, in particular, emphasizes how participation structures, motivational drivers, outputs, and organizational mechanisms shape collaborative dynamics (Malone et al., 2009). Overall, CI can be regarded as a strategic resource for learning, adaptation, and cooperation, contingent upon contexts that enable trust, knowledge sharing, and effective coordination (Broadbent and Gallotti, 2015).

2.2 AI as socio-technical infrastructure

Artificial intelligence (AI) has traditionally been defined as the capacity of machines to perform tasks requiring human-like intelligence, including learning, reasoning, and decision-making (Boden, 2016; Russell and Norvig, 2021). More recently, however, AI has been reconceptualized as a socio-technical infrastructure, whose logics, applications, and effects are deeply embedded within the social contexts of its development and use (Elish and Boyd, 2018).

Within this framework, AI cannot be considered neutral. Its outcomes are shaped by the values embedded in design processes, governance structures, and strategic objectives. In dominant economic paradigms, AI is frequently deployed to enhance efficiency and sustain economic growth, thereby reinforcing extractive dynamics and accelerating material and energy throughput (Hickel, 2020; Hogan, 2024; Jackson, 2014).

Conversely, a growing body of literature emphasizes AI's potential as an enabling technology for social innovation, supporting knowledge sharing, resource coordination, and participatory governance (Floridi et al., 2018; Kim et al., 2022; Manzini, 2015). In this sense, AI may function as an "informational glue" capable of integrating heterogeneous data, identifying patterns, and informing decision-making processes, provided that it is designed according to principles of transparency, inclusiveness, and democratic control (Illich, 1973; Milotay and Sgueo, 2020).

A critical issue concerns the relationship between AI and time. Automation holds the potential to liberate time from repetitive tasks, enabling social participation and care practices. However, without appropriate policy frameworks these gains may instead result in work intensification and the acceleration of everyday life (European Commission, 2024; Morandini et al., 2023).

Against this backdrop, the compatibility between AI and degrowth is contingent upon the criteria used to design and assess technological systems. The sufficiency perspective calls for moving beyond productivity- and efficiency-driven metrics, focusing instead on the forms of life, relationships, and social organization that AI enables (Meyers, 2024; Vetter, 2018; Sachs, 2024).

2.3 Degrowth

The degrowth paradigm constitutes a critical response to the dominance of economic growth as the organizing principle of contemporary societies (Hickel, 2020; Kallis et al., 2018). Rather than prioritizing GDP expansion, it advocates a reconfiguration of socio-economic systems based on sufficiency, social justice, and ecological limits (Latouche, 2014; Sachs, 2024).

Degrowth involves the intentional downscaling of material and energy throughput within planetary boundaries, with the objective of fostering human well-being, equity, and ecological regeneration (Hickel, 2020). Importantly, it should not be equated with recession, but understood as a deliberate and equitable transformation of economic structures (Victor, 2008). This approach calls for decoupling well-being from economic growth and redefining prosperity in qualitative terms, as the capacity to flourish within ecological constraints (Jackson, 2014).

At the core of this paradigm lies the principle of sufficiency, which promotes limiting production and consumption to sustainable levels while distinguishing between essential needs and excessive consumption (Latouche, 2014; Sachs, 2024). Consequently, innovation is assessed not only in terms of efficiency, but also in relation to its contribution to quality of life and collective well-being.

Degrowth is closely intertwined with social innovation, understood as the development of practices and organizational models that address societal needs through new forms of cooperation and collective action (Manzini, 2015; Murray et al., 2010). Within this framework, communities assume an active role in defining needs and co-producing context-sensitive solutions.

Complementary perspectives, such as Doughnut Economics, stress the importance of situating economic activity within a safe and just space, bounded by a social foundation and an ecological ceiling (Raworth, 2018). In the Italian context, the notion of "degrowth for well-being" foregrounds qualitative values such as time, sobriety, and solidarity, advocating a conscious reduction in consumption and a rebalancing of human–nature relations (Pallante, 2011).

Ultimately, the degrowth paradigm calls for a critical reassessment of technology. Innovation is not inherently beneficial, but must be evaluated according to its coherence with sufficiency, equity, and sustainability, avoiding the reproduction of extractive logics and structural inequalities (Berendt, 2019; Floridi et al., 2018; Hogan, 2024; Vetter, 2018).

2.4 Time and Leisure in the Challenge of Happy Degrowth

Within post-growth debates, time is increasingly conceptualized not as a residual outcome of economic activity, but as a social and political resource that conditions democratic participation, care practices, and socio-ecological regeneration. In this sense, time acquires a relational dimension and becomes subject to institutional and cultural transformation.

It is the distribution of time that constitutes a key dimension of contemporary inequality. The notion of time poverty captures situations in which, after accounting for paid work, unpaid work, and personal needs, individuals are left with insufficient discretionary time. This condition has significant implications for both well-being and social participation (Kalenkoski et al., 2011; OECD, 2020), as only a limited portion of time can be classified as leisure.

To clarify this distinction (Figure 1), it is useful to differentiate between residual time and leisure in a strict sense. Residual time includes all time remaining after paid work. It also includes necessary activities, such as unpaid work (care of the house and family) and personal care (sleep, nutrition, and other essential functions).

While essential, these activities are not fully discretionary, since they are constrained by physiological needs and domestic responsibilities. Authentic leisure, therefore, represents only a subset of time off, consisting of discretionary time available for social interaction, creativity, and personal fulfilment (Haworth and Lewis, 2005; OECD, 2020).

Time also has a significant ecological dimension. Accelerated temporal regimes tend to promote time-saving behaviours, often replacing slower, low-carbon practices, such as self-production, with more energy and resource-intensive alternatives (Smetschka et al., 2023).

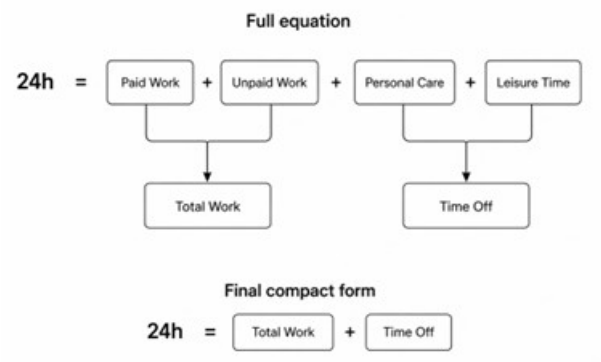

Figure 1. Daily time allocation
Source: Authors' own elaboration based on OECD (2020) data, with AI graphical support

In line with the social acceleration theory, increases in technical and productive speed may coexist with growing perceptions of time scarcity (Rosa, 2003). Although efficiency gains should theoretically liberate time, within profit-driven systems they are frequently absorbed through intensified workloads and expanding demands (Alcott, 2005; Rosa, 2003).

In degrowth scenarios, working time reduction plays a central role, both as a mechanism for redistributing employment and as a means of freeing time for socially valuable activities (Kallis et al., 2018; Lange, 2018).

Empirical evidence indicates that reduced working hours are associated with lower ecological footprints and carbon emissions (Knight et al., 2013), as well as improvements in well-being, including reduced stress and better work–life balance (Kelly et al., 2022). From this perspective, time emerges as a structural condition enabling or constraining participation and cooperation. Happy degrowth can thus be understood as a project of temporal reconfiguration, aimed not only at increasing available time, but at reclaiming it from accumulation logics and redirecting it toward shared well-being.

3 Methodology

The present study adopts an interdisciplinary, theoretical-exploratory approach to explore how the interaction between collective intelligence (CI) and artificial intelligence (AI) may contribute to degrowth pathways. The objective is not to establish causal relationships but to develop an interpretative framework grounded in the combined analysis of literature and illustrative cases.

The research is organized into two phases. First, a narrative review of the literature identifies key conceptual dimensions, including CI, AI as a socio-technical infrastructure, degrowth, and the role of time in post-growth societies. Second, a qualitative analysis of case studies is conducted. Cases are selected through purposive sampling to highlight configurations where CI–AI interactions are consistent with degrowth principles. These cases are not intended to be representative; rather, they are interpreted through the lens of the theoretical framework.

The analysis reveals recurring patterns that inform the development of the Cooperative Socio-Technical Regeneration Model (CSTRM), conceived as an interpretative framework outlining the conditions under which CI and AI can support degrowth. This study presents several limitations. The narrative review is selective and non-exhaustive. The qualitative case analysis is illustrative and does not allow generalization. Moreover, some contexts are evolving. Despite these limitations, the methodology offers an exploratory contribution that advances theoretical insight and supports future research.

4 Results and Discussion

4.1 CI and AI: Illustrative cases

This section examines a selection of cases in which interactions between CI and AI are associated with practices aligned with degrowth. The cases are not intended to be exhaustive. Rather, they serve to illustrate how CI and AI function as interdependent components of socio-technical systems in which human and computational capabilities co-evolve (Elish and Boyd, 2018; Malone et al., 2009).

Within these systems, CI arises from the capacity of heterogeneous actors to mobilize distributed knowledge, which is aggregated and translated into coordinated action (Benkler, 2013; Broadbent and Gallotti, 2015;

Malone et al., 2009). Digital platforms play a key role in enabling this process. AI operates as a complementary layer, supporting the organization of information and facilitating alignment between needs and available resources.

A first set of cases concerns distributed coordination under conditions of fragmentation and informational asymmetry. The Kudu agricultural marketplace in Uganda exemplifies this dynamic. Through an SMS-based platform, farmers and buyers exchange information on prices, quantities, and locations, while AI-based matching algorithms organize these data, incorporating transport costs (Newman et al., 2018; Shi et al., 2020).

However, the case reveals structural limitations. Data reliability issues and logistical constraints necessitate hybrid coordination mechanisms and ongoing human intervention. Furthermore, reliance on external inputs undermines long-term sustainability (Shi et al., 2020).

Despite these constraints, the case demonstrates that the primary value lies not in automation but in enabling localized cooperation. AI enhances rather than replaces human agency, facilitating the alignment of supply and demand as a form of socio-technical innovation (Manzini, 2015).

A comparable logic is evident in the Olio platform, which connects citizens, volunteers, and organizations for the redistribution of surplus food and goods. CI emerges through multi-level participation, where users share information, identify local availability, and respond to community needs. Volunteers, known as Food Waste Heroes, act as coordinating nodes within the network (Cahn, 2000), organizing collection and redistribution processes.

AI supports these interactions through image recognition, automated content generation, moderation, and matching functions (Olio, 2023). The platform also adopts low-energy computational models and promotes circular economy practices through partnerships (Olio, n.d.). Nevertheless, tensions arise. The system depends heavily on unpaid labor while generating potential economic value, raising concerns about the distribution of value and possible misalignment with degrowth principles (Benkler, 2013).

Beyond material coordination, other cases highlight the social recognition of care and everyday support. In these contexts, CI is expressed through trust, reciprocity, and cooperative practices embedded in communities (Manzini, 2015). Time banks represent a paradigmatic example. Based on egalitarian exchange, they assign equal value to all activities, with one hour of work corresponding to one credit (Cahn, 2000).

These systems foreground time as a central resource and make visible forms of labor typically excluded from market valuation (OECD, 2020). However, digital implementations may introduce distortions. The TimeRepublik platform illustrates a shift toward short-term, visibility-driven interactions aligned with self-promotion and market logics (Arcidiacono, 2016), thereby weakening collective orientations.

Mutual aid networks developed during the COVID-19 pandemic provide a more consistent alignment with degrowth principles. Local groups mobilized resources to address concrete needs, including food distribution and assistance to vulnerable populations (Chevée, 2022; Travlou, 2020). Digital tools facilitated coordination without displacing social relations, while trust and proximity remained central.

These cases demonstrate that lightweight digital infrastructures can support co-production as a core organizing principle (Cahn, 2000). Nonetheless, challenges persist, including cultural barriers, trust deficits, safety concerns, and stigma associated with requesting support (Verma et al., 2024).

Citizen science initiatives represent another domain of CI–AI interaction. In coral reef monitoring projects in the Pacific, local communities collaborate with digital tools to assess ecosystem health (Cui and Yasseri, 2024; Irwin, 1995). In resource-constrained environments, these practices assume a community-based configuration (Beery, 2025; Berkes, 2004).

Participants collect data using accessible technologies such as smartphones and underwater cameras. CI manifests in collective observation and interpretation grounded in local ecological knowledge. AI enhances these processes through automated image analysis and species classification, enabling shared knowledge production and environmental decision-making (Beery, 2025; Berkes, 2004). However, infrastructural limitations, funding dependencies, and reliance on volunteer labor may constrain sustainability.

Finally, CI–AI interactions are evident in deliberative democracy processes. Digital platforms enable various forms of e-participation, from information access to active engagement in decision-making (Macintosh, 2004). CI is expressed through the formation of shared judgments via public deliberation (Cohen, 2007). AI contributes by supporting information synthesis, classification, and visualization, helping identify patterns of consensus and disagreement (Cui and Yasseri, 2024; Fontes et al., 2024). The Decidim platform illustrates this dynamic. As an open-source infrastructure, it enables citizens to propose, debate, and vote on public policies (Aragón et al., 2017; García et al., 2023).

The resulting value lies in enhancing decision quality and legitimacy through participation (Berendt, 2019; Raskin et al., 2002). However, these outcomes depend on governance. Without transparency and inclusiveness, participation risks remaining symbolic, limiting democratic impact (Berendt, 2019).

Overall, these cases show that CI–AI interactions are shaped by socio-technical configurations and governance structures, enabling either cooperative and participatory outcomes or trajectories inconsistent with degrowth.

4.2 Toward a cooperative Socio-Technical Regeneration Model (CSTRM)

The cases discussed demonstrate that the interaction between CI and AI is contingent upon its configuration within specific social and institutional settings. Technology is not neutral but embedded in socio-technical systems that shape both its functions and outcomes (Elish and Boyd, 2018; Berendt, 2019). As such, the alignment between AI and degrowth is not inherent, but must be constructed through deliberate design and governance choices.

In response, this paper introduces the Cooperative Socio-Technical Regeneration Model (CSTRM) as a cyclical, non-linear conceptual framework (Figure 2). While the model does not follow a causal sequence, a conceptual entry point can be identified to facilitate its interpretation.

Figure 2. Interpretative Framework of the CSTRM
Source: Authors' own elaboration with AI-assisted graphical support

The model is grounded in the principles of sufficiency and degrowth, which provide its normative orientation. These principles shift the focus from production expansion to improving quality of life and reducing throughput, defined as the flow of energy and materials through the economic system, from resource extraction to production and waste (Kallis et al., 2018).

This orientation leads to a redistribution of social time, including through reduced working hours, with positive effects on well-being and work–life balance (Haraldsson and Kellam, 2021; Schor et al., 2022). Time freed from paid labor becomes available time, partially removed from accumulation logics, and constitutes a key condition for degrowth strategies (Hickel, 2020). The availability of time enables participation, care, and cooperation. In this context, CI acts as a cognitive engine for addressing complex problems, supporting deliberation and coordination (Cui and Yasseri, 2024; Malone et al., 2009), and is sustained by co-creation practices and participatory platforms.

A central role is played by commons, defined as shared resources collectively governed according to community-defined rules (Benkler, 2013; de Rosnay, 2020). Commons provide the foundation for integrated CI–AI configurations. Open infrastructures, data, and knowledge foster cooperation and experimentation, offering alternatives to proprietary models (Benkler, 2013).

AI functions as a socio-technical support when designed to incorporate the social contexts and decision-making processes in which it operates (Elish and Boyd, 2018). In this way, it supports inclusive deliberation, traceability, coordination, and co-production, contributing to the construction of a political "we" (García et al., 2023). Its impact depends on governance arrangements and alignment with equity and sufficiency goals.

These dynamics give rise to regenerative communities: adaptive socio-ecological systems characterized by cooperation, informal social relations, and the capacity to co-evolve with their environments (Gibbons, 2020).

Such communities represent the progressive outcome of the interaction between normative orientation, time availability, CI, and socio-technical support.

The CSTRM thus highlights that CI–AI collaboration can generate degrowth-oriented social innovation only when guided by sufficiency principles. Time emerges as a transversal common good enabling participation and transformation.

4.3 Theoretical and managerial implications

This paper advances the socio-ecological transition debate by conceptualizing CI and AI as interdependent elements of socio-technical infrastructures capable of supporting degrowth-oriented collective processes. Within this perspective, time emerges as a critical political resource that enables participation, care, and cooperative action (Haworth and Lewis, 2005; OECD, 2020; Rosa, 2003).

The proposed Cooperative Socio-Technical Regeneration Model (CSTRM) provides an interpretative framework connecting normative principles, time availability, CI activation, the situated deployment of AI, and the formation of regenerative communities (Gibbons, 2020).

Findings indicate that the relationship between CI, AI, and degrowth is contingent rather than deterministic. It is shaped by socio-institutional contexts and design choices, reinforcing the argument that AI is not neutral (Berendt, 2019; Vetter, 2018). Its potential contribution depends on governance structures and design principles that prioritize transparency and openness (Benkler, 2013; de Rosnay, 2020). While AI can enable cooperation, sharing, and regenerative practices (Manzini, 2015; Murray et al., 2010), it may also reproduce extractive dynamics and systemic inequalities (Floridi et al., 2018; Hickel, 2020; Hogan, 2024; Jackson, 2014).

Accordingly, AI should be assessed based on its capacity to support the common good, conceived as a dynamic, context-sensitive process of collective construction involving plural perspectives and inclusive decision-making (Berendt, 2019). The model emphasizes sufficiency as a normative criterion guiding technological development toward collective well-being.

Managerially, the results suggest the need to redefine design and evaluation criteria for digital systems. Participatory and inclusive design approaches should be prioritized to integrate stakeholder perspectives and distributed knowledge (Manzini, 2015; Benkler, 2013; Malone et al., 2009).

AI systems should be framed as cooperative infrastructures, emphasizing transparency, explainability, and collective oversight, while mitigating risks associated with algorithmic opacity (Elish and Boyd, 2018; Illich, 1973; Milotay and Sgueo, 2020; Floridi et al., 2018). Furthermore, developing low-impact technological solutions that are energy-efficient and locally adaptable is essential (Hickel, 2020; Kallis et al., 2018; Lange, 2018).

Public institutions are crucial in enabling sufficiency-oriented ecosystems by supporting open-source initiatives, digital commons, and equitable governance arrangements (Benkler, 2013; de Rosnay, 2020). Finally, integrating time into policy agendas—particularly through working time reduction and redistribution—can enhance participation, care, and cooperation (Kallis et al., 2018; Rosa, 2003).

4.4 Limitations and future research

This study presents several limitations. The theoretical–exploratory approach does not allow for the establishment of causal relationships or the empirical generalization of findings, as it is oriented toward conceptual development and pattern identification. The analyzed cases are qualitative and illustrative and are influenced by contextual factors, limiting the transferability of results to other settings.

Moreover, the narrative literature review may reflect interpretative selectivity, potentially introducing bias. More broadly, qualitative research entails limitations related to subjectivity and the difficulty of testing cause–effect relationships. An additional concern relates to the role of AI within socio-technical systems, which is subject to issues of transparency, bias, and context dependency.

Future research could adopt empirical approaches to further refine the CSTRM model. Longitudinal studies may examine the evolution of CI–AI configurations over time, while further investigations should explore governance mechanisms, value distribution, digital commons, and the relationship between time, technology, and social organization.

5 Conclusion

This study addressed the following research question: how can the interaction between collective intelligence (CI) and artificial intelligence (AI) contribute to enabling degrowth pathways, and what implications does this have for the community fabric? To clarify the findings, the question was articulated into two sub-

questions: (a) how can CI–AI interaction support degrowth pathways? and (b) what are the implications for community structures?

The analysis shows that the combination of CI and AI can support degrowth pathways when embedded within socio-technical systems oriented toward sufficiency and cooperation. In this perspective, CI functions as the cognitive engine of collective processes, grounded in participation, diversity, and co-creation. AI operates as an infrastructure that supports coordination, knowledge sharing, and the alignment between needs and resources. However, this contribution depends on design and governance choices that ensure transparency, inclusion, and democratic control.

Adopting sufficiency and degrowth as normative principles fosters a transformation of the community fabric. Under these conditions, communities strengthen their capacity for self-organization, co-production, and shared resource management. The role of commons and time emerges as central, as social and political resources that enable cooperation and care practices. Time, in particular, acts as a key enabling condition, making participation and collective action possible.

Such transformation requires a broader paradigm shift supported by institutional and cultural factors. On the one hand, coherent policies and governance arrangements aligned with sufficiency, equity, and participation are needed. On the other hand, these principles must be progressively internalized through processes of social institutionalization, becoming embedded in shared values and practices. In the absence of such orientation, CI–AI interactions risk reinforcing profit-driven dynamics and reproducing inequalities and exclusion.

The main contribution of this paper lies in the proposal of the Cooperative Socio-Technical Regeneration Model (CSTRM), which interprets the CI–AI relationship as a co-evolutionary process guided by degrowth principles. The model highlights the role of time as a social and political resource and of commons as the foundation for alternative configurations beyond market logics.

Ultimately, the issue assumes a political and cultural dimension, linked to the rethinking of development models and socio-technical infrastructures. In this sense, the CSTRM provides an interpretative lens to orient technological innovation within broader socio-ecological transitions.

6 Ethical Declaration

This research did not involve human or animal subjects, nor did it collect any sensitive data. Therefore, approval from an ethics committee was not required.

7 AI Declaration

A limited use of artificial intelligence tools was made exclusively for language support in translation and for the generation of the figures included in the paper. All ideas, structure, and content are original to the authors, who assume full responsibility for them.

Explainable AI as Decision Support in Automated Assessment: An Exploratory Study

Gabriele Creta, Andrea De Mauro
LUISS Guido Carli University, Rome, Italy

Abstract

This paper investigates how rubric-based Explainable Artificial Intelligence (XAI) outputs influence instructor trust and grading behavior in AI-assisted academic assessment. As AI technologies become increasingly integrated into educational evaluation workflows, understanding the cognitive mechanisms through which instructors interact with AI-generated scores is critical for designing effective human–AI collaboration in grading and for the broader governance of knowledge assets in higher education (Khosravi et al., 2022). Two competing hypotheses motivate the study: explanations may either mitigate automation bias by enabling critical evaluation, or amplify it by providing a rationalization for uncritical acceptance of AI recommendations. We present a within-subject pilot experiment in which university-level evaluators (n = 3) assessed 12 short student responses to Computer Science questions under three conditions: (a) AI-only, where only a numerical AI score was displayed; (b) AI + Explanation, where the AI score was accompanied by a four-criterion rubric breakdown and a textual justification; and (c) Anchoring, where evaluators first graded independently and then were exposed to the AI output with an option to revise. AI grading outputs were generated using a Retrieval-Augmented Generation (RAG) pipeline calibrated against three open-access essay scoring datasets (GRE Analytical Writing, DREsS, and ASAP2) and indexed in a FAISS vector store for similarity retrieval. Preliminary results from this pilot are consistent with rubric-based explanations reducing deviation between human and AI grades (mean |delta| = 1.2 vs. 1.9 for AI-only), doubling the observed revision rate in the anchoring condition (67% vs. 33%), and shifting all observed revisions toward the AI score. Qualitative evidence indicates that evaluators cite specific AI observations when revising with explanations but resist adjustment without them. A discrepancy between self-reported and observed AI influence further suggests a metacognitive blind spot consistent with the automation-bias literature. These preliminary findings are consistent with the hypothesis that structured XAI outputs may enhance evaluator reliance on AI grading systems and reshape evaluative judgment through anchoring mechanisms, with implications for the governance of human–AI assessment workflows in higher education.

Keywords: Explainable Artificial Intelligence; Human–AI Decision-Making; Automated Assessment; Decision Support Systems; Knowledge Governance

Paper type: Academic Research Paper

1 Introduction

Assessment represents a core educational practice through which knowledge is validated, academic standards are enforced, and institutional legitimacy is maintained. Grading decisions do not merely certify learning outcomes; they shape perceptions of fairness, influence trust in educational institutions, and contribute to the governance of academic systems. As artificial intelligence technologies become increasingly integrated into educational environments, assessment has emerged as a particularly critical domain where automated tools promise efficiency gains while simultaneously raising significant ethical, organizational, and governance-related concerns (Kasneci et al., 2023).

The rapid diffusion of Large Language Models (LLMs) within educational environments has introduced new challenges for automated assessment practices, including difficulties in understanding how grading decisions are produced, the emergence of potential biases embedded in model outputs, and a reduced visibility of human judgment in evaluative processes that were traditionally grounded in expert interpretation and contextual awareness (Baker and Hawn, 2021). As a result, educators may develop reduced trust in automated grading systems or, conversely, rely on them inappropriately—either by delegating evaluative responsibility uncritically or by rejecting potentially useful tools due to a lack of interpretability. Both dynamics risk compromising the effective and responsible integration of AI-based assessment systems in educational practice.

Explainable AI (XAI) offers a potential mechanism for promoting calibrated trust rather than blind reliance. In the context of AI-assisted assessment, XAI encompasses techniques that make AI grading decisions interpretable to human evaluators, from feature importance scores to natural language explanations of the reasoning behind an AI grade. Arrieta et al. (2020) provide a comprehensive taxonomy of XAI approaches, emphasizing that the goal of explainability is not complete access to a model's internal reasoning processes, but rather the ability to produce justifications that are understandable and verifiable by domain experts. In educational settings specifically, Khosravi et al. (2022) argue that explainability is essential for maintaining

accountability and trust when AI systems are deployed in contexts where automated decisions have direct consequences for individuals.

However, a parallel concern arises from cognitive psychology. Research on the anchoring-and-adjustment heuristic has established that individuals are susceptible to anchoring effects when making numerical judgments under uncertainty (Tversky and Kahneman, 1974). In the context of AI-assisted grading, an AI-generated score may serve as an anchor that systematically biases the instructor's final grade toward the AI suggestion, regardless of whether the AI assessment is accurate. This phenomenon is related to automation bias, where human decision-makers over-rely on automated systems without critically evaluating their outputs (Parasuraman and Riley, 1997). Explanations may either mitigate this bias by enabling critical evaluation or amplify it by providing a rationalization for uncritical acceptance of AI recommendations (Bansal et al., 2021).

This study addresses these competing hypotheses through a controlled within-subject experiment. Adopting a human-centered perspective, we conceptualize automated grading not as a replacement for educators' judgment, but as a decision-support mechanism integrated into existing assessment practices. In line with a human-centered interpretation of XAI, explainability is operationalized as the ability to justify scoring decisions through explicit, rubric-based criteria that are understandable and verifiable by educators. Specifically, we investigate two research questions:

- ***RQ1:*** *Does the presence of rubric-based XAI explanations increase evaluator reliance on AI grades compared to score-only output?*
- ***RQ2:*** *Do XAI explanations amplify or mitigate anchoring effects when evaluators are exposed to AI grades after forming their own initial assessment?*

2 Theoretical Background

2.1 Automated assessment and AI in education

Automated essay scoring (AES) systems have evolved significantly since their introduction in the 1960s. Contemporary systems leverage deep learning architectures and large language models to evaluate student writing across multiple dimensions including content accuracy, argumentation quality, and language proficiency (Ke and Ng, 2019). Despite improvements in accuracy, adoption in summative assessment contexts remains limited, largely due to instructor skepticism about the ability of AI to capture the nuanced qualitative judgments that characterize expert evaluation (Hockly, 2019). Recent advances in generative AI have introduced new capabilities for rubric-based grading that go beyond holistic scoring: LLMs can generate structured evaluations aligned with predefined criteria, producing not only scores but also detailed justifications that approximate the format of human feedback (Mizumoto and Eguchi, 2023). Yoo et al. (2025) demonstrate the viability of rubric-based essay evaluation using structured datasets such as DREsS, confirming that scoring rubrics can serve as structured knowledge representations that formalize evaluative criteria and make assessment logic explicit.

2.2 Explainable AI, trust, and automation bias

The field of XAI has emerged in response to concerns about the opacity of machine learning models and the need for transparency in high-stakes decision-making contexts. Arrieta et al. (2020) provide a foundational survey of XAI concepts and taxonomies, categorizing approaches by scope, methodology, and explanation type. In educational contexts specifically, Khosravi et al. (2022) identify explainability as a critical enabler for the responsible adoption of AI, arguing that without interpretable outputs, AI-driven educational systems risk undermining both pedagogical objectives and institutional trust.

Trust calibration—the alignment between a user's trust in an AI system and the system's actual reliability—is a central goal of XAI design (Lee and See, 2004). Miscalibrated trust manifests as either under-reliance (rejecting accurate AI outputs) or over-reliance (accepting inaccurate outputs without scrutiny). Explanations have been theorized to promote appropriate reliance by enabling users to evaluate the quality of AI reasoning on a case-by-case basis (Bansal et al., 2021). However, empirical evidence remains mixed: Vasconcelos et al. (2023) find that while explanations can reduce overreliance in some decision-making contexts, they may also increase automation bias by providing a rationalization for uncritical acceptance. Parasuraman and Manzey (2010) provide a comprehensive integration of the automation bias literature, demonstrating that the gap between perceived and actual reliance on automated systems is a robust and persistent phenomenon across professional domains.

2.3 Anchoring effects in evaluative judgment

The anchoring-and-adjustment heuristic, first described by Tversky and Kahneman (1974), refers to the tendency for individuals to insufficiently adjust their estimates from an initial reference value. In assessment contexts, exposure to prior evaluations or suggested scores has been shown to systematically influence subsequent judgments (Mussweiler and Strack, 1999). The introduction of AI-generated grades creates a novel anchoring scenario in which the anchor is produced by an automated system rather than a human peer, raising questions about whether the source of the anchor modulates its influence on evaluator behavior. Few studies have examined anchoring in the specific context of AI-assisted educational assessment, and fewer still have investigated how the presence or absence of AI explanations moderates anchoring strength. This study addresses this gap directly.

3 Research Design and Methodology

3.1 Experimental design

We employed a within-subject experimental design in which each participant evaluated 12 short student responses under three conditions. The within-subject approach controls for individual differences in grading severity, as each participant serves as their own control. The three conditions were: (a) AI-first AI-only (4 tasks), where participants viewed the student response alongside an AI-generated total score with no further explanation; (b) AI-first AI + Explanation (4 tasks), where participants viewed the response alongside the AI score, a criterion-level breakdown, and a textual explanation highlighting key strengths and weaknesses; and (c) Anchoring (4 tasks, 2 with score only and 2 with full explanation), where participants first assigned an initial grade without AI input, then on a subsequent page were shown the AI output and given the option to revise with a brief justification.

3.2 Stimuli: student responses

Twelve short written responses (50–150 words) to fundamental Computer Science questions were collected from undergraduate students in the final year of a Bachelor's degree program. Topics covered core CS concepts including data structures, algorithm complexity, databases, programming paradigms, version control, machine learning, neural networks, and data preprocessing. Responses were reviewed for authenticity; five responses exhibiting characteristics of AI generation (e.g., formulaic analogies, perfectly balanced paragraph structures) were rewritten to match natural student writing style, including realistic imperfections such as minor spelling errors, informal phrasing, and uneven argumentation depth.

3.3 AI grading pipeline

AI grades were generated using a Retrieval-Augmented Generation (RAG) pipeline designed to produce calibrated, rubric-aligned assessment outputs. Three open-access essay scoring datasets were ingested as calibration sources: the GRE Analytical Writing scoring guide with sample essays and reader commentaries at each level (0–6); the DREsS dataset comprising approximately 29,000 student essays scored on three analytic dimensions (Yoo et al., 2025); and the ASAP2 dataset containing approximately 24,000 student essays with holistic scores (1–6). Source texts were segmented into overlapping chunks, embedded using a sentence-level transformer model (all-MiniLM-L6-v2), and indexed in a FAISS vector store for cosine-similarity retrieval. For each student response, the system retrieved the most semantically relevant reference excerpts and injected them into the grading prompt. The Large Language Model used for grading was Claude Opus 4 (Anthropic), operating at low temperature (0.1) to ensure deterministic outputs. All outputs were frozen prior to participant exposure.

3.4 Rubric design

Table 1. Analytic rubric structure

Criterion	Scale	Description
Completeness / Coverage	0–8	Addresses all parts of the question; covers key concepts
Correctness / Conceptual Accuracy	0–8	Factual accuracy; appropriate use of terminology
Reasoning & Structure	0–7	Logical coherence; argument development; organization
Clarity of Language	0–7	Clarity; grammar; readability; conciseness
Total	0–30	Sum of all four criteria

Scoring rubrics were treated as structured knowledge representations that formalize evaluative criteria and make assessment logic explicit. Prior research has shown that rubric-based assessment supports transparency, consistency, and pedagogical effectiveness in grading practices (Yoo et al., 2025). The four-criterion rubric was designed to evaluate both content mastery (Completeness, Correctness) and communicative competence (Reasoning, Language), reflecting the multi-dimensional nature of academic assessment.

3.5 Participants and procedure

Three university-level evaluators participated in the study: two Researchers/Assistant Professors specializing in Artificial Intelligence (10 and 5 years of experience respectively) and one Associate Professor in Data Science (2 years of experience). All held teaching and assessment responsibilities at the university level and were familiar with the Computer Science topics covered. The experiment was administered through a Qualtrics online survey. After providing demographic information, participants completed the 12 evaluation tasks in randomized order. Backward navigation was disabled to prevent modification of initial grades after AI exposure. The survey concluded with a seven-item trust and perception questionnaire (7-point Likert scale). Completion time ranged from 9 to 25 minutes (mean: 17 minutes).

4 Results

4.1 AI-first conditions: effect of explanations on reliance

Table 2. Human grades versus AI scores in AI-first conditions

Condition	Topic	AI	P1	P2	P3	M	Δ
AI-only	Train/Val/Test	25	24	25	22	23.7	−1.3
AI-only	Struct. vs Unstruct.	28	28	27	29	28.0	0.0
AI-only	Relational vs NoSQL	24	25	25	23	24.3	+0.3
AI-only	API	17	25	22	18	21.7	+4.7
AI+Expl	Compiled vs Interp.	26	26	25	24	25.0	−1.0
AI+Expl	Version Control	24	26	24	24	24.7	+0.7
AI+Expl	Overfitting	28	30	27	27	28.0	0.0
AI+Expl	Data Normalization	24	28	24	25	25.7	+1.7

The mean absolute deviation from the AI score was 1.92 points in the AI-only condition and 1.17 points in the AI + Explanation condition, a pattern consistent with rubric-based explanations being associated with greater evaluator reliance on AI grades in this pilot sample. The effect is particularly visible in cases where the AI and human assessments diverge substantially: for the API question (AI score: 17), all three evaluators assigned markedly higher grades in both conditions (18–25), but the deviation was larger in the AI-only condition (mean delta: +4.7) where evaluators lacked access to the AI's reasoning about the response's circularity and superficiality.

4.2 Anchoring analysis: grade revision after AI exposure

Table 3. Anchoring effect: initial grades, AI scores, and revisions

Cond.	Topic	AI	P	Init.	Rev.	Adj.	Dir.
Only	Big O	20	P1	24	23	−1	Toward AI
Only	Big O	20	P2	24	—	0	—
Only	Big O	20	P3	16	18	+2	Toward AI
Only	Neural Net.	22	P1	27	—	0	—
Only	Neural Net.	22	P2	10	—	0	—
Only	Neural Net.	22	P3	22	—	0	—
Expl	API	17	P1	26	24	−2	Toward AI
Expl	API	17	P2	22	20	−2	Toward AI
Expl	API	17	P3	22	21	−1	Toward AI
Expl	Sup./Unsup.	28	P1	30	29	−1	Toward AI
Expl	Sup./Unsup.	28	P2	27	—	0	—
Expl	Sup./Unsup.	28	P3	29	—	0	—

In the AI-only anchoring condition, 2 out of 6 evaluator-task pairs (33%) resulted in grade revision. In the AI + Explanation condition, 4 out of 6 (67%) resulted in revision. All six observed revisions moved in the direction

of the AI score, confirming the presence of an anchoring effect consistent with the predictions of Tversky and Kahneman (1974). The mean adjustment magnitude was 1.5 points for AI + Explanation revisions compared to 0.5 for AI-only, suggesting that explanations not only increase the likelihood of revision but also produce larger adjustments toward the AI anchor.

4.3 Qualitative evidence: the role of explanations in revision reasoning

Analysis of open-ended revision justifications reveals a qualitative difference in reasoning between conditions. In the AI + Explanation condition, evaluators referenced specific observations from the AI explanation to justify their revisions. Participant 1 revised the API question from 26 to 24, stating that the AI "made me think about the shallowness and the lack of key aspects." Participant 2 revised the same question from 22 to 20, noting that "the explanation suggested additional limitations, to which I agree." For the supervised/unsupervised learning question, Participant 1 revised from 30 to 29, acknowledging that "the Netflix example is hybrid, not purely unsupervised."

In the absence of explanations, evaluators expressed explicit resistance to adjustment. Participant 1 stated: "Without explanation I just stick to my grade," providing direct evidence that rubric-based explanations serve as a cognitive mechanism enabling evaluators to identify specific grounds for revision, whereas a numerical score alone is insufficient to overcome confirmation of one's own judgment. This finding is consistent with Bansal et al.'s (2021) observation that explanations enable complementary team performance by providing decision-makers with information they can independently verify.

4.4 Trust and perception questionnaire

Table 4. Trust and perception questionnaire (1–7 Likert scale)

Statement	P1	P2	P3	M
AI grade was accurate and reliable	5	5	5	5.0
Confident in my final grade	6	6	6	6.0
AI influenced my evaluation	5	3	2	3.3
AI made evaluation faster	6	5	5	5.3
Understood AI grading logic	4	7	5	5.3
AI makes evaluation fairer	7	7	4	6.0
Would use AI grading regularly	7	7	3	5.7

The most notable finding is the discrepancy between self-reported and observed AI influence. Evaluators reported that the AI had limited influence on their evaluation (mean: 3.3/7, below the scale midpoint), yet the behavioral data show that 50% of all anchoring task pairs resulted in grade revision, with 100% of revisions moving toward the AI score. This pattern is consistent with the automation bias literature documenting a gap between perceived and actual reliance on automated systems (Parasuraman and Manzey, 2010). At the same time, evaluators expressed high confidence in their final grades (6.0/7) and strong agreement that AI makes evaluation fairer (6.0/7), suggesting that they value AI as a decision-support tool even while underestimating its influence on their own judgment.

5 Discussion

The results of this exploratory study provide preliminary evidence addressing both research questions and contribute to the emerging literature on human–AI collaboration in educational assessment.

Regarding RQ1, the AI + Explanation condition produced closer alignment between human and AI grades than the AI-only condition (mean |delta| = 1.17 vs. 1.92), a pattern consistent with rubric-based XAI outputs being associated with greater evaluator reliance on AI assessments. This finding is consistent with the trust calibration framework proposed by Lee and See (2004), which predicts that transparency in AI decision-making facilitates appropriate reliance. It also aligns with Khosravi et al.'s (2022) argument that explainability is essential for productive human–AI collaboration in educational contexts: structured explanations appear to provide the interpretive scaffolding that enables evaluators to engage meaningfully with AI outputs rather than simply accepting or rejecting them.

Regarding RQ2, the anchoring analysis suggests that, in this pilot sample, explanations may amplify rather than mitigate anchoring effects. Evaluators were twice as likely to revise their initial grade when presented with an explanation compared to a score alone, and all revisions moved toward the AI score. This finding challenges the optimistic view that XAI necessarily promotes critical evaluation. Instead, structured explanations may function as persuasive arguments that facilitate acceptance of the AI perspective, particularly when the

explanation identifies specific weaknesses that the evaluator had not independently considered. This interpretation is consistent with Vasconcelos et al.'s (2023) finding that explanations can increase overreliance in certain decision contexts.

The qualitative data provide a mechanistic account: when explanations are present, evaluators engage in a form of deliberative anchoring, evaluating the plausibility of specific AI observations and adjusting when they find the reasoning convincing. When explanations are absent, evaluators lack a cognitive basis for adjustment and default to their initial judgment. The trust questionnaire reveals an important metacognitive blind spot: evaluators perceive AI as accurate and fair but underestimate its influence, suggesting that AI-assisted grading may introduce systematic biases that evaluators are not consciously aware of. This has significant implications for the governance of AI-enabled assessment systems, aligning with broader concerns about accountability and transparency in algorithmic decision-making (Baker and Hawn, 2021).

5.1 Implications for practice

These findings carry practical implications for the design of AI-assisted assessment systems. First, structured explanations should be considered a design requirement: they meaningfully increase evaluator engagement with AI outputs and enable more informed grading decisions. Second, institutions deploying AI grading tools should implement awareness training to help evaluators recognize anchoring effects and automation bias. Third, assessment workflows should consider the sequencing of human and AI evaluation carefully, as the order of exposure fundamentally shapes the interaction between human judgment and AI suggestion. Finally, rubric-based explanations may serve a dual function as both a transparency mechanism and a calibration tool, helping to align grading standards across multiple evaluators.

6 Future Research Directions

As an exploratory pilot, this study opens several promising avenues for further investigation. The sample size (n = 3) is consistent with the proof-of-concept nature of this work: the within-subject design provides multiple observations per participant and supports the identification of behavioral patterns, while inferential statistical analysis is reserved for a planned full-scale extension with a substantially larger and more diverse evaluator pool. A second extension concerns disciplinary scope: all participants specialized in AI or Data Science, and replication with evaluators from non-technical disciplines (e.g., humanities, social sciences) will help establish whether the observed patterns generalize across academic fields. Third, the present pilot focused on short-answer responses in Computer Science; subsequent work will examine longer-form assessments and a wider range of disciplines, where rubric structure and evaluative complexity differ substantially. Fourth, the AI pipeline employed a single model and configuration, and future iterations will benchmark alternative LLMs and retrieval strategies to assess the robustness of the observed effects. Finally, while this pilot intentionally compared AI-only and AI + Explanation conditions, a follow-up design will incorporate a pure human-only baseline to quantify the marginal contribution of AI assistance to overall assessment quality. Taken together, these directions define a structured research agenda that builds directly on the present findings.

7 Conclusion

This study provides preliminary evidence that rubric-based Explainable AI outputs may meaningfully shape evaluator behavior in AI-assisted academic grading. In this pilot sample, the presence of structured explanations was associated with reduced deviation between human and AI grades, a higher likelihood of grade revision after AI exposure, and revisions that consistently moved toward the AI score. Qualitative evidence further suggests that explanations provide the cognitive scaffolding that enables evaluators to engage critically with AI reasoning, while the absence of explanations leads to resistance to adjustment. These findings contribute to the broader discourse on human–AI collaboration and knowledge governance in educational organizations, supporting the view that explainability is not an intrinsic property of the model alone, but rather an emergent characteristic shaped by the provision of contextual information, evaluative guidance, and structured justification. As AI tools become increasingly prevalent in educational assessment, designing systems that promote calibrated trust rather than uncritical adoption will be essential for preserving the integrity and fairness of academic evaluation.

8 Ethics declaration

This research involved voluntary participation in an anonymous online survey. No personal identifying information was collected beyond professional role and years of experience. Participation was voluntary and participants could withdraw at any time.

9 AI declaration

AI tools (Claude, Anthropic) were used in the following capacities: (1) as the grading engine within the RAG pipeline to generate AI assessment outputs used as experimental stimuli; (2) as an editorial aid for manuscript preparation. All substantive research design, data collection, analysis, and interpretation were conducted by the authors.

Appendix A. Example of AI grading output (AI + Explanation condition)

The following excerpt illustrates the structure of the AI grading output presented to evaluators in the AI + Explanation condition. It comprises (i) the question prompt, (ii) the verbatim student response, (iii) the AI-suggested score with rubric breakdown, and (iv) the textual explanation generated by the RAG pipeline.

Question (Q25). Explain what data normalization means in the context of data preprocessing. Why is it important before applying machine learning algorithms?

Student response. "Data normalization, used for preprocessing, is a way to convert numerical value scale of a dataset into a standard interval typically between 0 and 1. It ensures that all the features contribute equally to the model and that very large nominal value doesn't influence improperly the training phase. It is used to accelerate the training because algorithms can find optimal solution faster."

AI suggested score: 24/30. Completeness: 6/8 | Correctness: 7/8 | Reasoning: 5/7 | Language: 6/7.

Explanation. The answer covers the core definition (scaling to a standard interval) and two important reasons for normalization (equal feature contribution, faster training convergence), addressing the main parts of the question. Content is accurate, though "nominal value" appears to be a misuse — the student likely means "numerical value" or is confusing "nominal" (categorical) with "large-magnitude." The 0-to-1 range is correct

for min-max normalization but the answer doesn't distinguish it from standardization (z-score), which would strengthen completeness. The answer is concise and functional but could develop the reasoning further — for instance, explaining which algorithms are particularly sensitive to feature scaling (e.g., KNN, gradient descent-based methods) versus which are not (e.g., tree-based methods).

How Healthcare Artificial Intelligence Startups Impact Clinical Processes in the Healthcare Ecosystem

Nunzia Carbonara, Davide De Vita, Umberto Panniello, Elisabetta Vurchio
Polytechnic University of Bari, Italy

Abstract

Artificial Intelligence (AI) is increasingly recognized as a transformative force in healthcare, with the potential to enhance clinical efficiency, reduce costs, and enable more personalized care pathways. In parallel, AI has stimulated the emergence of numerous startups developing innovative healthcare solutions. However, existing research has largely focused on their technological features and business models, overlooking their broader systemic role. AI startups are entering healthcare ecosystems as new actors, establishing novel relationships with providers, patients, regulators, and technology suppliers, and potentially reshaping structures, coordination mechanisms, and value creation processes. This study addresses this gap by examining how European healthcare AI startups contribute to the redesign of clinical processes and the reconfiguration of value creation within healthcare ecosystems. Building on the ecosystem-as-structure perspective and a role-based view of ecosystem participation, healthcare is conceptualized as a complex system characterized by interdependencies among heterogeneous actors. Within this framework, AI startups are not merely technology providers but actors capable of altering activity flows, redistributing roles, and generating new connections among stakeholders. Adopting a service and ecosystem perspective, the study emphasizes that value does not reside in technological solutions per se but emerges through their use and integration within specific contexts. AI solutions may generate value for patients—through improved accessibility, personalization, and continuity of care—and for providers—through enhanced decision-making and efficiency. At the same time, they may also produce value destruction when they create workflow frictions, usability issues, or misalignment with clinical routines. Focusing on the European context, characterized by strong regulation and data governance constraints, the study employs a mixed-method approach. First, a large dataset of healthcare AI startups is analyzed using a hybrid natural language processing technique to classify firms into core clinical processes (diagnosis, treatment, monitoring/follow-up) and support processes (drug discovery, administrative support, and healthtech infrastructure). Second, user-generated reviews are examined to assess perceived value creation and value destruction across clinical phases and stakeholder groups. Preliminary findings suggest that AI startups play a dual role within healthcare ecosystems, intervening both directly in clinical activities and indirectly through enabling infrastructures and support functions. Their impact extends beyond isolated applications, depending on how they integrate into existing workflows and reshape interactions among ecosystem actors.

Keywords: Artificial Intelligence, Startup, Healthcare Ecosystem, Clinical Processes, Value Creation, Value Destruction.

Paper type: Academic Research Paper

1 Introduction

The impact of Artificial Intelligence (AI) on healthcare systems has been widely discussed in recent literature, with particular attention to its potential to improve clinical efficiency, reduce costs, and enable more personalized care pathways (Esteva et al., 2019; Davenport and Kalakota, 2019). Beyond transforming established practices, AI has catalysed the rise of startups developing AI-based healthcare solutions (Garbuio and Lin, 2019). While previous research on AI startups has mainly focused on their business model archetypes and technological innovations, it has often overlooked their broader systemic implications. In particular, by forging novel relationships with incumbent providers, patients, regulators, and technology suppliers, AI startups enter healthcare ecosystems as new actors that may reconfigure existing structures and dynamics (Chen and Décary, 2020; Wessel et al., 2021). Depending on the solutions they provide and the ties they cultivate, these ventures may act as complementors or emerge as orchestrators capable of reshaping coordination and control (Cozzolino and Geiger, 2024). Despite their growing importance, less attention has been devoted to the role of AI startups as ecosystem actors and to their effects on clinical processes and value creation mechanisms. This study addresses this gap by investigating how healthcare AI startups contribute to the redesign of clinical processes and to the reconfiguration of value creation within healthcare ecosystems. Building on the ecosystem-as-structure perspective proposed by Adner (2017) and the role-based taxonomy of Dedehayir et al. (2018), this research conceptualizes healthcare as a complex ecosystem characterized by multilateral interdependencies among heterogeneous actors, including providers, regulators, payers, technology suppliers, and patients. Within this context, AI startups are interpreted not merely as technology vendors, but as actors that may alter activity flows, redistribute roles, and create new connections among stakeholders such as clinicians, patients, healthcare

administrators, insurance companies, and public agencies. At the same time, the effects of AI startups cannot be inferred only from their technological features or self-described value propositions. From a service and ecosystem perspective, value is not embedded in a solution itself, but emerges through use, interaction, and context (Vargo and Lusch, 2008; Grönroos and Voima, 2013). For patients, value may involve accessibility, reassurance, understanding, personalization, or continuity of care (Hennrich et al., 2024). For providers, value may involve diagnostic support, workflow efficiency, reduced burden, and improved decision-making (Garbuio and Lin, 2019). However, AI-based solutions may also generate value destruction when they introduce usability problems, workflow frictions, uncertainty, dissatisfaction, or misalignment with clinical routines (Plé and Chumpitaz Cáceres, 2010; Echeverri and Skålén, 2011). Understanding the impact of healthcare AI startups therefore requires considering both where they are positioned in the ecosystem and how their solutions are experienced by key stakeholders. The study focuses on European healthcare AI startups, a particularly relevant context because European healthcare systems are characterized by strong institutional regulation, data governance constraints, public-sector involvement, and heterogeneous national healthcare arrangements. These conditions make Europe an appropriate empirical setting for studying how AI startups enter highly regulated ecosystems and how their solutions become embedded in existing clinical and organizational routines.

Accordingly, the research question guiding this study is:

How do European healthcare AI startups modify clinical processes and create value within healthcare ecosystems?

To address this question, we first examined a sample of healthcare AI startups in order to understand what these firms actually do and where their solutions are positioned within the healthcare value chain. Rather than approaching healthcare AI startups as a homogeneous category, we analysed their value propositions, descriptions, and application domains to identify the main functions through which they contribute to the healthcare ecosystem. This preliminary mapping showed that startups tend to cluster around a limited number of recurring process domains. Consistently with prior literature on AI in healthcare, we characterized the ecosystem around two broad groups of activities: core clinical processes and support processes (Davenport and Kalakota, 2019; He et al., 2019). The first group includes startups directly involved in the production of clinical value for patients, namely Diagnosis, Treatment, and Monitoring/Follow-up. The second group includes startups that support, enable, or accelerate healthcare activities without necessarily intervening directly in patient-facing clinical encounters, namely Drug Discovery, Clinical Administrative Support, and HealthTech Infrastructure. This distinction provides the basis for analysing how different types of healthcare AI startups modify clinical processes and create value for patients, providers, and other ecosystem actors. Empirically, the study was conducted in two stages. First, a population of European healthcare AI startups was identified through Crunchbase and used to construct a functional map of the ecosystem. A selected sample of 100 startups was then analysed in depth through a hybrid natural language processing procedure combining semantic embeddings and anchor-based lexical signals. This procedure enabled the classification of each startup according to its dominant positioning across the six process categories. Second, the process-level impact of healthcare AI startups was inferred from textual comments and reviews produced by users, including both patients and care providers. This step allowed the analysis to move beyond startups' self-descriptions and examine how their solutions are perceived in practice. Reviews were cleaned, normalized, translated into English where necessary, and segmented into sentence-level units. Each sentence was then associated with one or more clinical phases — Diagnosis, Treatment, and Monitoring/Follow-up — using a hybrid approach based on keywords and semantic similarity. For each active phase, the analysis identified whether the comment expressed value creation, value destruction, or a neutral effect, and whether this value concerned patients or providers. This methodological design allows the study to connect three levels of analysis: the functional positioning of AI startups within the healthcare ecosystem, their intervention in specific clinical or support processes, and the perceived value effects experienced by key stakeholders. In this paper, preliminary findings analysing the comments related to only a sample of AI Diagnostic start-ups are shown.

A key preliminary finding is that healthcare AI startups contribute to the ecosystem through a dual functional positioning. They intervene directly in core clinical processes, especially diagnosis, treatment, and monitoring/follow-up, while also enabling clinical value creation through drug discovery, administrative support, and HealthTech infrastructure. This suggests that their role cannot be understood only through isolated technological applications but depends on the functions they perform within the healthcare value chain and on how they connect patients, providers, infrastructures, and other ecosystem actors. The review-based analysis further shows that diagnostic AI startups generate perceived value for both providers and patients, particularly by supporting clinical interpretation, decision-making, and patient understanding. However, the presence of value destruction indicates that their effects are not uniformly positive and depend on workflow integration, user experience, and alignment with clinical routines. Moreover, although the analysis focuses on diagnostic

startups, user comments suggest that their impact may extend to downstream processes such as treatment and monitoring/follow-up.

The study contributes to the literature in three ways. First, it advances an ecosystem-level understanding of healthcare AI startups, showing that their impact depends on the roles they play, the processes they address, and the relationships they reshape (Adner, 2017; Dedehayir et al., 2018; Jacobides et al., 2018). Second, it provides an empirically grounded taxonomy distinguishing between core clinical and support processes. Third, it assesses the perceived effects of AI startups in terms of value creation and value destruction, contributing to service and ecosystem research on value-in-use and value co-destruction (Vargo and Lusch, 2008; Grönroos and Voima, 2013; Plé and Chumpitaz Cáceres, 2010; Echeverri and Skålén, 2011). From a managerial and policy perspective, healthcare AI startups should be evaluated not only for technological performance, but also for workflow fit, stakeholder experience, interoperability, and their effects on adjacent clinical processes.

2 Methodology

We adopted a computationally assisted mixed-method design to link the functional positioning of healthcare AI startups with their perceived impact on clinical value creation. The analysis was conducted in two sequential stages. The first stage aimed to construct and map the functional structure of the European healthcare AI startup ecosystem. The second stage focused on assessing how AI-based solutions are perceived by users, distinguishing between value creation and value destruction across different clinical phases and stakeholder groups. The initial population was retrieved from Crunchbase and included approximately 2,500 startups headquartered in Europe and operating at the intersection of healthcare and artificial intelligence (Dalle et al., 2017). To ensure consistency with the scope of the study, we retained firms whose industry tags, descriptions, or full descriptions indicated a clear connection with healthcare, medical technologies, digital health, biotechnology, clinical software, medical devices, or related HealthTech domains. In addition, the retained firms had to show evidence of AI-related activity, including artificial intelligence, machine learning, data analytics, automation, algorithmic decision support, or comparable data-driven capabilities. Records lacking sufficient textual information to assess either healthcare relevance or AI-related activity were excluded from the in-depth classification stage. The resulting dataset contained European healthcare AI startups described through both structured and unstructured textual variables, including Organization Name, Industries, Description, and Full Description. These fields were used to infer what each startup does and where its solution is positioned within the healthcare value chain. Before the analysis, textual data were cleaned and normalized. Text was converted to lowercase, recurrent acronyms such as “EHR” were expanded, expressions such as “B2B” were harmonized, irrelevant characters were removed, and spacing was standardized. For each startup, we then constructed three textual representations: a complete representation combining industries, description, and full description; a description-based representation emphasizing the firm’s main value proposition; and an industry-only representation capturing sectoral cues. This procedure allowed us to prioritize substantive narrative information while retaining the classification value of industry labels. The functional classification relied on a hybrid natural language processing procedure combining semantic similarity and lexical anchoring (Grimmer and Stewart, 2013; Nelson, 2020). First, the textual representations of startups were transformed into vector embeddings using the BAAI/bge-base-en-v1.5 model implemented through Sentence Transformers (Reimers and Gurevych, 2019; Xiao et al., 2023). Second, the semantic proximity between each startup and each predefined functional category was calculated using cosine similarity. The classification framework included six functional categories organized into two macro-groups. The first macro-group, Clinical Process, comprised startups directly involved in clinical value creation: Diagnostics, Treatment, and Monitoring/Follow-up. The second macro-group, Support Process, comprised startups that support, enable, or accelerate healthcare activities without necessarily intervening directly in patient-facing clinical encounters: Drug Discovery, HealthTech Infrastructure, and Administrative Process (Davenport and Kalakota, 2019; He et al., 2019; Vamathevan et al., 2019). For each category, we developed a reference semantic representation, which was also transformed into an embedding. The final classification combined the embedding-based similarity score with an anchor-based lexical component based on hard, soft, and negative keyword signals. Hard signals captured highly specific terms associated with a category; soft signals captured broader but still relevant semantic cues; negative signals reduced the likelihood of misclassification when terms appeared in unrelated contexts. These components were integrated into a final score for each category, allowing each startup to be assigned to its dominant functional position (Sebastiani, 2002). In the second stage, we analysed textual user comments and reviews to infer the perceived impact of healthcare AI startups on clinical processes. This step focused on three core clinical phases: Diagnosis, Treatment, and Monitoring/Follow-up. Reviews were first cleaned and normalized, translated into English where necessary to ensure linguistic comparability, and segmented into sentence-level units. Each sentence was then

classified according to the clinical phase or phases to which it referred. Phase identification relied on a hybrid procedure combining phase-specific keywords with semantic similarity based on embeddings. Since a sentence could refer to more than one clinical activity, the model allowed multiple phases to be activated simultaneously.

For each activated clinical phase, we assessed whether the sentence expressed value creation, value destruction, or a neutral effect. We define value creation as the perceived improvement in the actor's ability to accomplish a relevant clinical or care-related task, consistent with service-dominant and service-logic perspectives that conceptualize value as value-in-use and value-in-context rather than as an intrinsic property of the provider's offering (Vargo and Lusch, 2008; Grönroos and Voima, 2013). As a result, value creation captured perceived benefits such as improved efficiency, better clinical support, smoother processes, enhanced user experience, or increased accessibility. Conversely, we define value destruction as the negative counterpart of value creation, that is, as a perceived deterioration in an actor's ability to accomplish a relevant clinical or care-related task. This interpretation follows Schulz et al. (2021), who conceptualize value co-creation and value co-destruction as "two sides of the same coin", with value co-destruction understood as the antonym of value co-creation. This approach is consistent with earlier work defining value co-destruction as an interactional process that results in a decline in at least one actor's well-being (Plé and Chumpitaz Cáceres, 2010), as well as later reviews that frame value co-creation and co-destruction as alternative outcomes of interactive value formation (Echeverri and Skålén, 2021). As a result, value destruction captured negative effects such as problems, delays, inefficiencies, dissatisfaction, usability issues, or workflow frictions. The analysis also identified the stakeholder to whom the value effect referred, distinguishing between providers and patients. As in the functional classification stage, this assessment combined lexical signals and semantic embeddings. When a sentence activated a clinical phase but did not contain clear signals of either value creation or value destruction, it was classified as neutral.

3 Results

The initial query on Crunchbase returned 2.499 European startups active in the field of Healthcare AI. A first look at their geographical distribution (Figs. 1–2) reveals a strong concentration in high-GDP countries: more than 27% of firms are headquartered in the United Kingdom (676 start-ups, with 437 only in London), followed—at a considerable distance—by Germany (273 start-ups, 10.9%) and France (250 firms, 10.0%). Together, these three countries account for almost 48% of all startups. The remaining landscape is distributed across Spain and Switzerland, both with 155 firms (6.2% each), Italy and the Netherlands, both with 118 firms (4.7% each), and a long tail of smaller national ecosystems. This captures a core Western European concentration, although the broader dataset also highlights a more visible presence of Mediterranean, Nordic, Central and Eastern European countries.

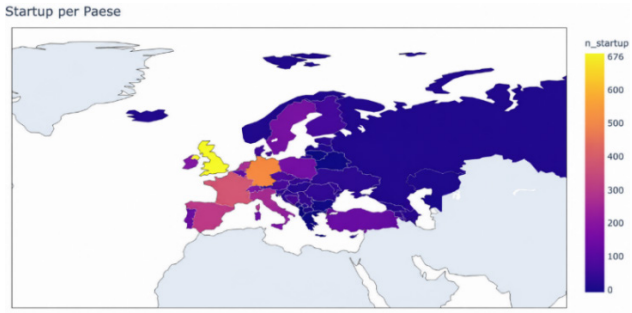

Figure 1: Distribution of European AI startups (Heat map) - Source: authors' elaboration based on Crunchbase data.

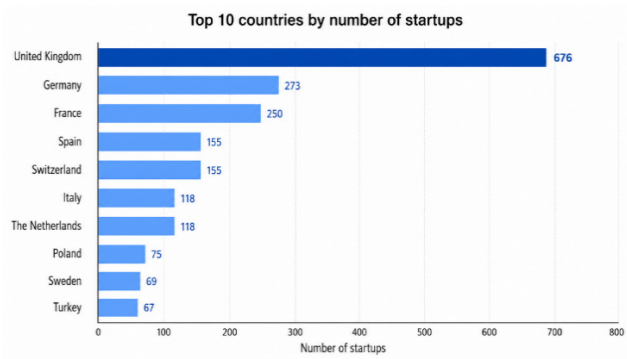

Figure 2: Distribution of European AI startups - Source: authors' elaboration based on Crunchbase data.

As for the founding date, available for 2,338 startups, the median founding year is 2019, and around 46% of firms with available data were founded between 2020 and 2026. This reinforces the idea that healthcare AI in Europe is a young and rapidly expanding entrepreneurial field. From an organizational perspective, the sample is dominated by small ventures. Out of 2,399 startups with available employee data, 1,321 firms (55.1%) employ between 1 and 10 people, while another 850 firms (35.4%) fall within the 11–50 employees range. Overall, more than 90% of firms with available data have fewer than 50 employees. Only 39 startups exceed 250 employees, equal to 1.6% of the employee-available sample. This confirms that the European healthcare AI landscape is mostly composed of early-stage or small-scale ventures rather than large consolidated companies.

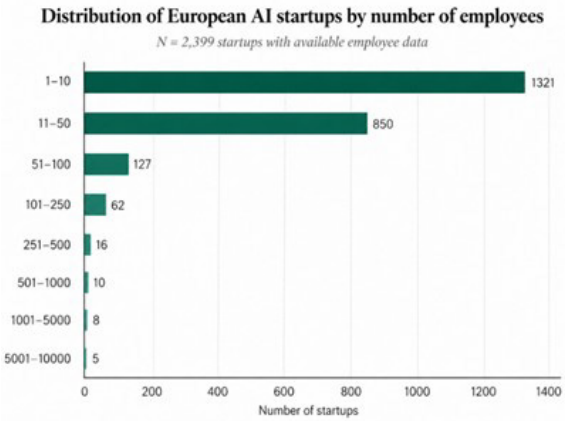

Figure 3: Distribution of European AI startups by number of employees – Source: authors' elaboration based on Crunchbase data.

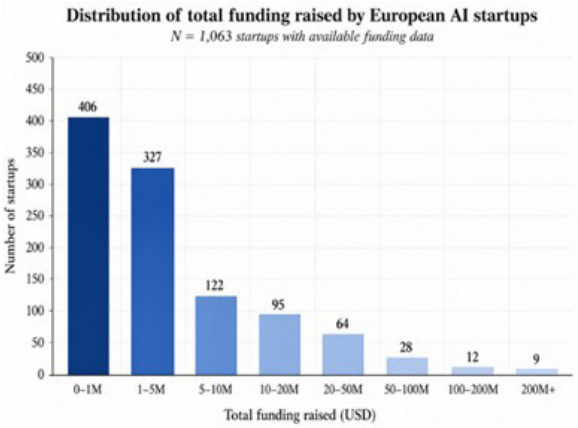

Figure 4: Distribution of total funding raised by European startups – Source: authors' elaboration based on Crunchbase data.

Given the heterogeneity of the startups identified, revenue remains a useful proxy for economic maturity and market traction. In the dataset, 1,219 records report an estimated revenue range. The majority of these firms, 706 startups (57.9%), fall within the $1M–$10M revenue bracket, while 412 firms (33.8%) report revenues below $1M. Only 80 firms (6.6%) are positioned in the $10M–$50M range, and very few exceed this threshold. This suggests that most healthcare AI startups have reached some degree of monetization, but remain far from the revenue scale typically associated with mature medium-sized enterprises. Total funding raised shows a highly skewed distribution. Funding data are available for 1,063 startups, which together account for approximately $12.83 billion in total funding. However, the median funding amount is only around $1.95 million, while the average is approximately $12.1 million, indicating the presence of a small number of highly funded outliers. Almost 89.4% of funded startups have raised less than $20 million, while only 21 firms — around 2.0% of those with funding data — have raised more than $100 million. The largest funded companies include Babylon, Isomorphic Labs, Cera, Exscientia, Dental Monitoring, Neko Health, Huma, BenevolentAI, Flo Health and Ada Health. The concentration is particularly strong: the top 20 funded companies account for approximately 44.6% of all funding captured in the dataset. The investor landscape also confirms the central role of public programs, accelerators and early-stage funding schemes. Based on the "Top 5 Investors" field, Innovate UK is the most recurrent investor, appearing in 53 funded companies, followed by EISMEA with 40, Bpifrance and the European Innovation Council with 33 each, Venture Kick with 32, and Google for Startups with 30. Other recurrent investors include Techstars, Plug and Play, Antler, Entrepreneurs First, EIT Health and MassChallenge. The prevalence of public innovation agencies, European funding bodies and accelerator programs suggests that institutional and semi-institutional support remains a structural component of the European healthcare AI ecosystem.

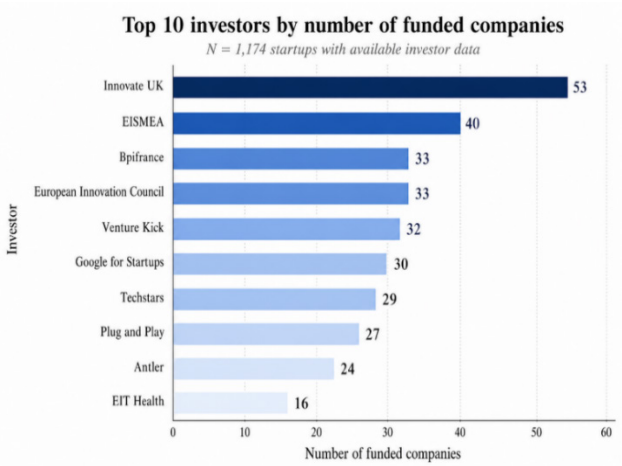

Figure 5: Top 10 investors by number of funded companies
Source: authors' elaboration based on Crunchbase data.

Among firms with last-funding-date data, almost 70% received their latest funding round in 2022 or later, and around 44% in 2024 or later. This suggests that the sector has remained financially active in the post-pandemic period, despite broader venture-capital selectivity. Furthermore, among startups with a recorded last funding type, Seed, Pre-Seed and Angel rounds account for about 50.7% of cases. By contrast, Series A and Series B together represent only around 11.1%. This supports the interpretation of a pipeline rich in early-stage experimentation but thinner in later-stage scale-up. Overall, this screening confirms several preliminary findings. First, the United Kingdom emerges as the most vital hub and the main entry point to the European market, followed by Germany and France, while southern and eastern Europe remain comparatively underrepresented. Second, the majority of startups are still in an "early scale" phase, with small organizational size, revenues concentrated in the lower brackets, and limited access to large-scale funding. Third, the ecosystem is strongly shaped by public programs and corporate accelerators, which play a central role in sustaining the pipeline of healthcare AI ventures. These insights guided the subsequent selection of the sample for in-depth analysis.

3.1 Preliminary findings

The preliminary analysis suggests that European healthcare AI startups are distributed across both core clinical processes and support processes, indicating that their role in healthcare ecosystems is not limited to direct patient-facing clinical applications. Instead, these firms contribute to healthcare transformation through a combination of clinical, infrastructural, administrative, and drug discovery-oriented activities. First, the functional classification of the startups shows a relatively balanced distribution between the two macro-groups. Core clinical processes account for 53.6% of the sample, while support processes account for 46.4%. This indicates that healthcare AI startups are only slightly more concentrated in directly clinical domains than in enabling or infrastructural domains. The result suggests that AI-driven transformation in healthcare does not occur exclusively at the bedside or within clinical decision-making, but also through the reconfiguration of the supporting conditions that make clinical work possible. At the level of specific functions, the two most represented categories are Drug Discovery and Diagnostics, which account for 27.8% and 27.1% of the sample respectively. This finding indicates that healthcare AI startups are particularly active in domains where AI can process complex data, identify patterns, and support knowledge-intensive tasks. Diagnostics represents the main clinical entry point for AI startups, while Drug Discovery represents the strongest support-oriented domain. By contrast, Treatment accounts for only 12.0% of the sample and Administrative Process for 3.0%, suggesting that some areas of the healthcare value chain remain less populated by AI startups or may present higher barriers to entry.

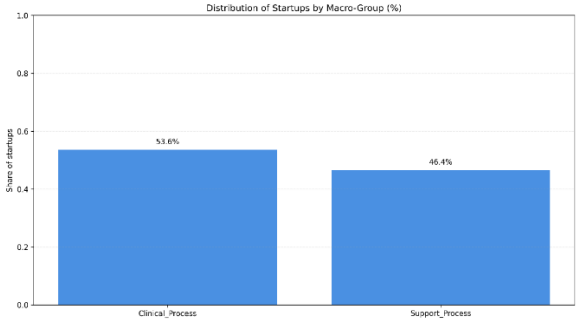

Figure 6: Distribution of Startups by Macro-Group

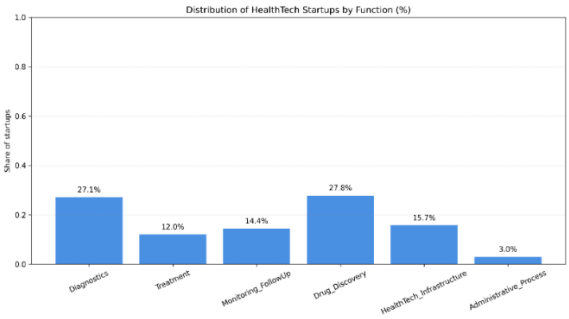

Figure 7: Distribution of HealthTech Startups by Function

The radial classification map (Figure 8) further suggests that the ecosystem is not composed only of sharply specialized firms. Several startups occupy intermediate positions between functional poles, indicating the presence of hybrid or polyfunctional business models. This is particularly relevant from an ecosystem perspective because it shows that AI startups may simultaneously contribute to multiple phases of the healthcare process, for instance by combining diagnostic support with monitoring capabilities, or infrastructure provision with clinical analytics. This hybridity points to a more complex form of ecosystem participation, where startups cannot always be reduced to a single clinical or support function.

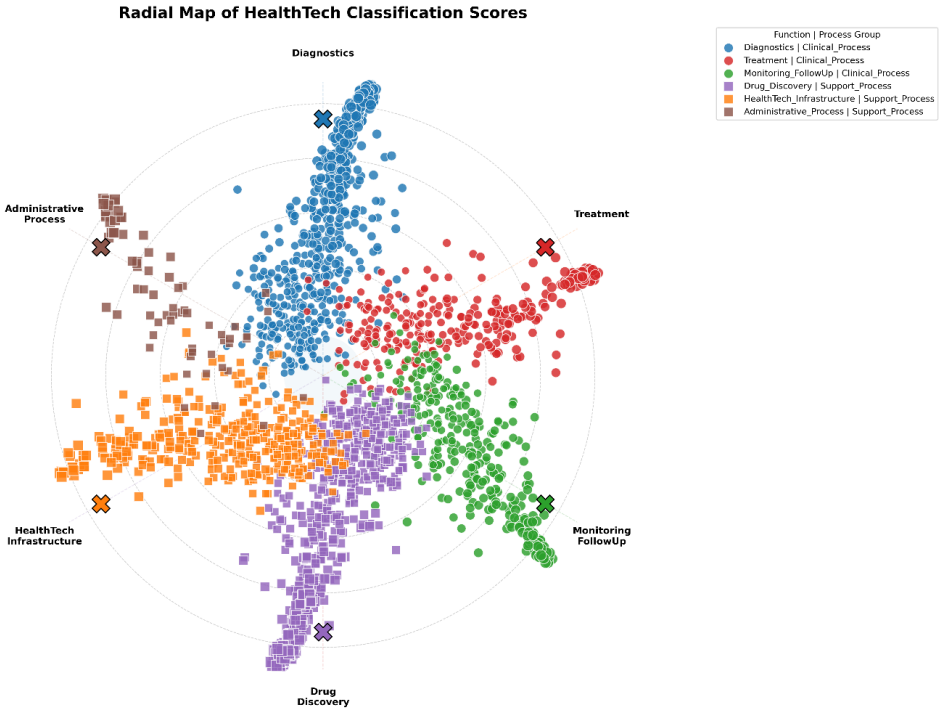

Figure 8: radial classification map of the AI-start-ups within clusters

Second, the analysis of user comments and reviews provides an initial indication of how these startups are perceived to affect clinical processes in practice. The review-based analysis focused preliminary on the Diagnostic phase and distinguished between value creation, value destruction, and neutral effects for two stakeholder groups: providers and patients. For providers, diagnosis contains 156 classified events, with a net value score of +18; for patients, it contains 140 events, with a net value score of +10. This suggests that diagnostic AI solutions generate visible value for both stakeholder groups, particularly by supporting clinical interpretation, decision-making, or patient understanding. However, the presence of both positive and negative events also indicates that diagnostic AI is not experienced as uniformly beneficial (see Figure 9 and 10). Its value appears to depend on how well the solution is integrated into clinical workflows, how reliable users perceive it to be, and whether it improves rather than complicates the diagnostic process.

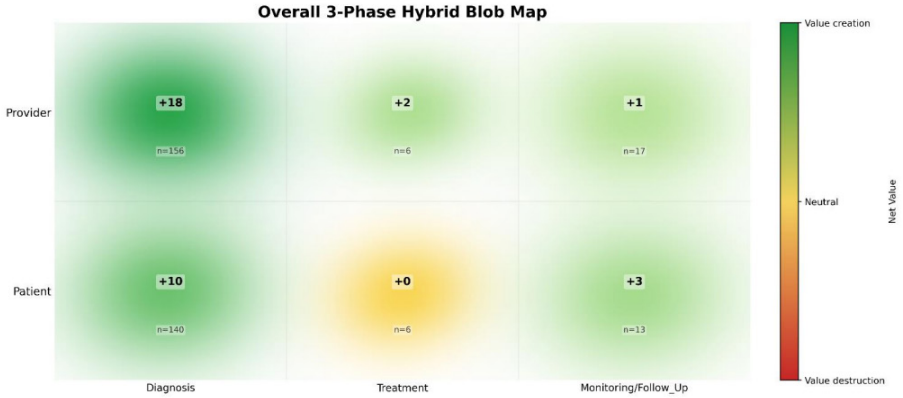

Figure 9: Value formation Heatmap for the diagnostic category sample

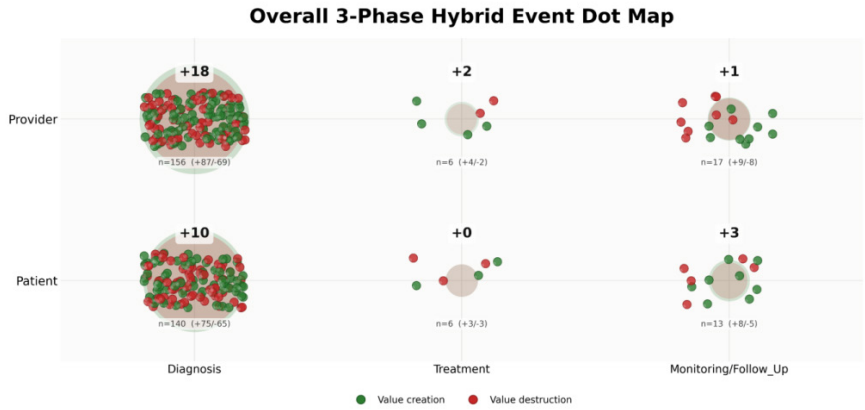

Figure 10: Value formation Dotmap for the diagnostic category sample

The review-based value analysis was conducted on diagnostic startups, but the comments were coded to capture whether the perceived value of diagnostic solutions extended beyond diagnosis and affected other clinical phases, such as treatment and monitoring/follow-up. Although these startups are primarily positioned in the diagnostic phase, users' comments sometimes reveal perceived effects that extend beyond diagnosis and spill over into downstream clinical processes. Treatment records six provider-related and six patient-related events, with limited net value effects, while Monitoring/Follow-up shows a somewhat stronger but still modest presence, with 17 provider-related and 13 patient-related events. These results suggest that diagnostic AI startups are perceived to create value mainly in relation to diagnostic activities, but their impact may also reverberate across the broader clinical pathway, especially when diagnostic outputs influence therapeutic decisions, patient management, or follow-up practices.

4 Conclusions

This study contributes to the literature in three main ways. First, it advances an ecosystem-level understanding of healthcare AI startups. Prior research has widely discussed the potential of AI to improve healthcare delivery, for instance by enhancing diagnostic accuracy, clinical efficiency, personalization, and decision-making (Esteva et al., 2019; Davenport and Kalakota, 2019). However, much of this literature remains centred on the technological capabilities of AI systems or on the business models of AI-based ventures (Garbuio and Lin, 2019). By contrast, this study shifts attention from the technology itself to the ecosystem role played by AI startups. Building on the ecosystem-as-structure perspective (Adner, 2017) and on ecosystem actor-role approaches (Dedehayir et al., 2018; Jacobides et al., 2018), we show that the impact of healthcare AI startups depends not only on what the technology can do, but also on where the startup is positioned in the healthcare activity system, which actors it connects, and which interdependencies it modifies. In this sense, AI startups are not interpreted merely as providers of technological solutions, but as ecosystem actors that may reconfigure relationships among patients, providers, infrastructures, regulators, and other healthcare stakeholders. This contributes to a less technology-deterministic understanding of AI in healthcare, showing that the transformative potential of AI emerges through the roles, relationships, and coordination mechanisms that

startups activate within the ecosystem. Second, the study provides an empirically grounded functional taxonomy of healthcare AI startups. Our analysis offers a more granular classification than previous studies (e.g., Garbuio and Lin) based on the actual function performed by startups within the healthcare value chain. Specifically, we distinguish between startups operating in core clinical processes — Diagnosis, Treatment, and Monitoring/Follow-up — and startups operating in support processes — Drug Discovery, Clinical Administrative Support, and HealthTech Infrastructure. This taxonomy is original because it is not derived only from theoretical categories or industry labels, but from the systematic analysis of a large number of startup descriptions, value propositions, and application domains. It therefore provides a structured map of how healthcare AI startups populate different areas of the ecosystem and clarifies that AI-driven transformation occurs both directly, through patient-facing clinical processes, and indirectly, through the infrastructures, administrative systems, and drug discovery activities that enable clinical value creation. These start-ups intervene directly in core clinical processes, especially diagnosis, where their effects are most visible in user reviews. Furthermore, they play a substantial enabling role through support processes such as Drug Discovery, Clinical Administrative Support, and HealthTech Infrastructure. Third, research on AI in healthcare often assumes that AI adoption produces positive effects, such as efficiency gains, improved decision-making, or better patient outcomes (Davenport and Kalakota, 2019; Topol, 2019). However, service and ecosystem research suggests that value is not embedded in a solution itself, but emerges through use, interaction, and context (Vargo and Lusch, 2008; Grönroos and Voima, 2013). By analysing user comments from patients and providers, this study moves beyond startups' self-representations and assesses the perceived effects of AI solutions in practice. This allows us to show that healthcare AI startups may create value but may also generate value destruction. The originality of this contribution lies hence in connecting the functional positioning of AI startups with their stakeholder-specific value effects, showing that the impact of healthcare AI is systemic, relational, and contingent on how solutions are embedded in clinical routines. From a managerial perspective, the evidence from diagnostic startups highlights that Diagnostic AI solutions appear to generate visible value for both providers and patients, but their impact may also extend to treatment decisions and follow-up practices. Managers should therefore assess diagnostic AI not as a narrow diagnostic tool, but as a technology that may affect downstream clinical processes and interdependencies among actors. Accordingly, healthcare managers should evaluate and implement diagnostic AI through a process-integration lens, considering not only accuracy and technical performance, but also workflow fit, stakeholder experience, data interoperability, and the potential effects on subsequent clinical decisions and care coordination.

5 Ethics Declaration

This research relied on publicly available secondary data and did not involve direct interaction with human participants.

6 AI tools Declaration

AI tools were used to support language editing and text refinement. The authors retained full responsibility for the conceptual development, analysis, interpretation of results, and final content of the paper.

Abstract

In the current context, public health systems are facing an unprecedented challenge, namely, being able to manage increasing complexity resulting from demographic aging, chronicity and the need to integrate frontier technologies in contexts of limited resources. In this scenario, the healthcare organization evolves from a simple bureaucratic structure to a "knowledge ecosystem". the healthcare organization becomes a dynamic network in which the value lies in individual services, but also and above all in the ability to generate, share and apply multidimensional knowledge. This study was born with the aim of exploring how organizational capabilities act as a fundamental pillar to support and, above all, make these ecosystems sustainable in the long term. The central objective of the research is to identify the key organizational capabilities necessary to overcome information fragmentation and promote real integration between the different players in the system (clinicians, managers, patients and technological partners). To achieve this aim, the study adopts a qualitative methodology based on interviews with strategic decision-makers, highlighting three macro-categories of essential capabilities.
First, the absorptive capacity emerges, therefore, the organization's propensity and ability to identify, assimilate and apply all those external innovations and complex clinical data to translate them into efficient operational protocols. Secondly, relational and collaborative skills, essential for breaking down functional silos and promoting more widespread leadership models. These capabilities allow the transition from hierarchical personnel management to a community of practice that enhances human capital as the driver of the ecosystem. Finally, strategic digital capabilities, understood not only as infrastructural equipment, but as the organization's ability to manage data interoperability and mitigate phenomena of resistance to change and technostress. The results suggest that the sustainability of a knowledge ecosystem does not depend exclusively on technological investment, but also on a strategic alignment between organizational culture and knowledge management processes. Without a solid foundation of organizational capabilities, digital infrastructures risk becoming mere repositories of unused data. The research contributes to the debate on healthcare management by proposing a model in which performance is directly proportional to the company's ability to continuously regenerate its knowledge assets.

Keywords: knowledge eco-system, public health care, organizational capabilities, strategic choice, interview

Paper type: Academic Research Paper

1 Introduction

Socio-demographic tendencies, rapid technological innovation and institutional reforms are some of the pressures for change driving contemporary public healthcare systems to radically evolve. At the same time, healthcare organizations must respond to growing and evolving social expectations, while constrained by limited financial resources (Khanuja, et al., 2025; Ahmad, et al.,2022; Binci, et al., 2022). These conditions are challenging traditional organizational models, exposing their limitations and consequential in reduced performance. Changes in healthcare organizations and processes have a direct impact on well-being and quality of life (Öberg and Lundberg, 2022; Maracine and Scarlat, 2009).

To address these limitations, healthcare organizations must reorient their strategic choices, and internal organizational process, by focusing on the enabling role of knowledge and organizational capabilities from a new strategic perspective (Khanuja, et al., 2025). In fact, healthcare organizations must support and implement the creation of knowledge ecosystems. From this perspective, this study aims to analyze knowledge ecosystems in the context of public healthcare. Therefore, this paper, from the theoretical perspective of knowledge management studies, aims to provide an overview of the elements and organizational capabilities that shape knowledge ecosystems. The study adopts an exploratory-interpretive qualitative methodology, with a process-oriented approach to organizational change. This methodological approach is particularly suited to capturing the dynamic, relational, and multilevel nature of knowledge ecosystems within complex public systems.

Empirical data was collected through in-depth, semi-structured interviews with key stakeholders involved in the governance and implementation of healthcare reform. Data analysis was conducted using thematic analysis, with the aim of identifying recurring patterns related to the processes of knowledge production, sharing, and valorization within processes. Emphasis was paid to knowledge flows between organizations, as well as the role of digital and collaborative technologies in supporting these dynamics.

This study offers a theoretical contribution to the reconfiguration of public healthcare systems as knowledge ecosystems, enriching the debate on knowledge management and organizational capacity. Overall, the findings of this study highlight that the sustainability and resilience of public healthcare systems depend on the ability to cultivate knowledge ecosystems capable of integrating human, organizational, and institutional intelligence.

From this perspective, the paper proposes an ecosystemic view of strategic change, in which capabilities are not isolated properties of individual organizations, but emerge from the interaction between institutional, organizational, and community actors. Knowledge ecosystems are described as dynamic configurations traversed by structural tensions: between standardization and local adaptation, between control and professional autonomy, between digital rationalization and human judgment.

The findings of this study have significant practical implications for public policymakers, managers, and professionals engaged in the design and governance of smart and sustainable organizations and communities.

2 Theoretical Background

2.1 Knowledge ecosystems in healthcare

Previous studies have analyzed knowledge ecosystems in various contexts, including regional startups and internal organizational environments, highlighting their structural characteristics and the composition of their actors (Clarysse et al., 2014; Miller et al., 2016; Sharma & Bhattacharya, 2013). However, much research has focused on the transition from knowledge ecosystems to business ecosystems, while limited attention has been paid to the organizational modalities required to achieve knowledge development objectives (Cobben et al., 2022).

In healthcare, the literature highlights how their development follows similar trajectories across countries, reflecting the broader evolution of organizational theories. In this context, Kernick (2004) identifies four phases in the development of the National Health Service (NHS) that help explain the current relevance of the ecosystem approach. The first three phases are characterized by a progressive transition from command-and-control models, based on rigid hierarchies and the mechanistic metaphor of organization, to market-oriented configurations and subsequently to hybrid forms that integrate cooperation and competition between public and private actors. The fourth phase introduces a radically different vision, interpreting the healthcare system as a set of interrelated systems that interact in a nonlinear fashion, in which the unit of analysis shifts from the individual patient to the patient-professional relationship. From this perspective, healthcare systems are conceived as complex ecosystems, characterized by diversity, connectivity, feedback, and self-organizing rules that foster the emergence of new behavioral patterns (Kernick, 2004).

The ecosystem approach emphasizes the impossibility of understanding individual actors in isolation, favoring instead a systemic and relational analysis (Royston & Dick, 1998). Broadly speaking, a healthcare ecosystem can be defined as a complex system in which a multitude of actors are intertwined – patients, healthcare professionals, healthcare facilities, public administrations and regulatory bodies – and a variety of resources, such as professional skills, clinical knowledge, technologies, tools and regulatory devices (Di Nauta et al., 2017). These elements do not operate separately, but as highlighted by Frow et al., (2016), they are interconnected through value propositions, which, within a complex framework, configure a network of relationships. Actors are motivated to actively participate in the ecosystem to the extent that sharing resources allows access to benefits that include and exceed the results that an individual action could bring. In this context, the healthcare ecosystem can be defined as a dynamic system; In the interaction of actors, a continuous reallocation and recombination of resources over time brings variance to the attractiveness of value propositions; these, however, through their configuration, define the modalities of interaction. From this perspective, practices play a primary role; that is, as sets of activities and interactions that are constructed in social contexts and that actors continually modify based on how they interpret the sociality of the construction (Kjellberg & Helgesson, 2007). The ecosystem evolves based on the value of the activities selected and modified by the actors involved. Co-creators of value possess resources that, when integrated with others, will become a benefit. The sharing of a patient's clinical data between a hospital and others (such as specialists or healthcare providers) enables personalized treatment. The importance of interactional collaboration in the healthcare system has made co-creation processes particularly attractive. Healthcare, traditionally unidirectional and

passive, where healthcare providers deliver care and patients receive it, now places patients in an active position. Recently, a new perspective has emerged that recognizes patients' active and participatory role in managing their health. This approach, known as patient-centered, focuses on designing healthcare services based on patients' specific needs, preferences, and conditions, leading to improved clinical outcomes and greater efficiency of the system as a whole. Adopting a patient-centered approach has expanded the number and variety of stakeholders involved in co-creating value. In addition to healthcare professionals, family and friends are increasingly being included, offering informational, emotional, and practical support throughout the care journey. Furthermore, there has been an increase in collaborative activities, which are no longer limited to sharing clinical decisions among experts but also include initiatives to improve patients' psychological and emotional well-being and the quality of their care experience. Despite these developments, healthcare literature has long neglected a systematic analysis of the interactions between the various actors involved and the collaborative practices that characterize this ecosystem. Only recently, with contributions such as that of Frow et al. (2016), has it become clearer how important it is to study relational dynamics and the mechanisms of value co-creation in healthcare from an ecosystemic perspective, capable of capturing the complexity, dynamism, and interdependence of this field.

From the above, it emerges that the concept of knowledge ecosystems has gained increasing over the years, as organizations increasingly move toward models that appear more interconnected and collaborative. A knowledge ecosystem is a dynamic network of actors, institutions, and technologies engaged in the co-creation, exchange, and application of knowledge. In the healthcare sector, knowledge ecosystems are particularly relevant due to the complexity of the sector itself, which involves multiple stakeholders, including physicians, administrators, policymakers, patients, and technology providers. These ecosystems are therefore characterized by distributed knowledge sources, interorganizational collaboration, and, above all, ongoing learning and adaptation processes.

Therefore, knowledge ecosystems in healthcare differ from traditional organizational models in that they emphasize relationships and flows rather than structures and hierarchies. Knowledge is not confined within organizational boundaries, but circulates through networks. All of this enables innovation and continuous improvement in service delivery.

2.2 Organizational capabilities in knowledge ecosystem

Hetemi et al (2026) argue that knowledge ecosystems differ from traditional hierarchical organizations in their organizational specificities (Kretschmer et al., 2022) namely, the nature of authority and control mechanisms; motivational structures and incentives for participation; and finally governance and coordination practices. Healthcare organizations are no longer viewed merely as service providers but as complex, knowledge-intensive systems. The growing relevance of knowledge as a strategic resource has led to the emergence of the concept of knowledge ecosystems**,** where multiple actors interact to produce, share, and apply knowledge across organizational and institutional boundaries. This transformation requires a shift in perspective: from hierarchical and siloed structures to more collaborative, adaptive, and networked configurations. From this perspective, knowledge ecosystems can be viewed as a community based on individuals and organizations that continuously interact and primarily co-evolve in their roles and capabilities to support the growth and sustainability of the ecosystems themselves. Specifically, as highlighted by Abbate et al. (2021), both individual and organizational capabilities can contribute to the creation of new knowledgeIn healthcare systems, organizational capabilities are important to understanding how can evolve toward knowledge ecosystems. As emphasized (Amit and Schoemaker, 1993, Teece et al., 1997), organizational capabilities are defined as a otganization's ability to employ its resources, whether tangible or intangible, to perform a task or activity in order to improve performance. Helfat and Peteraf (2003) define organizational capability as "an organization's ability to perform a coordinated set of tasks, using organizational resources, to achieve a particular end result." (Dosi et al., 2000) argue that organizational capabilities are critical to firms' ability to effectively solve their organizational problems. Researchers distinguish between different organizational capabilities. Collis (1994) proposed four categories of organizational capabilities. The first "concerns the ability to perform the basic functional activities of the organization" (Collis, 1994). The second category concerns dynamic improvements to the organization's activities, such as continuous improvement activities. The third category is "recognizing the intrinsic value of other resources or developing new strategies before competitors" (Collis, 1994). The fourth category is labeled "higher-order" or "meta-capabilities" and refers to learning capabilities. Winter (2003) proposes that there are zero-level capabilities, also called operational or ordinary capabilities, which he defines as those that allow the firm to earn a living in the present. He then explains that there are first-order capabilities that modify and transform zero-level capabilities. He also

suggests, similarly to Collis (1994), that there are higher-order capabilities that operate on top of first-level capabilities. Based on capabilities, organizations must be able to identify opportunities and threats, seize opportunities through various strategic actions and reconfigure resources to adapt to increasingly evolving and changing contexts. In the healthcare context, these capabilities are particularly important because of high levels of regulation, strong professional autonomy, and, above all, complex decision-making processes. Capabilities in the healthcare sector are therefore not limited to technical skills but also include managerial, relational and institutional dimensions. Organizational skills are considered mechanisms that enable (or hinder) the flow of knowledge between stakeholders, institutional levels, and disciplinary fields. A literature analysis shows that three main categories of capabilities are considered important. The first group includes relational capabilities, such as the ability to build trust and collaboration, as well as network coordination. a second group includes digital capabilities, therefore, data literacy and above all the use of digital tools, finally the third group contains institutional capabilities, which include alignment with policies and regulations and governance mechanisms.

3 Methodology

This study adopts a qualitative, exploratory research design (Yin, 2015), suitable for investigating complex and evolving phenomena such as knowledge ecosystems. The purpose of this paper is to explore how organizational capabilities support the development of knowledge ecosystems in public healthcare. Specifically, the study aims to identify the key capabilities required to sustain knowledge ecosystems. The study adopts semistructured interviews to identify critical factors in the knowledge ecosystem of the Calabrian healthcare system. This approach is consistent with an exploratory and interpretative design already applied to the study of public healthcare ecosystems. The interviews were conducted with five public policy makers operating in the healthcare sector of the Calabrian regional healthcare system, selected based on their strategic role in the system's decision-making and governance processes. This focus on decision makers is consistent with studies that analyze knowledge ecosystems starting with key governance and coordination actors (Primario et al., 2024; Eisenhardt and Graebner, 2007). Semistructured interviews were conducted, with an average duration of approximately 45 minutes each. Each interview was conducted in person by two researchers. One served as the primary interviewer and one as an observer, responsible for taking notes on the context, nonverbal cues, and interactive dynamics. The interviews were conducted with the objective to identify and validate the organizational capabilities of the healthcare knowledge ecosystem, identified in the literature.

4 Results

This study provides a comprehensive framework for understanding knowledge ecosystems within the public health sector by integrating three pivotal theoretical strands: knowledge management, innovation ecosystems, and interorganizational relationships. Despite the strategic importance of this convergence, identifying and defining organizational capabilities remains a significant challenge due to terminological ambiguity. To address this gap, the research conceptualizes organizational capabilities as enabling (or constraining) mechanisms that govern the multidirectional flow of knowledge across diverse actors, institutional echelons, and disciplinary domains.

Table 1 summarises some organizational capabilities emerging from the literature analysis and interviews.

Table 1 - Organizational capabilities in knowledge ecosystem

	Organizational capabilities	Description	Main References

5 Discussion and Conclusion

The shift to knowledge-based models in healthcare systems involves a shift away from fixed structures in favor of flexible systems. In this context, organizations are not simple units, but fluid structures shaped by the interactions between different actors. Research shows that an organization's strength and effectiveness depend not only on its resources, but also on the skills it develops over time. In particular, the ability to collaborate with others fosters teamwork, and digital skills facilitate the flow of information. Possessing the right organizational skills helps make strategic decisions in line with external regulations. Knowledge is created through collaboration between people. It is influenced by the organization's functioning and the coordination among its members. A key finding of the study is therefore that an organization's ability to adapt is linked to its self-knowledge. Organizations that understand their own strengths, weaknesses, and vulnerabilities are better at anticipating risks. Through knowledge management, past experiences can be transformed into learning, which reduces uncertainty in the decision-making process. The ability to change and adapt is crucial in this context because it allows organizations to better manage change. Furthermore, the study of relationships between organizations demonstrates that these can be both beneficial and problematic. Collaborative networks can contribute ideas and resources, but they can also create information gaps and bureaucratic problems. It is therefore essential to have systems that balance these different needs. From this perspective, this suggests that change should be allowed to occur spontaneously. This means investing not in individual skills, but in creating organizational systems that encourage continuous learning and teamwork.

Designing Hybrid Human–AI Knowledge Ecosystems for Sustainable Value Creation

Stefania D'Aprile, Giovanni Spatola, Maria Zifaro, Giuseppe Ambrosio, Marianna Mancino
Universitas Mercatorum, Rome, Italy

Abstract

In the current context, characterized by increasing digitalization and a growing emphasis on sustainability, Artificial Intelligence (AI) is increasingly recognized as a key enabler of organizational performance and innovation. However, many organizations struggle to translate investments in AI into sustainable value due to knowledge fragmentation, weak governance mechanisms and limited integration between human capabilities and digital systems (Alavi & Leidner, 2001; Markus, 2001).

Building on the Knowledge Management (KM) and hybrid intelligence literature, this study proposes an operational framework for the design and governance of hybrid human–AI knowledge ecosystems aligned with ESG objectives. The framework is structured along the knowledge journey, encompassing the phases of planning, acquisition, and distribution and impact, and is empirically illustrated through a qualitative case study of Aulab Srl, with particular reference to the implementation of the Confluence platform as a Knowledge Management (KM) system.

The findings highlight the critical role of structured knowledge management practices as an enabling condition for effective AI adoption and sustainable value creation.

Keywords: hybrid intelligence; knowledge management; artificial intelligence; ESG; sustainable value

Paper type: Practical Paper

1 Introduction

The increasing prominence of sustainability concerns, coupled with the pervasive diffusion of digital technologies, is profoundly reshaping organizational value creation models. Within this evolving landscape, Artificial Intelligence (AI) has emerged as a strategic driver of innovation and performance enhancement. Despite its potential, the effective implementation of AI remains a significant challenge, as many organizations struggle to translate technological investments into sustainable outcomes.

As emphasized in the extant literature, these challenges are not primarily attributable to technological limitations, but rather to organizational and cognitive issues, including knowledge fragmentation, weak governance mechanisms, and insufficient integration between human capabilities and digital systems (Alavi & Leidner, 2001; Markus, 2001). In this regard, Knowledge Management (KM) constitutes a critical lever for addressing such complexities, as it enables the systematic structuring, sharing, and reuse of organizational knowledge.

Furthermore, the advent of digital technologies and advanced algorithms is fundamentally transforming knowledge management practices as well as decision-making processes (Faraj et al., 2018). From this perspective, AI can be conceptualized as a socio-technical phenomenon, whose value is contingent upon its effective integration within organizational systems and processes (Jarrahi, 2018). In parallel, the paradigm of hybrid intelligence underscores that superior outcomes are achieved through the complementary design of human and artificial capabilities, rather than through substitution logics (Dellermann et al., 2019).

Notwithstanding these advancements, the literature still provides limited operational guidance on how to design and govern hybrid human–AI knowledge ecosystems oriented toward sustainability and aligned with ESG objectives (Mikalef et al., 2023). Against this backdrop, the present study aims to develop an operational framework that integrates Knowledge Management, hybrid intelligence, and ESG principles along the knowledge journey.

2 Theoretical Background

2.1 Knowledge Management and Value Creation

The Knowledge Management (KM) literature widely recognizes knowledge as a central strategic resource for achieving competitive advantage and fostering organizational innovation. Seminal contributions emphasize that the ability to generate, share and reuse knowledge constitutes a fundamental determinant of organizational performance (Alavi & Leidner, 2001; Markus, 2001).

From this perspective, KM can be conceptualized as an integrated set of practices, processes, and systems aimed at facilitating the integration and leveraging of distributed knowledge within the organization. Theoretically, KM is grounded in the knowledge-based view of the firm, which conceptualizes organizations as systems for the integration of specialized knowledge (Grant, 1996). Within this framework, value creation depends on the organization's capacity to coordinate such knowledge and transform it into distinctive organizational capabilities.

More recently, the literature has increasingly emphasized the digital dimension of KM, highlighting how collaborative platforms and advanced information systems contribute to making knowledge more accessible, scalable, and reusable (Majchrzak et al., 2016). However, the adoption of these technologies necessitates the implementation of appropriate governance mechanisms to mitigate risks such as information overload and knowledge fragmentation.

2.2 Artificial Intelligence and the Transformation of Knowledge Processes

The advent of Artificial Intelligence has introduced a profound shift in knowledge management processes, redefining the ways in which organizations generate, analyze and utilize information. As highlighted by Faraj et al. (2018), machine learning algorithms do not merely automate existing tasks; rather, they fundamentally transform organizational practices, reshaping the very nature of work and decision-making processes. In this context, AI is increasingly conceptualized as a socio-technical phenomenon, whose value emerges from the interaction between technological systems, human actors, and organizational structures (Jarrahi, 2018). Recent studies further emphasize that the adoption of AI necessitates new forms of organizational design and coordination, capable of integrating advanced analytical capabilities with complex decision-making processes (Raisch & Krakowski, 2021). At the same time, the literature underscores that the effectiveness of AI is highly contingent upon the quality of the data and knowledge on which it is grounded. In the absence of a robust Knowledge Management infrastructure, AI systems risk generating biased or unreliable outputs, thereby amplifying existing inefficiencies and distortions (Davenport & Ronanki, 2018).

2.3 Hybrid Intelligence: Complementarity Between Humans and AI

The concept of hybrid intelligence has emerged in response to the growing recognition of the inherent limitations of both human and artificial intelligence. From this perspective, value creation stems from the design of systems in which humans and AI operate in a complementary manner, combining computational capabilities with interpretative and cognitive skills (Dellermann et al., 2019).

The literature highlights that AI excels in processing large volumes of data, pattern recognition, and scalability, whereas human actors contribute critical thinking, ethical judgment and contextual understanding (Jarrahi, 2018). This complementarity is particularly salient in decision-making contexts characterized by uncertainty and ambiguity, where purely automated approaches prove insufficient.

Recent contributions further emphasize the importance of organizational design in shaping hybrid intelligence configurations, showing that value emerges from the effective orchestration of human–AI interactions within organizational processes and routines (Raisch & Krakowski, 2021). This entails a shift from substitution-based logics toward augmentation-oriented approaches, in which technology enhances rather than replaces human capabilities.

2.4 ESG, Sustainability and Knowledge Governance

The increasing focus on ESG (Environmental, Social, and Governance) objectives has introduced new challenges for knowledge and data management. In particular, achieving these objectives requires high levels of transparency, reliability and traceability of information, as well as heightened attention to ethical considerations and accountability (Floridi et al., 2018).

AI can play an enabling role in supporting sustainability goals, for instance through the analysis of environmental data or the monitoring of social performance. However, the literature also highlights the risks

associated with AI adoption, including algorithmic bias, opacity, and potential misalignment with organizational values (Vinuesa et al., 2020). These challenges underscore the need for robust governance mechanisms capable of ensuring the responsible and transparent use of such technologies.

In this context, Knowledge Management assumes a central role as an enabling infrastructure for sustainability, as it supports the structuring and accessibility of the knowledge required for informed and responsible decision-making. As recent studies suggest, knowledge management is deeply intertwined with digital transformation processes and represents a key pillar for the development of sustainable and resilient organizations (Heisig et al., 2022).

2.5 Research Gap and Study Contribution

Despite significant advancements across the individual streams of research, the literature remains fragmented, with limited integration among Knowledge Management, Artificial Intelligence and sustainability. In particular, there is a lack of operational models that provide clear guidance on how to design and govern hybrid human–AI knowledge ecosystems capable of supporting sustainable value creation (Mikalef et al., 2023).

This study positions itself within this research gap by proposing an integrated framework that connects Knowledge Management, hybrid intelligence and ESG principles along the knowledge journey, thereby contributing to the development of a unified theoretical and practical perspective. In doing so, it responds to the need to move beyond fragmented approaches and offers actionable insights for the design of knowledge ecosystems capable of sustaining innovation and long-term sustainability.

3 Methodology

This study adopts a qualitative approach based on a case study research design, which is particularly suitable for investigating complex, emerging and highly contextualized phenomena such as the design and governance of hybrid human–AI knowledge ecosystems. Consistent with methodological literature, the case study approach enables an in-depth understanding of organizational dynamics and socio-technical processes, proving especially appropriate when the boundaries between the phenomenon and its context are not clearly delineated (Yin, 2018).

Furthermore, in line with Eisenhardt's (1989) approach, the case study facilitates the generation of theoretical insights grounded in empirical analysis, thereby contributing to the development of conceptually robust and practice-based models. Case selection follows a theoretical sampling logic, identifying Aulab Srl as a particularly informative and revelatory context.

As a knowledge-intensive EdTech organization, Aulab represents a relevant empirical setting for examining the role of Knowledge Management as an enabling factor for the adoption of Artificial Intelligence and for supporting decision-making processes aligned with sustainability and ESG objectives. Moreover, the case provides a privileged opportunity to observe the interaction between knowledge management practices, digital infrastructures and governance mechanisms within a highly dynamic and innovation-driven environment.

Data collection was conducted through a combination of qualitative sources to ensure triangulation and analytical robustness. Specifically, the analysis draws on internal documentation, content available within the Confluence platform, organizational materials, and observations related to knowledge structuring and utilization processes. This plurality of data sources enabled a comprehensive reconstruction of Knowledge Management practices and governance mechanisms, as well as an analysis of their implications for the development of hybrid intelligence configurations.

The use of documentary and digital data is particularly consistent with the study's objectives, as it allows for direct observation of how knowledge is codified, organized and made accessible within the organizational ecosystem. The empirical analysis focuses on three main dimensions: (i) the design of the knowledge ecosystem, (ii) governance mechanisms and (iii) the role of digital platforms as enabling infrastructures for human–AI integration.

Through an iterative process between empirical evidence and the relevant literature, the study develops an interpretive framework that integrates Knowledge Management, hybrid intelligence and ESG principles along the knowledge journey.

Notwithstanding its contributions, the study presents several limitations. First, the qualitative nature of the research and the reliance on a single case study limit the generalizability of the findings, which should be interpreted in analytical rather than statistical terms. Second, the focus on a specific organization operating in the EdTech sector may not fully capture dynamics present in other organizational contexts. Additionally, the predominance of documentary data may not entirely capture implicit or informal dimensions of knowledge management, such as tacit practices and relational dynamics.

Future research could address these limitations by extending the analysis through comparative multi-case studies or by integrating qualitative and quantitative methodologies, thereby enhancing the validity and transferability of the findings.

4 A Framework for Hybrid Knowledge Ecosystems

The proposed framework is situated at the intersection of Knowledge Management literature, recent advancements in hybrid intelligence and the growing body of research on sustainability and ESG objectives, offering an integrated perspective on these domains along the knowledge journey (Heisig et al., 2022). Within this configuration, knowledge is conceptualized not as a static asset, but as a dynamic and cumulative process that unfolds across multiple stages of generation, codification, sharing and application, in continuous interaction with organizational structures, digital technologies and governance mechanisms.

From a theoretical standpoint, Knowledge Management assumes the role of an enabling socio-technical infrastructure, within which practices, routines and organizational mechanisms are articulated to systematize knowledge. In this view, the adoption of shared standards, taxonomies and templates is not merely an operational choice, but a mechanism for reducing ambiguity and enhancing organizational coordination, consistent with theories of knowledge integration and knowledge reuse (Alavi & Leidner, 2001; Markus, 2001). At the same time, the definition of roles and responsibilities, such as knowledge owners, contributes to the establishment of distributed accountability, strengthening processes of validation, updating, and knowledge quality assurance. This perspective positions KM as an organizational architecture capable of supporting complex decision-making processes and enabling the scalability of knowledge practices.

Within this infrastructure, the framework incorporates the paradigm of hybrid intelligence, conceptualized as an emergent configuration of complementarity between human and artificial capabilities. In line with a socio-technical perspective, Artificial Intelligence is not viewed as a substitute for human agency, but rather as an augmentative element that extends cognitive capabilities, particularly in terms of processing large volumes of data, identifying patterns, and providing analytical support (Dellermann et al., 2019; Jarrahi, 2018). Conversely, human actors retain a central role in sensemaking processes, meaning construction, and the exercise of ethical judgment, which are especially critical in contexts characterized by high levels of uncertainty and ambiguity.

Accordingly, the framework advocates for the intentional design of human–AI interactions oriented toward augmentation rather than substitution, emphasizing that value creation emerges from the effective orchestration of these interactions within organizational processes.

A further distinctive feature of the framework lies in the explicit integration of ESG objectives, which introduces a normative and value-based dimension into knowledge management. In this respect, the quality, traceability, and reliability of knowledge are not merely operational requirements, but become essential conditions for ensuring transparency, accountability, and alignment between organizational decisions and socio-environmental impacts (Floridi et al., 2018; Vinuesa et al., 2020). The integration of ESG within the knowledge journey thus entails a redefinition of knowledge evaluation criteria, extending beyond efficiency and effectiveness to encompass ethical and sustainability considerations.

Overall, the proposed framework conceptualizes hybrid knowledge ecosystems as complex adaptive systems, in which technological, organizational, and institutional dimensions co-evolve. Within this perspective, governance assumes a central role in orchestrating these dimensions, ensuring alignment between strategy, knowledge practices, and sustainability objectives.

The theoretical contribution of the framework lies in its ability to integrate traditionally separate domains—Knowledge Management, Artificial Intelligence, and sustainability—offering a unified interpretive lens through which to understand how organizations can design and govern knowledge ecosystems oriented toward long-term sustainable value creation.

5 The Knowledge Journey

The proposed framework unfolds across three interrelated phases of the knowledge journey, conceptualized as a dynamic and continuous process through which knowledge is not only generated and managed, but also progressively integrated into decision-making processes and value creation systems. The three phases—planning, acquisition, structuring, distribution and impac, should not be interpreted as rigidly sequential stages, but rather as interdependent and recursive dimensions, characterized by continuous feedback loops and organizational learning processes.

The **planning phase** represents the stage in which knowledge is recognized and formalized as a strategic resource. During this phase, organizations identify critical knowledge domains in alignment with business objectives and ESG orientations, while simultaneously defining the informational requirements necessary to

support decision-making processes. Planning also entails the design of knowledge governance mechanisms, including the definition of roles, responsibilities and dedicated organizational structures. In this perspective, top management plays a pivotal role in ensuring alignment between strategy, Knowledge Management and AI initiatives, thereby guiding the creation and utilization of knowledge toward sustainable value objectives. This phase can thus be understood as a moment of *strategic sensemaking*, in which the cognitive and informational priorities of the organization are established.

The **acquisition and structuring phase** concerns the processes through which knowledge is collected, codified, and made accessible. At this stage, organizations face the challenge of transforming tacit knowledge, often distributed across individuals and teams, and explicit knowledge embedded in documents, procedures and systems into structured and shared forms. The use of digital Knowledge Management platforms is critical in this regard, as it enables the systematization of content through the adoption of shared standards, templates and taxonomies (Majchrzak et al., 2016). Importantly, this process is not purely technical; it also entails a social dimension, involving the active participation of organizational actors and the development of shared practices for documentation and continuous updating. The quality of this phase directly influences the organization's ability to develop a coherent, reliable, and reusable knowledge base, which constitutes a prerequisite for the effective integration of AI.

The **distribution and impact phase** represents the stage in which structured knowledge is activated within organizational processes, contributing to value creation. In this phase, knowledge is disseminated, reinterpreted and reused within both operational and strategic decision-making processes, often supported by Artificial Intelligence tools that enhance analytical and predictive capabilities. AI can facilitate access to knowledge, support data analysis and improve decision quality; however, its effectiveness remains contingent upon the robustness of the underlying knowledge infrastructure. At the same time, this phase encompasses mechanisms for monitoring and evaluating outcomes, both in terms of organizational performance and alignment with ESG objectives. This enables the closure of the knowledge journey cycle, generating feedback that feeds back into the planning phase and fosters continuous learning processes.

Overall, the analysis of the knowledge journey highlights that sustainable value creation depends on the organization's ability to orchestrate these three phases in an integrated manner, overcoming fragmented approaches to knowledge management. From this perspective, the knowledge journey should not be conceived merely as a sequence of activities, but as a dynamic infrastructure through which organizations continuously build, transform and mobilize knowledge in response to the challenges posed by digitalization and sustainability.

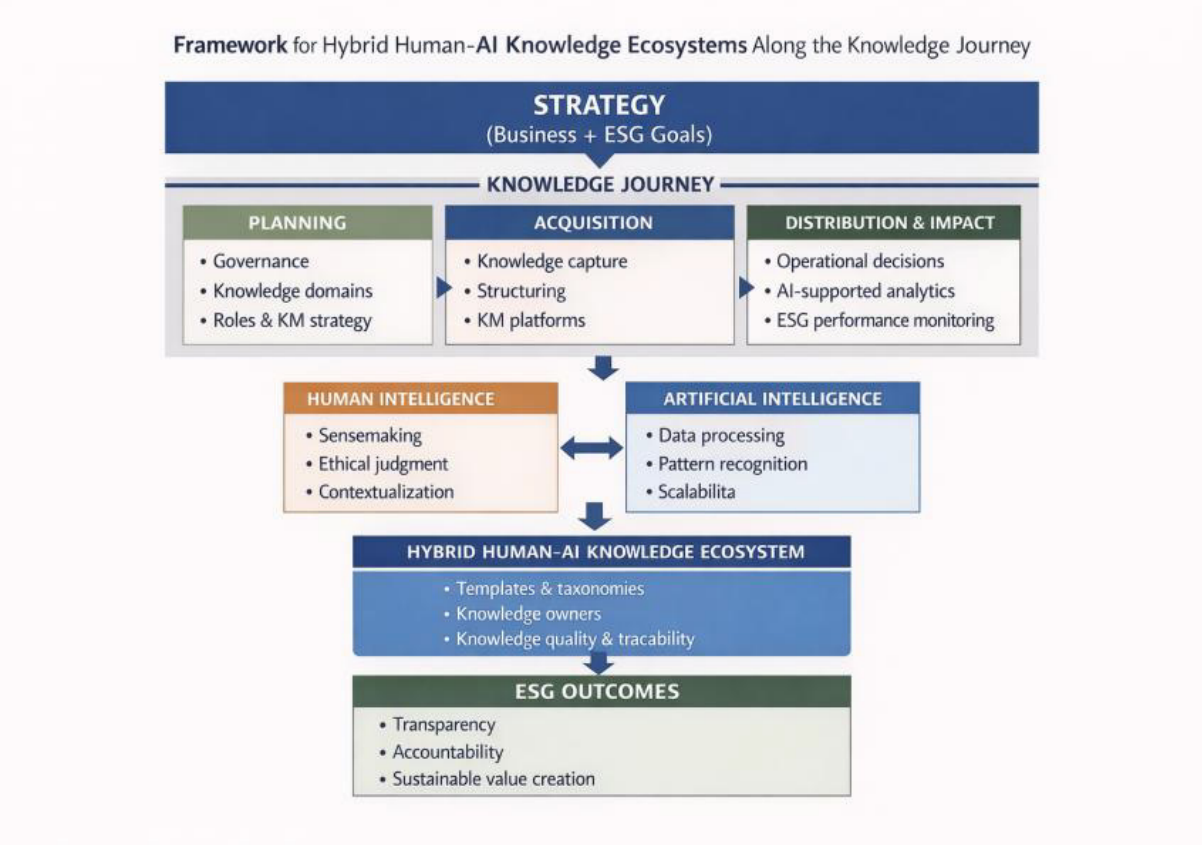

Figure 1: Framework for hybrid Human-AI knowledge ecosystem along the knowledge journey

6 Case Study: Aulab and the Implementation of Confluence

The case of Aulab Srl represents a particularly insightful context for examining how the systematic structuring of knowledge can act as a foundational condition for the evolution toward hybrid human–AI knowledge ecosystems. As a knowledge-intensive EdTech organization, Aulab operates in an environment where the ability to generate, update, share, and reuse knowledge constitutes a critical resource for both operational efficiency and the quality of decision-making processes.

Within this context, the implementation of the Confluence platform should not be interpreted merely as the adoption of a technological tool, but rather as an organizational intervention aimed at enhancing the visibility, accessibility, governability and integration of knowledge within business processes. More specifically, Confluence was introduced as a Knowledge Management infrastructure designed to collect and organize the organization's informational assets within thematic spaces aligned with its core knowledge domains, including educational processes, operational procedures, technological tools and elements related to organizational culture.

This structuring enabled the organization to move beyond a fragmented logic of information management, often dispersed across isolated documents, informal communications and individually held knowledge, toward a progressive codification of knowledge into shared and reusable forms. The adoption of standardized templates, common taxonomies and consistent documentation practices further reinforced this process, enhancing the comparability, updatability, and retrievability of content.

A particularly relevant aspect emerging from the case concerns the governance dimension of knowledge. The introduction of specific roles, such as knowledge owners, contributed to clarifying responsibilities related to the creation, validation, maintenance, and updating of content. In this sense, the platform not only improved information storage, but also fostered the development of a system of distributed accountability, in which knowledge quality becomes an explicit object of organizational oversight. This is especially critical in dynamic environments such as Aulab, where the rapid evolution of educational content, operational practices and digital tools requires continuous mechanisms of revision and alignment.

From an organizational outcomes perspective, the implementation of Confluence significantly reduced information fragmentation and the risk of loss of tacit knowledge, particularly that embedded in the day-to-day experience of individual actors. The systematization of content improved accessibility, quality, and traceability of information, facilitating not only internal coordination but also organizational learning and onboarding processes. In other words, the platform supported the transition from dispersed and localized knowledge toward more explicit, shared and potentially scalable knowledge.

From a theoretical standpoint, the Aulab case illustrates how the availability of a structured knowledge base constitutes a critical precondition for the effective adoption of Artificial Intelligence. AI systems derive value from the presence of organized, reliable, and semantically coherent data and content; in the absence of such an infrastructure, there is a risk of feeding automated processes with incomplete, inconsistent or weakly validated knowledge. In this sense, Confluence can be interpreted as an enabling infrastructure for future hybrid intelligence configurations, in which AI tools support the analysis, retrieval, and valorization of knowledge, while human actors continue to play a decisive role in interpretation, contextualization, and judgment.

Finally, the case also highlights a clear connection with ESG objectives. Increased transparency of information flows, traceability of sources and modifications, and the ability to reconstruct responsibilities and decision-making processes strengthen the conditions for more responsible and sustainable governance. From this perspective, the platform contributes not only to organizational efficiency, but also to the development of a knowledge ecosystem capable of supporting more informed, verifiable and ESG-aligned decision-making processes oriented toward long-term value creation.

7 Discussion

The findings of this study confirm that the effective adoption of Artificial Intelligence cannot be interpreted as a purely technological process, but must be framed within a broader transformation of knowledge management practices. In particular, the value of AI is shown to be highly contingent upon the quality, coherence, and governance of the knowledge on which it is grounded. In the absence of structured Knowledge Management practices, the introduction of AI risks amplifying existing inefficiencies, reproducing informational fragmentation and organizational inconsistencies, in line with prior research on the digital transformation of knowledge processes (Faraj et al., 2018).

The case analysis further highlights the centrality of governance in the configuration of effective knowledge ecosystems. The introduction of formalized roles, shared standards and integrated platforms contributes to reducing ambiguity and strengthening organizational coordination, thereby enabling the development of

knowledge that is more reliable, accessible and reusable. In this sense, governance should be understood not as a static set of rules, but as a dynamic orchestration mechanism that aligns actors, technologies, and practices.

From a hybrid intelligence perspective, the findings suggest that value creation does not stem from the mere adoption of AI tools, but from the intentional design of complementary configurations between human and artificial capabilities. While AI extends the analytical capacity of organizations, human actors retain a central role in processes of interpretation, contextualization and ethical evaluation. Consequently, the effectiveness of hybrid intelligence depends on the organization's ability to embed these complementary dimensions within established practices, rather than relying solely on technological availability (Dellermann et al., 2019; Jarrahi, 2018).

An additional contribution of this study concerns the integration of ESG objectives, which emerges as a structural rather than peripheral dimension. The availability of traceable and reliable knowledge enhances transparency and accountability, which are foundational elements of sustainable governance. In this regard, Knowledge Management plays a pivotal role not only in enabling AI adoption, but also in supporting the alignment between organizational performance and socio-environmental impacts (Floridi et al., 2018; Vinuesa et al., 2020).

Overall, the theoretical contribution of this work lies in its ability to integrate three traditionally distinct streams of literature, Knowledge Management, hybrid intelligence, and sustainability, into a unified perspective grounded in the knowledge journey. This integrative approach helps to overcome the fragmentation of existing research and provides a systemic lens for understanding the design and governance of hybrid knowledge ecosystems.

8 Managerial and Policy Implications

From a managerial perspective, the findings suggest that organizations should treat Knowledge Management as a strategic priority rather than a supporting activity. In particular, before embarking on advanced AI adoption initiatives, it is essential to invest in the structuring of knowledge through shared standards, taxonomies and integrated digital systems, in order to ensure the quality and reliability of data.

Moreover, there is a clear need to develop well-defined and formalized knowledge governance models, grounded in the specification of roles and responsibilities. The introduction of roles such as knowledge owners can strengthen accountability mechanisms and ensure the continuous updating of content, thereby reducing the risk of obsolescence and informational inconsistency.

A further critical aspect concerns the design of human–AI interactions. Organizations should move away from substitution-oriented approaches and instead adopt complementarity-based logics, designing decision-making processes in which the analytical capabilities of AI are effectively integrated with the interpretative and strategic competencies of human actors. This also entails the development of specific organizational capabilities, not only related to the use of technologies, but also to their meaningful integration within work processes.

Finally, the integration of ESG objectives requires a rethinking of knowledge management systems in terms of transparency, traceability and accountability. In this regard, Knowledge Management platforms can play a crucial role in supporting more informed decision-making practices and in ensuring alignment between corporate strategies and long-term socio-environmental impacts.

From a policy-making perspective, the findings highlight the need to foster institutional ecosystems that support the integration of Knowledge Management, Artificial Intelligence and sustainability. In particular, it's essential to promote the adoption of common standards for knowledge management and sharing, in order to enhance interoperability across organizations and facilitate the responsible use of data.

Furthermore, public policies should support the development of hybrid competencies, combining digital literacy, analytical capabilities and ethical awareness, to better prepare individuals and organizations to operate in contexts characterized by increasing human–AI integration. This implies investments in education, training, and reskilling programs focused on knowledge management and the responsible use of AI.

An additional area of intervention concerns the development of regulatory frameworks and guidelines aimed at ensuring transparency, accountability, and reliability in AI-based systems, particularly in relation to ESG objectives. Strengthening knowledge and data traceability practices can contribute to improving the quality of both public and private decision-making, while mitigating risks associated with algorithmic bias and process opacity.

Finally, policy makers can play a key role in promoting the diffusion of digital infrastructures and collaborative platforms that facilitate knowledge sharing between public and private actors, thereby fostering the development of innovation ecosystems oriented toward sustainability.

Overall, these interventions can contribute to establishing the institutional conditions necessary for the development of hybrid knowledge ecosystems capable of generating sustainable value in the long term.

9 Conclusions

This study demonstrates that the design of hybrid human–AI knowledge ecosystems is not merely an evolutionary option, but a fundamental strategic lever for organizations operating in contexts characterized by increasing complexity, digitalization and mounting sustainability pressures. By integrating Knowledge Management, hybrid intelligence and ESG objectives along the knowledge journey, the proposed framework highlights how sustainable value creation increasingly depends on the systemic orchestration of knowledge, technology and governance.

From this perspective, the contribution of the study extends beyond a purely technological understanding of AI, emphasizing that true competitive advantage lies in the ability to structure, make accessible and activate organizational knowledge within hybrid decision-making processes. Organizations that invest in robust Knowledge Management infrastructures and governance models are better positioned not only to adopt AI effectively, but also to direct its use toward transparency, accountability, and long-term value creation.

From a managerial standpoint, the findings point to a necessary paradigm shift: AI adoption should not be driven solely by technological considerations, but embedded within a broader knowledge management strategy. This entails rethinking roles, processes and organizational practices to foster the integration of human and artificial capabilities, thereby transforming knowledge into a key driver of sustainable innovation.

From an academic perspective, the study contributes to advancing the debate on hybrid intelligence by moving beyond a predominantly conceptual focus toward a more practice-oriented approach. In doing so, it offers an integrated framework that bridges theory and practice, addressing a gap in the existing literature while opening new avenues for research on the interplay between knowledge ecosystems, emerging technologies and sustainability.

Ultimately, the future of value creation will not depend solely on the adoption of Artificial Intelligence, but on organizations' ability to design knowledge ecosystems in which human and AI capabilities co-evolve, positioning knowledge as a strategic infrastructure for truly scalable and enduring sustainability. In this sense, the proposed framework not only fills a gap in existing literature, but also opens up new research avenues on the interaction between knowledge ecosystems, emerging technologies, and sustainability. In particular, future research could further investigate the empirical applicability of the model across different organizational contexts through comparative multi-case studies, as well as integrate quantitative methods to assess the impact of hybrid knowledge ecosystems on ESG performance. Additional studies could also explore the role of emerging technologies, such as generative AI, in enhancing knowledge creation and decision-making processes, as well as examine the ethical and governance implications associated with these developments.

10 Ethics Declaration

The authors declare that this study was conducted in accordance with the ethical standards generally accepted for scientific research. Where applicable, all experimental procedures were approved by the appropriate ethics committees and comply with national and international regulations. The authors declare no conflicts of interest.

11 AI Declaration

During the preparation of this manuscript, generative Artificial Intelligence tools were used to assist with writing and editing. Specifically, the language model ChatGPT developed by OpenAI (GPT-4 version) was employed to improve textual clarity, harmonize linguistic style, and provide suggestions for rephrasing complex sections, under the direct supervision and final approval of the human authors. No part of the content was generated autonomously by AI without human oversight. The authors take full responsibility for the scientific content and conclusions presented.

Abstract

Cyberbullying represents a pervasive and evolving threat within digital environments, exacerbated by the scale, anonymity, and immediacy of online interactions. While recent advances in Artificial Intelligence (AI), particularly in Natural Language Processing (NLP), have significantly improved the ability to automatically detect harmful content, a critical gap persists between detection and effective intervention. Existing approaches primarily focus on identifying cyberbullying instances, but they often lack mechanisms to operationalize prevention guidelines and translate them into consistent, actionable responses. This paper addresses this gap by proposing a novel framework that integrates AI-based cyberbullying detection with Business Process Model and Notation (BPMN) to transform textual prevention guidelines into executable workflows. The framework leverages AI models to analyze user-generated content and identify potential cyberbullying signals, which are then used to trigger BPMN-based processes representing structured intervention strategies. A key contribution of this work lies in the systematic mapping of unstructured policy documents into BPMN constructs, allowing organizations to bridge the gap between high-level guidelines and operational procedures. The proposed approach is illustrated through a detailed modeling of cyberbullying prevention guidelines, demonstrating how complex policies can be translated into actionable pipelines. By combining the strengths of AI-driven detection and process-oriented modeling, this work contributes to the development of more effective and scalable cyberbullying prevention systems. Ultimately, the framework aims to support the creation of safer digital environments by enabling not only the identification of harmful behavior but also the consistent execution of appropriate and timely responses, paving the way for future research at the intersection of AI, process management, and digital safety.

Keywords: BPMN, Cyberbullying, Artificial Intelligence, Process Modeling.

Paper type: Academic Research Paper

1 Introduction and Motivation

Cyberbullying has emerged as a pervasive cyber-social security challenge, producing significant psychological, social, and economic impacts across digital platforms (Giumetti and Kowalski, 2022). In particular, the rapid proliferation of digital communication platforms has fundamentally reshaped social interaction, enabling unprecedented connectivity while simultaneously amplifying harmful behaviors. Unlike traditional forms of bullying, cyberbullying is pervasive, persistent, and often difficult to detect due to the scale and velocity of online content generation. Social media platforms, messaging services, and online communities generate vast streams of user-generated data, making manual moderation approaches increasingly insufficient. As a result, the need for automated, scalable, and context-aware solutions to identify and mitigate cyberbullying has become a pressing concern for researchers, policymakers, and platform providers alike. Over the past decade, advances in Artificial Intelligence (AI), particularly in Natural Language Processing (NLP) and Machine Learning (ML), have enabled the development of sophisticated cyberbullying detection models. These systems can analyze textual, contextual, and behavioral signals to identify potentially harmful interactions with increasing accuracy. However, despite significant progress in detection capabilities, a critical gap remains between identifying harmful content and operationalizing appropriate intervention strategies. In practice, organizations often rely on textual guidelines, policy documents, or best practices for cyberbullying prevention, which are inherently abstract, ambiguous, and difficult to implement consistently across complex socio-technical systems (Rahman et al., 2025). This disconnect highlights a key limitation in current approaches: the lack of structured mechanisms to translate high-level prevention guidelines into executable processes.

While AI models can flag potentially harmful content, they do not inherently provide a standardized framework for deciding what actions should follow, how responsibilities should be distributed among stakeholders, or how interventions should adapt to different contexts. Consequently, responses to cyberbullying incidents may be inconsistent, delayed, or ineffective, undermining the overall goal of safeguarding users. To address this challenge, there is a growing need for methodologies that bridge the gap between detection and action by formalizing intervention workflows. Business Process Model and Notation (BPMN) offers a well-

established standard for modeling, analyzing, and automating organizational processes (Rosa et al., 2026). By representing activities, decision points, and information flows in a structured and visual manner, BPMN enables the transformation of informal guidelines into precise, executable workflows. Despite its widespread adoption in business process management, its potential in the domain of cyberbullying prevention remains largely unexplored.

This paper proposes a novel framework that integrates AI-based cyberbullying detection with BPMN modeling to transform textual prevention guidelines into actionable workflows. The core idea is to create a seamless pipeline in which detection outputs from AI models serve as triggers for BPMN-defined processes, enabling systematic and context-aware responses to cyberbullying incidents. By formalizing intervention strategies as process models, the framework aims to ensure consistency, transparency, and adaptability in handling harmful online behavior. The motivation behind this work is twofold. First, it seeks to enhance the practical applicability of AI-based detection systems by embedding them within structured decision-making processes. Second, it aims to support organizations, such as social media platforms, educational institutions, and regulatory bodies, in operationalizing their cyberbullying prevention policies in a clear and scalable manner. Ultimately, this approach contributes to the development of more resilient digital ecosystems, where harmful behaviors can be not only detected but also addressed through well-defined and effective intervention workflows.

The remainder of this paper is structured as follows. Section 2 presents the proposed framework architecture, detailing the integration between AI-based cyberbullying detection components and BPMN-driven process orchestration. Section 3 focuses on the modeling of cyberbullying prevention guidelines, illustrating how textual policies can be systematically translated into structured and executable BPMN workflows. Finally, Section 4 concludes the paper by summarizing the main contributions and outlining directions for future research.

2 Framework Architecture

The proposed architecture, depicted in Figure 1, integrates multiple components to support cyberbullying analysis. Specifically, it is organized into four main modules: data preparation; model building; platform integration; and end-user support.

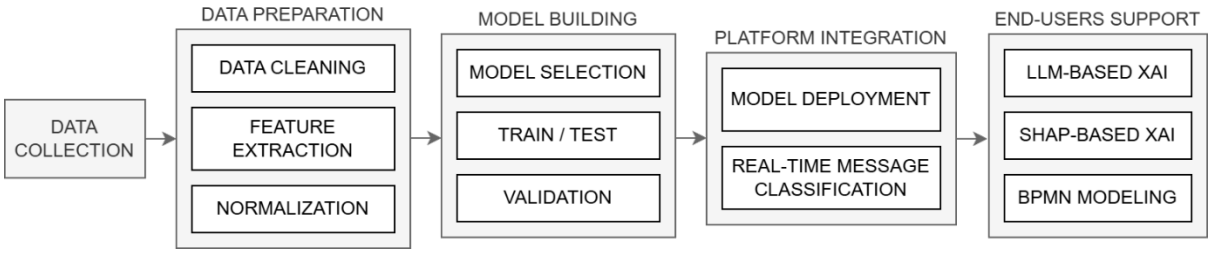

Figure 1 - Framework Architecture

The data preparation module is responsible for importing, cleaning, and preparing the reference dataset, to improve the quality and representativeness of the input data. The outcome of this phase is a structured and standardized dataset ready for model training and real-time inference. The core analytical component of the framework applies supervised learning algorithms for the classification of messages as cyberbullying or non-cyberbullying. Depending on the experimental configuration, both traditional ML models and Deep Learning approaches can be employed. The models are trained on pre-processed data and optimized using basic classification metrics such as accuracy, precision and recall. This module is designed for scalability and real-time execution to support continuous message analysis. The framework also integrates a web interface acting as the user-facing component of the system, simulating a social networking environment in which users can post, view, and analyze messages. It can integrate the reference classification model to provide immediate feedback on message content, displaying whether a given message is identified as cyberbullying. Finally, the eXplainable AI (XAI) module (see Loseto et al., 2026) enhances the transparency and interpretability of the classification process. It combines two complementary approaches: a local Large Language Model (LLM) capable of generating natural language explanations to communicate model reasoning to non-technical users, and the SHAP library, which provides quantitative and visual insights into the contribution of individual features.

XAI represents an additional element for increasing trust and transparency in automated decision-making systems. In the context of cyberbullying detection and broader cybersecurity applications, the ability to understand and communicate why a system produced a given prediction is as important as the prediction itself. When a message is flagged as harmful or dangerous, the XAI module provides a clear and human-readable

explanation allows users to understand which words, patterns, or contexts contributed to the decision. This transparency not only improves user trust but also offers an educational value by making users aware of the types of language or behavior that might be considered harmful in online communities. In turn, this can foster healthier digital interactions and reduce the risk of repeated offenses. From a cybersecurity perspective (Zhang et al., 2022), XAI is essential for ensuring that automated threat detection and anomaly detection systems remain auditable and reliable. Security analysts benefit from detailed, interpretable insights that can guide incident response and prioritization of alerts. For example, in a social platform monitoring scenario, XAI can help distinguish between false positives (benign messages incorrectly flagged as harmful) and true threats, improving system precision and reducing unnecessary intervention. Another significant benefit of XAI in these scenarios lies in regulatory and ethical compliance (Nannini, 2025). Many data protection frameworks emphasize the right to explanation when automated decision-making affects individuals. Integrating XAI into cyberbullying and cybersecurity tools ensures alignment with these principles and supports the development of responsible AI systems.

Following the classification and explainability stages, BPMN is leveraged to formally represent intervention strategies as process models, enabling traceability from detection events to preventive actions while embedding governance constraints such as privacy controls and accountability checkpoints.

3 Modeling of Cyberbullying Guidelines

In the context of cyberbullying detection and prevention, BPMN serves as a formalization layer that captures intervention logic, providing actionable support to end users. This design enables a clear separation between analytical processing and guideline modelling while ensuring continuity from detection to prevention. Among the wide range of policies and recommendations available, the following three key documents have emerged as the most relevant and have been adopted as reference sources for the BPMN-based modelling process:

- First, the international guidance provided by *UNICEF*[1] frames cyberbullying prevention as an integral component of child protection and digital rights. This perspective emphasizes the need for education on safe online practices, the empowerment of children and adolescents, capacity-building for parents and teachers, and stronger accountability mechanisms for digital platforms. UNICEF's approach highlights the importance of a multi-stakeholder ecosystem in safeguarding minors online.
- Second, the academic and practical guidance from the *Cyberbullying Research Center* (CRC) provides a set of evidence-based interventions that schools and local communities can adopt (Hinduja and Patchin, 2024). These include systematic assessment of bullying behaviors, the development of clear policies, specialized training for educators, continuous monitoring of incidents, and structured restorative responses. This framework is grounded in empirical research and focuses on practical measures that institutions can implement directly.
- Finally, the "Guidelines for the prevention and contrast of the phenomena of bullying and cyberbullying"[2] issued by the *Italian Ministry of Education and Merit* provide an operational framework tailored to the national school system. These guidelines translate broader principles into concrete responsibilities for schools, including defining school-level duties, establishing standardized reporting flows, mandating educational curricula on digital citizenship, and enhancing coordination with families, law enforcement, and local services. This national framework ensures consistency and accountability in the prevention and management of cyberbullying incidents across Italian educational institutions.

Overall, as reported in Table 1, the review of these three frameworks highlights a shared emphasis on education, early detection, coordinated intervention, and systemic collaboration as essential components of cyberbullying prevention and mitigation. Moreover, there is consensus on the necessity of multi-level interventions combining education, institutional policy, and technological safeguards. Early intervention and structured reporting mechanisms are critical to effective responses. Nonetheless, gaps remain, particularly regarding the accountability of private digital platforms. While UNICEF and research advocates emphasize platform responsibility, national school-centered frameworks often lack enforcement mechanisms beyond the school context. Additionally, the adoption of restorative practices remains uneven, and resource constraints pose practical barriers to effective program implementation.

Table 1 - Comparison of guidelines for cyberbullying prevention and regulation

Dimension / Guidelines	**UNICEF**	**Cyberbullying Research Center**	**Italian Ministry of Education & Merit**
Primary Focus	Child protection, digital rights, online safety education	Evidence-based identification, prevention, school/community interventions	School policies, administrative procedures, prevention & contrast of cyberbullying
Scope	International, child-centered	International (research), school-centric but applicable to communities	National (Italy), mandatory for schools
Underlying Principles	Protection of child dignity, empowerment, multi-stakeholder collaboration	Evidence-driven, whole-school approach, assessment & monitoring	Prevention, early intervention, coordination with families and authorities
Key Stakeholders	Children, parents, educators, governments, digital platforms	Students, educators, school administrators, law enforcement	School leadership, teachers, students, families, regional authorities
Definition & Framing of Cyberbullying	Online violence and digital-harm violating children's rights	Repeated, intentional harm via digital devices; aligned with bullying research	Behaviors that cause harm through digital means; aligned with national legal framework
Prevention Strategies	Digital citizenship, awareness campaigns, safe online behavior, resilience-building	Policies, curriculum integration, staff training, parental involvement	Mandatory school plans, education programs, digital citizenship, teacher training
Intervention & Response	Encourage reporting, ensure psychosocial support, platform reporting tools	Multi-tiered interventions: prevention, targeted support, disciplinary and restorativ e actions	Structured procedures for identification, reporting, involvement of families, referral to authorities
Monitoring & Data	Promote research globally, encourage governments to track incidents	Strong emphasis on systematic assessment and evaluation	Schools must monitor, document, and evaluate actions regionally and nationally
Platform Accountability	Strong emphasis on platform safety mechanisms, improved reporting an d removal tools	Limited (more research-oriented than regulatory)	Minor emphasis; focus remains o n school-level actions
Legal/Regulator y Basis	Non-binding international guidance	Research-driven, non-regulatory recommendations	Italian law, Ministerial Decree n.18/2021
Strengths	Holistic, rights-based, globally adaptable	Evidence-based, deeply practical for educators	Operational, enforceable, tied to national education system
Limitations	High-level; implementation varies across countries	Requires school capacity and resources to implement effectively	Limited influence over social platforms; uneven implementation across regions

Although existing guidelines are often very specific and detailed, their structure and presentation tend to be highly verbose, legalistic or technical. This level of complexity can pose a significant barrier for non-expert users (e.g., parents, students, educators not specialized in law or cyber-safety) who need to interpret and apply them in concrete circumstances. Dense paragraphs of legal or procedural text may end up discouraging engagement, hindering clarity about concrete responsibilities, workflows, and rights, and limiting the actual implementation of the guidelines in real-world contexts. Adopting a visual modelling or informational design approach can significantly enhance comprehension and practical application. When applied to cyber-social guidelines (e.g., rules, reporting procedures, roles and responsibilities, intervention flows), such a visual modeling approach can serve several functions. First, it can lower the barrier to comprehension; even users unfamiliar with legal terminology or institutional jargon can follow a structured flowchart. In addition, visual models foster shared mental models among diverse stakeholders. Such shared understanding becomes especially valuable in urgent situations or where multiple actors must coordinate also enhancing scalability and reuse. Once procedures are

modelled, they can be reused, updated, and disseminated more easily, supporting training, awareness campaigns, and easier onboarding of new staff or community members.

Among current modelling approaches, including UML activity diagrams, flowcharts, data-flow models, and state-based representations, BPMN emerged as the most suitable framework for describing processes related to cyberbullying detection and support. Unlike simpler diagramming techniques, BPMN incorporates explicit semantics for events, decisions and roles, making it particularly well-suited for contexts that require coordination among several actors (e.g., educators, administrators, and families). As described in Zhou et al. (2018), BPMN can be useful for structuring and standardizing processes for cybersecurity detection, reporting, and support. By providing a graphical and formal representation of workflows, BPMN enables organizations to model how information flows, how responsibilities are distributed, and how interventions should be coordinated across different actors. Particularly, in the context of cyberbullying detection, BPMN models can describe processes such as incident identification, automated alert generation, data validation, escalation pathways, and communication with responsible personnel.

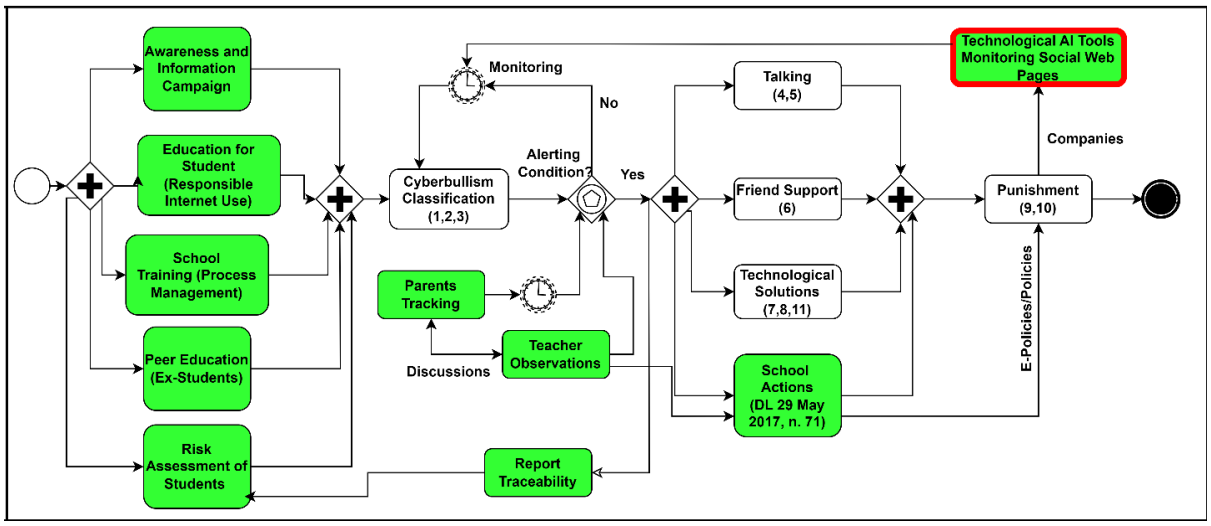

Figure 2 - BPMN model of national guidelines proposed by Italian Ministry of Education and Merit

The BPMN workflow may integrate automated monitoring tools (e.g., keyword detection or anomaly detection algorithms) with manual verification steps performed by teachers or designated school staff. Similarly, for support and response, BPMN can formally map actions including victim assistance, communication with families, documentation procedures, involvement of mental-health professionals, and, when necessary, referral to law enforcement or specialized services. For example, Figure 2 illustrates the processes defined by the Italian Ministry of Education and Merit. This BPMN diagram operationalizes the structured procedures mandated for Italian schools, including incident reporting, verification by designated school personnel, communication with families, activation of support measures, and coordination with local institutions or law-enforcement authorities when required. The model reflects the Ministry's school-centric approach by clearly delineating roles, responsibilities, and decision points that guide the response to cyberbullying cases within the national educational system.

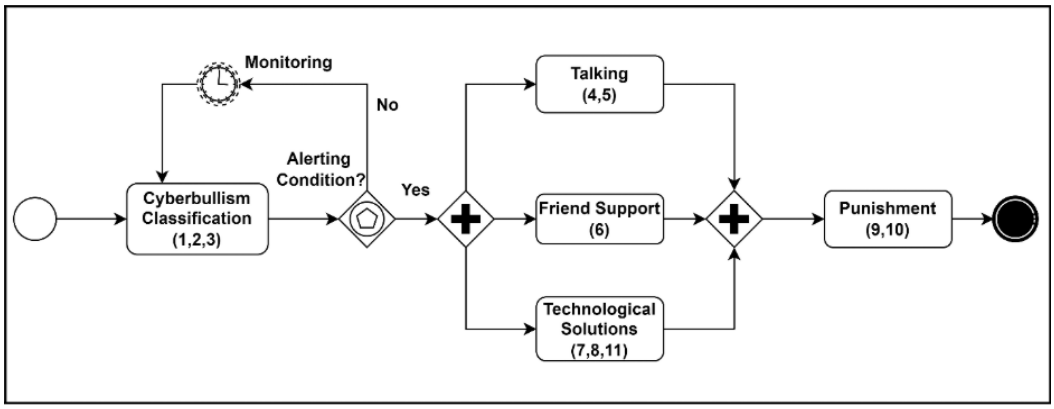

Figure 3 - BPMN model of UNICEF guidelines

Similarly, Figure 3 models the guidelines proposed by UNICEF, highlighting the multi-stakeholder nature of cyberbullying prevention as framed within child-protection and digital-rights principles. The BPMN model captures emphasis on awareness-raising, capacity-building for parents and educators, empowerment of children, and collaboration with digital platforms to enable effective reporting and response mechanisms. Events and message flows are used to illustrate how preventive education, early detection, and support actions interact across different actors.

However, the adoption of BPMN for cyberbullying detection and support also presents challenges. One limitation is that cyberbullying incidents are often context-dependent and emotionally sensitive, making it difficult to fully capture nuanced human judgment within a predefined process model. Additionally, effective workflows depend on accurate data collection and cooperation between multiple actors, e.g., students, teachers, administrators, families, and external agencies, which may not always be consistent or reliable. There are also technical challenges related to integrating BPMN-driven processes with automated detection tools, especially when these rely on privacy-sensitive data or advanced AI models. Finally, ensuring that all personnel are trained to understand and implement BPMN processes can require significant organizational effort. Despite these challenges, BPMN represents a valuable tool for operationalizing cyberbullying prevention and response efforts. By combining process transparency, standardization, and the ability to integrate both human and technological components, BPMN can help institutions create more effective, accountable, and timely interventions to protect young people in digital environments.

4 Conclusion and Future Work

In this work, we addressed the critical gap between the detection of cyberbullying incidents and the operationalization of effective prevention strategies. While AI-based approaches have significantly advanced the automatic identification of harmful content, their impact remains limited without structured mechanisms to guide consistent and timely interventions. To overcome this limitation, we proposed a unified framework that bridges detection and action by integrating AI-driven cyberbullying detection with process-oriented modeling through BPMN. First, we introduced an integrated architecture that combines AI-based detection capabilities with BPMN to enable traceable, structured, and auditable prevention processes. This integration allows detection outputs to seamlessly trigger predefined workflows, ensuring that responses to cyberbullying incidents are not only automated but also aligned with organizational policies and best practices. Second, we demonstrated how high-level prevention guidelines, often expressed as unstructured textual documents, can be systematically transformed into executable process workflows. This formalization enhances transparency by making decision logic explicit, improves accountability by clearly defining roles and responsibilities, and increases adaptability by allowing processes to be refined and extended as new requirements emerge. Moreover, the proposed approach lays a solid foundation for embedding risk management strategies and privacy-aware controls within AI-driven pipelines, supporting compliance with ethical and regulatory standards.

Future work will focus on extending the proposed framework along several directions. We aim to explore the integration of Generative AI techniques to enhance user interaction with prevention guidelines and process workflows. This includes the development of text-based, interactive explanation systems powered by large language models, capable of providing contextualized guidance, clarifying decision paths, and supporting stakeholders in navigating complex prevention procedures. Additionally, further research will investigate the incorporation of adaptive and self-improving workflows, as well as the evaluation of the framework in real-world scenarios to assess its effectiveness, usability, and scalability across different application domains.

Research Methods for Sustainable Organizations Using Intelligent Knowledge

Pierluigi Mascaro
Mercatorum Uniuversity, Rome, Italy

Abstract

The transition toward sustainable organizations has intensified the need for advanced knowledge systems capable of addressing complex economic, environmental, and social challenges. In this context, intelligent knowledge—defined as the integration of human expertise, organizational learning, and digital technologies such as artificial intelligence (AI) and data analytics—has emerged as a critical enabler of informed decision-making and long-term organizational resilience. This paper examines the research methods most suitable for investigating sustainable organizations through the lens of intelligent knowledge, with particular attention to their ability to capture complexity, dynamism, and socio-technical interactions.

The study adopts an integrative methodological perspective, combining insights from quantitative, qualitative, mixed-methods, design science, and participatory research approaches. Quantitative methods support the analysis of measurable relationships between knowledge capabilities and sustainability performance, while qualitative approaches provide in-depth understanding of organizational processes, cultural dynamics, and meaning-making practices. Mixed-methods designs enable the triangulation of findings, enhancing both validity and explanatory power. In addition, design science and action research approaches contribute to bridging theory and practice by supporting the development and evaluation of intelligent knowledge systems in real organizational contexts.

A central argument of the paper is that no single methodological approach is sufficient to address the multifaceted nature of sustainability challenges. Instead, the research highlights the necessity of methodological pluralism, emphasizing longitudinal and process-oriented designs, multi-level analysis, and the integration of ethical considerations related to AI and data use. The paper also underscores the importance of reflexivity and interdisciplinary collaboration in developing robust and context-sensitive research frameworks.

By providing a comprehensive overview of methodological approaches and their implications, this study contributes to the advancement of sustainability research and offers a coherent framework for analyzing how intelligent knowledge can support sustainable organizational transformation. The proposed methodological orientation is both theoretically grounded and practically relevant, enabling researchers and practitioners to better understand and navigate the complexities of sustainability in an increasingly data-driven world.

Keywords: Sustainable Organizations; Intelligent Knowledge; Research Methodologies; Artificial Intelligence; Socio-Technical Systems.

Paper type: Academic Research Paper

1 Introduction

The growing urgency of environmental degradation, climate change, and social inequality has fundamentally reshaped the role of organizations in contemporary society. Organizations are no longer evaluated solely on their economic performance but increasingly on their ability to generate sustainable value across environmental and social dimensions. This shift has led to the emergence of the concept of sustainable organizations, which integrate economic, environmental, and social objectives into their strategies and operations (Elkington, 1997; Dyllick & Muff, 2016).

At the same time, rapid advancements in digital technologies have transformed how knowledge is created, shared, and applied within organizations. Artificial intelligence, big data analytics, and digital platforms have enabled new forms of intelligent knowledge—knowledge that is not only accumulated but also processed, interpreted, and applied through advanced computational systems (Brynjolfsson & McAfee, 2017; Russell & Norvig, 2021). This convergence of sustainability and intelligent knowledge presents both opportunities and challenges for organizations seeking to navigate complex and uncertain environments.

Despite the growing importance of intelligent knowledge in sustainability, there remains a need for robust research methodologies capable of capturing its multidimensional nature. Traditional research approaches often fall short in addressing the dynamic, socio-technical, and multi-level characteristics of sustainable organizations. This paper aims to fill this gap by examining research methods suitable for studying sustainable organizations using intelligent knowledge and by analyzing the methodological implications of this research domain.

This transformation also implies a broader reconfiguration of how organizations conceptualize knowledge, shifting from linear and static models toward dynamic, adaptive, and systemically embedded understandings. In

such contexts, knowledge is increasingly shaped by the interaction between human cognition and algorithmic systems, requiring new analytical lenses capable of capturing co-evolutionary processes between technology, organization, and environment.

2 Theoretical Background

2.1 Sustainable organizations

The concept of sustainable organizations is rooted in the idea of the triple bottom line, which emphasizes the integration of economic, environmental, and social performance (Elkington, 1997). Over time, this concept has evolved into more comprehensive frameworks that highlight the systemic and transformative nature of sustainability in organizations (Dyllick & Muff, 2016).

Sustainable organizations are characterized by their ability to adapt to changing environmental conditions, manage stakeholder relationships, and innovate in ways that reduce negative impacts while creating long-term value. This requires not only technological capabilities but also organizational learning, cultural change, and strategic alignment (Hart & Dowell, 2011).

The systemic and multi-dimensional nature of sustainable organizations implies that their study requires multi-level and context-sensitive research designs. Methodologically, this entails combining firm-level analysis with broader ecosystem perspectives, including stakeholders, institutions, and environmental systems. It also necessitates the integration of qualitative approaches to capture cultural and strategic dimensions, alongside quantitative measures of sustainability performance. Furthermore, the adaptive and evolving character of sustainable organizations reinforces the importance of longitudinal and comparative studies, enabling researchers to observe how sustainability practices and outcomes develop over time across different organizational and institutional contexts.

2.2 Intelligent knowledge

Intelligent knowledge builds on the knowledge-based view of the firm, which considers knowledge as the most strategically significant resource (Grant, 1996). It extends this perspective by incorporating digital technologies and AI into knowledge processes. Intelligent knowledge involves the interaction between human cognition, organizational routines, and computational systems (Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998).

The integration of AI and data analytics allows organizations to process large volumes of data, identify patterns, and support decision-making in real time. However, intelligent knowledge is not purely technological; it also depends on social and organizational contexts, including trust, culture, and governance (Orlikowski, 2007).

The hybrid nature of intelligent knowledge—situated at the intersection of human, organizational, and technological domains—requires the adoption of socio-technical and multi-method research designs. Methodologically, this implies combining computational techniques (e.g., data analytics, machine learning validation) with qualitative approaches capable of capturing human interpretation, organizational routines, and cultural dimensions. It also necessitates careful consideration of data governance, algorithmic transparency, and epistemological assumptions embedded in AI systems. As a result, researchers must integrate technical rigor with interpretive depth, ensuring that both the performance and the meaning of intelligent knowledge are adequately analyzed.

2.3 Socio-technical systems perspective

Understanding intelligent knowledge in sustainable organizations requires a socio-technical perspective that considers both technological and social elements. Socio-technical systems theory emphasizes the interdependence between human actors and technological systems, highlighting the importance of alignment between them (Checkland, 1999).

This perspective is particularly relevant in sustainability research, where technological solutions must be integrated with organizational practices and societal values. It also underscores the need for research methods that can capture these complex interactions (Geels, 2002).

Adopting a socio-technical systems perspective entails methodological approaches that explicitly account for interactions, interdependencies, and co-evolution between social and technological components. This requires the use of integrative and systemic research designs, such as case studies, system dynamics modeling, and network analysis, capable of capturing relational complexity. Furthermore, it implies that unit-of-analysis choices must extend beyond individual organizations to include systems, ecosystems, and transitions.

Consequently, researchers must embrace methodological pluralism and develop frameworks that can bridge micro-level practices with macro-level transformations, ensuring a holistic understanding of sustainability processes.

3 Research Methodologies

3.1 Quantitative methods

Quantitative research methods are essential for analyzing measurable relationships between intelligent knowledge and sustainability outcomes. Surveys and statistical models allow researchers to test hypotheses and identify patterns across large samples (Alavi & Leidner, 2001).

Structural equation modeling (SEM) is widely used to examine relationships between latent variables such as knowledge management capabilities and sustainability performance. Panel data analysis enables the study of changes over time, providing insights into causal relationships (Bansal & DesJardine, 2014).

Big data analytics and machine learning further enhance quantitative research by enabling the analysis of large and complex datasets. These methods are particularly useful for studying energy consumption, supply chain efficiency, and environmental impacts (Wamba et al., 2015). However, they also introduce challenges related to data quality, bias, and interpretability.

The increasing reliance on quantitative and data-driven approaches implies a need for methodological rigor in data management, model specification, and validation procedures. Researchers must address issues related to data quality, completeness, and representativeness, particularly when using large-scale or unstructured datasets. Moreover, the use of advanced analytical techniques such as machine learning requires careful consideration of model transparency, reproducibility, and interpretability. This leads to a growing emphasis on hybrid analytical frameworks that combine predictive accuracy with explanatory clarity, ensuring that quantitative findings remain both robust and meaningful in sustainability contexts.

3.2 Qualitative methods

Qualitative research methods provide in-depth insights into the processes and contexts through which intelligent knowledge is developed and applied. Case studies are particularly valuable for exploring complex phenomena in real-world settings (Yin, 2018).

Interviews and ethnographic studies allow researchers to understand how individuals and groups interpret and use knowledge in sustainability initiatives. These methods are essential for capturing organizational culture, leadership dynamics, and ethical considerations (Eisenhardt, 1989).

Longitudinal qualitative research is especially important for studying organizational change over time. It enables researchers to trace the evolution of knowledge practices and sustainability strategies (Hart & Dowell, 2011).

The use of qualitative methods requires strong attention to contextualization, researcher reflexivity, and interpretive validity. Researchers must ensure transparency in data collection and analysis procedures, including coding strategies and case selection criteria. Furthermore, the emphasis on process and meaning implies that findings are often context-specific, which necessitates careful consideration of transferability rather than generalizability. Longitudinal qualitative designs also introduce challenges related to access, consistency, and data continuity, reinforcing the need for well-structured research protocols and sustained engagement with field settings.

3.3 Mixed-methods approaches

Mixed-methods research combines quantitative and qualitative approaches to provide a more comprehensive understanding of complex phenomena. By integrating numerical data with contextual insights, researchers can enhance the validity and relevance of their findings (Creswell & Plano Clark, 2018).

Sequential designs involve conducting one type of research before the other, while concurrent designs integrate both simultaneously. Mixed-methods approaches are particularly useful in sustainability research, where multiple perspectives and levels of analysis are required (Saunders et al., 2019).

The adoption of mixed-methods approaches introduces the challenge of methodological integration, requiring researchers to ensure coherence between quantitative and qualitative components. This includes aligning research questions, data collection strategies, and analytical frameworks across methods. Additionally, mixed-methods designs demand careful consideration of timing, priority, and weighting of different data

sources. Successfully addressing these challenges enhances triangulation and strengthens the robustness of findings, but also requires advanced methodological expertise and clear justification of design choices.

3.4 Design science research

Design science research focuses on the creation and evaluation of artifacts, such as models, systems, and tools. It is particularly relevant for developing intelligent knowledge systems that support sustainability (Hevner et al., 2004).

This approach involves iterative cycles of design, implementation, and evaluation, allowing researchers to refine solutions based on feedback. Action design research further integrates practical intervention with theoretical development (Sein et al., 2011).

Design science research shifts the role of the researcher from passive observer to active designer, which introduces important implications for evaluation and rigor. Methodologically, this requires clearly defined criteria for artifact effectiveness, utility, and generalizability. It also necessitates iterative validation processes involving stakeholders and real-world testing environments. Furthermore, the dual aim of theoretical contribution and practical relevance demands transparent documentation of design choices and learning cycles, ensuring that results are both scientifically credible and practically applicable.

3.5 Participatory and action research

Participatory and action research methods involve stakeholders in the research process, promoting collaboration and co-creation of knowledge. These approaches are especially important in sustainability research, where multiple stakeholders are involved (Reason & Bradbury, 2008).

Action research emphasizes learning through action and reflection, enabling organizations to implement changes while generating knowledge. This approach bridges the gap between theory and practice (Davenport & Prusak, 1998).

Participatory and action research approaches require a redefinition of the researcher's role, emphasizing collaboration, facilitation, and ethical responsibility. Methodologically, this entails managing power dynamics, ensuring inclusivity, and maintaining transparency throughout the research process. It also introduces challenges related to objectivity and bias, as researchers become embedded within the context they study. To address these issues, reflexivity, documentation, and iterative validation are essential. At the same time, these approaches enhance the practical relevance and societal impact of research, aligning closely with the goals of sustainability-oriented inquiry.

4 Methodological Implications

The integration of intelligent knowledge into sustainability research has significant methodological implications. First, it requires a shift toward longitudinal and process-oriented research designs. Sustainability and knowledge processes evolve over time, making static analyses insufficient.

Second, it necessitates multi-level analysis. Intelligent knowledge operates at individual, organizational, and societal levels, requiring methods that can capture interactions across these levels.

Third, it introduces ethical considerations related to AI and data usage. Researchers must address issues such as bias, transparency, and accountability.

Fourth, it blurs the boundary between research and practice. Methods such as design science and action research involve active participation in organizational processes, requiring reflexivity and ethical awareness.

Finally, it reinforces the importance of methodological pluralism. No single method can capture the complexity of sustainable organizations using intelligent knowledge.

These implications collectively require the development of integrative methodological frameworks that explicitly address temporality, scale, and ethics within a unified research design. Researchers must adopt flexible and adaptive methodologies capable of evolving alongside the phenomena under investigation. This includes combining longitudinal data collection with multi-level modeling techniques, integrating ethical assessment into research protocols, and ensuring continuous reflexivity throughout the research process. As a result, methodological rigor is increasingly defined not only by technical precision but also by the ability to capture complexity, ensure ethical responsibility, and generate actionable insights.

Methodologically, this means moving beyond isolated techniques toward coordinated research designs that combine longitudinal observation, multi-level modeling, and reflexive inquiry. It also requires embedding ethical governance directly into the research process, particularly when dealing with AI-driven systems and data-

intensive environments, ensuring that methodological choices remain aligned with both scientific rigor and societal responsibility.

5 Discussion

The findings highlight the need for integrative research approaches that combine multiple methodologies. Quantitative methods provide generalizable insights, while qualitative methods offer contextual understanding. Mixed-methods approaches bridge these perspectives, and design science and action research contribute practical solutions.

The role of intelligent knowledge in sustainability is likely to grow as technologies continue to evolve. Future research should explore emerging technologies such as explainable AI and their implications for sustainability.

The discussion underscores the necessity of designing research strategies that are inherently hybrid and forward-looking. Methodologically, this implies not only combining existing approaches but also continuously adapting them to emerging technological contexts. Researchers must develop capabilities to study evolving phenomena such as explainable AI, which require new evaluation criteria, interdisciplinary knowledge, and innovative data collection techniques. This dynamic orientation reinforces the need for methodological flexibility and continuous methodological innovation as core competencies in sustainability research.

This discussion implies that future research agendas must increasingly prioritize adaptability and methodological responsiveness to technological evolution. In particular, the growing presence of intelligent and explainable AI systems requires researchers to continuously update analytical frameworks, evaluation criteria, and data interpretation strategies. Methodologically, this translates into a stronger emphasis on iterative research designs, cross-disciplinary integration, and continuous validation processes, ensuring that methodological tools remain aligned with rapidly changing socio-technical realities.

6 Conclusion

This paper has examined research methods for studying sustainable organizations using intelligent knowledge. It has highlighted the importance of combining different methodological approaches to address the complexity of sustainability challenges.

The integration of intelligent knowledge requires new research paradigms that are adaptive, interdisciplinary, and practice-oriented. By adopting such approaches, researchers can contribute to both theoretical advancement and practical impact.

The conclusions of this study emphasize that future research must move beyond methodological fragmentation toward coherent and integrative research paradigms. This entails developing unified frameworks that systematically combine different methods while maintaining clarity in research design and purpose. Additionally, it highlights the importance of aligning methodological choices with both theoretical objectives and practical relevance, ensuring that research outcomes effectively support sustainable transformation. Ultimately, methodological innovation becomes a central driver of progress in the study of sustainable organizations using intelligent knowledge.

The enrichment of the conclusion reinforces the need for a holistic and forward-looking methodological orientation. Researchers must design studies that are not only methodologically sound but also capable of capturing emerging phenomena, integrating ethical considerations, and producing scalable insights. This entails combining rigor with flexibility, embracing interdisciplinary collaboration, and fostering continuous methodological learning. Ultimately, the ability to effectively study sustainable organizations using intelligent knowledge will depend on the development of research frameworks that are dynamic, integrative, and closely aligned with the evolving realities of both organizations and the broader socio-technical systems in which they operate.

7 Ethical Declarations

This study is based exclusively on theoretical and secondary literature analysis and does not involve human participants, clinical data, or any form of experimental intervention. As such, no formal ethical approval was required. Nevertheless, the research adheres to established academic standards of integrity, transparency, and responsible scholarship. All sources have been appropriately cited to ensure intellectual honesty and to avoid plagiarism. Particular attention has been given to the ethical implications of artificial intelligence and data-driven systems, especially regarding issues of transparency, bias, and accountability in the context of sustainable organizational research.

8 AI Declaration

Artificial intelligence tools were used in this study solely as a linguistic and editorial support instrument to assist with text refinement, structural organization, and clarity of expression. All conceptual development, analytical framing, and scientific content selection were conducted under full human authorship and responsibility. The use of AI did not involve autonomous generation of research data, empirical analysis, or scientific inference. The authors confirm that they critically reviewed, edited, and validated all AI-assisted outputs to ensure academic accuracy, coherence, and compliance with research integrity standards.

Research on Megatrends and the Evolution of ESG Standard

Giovanni Maiuri[2], Domenico Celenza[1], Alessia Nardecchia[2], Francesco Di Vona[2]
[1] University of Cassino and Southern Lazio, Cassino, Italy
[2] Independent scholar

Abstract

This paper examines how global megatrends can be transformed into actionable knowledge for the design of sustainability standards and the development of predictive environmental, social and governance reporting. The argument is grounded in the view that intelligent and sustainable organizations are not merely adopters of digital tools, but knowledge-processing systems that detect weak signals, translate them into governance priorities and combine human and artificial intelligence to support responsible value creation. The paper develops a conceptual framework linking megatrend research, European sustainability reporting traditions, knowledge management and artificial intelligence. The analysis identifies three historically rooted European trajectories: the German emphasis on measurement, comparability and procedural discipline; the French emphasis on public regulation, social responsibility and corporate accountability; and the Italian "Economia Aziendale" tradition, which connects economic performance, social embeddedness and systemic equilibrium. The paper argues that the next stage in the evolution of sustainability standards requires a shift from descriptive disclosure to predictive ESG intelligence, understood as the capacity to transform megatrend knowledge into forward-looking, scenario-based and accountable sustainability decisions. Artificial intelligence is interpreted as a cognitive infrastructure that can strengthen human interpretation by mapping weak signals, clustering heterogeneous information, modelling scenario-based risks and connecting sustainability variables with business continuity and organizational resilience. The contribution of the paper is twofold. First, it reframes ESG standards as dynamic knowledge artefacts rather than static compliance devices. Second, it proposes an AI-enabled pathway through which organizations can move from fragmented non-financial reporting to anticipatory, accountable and human-centred sustainability governance. An illustrative climate-transition example shows how a megatrend can be translated into dynamic ESG metrics, predictive outputs and strategic governance decisions. The paper concludes that predictive ESG intelligence can support intelligent organizations and communities only when embedded in ethical oversight, stakeholder dialogue and a relational view of value creation.

Keywords: megatrends; ESG standards; knowledge management; predictive analytics; artificial intelligence

Paper type: Academic Research Paper

1 Introduction

The future of organizations and communities increasingly depends on their capacity to combine knowledge, intelligence and sustainability. Demographic change, technological acceleration, climate pressure, geopolitical instability and evolving social expectations no longer operate as distant variables. They enter strategy, reshape business-model legitimacy and influence how value creation is evaluated by investors, regulators, workers, customers and communities. The ability to detect, interpret and govern megatrends has therefore become a condition of sustainable resilience (Ansoff, 1975). This paper starts from the proposition that sustainability standards are not neutral technical instruments. They are knowledge structures through which societies define what should be observed, measured, compared and reported. ESG standards reflect a changing understanding of the firm and of its relationship with the wider ecosystem. When reporting systems move beyond financial data, they recognise that organizational continuity depends on social trust, ecological viability, institutional accountability and stakeholder relations. From a knowledge management perspective, reporting identifies, codifies, shares and uses relevant knowledge to support decisions (Rohrbeck and Kum, 2018).

The debate on intelligent organizations and communities adds a further dimension. Intelligence cannot be reduced to artificial intelligence or individual cognition. It includes collective sensemaking, organizational learning, community participation and the ability to connect dispersed information with coherent action. Intelligent organizations are hybrid systems in which human judgement, digital infrastructures and collaborative practices interact. Technologies expand learning capacity, but organizations remain accountable for how knowledge is selected, interpreted and applied.

The aim of the paper is to develop a conceptual framework on megatrends and ESG standards, aligned with the IFKAD debate on intelligent knowledge for sustainable organizations. The research question is: how can organizations transform megatrend analysis into predictive ESG intelligence for sustainable value creation and resilience? The answer is theoretical and integrative, combining European corporate social responsibility, knowledge-based views of the firm and AI-enabled predictive analytics. Predictive ESG intelligence denotes a

knowledge-based dynamic capability through which an organization transforms megatrend knowledge into anticipatory evaluations for strategy, risk management and resilience. Cognitive infrastructure is the socio-technical framework through which artificial intelligence structures information flows and helps human agents identify patterns, anomalies and emerging risks. Dynamic ESG metrics preserve comparability while remaining responsive to new risks and regulatory changes. Knowledge artefacts are standards, metrics, reports or models that allow organizations to codify and disseminate knowledge. ESG standards can therefore define how sustainability phenomena are observed, measured and discussed in governance processes.

2 Theoretical Background

2.1. Megatrends as strategic knowledge

Megatrends are long-term transformations that reshape the conditions under which organizations operate. They include demographic ageing, urbanization, digitalization, climate transition, resource scarcity, geopolitical fragmentation and changing expectations concerning work and quality of life. Their relevance lies not only in their scale, but also in their systemic character. A megatrend rarely affects one function or industry. It alters markets, institutions, technologies and social practices simultaneously, so organizations that treat it as an isolated risk tend to underestimate its cumulative effects.

Megatrends can be understood as strategic knowledge objects because they are not immediately available as stable facts. They must be constructed through data collection, interpretation, comparison and dialogue. Organizations decide which signals are meaningful, which sources are credible and which time horizons matter. The knowledge-based theory of the firm suggests that advantages depend on the capacity to integrate specialized knowledge (Grant, 1996). Megatrend analysis extends this view by requiring organizations to integrate external, uncertain and ambiguous knowledge (Weick, 1995).

This requirement recalls Nonaka and Takeuchi (1995), who described knowledge creation as a dynamic interaction between tacit and explicit knowledge. Sustainability challenges require this interaction. Quantitative indicators are necessary, but they do not exhaust the meaning of climate vulnerability, community well-being or organizational resilience. Tacit knowledge from workers, managers, communities and stakeholders helps interpret data and prevents narrow measurement. Intelligent ESG governance therefore requires mechanisms through which data become shared understanding.

The treatment of megatrends as knowledge also connects sustainability to resource-based and dynamic capability perspectives. Knowledge becomes strategic when it is difficult to imitate, embedded in routines and recombined with external signals (Barney, 1991; Teece et al., 1997). In digital transformation, this recombination depends on data quality, interpretive routines and capabilities for translating information into action (Davenport and Prusak, 1998; De Mauro et al., 2016; Vial, 2019). Megatrends such as climate transition or demographic ageing should therefore be read as socio-technical transitions requiring distributed knowledge, experimentation and coordinated learning (Geels, 2002; George et al., 2016).

2.2. Sustainability standards as institutionalised knowledge

Sustainability standards identify disclosure categories, define metrics, impose comparability and support accountability. They also shape internal learning. When an issue enters a reporting framework, it becomes more visible to managers and governance bodies. What is measured tends to enter routines, risk maps and performance discussions. ESG standards are therefore institutionalised knowledge: they stabilize social expectations and translate them into organizational language.

The rise of non-financial reporting reflects a broader transformation in the concept of the firm. Classical financial reporting privileges profitability, solvency and asset valuation. Sustainability reporting expands the field by including conditions that make value creation durable and legitimate. This expansion is consistent with European corporate social responsibility and with approaches that view the enterprise as an open system. In the Italian Economia Aziendale tradition, the firm is a coordinated institution whose equilibrium depends on economic, social and environmental relations (Ferrero, 1968; Onida, 1971; Borgonovi and Anessi Pessina, 2018).

The contemporary European agenda can therefore be read as regulatory innovation and intellectual continuity. The Corporate Sustainability Reporting Directive reinforced the idea that sustainability information is relevant for governance and stakeholders, not merely reputation (European Commission, 2022). Yet the underlying principle is older: the enterprise must be understood in relation to the community and to the conditions of continuity. Cassandro (1978) expressed this idea by presenting the firm as a responsible actor whose conduct has social consequences.

Sustainability also creates tensions. Organizations must balance short-term performance with long-term resilience, shareholder expectations with stakeholder claims and standardized indicators with context-specific meanings. Such tensions are intrinsic to sustainability and should not be eliminated prematurely (Hahn et al., 2010; Van der Byl and Slawinski, 2015). ESG standards can support this balance only if treated as learning devices, not only as compliance checklists.

This institutionalization is visible in European and global reporting architectures. The European Sustainability Reporting Standards operationalize double materiality, while International Sustainability Standards Board standards emphasize decision-useful sustainability-related financial information (European Commission, 2023; EFRAG, 2023; IFRS Foundation, 2023a; IFRS Foundation, 2023b). GRI, ISO 26000 and TCFD contributed to a shared vocabulary for responsibility, impact and risk (GRI, 2021; ISO, 2010; Task Force on Climate-related Financial Disclosures, 2017). These developments extend stakeholder theory and sustainable development thinking, from the Brundtland definition to triple bottom line debates (Freeman, 1984; World Commission on Environment and Development, 1987; Elkington, 1997).

2.3. Artificial intelligence as cognitive infrastructure

Artificial intelligence introduces new possibilities for sustainability reporting because it can process large and heterogeneous datasets beyond traditional managerial routines. Machine learning, natural language processing and predictive analytics may help organizations analyse public documents, regulatory changes, scientific evidence, market signals, stakeholder sentiment and operational data. These tools detect patterns, identify anomalies and model alternative scenarios, extending the statistical and computational capacity for inference and prediction (Hastie et al., 2009; Russell and Norvig, 2021).

AI should not, however, be framed as an autonomous solution. The central issue is not only prediction, but interpretation. Predictive systems may estimate probabilities, but governance bodies decide which risks are material, which trade-offs are acceptable and which actions are legitimate. This distinction is important in ESG reporting, where decisions affect diverse stakeholders, communities, employees and future generations. AI strengthens organizational intelligence only when embedded in human judgement, transparency and accountability.

The concept of cognitive infrastructure is useful here. AI systems can organize information flows, support sensemaking and make weak signals more visible. They can also connect sustainability variables with financial and operational risk. However, they remain part of a broader socio-technical system. If data are biased or poorly interpreted, outputs may reinforce narrow assumptions. If governance processes are weak, predictive analytics may become decorative. Predictive ESG intelligence therefore requires technological capability and organizational maturity.

3 European Trajectories in the Evolution of ESG Standards

Three European trajectories are useful for understanding the evolution of sustainability standards: German, French and Italian. They should not be treated as rigid national stereotypes, but as historically formed orientations that emphasize different dimensions of organizational knowledge. Their convergence helps explain why European sustainability reporting combines measurement, regulation, narrative disclosure and systemic thinking.

The German trajectory is associated with structured indicators, measurability, standardization and procedural discipline. Sustainability information gains credibility when supported by precise metrics and comparable methods. Research on German non-financial reporting shows the movement from voluntary disclosure to mandatory obligations after the CSR Directive Implementation Act, while emphasizing report quality and links between financial and non-financial information (Hoffmann, Dietsche and Hobelsberger, 2018). The German Sustainability Code reflects the same orientation through 20 criteria for transparency and comparability (German Council for Sustainable Development, 2020). This contribution strengthens the reliability of sustainability standards and supports AI-enabled reporting, because predictive analytics requires structured data.

The French trajectory assigns a strong role to public regulation, corporate accountability and social responsibility. It emphasizes institutions in defining what organizations owe to society. This legal tradition is visible in the Nouvelles Régulations Économiques framework and in later reforms that expanded social and environmental disclosure. Studies of French CSR disclosure confirm that national legal, cultural and institutional traditions shape the legitimacy of corporate responsibility reporting (Antal and Sobczak, 2007; Chauvey et al., 2015). ESG standards therefore express public expectations concerning labour, inclusion, governance quality, environmental transition and corporate legitimacy.

The Italian trajectory, rooted in Economia Aziendale, offers a systemic interpretation (Zappa, 1927). The firm is viewed as an institution that must preserve equilibrium across economic, patrimonial, social and organizational dimensions. Onida's conception of the enterprise as an open system implies that continuity cannot be reduced to financial solvency (Onida, 1971). Cassandro's institutional view reinforces the firm's responsibilities towards the broader community (Cassandro, 1978). This perspective connects sustainability with business continuity, stakeholder relations and long-term viability. Taken together, these trajectories provide a European basis for moving from descriptive reporting to anticipatory governance. The German emphasis on measurement supports data quality. The French emphasis on accountability supports legitimacy. The Italian emphasis on systemic equilibrium supports integrated interpretation. Predictive ESG intelligence requires all three dimensions: measurable data, public responsibility and a systemic understanding of value creation.

4 An AI-Enabled Pathway to Predictive ESG Intelligence

The proposed framework defines predictive ESG intelligence as the capacity to transform megatrend knowledge into forward-looking sustainability decisions through human judgement, collective learning and AI-enabled analytics. This capacity develops through three phases: mapping megatrends and weak signals, embedding them into dynamic ESG metrics and connecting them with scenario-based sustainability risk intelligence. In practice, organizations move among these phases as new information emerges.

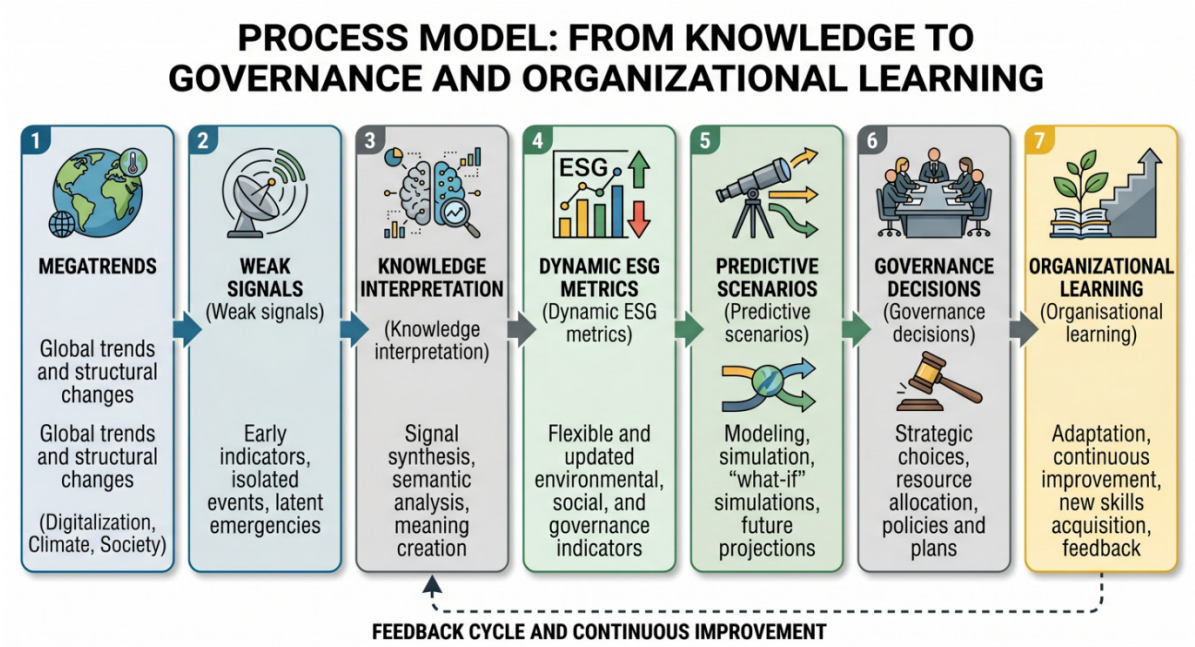

Figure 1. From megatrends to predictive ESG intelligence.

The figure shows how organizations can transform broad external transformations into actionable sustainability knowledge. AI supports the detection and organization of weak signals, while human and collective judgement remain responsible for interpretation, materiality assessment and governance action.

4.1. Mapping megatrends and weak signals

The first phase concerns the identification and interpretation of megatrends. Organizations collect large volumes of information, but much remains fragmented across departments, platforms and external sources. AI can assist through semantic analysis, text mining and thematic clustering, organizing heterogeneous material into interpretable domains. Climate regulation, energy prices, technological disruption and supply-chain instability may be connected as broader transition risk. The value of AI lies in making such relationships more visible.

Mapping is not a purely technical act. It requires the definition of boundaries, categories and relevance criteria. A weak signal may be insignificant in one context and strategically important in another. Organizations must therefore combine automated detection with deliberative interpretation. Cross-functional teams, sustainability experts, risk managers and stakeholders can help evaluate whether a trend is material. This

collaborative process prevents predictive systems from becoming detached from organizational knowledge and local experience.

The output of this phase is a structured megatrend knowledge base. It should be updated as new evidence, regulations and stakeholder expectations emerge, and it should distinguish between transient noise and persistent transformation. This distinction matters because sustainability governance requires attention to long-term change, whereas digital information environments often reward immediate reaction.

4.2. Embedding megatrends into dynamic ESG metrics

The second phase translates megatrend knowledge into ESG metrics and reporting categories. Traditional disclosure systems often describe past performance. Predictive ESG intelligence adds forward-looking indicators showing how external transformations may affect future conditions, including climate exposure, dependence on scarce resources, workforce skills, social acceptance of business models and governance readiness for regulation.

Dynamic metrics do not abandon standardization. They require a stable architecture for comparison over time and across units, while remaining flexible enough to incorporate emerging risks. A reporting system that cannot register new social or environmental vulnerabilities becomes obsolete. The challenge is to combine comparability with adaptability through processes for revising indicators, documenting assumptions and explaining why measures change.

The incorporation of megatrends into ESG metrics also changes the meaning of materiality. Materiality is not only a backward-looking assessment of issues that have already affected performance. It becomes an anticipatory judgement about issues that may influence value creation, stakeholder well-being and organizational continuity. Predictive analytics can support this judgement, but materiality remains a governance decision involving values, responsibilities and accountability.

4.3. Developing scenario-based sustainability risk intelligence

The third phase connects ESG indicators with scenario-based risk intelligence. Predictive systems can model how different megatrends may combine under alternative futures. An organization may assess how climate policy, energy transition, demographic change and digital automation jointly affect supply chains, labour requirements and community relations. The aim is not to forecast one future with certainty, but to improve preparedness by testing strategic assumptions under uncertainty.

This approach resonates with complexity thinking. Organizations are embedded in systems where small changes may generate large effects and feedback loops are difficult to predict (Bateson, 1972; Mitchell, 2009). Scenario-based ESG intelligence acknowledges this complexity. It supports strategies that are robust across plausible futures rather than optimized for one expected path. It also helps identify opportunity spaces, such as circular innovation, inclusive services, sustainable urban partnerships or knowledge-intensive collaborations with communities.

Predictive ESG intelligence should therefore be integrated into strategic planning, risk management and governance reporting. Its value is highest when it changes decisions rather than merely producing dashboards. Boards and management teams can use predictive outputs to discuss vulnerabilities, allocate resources, redesign processes and engage stakeholders. At the same time, they must disclose the assumptions behind predictive models. Transparency is essential because future-oriented reporting can easily become speculative if uncertainty is understated.

Scenario work also has a behavioural dimension. It can reduce dependence on a single expected future, but it may reproduce cognitive biases when assumptions remain implicit (Ariely, 2008; Schoemaker, 1995). Predictive ESG intelligence should therefore include assumption registers, sensitivity analysis and structured disagreement. It should also consider the safe and just operating space in which economic activity occurs (Raworth, 2017). Its value emerges when sustainability supports innovation in products, processes and business models (Nidumolu et al., 2009; Schaltegger et al., 2017).

Table 1. From European reporting traditions to predictive ESG intelligence

Trajectory	Core knowledge logic	Contribution to ESG standards	AI-enabled extension
German	Measurement, standardisation and procedural discipline	Improves comparability, auditability and data reliability	Supports structured datasets and consistent predictive indicators
French	Public regulation, social responsibility and accountability	Links reporting to legitimacy, oversight and stakeholder expectations	Guides model use through transparency, responsibility and public purpose

Trajectory	Core knowledge logic	Contribution to ESG standards	AI-enabled extension
Italian	Systemic equilibrium and institutional continuity	Integrates economic, social and environmental dimensions of the firm	Connects ESG variables with resilience, continuity and scenario analysis

4.4. Illustrative example: climate transition as predictive ESG intelligence

The climate transition illustrates how a megatrend can become dynamic ESG insight and governance action. The initial focus is not a single environmental indicator, but a system of weak signals that may affect the organization over time: energy price volatility, regulatory pressure, carbon-related disclosure mandates, supplier vulnerability and changing consumer expectations.

In a descriptive framework, the organization may disclose current energy use or emissions. In a predictive ESG intelligence framework, the same information is linked to prospective exposure. A relevant indicator may include the proportion of strategic suppliers exposed to transition risk, with expected procurement or energy cost increases under different regulatory scenarios. The predictive output is not deterministic; it is a scenario-based estimate of cost increases, supply-chain vulnerabilities and implications for continuity.

The related governance decision may involve supplier diversification, energy-efficiency investment, revision of the transition strategy, contract renegotiation or stakeholder engagement. In summary: megatrend, climate transition; weak signals, energy price volatility, regulation and supply-chain exposure; dynamic metric, percentage of suppliers exposed to transition risk; predictive output, scenario-based estimate of cost increases; governance decision, supplier diversification and transition-plan revision. Predictive ESG intelligence is therefore a cognitive and organizational process that converts external transformations into measurable insights, scenarios and responsible action.

5 Discussion: Implications for Intelligent Organizations and Communities

The proposed framework has implications for both organizations and communities. For organizations, predictive ESG intelligence reframes sustainability reporting as a knowledge creation process. The organization does not simply collect information to satisfy external requirements. It learns how global transformations affect its business model, stakeholder relationships and capacity for continuity. This learning process can improve resilience because it enables earlier identification of vulnerabilities and more coherent responses to uncertainty (Zuboff, 1988).

For communities, the framework is relevant because organizational decisions shape social and urban ecosystems. Firms influence employment, skills, environmental quality, infrastructure use, innovation networks and quality of life. When organizations use megatrend analysis only for internal advantage, they may overlook broader effects. When they embed predictive intelligence in stakeholder dialogue, they can support shared value and inclusive growth. This matters in smart and hybrid environments, where work, public services and community interactions are increasingly mediated by digital technologies.

The framework also clarifies the relationship between human and artificial intelligence. AI can expand analytical capacity, but human intelligence remains responsible for interpretation, judgement and ethical direction. Collective intelligence is equally important because sustainability challenges cannot be solved within isolated hierarchies. Workers, experts, citizens, regulators and communities hold knowledge that may not be captured in formal datasets. Intelligent organizations must therefore design spaces for knowledge sharing, including hybrid workplaces, collaborative platforms and participatory governance mechanisms.

A further implication concerns compliance reductionism. ESG reporting can become formal when organizations focus only on producing documents. Predictive ESG intelligence resists this tendency by linking reporting with strategy and learning. However, it introduces risks. Models may create an illusion of certainty, automated systems may privilege measurable variables and organizations may overstate predictive capacity. These risks reinforce the need for governance oversight and for a clear distinction between analytical support and managerial responsibility.

From a practical perspective, organizations should begin with a diagnostic assessment of data, knowledge flows and governance routines. They should identify relevant megatrends, update indicators and establish interdisciplinary teams capable of interpreting predictive outputs. They should also document assumptions and expose them to challenge. This connects predictive ESG intelligence with corporate governance scholarship on board monitoring, strategic guidance and accountability (Zattoni and Pugliese, 2019). The objective is to make sustainability governance more informed, anticipatory and accountable (Kellogg, Valentine and Christin, 2020).

A final practical implication concerns algorithm and data governance. Predictive ESG systems should be assessed for explainability, fairness, auditability and proportionality, because technical opacity can weaken

accountability (Binns, 2018; Floridi et al., 2018). OECD principles link trustworthy AI with human-centred values, transparency, robustness and responsible stewardship (OECD, 2024). These requirements define when digital tools become legitimate organizational knowledge rather than unexamined technical authority (Kitchin, 2014; Orlikowski, 2007).

6 Conclusions

This paper has argued that the future of ESG standards depends on transforming megatrend research into predictive sustainability intelligence. Intelligent and sustainable organizations are not defined by digital adoption alone. They are defined by their ability to manage knowledge, interpret complexity and combine human and artificial intelligence in responsible value creation. The central contribution is the interpretation of ESG standards as dynamic knowledge artefacts and of AI as cognitive infrastructure for anticipatory sustainability governance.

The paper contributes to the IFKAD debate by connecting megatrends, sustainability standards, knowledge management and AI within a European intellectual framework. The analysis of German, French and Italian trajectories shows that contemporary sustainability reporting is grounded in complementary knowledge regimes: measurement, accountability and systemic equilibrium. These regimes converge in the need for reporting systems that are comparable, legitimate and capable of anticipating future conditions.

The proposed AI-enabled pathway moves through three phases: mapping megatrends and weak signals, embedding them into dynamic ESG metrics and developing scenario-based sustainability risk intelligence. The climate-transition example shows how this pathway translates a broad transformation into weak-signal interpretation, dynamic metrics, predictive scenarios and governance decisions. This supports the shift from descriptive disclosure to anticipatory governance and confirms that predictive systems strengthen resilience only when embedded in ethical oversight, stakeholder engagement and organizational learning.

The paper remains conceptual. It does not test the proposed framework empirically, nor does it compare specific AI tools or reporting systems. Future research could examine how organizations in different sectors implement predictive ESG analytics, how boards use forward-looking sustainability information and how communities participate in the interpretation of megatrends. Empirical studies could also explore whether predictive ESG intelligence improves resilience, innovation capacity and stakeholder dialogue.

7 Ethics Declaration

This paper is conceptual and does not report research involving human participants, personal data, confidential organizational records or experimental interventions. Ethical clearance was therefore not required.

8 AI Declaration

AI-assisted drafting support was used to structure and refine the paper from the authors' extended abstract and the conference template. The resulting text was reviewed and amended by the authors, who retain responsibility for the argument, citations, accuracy and final wording.

Abstract

This paper examines the experience of error in business-administrative judgement as a constitutive dimension of knowledge creation and as a critical object of governance in intelligent and sustainable organisations. The central thesis is that error is not a residual disturbance to be eliminated by predictive technologies, but a structural component of organisational knowledge that must be governed through hybrid human-AI arrangements. The analysis focuses on predictive assessment in the early emergence of corporate distress, a field in which managerial judgement, financial information, organisational arrangements and algorithmic models interact under conditions of uncertainty.

The paper argues that organisational intelligence cannot be reduced to the adoption of digital technologies or artificial intelligence systems. It depends on the capacity of organisations to recognise fallibility, interpret weak signals, transform mistakes into shared knowledge and design decision routines that strengthen resilience over time. The duty to establish adequate organisational, administrative and accounting arrangements under the Italian Code of Corporate Crisis and Insolvency is interpreted as an institutional response to the structural limits of judgement. Artificial intelligence can reinforce this infrastructure by processing large volumes of heterogeneous data, detecting non-obvious patterns and supporting early-warning systems. At the same time, predictive technologies introduce new forms of error, including poor data quality, model opacity, automation bias and the displacement of responsibility from human decision-makers to technical systems.

The paper therefore proposes a detection-interpretation-decision-learning framework of hybrid predictive governance. In this framework, AI supports the identification of patterns, weak signals and anomalies; human judgement interprets the organisational and strategic context; boards and management assume responsibility for decisions; model and organisational errors are reviewed; and the system learns and improves over time. The contribution is conceptual. It advances the debate on intelligent organisations and communities by showing that technology does not make organisations intelligent by itself. Organisations become intelligent when they develop the cultural, informational and technological capacity to learn from error before it becomes irreversible corporate failure.

Keywords: Intelligent organisations; knowledge management; artificial intelligence; corporate distress; predictive governance; organisational learning.

Paper type: Academic Research Paper.

1 Introduction

Sustainable value creation increasingly depends on organisations that can combine knowledge, technology and responsibility. Digital transformation, artificial intelligence and data-intensive control systems are often expected to make organisations more responsive, resilient and capable of anticipating discontinuities. Yet this expectation remains incomplete if it does not address a basic condition of managerial action: judgement is fallible. Firms do not operate in transparent environments. They interpret incomplete signals, rely on provisional models, select certain indicators while neglecting others, and construct narratives of continuity that may later prove fragile. An intelligent organisation is therefore not an organisation without error. It is an organisation that can recognise, process and govern error as part of its learning capacity.

This paper examines this issue through the specific case of predictive assessment in the early emergence of corporate distress. Corporate distress rarely appears as a sudden and isolated event. It typically develops through weak signals, such as declining margins, liquidity tensions, delayed payments, deteriorating customer relationships, operational rigidity, worsening credit conditions or the progressive loss of strategic coherence. These signals may be observable before insolvency becomes evident, but availability is not equivalent to knowledge. Data become useful only when they are interpreted, connected to organisational memory, discussed in appropriate decision arenas and translated into timely action. The problem is therefore not merely informational. It is cognitive, organisational and technological at the same time.

The central thesis of the paper is that error is not a residual disturbance to be eliminated by predictive technologies, but a structural component of organisational knowledge that must be governed through hybrid

human-AI arrangements. This thesis shifts attention from the ambition to remove error through automation to the design of governance systems capable of making error visible, interpretable and learnable. Predictive technologies may improve detection, but they cannot decide by themselves what a signal means, which trade-offs are acceptable or which response is responsible. The organisational challenge is not to delegate judgement to AI, but to build arrangements in which artificial intelligence, human judgement and collective governance correct and strengthen one another (Raisch and Krakowski, 2021).

In such hybrid arrangements, AI helps detect patterns, weak signals and anomalies; human judgement interprets the organisational and strategic context; boards and management assume responsibility for decisions; model and organisational errors are reviewed; and the system learns and improves over time. The paper translates this logic into a detection-interpretation-decision-learning framework, which is introduced at the beginning of the manuscript and then developed throughout the analysis. The framework is intended as an interpretive map rather than as a rigid procedural checklist. Its purpose is to show how predictive governance can transform error from a source of failure into a source of organisational learning.

The argument develops from a philosophical and epistemological understanding of error and reinterprets it in the context of artificial intelligence and predictive governance. Rather than treating error as an external disturbance to be removed by increasingly sophisticated technologies, the paper considers fallibility as a constitutive dimension of knowledge creation, organisational learning and managerial judgement. Selected epistemological accounts show that error is not external to knowledge, but is part of the process through which assumptions are tested, corrected and revised. This perspective is then connected to cognitive psychology, which demonstrates that managerial judgement is systematically exposed to biases such as anchoring, availability, representativeness and overconfidence (Tversky and Kahneman, 1974; Kahneman, 2011).

The Italian tradition of Economia Aziendale further reinforces the argument by interpreting the firm as a systemic and unitary phenomenon, in which economic, financial, patrimonial and organisational dimensions must be evaluated jointly (Zappa, 1927; Onida, 1971; Ferrero, 1968; Amaduzzi, 1963). Finally, studies on knowledge management and artificial intelligence explain how organisations can transform dispersed information into collective intelligence, while also showing that digital systems may introduce new vulnerabilities, including data bias, model opacity, automation bias and the displacement of responsibility from human decision-makers to algorithmic infrastructures (Nonaka and Takeuchi, 1995; Grant, 1996; Davenport and Prusak, 1998; Russell and Norvig, 2021).

2 A Framework of Hybrid Predictive Governance

The proposed framework places the detection-interpretation-decision-learning cycle at the core of predictive governance. Its first assumption is that corporate distress is not only a financial condition, but also a knowledge failure. Relevant information may be absent, delayed, fragmented, misinterpreted or politically suppressed. Predictive systems can increase the visibility of weak signals; however, the meaning of those signals remains context-dependent. For this reason, organisations must integrate algorithmic detection with human interpretation, responsible decision-making and systematic learning from predictive failures.

The framework consists of four interdependent layers. The first layer is detection: which weak signals are visible, and which remain obscured? The second layer is interpretation: what do those signals mean within the specific organisational, strategic and financial context of the firm? The third layer is decision: who is required to act, when, and with what level of responsibility? The fourth layer is learning: what did the prediction get right or wrong, and how should the organisation revise its data, models, assumptions and routines? The framework therefore rejects both technological determinism and purely intuitive judgement. It conceives predictive governance as a hybrid collaboration between human and artificial intelligence.

Figure 1 summarises the logic of the framework. AI expands the organisation's capacity to detect patterns, weak signals and anomalies. Human judgement connects those signals with tacit knowledge, strategic context and ethical considerations. Boards and management remain responsible for decisions because algorithmic outputs are inputs into governance, not substitutes for governance. Finally, errors are reviewed not only to allocate responsibility, but also to improve the system. False positives, false negatives, ignored warnings and delayed reactions become learning events.

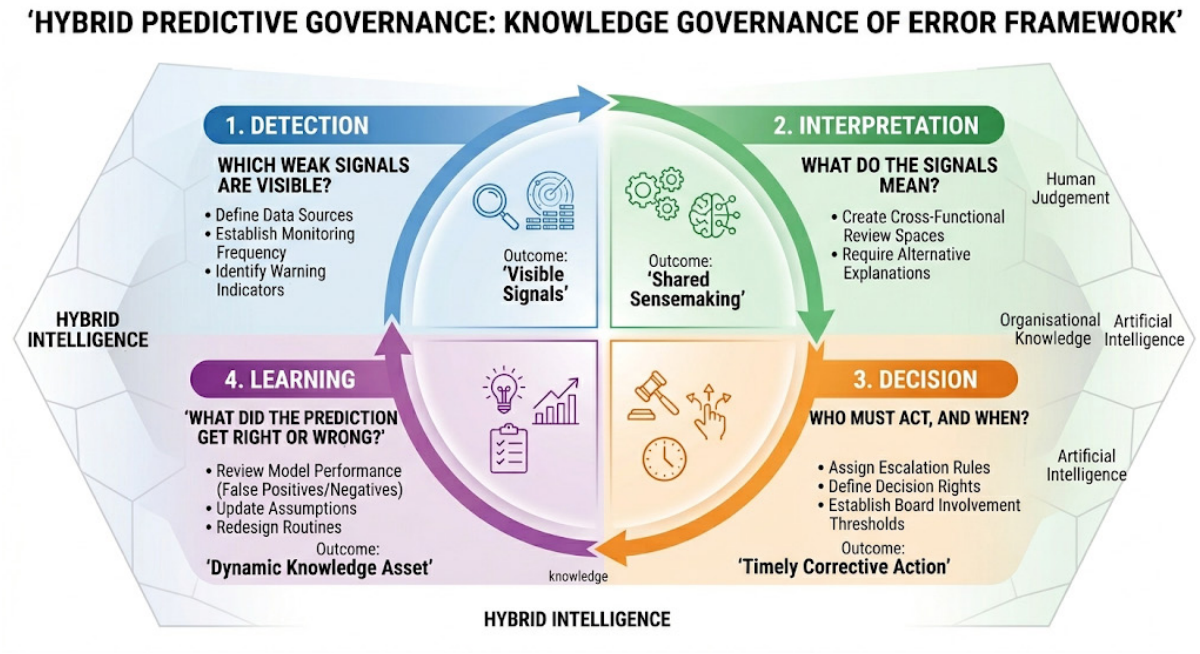

Figure 1. Hybrid predictive governance: knowledge governance of error framework.

Table 1. Knowledge governance of error in predictive assessment

Layer	Main question	Typical error	Governance response
Detection	Which weak signals are visible?	Relevant data are missing, delayed or fragmented.	Define data sources, monitoring frequency and warning indicators.
Interpretation	What do the signals mean?	Signals are normalised, rationalised or read through biased narratives.	Create cross-functional review spaces and require alternative explanations.
Decision	Who must act, and when?	Knowledge does not translate into timely corrective action.	Assign escalation rules, decision rights and board-involvement thresholds.
Learning	What did the prediction get right or wrong?	False positives and false negatives remain unexplained.	Review model performance, update assumptions and redesign routines.

Table 1 presents the same framework in analytical form. It highlights the main question, typical error and governance response associated with each layer.

3 Error as an Organisational Knowledge Experience

The experience of error is relevant for organisational theory because every managerial decision presupposes a representation of reality, and every representation may be partial. Organisations decide under uncertainty. They simplify complexity, select indicators, rely on forecasts and interpret signals through existing narratives. Error therefore cannot be understood only as an individual mistake. It often reveals the limits of the organisational knowledge system: what the organisation observes, what it ignores, how it interprets information and how it reacts when evidence contradicts expectations.

A concise epistemological reading is useful here insofar as it supports the organisational argument. Popper's view of knowledge as conjectural and exposed to falsification is particularly relevant (Popper, 1972). Knowledge grows when assumptions are tested and revised. In organisations, the same principle applies when forecasts, dashboards, risk classifications or managerial narratives are compared with subsequent events. A wrong prediction may be damaging, but it can also reveal why organisational assumptions were incomplete. Error becomes productive when it is not hidden, normalised or reduced to blame, but used to revise the system that generated it.

In organisational terms, error becomes meaningful when it is investigated as a symptom of a wider knowledge process. A wrong forecast may reveal poor data quality. A delayed reaction may reveal hierarchical silence. A distorted assessment may reveal incentives to preserve optimistic narratives. An ignored warning may reveal the absence of legitimate spaces for contradiction. The epistemology of error therefore becomes a theory of organisational learning. The organisation learns when it can move from the occurrence of error to its explanation, and from explanation to redesign.

This reasoning is close to the distinction proposed by Argyris and Schon (1978) between single-loop and double-loop learning. Single-loop learning corrects action while preserving the assumptions that generated it. Double-loop learning questions those assumptions. In the field of corporate distress, single-loop learning may add a new financial indicator or increase reporting frequency. Double-loop learning asks why existing indicators were not taken seriously, why weak signals were normalised and why decision-makers delayed corrective intervention. It is this second level that turns error into a strategic knowledge asset.

The perspective also resonates with knowledge-management theory. Nonaka and Takeuchi (1995) emphasise that knowledge creation depends on the interaction between tacit and explicit knowledge. Grant (1996) interprets the firm as an institution for integrating specialised knowledge. Davenport and Prusak (1998) similarly stress that organisational knowledge requires practices, processes and contexts that allow information to become actionable. These approaches suggest that organisational intelligence does not reside simply in databases or analytical tools. It lies in the capacity to connect experience, interpretation and action. Error is one of the occasions through which this connection can be tested. If an organisation suppresses or hides errors, it impoverishes its knowledge base. If it analyses them, it increases its capacity to perceive emerging vulnerabilities.

4 Managerial Judgement, Bias and Corporate Distress

Corporate distress is a useful field for observing the organisational consequences of judgemental error. The prediction of failure has a long tradition in accounting and finance. Beaver (1966, 1968) and Altman (1968) showed that financial ratios can provide meaningful indications of impending failure. Later models refined the analysis through hazard models, international comparisons and machine-learning approaches (Shumway, 2001; Altman et al., 2017). These contributions are essential, but they do not remove the role of judgement. Indicators must be selected, interpreted, contextualised and acted upon. The presence of a warning signal does not guarantee that the organisation will understand it.

Cognitive psychology explains why this gap persists. Tversky and Kahneman (1974) demonstrated that judgement under uncertainty is shaped by heuristics. Heuristics are useful because they reduce complexity, but they may also generate systematic biases. Anchoring can lead managers to interpret current performance through the lens of past success. Availability can make recent or emotionally salient events more influential than structural trends. Representativeness can encourage decision-makers to treat a temporary recovery as evidence that the business model remains robust. Overconfidence can lead management to underestimate both the probability and the speed of deterioration.

These biases are particularly dangerous in the early stages of crisis. A firm may still be operating, selling, paying wages and maintaining relationships with banks and suppliers. The visible continuity of operations can conceal a progressive erosion of economic equilibrium. Managers may treat volatility as noise, temporary liquidity shortages as manageable timing problems or commercial decline as a reversible market fluctuation. The more the organisation has invested its identity in a narrative of competence and control, the more difficult it becomes to accept that weak signals may be symptoms of deeper imbalance.

The psychology of error must therefore be connected to the sociology of organisations. Biases do not operate only inside individual minds. They are reinforced or weakened by organisational routines, incentive systems and power relations. A board that receives highly aggregated reports may be formally informed but substantively unable to understand the sources of risk. A chief financial officer may identify anomalies but fail to obtain attention if the dominant strategic narrative is expansionary. Middle managers may possess tacit knowledge of operational fragility, but that knowledge may not reach the governance level. Error is thus not only cognitive. It is distributed across information flows, reporting formats and decision rights.

Simon (1997) described administrative behaviour as boundedly rational. Decision-makers search, simplify and satisfice because perfect rationality is impossible. The issue is not to replace bounded rationality with an ideal of total optimisation, but to design arrangements that compensate for its limits. In the context of distress prediction, this means constructing processes that make weak signals visible, require competing interpretations and reduce the dependence of strategic decisions on intuition alone. The aim is not to distrust managerial experience, but to embed that experience in a corrective architecture of knowledge.

For this reason, the language of error should not be reduced to blame. Blame may be appropriate in cases of negligence, opportunism or concealment, but a generalised culture of blame can weaken learning by encouraging defensive behaviour. The relevant question for intelligent organisations is not only who made a mistake, but also what conditions made the mistake plausible, persistent or invisible. This shift is essential for organisations that aspire to be sustainable. Sustainability requires continuity of value creation, and continuity requires the ability to detect deterioration before it becomes irreversible.

5 “Economia Aziendale” and Adequate Arrangements

The Italian tradition of “Economia Aziendale” offers an important theoretical basis for linking error, knowledge and governance. Zappa (1927, 1956) placed the firm within a unitary and dynamic conception of economic activity. Onida (1971), Amaduzzi (1963) and Ferrero (1968) developed the idea that business administration must consider the firm as a system in which economic, financial, patrimonial and organisational aspects are interdependent. More recent contributions have confirmed the relevance of this integrated view for understanding the firm as a complex institution of value creation and accountability (Borgonovi and Anessi Pessina, 2018). The assessment of corporate conditions cannot be reduced to isolated ratios or single episodes. It requires an integrated judgement that connects income generation, financial equilibrium, assets, liabilities, organisational structures and strategic direction.

From this perspective, error often emerges from partiality. The evaluator may focus on profitability while neglecting cash generation, observe liquidity while neglecting debt sustainability, read accounting data without understanding operational processes, or treat organisational disorder as secondary to financial measurement. Such partiality is especially problematic in crisis prevention because distress is systemic. It develops when multiple dimensions of the firm cease to support one another. A knowledge-driven assessment must therefore preserve the unity of the business phenomenon while still using specialised indicators.

The Italian Code of Corporate Crisis and Insolvency gives this problem a specific institutional form. The duty to establish adequate organisational, administrative and accounting arrangements can be interpreted as a legal and managerial response to fallibility. Adequacy does not merely require the existence of formal procedures. It requires the capacity to detect imbalances, monitor business continuity, produce reliable information and support timely intervention. In this sense, the law translates an epistemological problem into a governance requirement: because judgement is fallible, organisations must create arrangements that reduce the probability that relevant signals remain unseen or misunderstood.

The notion of adequacy is therefore close to knowledge management. Adequate arrangements are not only controls in a narrow compliance sense. They are infrastructures for producing, validating and circulating knowledge about the firm. They define what information is collected, how it is processed, who receives it, which thresholds trigger attention, how alternative explanations are discussed and how responsibility for action is allocated. Their quality should be assessed not only by their formal existence, but by their capacity to support intelligent interpretation.

This reading is also consistent with contemporary debates on corporate governance. Boards are increasingly expected to oversee not only financial performance but also risk, sustainability, digital transformation and organisational resilience (Zattoni and Pugliese, 2019). However, board oversight is effective only if the board receives information that is timely, intelligible and connected to the strategic context. A dashboard that produces numerous indicators without meaningful interpretation may create a false impression of control. Conversely, a well-designed governance process can use indicators as starting points for informed questioning.

Adequacy thus has a relational dimension. It depends on the interaction among managers, accountants, controllers, auditors, directors and, where relevant, external advisers. Each actor holds partial knowledge. The task of governance is to connect these fragments into a sufficiently coherent view of the firm's condition. The early emergence of distress is precisely the situation in which this connection matters most. At that stage, the organisation still has choices. The quality of knowledge integration can determine whether those choices are recognised in time.

6 Artificial Intelligence in Early-Warning Systems

Artificial intelligence changes the relationship between error and judgement. Predictive algorithms can process volumes of data that exceed the capacity of individual decision-makers. They can detect non-linear relationships, compare current patterns with historical cases, update predictions as new information arrives and generate early warnings that may not be visible through traditional reporting. In the field of distress prediction, machine-learning tools can integrate financial ratios, payment behaviour, market data, textual information, operational indicators and external signals. Used appropriately, they expand the perceptual capacity of the organisation.

This expansion is important for intelligent and sustainable organisations. Sustainability is not only environmental or social; it also concerns the durability of value creation and the capacity to preserve productive relationships with employees, creditors, suppliers, customers and communities. Early-warning systems contribute to this objective by increasing the probability of timely intervention. They can support turnaround actions, debt restructuring, strategic repositioning or the redesign of business processes before value destruction becomes irreversible (Guatri, 1995).

However, artificial intelligence does not eliminate error. It relocates and transforms it. Data-quality problems may lead models to learn from incomplete, obsolete or biased information. Model risk may arise when an algorithm performs well on historical data but poorly in new circumstances. Opacity may prevent users from understanding why a warning has been produced. Automation bias may induce decision-makers to accept the algorithmic output without sufficient scrutiny. Conversely, algorithm aversion may lead experienced managers to reject useful warnings because they conflict with intuition or established narratives. The intelligent organisation must govern both forms of bias: excessive trust in the model and defensive rejection of the model.

The problem is not merely technical. It is organisational and ethical. Predictive systems influence attention and may affect access to credit, restructuring decisions and relationships among stakeholders. If the model is treated as neutral, responsibility may be displaced from human judgement to technical infrastructure. Yet algorithms are designed, trained, selected and interpreted by organisations. Their outputs are not decisions; they are inputs into decision processes. For this reason, AI governance must be integrated with corporate governance and knowledge governance.

Russell and Norvig (2021) define artificial intelligence in terms of systems that perceive, reason and act. In organisations, however, perception, reasoning and action are distributed across people and technologies. An early-warning algorithm may perceive patterns, but human actors must decide whether those patterns are strategically meaningful. It may generate a probability of distress, but it cannot by itself determine what level of risk is acceptable, which trade-offs are legitimate or how the consequences of intervention should be allocated. These are managerial and ethical questions.

The central issue is therefore the design of human-in-the-loop arrangements. Such arrangements should specify the data used by the model, the frequency of monitoring, the thresholds for escalation, the criteria for explanation, the responsibility for review and the procedures for challenging or validating the output. They should also include feedback loops. If a model produces false positives or false negatives, the organisation should not simply record the event. It must investigate why the error occurred and whether it reflects data limitations, model design, contextual change or interpretive failure. In this way, algorithmic error becomes part of organisational learning rather than a hidden technical defect.

The solution is therefore not to let AI decide everything (Parasuraman and Manzey, 2010). The solution is to build hybrid arrangements in which AI identifies signals that humans may miss, while human and collective judgement interpret those signals responsibly. This hybrid logic is particularly important in the early emergence of corporate distress, where signals are ambiguous, consequences are distributed among multiple stakeholders and decisions must often be taken before certainty is available.

7 Discussion: Intelligent, Sustainable and Inclusive Organisations

The proposed framework contributes to the debate on intelligent and sustainable organisations by shifting attention from technological adoption to knowledge governance. Organisations often describe themselves as intelligent because they use advanced analytics, dashboards or AI-based platforms. Such technologies are useful, but they do not by themselves create intelligence. Intelligence is relational. It emerges when information is made available to the right actors, when interpretation can be challenged, when decisions are connected to evidence and when the outcomes of decisions are used for learning.

This point has consequences for sustainability. Sustainable organisations must manage tensions among economic performance, social responsibility and long-term resilience (Hahn et al., 2010; Van der Byl and Slawinski, 2015). Corporate distress is not only a private problem of shareholders. It can affect employment, suppliers, creditors, local communities and the continuity of productive knowledge. Early-warning systems, if properly governed, can therefore support a broader form of value preservation. They allow organisations to intervene before crisis destroys relationships and before restructuring options become narrow.

The argument also has implications for inclusive innovation. A predictive governance system should not centralise intelligence exclusively in top management or technical experts. It should recognise that relevant knowledge is distributed. Employees may observe operational inefficiencies before they appear in accounts. Sales teams may perceive customer fragility before it affects revenues. Accountants may identify payment irregularities before management accepts their strategic significance. External stakeholders may provide signals that internal actors ignore. An inclusive intelligent organisation creates channels through which such knowledge can enter the assessment process.

Digital and hybrid work environments make this objective both easier and more difficult. They can facilitate the rapid sharing of information across geographical boundaries and organisational units. They can also fragment attention, multiply reports and weaken informal interpretation. The challenge is to build digital meeting spaces that support collective sensemaking. A dashboard is not a community of interpretation. A community of interpretation requires trust, accountability and the possibility of raising inconvenient questions without immediate defensive reaction.

The framework also suggests that AI ethics should be connected to organisational learning. Many discussions of AI ethics focus on fairness, transparency and accountability. These principles are essential, but they must be translated into everyday governance practices. In early-warning systems, transparency means that decision-makers understand the main drivers of a prediction. Accountability means that the organisation can identify who reviewed the output and what action was taken. Fairness means that the consequences of predictive classifications are considered in relation to stakeholders. Learning means that errors in prediction are not hidden, but used to improve the system.

Finally, the paper clarifies a paradox of intelligent organisations. The more an organisation aspires to be intelligent, the more it must institutionalise doubt. Confidence in technology, strategy or past success can become a source of blindness. Intelligent organisations are therefore not those that declare certainty, but those that maintain the capacity to revise themselves. They design routines that make error discussable, data contestable and judgement accountable. This is not a sign of weakness. It is a condition of resilience.

7 Conclusions

This paper has developed a conceptual account of the experience of error in business-administrative judgement, with particular reference to predictive assessment in the early emergence of corporate distress. Its central thesis is that error is not a residual disturbance to be removed by automation, but a structural dimension of organisational knowledge that must be governed. The paper has argued that predictive technologies can improve the detection of weak signals, but they cannot eliminate the need for human interpretation, board responsibility and organisational learning.

The contribution of the paper is threefold. First, it reframes error as a knowledge asset for intelligent organisations. Error indicates where information, interpretation and action have failed to connect. Second, it interprets adequate organisational, administrative and accounting arrangements as knowledge infrastructures aimed at governing managerial fallibility. Third, it proposes a detection-interpretation-decision-learning framework of hybrid predictive governance in which artificial intelligence supports, but does not replace, human and organisational judgement.

The practical implication is that organisations should not evaluate early-warning systems only by their technical accuracy. They should also assess whether those systems improve the circulation of knowledge, clarify responsibility, support timely decision-making and generate learning from false positives and false negatives. A predictive model that is accurate but ignored is not useful. A model that is trusted blindly is dangerous. The organisational challenge is to create a balanced relationship between computational intelligence and critical judgement.

The paper is limited by its conceptual nature. It does not test the proposed framework empirically. Future research could examine how firms design adequate arrangements, how boards interpret AI-generated warnings, how different organisational cultures respond to prediction errors and how stakeholders are affected by early-warning classifications. Comparative studies across legal systems and industries would also be valuable. Nonetheless, the theoretical argument is clear: intelligent and sustainable organisations are not defined by the absence of error. They are defined by the capacity to learn from error before it becomes organisational decline.

8 Ethics Declaration

This paper is conceptual and does not report research involving human participants, personal data, experiments, interviews or confidential organisational records. Ethical clearance was therefore not required. Should the framework be applied in future empirical research, the authors will seek the necessary ethical approval and ensure compliance with applicable rules on confidentiality, informed consent and data protection.

9 AI Declaration

An AI writing assistant was used as a drafting and language-support tool to expand the extended abstract into a full paper, improve coherence and check alignment with the conference template. The conceptual framing, selection of sources, legal interpretation, final judgement and responsibility for the submitted text remain with the authors. AI-generated material should be reviewed, edited and verified before submission.

Research on AI and Sustainability Ratings: Evidence from the Noverim Case

[2] Independent scholar

Abstract

The convergence between artificial intelligence, sustainability measurement and knowledge management is reshaping how organisations diagnose vulnerability, create value and build resilience. This paper examines the Noverim case as the basis for a study hypothesis: AI-enabled sustainability ratings may help identify organisational disequilibrium before conventional accounting data reveal it. The article does not present original empirical evidence. It develops a conceptual and case-based framework centred on an intelligent predictive system for assessing sustainability and business equilibrium. The reference to 500 Italian knowledge-intensive firms is used solely as a prospective field for future validation; it is not an observed sample, a tested dataset or evidence supporting the hypothesis. The study asks how heterogeneous knowledge assets, sustainability ratings and predictive analytics can be integrated to support early diagnosis, resilience-building and knowledge-driven innovation. The proposed framework interprets sustainability as an endogenous component of equilibrium, since ESG and organisational conditions affect risk exposure, adaptive capacity, stakeholder trust and the durability of value creation. The Noverim architecture combines supervised machine-learning techniques with unsupervised behavioural clustering to identify latent risk profiles and possible trajectories of imbalance. On this basis, the paper formulates three propositions: first, such systems may anticipate disequilibrium over a 12-to-18-month horizon; second, weak signals such as reduced intangible investment, turnover of key personnel, deteriorating internal sustainability indicators and strategy-conduct misalignment may reveal early fragility; third, intelligent ratings may help distinguish reversible from structural crises. These propositions require future empirical testing. The paper contributes to the literature on knowledge-based organisations by conceptualising predictive intelligence as a knowledge infrastructure for organisational learning, resilience mapping and accountable decision-making.

Keywords: predictive analytics, sustainability ratings, corporate equilibrium, organisational resilience, machine learning

Paper type: Academic Research Paper

1 Introduction

Intelligent organisations are increasingly expected to combine economic performance, social responsibility and the capacity to learn from data. This expectation is particularly relevant for knowledge-intensive firms, whose competitiveness depends on specialised expertise, organisational routines, relational capital, digital capabilities and the interpretation of weak signals. In these firms, distress rarely begins as a purely accounting event. It usually appears through dispersed and initially ambiguous symptoms: a slowdown in knowledge investment, the loss of key personnel, inconsistent strategic choices, fragile cash-flow planning or a declining capacity to translate sustainability commitments into managerial practice.

This issue is directly connected with the debate on intelligent and sustainable organisations. Digital transformation has expanded the volume, velocity and variety of data available to firms, but data availability does not automatically generate organisational intelligence. Intelligence emerges when information is selected, interpreted and converted into knowledge that can guide action. Artificial intelligence (AI) can therefore be understood not merely as a technical layer, but as one component of a broader knowledge infrastructure through which organisations learn, anticipate and coordinate decisions.

The paper examines the Noverim case as a predictive architecture applied to sustainability ratings and corporate equilibrium assessment. The case is treated as an analytical hypothesis for the IFKAD 2026 debate: if sustainability-related knowledge, organisational signals and predictive analytics are integrated within a coherent rating architecture, firms may be better able to identify emerging disequilibrium before it appears in conventional financial indicators. The reference to 500 Italian knowledge-intensive firms defines only a prospective field of investigation associated with the Noverim framework. It must not be read as empirical evidence, as a validated sample or as the basis of statistical results.

This framing reflects a broader development in management research. Sustainability is no longer only a matter of external legitimacy, disclosure or compliance; it is increasingly recognised as a condition that

influences resilience, stakeholder relationships, innovation capacity and long-term value creation. For knowledge-intensive firms, this point is especially important because value creation depends on intangible assets that are difficult to observe directly but may deteriorate before financial results reveal the decline.

The guiding research question is therefore the following: how can AI-enabled sustainability ratings support early diagnosis, organisational resilience and knowledge-based value creation in knowledge-intensive firms? The paper offers three contributions. Theoretically, it links the knowledge-based view, sustainability management and predictive analytics. Methodologically, it shows how supervised and unsupervised machine-learning approaches may be combined to classify risk and identify trajectories of imbalance. Practically, it advances the notion of a resilience map, in which firms are interpreted through the dynamic interaction of economic, financial, organisational and sustainability dimensions.

2 Theoretical Background

The study is grounded in the view that firms are systems of knowledge, capabilities and relationships. The resource-based view argues that sustained competitive advantage depends on resources that are valuable, rare, imperfectly imitable and organisationally embedded (Barney, 1991; Wernerfelt, 1984). The knowledge-based view extends this argument by treating knowledge as the central productive resource of the firm (Grant, 1996). In knowledge-intensive firms, value creation depends on expertise, problem-solving routines, technological experimentation and the continuous recombination of information. The same features also create vulnerabilities when key knowledge holders leave, learning routines weaken or organisational memory becomes fragmented.

Knowledge management is therefore part of business equilibrium rather than a merely supportive function. Nonaka and Takeuchi (1995) describe knowledge creation as a dynamic process through which tacit and explicit knowledge are continuously converted. Cohen and Levinthal (1990) show that absorptive capacity depends on the ability to recognise, assimilate and exploit external knowledge. These insights are central to resilience: a firm may possess abundant data and still fail to respond if learning routines, governance structures and interpretive capacities are weak.

Sustainability management adds a relational and institutional dimension. Stakeholder theory argues that firms create and preserve value through relationships with multiple constituencies rather than through shareholder interests alone (Freeman, 1984). Corporate sustainability research has shown that environmental, social and governance practices can influence organisational processes, risk exposure and financial performance (Eccles et al., 2014; Maas et al., 2016). This is particularly relevant in knowledge-intensive sectors, where reputation, human capital, trust and legitimacy affect the ability to attract clients, partners and employees.

Predictive analytics shifts the analytical focus from retrospective reporting to forward-looking diagnosis. Prediction is a distinct and valuable objective in information systems research (Shmueli and Koppius, 2011). In management contexts, predictive models can reveal combinations of variables that are difficult to detect through linear reasoning or conventional performance dashboards. Their value, however, depends on interpretability, data quality, validation procedures and managerial judgement. Machine learning should support inquiry and decision-making; it should not replace managerial responsibility.

2.1 Intelligent and sustainable organisations

An intelligent organisation is capable of sensing change, integrating knowledge and adapting behaviour. Intelligence is not reducible to automation; it includes human intelligence, collective intelligence, organisational memory and the selective use of AI. Sustainable organisations pursue economic viability while preserving the social and environmental conditions required for long-term value creation. The intersection of these ideas suggests that sustainability requires intelligence, and intelligence requires sustainability. A technologically advanced firm may remain fragile if it ignores stakeholder trust, employee well-being, governance quality or the ecological and social consequences of its operations.

Hybrid and smart workplaces intensify this connection. Distributed work, digital platforms and collaborative technologies have made knowledge more mobile, but also harder to coordinate and institutionalise. In knowledge-intensive firms, the quality of internal communication, the continuity of learning and the retention of talent become decisive components of resilience. Indicators such as turnover among key people, delays in innovation projects, weak knowledge-sharing routines or reduced investment in training may reveal emerging disequilibrium earlier than conventional financial ratios.

2.2 Corporate equilibrium and early-warning systems

Corporate equilibrium may be understood as the dynamic alignment of profitability, liquidity, capital structure, operational capacity, governance and strategic coherence. Traditional early-warning models made important contributions to bankruptcy prediction through financial ratios and statistical techniques (Altman, 1968; Ohlson, 1980). These models remain useful, but they may be less sensitive to the early phases of decline in firms whose assets are largely intangible and whose vulnerabilities are organisational before they become financial.

A multidimensional equilibrium approach broadens the diagnostic perimeter. It asks whether the firm is economically viable, financially balanced, organisationally coherent and sustainable in its relationships with stakeholders. This view is consistent with integrated risk management (Gatzert and Martin, 2015; Trucco, 2015) and balanced performance measurement (Kaplan and Norton, 1996). The distinctive element of the Noverim case lies in connecting this broader diagnostic logic with predictive intelligence and sustainability ratings.

3 Conceptual Design and Case-Based Analytical Setting

The paper adopts an interpretive, case-based conceptual design centred on the Noverim sustainability-equilibrium model. The aim is not to present a validated predictive formula or original empirical results, but to develop a theoretically grounded study hypothesis on how an intelligent rating architecture could support early diagnosis and resilience-building in knowledge-intensive firms. The case is suitable for this purpose because it connects three dimensions that are often examined separately: corporate crisis prediction, sustainability assessment and knowledge-based organisational resilience.

The analytical setting is defined with reference to a hypothesised group of 500 Italian firms operating in high cognitive-intensity sectors, including advanced professional services, information and communication technology, consulting, applied research, industrial design and high-technology manufacturing. This figure is part of the proposed study design and identifies the potential empirical field on which the Noverim framework could be validated in future research. It does not constitute an observed dataset, an analysed sample or empirical evidence within the present article. Such firms typically depend on qualified human capital, intangible processes and rapid innovation cycles. Their competitive advantage is embedded in people, routines and relationships, but they may also face demand volatility, project-based cash flows, talent dependence and difficulties in translating growth into stable organisational structures.

Methodological clarification: throughout the paper, the expression '500 Italian knowledge-intensive firms' denotes a proposed empirical population for a future validation study. No firm-level observations from these 500 firms are analysed here, and no empirical findings are inferred from them. The present contribution is therefore conceptual and hypothesis-generating, not empirical.

The analysis develops the conceptual structure reported in the extended abstract into a full academic paper. For this reason, all statements concerning predictive capacity, anticipation horizons and crisis patterns are formulated as study hypotheses or analytical propositions. The Noverim case is used as a conceptual and practice-oriented reference, rather than as empirical evidence of model performance. Any future use of the 500-firm reference would require the explicit construction of a dataset, the definition of sampling criteria, the specification of an observation period and the application of appropriate validation metrics. Detailed statistical metrics, calibration procedures, external validation and robustness tests should be developed in a subsequent empirical study if firm-level data become available.

3.1 The Noverim sustainability-equilibrium framework

The Noverim model rests on the assumption that firm viability depends on the interaction of economic, balance-sheet, financial, organisational and sustainability-related conditions. Economic equilibrium concerns margins and productivity. Balance-sheet equilibrium concerns the composition and stability of assets and liabilities. Financial equilibrium relates to liquidity and cash-flow adequacy. Organisational equilibrium concerns governance, internal control and decision quality. Sustainability equilibrium refers to the ways in which environmental, social and governance factors affect risk exposure, adaptive capacity and long-term value creation.

The framework avoids a narrow interpretation of sustainability. In many firms, sustainability information is produced mainly for external reporting, legitimacy or reputational purposes. In the Noverim approach, sustainability is treated as an endogenous determinant of equilibrium. Poor workforce stability, weak governance, inconsistent stakeholder communication or declining investment in capabilities are not peripheral issues. They can alter the firm's risk profile and reduce its capacity to withstand shocks.

Table 1 summarises the main equilibrium dimensions considered in the model. The table should not be read as a mechanical checklist, but as a conceptual map showing how different forms of organisational knowledge can be connected within a predictive architecture. The central diagnostic question is whether signals across dimensions move in a coherent or contradictory direction.

Table 1: Equilibrium dimensions and indicative early-warning signals

Dimension	Knowledge focus	Indicative warning signals
Economic	Margins, productivity and operating continuity	Declining profitability and weaker revenue quality
Balance-sheet	Asset-liability structure and capital solidity	Excessive leverage and fragile capital buffers
Financial	Liquidity, cash-flow timing and debt-service capacity	Cash-flow pressure and dependence on short-term financing
Organisational	Governance, control and decision quality	Key personnel turnover, weak controls and slow response
Sustainability	ESG practices, stakeholder trust and strategic coherence	Deteriorating indicators and strategy-conduct gap

3.2 Predictive architecture

The predictive architecture combines supervised and unsupervised machine-learning techniques. Supervised learning estimates the probability of disequilibrium and improves classification under non-linear conditions. Relevant methods include regression-based approaches, decision-tree models and neural networks. Decision-tree models are useful because they capture interactions among variables and offer a relatively interpretable structure. Neural networks may improve pattern detection in complex data, although their use requires specific attention to transparency, validation and managerial explainability.

Unsupervised learning performs a complementary function. Behavioural clustering detects latent structures among firms and segments them according to similarity in risk profiles and imbalance trajectories. This is particularly useful in knowledge-intensive sectors because crisis pathways are not uniform. Some firms experience liquidity stress after rapid growth; others deteriorate through strategic drift, governance weaknesses or erosion of intangible capabilities.

A key feature of the system is the integration of heterogeneous data at scale. Traditional quantitative indicators are combined with sustainability ratings, organisational variables, qualitative weak signals and information derived from unstructured sources. This extension of the analytical perimeter is valuable, but it also increases the need for data governance, reliability assessment and interpretive discipline.

4 Study Hypotheses and Analytical Propositions

Because the article does not contain original empirical analysis, this section does not report findings in the strict sense. It formulates three study hypotheses derived from the Noverim case and from the theoretical framework. First, the integration of sustainability and organisational indicators with conventional financial measures may improve the anticipation of disequilibrium. Second, knowledge-intensive firms may display recurring pre-crisis patterns that precede visible accounting deterioration. Third, a multidimensional rating architecture may support a meaningful distinction between reversible and structural crises.

4.1 Anticipating disequilibrium

The first study hypothesis is that the Noverim model could anticipate potential imbalance scenarios over an average horizon of 12 to 18 months. This proposition should be treated as an analytical assumption requiring empirical validation, not as a result established by the present article. If confirmed, it would shift the function of rating systems from ex post evaluation to early diagnosis. Conventional financial indicators would remain necessary, but they would become more informative when interpreted together with organisational and sustainability-related signals. A liquidity decline, for example, may be more critical if it coincides with reduced training, increasing turnover and weaker governance quality.

Anticipation should not be confused with deterministic forecasting. A predictive signal indicates an increased probability of disequilibrium, not the certainty of a future event. Its practical value depends on intervention. If managers use the signal to revise strategy, strengthen governance or rebuild knowledge capabilities, the predicted crisis may not occur. In this sense, the absence of a subsequent crisis may indicate the effectiveness of early warning rather than the failure of prediction.

4.2 Recurring pre-crisis patterns

The second study hypothesis concerns the existence of recurring pre-crisis patterns. A first expected pattern is the progressive contraction of intangible investment, including training, research, digital systems, client knowledge and organisational routines. Such reductions may temporarily protect margins, but they can weaken the firm's capacity to innovate, absorb external knowledge and adapt to changing conditions.

The second pattern is increasing turnover among key personnel. Employee mobility is normal in knowledge sectors, but the loss of critical knowledge holders can damage client relationships, project delivery and internal learning. Turnover becomes a warning signal when it affects people who hold tacit knowledge, coordinate strategic projects or maintain important external relationships.

The third pattern is the deterioration of internal sustainability indicators, including governance quality, employee well-being, environmental discipline, transparency and stakeholder engagement. The fourth pattern is growing misalignment between declared strategy and operational behaviour. Such misalignment suggests that the firm may lack the capabilities, governance structures or knowledge routines required to implement its strategic commitments.

These patterns clarify why sustainability ratings can contribute to risk diagnosis. A single weakness does not necessarily imply disequilibrium. However, the simultaneous presence of weaknesses across intangible investment, key personnel stability, governance and operational coherence suggests an erosion of the firm's knowledge base and adaptive capacity.

4.3 Reversible and structural crises

The third study hypothesis concerns the distinction between reversible and structural crises. Reversible crises may be associated with temporary shocks, managerial inefficiencies or limited imbalances that can be corrected through focused intervention. A firm may experience short-term liquidity pressure or delayed projects while remaining viable if its knowledge base, governance quality and stakeholder relationships remain sound.

Structural crises are characterised by simultaneous deterioration across multiple equilibrium dimensions. They may involve declining margins, fragile liquidity, weak governance, reduced intangible investment, loss of key personnel and poor strategic execution. For knowledge-intensive firms, this condition is particularly critical because the assets that disappear are difficult to rebuild quickly. The model supports managerial judgement by showing whether warning signals are concentrated in a limited area or dispersed across the organisational system.

5 Discussion

The analytical propositions developed in this article contribute to the debate on intelligent and sustainable organisations by framing predictive analytics as a potential knowledge-management device. The model does not merely calculate risk. It organises heterogeneous information in a form that may enable managers to observe relationships among sustainability, financial equilibrium and organisational capability. In this sense, the rating process can be interpreted as a possible mechanism of organisational learning.

The case also supports a relational view of sustainability. ESG indicators are not only signals for investors or regulators. They can reveal the quality of governance, the stability of human capital, the credibility of strategy and the capacity to maintain trust. This is important in knowledge-intensive firms, where value is co-produced with employees, clients, partners and communities.

The relationship between human and artificial intelligence is central. AI can improve pattern recognition, but the interpretation of organisational disequilibrium remains a human responsibility. Managers must assess whether model outputs are plausible, ethically acceptable and actionable. From a human-centred perspective, predictive intelligence should support responsible action rather than automate judgement.

The Noverim case also has ecosystem relevance. Knowledge-intensive firms operate within social, business and urban ecosystems where resilience is interdependent. Intelligent rating systems may support not only individual firm management, but also inclusive growth by identifying vulnerabilities, directing advisory support and encouraging preventive intervention before crisis becomes irreversible.

A further issue concerns explainability and organisational acceptance. Managers are more likely to use predictive ratings when they understand the main drivers of a classification and can connect them to lived organisational experience. Feature importance, scenario analysis and structured review meetings can help transform algorithmic output into shared managerial knowledge. Without this interpretive layer, even accurate models may remain external artefacts, consulted for compliance but not embedded in decision-making.

6 Implications for Managers and Policymakers

For managers, the main implication is that sustainability ratings should be used as diagnostic instruments rather than as communication labels. A high score has limited value if it does not inform decisions. A lower score can be useful if it reveals where capabilities need to be strengthened. Managers should monitor the interaction between financial indicators and knowledge-related signals, including training, innovation investment, turnover, client dependence, governance routines and strategic execution.

A second implication concerns measurement culture. Firms with integrated control systems and stronger governance can be hypothesised to be better equipped to prevent disequilibrium. Measurement culture should not be understood as bureaucratic dependence on indicators. It is the disciplined capacity to observe relevant phenomena, discuss signals and act on them. Predictive systems are likely to be useful when they are embedded in such a culture.

For policymakers and ecosystem actors, the case suggests that intelligent sustainability ratings can support preventive approaches to corporate distress. Public agencies, professional associations, financial institutions and innovation intermediaries could use multidimensional early-warning systems to identify firms needing support before insolvency becomes likely. Rating outputs should not become punitive labels, but prompts for advisory, financial and organisational intervention.

For professional practice, the case implies a broader competence profile. Accountants, consultants and managers need to combine financial analysis, sustainability literacy, data interpretation and organisational diagnosis. The future of assessment is unlikely to be purely numerical. It will require the ability to read patterns across multiple domains and to decide whether a signal calls for immediate action, deeper investigation or contextual adjustment.

7 Ethical and Governance Considerations

The use of AI in sustainability ratings raises significant ethical and governance issues. Predictive systems may influence access to credit, investor perceptions, managerial decisions and stakeholder trust. Errors, bias or poor interpretation can therefore produce unfair or disproportionate consequences. Governance should include clear data policies, validation procedures, human oversight and mechanisms for contestability. Firms assessed by such systems should be able to understand the basis of evaluation and correct inaccurate data.

Bias may arise from historical data, incomplete unstructured sources or indicators that reward reporting capacity more than substantive performance. A responsible model should distinguish between absence of evidence and evidence of weakness. It should also avoid over-penalising firms that are transparent about problems while rewarding firms that are merely skilled at disclosure. Human-centred governance is therefore essential to ensure that predictive intelligence supports accountability rather than opacity.

8 Limitations and Future Research

The paper has important limitations. It develops a conceptual argument from the extended abstract and does not report original empirical analysis, statistical metrics, calibration procedures or robustness tests. Consequently, all statements concerning predictive capacity, anticipation horizons, crisis patterns and the 500-firm reference are hypotheses to be tested, not validated results. A future empirical study should define the dataset, sampling criteria, observation period, model specification and validation strategy before any claim of empirical validity is advanced.

Future research could develop longitudinal analyses comparing firms that recover after early-warning signals with those that enter structural decline. Further work should also investigate how managers interpret algorithmic outputs, how explanations affect trust and how predictive systems can support dialogue rather than passive acceptance. Comparative studies across rating architectures would be useful, especially given the divergence in ESG measurement.

9 Conclusions

This paper examined the Noverim case as an analytical hypothesis on how AI-enabled sustainability ratings may support intelligent and sustainable organisations. The argument developed here suggests that corporate equilibrium in knowledge-intensive firms should not be assessed only through conventional accounting indicators. It depends on the interaction of economic performance, financial stability, organisational quality, governance, stakeholder relationships and sustainability-related capabilities.

The central argument is that sustainability is an endogenous component of equilibrium. In knowledge-intensive firms, sustainability indicators often capture the condition of the intangible assets on which value

creation depends: human capital, trust, routines, innovation capacity and strategic coherence. When these assets deteriorate, the firm may become fragile even if short-term financial indicators remain acceptable.

The study hypothesis is that the model may anticipate disequilibrium over a 12-to-18-month horizon and identify patterns such as reduced intangible investment, key personnel turnover, worsening internal sustainability indicators and misalignment between strategy and operations. This claim requires empirical validation before it can be presented as evidence. The same applies to the 500-firm reference, which defines a future field of study, not an empirical basis already analysed in this paper. More broadly, the case suggests that intelligent rating systems can become knowledge infrastructures for resilience-building if they are transparent, ethically governed and embedded in human-centred decision processes.

10 Acknowledgements

The authors acknowledge the contribution of Noverim in developing the sustainability-equilibrium framework discussed in this paper. Any remaining errors or interpretive limitations are the responsibility of the authors.

11 Ethics Declaration

The research design discussed in this paper is conceptual and case-based and does not involve medical experimentation or direct intervention on human subjects. If a future empirical study uses confidential firm-level information, personal data or interviews, the authors should verify whether institutional ethical clearance, informed consent or data-processing approval is required and insert the relevant approval reference before submission.

12 AI Declaration

Generative AI assistance was used during the preparation of this draft to support language refinement, structural expansion from the extended abstract and formatting according to the conference template. The authors should review, revise and validate the full text, conceptual claims, references and final wording before submission. The authors remain responsible for the intellectual content, accuracy and integrity of the submitted paper.

Intelligent Knowledge, Corporate Crisis and Criminal Liability: Incentive Structures for Sustainable Governance in the Italian Framework

Alfonso Laudonia
Universitas Mercatorum, Rome, Italy

Abstract

The paper investigates how intelligent knowledge systems reshape incentives and responsibilities in corporate crisis governance under the Italian legal framework. It focuses on the interaction between the Code of Business Crisis and Insolvency (CCII) and Legislative Decree 231/2001 on corporate criminal liability, analysing how legal duties of early detection and adequate organisational arrangements intersect with the emerging use of AI-enabled early-warning and monitoring tools. The central question is under which conditions these systems function as levers for sustainable and responsible governance, and when they instead generate new risks of moral hazard, scapegoating and purely formalistic compliance.

Theoretically, the paper bridges three strands of literature: knowledge management and organisational learning, which conceptualise knowledge as a strategic asset increasingly mediated by digital technologies (Nonaka and Takeuchi, 1995; Argote, 2013; Schiuma, 2011); law and economics of corporate crisis and insolvency, which examines how sanctions and incentives shape directors' behaviour in the vicinity of insolvency (Jensen and Meckling, 1976; Coffee, 2006; Armour and Ringe, 2020); and socio-legal and criminological studies on corporate crime and compliance, which highlight the role of organisational cultures and control architectures in enabling or constraining wrongdoing (Clinard and Yeager, 1980; Braithwaite, 1989; Parker, 2002). Building on these perspectives, the paper proposes to conceptualise corporate crisis governance as a knowledge-based regulatory game in which legal rules, intelligent knowledge systems and organisational cultures jointly determine the information and payoff structures faced by corporate actors.

Methodologically, the study adopts a qualitative, analytical-conceptual design that combines doctrinal analysis of the CCII and Legislative Decree 231/2001 with theory-informed discussion of AI-enabled early-warning and HR-analytics-based frameworks, including prior empirical work by the author on predictive HR analytics for financial risk prevention (Laudonia et al., 2025).

The analysis shows that intelligently designed and well-governed knowledge systems can enhance the preventive aims of the CCII and the compliance-oriented incentives of the 231 regime by reducing information asymmetries, supporting timely escalation and enabling more informed restructuring decisions. However, it also warns against the risks of black-box solutions that may foster over-reliance on algorithms, diffusion of responsibility and symbolic compliance. The paper concludes by outlining design principles for intelligent knowledge systems in crisis governance—transparency, explainability, preservation of professional judgement, robust data-governance and learning-oriented feedback loops—and by deriving implications for regulators, boards and compliance officers concerned with aligning legal accountability, effective risk reduction and long-term organisational sustainability.

Keywords: intelligent knowledge systems; corporate crisis governance; early-warning; criminal liability; sustainable governance.

Paper type: Academic Research Paper

1 Introduction

1.1 Background and problem statement

The convergence between corporate crisis management, corporate criminal liability and knowledge management is reshaping how organisations govern financial distress in complex and uncertain environments. In many jurisdictions, and particularly in Italy, recent legal reforms have strengthened directors' duties to detect and address business crisis at an early stage, while expanding corporate and quasi-criminal liability for organisational failures under regimes such as the Codice della crisi d'impresa e dell'insolvenza (CCII) and Legislative Decree 231/2001. At the same time, advances in artificial intelligence (AI), data analytics and digital infrastructures have enabled new forms of "intelligent knowledge" systems that integrate human expertise, organisational routines and algorithmic tools in monitoring, decision-making and control processes (Nonaka and Takeuchi, 1995; Arrieta et al., 2020; Rame, 2024). Yet it remains unclear under which conditions these systems actually enhance sustainable and responsible governance, and when instead they generate new risks of moral

hazard, formalistic compliance or diffusion of responsibility among corporate actors (Laudonia et al., 2025; Gilad, 2010).

1.2 Research gap and research questions

The knowledge management and organisational learning literature has extensively analysed how knowledge assets, learning routines and digital technologies contribute to organisational performance and resilience (Nonaka and Takeuchi, 1995; Argote, 2013; Schiuma, 2011), but has paid limited attention to the specific context of corporate crisis governance and to the interaction with legal liability regimes. In parallel, the law and economics literature on corporate crisis and insolvency has focused on sanctions, incentives and early-warning mechanisms, often modelling directors' behaviour under conditions of information asymmetry and moral hazard (Coffee, 2006; Armour and Ringe, 2020), yet it has rarely incorporated the role of knowledge flows, AI-based analytics and organisational learning. Socio-legal and criminological studies on corporate crime and compliance have examined organisational cultures, control systems and "tone at the top" (Clinard and Yeager, 1980; Braithwaite, 1989), but they have not systematically integrated the emerging class of AI-enabled early-warning and monitoring tools into their analyses (Arrieta et al., 2020; Parker, 2002).

As a result, there is still no integrated framework that conceptualises corporate crisis governance as a knowledge-based regulatory game in which legal rules, intelligent knowledge systems and organisational cultures jointly determine the incentives, perceived risks and actual choices of corporate actors. This paper addresses this gap by asking two research questions: RQ1: How do intelligent knowledge systems, including AI-based early-warning and monitoring tools, interact with the Italian legal framework on business crisis and corporate criminal liability, particularly the CCII and Legislative Decree 231/2001? RQ2: Under what conditions do these systems function as levers for sustainable and responsible governance, rather than as catalysts of new risks and dysfunctional behaviours?

1.3 Purpose and contributions of the paper

The purpose of the paper is to develop a conceptual model of corporate crisis governance that explicitly integrates legal-institutional arrangements, intelligent knowledge systems and incentive structures. Building on knowledge management (Nonaka and Takeuchi, 1995; Schiuma, 2011), law and economics of corporate governance and insolvency (Coffee, 2006; Armour and Ringe, 2020), and corporate crime and compliance studies (Braithwaite, 1989; Parker, 2002), the paper offers three main contributions. First, it bridges these strands of literature by articulating how knowledge flows and AI-mediated analytics interact with sanctions, rewards and organisational cultures in the context of business crisis. Second, it refines the analysis of sanctions and incentives in corporate and insolvency law by incorporating dimensions of knowledge quality, organisational learning and technological mediation, drawing on empirical evidence about AI-driven early-warning and HR analytics in crisis prevention (Laudonia et al., 2025; Altman, 1968). Third, it proposes design principles for intelligent knowledge systems in crisis governance that aim to align legal compliance, effective risk reduction and long-term organisational sustainability.

1.4 Structure of the paper

The remainder of the paper is structured as follows. Section 2 reviews the main strands of literature and synthesises the theoretical gap. Section 3 presents the Italian legal and institutional context. Section 4 outlines the methodology. Section 5 discusses intelligent knowledge systems in corporate crisis governance, with particular attention to AI-enabled early-warning tools. Section 6 develops the core analysis on incentives, liability and governance outcomes. Section 7 derives design principles and policy implications, and Section 8 concludes.

2 Theoretical Background and Literature Review

2.1 Knowledge management, intelligent knowledge and organisational learning

Knowledge management (KM) literature has long conceptualised knowledge as a strategic resource embedded in organisational routines, processes and social relationships (Nonaka and Takeuchi, 1995; Argote, 2013). Dynamic perspectives on organisational learning emphasise how firms develop and renew knowledge-based capabilities through exploration, exploitation and feedback loops between individual and collective levels (March, 1991; Crossan et al., 1999). More recent work has highlighted the role of digital technologies and analytics in enabling new forms of "intelligent" knowledge systems that combine human cognition with

algorithmic processing and data-driven insights (Schiuma, 2011; Rame, 2024). In this view, intelligent knowledge emerges from the interaction between human judgement, data architectures and AI-enabled tools that support interpretation, prediction and decision-making under uncertainty (Arrieta et al., 2020; Witten et al., 2016). However, this stream has rarely engaged with legal constraints and liability regimes that shape how knowledge is produced, shared and used in high-stakes contexts such as corporate crisis governance.

2.2 Law and economics of corporate crisis and insolvency

Law and economics scholarship explains corporate crisis and insolvency primarily through incentives, information asymmetries and moral hazard. In this perspective, legal rules on early warning, directors' duties and restructuring are designed to encourage timely intervention and discourage opportunistic conduct (Jensen and Meckling, 1976; Coffee, 2006; Armour and Ringe, 2020; Eidenmüller, 2017). However, this literature has paid less attention to the organisational and technological infrastructures through which relevant knowledge is generated, processed and acted upon, especially in the context of AI-based monitoring and prediction.

2.3 Corporate crime, organisational wrongdoing and compliance architectures

Socio-legal and criminological research has shown that organisational misconduct is shaped not only by formal rules, but also by cultures, control systems and internal compliance architectures (Clinard and Yeager, 1980; Braithwaite, 1989; Parker, 2002; Gilad, 2010). More recent studies on AI governance and corporate compliance suggest that algorithmic monitoring tools may affect accountability, auditability and oversight, but they have not yet systematically integrated AI-enabled early-warning systems into broader models of corporate wrongdoing and compliance.

2.4 Synthesis and identified literature gap

Taken together, these strands of literature show an important gap. Knowledge management research explains how intelligent systems support organisational adaptation, law and economics clarifies how legal rules shape incentives in crisis, and corporate crime scholarship highlights the role of culture and compliance architectures; yet none of these perspectives, taken alone, offers an integrated account of how legal rules, intelligent knowledge systems and organisational cultures jointly shape behaviour in corporate distress. This paper addresses that gap by conceptualising corporate crisis governance as a knowledge-based regulatory game, with specific reference to the interaction between the Italian CCII, Legislative Decree 231/2001 and AI-enabled early-warning systems.

3 Legal and Institutional Context: the Italian Framework

3.1 The Italian Code of Business Crisis and Insolvency (CCII)

The Italian Code of Business Crisis and Insolvency (CCII) marks a shift from a liquidation-centred approach to a preventive model of crisis governance. It requires directors to adopt adequate organisational, administrative and accounting arrangements capable of detecting early signs of distress and supporting timely intervention, thereby making information quality and internal monitoring central to corporate crisis management (Armour and Ringe, 2020).

3.2 Corporate criminal liability and organisational models under Legislative Decree 231/2001

Legislative Decree 231/2001 establishes corporate liability for offences committed in the entity's interest or to its advantage, unless the firm can demonstrate the adoption and effective implementation of adequate organisation, management and control models. From this perspective, 231 models are not only compliance documents, but governance architectures based on procedures, information flows, risk mapping and oversight mechanisms, increasingly supported by digital reporting and monitoring tools (Coffee, 2006; Parker, 2002).

3.3 Recent reforms and debates on crisis, liability and sanctions

Recent Italian debates on crisis governance and sanctions have reinforced attention to directors' responsibilities, the calibration of deterrence, and the coordination between insolvency, corporate and criminal law, while also raising new questions about how AI-based monitoring tools should be assessed in terms of adequacy and accountability (Eidenmüller, 2017; Arrieta et al., 2020; Laudonia et al., 2025).

3.4 Intelligent knowledge and governance in the Italian context

Taken together, the CCII and Legislative Decree 231/2001 make the Italian framework a particularly relevant setting for analysing intelligent knowledge systems in corporate crisis governance. Both regimes depend, implicitly or explicitly, on the organisation's ability to generate, process and use reliable knowledge about risk, distress and misconduct; for this reason, the Italian case is especially useful for examining how AI-enabled early-warning systems may strengthen prevention and compliance, but also create new risks of opacity, formalism and responsibility-shifting.

4 Methodology

4.1 Overall research design

The paper adopts a qualitative, analytical-conceptual design that combines doctrinal legal analysis with theory-informed examination of organisational and technological developments (Eisenhardt, 1989; Yin, 2018). Rather than testing specific hypotheses on a large-N dataset, it aims to build an integrated framework linking legal-institutional arrangements, intelligent knowledge systems and incentive structures in corporate crisis governance.

4.2 Sources and data

The analysis relies on three main categories of sources. First, primary legal materials, including the CCII and Legislative Decree 231/2001, are used to reconstruct duties, sanctions and institutional mechanisms shaping corporate crisis governance (Armour and Ringe, 2020). Second, secondary legal and socio-legal literature on corporate governance, insolvency, corporate crime and compliance informs the main debates on incentives and liability (Coffee, 2006; Parker, 2002; Gilad, 2010). Third, empirical and conceptual studies on AI-enabled early-warning systems and HR-analytics-based crisis prediction provide evidence on how intelligent knowledge systems operate in practice and affect information flows and decision-making under distress, including previous co-authored work on AI-driven HR analytics and financial risk prevention (Laudonia et al., 2025; Altman, 1968).

4.3 Analytical strategy

Analytically, the paper proceeds in three steps. First, it maps how the CCII and Legislative Decree 231/2001 allocate responsibilities, define "adequate" organisational and control arrangements, and link them to corporate and personal liability (Armour and Ringe, 2020; Coffee, 2006). Second, it overlays this legal structure with insights from knowledge management and organisational learning to conceptualise the underlying knowledge infrastructures and identify where AI-based tools are most likely to be embedded in crisis governance processes (Nonaka and Takeuchi, 1995; Argote, 2013; Schiuma, 2011). Third, it uses selected examples from AI-enabled early-warning and HR-analytics systems, together with law-and-economics reasoning, to articulate how different configurations of legal rules, knowledge systems and organisational cultures generate distinct incentive patterns (Laudonia et al., 2025; Gilad, 2010).

4.4 Limitations

This approach has the usual limitations of analytical-conceptual and case-informed research designs (Eisenhardt, 1989; Yin, 2018). The study does not provide large-scale empirical testing or quantitative estimates of the impact of intelligent knowledge systems on crisis outcomes or liability exposure, and its empirical base relies on existing studies and doctrinal interpretation rather than original fieldwork (Laudonia et al., 2025). The focus on the Italian context may also constrain direct generalisation to other legal systems with different corporate and insolvency law architectures (Armour and Ringe, 2020), although the framework is intended to support subsequent empirical and comparative research (Eidenmüller, 2017).

5 Intelligent Knowledge Systems in Corporate Crisis Governance

5.1 From traditional early-warning systems to intelligent knowledge

Traditional early-warning systems (EWS) for corporate crises have relied mainly on financial ratios, balance-sheet indicators and static thresholds to signal distress (Altman, 1968; Armour and Ringe, 2020). These tools capture deteriorating solvency or liquidity, but struggle to anticipate crises driven by human capital dynamics,

organisational misalignment or slow capability erosion (Rame, 2024). In more complex Industry 5.0 environments, early-warning therefore needs to integrate heterogeneous data sources, including HR indicators, operational signals and qualitative assessments of organisational climate. Intelligent knowledge systems extend traditional EWS by combining structured and unstructured data, using machine-learning and natural language processing to detect latent risk patterns, and embedding these outputs into governance processes where human decision-makers can interpret and act on them (Witten et al., 2016; Arrieta et al., 2020).

5.2 AI-based early-warning and HR analytics as a paradigmatic case

AI-driven HR analytics provide a paradigmatic example of intelligent knowledge systems for crisis governance. Laudonia et al. (2025) develop a framework in which HR variables—such as turnover, skill gaps, training investments and sentiment from performance reviews—are combined with financial indicators to predict financial distress. Their results suggest that predictive HR analytics can reduce false alarms and identify a substantial share of crises in advance, improving the sensitivity and precision of early-warning signals (Laudonia et al., 2025). These frameworks rely on integrating HR and financial data with text-mining applied to qualitative sources, using machine-learning models to detect patterns associated with subsequent downturns (Witten et al., 2016), while supporting rather than replacing managerial judgement in strategic and governance decisions.

5.3 Embedding intelligent knowledge systems into CCII and 231 governance architectures

In the Italian framework, intelligent knowledge systems intersect directly with duties and incentives under the CCII and Legislative Decree 231/2001. Under the CCII, advanced predictive analytics can form part of the "adequate organisational, administrative and accounting arrangements" required to detect early signs of crisis and support timely intervention, as long as they remain transparent, reliable and aligned with decision-making processes (Armour and Ringe, 2020; Laudonia et al., 2025). Within the 231 regime, organisation, management and control models are assessed for their adequacy to prevent offences and ensure effective risk monitoring; intelligent systems that integrate HR, operational and financial data can enhance these models by enabling granular risk mapping, continuous anomaly detection and evidence-based oversight (Coffee, 2006; Parker, 2002). At the same time, complex AI-driven tools raise concerns about accountability, explainability and "black box compliance", where formal reliance on sophisticated systems masks weaknesses in governance or culture and complicates the assessment of directors' and entities' liability (Arrieta et al., 2020; Eidenmüller, 2017; Gilad, 2010).

6 Analysis and Discussion: Incentives, Liability and Governance Outcomes

6.1 Intelligent knowledge as a lever for sustainable and responsible governance

When intelligently designed and properly embedded, knowledge systems can strengthen the preventive and sustainability-oriented aims of corporate crisis governance. By integrating financial, HR and operational indicators into robust early-warning architectures, they help boards and managers detect weak signals of distress, evaluate options and initiate timely restructuring or negotiation with creditors (Altman, 1968; Armour and Ringe, 2020). This supports the policy objectives of the CCII and European preventive restructuring frameworks and, from an incentive perspective, modifies directors' perceived payoff structure: credible, data-driven tools increase the expected costs of concealment and inaction relative to early disclosure and proactive engagement (Coffee, 2006; Armour and Ringe, 2020; European Commission, 2025). When oversight bodies have access to granular, up-to-date information, they are also better placed to exercise effective monitoring and counter the normalisation of deviance (Braithwaite, 1989; Vaughan, 1999).

6.2 Risks of moral hazard, scapegoating and formalistic compliance

If poorly designed or weakly governed, AI-enabled early-warning and monitoring tools can generate new forms of moral hazard and opportunities for scapegoating. Managers may treat sophisticated analytics as substitutes rather than complements to their own vigilance, leading to over-reliance on algorithmic outputs and under-investment in qualitative assessment (Arrieta et al., 2020). Boards and oversight bodies may invoke the mere existence of advanced systems as evidence of "adequate" arrangements, even when those systems are poorly calibrated, under-resourced or routinely ignored, thereby reinforcing patterns of window-dressing and paper compliance already documented in the corporate crime literature (Parker, 2002; Laudonia et al., 2025). In

such scenarios, intelligent knowledge systems risk becoming shields rather than levers for accountability, complicating the attribution of fault under regimes such as the CCII and Legislative Decree 231/2001 (Coffee, 2006; Eidenmüller, 2017).

6.3 Corporate crisis governance as a knowledge-based regulatory game

The interplay between legal rules, intelligent knowledge systems and organisational cultures can be conceptualised as a knowledge-based regulatory game. The main players—directors, managers, oversight bodies, regulators and, indirectly, creditors and employees—interact within legal and organisational rules that define duties, sanctions, rewards and information rights (Jensen and Meckling, 1976; Coffee, 2006). The state of the game depends on the quality and distribution of knowledge about the firm's condition, the configuration of intelligent knowledge systems (their scope, transparency and governance), and the expectations that players hold about how others will react to distress signals. Intelligent systems thus reshape both the information and the payoff structure of the game, influencing whether early disclosure of crisis is perceived as a dominated strategy or as a potentially advantageous move under regimes such as the CCII and 231 (Witten et al., 2016; Laudonia et al., 2025; Armour and Ringe, 2020).

6.4 Implications for sanctions, enforcement and organisational learning

Viewing corporate crisis governance as a knowledge-based regulatory game has several implications for sanctions and enforcement. Liability assessments should consider not only the formal existence of intelligent knowledge systems, but also their substantive functioning, including responsibility for their design and maintenance, documentation of outputs and actual responses to early-warning signals (Gilad, 2010; Laudonia et al., 2025). Enforcement strategies could be calibrated to reward transparent, explainable and well-governed systems and to penalise purely symbolic or black-box implementations (Arrieta et al., 2020; European Commission, 2025). Finally, crisis events and enforcement outcomes can themselves become sources of organisational learning, fostering a co-evolution of intelligent knowledge and legal incentives towards more sustainable and responsible corporate governance (Nonaka and Takeuchi, 1995; Schiuma, 2011).

7 Design Principles and Policy Implications

7.1 Design principles for intelligent knowledge systems in crisis governance

A first implication of the analysis is the need to design intelligent knowledge systems according to principles that align legal compliance, effective risk reduction and organisational sustainability. Transparency and explainability are essential: AI-enabled tools used for early-warning and monitoring should provide interpretable outputs and clear decision-rules so that directors, oversight bodies and regulators can understand how signals are generated and on what basis they should act (Arrieta et al., 2020; Witten et al., 2016). A second principle is the preservation and valorisation of professional judgement, ensuring that human decision-makers retain ultimate responsibility and that algorithms are used to augment, not replace, critical assessment (Nonaka and Takeuchi, 1995; Laudonia et al., 2025). Third, intelligent knowledge systems should be tightly coupled with organisational routines and escalation procedures, so that early-warning signals systematically trigger documented discussions, decisions and follow-up actions (Armour and Ringe, 2020; Gilad, 2010). A fourth principle concerns the integration of ethical, data-protection and fairness safeguards, particularly when HR and other sensitive data are involved (European Commission, 2025). Finally, intelligent knowledge systems should incorporate feedback loops that transform crisis experiences and enforcement outcomes into learning opportunities (Schiuma, 2011; Rame, 2024).

7.2 Implications for regulators and policymakers

For regulators and policymakers, the findings suggest that legal frameworks such as the CCII and Legislative Decree 231/2001 should explicitly recognise the role of intelligent knowledge systems while setting expectations regarding their governance. Guidance and soft-law instruments could clarify how AI-enabled early-warning and monitoring tools may contribute to "adequate organisational and control arrangements", and which minimal standards of transparency, documentation and oversight are required for such tools to be considered in liability assessments (Armour and Ringe, 2020; Eidenmüller, 2017). Policymakers might also explore incentive schemes—such as reduced sanctions or procedural advantages—for firms that adopt robust, explainable and independently audited knowledge systems, thereby steering investments towards genuinely effective

infrastructures rather than symbolic compliance (Coffee, 2006; European Commission, 2025). At the same time, regulators should remain attentive to the risks of over-reliance on technology, and supervisory practices may need to develop specialised competences in assessing AI-enabled systems, including the capacity to scrutinise data-governance arrangements and model validation procedures (Arrieta et al., 2020; Gilad, 2010).

7.3 Implications for boards, compliance officers and practitioners

For boards of directors, compliance officers and other practitioners involved in crisis governance, the analysis underscores the strategic nature of intelligent knowledge systems. Boards should treat the design and oversight of these systems as a core governance responsibility, ensuring alignment with the firm's risk appetite, values and legal obligations, and avoiding delegation of critical design choices solely to technical experts or external vendors (Braithwaite, 1989; Parker, 2002). Compliance and risk-management functions should work closely with HR, finance and IT departments to integrate data sources, define meaningful indicators and develop protocols that translate early-warning signals into concrete actions and accountability trails (Laudonia et al., 2025). Practitioners should also be aware of the reputational and legal implications of black-box solutions: investing in explainability, documentation and training for users can not only improve the effectiveness of intelligent knowledge systems, but also demonstrate diligence and good faith in the event of investigations or litigation related to crisis management failures (Arrieta et al., 2020; Gilad, 2010). Ultimately, the practical challenge is to move from viewing intelligent knowledge systems as compliance add-ons to recognising them as central components of a broader governance architecture in which legal rules, organisational culture and technological infrastructures co-evolve.

8 Conclusions

This paper has argued that corporate crisis governance can be fruitfully conceptualised as a knowledge-based regulatory game, in which legal rules, intelligent knowledge systems and organisational cultures jointly shape the incentives, perceived risks and behavioural choices of corporate actors. By integrating insights from knowledge management and organisational learning, law and economics of crisis and insolvency, and socio-legal studies of corporate crime and compliance, the analysis has highlighted how AI-enabled early-warning tools and HR-analytics-based frameworks—such as those proposed by Laudonia et al. (2025)—can transform the information structures underpinning directors' duties and liability regimes under the Italian CCII and Legislative Decree 231/2001 (Nonaka and Takeuchi, 1995; Coffee, 2006; Laudonia et al., 2025).

The main contribution is twofold. Theoretically, the paper offers an integrated framework that foregrounds the role of intelligent knowledge in mediating between legal incentives and organisational behaviour, showing that the effectiveness of preventive and sanctioning mechanisms depends crucially on the design and governance of socio-technical knowledge infrastructures. Practically, it derives design principles and policy implications for boards, compliance officers and regulators, emphasising transparency, explainability, preservation of professional judgement, robust data-governance and the embedding of feedback loops that turn crisis experiences and enforcement outcomes into organisational learning (Arrieta et al., 2020; Schiuma, 2011; European Commission, 2025).

The analysis is not without limitations. It rests on an analytical-conceptual approach and on existing empirical studies, including prior work by the author, rather than on original large-scale data, and it focuses primarily on the Italian context, which may differ significantly from other legal systems (Eidenmüller, 2017; Armour and Ringe, 2020). Future research could extend the framework through comparative studies of different jurisdictions, in-depth case studies of firms implementing intelligent knowledge systems in crisis situations, and quantitative assessments of how such systems affect crisis trajectories, enforcement outcomes and the calibration of sanctions. By pursuing these lines of inquiry, scholars and practitioners can further refine our understanding of how intelligent knowledge can support truly sustainable and responsible corporate governance in times of financial distress.

From Cost to Social Capacity: Governing AI-Released Time with STRR and S-STRR

Barbara Fasoli Braccini, Federico Gaeta
University of Rome UnitelmaSapienza, Rome, Italy

Abstract

The adoption of generative artificial intelligence and automation technologies is reshaping how organisations create and allocate value. While a growing body of evidence shows that AI can generate measurable productivity gains, support workplace learning, and improve selected aspects of job quality, both research and managerial practice still lack an auditable pathway capable of linking AI-enabled time savings to reinvestment decisions and their internal and societal effects.

Starting from this gap, the paper introduces a fundamental distinction between *Created Value* and *Released Time* (RT). Created Value refers to the economic and competitive output generated through organisational activities, whereas Released Time identifies the stock of time, attention, and relational capacity made available by the reduction of routine or low-value tasks. We conceptualise Released Time as a governable resource rather than an automatic source of value.

Building on this foundation, the paper develops an integrated measurement-to-governance architecture. First, Released Time is quantified through Time-Driven Activity-Based Costing (TDABC) time equations, adjusted by a quality–risk–compliance factor to exclude spurious efficiency gains. Second, we introduce the *Social Time Reinvestment Ratio* (STRR), a micro-level governance indicator (0–1) that captures the share of eligible Released Time intentionally reallocated to work-life balance, learning and coordination, and skills-based volunteering. STRR is designed to be auditable through allocation logs, eligibility rules, documentary evidence, and reconciliation with process accounts.

The framework is then extended to the *Societal STRR* (S-STRR), which connects reinvested time portfolios to Social Return on Investment (SROI) logic models and proxy maps, incorporating standard adjustments such as deadweight, attribution, displacement, and drop-off. This enables the identification of a "double dividend": internal human capital strengthening and monetised societal value.

Methodologically, the paper adopts a conceptual-development approach with an explicit early-stage validation protocol. It defines constructs, operational rules, and an evidence framework ensuring reliability (inter-rater agreement on allocation decisions) and integrity (reconciliation between released time and TDABC accounts).

By integrating previously disconnected literatures, namely AI productivity, TDABC, SROI, skills-based volunteering, and AI governance, the paper contributes an auditable measurement-to-governance architecture.

Keywords: Time-Driven Activity-Based Costing; Released Time; Social Time Reinvestment Ratio; Skills-based Volunteering; Social Return on Investment.

Paper type: Academic Research Paper

1 Introduction

Generative artificial intelligence is producing measurable productivity gains in real workplace settings, from controlled experiments to large-scale deployments in knowledge work. Evidence shows that AI can increase efficiency, support learning, and improve aspects of job quality. However, these gains are highly heterogeneous and do not automatically translate into sustainable organisational capability or societal value.

This highlights a critical governance gap in the way organisations manage Released Time. Organisations lack an auditable pathway linking AI-enabled time savings to reinvestment decisions and to their internal and external effects. As a result, Released Time may be dissipated, absorbed into work intensification, or only partially converted into higher-value or socially relevant activities.

Part of this problem reflects the fragmentation of the literature. Research on AI productivity, Time-Driven Activity-Based Costing (TDABC), and Social Return on Investment (SROI) remains largely disconnected, while AI governance studies often struggle to translate principles into operational and measurable practices. We treat Released Time as a governable stock, not value.

By integrating AI productivity, TDABC, SROI, and governance literatures, the paper develops an auditable framework that connects measurement with organisational decision-making.

This perspective is also consistent with the intellectual capital tradition, which conceptualises organisational value as the result of interactions between human, structural, and relational capital (Edvinsson and Malone, 1997). In this view, AI-enabled Released Time can be interpreted as a latent form of multi-capital resource, comprising time, attention, and relational capacity, that may be converted into human capital (through learning and skill development), structural capital (through codification and coordination), and relational capital (through

skills-based volunteering and stakeholder engagement) (Nonaka and Takeuchi, 1995). This positioning reinforces the need to treat Released Time not as a residual outcome of efficiency, but as a governable driver of knowledge-based value creation.

This study adopts a conceptual-development and design-oriented research approach, aimed at constructing an auditable governance artefact rather than testing causal relationships.

2 Why Existing Approaches are Insufficient for Governing Released Time

Current AI productivity research measures output and time savings and increasingly documents heterogeneity and task reallocation. For example, developer studies show both productivity increases and shifts away from non-core activities (Hoffmann et al., 2025), while large-scale field experiments highlight time saved in communication and after-hours work without necessarily changing task composition (Dillon et al., 2025). These findings sharpen the governance gap: time is released, but organisational reinvestment is not automatically observed or governed.

TDABC's strength is to quantify time at activity level through time equations and capacity cost rates, enabling transparent measurement and reconciliation (Etges, Polanczyk and Urman, 2020). Recent reviews stress the expanding role of TDABC and the need for standardised reporting to improve comparability and reduce variability (Etges et al., 2024; Shakya et al., 2025). However, TDABC does not specify where released time goes, nor does it specify governance rules for reinvestment portfolios, making measurement alone insufficient.

SROI frameworks are increasingly refined and reviewed, with advances aimed at improving transparency and comparability (Ashton et al., 2024; Gutiérrez-Nieto et al., 2025). Yet SROI typically starts from interventions and outcomes, not from micro time allocations within organisational processes. Even recent systematic reviews highlight persistent methodological variation and proxy justification challenges (Sillcox et al., 2026). Therefore, SROI requires a disciplined "input accounting" layer to connect AI-enabled released time to intervention design and evidence.

Existing approaches measure productivity, cost, or social outcomes separately, but do not provide an integrated and auditable mechanism linking these dimensions within organisational decision-making.

3 Released Time (RT): Definition and TDABC-Based Quantification

TDABC provides the technical foundation for quantifying Released Time (RT), extending time equations with complexity drivers and valuing capacity through capacity cost rates (Etges, Polanczyk and Urman, 2020; Etges et al., 2024). We define Released Time in period t as the sum of baseline-to-post reductions in task time, adjusted by a quality-risk-compliance factor that preserves neutrality with respect to service quality and operational risk:

$$RT_t = \sum_{i \in T} \left(T_{i,t}^{\text{baseline}} - T_{i,t}^{\text{post}} \right) \cdot \varphi_{i,t}$$

where T is the set of tasks affected by AI, $T_{i,t}^{\text{baseline}}$ is the standard execution time of task $i$before AI implementation, $T_{i,t}^{\text{post}}$ is the observed execution time after AI implementation, $\varphi_{i,t} \in (0,1]$ is the quality–risk–compliance adjustment factor.

The factor operationalises a core governance premise: Released Time is counted only when time reductions are compatible with quality standards, safety requirements, and compliance controls, a requirement particularly evident in regulated settings where technology can reduce effort while increasing verification obligations (Mátó and Vilmányi, 2024).

Released Time can be treated as a governable stock only when it is traceable to process data and reconcilable with management control systems. Standardisation and reporting discipline in TDABC implementations are therefore not ancillary; they are enabling conditions for the governance indicator we propose (Shakya et al., 2025).

4 Social Time Reinvestment Ratio (STRR): Allocation and Decomposition

Let K={strategy/coordination, WL, VOL, other} be the set of reinvestment categories and let $a_{k,t}$denote the number of hours allocated to category $k \in K$in period t. The allocation must satisfy:

$$\sum_{k \in K} a_{k,t} \leq RT_t$$

The weak inequality is intentional: it allows conservative governance (unallocated RT pending verification) and supports auditability. We define the Social Time Reinvestment Ratio (STRR) as the share of Released Time reinvested into two governance-salient domains: work-life balance and skills-based volunteering.

$$STRR_t = \frac{a_{\mathrm{WL},t} + a_{\mathrm{VOL},t}}{RT_t}$$

with two decompositions:

$$STRR_t^{\mathrm{WL}} = \frac{a_{\mathrm{WL},t}}{RT_t}$$
$$STRR_t^{\mathrm{VOL}} = \frac{a_{\mathrm{VOL},t}}{RT_t}$$

STRR is a micro KPI (0–1) that makes visible the share of Released Time reinvested in sustainability-consistent categories. STRR reframes AI productivity from a cost narrative into a capacity narrative that can be budgeted and governed. This is particularly relevant given evidence that generative AI may reduce time in communication work (e.g., email) and after-hours work (Dillon et al., 2025), making WL reinvestment a measurable governance outcome rather than an aspirational HR claim.

The decomposition reflects different governance logics. Work-life balance interventions and occupational balance are increasingly studied with systematic evidence on effectiveness and variability (Lentner et al., 2025). Skills-based or occupation-related volunteering, by contrast, links workforce capability to external social value creation and has an expanding conceptual and empirical base (Dempsey-Brench and Shantz, 2022; Biermann, Breitsohl and Meijs, 2024).

5 Governance and Allocation Rules (Who Decides, with What Constraints, and on What Basis)

We now specify a minimal governance architecture that makes STRR implementable and assurance-ready. The proposed model is structured around a cross-functional STRR Steering Group with clearly defined roles and decision rights. The Process Owner (PO) is responsible for validating time equations, baseline and post-AI measurements, and the appropriateness of the quality–risk–compliance adjustment factor ϕ_{i,t}. The Controlling or TDABC Lead (CL) reconciles Released Time with TDABC accounts and underlying capacity logic, ensuring traceability. The HR and Learning Lead (HRL) designs eligible work-life balance (WL) and learning or coordination initiatives while ensuring equitable access across organisational units. The Sustainability or Impact Lead (SIL) curates volunteering portfolios and maintains SROI logic models and proxy mappings (Ashton et al., 2024; Nieto et al., 2024). Ethical oversight is ensured through Worker Representation (WRE), which supervises voluntariness, fairness, and grievance channels.

Eligibility rules and evidence requirements ensure auditability. Every allocation must satisfy a predefined catalogue of admissible activities, including work-life balance practices, structured learning and coordination routines, and verified volunteering roles. Allocations must be supported by verifiable evidence, such as attendance and completion records for learning activities, scheduling data for work-life balance, and timesheets or role documentation for volunteering. A non-substitution rule applies: allocated hours must be attributable to genuinely generated Released Time and cannot represent a relabelling of existing budgets. Reconciliation with TDABC accounts constitutes the primary control mechanism (Etges, Polanczyk and Urman, 2020).

The governance framework is further defined by a set of constraints relating to quality, continuity, equity, and voluntariness. The quality constraint is enforced through the adjustment factor ϕ_{i,t} and service-level verification checks (Mátó and Vilmányi, 2024). Continuity constraints ensure minimum staffing and operational coverage, preventing service degradation. Equity constraints require monitoring of allocation distributions across roles and organisational units. Voluntariness constraints ensure that participation in volunteering activities is strictly opt-in; corresponding evidence and participation rules reflect the established importance of experience quality, leadership, and organisational support for volunteer retention and outcomes (Forner et al., 2024; Holtrop et al., 2024).

The governance process follows a structured quarterly decision cycle. Released Time is first measured through TDABC time equations combined with quality adjustments. A conservative Released Time budget is then declared, allowing for the possibility of unallocated Released Time pending verification. This budget is subsequently allocated across portfolios, including work-life balance and volunteering, according to catalogue priorities. Assurance activities follow, involving verification of evidence logs, computation of STRR, and

reconciliation with process accounts. Finally, learning feedback loops are activated to refine both AI deployment priorities and reinvestment design.

From a control perspective, the proposed governance architecture combines diagnostic and boundary systems (Simons, 1995). Diagnostic controls are reflected in the measurement and monitoring of Released Time and STRR, ensuring comparability and accountability across organisational units. Boundary controls are embedded in eligibility rules, voluntariness constraints, and non-substitution principles, preventing the misuse of Released Time and ensuring alignment with organisational values and stakeholder expectations. This dual control structure strengthens the robustness and credibility of the governance mechanism.

6 From STRR to S-STRR: Micro-To-Macro Linkage via SROI

STRR governs the share of Released Time reinvested but does not itself monetise social outcomes. To evidence societal value, the volunteering portfolio is linked to SROI logic models and proxy maps, explicitly drawing on established guidance while acknowledging methodological variation and uncertainty (Ashton et al., 2024; Sillcox et al., 2026).

We define the Societal Social Time Reinvestment Ratio (S-STRR) as:

$$S\text{-}STRR_t = \frac{\widehat{SV}_t}{RT_t}$$

where $\widehat{SV}_t$ denotes the monetised social value generated in period t, estimated through SROI procedures, including stakeholder identification, outcome mapping, proxy valuation, and adjustments for deadweight, attribution, displacement, and drop-off (Ashton et al., 2024; Gutiérrez-Nieto et al., 2025).

A modular adoption strategy ensures that implementation effort remains proportionate by leveraging management control and HR data (Jorgji et al., 2024), while scaling SROI only as governance maturity increases, moving from STRR-only configurations to pilot SROI applications and, ultimately, to fully developed S-STRR implementations.

7 Design and Early-Stage Validation Protocol

7.1 Design method (conceptual engineering + measurement protocol)

The framework follows a design and validation logic appropriate for conceptual and methodological contributions. It is grounded in a conceptual engineering approach combined with a structured measurement protocol. Within this approach, the core constructs, namely Released Time (RT), the Social Time Reinvestment Ratio (STRR), and the Societal STRR (S-STRR), are specified as governance constructs, providing a structured basis for measuring, allocating, and accounting for AI-enabled Released Time within organisational processes.

Operationalisation is achieved through a set of rules governing time equation measurement, the application of the quality–risk–compliance adjustment factor ϕ_{i,t}, the definition of an eligibility catalogue, the enforcement of evidence discipline, and reconciliation procedures linking allocations to TDABC accounts.

Particular attention is devoted to auditability: allocation logs, decision rights, and assurance routines are explicitly defined and anchored to TDABC reporting discipline, in line with recent standardisation efforts (Etges et al., 2024; Shakya et al., 2025).

The framework is further designed to be modularly implementable, allowing for progressive configurations that reduce reporting burden in early stages while supporting scalability and increasing adoption feasibility over time.

7.2 First-stage test (non-causal): reliability + reconciliation

The initial empirical step is explicitly non-causal and is aimed at assessing whether STRR can be measured reliably and reconciled with process-level accounts. Reliability is evaluated through inter-rater agreement in the classification of allocation activities. Independent raters assign activities to categories $k$based on the eligibility catalogue, with target thresholds set at Cohen's κ ≥ 0.70 or, alternatively, agreement levels of at least 80%, consistent with the exploratory analysis (EA) design.

Reconciliation integrity is assessed by comparing allocation logs with TDABC-derived Released Time totals. The acceptable deviation threshold is set at ≤ 5% at the unit or process level, ensuring consistency between measured Released Time and allocated Released Time. Meeting these thresholds constitutes the condition for progressing to subsequent stages, including field applications and the development of full SROI chains. In the initial pilot, we plan to apply the protocol in some knowledge-intensive, public-facing service unit implementing

AI-assisted drafting, using a quarterly observation window and process-level TDABC accounts as the reconciliation backbone.

Table 1. Auditability evidence map for RT, STRR, and S-STRR. The table links each construct to primary data sources, traceable artefacts (audit trail), and assurance tests/thresholds.

Construct / object	Primary data source(s)	Evidence artefacts (audit trail)	Assurance test(s) / threshold
Released Time (RT)	TDABC time equations; baseline vs post-AI task timing; capacity cost rates; quality–risk–compliance factor ϕ	Time-equation specification sheet; parameter change log; baseline/post measurement log; evidence for ϕ (quality checks, compliance controls)	Traceability to process data; sign-off by Process Owner; stability checks on parameters across periods
Allocation categories (k) and eligibility	Eligibility catalogue; policy/rules repository; volunteering role descriptions; WL/learning initiative registry	Versioned catalogue; decision rights and minutes; admissibility checklists; non-substitution declarations	Catalogue completeness review; exception log review; evidence sufficiency sampling
STRR (0–1)	Allocation log of hours $a_{k,t}$; RT totals from TDABC; HR/timekeeping records (where available)	Signed allocation log; supporting evidence (attendance/completions, schedules, volunteering timesheets); computation worksheet	Inter-rater agreement on category assignment: Cohen's κ ≥ 0.70 (or ≥80% agreement); reconciliation to TDABC RT: deviation ≤ 5%
S-STRR (portfolio → SROI)	SROI logic model; outcome indicators; proxy map; adjustment parameters (deadweight, attribution, displacement, drop-off)	Outcome map; proxy justification file; stakeholder register; assumptions register; sensitivity/uncertainty notes	Conservatism checks on assumptions; documentation of proxy sources; reproducibility of valuation steps; governance sign-off by Impact Lead

Note: RT = Released Time; STRR = Social Time Reinvestment Ratio; S-STRR = Societal STRR; κ denotes inter-rater agreement (Cohen's kappa). Reconciliation threshold refers to deviation between allocation logs and TDABC-derived RT totals (≤ 5%).

7.3 Construct validity boundaries

The construct validity of STRR is defined in terms of its intended scope and limits. STRR claims the ability to make visible and measurable quality-adjusted Released Time, to support auditable allocation processes, and to provide governance visibility over the reinvestment of organisational resources. However, it does not claim causal impact on organisational or societal outcomes at this stage. This limitation is consistent with the exploratory scope of the framework and reflects the methodological positioning adopted in this initial phase of development.

8 Illustrative Implementation Pathway (Non-Empirical)

To provide a concrete illustration of the proposed framework, an illustrative and non-empirical implementation pathway is presented. The setting is a public-facing service unit that introduces AI-assisted drafting for citizen requests. Field evidence suggests that such tools can reduce time spent on writing-intensive activities and email, with potential reductions in after-hours work (Dillon et al., 2025).

The implementation begins with process mapping and the quantification of Released Time. The unit identifies and maps key activities, including triage, drafting, verification, and escalation. Baseline and post-AI execution times are measured, and the quality–risk–compliance adjustment factor ϕ_{i,t} is applied to discount any apparent time savings that require additional verification for compliance purposes. The resulting output is the measure of Released Time, RT_t.

On this basis, governance allocation is carried out by the STRR Steering Group. Released Time is distributed across three main categories: work-life balance interventions, such as scheduling buffers aimed at reducing after-hours work; learning and coordination activities, including structured "knowledge clinics" designed to codify recurrent cases; and skills-based volunteering initiatives, for example through partnerships that support digitally excluded citizens.

Following allocation, all activities are documented through verifiable evidence, enabling the computation of STRR and its decompositions. This allows the organisation to compare units, identify where AI adoption effectively releases time, and make reinvestment decisions both visible and budgetable within a governance framework.

In a subsequent stage, the volunteering portfolio may be linked to a simplified SROI model, supported by proxy guidance and conservative adjustments in line with established practice (Ashton et al., 2024; Sillcox et al., 2026). This enables the transition from internal capacity governance to the estimation of monetised social value.

Overall, the scenario illustrates the full pathway connecting measurement and governance, showing how AI adoption leads to Released Time, how allocation rules translate into STRR, and, where implemented, into S-STRR. This integrated sequence constitutes the core contribution of the framework by making explicit the link between measurement, allocation, and governance.

9 Discussion: Contributions and Implications

Theoretical contribution. We extend debates on AI productivity by formalising a distinction between Created Value and Released Time: AI releases time, but social capacity emerges only through governed reinvestment. This is consistent with evidence that AI affects work patterns and task allocation in heterogeneous ways (Brynjolfsson, Li and Raymond, 2025; Hoffmann et al., 2025).

The organisational capacity enabled by Released Time can be interpreted as a form of technology-enabled slack. Classic contributions have shown that slack is not merely inefficiency but can support innovation and adaptability when appropriately managed (Bourgeois, 1981). However, unlike traditional slack, AI-generated released time is process-based, time-specific, and contingent on technological deployment. Its value is therefore not inherent but depends on governance choices. This reframing extends slack theory by introducing a measurable and auditable form of slack that can be intentionally directed towards both organisational and societal objectives.

This argument also resonates with the attention-based view of the firm, according to which organisational behaviour depends on how decision-makers allocate and channel attention (Ocasio, 1997). AI may compress execution time, but it does not determine how the resulting capacity is used. The allocation of activities enabled by Released Time therefore becomes an attention-allocation problem: which activities, stakeholders, and time horizons are prioritised. In this sense, STRR functions not only as a measurement device, but also as a cognitive and governance mechanism that makes the destination of organisational attention explicit and accountable.

Managerial contribution. STRR functions as a governance-ready KPI to steer reinvestment portfolios and prevent the “efficiency trap” in which Released Time is absorbed invisibly. Given evidence that volunteering quality, leadership, and role alignment influence retention and outcomes, governance constraints are not optional but constitute the core mechanism (Forner et al., 2024; Bansi et al., 2025).

Reporting/assurance relevance. STRR is aligned with the need for workforce-related disclosures (ESRS S1 includes metrics and targets for training/skills and work-life balance), and with global human capital reporting standards (ISO 30414:2025).

Finally, the framework is consistent with the concept of absorptive capacity, which emphasises the role of organisational capabilities in recognising, assimilating, and applying new knowledge (Cohen and Levinthal, 1990). By reallocating Released Time towards learning, coordination, and knowledge-sharing activities, organisations can transform AI-enabled efficiency gains into enhanced absorptive capacity, thereby strengthening long-term adaptability and innovation potential.

The framework therefore redefines AI productivity not as a cost phenomenon, but as a governance problem centred on the allocation and accountability of organisational capacity.

10 Limitations and Research Agenda

This paper is deliberately limited to a first-stage, non-causal validation of STRR (reliability + reconciliation). Future research should extend the framework through field studies, causal contrasts, longitudinal evaluation of retention and learning outcomes, and full SROI chains with sensitivity analysis, consistent with the methodological variability highlighted in SROI reviews (Sillcox et al., 2026).

11 Conclusions

Generative AI can free time, but organisations require a governance mechanism to ensure that Released Time becomes sustainable organisational capability and, where relevant, societal value. By quantifying Released Time through TDABC and introducing STRR as an auditable reinvestment ratio, extended to S-STRR through disciplined SROI integration, this paper provides a bridge between measurement and governance that operationalises the shift from cost to social capacity.

12 Ethics Declaration

No ethical clearance was required for this conceptual and methodological paper. (Future field studies will seek relevant approval where required.)

13 AI Declaration

AI tools were used for language refinement and drafting support. All constructs, formulae, governance rules, and methodological choices were defined and critically validated by the authors, who retain full responsibility for the paper.

How European Living Labs Contribute To the Creation of Ecosystems of Innovation: A Social Network Analysis (SNA) of Project-Based Collaboration

Sara Gigli[1], Anna Turchetta[2]
[1] University of Cassino and Southern Lazio, Cassino, Italy
[2] Independent PhD, Aquino, Italy

Abstract

In recent years, increasing attention has been devoted to the role of collaboration and innovation in addressing sustainability challenges. Sustainable innovation has become a key driver of long-term value creation. Technological progress and knowledge exchange are crucial enablers of such innovation, especially within the open innovation framework, where firms integrate internal and external knowledge sources.

Within this evolving landscape, living labs have emerged as pivotal actors in innovation ecosystems. Based on principles of co-creation, experimentation, and user involvement, living labs facilitate the development and testing of innovative solutions in real-life contexts. By bringing together multiple stakeholders, they foster collaborative processes to tackle complex societal challenges and advance sustainability transitions.

This study addresses the following research question: *How do knowledge collaboration networks among living labs contribute to territorial innovation ecosystems?* To answer this question, we adopt a Social Network Analysis (SNA) approach, which is particularly suitable for examining patterns of collaboration and knowledge exchange. Data were manually collected from the websites of living labs listed in the European Network of Living Labs (ENoLL) database. The analysis focuses on four European countries (France, Germany, Italy, and Spain) selected due to their high concentration of living labs and the availability of comparable data.

In the constructed network, nodes represent organizations involved in living lab activities, and edges represent project-based collaborations. Each tie is characterized by attributes such as the number of shared projects, collaboration intensity, domain, and interaction type. Using RStudio, we analyse both global network properties and node-level centrality measures to assess the structural role of living labs within the ecosystem.

Preliminary findings reveal a partially connected network characterized by heterogeneous collaboration patterns. While the overall network density is relatively low, a very small number of living labs act as central hubs. This study contributes to the literature on knowledge management and innovation ecosystems by providing empirical evidence on the relational mechanisms underpinning knowledge-driven innovation. However, limitations related to data availability suggest the need for future research integrating longitudinal and qualitative approaches to better capture the evolution of living lab networks.

1 Introduction

To achieve the SDGs by 2030, national and international strategies have increasingly emphasized sustainability challenges in business (Zbuchea et al., 2024). Collaboration among different actors in society has had a positive impact on sustainability. For instance, knowledge spillovers generated by industrial collaboration have accelerated the low-carbon transition (Wu and Xu, 2025; Truong et al., 2026). Innovations that improve sustainability performance across social, ecological, and economic dimensions are referred to as sustainable innovations (Boons et al., 2013; Perriton et al., 2025). In this scenario, technology is increasingly essential for driving business innovation (Munteanu et al., 2025).

Schumpeter defined innovation as the motor of the economy (1934). In contemporary societies, innovation and knowledge creation are accelerating (De Jong et al., 2010; Lehmann et al., 2015). Particularly, technological innovation is crucial for sustainable development amid globalization and climate change (Yi et al., 2023; Truong et al., 2026). Innovation is not limited to the output of an internal, closed company process. It is born of ideas, knowledge, and technologies from both within and beyond firm boundaries. This new approach to innovation was first defined by Chesbrough et al. (2005) as open innovation (OI) (Chesbrough, 2006; Schuurman et al., 2016; Sergianni et al., 2024; Pacheco et al., 2025). According to this new framework, innovation is a nonlinear process in which internal R&D departments and the outside world collaborate. In this context, companies benefit from collaboration synergies.

In this scenario, the living lab plays a crucial role in an innovation ecosystem (Tagliazucchi et al., 2024; Najda-Janoszka et al., 2025). Living labs build on the principles of co-creation, exploration, experimentation, and innovation, where user-citizens are at the source of creation (Roy, 2011; Ondiek and Moturi, 2019). They have arisen as "a prominent approach to structure and stimulate innovation by testing new sociotechnical arrangements *in situ* and at a meso-scale" (Engels et al., 2019, p. 1). According to Leminen et al.'s (2012) empirical investigation, there are four leading living lab actors: utilizers, enablers, providers, and users. Through living labs, it is possible to co-create participatory approaches to deal with wicked challenges (Wamsler et al., 2020; Paskaleva and Cooper, 2021; Tiwari et al., 2025). Living labs operate sustainability transformation through experimentation (Cacciolatti et al., 2025).

Our research question is:

"How do knowledge collaboration networks among living labs contribute to territorial innovation ecosystems?"

To carry out our research, we applied Social Network Analysis (SNA) because it is well-suited to analysing collaboration networks (Borgatti and Li, 2009; Arranz et al., 2020). Originally, SNA was used in sociology (Moreno, 1934; Lewin, 1936), but since the 1990s, it has also been introduced in management research (Zheng et al., 2016). Data were collected manually by consulting the websites of living labs. We downloaded the list of living labs, including those in the European Network of Living Labs (ENoLL) database. We consider only France, Germany, Italy, and Spain as these countries show a high concentration of living labs and provide sufficiently comparable and reliable data on project-based collaborations. For each living lab, we analysed projects that they carried out. In our network, nodes are represented by organizations connected by project-based collaborations (edges). Edges represent collaborative ties established through shared projects. They are enriched with multiple attributes, including the number of shared projects, collaboration intensity (low, medium, high), collaboration domain (e.g., agrifood, sustainability, digital innovation), type of collaboration, and tie weight, capturing the strength of inter-organizational relationships. We used RStudio to process the data. Using SNA techniques, the study aims to examine both global network properties and node-level centrality measures to assess the structural role of living labs within the collaboration network.

Preliminary findings reveal a partially connected network characterized by heterogeneous collaboration patterns. While the overall network density is relatively low, a limited number of living labs emerge as central hubs, concentrating a significant share of collaborations, while most organizations remain weakly connected. In addition, cross-regional and cross-sectoral collaborations underscore the role of these key actors in bridging institutional and geographical boundaries. Theoretically, our research contributes to the knowledge management and innovation ecosystem literature by providing empirical evidence on the relational mechanisms through which living labs enable knowledge-driven innovation. In addition, the results underscore the strategic importance of supporting living labs as ecosystem orchestrators, capable of strengthening collaborative intensity. Not all living labs analysed have a website section where all projects and partners can be consulted. These represent key limitations of this research because we can't map all effective collaboration. Finally, future research could extend the analysis longitudinally and integrate qualitative insights better to capture the evolutionary dynamics of living lab-based innovation ecosystems.

2 Literature Review

Innovation, defined by Schumpeter (1934) as the motor of the economy, is accelerating rapidly in our contemporary society (De Jong et al., 2010; Lehmann et al., 2015). At the beginning of the 2000s, Chesbrough et al. (2005) introduced the concept of open innovation (OI). The concept of open innovation highlights practices that cross organizational boundaries to accelerate the creation and appropriation of value (Pacheco et al., 2025). Indeed, OI "enables the pooling of resources and capabilities from various companies and organisations of all kinds" (Sergianni et al., 2024, p. 189).

Living labs are born on the philosophy of the OI paradigm and are considered open innovation networks (Sergianni et al., 2024). They are open innovation ecosystems that support research and innovation activities by embedding them within real-world contexts (Hossain et al., 2019; Tagliazucchi et al., 2024). Nowadays, Europe has a high confluence of operating living labs (Hossain et al., 2019).

In accordance with living labs' philosophy, experimentation is the key mechanism to generate sustainable transformation (Cacciolatti et al., 2025). Living labs assume a pivotal role within innovation ecosystems nowadays (Tagliazucchi et al., 2024; Najda-Janoszka et al., 2025). They are grounded in principles such as co-creation, exploration, experimentation, and innovation, with citizens and users actively involved in generating value (Roy, 2011; Ondiek and Moturi, 2019). Living labs have emerged as "a prominent approach to structure

and stimulate innovation by testing new sociotechnical arrangements *in situ* and at a meso-scale" (Engels et al., 2019, p. 1).

Drawing on the empirical work of Leminen et al. (2012), four main categories of actors can be identified within living labs: utilizers, enablers, providers, and users. These environments enable the development of participatory and collaborative approaches to address complex and "wicked" societal challenges (Wamsler et al., 2020; Paskaleva and Cooper, 2021; Tiwari et al., 2025). Furthermore, living labs contribute to sustainability transitions by fostering experimentation and iterative learning processes (Cacciolatti et al., 2025).

3 Methodology

To answer our research question, we applied Social Network Analysis (SNA) (Moreno, 1934; Lewin, 1936; Borgatti et al., 2009; Zheng et al., 2016).

According to this methodology, organizations are conceptualized as nodes connected through relational ties (Borgatti and Li, 2009; Borgatti et al., 2009; Arranz et al., 2020). In our study, ties are operationalized as project-based collaborations, representing discrete interactions that serve as proxies for underlying relational structures and knowledge exchange processes. To construct the network, we developed a one-mode network of living labs, where ties indicate shared participation in at least one project.

We started our analysis of living labs, focusing on those included in the European Network of Living Labs (ENoLL). We considered only ENoLL members from Italy, France, Germany, and Spain. For each of them, we consulted their websites to find projects they had carried out. When we identified these projects, we began gathering more information about all partners who had participated. For all members, we assigned a unique ID to each node. This was the most difficult passage because not all websites showed detailed information on their project partners. All edges are enriched with multiple attributes, including the number of shared projects, collaboration intensity (low, medium, high), collaboration domain (e.g., agrifood, sustainability, digital innovation), collaboration type, and tie weight, which captures the strength of inter-organizational relationships.

After this first phase of our research, when all data were collected manually, we began the analysis in RStudio. There, we calculated key network metrics, including density and centrality measures. In this process, we applied the SNA protocol (Moreno, 1934; Lewin, 1936; Borgatti et al., 2009; Zheng et al., 2016).

4 Findings and Discussion

The social network analysis (SNA) reveals a network composed of 167 nodes and 163 edges, indicating a relatively sparse structure. The network density is very low (0.0118), suggesting limited collaboration among actors. Furthermore, the global clustering coefficient results equal zero, indicating the absence of cohesive subgroups and triadic closure. This implies that collaborations are predominantly dyadic and not embedded within broader collaborative clusters. Finally, the network diameter is 4, suggesting that, despite low connectivity, the network remains relatively compact (see Table 1).

Table 1**:** Social Network Analysis (SNA) metrics

Metric	Value
Nodes	167
Edges	163
Density	0.0118
Clustering coefficient	0
Diameter	4

Overall, these results indicate that the network cannot be considered a fully developed collaborative ecosystem. Rather, it is characterized by weak connectivity, a limited number of relationships, and the absence of cohesive clusters. This suggests that interactions among living labs are fragmented and lack an integrated structure.

To further explore the network's structure, degree centrality was used to identify the most influential actors. The results highlight a highly uneven distribution of connections, with a small number of nodes serving as central hubs, while most actors exhibit very low connectivity.

Table 2: Top hubs in the living labs network

Node	Country	Degree
Santa Chiara Lab	Italy	38
SSI living lab - Home care lab	Spain	36
VidAAS Centre	Spain	30
Gérontopôle Nouvelle-Aquitaine	France	20
K8 Institute for Strategic Aesthetics	Germany	18

These findings suggest that the network is highly centralized, relying on a limited number of key actors rather than a distributed, collaborative structure. Consequently, interactions are concentrated around these hubs, rather than evenly spread across the network.

The network visual representation (Figure 1) further supports these results. It reveals a fragmented configuration composed of multiple disconnected components, each typically organized around a central node and several peripheral actors. The visualization reveals a hub-and-spoke structure, with several disconnected components organized around central actors, further confirming the high level of network centralization.

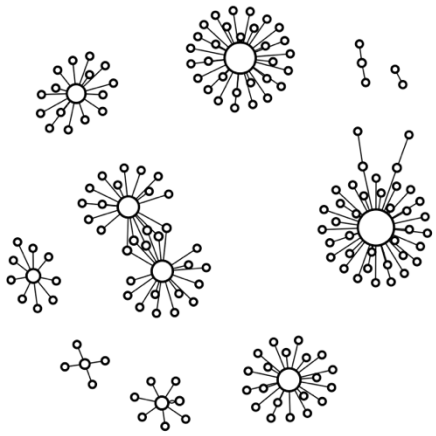

Figure 1: Living Labs Collaboration Network

Living labs are described as platforms where heterogeneous actors collaborate to develop and test innovative solutions (Hossain et al., 2019; Leminen et al., 2016). Within this perspective, they are expected to operate as interconnected ecosystems enabling distributed knowledge flows and collaborative innovation.

However, the empirical evidence emerging from this study provides a more nuanced and, in part, contrasting perspective. The social network analysis reveals a fragmented, weakly connected structure characterized by low density, the absence of cohesive subgroups, and strong centralization around a limited number of actors. These findings suggest that collaboration among living labs is not evenly distributed and does not translate into a fully integrated ecosystem. This result contrasts with several contributions that emphasize the collaborative potential of living labs in addressing complex societal challenges. For example, living labs are often portrayed as enabling stakeholder collaboration and participatory decision-making, particularly in sustainability and climate-related contexts (Tiwari et al., 2025). Similarly, studies on urban agroecosystem living labs highlight their role in fostering co-creation, stakeholder engagement, and sustainable development outcomes (Riaño-Herrera et al., 2025). These perspectives tend to describe living labs as cohesive and effective collaborative environments.

Nevertheless, a growing body of literature suggests that such outcomes are not automatic but depend on specific structural and organizational conditions. Co-creation processes require favourable configurations of cognitive, organizational, and contextual factors, as well as effective mechanisms for integrating knowledge (Centeno et al., 2026). From this perspective, the effectiveness of living labs depends on the presence of enabling conditions. The results of this study align with this view, indicating that the absence of strong and widespread connections may hinder the emergence of integrated collaboration.

Moreover, prior research highlights several structural and managerial challenges associated with living labs. These include governance complexity, scalability issues, stakeholder heterogeneity, and difficulties in sustaining collaboration over time (Hossain et al., 2019; Gibert and Plantec, 2026). In particular, the role of living labs as intermediaries requires them to coordinate actors with divergent interests and expectations, making collaboration inherently complex. These challenges are consistent with the network structure observed in this study. The presence of multiple disconnected components and hub-dominated configurations suggests that

collaboration is localized and does not easily scale across the broader ecosystem. In line with this, previous studies on urban experimentation and living labs also question their transformative capacity, highlighting that their impact is often difficult to measure and may be limited by institutional and structural constraints (Kropp, 2025). Similarly, research on circular economy living labs identifies coordination challenges, infrastructural limitations, and difficulties in aligning stakeholders as key barriers to effective collaboration (Elbroumi et al., 2025). These insights help explain why, despite their theoretical promise, living labs may fail to generate fully integrated innovation ecosystems in practice.

5 Conclusions

Living labs are increasingly recognized as key actors within innovation ecosystems. They facilitate fostering collaboration, co-creation, and knowledge exchange among diverse stakeholders (Roy, 2011; Leminen et al., 2012; Wamsler et al., 2020). In line with the literature on open and sustainable innovation, they are expected to facilitate distributed and interconnected knowledge dynamics that contribute to territorial innovation ecosystems (Chesbrough, 2006; Boons et al., 2013; Pacheco et al., 2025).

However, our findings provide a more complex perspective. The empirical evidence from the social network analysis reveals that, rather than forming a cohesive and integrated ecosystem, living labs are embedded in a fragmented and weakly connected network. Collaboration patterns appear limited and unevenly distributed, with interactions concentrated among a small number of central actors, while most living labs remain only marginally connected. These results suggest a discrepancy between the theoretical expectations of living labs as collaborative innovation ecosystems and their actual structural configuration. Instead of a distributed, interconnected network, the observed structure is characterized by isolated clusters and hub-dominated interactions, suggesting that knowledge-exchange processes may be less pervasive and inclusive than expected.

This study aims to contribute to the literature on knowledge management and innovation ecosystems by highlighting the importance of network structure in shaping collaborative dynamics (Borgatti and Li, 2009; Arranz et al., 2020). Specifically, it shows that the mere presence of collaborative initiatives does not necessarily translate into an integrated ecosystem; rather, it may result in fragmented configurations with limited systemic impact. Our findings underscore the need for policymakers and ecosystem orchestrators to foster stronger, more widespread connections among living labs. Enhancing interconnectivity and promoting cross-cluster collaboration could improve knowledge diffusion, increase innovation capacity, and better support the achievement of sustainability goals (Zbuchea et al., 2024; Wu and Xu, 2025).

This study is subject to some limitations. Data were manually collected from publicly available sources, and not all living labs provide complete information on their projects and partners. As a result, some collaborative ties may not have been captured. Future research could extend this work by adopting longitudinal approaches and integrating qualitative methods to understand better the evolution and governance of living lab networks over time.

Legality Rating and Performance of Italian Companies: Face or Mask?

Abstract

With Decree-Law of January 24, 2012, Italy introduced the Legality Rating to encourage small and medium-sized enterprises to adopt ethical behaviours and comply with principles of legality. Awarded by the Italian Competition Authority (AGCM) on a scale from one to three stars, the Rating provides certified firms with several advantages, including preferential conditions in accessing bank credit, reputational improvements, and access to public funding. Within a civil-law jurisdiction characterised by concentrated ownership and weak formal investor protection, the Rating has been theoretically conceived as a credible signalling and governance device that should reduce information asymmetries, constrain managerial discretion, and align corporate conduct with ethical standards.

Prior empirical evidence on the Legality Rating remains mixed: some studies document better profitability, lower insolvency risk, and improved earnings quality among certified firms, while others suggest that weaker or less profitable firms may use the Rating as a symbolic management tool. Drawing on agency theory, stakeholder theory, and signalling theory, this study revisits this debate by jointly examining default risk, operational risk, and agency costs.

Using a sample of 1,925 Italian firms holding the Legality Rating, for a total of 7,700 firm-year observations over the period 2020–2023, we apply a fixed-effects econometric model to test the relationship between the Rating score and firm performance. Performance is measured through Altman's Z_SCORE (default risk), the standard deviation of ROA over five years (operational risk), and the ratio of operating expenses to total assets (agency costs), while controlling for size, age, ownership concentration, profitability, leverage, industry, and year effects. We investigate whether firms holding the Rating, and thus considered more virtuous, actually mitigate agency costs and reduce financial distress risk, or whether they hide behind it to pursue window-dressing strategies.

Contrary to expectations, the results do not support the formulated hypotheses. Higher Rating scores are systematically associated with higher operating expenses, greater ROA volatility, and lower Z_SCORE values, suggesting that more highly rated firms exhibit higher operational risk, higher agency costs, and greater proximity to the financial distress zone. These findings raise concerns about the effectiveness of the Rating as a governance and risk-mitigating mechanism and are consistent with a window-dressing interpretation, whereby financially fragile firms strategically use the certification to enhance reputation, attract preferential credit conditions, and conceal underlying weaknesses. The study contributes to the literature on ethical certifications, signalling, and corporate transparency, and offers practical insights for investors, creditors, and minority shareholders.

Keywords: legality rating, Italian firms, firm performance, window dressing, risk-taking

Paper type: Academic Research Paper

1 Introduction

A vast literature has empirically demonstrated that the development of an economic system, firm growth, capital market development, and a country's legal system are closely interrelated (e.g., La Porta et al., 1997). One of the main differences between civil law and common law countries lies in the level of stakeholder protection, which appears higher in common law systems. Firms more virtuous in terms of legality, transparency, and corporate social responsibility are expected to reduce agency conflicts (Jensen and Meckling, 1976) and increase firm value. With Decree-Law of January 24, 2012, Italy introduced the Legality Rating to encourage SMEs to adopt ethical behaviours, providing economic, reputational, and financing benefits to certified firms.

Several studies have investigated the relationship between the Rating and firm performance with mixed results. Caputo and Pizzi (2019) find that the Rating is associated with significantly higher EBITDA and liquidity ratios and lower debt-to-equity ratios. Alfano et al. (2024) document higher profitability and liquidity among certified firms, attributing the differences to reputational effects, and Lo Conte and Sancetta (2023, 2024) confirm these findings. By contrast, La Rosa et al. (2021) show that firms with lower profitability or higher insolvency risk tend to achieve higher rating scores, suggesting that weaker firms use the Rating as a symbolic management tool. They also argue that the Rating is mainly adopted by firms that already comply with legal and ethical standards, and is therefore unlikely to change corporate behaviour.

A growing body of research examines performance through the lens of financial stability. Pizzi et al. (2020), using Altman-type indicators, document that ethically and legally compliant firms exhibit lower insolvency risk. Bertacchini et al. (2025) extend this stream by linking the Rating to lower earnings management, although they note that improved earnings quality may also reflect more conservative accounting practices.

Using a sample of 1,925 Italian firms holding the Legality Rating (7,700 firm-year observations), this study investigates whether rated firms actually mitigate agency costs and reduce financial distress, or whether they hide behind the Rating to pursue window-dressing strategies.

2 Literature Review and Hypothesis Development

2.1 Agency Costs, Corporate Social Responsibility, and the Legality Rating

2.1.1 Agency theory and the ownership–control nexus

The separation of ownership and control is a foundational problem in corporate finance (Berle and Means, 1932; Jensen and Meckling, 1976). Within Jensen and Meckling's (1976) framework, agency costs arise from divergent incentives of principals and agents and comprise monitoring, bonding, and residual loss; they vanish when the owner-manager retains the entire stake and intensify as outside equity increases.

The original Agency Problem Type I focuses on the conflict between dispersed shareholders and professional managers. With concentrated ownership, typical of European economies, the dominant concern shifts to expropriation of minority shareholders by controlling blockholders,Agency Problem Type II (Villalonga and Amit, 2006). La Porta et al. (1999, 2000) document that, outside the United States, most listed firms feature a single controlling shareholder; when that blockholder is an individual or a family, the incentive to extract private benefits makes the Type II problem more relevant. Villalonga et al. (2015) extend this taxonomy in family firms, identifying four agency problems: owner–manager (Type I), controlling–minority shareholder (Type II), shareholder–creditor (Type III), and intra-family (Type IV).

2.1.2 Legal systems, investor protection, and capital markets

The legal environment plays a crucial role in shaping agency dynamics. La Porta et al. (1997) demonstrate a systematic relationship between legal origin and capital market development across 49 countries: common law countries offer stronger investor protection and have larger, more developed markets. Djankov et al. (2008) refine this with the anti-self-dealing index, confirming that countries with weaker provisions exhibit less developed capital markets.

Italy belongs to the civil law tradition and is characterised by relatively weak formal investor protection. Faccio and Lang (2002) document that the majority of continental European firms are controlled by families or the State, with widespread use of pyramidal structures and dual-class shares, a pattern especially pronounced in Italy. The Type II agency problem is therefore particularly relevant, and voluntary mechanisms credibly signalling commitment to legality become especially valuable as complements to thin formal protections.

2.1.3 CSR, stakeholder governance, and agency cost mitigation

A growing literature links CSR to agency cost mitigation: CSR practices reduce information asymmetries, constrain managerial opportunism, and strengthen monitoring (e.g., Ferrell et al., 2016; Jo and Harjoto, 2011). From a stakeholder perspective (Freeman, 1984), CSR aligns managerial interests with those of a broader set of stakeholders through reputational and governance channels.

However, the relationship is not unambiguously positive. Barnea and Rubin (2010) show that insiders with low ownership stakes promote CSR over-investment to enhance personal reputation at the expense of shareholder value. Cespa and Cestone (2007) develop a model in which managers use CSR as an entrenchment mechanism, building stakeholder alliances to insulate themselves from disciplinary takeovers. The agency implications of CSR thus depend on whether ethical practices are adopted as genuine governance tools or as instruments of managerial self-interest.

2.1.4 The Legality Rating as a governance and signalling mechanism

Within the agency-theoretic framework, the Legality Rating operates through two channels: it imposes governance standards that promote transparency and constrain managerial discretion, and it functions as a credible signal to external stakeholders. Signalling theory (Spence, 1973) holds that informed parties can convey unobservable qualities through costly and observable actions; Connelly et al. (2011) emphasise that effective signals must be costly to obtain and difficult to imitate. The Rating satisfies these conditions: it requires verifiable

compliance with legal standards, is awarded by an independent authority (AGCM), and is publicly observable, lowering the cost of external financing.

2.2 Legality Rating and risk

The relationship between CSR and firm risk is a well-established area of inquiry. Building on stakeholder theory (Freeman, 1984), substantial research challenges the Friedmanite view that ethical conduct and economic performance are inherently in tension, arguing instead that they are mutually reinforcing (Porter and Kramer, 2002). CSR benefits encompass improved financial performance, enhanced reputation, lower transaction costs, and reduced firm risk (Weber, 2008). The Legality Rating, by requiring compliance with legal standards verified by an independent authority, can be interpreted as a proxy for CSR in the Italian setting. As Carroll (1991) observed, compliance with the law is a foundational pillar of socially responsible conduct, while McWilliams and Siegel (2001) emphasise that genuine CSR goes beyond mere legal obedience.

2.2.1 CSR, financial stability, and default risk

Empirical evidence consistently supports a negative association between CSR engagement and firm risk. Tsoutsoura (2004) documents that S&P 500 CSR practices are associated with higher accounting performance (ROA, ROE, ROS). Orazalin et al. (2019), focusing on the Russian oil and gas industry, find that sustainability disclosure quality is positively related to Z-scores, indicating greater financial stability among more transparent firms.

A complementary strand examines the link between CSR and default risk across institutional environments. Shahrour et al. (2021), analysing 412 Eurozone firms over 2003–2017, document a negative relationship that intensifies during downturns, providing insurance-like protection. Sun and Cui (2014) reach analogous conclusions, showing that CSR-engaged firms benefit from a lower cost of debt and improved credit ratings. Do (2022), in an international study covering 36 countries, finds that the risk-mitigating effect of CSR is more pronounced for firms with sustained, long-standing commitment.

2.2.2 CSR and risk-taking behaviour

Beyond default risk, an extensive literature investigates the impact of CSR on managerial risk-taking. Orlitzky and Benjamin (2001), in a meta-analytic review, document a robust negative correlation between corporate social performance and financial risk, attributable to trust-building among stakeholders, accumulated social capital, and reduced uncertainty. Mulia and Joni (2020), examining Indonesian listed firms with both operational and market risk measures, find that CSR adoption significantly reduces both, particularly in high-risk emerging-market settings. Harjoto and Laksmana (2018) show that CSR engagement constrains both excessive and insufficient risk-taking, aligning corporate decisions with optimal risk levels.

Taken together, these contributions suggest that CSR operates as a risk-mitigating mechanism by lowering information asymmetries, strengthening trust-based stakeholder relationships, and curbing managerial discretion in risky strategies.

2.2.3 Evidence on the Legality Rating and firm risk

The empirical literature on the Legality Rating, although limited, supports the risk-mitigating interpretation. Caputo and Pizzi (2019) document that voluntary adoption is associated with improved economic, financial, and stock-market performance. La Rosa et al. (2021) argue that the Rating is predominantly adopted by firms whose governance is already attentive to ethical and legal matters. La Rosa (2020) notes that, while in the short term stakeholders reward firms primarily for meeting minimum legality standards, the highest scores serve a longer-term reputational purpose.

Several contributions examine the link between the Rating and firm risk. De Benedetto et al. (2024), using conditional nonparametric frontier analysis, show that the Rating enhances corporate efficiency by mitigating risks, facilitating bank credit access. Lo Conte and Sancetta (2023), comparing 100 service-sector rated firms with a control group, find significant reductions in insolvency risk (higher Z-scores). Pizzi et al. (2020), focusing on 148 firms with the maximum three-star score, reach analogous conclusions and suggest that the Rating may moderate the bankruptcy risk associated with firm age.

2.3 Hypothesis development

2.3.1 Legality Rating and risk

The reviewed evidence is broadly consistent: CSR engagement is systematically associated with lower default risk, lower operational and market risk, and more disciplined risk-taking. The Legality Rating, conceived as a credible signal of legal compliance and as a governance mechanism, can be expected to operate through the same channels (Spence, 1973; Connelly et al., 2011). Accordingly, we formulate:

H1: There is a negative relationship between the Legality Rating score and firms' risk-taking.

2.3.2 Legality Rating and agency costs

Two competing perspectives map onto the "face or mask" question. Under the dominant view, building on agency, stakeholder, and signalling theory, if the Rating represents a genuine commitment to governance quality (the "face" of corporate virtue), then higher scores should correspond to lower agency costs through governance standards constraining managerial discretion, transparency requirements lowering information asymmetries, and the credibility of an independently verified, publicly observable signal (Spence, 1973; Connelly et al., 2011). In concentrated ownership settings with weak formal investor protection (La Porta et al., 1997; Djankov et al., 2008), credible certification may further constrain expropriation.

A contrasting strand treats CSR and ethical certifications as a potential source of agency conflicts. Barnea and Rubin (2010) show managerial over-investment in CSR for personal reputation; Cespa and Cestone (2007) argue that CSR can serve as entrenchment. Applied to the Rating, this suggests certification may function as a "mask" projecting ethical virtue while underlying agency problems persist, with firms with higher agency costs seeking the Rating to compensate for governance weaknesses (La Rosa et al., 2021). We consider this perspective less compelling than in the broader CSR setting, given the Rating's mandatory eligibility requirements and independent verification. We therefore formulate:

H2: There is a negative relationship between the Legality Rating score and agency costs.

3 Methodology and Data Analysis

To test the hypotheses, we constructed a sample of firms holding the Legality Rating, obtained from the Italian Competition Authority (AGCM). Since historical data are not available, the analysis focuses on firms that renewed the Rating between 2022 and 2024 (latest update October 24, 2024). The lack of information on past renewals led us to assume a single renewal per firm.

The sample includes only joint-stock and limited liability companies, excluding partnerships, cooperatives, financial firms, and utilities. These criteria reduced the initial sample of over 10,000 firms to 1,925. The analysis covers 2020–2023, with firm-level financial data from the AIDA database (Bureau van Dijk). All variables were winsorized at the 5th and 95th percentiles.

Firm risk, used to test H1, was measured through Z_SCORE and the standard deviation of ROA. The Z_SCORE has been widely adopted in the legality rating literature (Pizzi et al., 2020; Lo Conte and Sancetta, 2023) and was computed following Altman (1993) for non-listed firms and Altman (1968) for the seven listed firms in the sample. The standard deviation of ROA over five years captures operational risk (Mulia and Joni, 2020; Harjoto and Laksmana, 2018). To test H2, we employed operating expenses (OPEX), as the ratio of operating expenses to total assets, following Ang et al. (2000) as a proxy for agency costs.

The independent variable is the legality rating score, consistent with La Rosa (2020). Star ratings were converted into a numerical scale from 1 to 7 (one star = 1; three stars = 7). Table 1 illustrates the conversion and shows a higher concentration of firms with lower scores.

Table 1: Legality score

Score	Rating	% of firms
Star	1	0.2 %
Star and one "+"	2	5.3 %
Star and two "+"	3	28.4 %
Two stars	4	21.8 %
Two stars and one "+"	5	12.8 %
Two stars and two "+"	6	11.7 %
Three stars	7	19.8 %

Source: Author's own work

Control variables include firm size (log of total assets), age (log of years since establishment), the ownership share of the largest shareholder, profitability (ROA), leverage, and Industry and Year dummies.

Table 2: Description and measurement of variables

Variables	Description	Data Source
Dependent Variables		
Z_SCORE	It was measured according to Altman (1968)	AIDA Bureau van Dijk.
OPEX	Ratio of operating expenses to total assets	AIDA Bureau van Dijk.
SD(ROA)	Standard deviation of ROA over a five-year time horizon	AIDA Bureau van Dijk.
Independent Variables		
RATING	Score varies from 1, if it does not satisfy any requirement of Article 3, to 7, if it satisfies at least 6 requirements of the same article of the conformity provided by AGCM	The Italian Competition Authority (*Autorità Garante della Concorrenza e del Mercato* – AGCM)
Control Variables		
SIZE	Total assets (in logarithmic form)	AIDA Bureau van Dijk.
AGE	Years since firm was established (in logarithmic form)	AIDA Bureau van Dijk.
OWNERSHIP	The percentage of shares held by controlling shareholder	AIDA Bureau van Dijk.
ROA	Yearly EBIT/total assets*100	AIDA Bureau van Dijk.
LEVERAGE	Financial debt divided by total assets	AIDA Bureau van Dijk.
INDUSTRY	Four-digit SIC (Standard Industrial Classification) codes. A dummy variable that takes the value 1 if it belongs to a specific industry sector and 0 otherwise	AIDA Bureau van Dijk.
YEAR	Dummy variables (1, 0) associated with the years	AIDA Bureau van Dijk.

Table 3: Descriptive statistics

Variables	Average	Median	Standard Dev.	Min.	Max.
Z_SCORE	1,87	1,75	0,8	0,59	3,59
OPEX	0,55	0,46	0,33	0,15	1,4
SD(ROA)	3,37	2,55	2,62	0,5	10,18
RATING	4,56	4	1,6	1	7
SIZE	9,25	9,19	1,63	0	16,05
AGE	3,15	3,26	0,67	0	4,66
OWNERSHIP (%)	64,9	60,8	30,1	0,00	100,00
ROA (%)	7,01	5,23	6,25	-0,85	22,78
LEVERAGE	0,57	0,58	0,2	0,19	0,87

Source: Author's own work

In order to verify the effectiveness of the Legality Rating in reducing risk-taking and agency costs, we adopted a fixed-effects econometric model whose equation is as follows:

$$Y_{i,t} = \alpha_i + \beta_1 RATING + \beta_2 SIZE + \beta_3 AGE + \beta_4 ROA_{i,t} + \beta_5 OWNERSHIP + \beta_6 LEVERAGE + \gamma_s + \delta_t + \varepsilon_{i,t}$$

Y_(i,t) represents the dependent variable (Z_SCORE, OPEX, SD(ROA). The independent variable is the Legality Rating (Rating), and ranges from "1" to "7". The control variables are firm size (SIZE), firm age (AGE), percentage of majority shareholder (OWNERSHIP), return on assets (ROA), and firm debt level (LEVERAGE). γ_s represents the sector dummies (Sector), δ_t are the time dummies (Year), and ε_(i,t) is the error term.

4 Results

Table 4 reports the main results. Column (1) shows the regression with Z_SCORE as dependent variable. Since a higher Z_SCORE corresponds to lower default risk, the negative and significant coefficient on Rating (-0.0192, $p < 0.001$) implies that higher rating scores are associated with greater default risk. Column (3) reports results for SD(ROA): the positive and significant coefficient (0.1074, $p < 0.001$) indicates that higher rating scores are associated with greater ROA volatility, suggesting higher operational risk. These findings do not support H1, raising doubts about the effectiveness of the Rating as a risk-mitigating mechanism.

Table 4: Main findings

	Z_SCORE (1)	OPEX (2)	SD(ROA) (3)

Source: Author's own work

Column (3) presents the results for the variable SD(ROA), i.e., the standard deviation of ROA, used to measure the firm's operational risk. The coefficient of the Rating variable is positive (0.1704) and statistically significant ($p < 0.001$), suggesting that higher rating scores are associated with greater volatility in ROA. This result indicates that firms meeting more additional requirements exhibit higher operational risk compared to those with a lower legality rating score.

Overall, these findings do not support hypothesis H1, as a higher rating score does not correspond to a reduction in risk-taking, contrary to what would reasonably be expected. The results raise doubts about the effectiveness of the legality rating in reducing firm risk, as firms with higher ratings were expected to be more prudent and less risky.

Column (2) reports the regression results for the dependent variable OPEX, calculated as the ratio of operating expenses to total assets and used as a proxy for agency costs. The coefficient of the Rating variable is positive (0.0121) and statistically significant ($p < 0.001$), indicating that an increase in the rating score is associated with higher operating expenses and, consequently, higher agency costs. H2 is therefore also rejected.

Regarding the control variables, all coefficients are statistically significant ($p < 0.001$). In particular, Size has a positive effect on all three dependent variables, showing a positive coefficient with respect to Z_SCORE and SD(ROA), and a negative coefficient with respect to OPEX. This suggests that larger firms benefit from lower default and operational risk and are more efficient in reducing agency costs.

The ROA variable consistently shows a positive coefficient, indicating that higher profitability improves the Z_SCORE while increasing the volatility of returns on assets.

Conversely, Age shows a negative coefficient across all models, suggesting that older firms experience lower operational risk and reduced operating expenses, but greater exposure to default risk.

Finally, LEVERAGE exhibits a negative coefficient with respect to Z_SCORE and SD(ROA), and a positive coefficient with respect to OPEX. This implies that as leverage increases, firms improve their Z'-score, but agency costs and ROA volatility also increase. Regarding the OWNERSHIP variable, the sign of the coefficient appears ambiguous. On the one hand, a high concentration of ownership would improve the Z_SCORE, but on the other, it would increase risk. This apparent contradiction could be explained by the fact that the controlling shareholder could venture into riskier investments but, at the same time, would ensure prudent financial management that does not jeopardize the company's default.

The results contradict the hypothesised negative relationships. The average Z_SCORE among rated firms is 1.86, comparable to the 1.43 reported by Caputo et al. (2020). These values place rated firms in the Altman "grey area", close to the distress zone (threshold of 1.23).

Two explanations can be proposed. First, beyond economic benefits, firms may use the Rating to mask their financial condition, leveraging the reputational advantage to gain stakeholder trust while concealing fragility.

Firms in serious difficulty may also seek the Rating for easier access to public and bank financing. Similar conclusions are reached by La Rosa et al. (2019), who argue that firms with lower profitability are more likely to pursue higher legality scores to signal a positive attribute that improves the perception of their condition.

These findings raise doubts about whether the Rating is pursued as a genuine certification of transparency or as a form of "window dressing". Maurutto (2024) defines window dressing as a form of organisational hypocrisy. If the Rating truly reflected stability, the hypotheses would have been confirmed; the opposite pattern raises the possibility that more fragile firms opportunistically obtain the Rating as a masking mechanism.

A key limitation is the absence of a control group of comparable unrated firms. An alternative interpretation is that a longer time horizon may be required for the benefits of the Rating to materialise: a four-year window may be insufficient. In the short term, firms targeting higher scores may incur costs that exceed immediate benefits, which could be interpreted as investments for long-term gains.

5 Conclusion

This study examines the relationship between the Legality Rating and corporate performance using a sample of 1,925 Italian rated firms (7,700 firm-year observations). The results do not support the hypotheses: higher scores are linked to increased OPEX (agency costs) and greater SD(ROA) (operational risk), alongside a decrease in Z_SCORE (default risk). Future research could extend the analysis by including additional dimensions (e.g., earnings management, accruals) and a control sample for comparison. These findings may interest investors and minority shareholders by helping them assess whether corporate actions genuinely enhance reputation or instead serve to mask the expropriation of minority interests.

6 Ethics Declaration

The authors state that no ethical clearance was required for the research presented in this paper. The authors also declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper

Beyond Automation: Strategic Human-Machine Partnerships in Social Enterprise HRM: A Systematic Literature Review

Giuseppe Ambrosio[1], Maria Zifaro[1], Federica Bandini[2], Stefania D'Aprile[1], Giovanni Spatola[1], Marianna Mancino[1]
[1] Universitas Mercatorum, Roma, Italy
[2] Università di Bologna, Bologna, Italy

Abstract

The intersection of artificial intelligence (AI), machine learning technologies, and human resource management (HRM) represents a transformative shift in organisational development. This paper presents a systematic literature review (SLR) examining peer-reviewed evidence on human-machine collaboration in HRM within social enterprises and mission-driven organisations. Using the SPIDER framework and PRISMA guidelines, the review conducted a systematic search on Scopus retrieving 96 peer-reviewed articles, supplemented by backward snowballing.

A critical methodological finding emerged during string construction: incorporating AI-related terms (Cluster C) into the automated TITLE-ABS-KEY search reduced the corpus by 97%, from 245 results to fewer than 12. This reflects a publishing convention whereby AI is discussed substantively in article bodies without being foregrounded in searchable metadata. Cluster C was therefore applied as a manual inclusion criterion during screening rather than as an automated filter.

The review's primary substantive finding is structural: the three-way intersection of AI, HRM, and the third sector is demonstrably scarce in the indexed peer-reviewed literature. The single article meeting all inclusion criteria - Alnamrouti, Rjoub and Ozgit (2022) - provides empirical evidence that AI positively influences sustainable organisational performance in an NGO context, functioning primarily as a mediator amplifying the effect of organisational learning. Backward snowballing on seven references yielded zero additional inclusions, independently corroborating the structural scarcity finding.

Three major research gaps are identified: (1) the absence of domain-specific empirical evidence on AI adoption in social enterprise HRM functions (recruitment, performance management, learning and development, workforce planning, employee engagement); (2) the complete absence of research on ethical and algorithmic risks in mission-driven HRM contexts; and (3) the lack of engagement with established human-machine collaboration frameworks in third-sector management research. These findings establish a documented evidence baseline for a nascent research field, grounding the broader theoretical paper on human-machine partnerships.

Keywords: Human resource management; Social enterprise; Human-machine collaboration; Artificial intelligence; Systematic literature review

Paper type: Academic Research Paper

1 Introduction

The integration of AI into human resource management is reshaping how organisations recruit, develop, and engage their workforces (Malik, Budhwar and Kazmi, 2023; Zhang and Chen, 2024). For social enterprises - organisations defined by the dual imperatives of creating social value while maintaining financial sustainability - this transformation carries distinctive challenges: mission alignment, stakeholder accountability, workforce heterogeneity, and the ethical governance of algorithmic systems operating in contexts where discrimination would directly contradict organisational purpose (Goldkind, Ming and Fink, 2025; Raza Khan et al., 2025).

Despite this theoretical relevance, the peer-reviewed literature has developed in parallel tracks. AI-assisted HRM research concentrates in for-profit settings (Wesche and Sonderegger, 2021; Ruiz, Braojos and Benitez, 2024); social enterprise HRM research is well-developed but largely pre-digital (Oliveira et al., 2021). Their explicit intersection - systematic engagement with how human-machine collaboration is reshaping HRM in mission-driven organisations - is largely absent.

This paper addresses that gap through a systematic literature review. It pursues three research questions:

- *(RQ1) in which HRM domains are social enterprises adopting human-machine collaboration, and what impacts does this generate?*
- *(RQ2) what ethical challenges and algorithmic risks emerge from AI use in mission-driven HRM?*
- *(RQ3) what theoretical frameworks have been mobilised to explain human-machine collaboration in HRM, and what interdisciplinary integration do they evidence?*

The contribution is threefold: the first systematic mapping of peer-reviewed literature at this intersection; empirical documentation of its structural scarcity; and identification of the theoretical and ethical priorities future scholarship must address.

2 Theoretical Background

2.1 Human-machine collaboration beyond automation

Early framings of AI adoption centred on automation - substitution of human labour by systems performing routine tasks more efficiently (Wesche and Sonderegger, 2021). The complementarity perspective offers a more productive account: humans and machines possess systematically different cognitive profiles. Machines excel at processing large data volumes, identifying patterns, and executing consistent procedures without fatigue; humans bring contextual and ethical reasoning, emotional intelligence, and the capacity to navigate value-laden decisions irreducible to optimisation (Jarrahi, 2018; Li et al., 2023). Human-machine collaboration is thus not a transitional state toward full automation but a stable configuration where both jointly accomplish tasks neither could perform as effectively alone (Puranam et al., 2021).

Three frameworks formalise this logic. Wilson and Daugherty (2018) articulate a collaborative intelligence model in which AI augments human capabilities across five dimensions: amplifying cognitive strengths, interacting at scale, embodying skills in physical processes, and enabling new forms of teaming. Jarrahi (2018) develops a human-AI symbiosis perspective emphasising reciprocal learning: AI improves from human feedback while humans develop new competencies. Puranam et al. (2021) situate collaboration within organisational design theory, arguing that task allocation between humans and machines is a deliberate design variable. In HRM, these frameworks converge on a common insight: the value of AI derives not from its capacity to replace human judgement but from its capacity to enhance the quality, consistency, and reach of human decision-making by handling the data-intensive, pattern-recognition, and process-execution dimensions of complex tasks - freeing HR professionals to concentrate on the relational, evaluative, and strategic dimensions of their role that require human sensitivity and contextual understanding (Malik, Budhwar and Kazmi, 2023; Sun and Qiu, 2025).

2.2 AI-Assisted HRM in social enterprises

AI has been applied across five HRM domains relevant to social enterprises. In recruitment and selection, AI screens applications and conducts preliminary interviews via natural language processing (Wesche and Sonderegger, 2021). For resource-constrained social enterprises, this enables processing of larger applicant pools, but human involvement remains essential for assessing mission alignment and ensuring diversity, equity, and inclusion commitments are upheld. In performance management, technology-enabled platforms collect data continuously, provide real-time feedback, and identify competency gaps (Ruiz, Braojos and Benitez, 2024). For social enterprises, systems can integrate multiple dimensions - individual productivity, contribution to social outcomes, and embodiment of organisational values - addressing the subjective biases of traditional appraisal.

In learning and development, adaptive platforms customise content by learning style, pace, and prior knowledge, democratising professional development access (Vardarlier, 2020; Zhang and Chen, 2024). In workforce planning, optimisation algorithms balance operational requirements with employee preferences while predictive models enable proactive resource allocation - critical for social enterprises managing fluctuating demand and volunteer coordination (Malik, Budhwar and Kazmi, 2023). In employee engagement, sentiment analysis tools assess organisational climate continuously. Where commitment to social mission represents a crucial competitive advantage, early detection of emerging tensions enables timely human intervention through authentic relationship-building and values-based dialogue (Ameen et al., 2024). Machine learning can further personalise development pathways for heterogeneous workforces combining paid staff, volunteers, and ex-beneficiaries - while human managers ensure recommendations align with organisational values and individual dignity (Sun and Qiu, 2025).

2.3 Ethical dimensions in mission-driven contexts

Algorithmic bias - systematic unfair differentiation in AI outputs across demographic groups - represents the most consequential risk in HRM adoption (Dima et al., 2024; Raza Khan et al., 2025). For social enterprises, these risks carry distinctive moral weight: organisations whose mission is to promote social inclusion cannot deploy HRM systems that reproduce the inequalities they exist to address without entering into fundamental contradiction with their institutional purpose (Goldkind, Ming and Fink, 2025). Effective governance requires

algorithmic auditing, human override mechanisms, transparent communication about AI use, and proportionate accountability structures - designed to be adequate to the ethical stakes while respecting resource constraints.

3 Methods

3.1 Review design

This study adopts a systematic literature review (SLR) methodology following PRISMA guidelines. Research questions were operationalised using the SPIDER framework (Cooke, Smith and Booth, 2012) which captures qualitative, quantitative, and theoretical contributions across heterogeneous study designs, appropriate for complex organisational phenomena. Table 1 presents the full operationalisation.

Table 1: SPIDER framework operationalisation

SPIDER	RQ1 - Adoption & impacts	RQ2 - Ethical dimensions	RQ3 - Theoretical frameworks
S - Sample	Social enterprises, nonprofits, third sector	Mission-driven orgs, HR stakeholders	Interdisciplinary academic literature
PI - Phenomenon	AI/ML in HRM + performance effects	Algorithmic bias, fairness, AI governance	Theories of human-machine collaboration
D - Design	Case study, survey, mixed-methods	Critical analysis, normative frameworks	Literature review, bibliometrics
E - Evaluation	Efficiency, engagement, social outcomes	Discriminatory risks, mitigation strategies	Dominant theories, theoretical gaps
R - Research type	Empirical	Theoretical, normative, empirical	Theoretical, bibliometric

Source: Authors' elaboration

3.2 Search strategy

The bibliographic search was conducted on Scopus. The string combined Cluster A (organisational context: social enterprises, nonprofits) and Cluster B (HRM domain: human resource management, talent management). AI and human-machine collaboration terms (Cluster C) were deliberately excluded from the automated string and applied as a manual inclusion criterion during screening.

This choice was motivated by systematic diagnostic testing: 14 iterative tests showed that incorporating Cluster C into TITLE-ABS-KEY reduces the corpus by approximately 97% (from 245 to fewer than 12 results). This reflects a publishing convention - AI is treated substantively in article bodies without being foregrounded in searchable metadata. Embedding Cluster C automatically would systematically exclude pertinent contributions. The final string was:

TITLE-ABS-KEY (("social enterprise" OR "nonprofit*" OR "non-profit organization*") AND ("human resource management" OR "HRM" OR "talent management")) AND DOCTYPE (ar) AND LANGUAGE (english) AND PUBYEAR > 2020*

String parameters (peer-reviewed articles, English, published 2021+) automatically satisfied inclusion criteria for document type, language, and publication period.

3.3 Inclusion and exclusion criteria

Three manual inclusion criteria were applied sequentially during screening (I1 → I2 → I3). Criteria for document type, publication period, and language were pre-empted by the search string. Table 2 presents both inclusion and exclusion criteria.

Table 2: Manual screening criteria (I1–I3 and E1–E3)

Code	Criterion	Description
I1	Organisational context	Social enterprises, nonprofits, not-for-profit, third sector or mission-driven organisations
I2	HRM domain	At least one HRM area: recruitment, performance management, talent management, workforce planning, employee engagement, or L&D
I3 *	AI / human-machine collab.	Substantive engagement with AI, ML, algorithms, automation, or human-machine collaboration in the HRM context

Code	Criterion	Description
E1	Non-pertinent context	Profit-oriented, public administration, or industrial/manufacturing organisations
E2	HRM absent	No HR management dimensions - focus on finance, marketing, or operations
E3	AI absent or marginal	AI or digital technology mentioned only marginally without substantial analytical contribution

** I3 = Cluster C applied manually. Criteria for document type (peer-reviewed), period (2021+) and language (English) are guaranteed by string parameters.*
Source: Authors' elaboration

3.4 Screening and Snowballing

The 96 retrieved records were imported into Rayyan. Duplicate detection confirmed zero duplicates. Title, abstract, and keyword screening applied I1–I3 sequentially. Two articles satisfied I1 and I2; full-text assessment confirmed one - Alnamrouti, Rjoub and Ozgit (2022) - met all three criteria. Lin, Lu and Sun (2023) was excluded under E3: its use of data analytics in a blood bank staffing context did not constitute AI or human-machine collaboration substantively. The 31 'Maybe' records - pertinent to context and HRM but lacking technological signal in metadata - were excluded under E3.

Backward snowballing following Wohlin (2014) analysed seven references from Alnamrouti et al. (2022). None met all inclusion criteria (Table 3). Forward snowballing was not conducted: backward snowballing corroborated the structural scarcity independently, and the expected yield of articles citing a 2022 paper at the exact three-way intersection was assessed as negligible.

Table 3: Backward snowballing results - Alnamrouti et al. (2022)

#	Reference	Verdict	Exclusion criterion
1	Wamba-Taguimdje et al. (2020) - AI influence on firm performance. Business Process Management Journal	Excluded	E1 + E2
2	Hamadamin & Atan (2019) - SHRM and competitive advantage. Sustainability	Excluded	E1 + E3
3	Al Aina & Atan (2020) - Talent Management and SOP. Sustainability	Excluded	E1 + E3
4	Mikalef & Gupta (2021) - AI capability. Information & Management	Excluded	E1
5	Tariq et al. (2021) - Operational Excellence Through AI. Frontiers in Psychology	Excluded	E1
6	Sarker & Rahman (2018) - SHRM Practices in NGOs. European Journal of Business and Management	Excluded	E3
7	Oliveira et al. (2021) - Strategy and HRM in Non-Profits. Journal of Open Innovation	Excluded	E3

Source: Authors' elaboration

Data extraction from the included article used a structured grid organised around the three RQs. Given the corpus size of one article, a narrative synthesis approach was adopted consistent with best practice for limited corpora (Tranfield, Denyer and Smart, 2003).

4 Results and Discussion

4.1 Search results

The Scopus search returned 96 articles; no duplicates were found. Screening identified two articles satisfying I1 and I2; full-text assessment confirmed one as meeting all three inclusion criteria. Backward snowballing on seven references yielded zero additional inclusions. Figure 1 [PRISMA flow diagram - see attached] illustrates the complete screening process.

4.2 Structural scarcity as a primary finding

The most significant finding emerges from the search process itself: the three-way intersection of AI/human-machine collaboration, HRM, and the third sector is structurally scarce. The HRM-in-third-sector literature (A+B: 245 results) and the HRM-and-AI literature (B+C: 3,406 results) are individually substantial; their three-way intersection collapses by 97%. Backward snowballing corroborates this independently: zero of seven references from the sole included article satisfies the intersection. This scarcity is a feature of the literature, not a methodological artefact, and constitutes original empirical evidence in its own right - signalling a consequential blind spot in management and organisation research.

4.3 Characteristics of the included study

Alnamrouti, Rjoub and Ozgit (2022) conducted an empirical quantitative study in Jordan, drawing on 171 HR professionals from 21 United Nations agencies and 70 NGOs. Using PLS-SEM (WarpPLS 7.0), they tested a structural model in which organisational learning (OL) and corporate social responsibility (CSR) predict sustainable organisational performance (SOP), mediated by strategic HRM (SHRM) and AI. Table 4 presents the structured data extraction.

Table 4: Data extraction - Alnamrouti, Rjoub and Ozgit (2022)

Dimension	Alnamrouti, Rjoub & Ozgit (2022)
Journal	Sustainability (MDPI), 14, 7327
Country / context	Jordan - 21 UN agencies + 70 NGOs
Method	Quantitative survey - PLS-SEM (WarpPLS 7.0), n = 171
AI construct	6-item scale - AI as general organisational capability
Key finding RQ1	AI → SOP: β = 0.13, p = 0.04 (direct effect); OL → AI → SOP: β = 0.56, p = 0.03 (strongest mediation path)
Key finding RQ2	Not addressed. Sole normative note: recommendation to establish a 'control tower for data ethics'
Key finding RQ3	RBV + OL Theory + IT Capability Theory. No engagement with human-machine collaboration frameworks
Model fit	GOF = 0.667 (large); SRMR = 0.096 (acceptable); R^2 SOP = 0.09 (low)
Main limitation	Non-probability sampling; single sector (Jordanian NGOs); AI as aggregate construct - no HRM domain specificity

Source: Authors' elaboration from full-text analysis

4.4 Findings by research question

RQ1 - Adoption and Impacts

Alnamrouti et al. (2022) provide the only peer-reviewed empirical evidence that AI positively influences organisational performance in a nonprofit context. AI functions as a direct predictor of SOP (β = 0.13, p = 0.04) and, more substantially, as a mediator amplifying organisational learning's effect on performance (β = 0.56, p = 0.03 - the model's strongest path). However, AI is treated as an aggregate capability construct: no empirical evidence addresses specific HRM domain applications in social enterprises. The mediation result is consistent with the complementarity perspective (Wilson and Daugherty, 2018; Puranam et al., 2021), though this connection is not developed by the authors. The low explained variance (R^2 = 0.09) suggests additional variables - including domain-specific human-machine collaboration constructs - may be relevant.

RQ2 - Ethical Dimensions

The included study does not address algorithmic bias, fairness, data governance, or ethical implications of AI in HRM. The sole normative indication is a brief recommendation to establish a 'control tower for data ethics'. This silence is representative of a broader structural gap: the AI ethics in HRM literature (Dima et al., 2024; Raza Khan et al., 2025) has developed independently of the nonprofit and social enterprise context. The ethical risks well-documented in for-profit settings - discriminatory screening, biased performance appraisal, opacity in automated decisions - remain empirically uninvestigated in organisations whose mission is to counter precisely the inequalities biased algorithms can reproduce.

RQ3 - Theoretical Frameworks

The included study mobilises Resource-Based View (Barney, 1991), Organisational Learning Theory (Argyris and Schon, 1978), and IT Capability Theory (Wamba-Taguimdje et al., 2020). This grounding is appropriate for performance-oriented quantitative modelling but does not engage with frameworks developed specifically for human-machine collaboration - the complementarity perspective (Puranam et al., 2021), the human-AI symbiosis model (Jarrahi, 2018), or collaborative intelligence (Wilson and Daugherty, 2018). The absence of these frameworks from the third-sector HRM literature represents a theoretical gap and the clearest opportunity for the present paper's contribution.

5 Conclusions

5.1 Summary and theoretical contributions

This systematic review mapped peer-reviewed evidence on human-machine collaboration in HRM within social enterprises. The primary result is structural: one study meets all inclusion criteria. Three theoretical

contributions follow. First, this review provides systematic evidence that the intersection of AI, HRM, and the third sector constitutes a largely uncharted research territory. Prior work has documented the rapid development of AI-assisted HRM in for-profit organisations (Malik, Budhwar and Kazmi, 2023; Zhang and Chen, 2024) and has separately examined HRM challenges specific to social enterprises and nonprofits (Barenblat and Gosselink, 2024; Goldkind, Ming and Fink, 2025), but the two streams have not converged. The present review documents this non-convergence systematically, establishing a baseline against which future research accumulation can be measured. Second, the review reveals a theoretical mismatch between the frameworks available in the literature and the phenomenon under investigation. The frameworks mobilised in the sole included study - RBV, OL theory, IT capability theory - are well-suited to performance-oriented quantitative modelling but do not capture the complementarity dynamics, ethical tensions, and mission-alignment challenges that characterise human-machine partnerships in organisations driven by social purpose. The collaborative intelligence model (Wilson and Daugherty, 2018), the human-AI symbiosis perspective (Jarrahi, 2018), and the human-machine teaming literature (Puranam et al., 2021) offer conceptual resources that have yet to be applied in this context. Their integration with theories of social entrepreneurship and stakeholder management represents a productive direction for future theoretical development. Third, the review establishes that the ethical dimension of AI in social enterprise HRM is not merely understudied but absent from the empirical literature. This absence is particularly significant because the risks associated with algorithmic decision-making in HRM - discriminatory screening, biased performance appraisal, opacity in automated decisions - are well-documented in for-profit contexts (Dima et al., 2024; Raza Khan et al., 2025) but have never been examined in organisations whose explicit mission is to counter precisely the forms of inequality that biased algorithms can reproduce. Establishing an empirical and normative agenda for AI ethics in social enterprise HRM is therefore both theoretically urgent and practically consequential.

5.2 Practical Implications and Limitations

For organisational leaders, the review signals that evidence-based guidance on AI adoption in nonprofit HRM does not yet exist at domain-specific level. Tools validated in for-profit settings carry assumptions about performance metrics and workforce composition that may not translate. The establishment of internal governance mechanisms - including algorithmic auditing and transparent employee communication - is advisable regardless of external evidence maturity. For policymakers, structural scarcity points to urgent need for sector-specific research investment: the rapid diffusion of AI-powered HRM tools (Barenblat and Gosselink, 2024; Brine et al., 2025; Valenti, 2025) is proceeding without peer-reviewed evidence on effectiveness, equity, or mission alignment.

This review is limited to a single database (Scopus) and to English-language articles published from 2021 onwards. The restriction to English is a potentially significant limitation given the geographical concentration of social enterprise research in non-Anglophone European countries, including Italy, France, and Spain - precisely the contexts most relevant to the phenomenon under investigation. The corpus of one article precludes meta-analytic synthesis - a constraint reflecting the state of the field, not the methodology. Future priorities include domain-specific empirical studies on AI in social enterprise HRM (particularly in the Italian and European context given the sector's institutional maturity), empirical investigation of algorithmic risk in nonprofit HRM, and theoretical integration of human-machine collaboration frameworks with social enterprise theory and institutional logics.

6 Ethics Declaration

This research did not required official ethical approvement

7 AI Declaration

This paper was developed with the support of Claude (Anthropic), an AI assistant, which was specifically used to: (1) support the diagnostic testing of the Scopus search string; (2) support the data extraction; and (3) assist in revising the paper in english. All methodological decisions - including the choice of search strategy, inclusion and exclusion criteria, the decision not to conduct forward snowballing, and all analytical interpretations - were made exclusively by the authors.

The Italian Crisis and Insolvency Code (CCII) Adequate Organisational Frameworks and AI Predictive Judgments

Domenico Celenza[1], Marcella Caradonna[2], Francesca Francioli[3], Stefano Gazzani[1]

[3] University of Genoa, Genoa, Italy

Abstract

The Italian Crisis and Insolvency Code has moved corporate governance from a reactive idea of crisis management to a preventive model in which firms are expected to organise information, responsibilities and controls before distress becomes irreversible. This paper develops a conceptual framework for interpreting adequate organisational, administrative and accounting arrangements as an intelligent and sustainable governance infrastructure. It argues that Artificial Intelligence (AI) can enhance such arrangements not simply by improving insolvency prediction, but by transforming dispersed organisational data into shared knowledge for timely, accountable and human-centred decisions. The analysis is positioned at the intersection of the knowledge-based theory of the firm, management control, corporate governance and the literature on algorithmic decision support. It considers adequate arrangements as dynamic knowledge architectures that connect monitoring, interpretation and intervention, and it examines how predictive analytics, machine learning and explainable AI may support early warning systems, business continuity and organisational resilience. The contribution of the paper is threefold. First, it reframes legal adequacy as a managerial and knowledge-management capability, rather than as a formal compliance exercise. Second, it proposes an AI-enabled model in which data governance, predictive judgement, human oversight and ethical accountability are treated as mutually dependent elements of the same control environment. Third, it links crisis prevention to the broader agenda of intelligent and sustainable organisations, showing that predictive systems can help boards and managers reconcile continuity, stakeholder protection and sustainable value creation. The paper also discusses critical risks associated with AI adoption, including model opacity, poor data quality, bias, cybersecurity vulnerability and excessive delegation of judgement to automated systems. These risks require boards to preserve interpretive responsibility and to build validation, auditability and learning routines into the design of intelligent arrangements. The paper concludes that AI may strengthen the practical effectiveness of adequate arrangements only when embedded in relational governance, organisational learning and explicit ethical safeguards. Its main implication is that the future of crisis governance depends less on technological sophistication alone than on the capacity of organisations to combine human and artificial intelligence in a coherent knowledge system.

Keywords: corporate governance, adequate organisational arrangements, insolvency prediction, artificial intelligence, business continuity.

Paper type: Academic Research Paper

1 Introduction

The future of sustainable organisations depends on their capacity to transform intelligence into responsible action. In turbulent environments, intelligence cannot be reduced to the possession of data or to the adoption of advanced digital tools. It concerns the ability to notice weak signals, understand their meaning, share them across organisational boundaries and translate them into timely decisions. This problem is particularly visible in crisis governance. Financial distress is rarely a sudden event. It is normally preceded by declining margins, tensions in working capital, delays in payments, deteriorating relations with banks or suppliers, and managerial hesitation in acknowledging unfavourable signals. The challenge is therefore not only to predict crisis, but to organise knowledge before crisis disables the organisation's capacity to act.

The Italian Crisis and Insolvency Code, introduced by Legislative Decree No. 14/2019 and subsequently amended, gives legal force to this preventive orientation. It requires entrepreneurs and corporate bodies to adopt measures and arrangements capable of detecting the state of crisis promptly and of supporting action for business continuity. In this respect, the Code should be read not only as an insolvency reform, but also as a governance reform. It shifts attention from ex post allocation of losses to ex ante organisation of information flows, responsibilities and controls. The duty to establish adequate organisational, administrative and accounting arrangements asks the firm to become intelligible to itself. It requires an internal architecture through which dispersed operational events can be converted into reliable managerial knowledge.

This paper develops the argument that adequate arrangements are a specific form of intelligent organisation. They are intelligent because they connect sensing, interpretation and response; they are sustainable because their purpose is not mere short-term survival, but the preservation of business continuity, stakeholder confidence and value creation. The topic is aligned with the debate on intelligent and sustainable communities and organisations, where human, collective and artificial intelligence interact to support innovation, resilience and inclusive growth. The firm that prevents crisis through better knowledge does not only protect shareholders. It protects employees, creditors, local communities, supply chains and public confidence in economic activity.

Artificial Intelligence (AI) offers a powerful but ambivalent contribution to this transition. Machine learning techniques can process large quantities of accounting, operational and contextual data, detect non-linear patterns and generate early warnings that traditional ratio-based models may miss. AI can reduce information asymmetries and support boards in the continuous monitoring of business continuity. However, algorithmic prediction is not equivalent to managerial judgement. A model may classify a firm as risky without explaining why; it may reproduce biases contained in historical data; it may appear objective while hiding fragile assumptions; it may encourage excessive reliance on automated outputs. Consequently, AI can strengthen adequate arrangements only if it is embedded in a governance system that preserves human accountability, transparency, validation and organisational learning.

The research question guiding the paper is therefore: how can AI be integrated into adequate organisational, administrative and accounting arrangements so as to support sustainable crisis governance and knowledge-driven value creation? The paper adopts a conceptual research design. It synthesises legal and managerial interpretations of adequate arrangements with knowledge-management theory, insolvency prediction literature and AI governance studies. The aim is not to test a predictive model, but to propose a coherent framework for understanding the role of AI within the governance of continuity.

The remainder of the paper is organised as follows. The next section discusses adequate arrangements through the lens of management control and knowledge-based theory. The third section examines AI-enabled insolvency prediction and its limits. The fourth section proposes a conceptual architecture for AI-enabled adequate arrangements. The fifth section discusses implications for boards, control bodies and practitioners. The final section summarises contributions, limitations and future research directions.

2 Adequate Arrangements as Knowledge Infrastructure

In the Italian aziendalistica tradition, organisational adequacy is not a purely formal requirement. It concerns the correspondence between organisational structures, administrative procedures, accounting systems and the complexity of the firm. An arrangement is adequate when it allows the organisation to function coherently, when it clarifies responsibilities, when it supports planning and control, and when it produces information that is sufficiently reliable, timely and relevant for decision-making. From this perspective, adequate arrangements are close to the classical idea of economic order within the firm: they make action possible because they stabilise roles, connect activities and create a common informational basis.

The Crisis and Insolvency Code reinforces this interpretation by linking adequacy to the prompt detection of crisis and to the preservation of business continuity. The legal obligation is therefore inseparable from managerial capability. It is not enough to possess accounting records or periodic reports. The firm must be able to recognise emerging imbalances, evaluate their causes, identify available responses and document the reasoning that leads to action or inaction. Adequacy is a functional criterion: the same tool may be sufficient in a small, simple business and inadequate in a complex group exposed to volatile markets, international supply chains and financial leverage.

This functional reading connects the legal framework with the knowledge-based theory of the firm. Grant (1996) argues that firms exist because they integrate specialised knowledge that individuals hold separately. Nonaka and Takeuchi (1995) describe knowledge creation as a dynamic process in which tacit and explicit knowledge interact. Applied to crisis prevention, these theories show that distress signals do not become useful simply because they exist in databases. They become useful when they are interpreted, shared, challenged and incorporated into decisions. A late payment from a strategic customer may be an isolated event, a symptom of sectoral stress or the beginning of a liquidity shortage. The meaning depends on the organisation's capacity to combine accounting data, commercial information, operational experience and external context.

Adequate arrangements can therefore be understood as knowledge infrastructures. They define what information is collected, who is responsible for it, how often it is updated, how it is validated, who receives it and how it enters the decision process. They also shape the relationship between formal data and practical judgement. In many firms, relevant knowledge is local: sales staff perceive deteriorating customer behaviour, purchasing managers see supplier tensions, financial officers notice covenant pressure, and operational

managers observe productivity losses. If these signals remain fragmented, governance bodies receive information too late or in a form that does not support action. The purpose of adequate arrangements is to avoid this fragmentation.

The sustainability dimension arises because crisis prevention protects the conditions for long-term value creation. Business continuity is not only a financial concept. It involves the capacity to maintain employment, fulfil obligations, preserve knowledge assets, protect relationships with stakeholders and avoid the destruction of organisational capabilities. Sustainable governance therefore requires a broader view of performance in which liquidity, profitability, resilience, environmental and social impacts are observed together. The firm must not become sustainable after crisis; it must organise itself sustainably in order to avoid crisis or to manage it without unnecessary loss of value.

3 Artificial Intelligence and Predictive Crisis Governance

Insolvency prediction has a long history in accounting and finance. Beaver (1966) showed that financial ratios could anticipate failure, and Altman (1968) developed a discriminant model that became a reference point for bankruptcy prediction. Later models, including Ohlson's logit approach and Shumway's hazard model, improved statistical treatment and incorporated the dynamic nature of failure risk. These contributions remain important because they clarify the informational content of accounting and market variables. Yet traditional models also display limits. They often assume relatively stable relationships among variables, rely on restricted financial indicators and struggle to capture qualitative signals, structural breaks and non-linear interactions.

AI-based models respond to some of these limits. Machine learning algorithms can analyse larger and more heterogeneous datasets, including accounting ratios, cash-flow indicators, payment behaviour, tax and social security exposures, operational performance, sectoral trends, supply-chain disruptions and macroeconomic conditions. They can identify interactions that are difficult to specify ex ante and can update predictions as new information becomes available. In a governance context, this may improve the timeliness of early warnings and reduce false negatives, which are particularly dangerous because they lead boards to underestimate emerging distress.

However, predictive accuracy is only one dimension of crisis governance. A model that predicts well but cannot be explained may be difficult to use in board deliberations, internal audit reviews or negotiations with stakeholders. Directors need to know which variables drive the alert, whether the result is robust, how it compares with managerial evidence and what actions are available. Inadequate explanations may turn AI into a black box that increases, rather than reduces, uncertainty. Explainable AI techniques, such as local explanation methods and interpretable models, can help by showing the contribution of specific variables to a prediction. Still, explanation is not merely a technical add-on; it is part of the governance process through which a prediction becomes accountable knowledge.

AI also changes the temporal structure of control. Traditional control systems are often periodic. They compare actual results with budgets, analyse deviations and prepare reports at monthly or quarterly intervals. Predictive systems can operate more continuously. They can monitor cash conversion cycles, customer concentration, cost inflation, covenant headroom and risk indicators in near real time. This continuous orientation is useful only if the organisation defines thresholds, escalation rules and responsibilities. Otherwise, the multiplication of alerts may produce noise, alert fatigue or defensive behaviour. The intelligence of the system depends on the relationship between algorithmic detection and organisational response.

The adoption of AI also introduces new risks. Data quality is central: incomplete, inconsistent or biased data generate misleading outputs. Model risk is equally important: algorithms trained on past failures may not perform well in new economic conditions or in sectors with specific characteristics. Cybersecurity and access controls matter because predictive systems often concentrate sensitive information. Finally, overreliance on AI may weaken managerial responsibility. If directors treat the model as a substitute for judgement, the organisation may become technologically advanced but governantly weak. The appropriate objective is therefore not automation of crisis governance, but augmentation of human and collective intelligence.

4 Research Design and Conceptual Synthesis

This paper is conceptual and theory-building in nature. It does not present an empirical test or a new algorithm. Instead, it integrates four streams of literature and practice: the Italian debate on adequate organisational, administrative and accounting arrangements; knowledge-management theory; insolvency prediction research; and AI governance. The synthesis is justified by the fact that each stream captures only part of the problem. Legal and accounting literature clarifies duties, controls and continuity. Knowledge-management theory explains how information becomes organisational knowledge. Insolvency prediction

studies focus on the anticipation of failure. AI governance addresses transparency, accountability and the responsible use of algorithmic systems.

The conceptual logic is based on three assumptions. First, crisis prevention is a knowledge process. It begins with data collection but requires interpretation, communication and decision. Second, AI is an enabling technology rather than an autonomous governance subject. Its value depends on organisational routines, data governance and human oversight. Third, sustainability and resilience are not external additions to crisis governance. They are part of the same managerial problem because a firm that fails to preserve continuity destroys economic, social and relational value.

On this basis, the paper proposes a framework in which adequate arrangements are organised around four connected layers: data and knowledge governance, predictive analytics, human oversight, and sustainable response. The first layer concerns the quality, ownership and integration of information. The second layer concerns the analytical tools used to detect risks and develop scenarios. The third layer concerns the deliberative mechanisms through which boards, executives and control bodies interpret AI outputs. The fourth layer concerns the actions taken to preserve continuity and stakeholder value. The four layers are mutually dependent. A sophisticated algorithm is ineffective without reliable data; reliable data are insufficient without interpretation; interpretation has limited value without timely intervention; intervention is fragile if it ignores stakeholder and sustainability effects.

This architecture also allows a more precise understanding of the term predictive judgement. Prediction is the statistical estimation of possible outcomes. Judgement is the managerial and governance act of interpreting those outcomes in context. AI can support prediction, but judgement remains a human and collective responsibility. Adequate arrangements must therefore be designed to connect prediction and judgement without confusing them. The board should not ask whether the model has decided that the firm is in crisis. It should ask what the model indicates, why it indicates it, what alternative evidence exists, which assumptions are critical and what actions are proportionate.

5 A Framework for AI-Enabled Adequate Arrangements

An AI-enabled adequate arrangement can be described as an integrated system that transforms organisational signals into accountable decisions for continuity and sustainability. The system begins with data governance. Relevant data are not limited to annual financial statements. They include management accounts, cash forecasts, overdue receivables, supplier payment terms, inventory rotation, customer concentration, order backlog, bank covenants, tax liabilities, litigation risks, employee turnover and external indicators. The organisation must define who owns each data source, how data are verified, how inconsistencies are resolved and how updates are documented. Without this foundation, AI amplifies disorder rather than intelligence.

The second component is predictive analytics. Algorithms may classify risk, estimate probability of default, simulate liquidity scenarios or detect anomalies in accounting and operational flows. Different tools can coexist. Transparent scorecards may support communication with boards and smaller firms, while more complex models may be used for scenario analysis in larger organisations. The key is proportionality. Adequacy does not require every firm to adopt the most sophisticated AI system. It requires a system appropriate to size, sector, risk profile and organisational complexity. In many cases, a hybrid architecture combining rule-based indicators, statistical models and managerial dashboards may be more useful than an opaque algorithm claiming high accuracy.

The third component is interpretive governance. AI outputs should enter a structured decision process. Alerts must be assigned to responsible managers; material risks must be escalated to directors and control bodies; the reasons for accepting, revising or rejecting an alert must be documented. Internal audit or equivalent control functions should periodically test data quality, model performance and compliance with governance procedures. The board should receive information in a form that is concise but not simplistic: risk scores, drivers, sensitivity analysis, trend changes and suggested questions for deliberation. Such practices transform AI from a technical application into a knowledge-management routine.

The fourth component is ethical and legal accountability. The European regulatory environment increasingly emphasises transparency, risk management and human oversight in AI systems. Even where a crisis-prediction tool does not fall into the most restrictive legal categories, firms should apply prudent governance principles because the consequences of erroneous predictions can be serious. A false positive may damage reputation, influence credit relations or trigger unnecessary restructuring. A false negative may delay intervention and increase losses. Responsible AI use therefore requires clear documentation of model purpose, training data, validation results, limitations, access rights and escalation procedures.

The fifth component is sustainable response. The purpose of early warning is not to produce anxiety but to create time for action. If an AI system identifies liquidity deterioration, the organisation should be able to revise

cash planning, negotiate with financial partners, adjust investment timing, review cost structures, protect critical knowledge assets and communicate with stakeholders when appropriate. The response should not be limited to financial repair. It should consider operational resilience, employee implications, supplier continuity, environmental commitments and the reputational effects of managerial choices. In this way, AI-enabled arrangements support both crisis prevention and sustainable value creation.

Table 1: A conceptual architecture for AI-enabled adequate arrangements

Layer	Knowledge function	AI contribution	Governance safeguard
Data governance	Creates a reliable common base for interpretation	Integrates accounting, operational and contextual data	Ownership, validation, access rules and audit trails
Predictive analytics	Transforms signals into risk scenarios	Detects patterns, anomalies and probability of distress	Model validation, proportionality and explainability
Human oversight	Connects prediction with deliberation	Provides dashboards and decision support	Board accountability, escalation rules and documented judgement
Sustainable response	Converts warnings into continuity actions	Supports scenario planning and resource prioritisation	Stakeholder assessment and review of outcomes

6 Discussion

The proposed framework has implications for both theory and practice. At the theoretical level, it suggests that adequate arrangements should be interpreted as a bridge between corporate law, management control and knowledge management. The legal requirement to detect crisis becomes meaningful only when translated into routines for knowledge creation and use. This interpretation avoids two opposite reductions. The first is formalism, where adequacy is treated as the presence of documents, charts and procedures that do not affect decision-making. The second is technicism, where predictive software is treated as sufficient evidence of good governance. In both cases, the organisation may appear compliant while remaining unable to learn from weak signals.

The knowledge-management perspective also clarifies the relational dimension of crisis prevention. A firm is not an isolated calculator. It is embedded in financial, commercial, professional and community relationships. Early warning systems should therefore support dialogue among directors, managers, auditors, advisors, banks and other stakeholders. AI can improve the quality of such dialogue by producing more timely and structured information. Yet dialogue remains essential because recovery options depend on trust, credibility and negotiated commitments. In this sense, intelligent arrangements are also collaborative arrangements.

For boards of directors, the framework implies a shift in agenda. Directors should not limit their attention to annual accounts or retrospective reports. They should periodically examine forward-looking indicators, model assumptions, risk thresholds and the quality of managerial responses. They should ask whether the organisation can explain its alerts, whether different functions share the same interpretation of risk and whether corrective actions are implemented. The board's responsibility is not to become a data-science team, but to ensure that data science is governed as part of the control environment.

For control bodies and internal auditors, AI introduces the need to extend assurance activities to data and models. Traditional checks on accounting processes remain necessary, but they should be complemented by review of data lineage, access rights, model change management, validation frequency and exception handling. The audit question is no longer only whether a report is correct. It is also whether the system that produces predictions is reliable, explainable and monitored. This is especially important when AI outputs influence decisions on financing, restructuring, investments or communications with stakeholders.

For small and medium-sized enterprises, the framework should not be interpreted as a call for expensive technological infrastructures. Proportionality remains essential. Many smaller firms can benefit from simpler dashboards, automated cash-flow monitoring, structured checklists and external advisory support. The point is not the adoption of a particular technology, but the creation of a disciplined link between signals and decisions. AI may be delivered through accounting platforms, banking tools or advisory services, but the entrepreneur and governance bodies must still understand the logic, limitations and consequences of the information received.

The discussion also highlights a broader implication for intelligent and sustainable organisations. AI-enabled crisis governance is not only defensive. It can strengthen innovation and resilience because it improves the organisation's capacity to learn from data, coordinate responses and allocate resources. A firm that understands its vulnerabilities can invest more selectively, protect critical capabilities and design more robust relationships

with stakeholders. In this respect, crisis prediction and sustainable innovation are connected. Both require the conversion of dispersed knowledge into collective action under uncertainty.

7 Conclusions

This paper has argued that the integration of AI into adequate organisational, administrative and accounting arrangements represents a significant opportunity for sustainable crisis governance, but only under precise organisational conditions. The Crisis and Insolvency Code has made prevention a central duty of corporate governance. AI can support this duty by improving the detection of weak signals, integrating heterogeneous data and generating forward-looking scenarios. Nevertheless, AI does not remove the need for human judgement. On the contrary, it makes the quality of judgement more visible because directors must interpret, challenge and document the meaning of algorithmic outputs.

The main contribution of the paper is the conceptualisation of adequate arrangements as intelligent knowledge infrastructures. This view connects legal compliance with organisational learning and sustainable value creation. Adequacy is not a static state. It is a dynamic capability through which the firm senses emerging risk, interprets it collectively and acts before value is irreversibly destroyed. AI can enhance this capability when it is governed through reliable data, transparent models, clear responsibilities and ethical safeguards.

The paper is limited by its conceptual nature. Future research could test the proposed framework through case studies of firms that have adopted AI-based monitoring systems, comparative analysis across sectors, or empirical evaluation of how boards use predictive information. Further research is also needed on the role of professional advisors, banks and public institutions in creating shared early warning ecosystems. A promising direction concerns the relationship between crisis prediction and sustainability indicators, because environmental and social vulnerabilities may become financially material before they appear in traditional accounting measures.

For practitioners, the message is direct. The value of AI in crisis governance depends less on technological novelty than on organisational discipline. Firms should begin by mapping information flows, clarifying responsibilities, improving data quality and defining escalation routines. Only then can predictive systems become meaningful tools for continuity and resilience. The intelligent organisation of the future will not be the one that delegates governance to algorithms, but the one that combines human, collective and artificial intelligence in accountable decisions for sustainable value creation.

Abstract

In the last years it has been widely recognized the great relevance to identify and manage leadership traits in agile and remote working organizational settings. Entrepreneurs and top managers are increasingly playing a fundamental role in addressing the organizational changes determined by digital transformation and the adoption of new ways of working by rethinking consolidated structures and processes, fostering a culture of innovation and leading HR to adopt new mindsets, knowledge, and attitudes to thrive under continuous change and challenges. Despite this importance and the attention recently paid by academic and managerial studies trying to shed light on these issues, a full and shared setting of findings, insights and managerial and policy guidelines about the new styles of leadership and the required characteristics for a leader best suited the creation and the management of agile and remote working teams is still limited and also results are presented often in a jeopardized way. This paper analysed the main results of a scoping literature review on the main trends regarding challenges and opportunities for leadership in agile and remote working and the characteristics and skills required to entrepreneurs and managers to lead the organization in remote working contexts. The theoretical insights have been then examined and tested in Basilicata, a rural region in the southern Italy. In such a prospect, the research explored whether and how companies headquartered in Basilicata adopt remote working practices and analysed the leadership traits essential for their successful implementation.

Keywords: Leadership; Organizational Development; Remote Working; Rural Areas.

Paper type: Academic Research Paper

1 Research Background

Different scholars have recently argued that the exponential development and adoption of increasingly high-performing technologies and the significant impact of the digital transformation on the business processes have determined – among the different effects – also the emergence of different ways of working characterised by the possibility to perform at any location and at any time (Choudhury et al., 2021). While organisations of different industries were getting for the technology-driven future, the world has been unexpectedly hit by the COVID-19 pandemic. Beyond the dramatic aspects of the humanitarian crisis, it determined a breakthrough of all the economic activities. Accordingly, in order to guarantee economic survival and business continuity avoiding social contacts, companies and organisations encouraged and supported employees to work from home as much as possible. In this way, the most significant organisation and workplace design shock of our recent lifetimes was happening (Contreras et al., 2020; Hoff, 2021). However, it is important to underline that, before the COVID-19, these ways of working were steadily growing globally across many industries and infrastructures already existed (He et al., 2020): in this sense, the pandemic only accelerated this processes (Varma et al. 2022).

Consequently, the expressions *"agile working"* and *"remote working"* , as well as the related *"smart working"* and *"teleworking"*, emerged as mainstream concepts to identify and synthesize these new trends as well as the technological, organizational and human resource-related variables involved, the positive and negative consequences and finally the effects, the opportunities and the challenges both at individual, organizational and societal level (Grant, 2020). Accordingly, a full comprehension of these new approaches and related implications for HRM and a suitable and coherent leadership capable to serve as a guide for organizations and for existing and future leaders is fundamental for scientists as well as for practitioners involved on these fields.

The notion of "agility" is traditionally related to the organizational capacity to identify new trends, opportunities and threats, to be fast, pro-active and resilient, to have change-ready mindset to keep moving, changing and adapting to the general and task environment in which operates or could operate, mainly innovating business modelling, rethinking products and services to be addressed to actual and potential customers/users, revisiting operations, exploring the value of new resources and assets and defining a new platform of commercial and non-commercial relationships (Zheltoukhova, 2014). In relation to work practices, different scholars have focused the perspective of the *"agile working"* and have referred to agility as *"the ability to react quickly to fragmented world market situations full of constant and unexpected changes"* (Goldman,

1995), as the set of practices used to determine solutions using cross-functional and self-organized teams (Denning, 2016), as the *"summa of the adaptability, the quick response and the great execution"* (Accenture, 2015), as the capacity of a company to predict, perceive and respond to market volatility in a way that creates value (Balog, 2020). Other scholars, instead, have paid attention to the perspective of the "workforce agility", defined as the capacity of the employees to be *"well-trained and flexible, capable to adapt quickly and easily to new opportunities and market circumstances"* (Muduli, 2013). The same author also identified seven key attributes of an agile workforce, such as adaptability, flexibility, positive attitude towards development, speed, collaboration, competence and information (Richter et al., 2018). Shafer et al. (2001) define the agile workforce as a workforce each of whom is trained to do multiple jobs in the company to which they belong, while Nawaz and Gomes (2020), in connection to this, underline the necessity of replacing multi-level and rigid management structures with leaner and more flexible forms to better receive feedback allowing adaptation to customers requests and needs. The effect of the adoption of agile forms on organizational HRM practices is also a topic of the Manifesto for the Agile Development of Human Resources (2017) stating that *"the new mission of HRM is to push people towards new frontiers by motivating them and exploiting their strengths so that required goals can be achieved"*. This implies that HR managers should encourage the growth of individual talents by making them responsible for the role they play in the company, also in relation to the greater freedom in organizing and planning their activities anywhere and at any time (Pontillo et al., 2022).

Together with the agile working, a further relevant concept introduced to analyse the new work environments and practices is remote working, often used as umbrella notion embracing other terms such as smart working (Bednar and Welch, 2020; Boorsma and Mitchell, 2011; Lake, 2013; McEwan, 2016), teleworking, working at home, and home-based work (The International Labor Organizations, 2020; Nayani et al., 2018). It can be considered, then, a wide-ranging concept covering any paid work performed from a distance in any place different from the physical presence in the organization where employees meet organizational objectives through ICTs at their preferred time (Golden et al., 2008; Lautsch et al., 2009; Wojcak et al., 2016).

Despite different contributions have been provided to define and operationalize it (Mirchandani, 2020; Sullivan, 2003), unfortunately remote working till now does not have a universally-accepted definition and often it is overlapped with the agile working one (Tursunbayeva et al., 2021; Pontillo et al., 2021; International Labor Organization, 2020). This orientation is confirmed also by Gastaldi *et al.* (2014) describing remote working as *"an agile and dynamic way of working that leads to high performance, greater productivity and better satisfaction" for organizations and employees".* This tendency to use the concepts interchangeably is confirmed by the analysis of the research aimed to explore the nature, the effects and the advantages and disadvantages determined by such ways of working as well as to the challenges and opportunities that will be analysed in the following sections. For simplicity purposes, in the next sections the two concepts will be used merging them in the unique wider notion of remote working.

2 Challenges and Opportunities in Remote Working Settings

A rather wide literature has highlighted, in the last years, the advantages and the risks of the remote working (Contreras et al., 2020; Varma et al., 2022; Wojcak et al., 2016; Steude, 2021). Understanding and deeply analyzing these aspects represent a fundamental propaedeutic conditions to try to identify and delineate challenges and opportunities for leadership. In order to carry on a rigorous analysis of these multifaceted issues, following the main framing used by Steude (2021), it could useful to distinguish the perspectives of analysis, considering separately the *employees' view*, the *company view* and *the social view*. In fact, although very interconnected, the same phenomena may determine different perceptions and usefulness.

According to an *employees' view*, in terms of advantages, well-being is identified as the main positive effect (Charalampous, 2020; Hill et al., 2008), thanks to the greater flexibility and a better balance between private and professional life enabling higher level of productivity and efficiency (Gastaldi et al., 2014; Zheltoukhova, 2014; McEwan, 2016; Allen et al., 2015; Martin and MacDonnel, 2012). On these basis, empirical studies have found favorable outcomes of agile and remote working in specific elements such job performance, job satisfaction, work-life balance (Fedakova and Istonova, 2017), reduced rates of stress and better productivity (Gaiendran and Harrison, 2007; Pavlova, 2019), time of commuting, costs savings related to daily transport, reduced turnover intentions (Kossek et al., 2006; Fonner and Roloff, 2010; Coenen and Kok, 2014; Vega et al., 2015; Otham et al., 2009) till to reach a better employees' quality of life and happiness (Azarbouyeh and Naini, 2014; Kazakami, 2020). Always in this vein, Bentley (2014) highlights effectively the role of the technological support in activating these positive dynamics, while Morgan (2004) underlines the possibility to increase job opportunities for women and people with disabilities. However, also negative consequences have been mapped, such as isolation, loneliness and burnout (Moss, 2018) and forms of technostress related to multitasking,

permanent connectivity, anxiety about the possible shrinking of career prospects owing to reduced visibility (Maruyama and Tietze, 2012), overload of information (Kraut, 1989; Moore, 2006) capable to determine increasing demotivation (Wojcak et al., 2016; Fedakova and Istonova, 2017), work-family struggles (Golden et al., 2008) till to quite-quitting behaviours and workforce turnover.

According to a *company view*, advantages are traced in contributing to the organizational commitment (Nakrošien˙et al., 2019; Klopotek, 2017), in reducing the rate of absenteeism, in enhancing the process of standardization of procedures (Cortellazzo et al., 2019), in influencing the reputation and the corporate image due to the "*green-oriented*" behaviours related to reduction of traffic and daily transports, pollution, and use of energy sources within the workplaces (Giovanis, 2018). Moreover, companies may have access to specialized expertise, regardless of the team members' location, which allows companies to find more creative solutions (Malhotra et al., 2007). At the same time, different scholars (Contreras et al.,, 2020; Steude, 2021; Varma et al., 2022) highlight that also potential disadvantages emerge, as negative impact on the organizational culture and values (Wojcak et al., 2016; Ware and Grantham, 2010; Flood, 2019), difficulties in managing conflicts, team building, team working and engagement (Cooper and Kurland, 2002; Jaiswal and Arun, 2020; Younger and Kearns, 2017), difficulties of monitoring and coaching remote workers and preserving experiential knowledge (Golden et al., 2008), possibilities of decreasing mutual trust and company loyalty due to the physical absence from the company (Nayani et al., 2018), risks for the IT security of the company (Steude, 2021).

Finally, according to a *social view*, reduction of pollution and reduction of time for transportation and commuting are identified as the main environmental and social benefits. Also upgrading of the interest and the attractive capacity of the rural areas and the reduction of the cities' congestion can be considered further elements of advantages (Steude, 2021). At the same time, exacerbation of the digital divide between countries, and above all between organizations and employees accessing and using these opportunities and traditional and not-ready ones can be identified as further dysfunctionalities. On these basis, in the last times, it strongly emerges the need to define and analyse which kind of leadership styles are best suited and fitted to the agile and increasingly digitised organizational contexts. In particular, the profiling of the remote leader is fundamental to lead modern organisations to identify and select effectively managers capable to successfully meet the challenges and the opportunities of the new modelling of the work activities.

3 Leadership in Remote Work Settings: Key Characteristics and Competences

Identifying the traits and competences needed for leadership in remote work settings is crucial for generating suggestions for organizations adopting these modes of working and uncovers some potential needs of leaders who might face the challenges and opportunities of "digital revolution". Recently, different scholars have explored the topic of leadership in the context of remote work, motivated also by the spread of the digital transformation process in organizations and the effects produced by the pandemic (Avolio et al., 2014; Van Wart et al., 2019; Coun et al., 2021; Terkamo-Moisio et al., 2022; Harris and DeFlaminis, 2016; Iannotta et al., 2020; Tandon, 2021; Contreras et al., 2020; Cortellazzo et al., 2019; Pontillo et al., 2022).

In their work Zeuge et al. (2020) identify several emerging key leadership characteristics in remote work settings. Drawing on the results of a narrative literature review on leading virtual teams, the scholars point out which behaviours and traits a good virtual leader should have. According to the scholars a leader operating in remote working "should build trust, be empathetic and be open to diverse groups (starting with the tolerance for several time zones). At the same time, it is her or his responsibility to create a culture of "belonging" and 'being there for one another', 'caring', 'listening' and empathy. What is required here is the ability to communicate and to have emotional intelligence. A virtual leader is always available, approachable, addressable, and open. She or he demands by promoting an open mindset, because she or he is a good example herself or himself" (p. 7). Additionally, Zeuge et al. (2020) underscores that leading team in remote working requires building trust and a culture of collaboration and support among team members. According the authors, leaders should manage conflicts and identify frustration in the team early on as well as organize regular meetings, either formal or informal, where team members can socialize.

The crucial importance of meeting all remote workers, also in person if possible, and enhancing social interactions to reduce misunderstanding and feelings of loneliness typically experienced by remote workers, have been addressed by several authors (e.g. Brake, 2006; De Rosa, 2009; Thomas and Bostrom, 2008). Other authors have analysed the style to build effective interactions and relationships in remote working. According to some authors (e.g. Hart and McLeod, 2003; Madlock, 2018), remote leaders should adopt a task oriented leadership style to build effective and trusted relationships and job satisfaction in teams. They should promote among workers an intensive task-related orientation at a distance, then facilitate face-to-face social opportunities, and finally allow workers return to remote locations to continue work. There are some empirical

evidences that a task-oriented leadership style would produce more communication satisfaction, job satisfaction and telecommuter organisational commitment than relational-oriented leadership. However, these findings contrast with other studies (e.g., Brake, 2006; Hunsaker and Hunsaker, 2008; Maduka et al., 2018 pointing out the relevance of relationship-oriented leadership. According to these studies, leaders should be relationships-oriented as stronger relationships support a more developed mutual understanding, because the messages exchanged are more frequent and briefer and characterized by a more proactive focus on the problems or challenges faced by the work. This is particularly important considering the fact that challenges and conflicts are increasingly difficult to resolve in remote communities compared to traditional contexts (Brake, 2006). In remote setting increased technological frustrations, barriers to performance, loss of interest, and cultural differences can undermine problem solving process. Remote leaders must adopt a proactive role and establish rules and procedures to resolve problems that arise (e.g., Harris et al., 2001).

The crucial importance of relationships, meetings, building trust, effective communication is widely highlighted also by Contreras et al. (2020). These latter scholars, investigating tele-working and e-leadership, underline that e-leaders must develop technical competencies to monitor, coordinate, and align work through technology-supported structures, reducing barriers. They must be expert with latest ICTs and create awareness for teleworking. Remote leaders should stay updated on technological advancements, seek out technological solutions, and remain informed about recent developments in their areas of expertise (e.g. Cortellazzo et al., 2019; Harris et al., 2001; Maduka et al., 2018).

As remote environments can influence workers' behaviors, emotions, thoughts, and performance, according to Contreras et al. (2020) e-leaders must reduce physical and psychological distances, by being close to employees, creating trust through interrelationship and avoiding to organize fragmented tasks. Moreover, they confirm the importance of shared leadership as stimuli to team members to take responsibility for their work and the project, promoting identification within the team and initiating action flows for goal achievement.

Analogously, Flood (2019) states that “beyond technical and business skills, leadership must acquire specialized aptitudes for coaching, adaptability, career guidance, communicating, interpersonal relationships, and developing cultural sensitivity” (p. 3), while other scholars highlight the fundamental role of the communication abilities (e.g. Roy, 2012; Zaccaro and Bader, 2003; Cortellazzo et al., 2019; Owens et al., 2011; Harris et al., 2001). Very interesting is also the work Pontillo et al. (2022). Through a scoping literature review of 54 relevant studies, they identified leadership qualities, potential skills, and how varied leadership approaches can foster fitting innovative work behaviors, in agile and remote work settings. They specifically identified styles of leadership as directive, catalyst, resonant, servant, transformational, simplifying, and distributed.

The review of management literature shows that to date the research on the leadership in remote settings is still limited, but also wide-ranging and promising. The researchers in their studies have examined one or more traits and competences characterizing leaders and their leading action in remote setting. The developed analysis of management literature on leaderships characteristics in remote working, suggest some key competences that leaders operating in such a context should have. They can be grouped as showed in Figure 1. Certainly the list of the reported distinguishing competences is not exhaustive and additionally may vary depending on the organization's culture, industry, and the nature of the remote work being conducted.

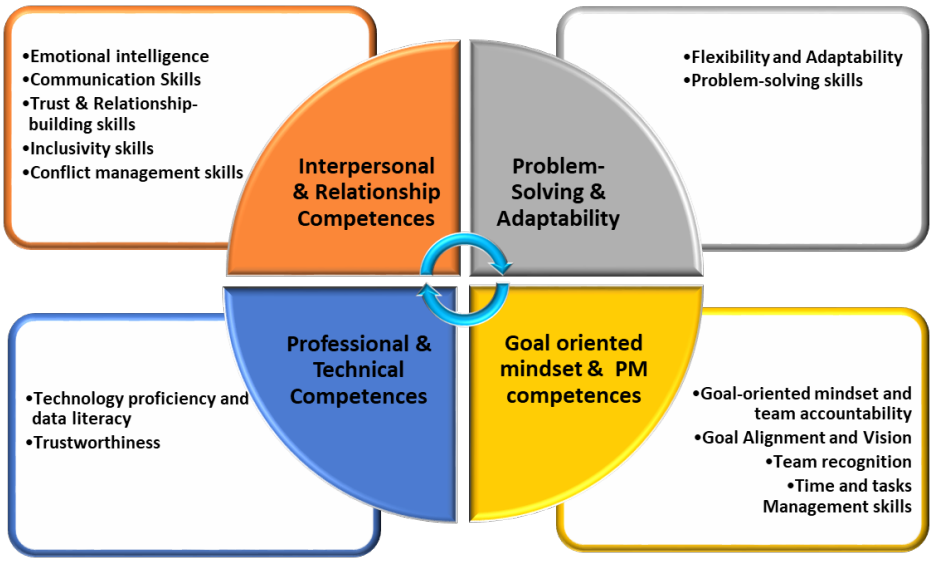

Figure 1. Leadership competences in remote working setting (our elaboration)

4 Empirical Analysis

The findings and insights from the desk analysis have been examined and tested in Basilicata, a region in southern Italy. Basilicata is a rural area with low population density, reliance on agriculture and services, mainly related to Public Administration bodies, predominance of natural landscapes, and the presence of small and rather isolated communities with unsatisfactory urban infrastructures and very limited cities acting as economic and social hubs for the whole region. Depopulation, particularly among young people, is a noteworthy phenomenon in Basilicata, driven by limited job opportunities and the migration of younger generations abroad in search of education and employment. Accordingly, remote working could have the potential to nourish socio and economic development of rural area, fostering economic growth, social revitalization, and environmental sustainability. In such a prospect, the research explored whether and how companies headquartered in Basilicata, or primarily operating within the region, adopt remote working practices and analysed the leadership traits essential for their successful implementation.

The empirical analysis was developed according to three main stages. The *first stage* was aimed at identifying the companies and the organizations to be potentially involved in the study. For operative purposes, it was divided into *three macro-activities*.

The *first macro-activity* involved a scoping desk analysis using different sources - mainly web-based - to collect preliminary inputs and suggestions regarding industries, companies and organizations based in Basilicata and applying remote working practices. Unfortunately, this activity revealed the limited use of remote working.

The *second macro-activity* was related to the contact and the engagement of experts and leaders of the local business and managerial world, and relevant actors and stakeholders such as Confindustria Basilicata and Federmanager Basilicata. These interactions confirmed the concerns about the identification of suitable companies and organizations to participate in the study due to the region's specific gaps, including a generally low availability and use of technological and digital tools, a very limited number of companies with robust organizational structures and an explicit need for remote working practices, and little attention to HRM, to name a few of the most commonly cited issues.

Matching the results and the insights derived from the first macro-activity with the very useful suggestions gathered in the second macro-activity through the interactions with the local experts and the stakeholders, it was possible to elaborate, as *third macro-activity*, consisting in delineating a preliminary list of companies and organizations based in or mainly operating in Basilicata that could potentially be considered and contacted for the ongoing empirical study.

In the *second stage* of the empirical investigation, the companies and the organizations identified in the preliminary list were contacted by mail and phone. All of them responded positively to the information asked and were open to engaging with the research team. Following this initial contact, the list was revised and refined to include only those companies that were structurally implementing remote working practices. As hypothesized, these companies were all operating in industries related to ICT products and services.

Finally, in the *third stage* of the empirical investigation, the five companies selected were contacted again to schedule specific dates, times, and modalities for submitting and sharing the questionnaire that had been developed for this purpose and to have direct interviews virtually or on-site, aimed to explore and capture additional thoughts and qualitative comments from the questionnaire's respondents. The questionnaire was structured into two main sections: the first section gathered important information for company profiling, while the second section focused on understanding the modalities and impact of remote working practices within the organizations, as well as the related leadership styles and practices adopted by entrepreneurs, CEOs, and top managers. A synthesis of the companies' profiles – labelled anonymously using greek letters for privacy purposes - and the global insights derived from the empirical investigation are summarized in the following.

The first company analysed was *Alfa s.r.l.*, a limited liability company based in Matera engaged in "*consultancy in the technology sector of information*". Founded in 2010, *Alfa* is a software house specialized in offering software products and services based on advanced technologies. Leveraging its accumulated expertise, the company has developed a deep know-how in all phases of the software life cycle, including design, maintenance, and support.

Founded in 2000, the second company analysed was *Beta*, which represents one of the main, and longest-standing, existing realities in the Lucanian ICT sector. Currently, the company is configured as a corporate structure of a joint stock company and has its main headquarter in Basilicata, in Sant'Angelo Le Fratte, near the city of Potenza. It operates through eight plants, whose five are based in Basilicata, and counts over 1.000 employees.

The third company identified as empirical setting was *Gamma*. It is one of the oldest companies in the IT sector in Basilicata. The company locates its headquarter in Tito, in the province of Potenza.

The fourth company under investigation was *Delta*. The company deals with the "production of software not connected to the edition". It is based in Matera and is configured in the corporate structure of a joint-stock company (S.P.A). The company represents a thriving Lucanian company operating in the ICT sector, since 2001. The foundation of the company falls within the framework of the ESA project (The European Space Agency) called COSMO-SkyMed (Constellation of small Satellites for the Mediterranean Basin Observation), with the role of algorithmic developer for the first dual system (military and civil) of earth observation radar satellites.

Finally, is was identified the *Theta* company. It is a limited liability company (s.r.l.) founded in 2001 in Matera, with operational offices also in Potenza, Bari and Milano. The company's core business is focused on the outsourced contact center sector, i.e. the delegation of call centre activities by a company to a specifically dedicated external organisation and market research.

5 Discussion and Implications

The study highlighted that remote working practices in the analyzed cases are mainly adopted by companies with a mature and established corporate history. These companies have experienced growth over the years in terms of both turnover and employee numbers. The COVID-19 pandemic, from this point of view, was often perceived by these companies as a catalyst for starting a transition process towards a qualitative leap in their organisation. This leap has included the dynamics linked to remote working practices.

Initially adopted as a mere mandatory measure for company operations, remote working has ended up becoming an essential pillar of business re-organization. However, the perception of its need and effectiveness - as well as its adoption - has not been uniformly positive. The spectrum of reactions varies from more typically "techno-enthusiastic" companies, that proactively embrace the benefits of remote work- compensating for the apparent loss of control over the employees and satisfied about the workforce results in terms of productivity, to organizations that are more reluctant to accept these working practices.

A common concern within all the organizations involved in the research is represented by the idea that it is considerably more complex, for employees joining the company from scratch, easily building their active participation in the corporate culture, remotely conveying those values and exemplary behaviours that progressively cement employees' adherence to a certain value system and professional mentality.

At the same time, a commonly perceived benefit is the possibility of recruiting professionals without geographical constraints. On the one hand, this is an element to increase an organisation's attractiveness and competitiveness within a territory, by allowing access to the specific know-how that is needed and minimizing the training required for employees who may lack certain skills. On the other hand, this dynamic also takes the form of a defensive and preventive measure against internal turnover and external dumping. As highlighted in the interviews, remote working has often allowed ICT organizations to minimize the theft of their human capital by big companies of international importance.

To counteract the challenges inherent in remote working, companies are trying to create alternative moments of conviviality for in-person interactions, sharing organizational culture, impressions, feelings and values. When asked about their chosen leadership style, based on the provided nomenclature, the answers were rather heterogeneous and debated: catalyst, servant and transformational - or a holistic sum of all the leadership styles presented – appear to be the driving methods in which the entrepreneurs and managers who participated in the survey best identified themselves. Table 2 summarizes the main benefits and challenges of adopting remote working perceived by the investigated companies.

Table 1. The main benefits and challenges of adopting remote working perceived by the analyzed companies

Benefits	Challenges
Increase of productivity and reduction of absenteeism: Higher workforce productivity, greater organizational commitment, and trust between employees and management, with a reduction in absenteeism.	**Difficulties in cultural absorption**: Greater challenges for new employees in absorbing the company's culture, values, and professional mindset.
Access to a broader talent pool: Recruitment is no longer limited by geographic location, allowing access to specialized skills and reducing the need for training.	**Challenges in preserving corporate culture**: Difficulties in transmitting and aligning the company's values, and challenges in consolidating a strong and shared corporate culture among remote workers
Costs saving: Reduction in costs related to decreased training needs, savings on expenses such as office-related costs, transportation, and energy.	**Complex onboarding**: Difficulties for new hires to become active participants in corporate culture and internal organizational dynamics.
Talent retention: Preventing turnover and protecting companies from losing staff to international competitors.	**Increased workers' isolation and loneliness & risk of techno-stress**

Benefits	Challenges
Improvement of work-life balance: Enhanced balance between employees' professional and personal lives, with reduced commuting times and greater scheduling flexibility.	**Management and monitoring of remote work**: Challenges in effectively monitoring and supporting remote employees, particularly concerning teamwork and conflict management
Improvement of the company's reputation	**Lack of face-to-face interactions:** The absence of physical interaction moments can lead to a reduced sense of belonging and engagement, with potential negative effects on team cohesion and collaboration
	IT security risks

Companies share both similar advantages and challenges of remote work. Although they have benefited in terms of improved productivity, recruitment, cost saving, reputation and employee well-being, they face several difficulties related to increased workers' isolation and loneliness, organizational culture absorption and preserving, IT security risks, and remote team management. To face these difficulties, the investigated companies have developed several initiatives often creating meetings, both virtual and in-person, to mitigate negative effects of remote working. In particular, there are several practices that the companies involved in the research are adopting to address the mentioned challenges. These are good practices that - despite the diversity of their business and organizational contexts - have common objectives, such as reducing isolation, strengthening corporate culture, and optimizing remote work performance assessment and management. Table 3 reports the good practices cited by the companies, clustered by the main objective.

Table 2. Good practices of the analyzed companies

Objective	Good practices implemented by the analyzed companies
Mitigating Isolation	· Introduction of "unexpected" elements to alleviate isolation and routine fatigue. · Creation of social events like "Start Days" and CUBE associations to foster connections. · Family-oriented social events to reduce isolation among remote workers. · Hybrid model tailored to employee proximity (remote for those farther away).
Strengthening Corporate Culture	· Use of hybrid interaction events to reinforce corporate culture.
Performance Assessment and Management	· Meritocratic performance evaluations based on quantitative and qualitative metrics. · Continuous training for team leaders to improve remote team management and engagement.

Regarding the traits characterizing an adequate leadership style referred to the adoption of remote working practices, empathy and communication skills emerge as fundamental for maintaining employee trust and engagement, collaboration and organizational cohesion. Certainly, these characteristics are challenging to cultivate and put into practice where daily face-to-face contact is lacking and is filtered through purely virtual forms of interaction. Looking ahead to the future of remote working, the process is perceived as inevitable. Conversely, it emerges a strong need to increase the compensation of the same by increasing opportunities for genuine human interaction.

In inner mountain areas, remote working can represent an important opportunity and has great potential to regenerate local economies and communities. However, it must be approached carefully. Good practices, such as creating hybrid remote working spaces, investing in continuous training for managers and entrepreneurs to acquire proper skills for managing remote teams and work, and nurturing a remote working culture, can promote long-term residency, attract expert workers from outside, reduce migration, preserve the survival of local businesses, and ensure their competitiveness. However, to avoid failure, it is crucial to consider local community needs, to avoid focusing merely on attracting remote workers from outside (e.g. digital nomads) and to balance the requests of local development with business growth. It is also important to have managers and entrepreneurs able to address the strategic and operational challenges of remote working. More generally, remote working can contribute to the growth of inner mountain economies and societies only if there is a balance between the opportunities of remote working, the need for sustainable development, and the integration of the local community with its needs and culture.

When Does AI Become Knowledge? Organizational Conditions for Epistemic Learning in Public Administration

Emilia Romeo, Nicola Capolupo
San Raffaele Roma University, Rome, Italy

Abstract

The growing adoption of Artificial Intelligence (AI) in public administration has largely been framed in terms of efficiency gains and decision-making enhancement. However, this perspective overlooks a deeper transformation concerning the reconfiguration of organizational knowledge processes. This study aims to examine how AI contributes to knowledge creation, interpretation, integration, and institutionalization within public administrations, and to identify the organizational and institutional conditions that enable or constrain these processes. By viewing AI not just as a technical tool but as a system that shapes how knowledge is created, interpreted, and used, this study aims to provide a deeper understanding of public organizations as knowledge-based systems.

Methodologically, the research adopts a qualitative meta-synthesis of interdisciplinary literature on AI in public administration. A structured search was conducted in the Scopus database, resulting in a corpus of 108 relevant studies. The analysis combines computational text analysis techniques—such as lexical mapping and heuristic scoring—with an interpretive thematic synthesis. This approach enables the systematic identification of recurring knowledge processes, enabling mechanisms, and contextual constraints shaping the role of AI in organizational knowledge dynamics.

The findings reveal that AI operates as a knowledge-enabling and knowledge-processing infrastructure through three interrelated processes. First, AI enhances knowledge creation by identifying patterns and transforming data into actionable insights. Second, it supports knowledge interpretation and integration by enabling interactive and dialogical processes between human judgment and algorithmic outputs. Third, AI facilitates the institutionalization of knowledge through feedback loops, continuous learning, and adaptive system updates. However, the effectiveness of these processes depends on key organizational conditions, including transparent and participatory governance, experimental leadership, supportive organizational cultures, and adequate technical and infrastructural capabilities. Conversely, rigid hierarchies and control-oriented approaches tend to limit AI's role to procedural functions, constraining knowledge development.

From a theoretical perspective, the study contributes to knowledge management and public administration literature by integrating fragmented research streams into a unified framework that conceptualizes AI as a socio-technical knowledge infrastructure. It challenges traditional views of rational decision-making by highlighting the emergence of hybrid knowledge processes that combine human and algorithmic reasoning. Practically, the findings suggest that public organizations should design governance mechanisms that promote transparency, participation, and learning, invest in leadership and data literacy, and adopt flexible regulatory frameworks to fully leverage AI as a generative knowledge resource.

Keywords: Artificial Intelligence; Public Administration; Organizational Learning; Knowledge

Paper type: Academic Research Paper

1 Introduction

The advent of Artificial Intelligence (AI) in public sector has brought widespread optimism regarding its power to improve decision-making (Oryshchuk and Minenko, 2024). Nevertheless, this single exploitable view tends to overlook a more profound transformation that AI is affecting organizations, namely a reconfiguration of organizational knowledge processes, including knowledge creation, integration, and application in collective decision-making (Bolton et al., 2021; Leoni et al., 2024). Sticking with this perspective, public administrations can increasingly be understood as knowledge-based organizations, that is, arrangements wherein the functioning depend on the continuous production, sharing, and utilization of knowledge assets (Knorr Cetina, 2007; Patriotta, 2004). In these types of organizations, legitimacy and authority are not simply rooted in hierarchical domination but also in the capacity to generate, mobilize, and govern knowledge effectively. Therefore, the emergence of AI not merely alters bureaucratic practice but also transforms the underlying knowledge management mechanisms through which organizations identify problems, interpret information, and support decision-making processes. AI systems participate in organizational knowledge processes through shaping the manner in which evidence is collected, patterns are discerned, and interpretations are stabilized, thus contributing to the development and redistribution of knowledge across human and non-human actors.

While several studies have been done on AI adoption by the lens of governance, ethics, and automation (Camilleri, 2024), attempts at how it has been instrumental in altering knowledge creation, sharing, and utilization processes within public organizations under conditions of uncertainty (Albous and Alboloushi, 2025)

have been less emphasized. That is, AI is studied primarily as a technical innovation, while AI as a knowledge infrastructure enabling the development, integration, and application of organizational knowledge is seldom researched (Larsen, 2021). This perspective is particularly relevant when public administrations face complex challenges requiring not only faster decisions but also more effective knowledge integration processes capable of combining human judgment and algorithmic inference.

Thus, this research seeks to examine how AI is employed in the support and enhancement of organizational knowledge processes, including knowledge generation, interpretation, and integration within administration and under what organizational and institutional conditions such applications are feasible or constrained. This view challenges the technical-bureaucratic control dichotomy by examining how AI interacts with the knowledge management dimensions of public decision-making and thereby contributes to the construction of public administration as a dynamic knowledge-based organization in which knowledge itself is the critical site for governance.

2 Methodology

A qualitative meta-synthesis of current scientific literature on the interface between public administration and AI was conducted (Walsh and Downe, 2005). This research allows for the results of various studies to be combined while unlocking conceptual and analytical elements related to organizational knowledge processes and knowledge management practices in the public sector in the context of AI. The study employed a multi-step approach for qualitative meta-synthesis following Noah (2017) and Weinberger (2022).

Some details of the protocol employed are provided as follows. Two research questions were formulated to delineate the boundaries of knowledge processes and knowledge management dynamics of the study:

- *RQ1. What mechanisms facilitate the creation, integration, and application of knowledge through AI in public administration?*
- *RQ2. Under which organizational and/or institutional conditions do these knowledge processes and knowledge management functions flourish or stagnate?*

To collect the relevant material a structured search in Scopus database was carried out using the following prompt query:

TITLE-ABS-KEY ((“artificial intelligence” OR AI OR “machine learning” OR “generative AI” OR chatbot* OR “algorithmic system*”)
AND (“knowledge sharing” OR “knowledge management” OR “organizational learning” OR “knowledge transfer” OR “knowledge creation” OR “epistemic organization*” OR “epistemic community” OR “knowledge governance”)
AND (“public administration” OR “public sector” OR “government organization*” OR “public institution*” OR “public policy” OR “e-government” OR “digital government”)).

Following the protocol, the review included peer-reviewed academic studies from 2003 to date. This temporal boundary was deliberately adopted to capture the evolution of the epistemic mechanisms through which different types of algorithmic systems have been progressively integrated into organizational decision-making processes, rather than providing a technically uniform definition of AI. The inclusion criteria required that selected studies explicitly address the application of AI or algorithmic systems within the public sector in relation to knowledge processes, knowledge management, decision support, discovery, or policy innovation, while purely technical contributions without organizational implications were excluded.

Adopting a longitudinal perspective allows the analysis to account for the transformation of AI’s role in organizations over time. Earlier contributions, largely associated with rule-based systems, portray AI as exerting a predominantly procedural and normative influence, supporting routine decision-making, reinforcing standardization, and extending bureaucratic rationality. Accordingly, the mechanisms emphasized in this phase mainly concern efficiency and decision consistency.

However, with the emergence of more advanced approaches—particularly from the mid-2010s onwards, a qualitative shift becomes evident. AI increasingly shapes not only decisions themselves but also their underlying premises, enabling pattern recognition, hypothesis generation, problem reframing, and sensemaking processes. This transition marks the growing relevance of the mechanisms central to this study, namely AI as a cognitive infrastructure, an interpretive device, and a driver of organizational learning.

By incorporating studies across this temporal span, the meta-synthesis does not treat the evidence as homogeneous; rather, it adopts a processual perspective that allows the study to trace how these epistemic mechanisms intensify and transform alongside technological developments, thereby strengthening the explanatory power of the resulting conceptual framework.

Figure 1 displays the initial corpus of contributions per year retrieved by the analysis and shows steady growth over time, with a particularly marked increase in the most recent period. After a slow start between 2007 and 2017, production increased significantly from 2017 onwards. The period 2021–2026 marks a substantial quantitative leap, more than doubling previous values.

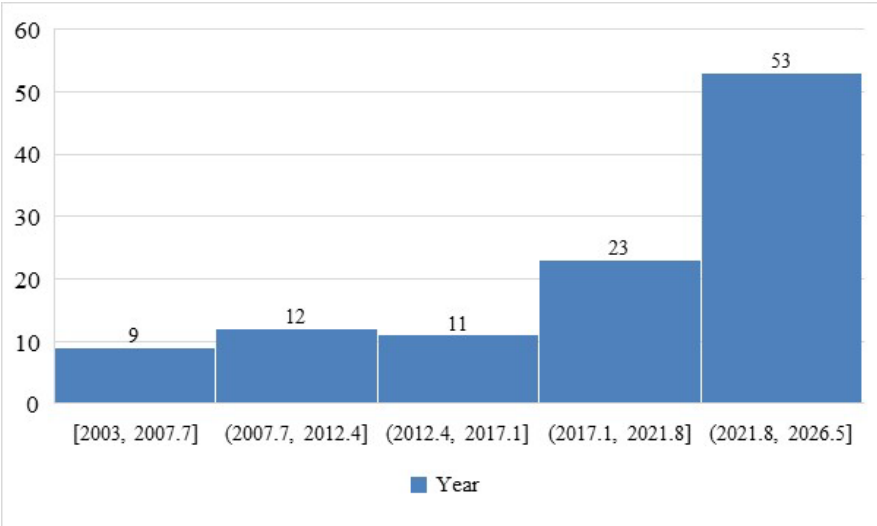

Figure 1: Pre-screening articles distribution per year

Table 1 shows a clear prevalence of conference-related contributions, with 43 conference papers and 16 conference reviews, representing over half of the total. These are followed by scientific articles (34), while book chapters (9) and books (4) are less frequent. Reviews and retracted articles are marginal, with only one case each.

Table 1**:** Types of contribution distribution

Type of contribution	Values
Article	34
Book	4
Book chapter	9
Conference paper	43
Conference review	16
Retracted	1
Review	1
Final value	108

To analyze the selected studies, a qualitative meta-synthesis supported by computational text analysis techniques was employed. The corpus of 108 articles was first examined through computational techniques such as lexical mapping and heuristic scoring, aimed at identifying recurrent concepts and patterns and supporting the systematic exploration of the literature. These techniques were used to enhance the transparency and consistency of the analytical process, rather than to replace interpretive analysis.

Subsequently, thematic synthesis was employed to integrate findings across different fields, including organizational studies, governance research, and information systems. This interpretive phase enabled the identification of recurrent knowledge processes, enabling mechanisms, and contextual constraints shaping the use of AI.

As such, through qualitative meta-synthesis, data were not simply aggregated but systematically interpreted to develop a conceptual framework that explains how AI reshapes organizational knowledge creation, integration, and application processes within public institutions.

3 Findings

The findings indicate that AI is a knowledge-enabling and knowledge-processing infrastructure, rather than a decision aid. Three interrelated knowledge processes emerge from the literature (RQ1).

First, machine-learning and data-driven systems enhance organizations' cognitive capacity knowledge creation capacity by allowing them to identify underlying correlations and patterns and converting information into potential hypotheses actionable knowledge and insights for public decision-making (Janssen et al., 2017).

Second, AI supports knowledge interpretation and integration in explainable and interactive systems that offer dialogue between human experience and algorithmic inference (Giraldi et al., 2024). These systems mediate interpretation rather than suppress it, enabling administrators to co-construct meaning, validate insights, and critically assess underlying assumptions embedded in the data.

Third, AI functions as an infrastructure for knowledge institutionalization and continuous knowledge development (Laihonen and Kokko, 2023). AI can power adaptive organizational knowledge processes through feedback loops, continuous model updates, and revisions based on errors.

Combined, such processes suggest that AI has the potential to transform public administration into a more exploratory, reflective, and adaptive knowledge-based system, rather than a purely rule-based mechanism (Babšek et al., 2025).

At the same time, the analysis concludes that the actualization of these cognitive capacities knowledge processes and knowledge management capabilities depends on a set of organizational and institutional conditions (RQ2). Governance arrangements characterized by transparency and participation are necessary to ensure that algorithmic systems operate as shared knowledge assets, rather than tools of control (Olsen et al., 2024).

Experimental leadership and deliberative practices contribute to the development of a knowledge-sharing culture, enabling the use of AI for knowledge exploration rather than mere surveillance or compliance. Furthermore, adaptable regulatory frameworks, adequate infrastructural resources, and critical capabilities—such as access to data, financial resources, and technical expertise—are required to support the effective development and use of AI-driven knowledge processes within public administrations.

Conversely, rigid hierarchies, technocratic mindsets, and excessive regulatory oversight tend to suppress knowledge creation and sharing processes, limiting the role of AI to procedural or predictive functions.

Therefore, the analysis shows that AI's contribution to knowledge management and organizational knowledge development in public administration emerges from an organizational transformation in which human judgment, knowledge processes, and algorithmic reasoning are effectively aligned (Mainardi, 2025; Tangi et al., 2025).

4 Discussion and Conclusion

This study contributes to the existing debate on AI and governance by reframing public administration as a knowledge-based system in which the value of AI extends beyond efficiency and automation to encompass its role in supporting organizational knowledge dynamics. Specifically, the findings highlight how AI enables the development and coordination of key processes related to the generation, interpretation, and use of knowledge within decision-making contexts (Janssen et al., 2017).

From this perspective, the contribution of the study lies in showing that the impact of AI is contingent upon the presence of appropriate organizational and institutional arrangements. In particular, governance architectures, leadership approaches, and accountability frameworks play a critical role in enabling AI to function as a shared and generative resource, rather than as a purely technical or control-oriented tool (Olsen et al., 2024).

Figure 1 illustrates the conceptual framework emerging from the analysis, positioning AI as a knowledge infrastructure embedded within organizational processes. The model integrates the study's key findings into a systemic representation that highlights how AI contributes to the generation, transformation, and institutionalization of knowledge in public administration.

At the core of the framework are three interrelated knowledge processes: knowledge creation, knowledge interpretation and integration, and knowledge institutionalization. These processes reflect the central mechanisms identified in literature. These processes are not conceived as linear stages but as mutually reinforcing, dynamically interconnected activities. This perspective aligns with the knowledge management literature, which emphasizes the continuous and iterative nature of knowledge development within organizations (Nonaka, 1994; Grant, 1996), as well as with more recent studies highlighting the role of digital technologies in enabling distributed and collaborative knowledge processes.

AI systems operate as enabling infrastructures that enhance these processes by supporting pattern detection, facilitating interpretive interactions, and enabling continuous feedback loops. In this sense, AI does not replace human cognition but augments organizational knowledge processes by integrating algorithmic

reasoning and human judgment, contributing to the co-construction of meaning and the validation of knowledge within institutional contexts (Larsen, 2021; Leoni et al., 2024).

Surrounding these processes, the framework identifies a set of enabling conditions that shape the extent to which AI can function as a generative knowledge resource: 1) knowledge governance, 2) leadership, 3) organizational culture, and 4) capabilities. These conditions reflect existing insights from both knowledge management and public administration literature, which emphasize the importance of governance mechanisms, participatory practices, and cultural openness in supporting knowledge sharing and learning (Tangi et al., 2025). The transformation of knowledge processes leads to the development of organizational knowledge assets, including shared knowledge, validated insights, and institutional memory. This layer represents a critical conceptual advancement, as it shifts the focus from knowledge as a process to knowledge as an organizational resource that can be mobilized and leveraged in decision-making contexts.

Finally, the framework highlights key outcomes in terms of knowledge-based decision-making, adaptive capacity, and the development of more reflective and responsive public administrations. Importantly, the inclusion of feedback loops emphasizes the recursive nature of AI-enabled knowledge systems, in which outcomes continuously inform both the evolution of AI systems and the refinement of organizational knowledge processes.

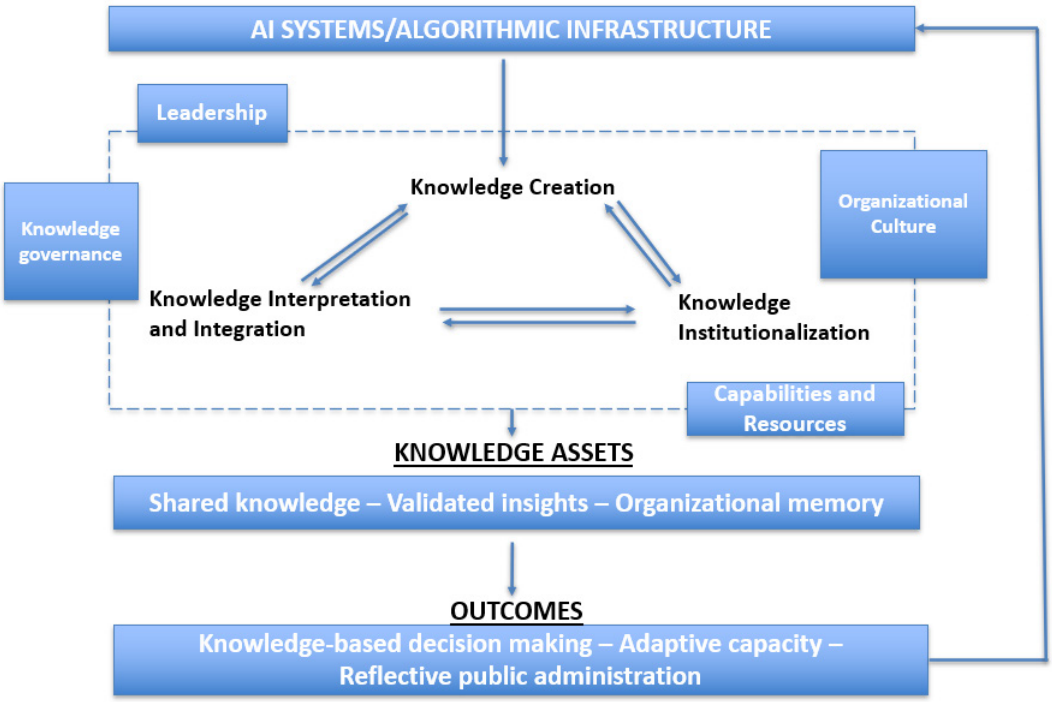

Figure 2: AI as a Knowledge Infrastructure in Public Administration

Building on the findings, the study also identifies a set of emerging research directions to further advance understanding of AI as a knowledge infrastructure in public administration.

First Research direction

Future research should explore how different configurations of AI systems influence specific knowledge processes, particularly the interplay between knowledge creation, integration, and institutionalization. Less is known, in fact, about how different technological architectures shape the quality, reliability, and usability of knowledge within organizations.

Second Research direction

There is a need to investigate the role of knowledge governance mechanisms in mediating the relationship between AI and organizational outcomes. In particular, future studies could examine how transparency, accountability, and participation affect the transformation of algorithmic outputs into shared and legitimate knowledge assets.

Third Research direction

Further attention should be devoted to the development of knowledge capabilities at both individual and organizational levels. This includes understanding how skills such as data literacy, interpretive capacity, and interdisciplinary collaboration contribute to the effective use of AI in knowledge-intensive contexts.

Fourth Research direction

Future research should explore the potential tensions between knowledge exploration and control, especially in highly regulated public environments. While AI enables experimentation and adaptive learning, institutional constraints may limit the development of open and reflexive knowledge processes.

Fifth Research direction

Longitudinal and comparative studies are needed to assess how AI-driven knowledge processes evolve over time and across different administrative contexts, contributing to a deeper understanding of how public organizations transition toward knowledge-based systems.

4.1 Theoretical implications

From a theoretical perspective, the present study advances knowledge management literature by integrating previously fragmented research streams, such as organizational learning, decision-making, and digital governance, into a unified framework that conceptualizes AI as a knowledge infrastructure embedded within organizational processes.

In doing so, the study not only consolidates existing theoretical perspectives but also proposes a structured research agenda that identifies key directions for future inquiry on AI-enabled knowledge processes in public administration.

Meta-synthesis has, in fact, pointed towards algorithms not just enhancing analytical capacity but also being involved in knowledge interpretation, integration, and transformation through interaction, feedback, and interpretive translation.

This insight calls for re-examining traditional assumptions about the rationality of public administration. The decision-making process is no longer constrained by human cognition or institutional routines alone but is increasingly enabled by hybrid knowledge processes emerging from the interaction between human judgment and algorithmic reasoning.

This entails a shift from a static notion of “technology adoption” toward a dynamic knowledge-based view of organizations, in which AI, data infrastructures, and human competencies jointly constitute evolving knowledge systems and knowledge assets.

The study therefore contributes to the literature by showing how AI enables the transformation of organizational knowledge processes—specifically knowledge creation, knowledge integration, and knowledge institutionalization, thereby reframing public administration as a system capable of continuously generating and reconfiguring its knowledge base.

4.2 Practical implications

From a practical perspective, the findings provide actionable insights for public managers and policymakers aiming to design and implement AI systems.

First, the findings emphasize the importance of governance architectures that balance surveillance and transparency, ensuring that AI systems function as shared knowledge assets rather than instruments of control. For instance, cross-functional data labs, steering boards, and participatory audit mechanisms can facilitate the transformation of algorithmic outputs into collectively validated organizational knowledge.

Second, capacity-building and leadership development emerge as critical levers. Leaders who promote dialogue, experimentation, and reflexivity foster knowledge-sharing cultures in which AI is used to support exploration and learning rather than compliance. In such contexts, errors and model revisions become opportunities for knowledge refinement and organizational learning.

Third, the study highlights the need for regulatory flexibility through frameworks that preserve ethical standards while enabling adaptive experimentation, such as regulatory sandboxes and iterative evaluation mechanisms (Ranchordas, 2021). These approaches support the continuous development and adjustment of AI-driven knowledge processes.

Finally, investments in interdisciplinarity and data literacy are essential to strengthen knowledge integration capabilities across different professional domains (Romeo et al., 2025). Enhancing collaboration between public officials, technical experts, and citizens enables the co-production and circulation of knowledge within public organizations.

Where these elements converge, AI evolves from a generative learning infrastructure to a generative knowledge infrastructure, capable of supporting continuous knowledge development and improving the adaptive capacity of public institutions.

5 Ethics Declaration

No ethical approval was required for this study. The research is based on a qualitative meta-synthesis of existing literature and does not involve human participants, personal data, or primary data collection.

6 AI Declaration

The authors declare that generative artificial intelligence (AI) tools, specifically ChatGPT, were used solely to improve the clarity and quality of the English language. As Italian is the authors' native language, AI support was limited to linguistic refinement. All intellectual content, analysis, and conclusions are entirely the responsibility of the authors.

The Social Cost of Digital Banking: Branch Desertification and Inequalities in Access to Financial Services

Giuseppe Bruno, Carmela Piccolo, Eduardo Pipicelli
University of Naples Federico II, Naples, Italy

Abstract

In recent years, the banking sector has undergone a profound transformation driven by the widespread diffusion of digital technologies, which has progressively reshaped service delivery models and reduced the role of physical branches. This shift has been accompanied by a significant contraction of branch networks across Europe, raising concerns about its implications for access to financial services, particularly in less advantaged territorial contexts. Against this background, this study investigates the social costs associated with the digitalization of banking services by analyzing how branch network contraction affects spatial accessibility across different territorial contexts. The empirical analysis focuses on a regional case study in Italy, Emilia-Romagna, characterized by a high degree of heterogeneity in socio-economic and digital conditions. Accessibility is assessed through two complementary dimensions: the *availability* of branches within given distances and the *proximity* to the nearest facility. The analysis is conducted for three reference years (2010, 2017, and 2024), enabling a detailed comparison of the evolution of accessibility patterns across urban, suburban, and rural areas. The results show that, although branch closures have occurred throughout the region, their impact has been significantly more pronounced in suburban and rural areas, where both availability and proximity indicators reveal a marked deterioration of accessibility conditions. Building on this evidence, the study further explores the relationship between physical accessibility and digital development, showing that the areas most affected by the reduction in physical infrastructure are also characterized by weaker digital conditions. In these contexts, digital channels do not adequately compensate for the loss of physical access, leading to a cumulative effect of disadvantage. Overall, the findings suggest that the ongoing digital transformation of the banking sector entails non-negligible social costs, as it disproportionately affects more vulnerable populations and contributes to widening territorial disparities in access to financial services. The study highlights the need to account for spatial and digital inequalities when designing policies aimed at promoting financial inclusion in the context of digital transition.

Keywords: Banking desertification; Digitalization; Accessibility; Financial Inclusion, Social Sustainability.

Paper type: Academic Research Paper

1 Introduction and Background

Over the last few decades, the banking sector has undergone a profound transformation driven by the combined effects of financial crises and rapid technological innovation (Felipe et al., 2025; Kitsios et al., 2021). The diffusion of online banking platforms has progressively reshaped the organization of financial activities, encouraging institutions to move toward increasing digital business models (Thakor, 2020). Within this transformation, a growing share of banking services is performed through remote interfaces, reducing the centrality traditionally played by physical branches. For this reason, many banking institutions have progressively rationalized their branch networks in order to reduce operational costs and adapt their distribution strategies to the new environment (Baldassarre et al., 2024).

As a consequence, the number of bank branches has declined significantly in many European countries, contributing to the emergence of bank branch desertification (Langford et al., 2024). While this process is often interpreted as the result of technological progress and efficiency-oriented strategies, it has also raised concerns regarding its implications for financial inclusion, particularly in rural and remote areas (Baldassarre et al., 2025; Demirgüç-Kunt et al., 2021).

The extent to which physical banking services can be substituted by digital channels depends on factors such as connectivity and the diffusion of digital capabilities, which vary significantly across territories and socioeconomic groups (Calzada & Pablo, 2026). As a result, in contexts where these conditions are less developed, the contraction of branch networks may reduce effective access to financial services, generating non-negligible social costs and reinforcing existing territorial disparities (Bruno et al., 2023).

Against this background, an increasing body of literature on banking digitalization has examined the implications of branch network contraction for access to the service, with particular attention to financial inclusion and territorial inequalities (Leyshon et al., 2008; Hegerty, 2016). In this context, several contributions have analyzed spatial accessibility using quantitative and spatial approaches, showing how changes in network dimensions translate into variations in physical access to banking services (Galardo et al., 2021; Higgs et al.,

2022). These analyses consistently point to the emergence of uneven access conditions, as branch closures tend to disproportionately affect already disadvantaged areas, contributing to the persistence and, in some cases, the intensification of territorial disparities (Hegerty, 2020; Langford et al., 2021; Pardue & Shelton, 2025).

While existing contributions document the spatial implications of branch network contraction, limited attention has been devoted to empirically assessing how these effects impact more fragile areas, with lower structural and digital conditions. This aspect is crucial, as in such contexts the reduction of physical access may not be offset by digital channels, compounding existing disadvantages and ultimately exacerbating territorial divides (de Ibarreta et al., 2025).

Building on this perspective, the present study aims to investigate the social costs of banking digitalization by addressing the following research question (RQ): *How does bank branch desertification, driven by digitalization, exacerbate territorial inequalities in access to financial services?*

To address this research question, the analysis focuses on a regional case study in Italy, namely Emilia-Romagna, a context characterized by significant branch desertification and a heterogeneity in economic and digital conditions across urban, suburban, and rural areas. Within this setting, the study evaluates spatial accessibility to bank branches (measured in terms of availability and proximity) across different territorial contexts, tracking its evolution over approximately fifteen years, with a focus on the years 2010, 2017, and 2024.

The results show that, although branch closures have been distributed across the entire regional territory, their impact has been more pronounced in rural (and suburban) areas, where they have led to a more marked deterioration of accessibility conditions. These effects are particularly critical, as lower levels of digital development in these areas are often insufficient to compensate for reductions in physical infrastructure, thereby exacerbating existing disparities.

The remainder of the paper is organized as follows. Section 2 introduces the Italian case study, with a focus on bank branch desertification in the Emilia-Romagna region. Section 3 presents the methodology adopted for the spatial accessibility analysis and discusses the corresponding results. Section 4 provides additional insights into the relationship between physical and digital accessibility, highlighting its implications for territorial inequalities. Finally, Section 5 concludes the paper by discussing its main limitations and outlining directions for future research.

2 Bank Branch Desertification in Italy and the Emilia-Romagna Case Study

Over the last decade, the Italian banking system has undergone a progressive reorganization of its territorial structure, reflected in a widespread reduction in the number of physical branches. This process has affected all regions, although with different intensities, and represents one of the most visible outcomes of the ongoing transformation of banking distribution models.

Table 1 reports the evolution of the number of bank branches across Italian regions between 2010 and 2024, together with the corresponding percentage variations (Banca di Italia, 2025). The data show a generalized contraction of branch networks. At the national level, the number of branches declined from 33,663 units in 2010 to 19,655 in 2024, corresponding to a reduction of approximately 42%. In general, the closures appear consistent across the country, although their intensity slightly varies by region. In several cases, the reduction exceeds 45%, as observed in regions such as Marche, Molise, Umbria, Veneto, and Emilia Romagna.

Table 1: Number of branches per region

Region	Population	Number of branches		
		2010	2017	2024
Abruzzo	1,272,627	701	587 (−16%)	400 (−43%)
Basilicata	537,577	250	226 (−10%)	163 (−35%)
Calabria	1,846,610	519	422 (−19%)	315 (−39%)
Campania	5,609,536	1,637	1,368 (−16%)	1,008(−38%)
Emilia-Romagna	4,425,366	4,149	3,357 (−19%)	2,073 (−50%)
Friuli-Venezia Giulia	1,194,248	955	776 (−19%)	560 (−41%)
Lazio	5,720,536	2,768	2,294 (−17%)	1,607 (−42%)
Liguria	1,507,636	962	767 (−20%)	560(−42%)
Lombardia	9,976,509	6,611	5,431 (−18%)	3,769 (−43%)
Marche	1,484,298	1,206	904 (−25%)	613 (−49%)
Molise	290,636	146	119 (−18%)	76 (−48%)
Piemonte	4,251,351	2,696	2,252 (−16%)	1,574 (−42%)
Puglia	3,907,683	1,410	1,203 (−15%)	923 (−35%)
Sardegna	1,578,146	667	568 (−15%)	454 (−32%)
Sicilia	4,814,016	1,759	1,416 (−19%)	1,030 (−41%)

Region	Population	Number of branches		
		2010	2017	2024
Toscana	3,661,981	2,548	2,093 (−18%)	1,472 (−42%)
Trentino-Alto Adige	1,077,143	979	789 (−19%)	658 (−33%)
Umbria	856,407	581	458 (−21%)	317 (−45%)
Valle d'Aosta	12,313	98	93 (−5%)	66 (−33%)
Veneto	4,849,553	3,625	2,801 (−23%)	2,007 (−45%)
Italy	58,997,201	33,663	27,374 (−19%)	19,655 (−42%)

These results indicate that the contraction of the bank branch network is a systemic process affecting the entire country; however, in more densely populated and economically developed areas, the reduction may have limited consequences. By contrast, in more peripheral contexts, it can contribute to the emergence of bank branch desertification, potentially leading to financial exclusion when the loss of physical infrastructure is not compensated by alternative channels.

Against this background, we focus our analysis on the Emilia-Romagna region, which experienced the highest percentage reduction in the country (−50%) and is characterized by heterogeneity in economic and digital conditions across different areas.

Beyond population distribution, the region's socio-economic structure also reflects territorial differences, as reported in Table 2 and illustrated in Figures 1c and 1d, based on data from Regione Emilia-Romagna (2025). In particular, per capita income tends to decrease from urban to suburban and rural areas, with a gap of about 4,000 euros between the former and the latter. This pattern is further reinforced by the distribution shown in Figure 1d, which reports the share of taxpayers with total income below €10,000. Higher concentrations of low-income individuals are observed in peripheral and rural municipalities, while urban areas display systematically lower shares. These outcomes highlight a socio-economic divide across the region, with more fragile conditions concentrated outside the main urban centres.

With respect to the distribution of bank branches, the reduction follows a broadly similar pattern across areas. As noted, the region experienced a substantial contraction of approximately 50% between 2010 and 2024, which appears relatively homogeneous across territorial contexts, as also suggested by the spatial distribution of branches in Figure 1b. However, while urban areas still benefit from a relatively dense network (791), in rural contexts the same reduction translates into much more limited branch availability for potential users (449).

Taken together, these elements point to the need for a more careful assessment of accessibility conditions across the region. In fact, while the contraction of the networks is broadly distributed, its effects on financial exclusion are likely to be more critical in suburban and rural areas that are economically weaker.

Table 2: Key characteristics of Emilia-Romagna by area

Area	Municipalities		Census tracts		Population		Per capita income (Euro)	No. of branches		
	#	%	#	%	#	%		2010	2017	2024
Urban	11	3%	17,001	29,231.7	1,703,827	39%	29,231.7	1746	1370 (-22%)	791 (-55%)
Suburban	112	34%	12,626	26,907.3	1,804,646	41%	26,907.3	1620	1310(-19%)	833 (-49%)
Rural	207	63%	11,864	25,268.9	916,893	21%	25,268.9	783	677 (-14%)	449 (-43%)
Total	330	100%	41,491	27,462.8	4,425,366	100%	27,462.8	4,149	3,357 (-19%)	2,073 (-50%)

3 Spatial Accessibility Analysis

This section presents the empirical analysis of spatial accessibility to banking services. It begins with a description of the methodological framework (Section 3.1) and then discusses the main results, with a focus on how accessibility conditions evolve across different territorial contexts (Section 3.2).

3.1 Methodology

Spatial accessibility is commonly defined as the ease with which individuals can reach a given service, and it has been widely examined in the literature through different methodological approaches (Neutens, 2015). Among these, distance-based measures are among the most widely adopted, as they provide a consistent way to capture spatial interaction between demand and supply.

In this study, accessibility to banking services is assessed considering two metrics: *availability* of alternative branches within given distances and *proximity* to the closest facility. The former reflects the range of opportunities available to users within given distance thresholds, while the latter captures the minimum effort (in terms of distance) required to access financial services.

From an interpretative perspective, considering both availability and proximity is essential to properly assess access conditions to banking services. Availability captures the number of alternatives accessible within a given distance, thus reflecting the variety of options available to users. This aspect is particularly relevant for services such as banking, where customers may differ in their preferences across institutions in terms of costs, services, or existing relationships. However, access is not only a matter of choice, but also of reachability. In this sense, proximity complements availability by capturing the distance that users must cover to reach the closest branch, providing a direct indication of physical access.

The analysis is conducted at the level of census tracts, which are used to discretize the spatial distribution of demand, as each tract is represented by its centroid, approximating the location of the resident population. Let I denote the set of demand locations, corresponding to census tract centroids, and let J^tbe the set of active bank branches at time $t \in \{2010,2017,2024\}$. Each location $i \in I$ is associated with a demand u_i, representing the number of potential users and defined as individuals aged between 20 and 75 years. Bank branches are georeferenced, and distances d_{ij}between demand nodes and facilities are computed as shortest paths along the road network using the open-source software QGIS.

The first dimension of accessibility is availability, which captures the number of alternative branches that can be reached within a given distance. For each location $i \in I$and a distance threshold $\bar{d}$, availability is defined as $A_i^t(\bar{d}) = |\{j \in J^t : d_{ij} \leq \bar{d}\}|$.

From this measure, two indicators are derived as follows.

- The fraction of users with at least a given number of opportunities $k$within a distance threshold $\bar{d}$:

$$G_k^t(\bar{d}) = \frac{\sum_{i \in I: A_i^t(\bar{d}) \geq k} u_i}{\sum_{i \in I} u_i}. \qquad (1)$$

- The average number of branches accessible to potential users within the given distance threshold $\bar{d}$:

$$A_{\text{avg}}^t(\bar{d}) = \frac{\sum_{i \in I} u_i \, A_i^t(\bar{d})}{\sum_{i \in I} u_i}. \qquad (2)$$

The second dimension of accessibility is proximity, defined as the minimum distance between each demand location and the nearest active branch. Formally, for each $i \in I$, proximity is measured as $d_i^t = \min_{j \in J^t} \{d_{ij}\}$.

From this, two indicators are derived as follows.

- The fraction of users that can reach the closest branch within a predefined distance $\bar{d}$:

$$F^t(\bar{d}) = \frac{\sum_{i \in I: d_i^t \leq \bar{d}} u_i}{\sum_{i \in I} u_i}. \qquad (3)$$

- The average distance that a potential user must travel to reach the closest branch:

$$d_{\text{avg}}^t = \frac{\sum_{i \in I} u_i \, d_i^t}{\sum_{i \in I} u_i}. \qquad (4)$$

On the basis of these measures, the analysis is then carried out on the case study, allowing us to assess how accessibility conditions evolve across different territorial contexts over time, as presented in the next section.

3.2 Results

The results are presented with respect to the indicators introduced in Section 3.1, considering the three reference years (2010, 2017, and 2024) and distinguishing across the three territorial contexts (urban, suburban, and rural areas).

We begin by discussing availability, reported in Table 3. For the sake of clarity, we specify that results are presented with reference to a distance threshold of 2.0 km, which represents a reasonable compromise between very short distances, often too restrictive, and larger thresholds that tend to smooth out territorial differences.

The table reports the fraction of users who can access at least k branches within this distance, G_k^t, together with the corresponding average number of opportunities, A_{avg}^t.

Over time, the contraction of branch networks significantly reduces the number of accessible opportunities, especially in suburban and rural contexts. For instance, the share of users with access to at least three branches within 2.0 km declines by 18% in suburban areas and by 39% in rural areas, compared to a reduction of 7% in urban areas. A similar pattern emerges when considering higher levels of availability. When considering four accessible branches, the reduction reaches 20% in suburban areas and 58% in rural areas, while remaining at 8% in urban contexts. This dynamic is also reflected in the average number of available branches, which decreases from 43 to 19 in urban areas, from 10 to 5 in suburban areas, and from 3 to 2 in rural areas.

As a result, by 2024, availability conditions markedly differ across territorial contexts. In urban areas, a large share of the population still has access to multiple branches within 2 km, preserving a relatively high degree of choice. By contrast, in suburban and especially rural areas, the reduction in opportunities leads to much lower levels of availability, with several users having access to only a few branches.

Table 3: Availability results: *fraction of users* (G_k^t, in %) by k and average distance A_{avg}^t ($\bar{d} = 2.0\ km$)

These results highlight a substantial reduction in the range of accessible opportunities, particularly in suburban and rural areas. However, to provide a more complete picture of accessibility, we also consider the distance that potential customers must travel to reach the nearest branch, as captured by the proximity indicators (Table 4).

The latter reports the fraction of users that can reach the closest branch within increasing distance thresholds F^t, together with the corresponding average distance d^t_{avg}.

A first relevant aspect is that, even before the contraction of branch networks, accessibility conditions were already markedly different across territorial contexts. In 2010, for instance, 82% of the urban population could reach a branch within 1 km, compared to 65% in suburban areas and 53% in rural ones, with a clear initial gap in proximity conditions.

The reduction of branches over time has further amplified these differences. In fact, although closures have been broadly distributed across the region (see Table 2), their relative impact appears more pronounced in suburban and rural areas, which were already characterized by less favorable conditions. For example, within 1 km, the share of covered population in urban areas decreased by 10%, reaching 73% in 2024. By contrast, the reduction amounts to 17% in suburban areas and 15% in rural areas, leading to significantly lower coverage levels of 54% and 45%, respectively.

Similar patterns emerge across higher distance thresholds and in the average distance, where comparable increases translate into more critical accessibility conditions in suburban and rural areas.

4 Additional Insights: Digital Divide and Territorial Inequalities

The evidence discussed in Section 3 highlights a more pronounced deterioration of physical accessibility in suburban and rural areas. Clearly, given that the contraction of branch networks is largely driven by the digitalization of banking services, a key question is whether areas more exposed to this process are characterized by adequate levels of digital development.

To address this aspect, we consider two complementary indicators, retrieved from Regione Emilia-Romagna (2026): (i) the share of households covered by FTTH (Fiber to the Home), which captures the level of development of digital infrastructure; and (ii) the share of citizens with a digital identity, which reflects the

degree of digital familiarity and readiness to access online services. Together, these measures provide a synthetic view of both the infrastructural and skills dimensions of digital access.

The spatial distribution of these indicators, reported in Figure 2, reveals a clear territorial pattern. As shown in Figure 2a, FTTH coverage is higher in urban municipalities, while suburban and especially rural areas exhibit lower levels of infrastructure deployment, with several peripheral zones still characterized by limited connectivity. Indeed, on average, FTTH coverage reaches around 56% in urban areas, compared to approximately 20% in suburban areas and 22% in rural ones, pointing to a substantial infrastructural gap.

A similar result emerges when considering digital identity adoption, reported in Figure 2b. While the differences across areas are less pronounced than for infrastructure, urban contexts still display higher levels of digital engagement. The average share of citizens with a digital identity is approximately 36% in urban areas, compared to 34% in suburban areas and 29% in rural ones. Again, the lower values observed in rural areas suggest a weaker capacity to effectively rely on digital services.

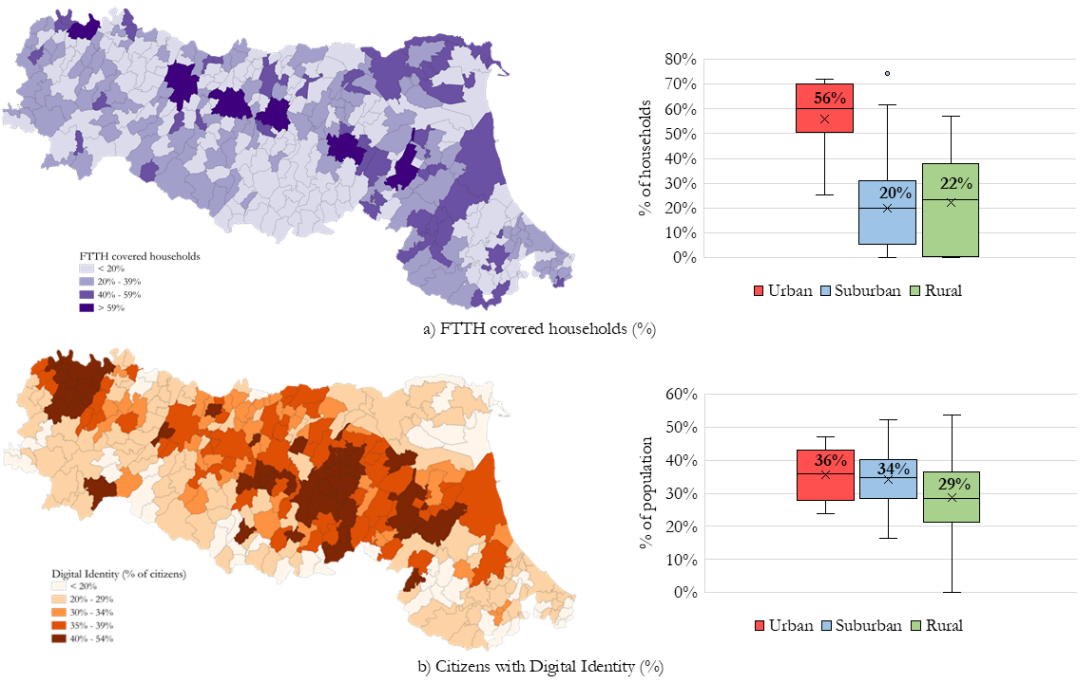

Figure 2: Digital infrastructure and digital identity indicators across municipalities

Taken together, these results indicate that the territories most affected by the reduction in physical accessibility are also those characterized by less favorable digital conditions. This represents a particularly relevant insight, as in urban areas the (contained) reduction of physical infrastructure is partially offset by relatively high levels of digital development, whereas in suburban and rural contexts this does not occur. Rather, as the quality of physical access to banking services deteriorates, the ability to compensate for this loss through alternative digital channels remains limited.

As a result, what is essentially a process of digital transformation in the banking sector entails a non-negligible social cost, mainly stemming from its disproportionate impact on more vulnerable populations, whose access to services worsens as it increasingly depends on digital channels to which they are comparatively less equipped to adapt.

5 Conclusions

The ongoing digital transformation of the banking sector is reshaping the way financial services are delivered, progressively reducing the role of physical infrastructure. While this process is often associated with efficiency gains and improved service provision, its implications are not evenly distributed across territories.

In this study, we investigated the social costs associated with this transition by analyzing how the contraction of branch networks affects accessibility to banking services across different territorial contexts. Focusing on the Emilia-Romagna region, the empirical analysis shows that, although branch closures have occurred throughout the entire territory, their impact has been significantly more pronounced in suburban and rural areas. These

contexts, already characterized by less favorable accessibility conditions, experienced a more substantial deterioration both in terms of availability of services and proximity to the nearest branch.

Building on this evidence, the analysis further highlights that such patterns are closely intertwined with the uneven distribution of digital development across the region. In particular, the areas most affected by the reduction in physical accessibility are also those with comparatively weaker digital infrastructure and capabilities. As a result, the transition toward digital service provision does not serve as a compensatory mechanism but rather amplifies existing territorial disparities.

From this perspective, the main contribution of the paper lies in providing empirical evidence of a cumulative effect of disadvantage for more vulnerable populations. In this sense, the digitalisation of banking services entails a non-negligible social cost, as it strongly reinforces inequalities in access to essential financial services.

These findings have relevant policy implications for public stakeholders committed to reducing territorial disparities. In particular, they suggest that the ongoing digital transformation of the banking sector should be accompanied by targeted interventions to support more fragile areas, including investments in digital infrastructure, initiatives to enhance digital skills, and alternative service delivery solutions capable of ensuring minimum access conditions in contexts affected by branch desertification.

Clearly, the study presents some limitations that open to future research. First, the analysis focuses on a single regional case study, and further investigations could extend the approach to other contexts to assess the generalizability of the results. Second, while accessibility is measured in spatial terms, future research could integrate behavioral dimensions, such as actual usage of digital banking services, to better capture effective access. Moreover, exploring the role of alternative financial channels could provide additional insights into how to mitigate the emerging gaps identified in this study.

Assessing VSME Alignment in Voluntary Sustainability Reporting by SMEs: Evidence from the Italian Chemical Sector

Manuel Cavola[1], Patrice De Micco[2], Niccolò Parissi[2]
[1] Università Telematica Pegaso, Napoli, Italy
[2] Università degli Studi di Siena, Siena, Italy

Abstract

Small and medium-sized enterprises (SMEs) play a central role in the European transition towards a more sustainable economy, yet their sustainability reporting practices remain less developed and less standardised than those of large firms. This issue is particularly relevant in the context of the Corporate Sustainability Reporting Directive (CSRD), the European Sustainability Reporting Standards (ESRS), and the increasing sustainability-related information demands that SMEs face from large companies, financial institutions, and other stakeholders. In response to proportionality concerns, the EFRAG Voluntary Sustainability Reporting Standard for non-listed SMEs (VSME) provides a simplified framework intended to support voluntary sustainability disclosure by SMEs. However, empirical evidence on the extent to which SME sustainability reports are aligned with the VSME remains limited.

This paper assesses the alignment of voluntary sustainability reporting by SMEs operating in the Italian chemical sector with VSME disclosure requirements. The empirical analysis focuses on firms classified under the C20 division of the NACE industrial classification. Starting from a population of Italian chemical firms identified through the AIDA database, the study selects SMEs that had published a sustainability report or an equivalent sustainability-related disclosure document. A stratified sampling strategy was then adopted, and the final analytical dataset was obtained after a quality-control procedure on document extraction.

The analysis applies an AI-assisted content analysis protocol based on a VSME coding grid composed of 20 disclosure items, covering the Basic and Comprehensive Modules and four thematic areas: General information, Environment, Social, and Governance. Each firm-item pair was assessed through a three-level scoring scale distinguishing between no alignment, partial alignment, and full substantive alignment with the VSME requirements.

The results show a moderate and uneven degree of alignment with the VSME. Full and partial alignment are both relatively frequent, while non-coverage remains substantial but not dominant. At firm level, the findings indicate relevant heterogeneity across companies. General information records the highest alignment, followed by Social and Environment, whereas Governance is the weakest area. At item level, firms perform better on business-model descriptions, sustainability initiatives, and human-rights policies, while weaker alignment emerges for biodiversity, pollution, climate-transition targets, corruption-related sanctions, and sensitive-sector revenues. Overall, the findings suggest that Italian chemical SMEs are more advanced in qualitative and narrative sustainability reporting than in systematic, quantitative, and VSME-specific disclosure.

Keywords: Voluntary sustainability reporting; Small and medium-sized enterprises (SMEs); European sustainability standards; Environmental sustainability; Chemical Sector

Paper type: Academic Research Paper

1 Introduction

The European Commission consistently highlights that the transition towards a more sustainable and digitally advanced economy depends on the effective involvement of small and medium-sized enterprises (SMEs), given their structural importance within the business landscape (Schulze et al., 2025).

Indeed, from a structural perspective, SMEs represent 99.8% of all enterprises in the EU non-financial business sector and contribute substantially to employment and value creation. They therefore constitute a cornerstone of the European economic system, accounting for a large share of employment creation and value added across ecosystems and, in several sectors, acting as a primary driver of net employment growth (Schulze et al., 2025).

Their capacity to engage in the green and digital transitions is therefore considered essential for achieving the objectives outlined in the European Green Deal, and SMEs will be required to transform both digitally and environmentally (European Commission, 2025a). This double challenge is likely to be particularly demanding for enterprises, especially considering the supply-chain pressures exerted both upstream and downstream. These pressures, both explicit and implicit, increasingly require SMEs to align with evolving expectations in terms of Corporate Social Responsibility (Harness et al., 2018; Choi et al., 2019; Stekelorum, Courrent, & Spence, 2024) and digital transformation (Mcilveene, 2026; Pálka et al., 2026). At the same time, SMEs face well-documented

structural constraints in engaging with digital and sustainability-related practices, including limited financial resources, skills shortages, and constrained managerial capacity (Álvarez Jaramillo, Zartha Sossa, & Orozco Mendoza, 2019; Madrid-Guijarro & Duréndez, 2024; Leipziger et al., 2025).

These challenges are particularly evident in the field of sustainability reporting, where disclosure frameworks have traditionally been developed with large and resource-rich firms in mind (Aureli et al., 2020; De Micco et al., 2021). With reference to sustainability reporting in SMEs, the literature consistently highlights structural limitations that affect both the adoption and the quality of disclosure practices. Resource constraints, in terms of time, financial capacity, and technical expertise, represent a primary barrier, limiting SMEs' ability to implement structured reporting processes and align with established standards. Consequently, reporting among SMEs tends to be predominantly qualitative and narrative-based, fragmented, weakly standardised, and often difficult to compare across firms (Steidle et al., 2025).

Within this context, the recent introduction of the Corporate Sustainability Reporting Directive (CSRD) and the European Sustainability Reporting Standards (ESRS) represents a major shift in the European sustainability reporting landscape (European Union, 2022; EFRAG, 2022). One of the main innovations of the CSRD is the extension of reporting obligations to listed SMEs, which represent only a small share of the overall SME population in Europe (European Commission, 2021). As a consequence, most SMEs remain outside the scope of mandatory reporting requirements. Nevertheless, many SMEs may still be indirectly affected through the so-called trickle-down effect, whereby firms subject to reporting obligations request sustainability-related information from companies within their value chains. This dynamic may generate additional reporting burdens for non-listed SMEs, even though they are not formally subject to sustainability reporting requirements (European Commission, 2025b).

In this respect, SMEs may face significant challenges in identifying, collecting, and managing sustainability-related data, both internally and along the value chain, particularly when dealing with the double materiality perspective and the interpretation of ESG reporting standards (Cavaliere, Bellazzecca, & di Castiglionchio, 2026). These structural and operational constraints are reflected in the still limited diffusion of environmental measurement practices. For instance, only a small proportion of SMEs have implemented advanced monitoring systems, such as the measurement of Scope 3 emissions or detailed carbon footprints (Schulze et al., 2025). This indicates a substantial gap between regulatory expectations and actual reporting capabilities, suggesting that the primary barrier to sustainability disclosure is not only reporting itself, but also the upstream process of data generation and measurement.

In response to concerns related to proportionality and administrative burden, the European Commission has promoted simplified and voluntary frameworks tailored to SMEs, most notably the Voluntary Sustainability Reporting Standard for non-listed SMEs (VSME) (EFRAG, 2023; Momtaz & Parra, 2025). As stated in the objectives of the VSME (EFRAG, 2024), the standard has been developed to support non-listed micro-, small- and medium-sized enterprises in addressing increasing sustainability-related information demands. In particular, it aims to enable SMEs to respond to data requests from large companies within the supply chain, as well as from banks and investors, thereby facilitating access to finance.

At the same time, the VSME is designed to support the internal management of environmental, social and governance issues, contributing to improved organisational practices, enhanced resilience, and long-term competitiveness. Although non-listed SMEs fall outside the scope of the CSRD, they are encouraged to adopt the VSME, which covers the same broad sustainability topics as the ESRS but in a more proportionate and simplified manner (EFRAG, 2024).

In this evolving regulatory context, assessing not only whether SMEs disclose sustainability information, but also the extent to which their voluntary disclosures are aligned with emerging European reporting standards becomes increasingly relevant. Prior research on sustainability reporting quality has shown that the presence of information alone is insufficient to ensure transparency and comparability, as firms may engage in symbolic disclosures that provide limited informational value (Michelon et al., 2015). However, empirical evidence on the quality and standard-alignment of sustainability reporting by SMEs remains scarce, particularly with regard to non-listed firms operating in environmentally intensive sectors and to the extent to which their sustainability practices are formally communicated through reporting mechanisms (Galli, Torelli, & Caccialanza, 2023).

This gap is especially relevant in the chemical industry. The chemical sector is among the largest manufacturing sectors in Europe, the third-largest manufacturing industry in the EU27, with over 30,000 SMEs accounting for a substantial share of employment and sales (Cefic, 2025). It is also one of the most environmentally relevant industries, in terms of greenhouse gas emissions, energy consumption, resource use, pollution, and potential impacts along the value chain. While sustainability reporting practices of large chemical corporations have been widely analysed, little is known about how chemical SMEs engage with voluntary sustainability reporting and how aligned their disclosures are with emerging European reporting standards.

Against this background, this paper assesses the quality of voluntary sustainability reporting by SMEs operating in the Italian chemical sector. More specifically, it evaluates the degree of alignment between firms' sustainability reports, or equivalent sustainability-related disclosures, and the EFRAG Voluntary Sustainability Reporting Standard for non-listed SMEs. In this study, reporting quality is operationalised as the degree of alignment with the VSME disclosure requirements. Empirically, the analysis focuses on firms classified under the C20 division of the NACE industrial classification, corresponding to the manufacture of chemicals and chemical products.

The study addresses the following research question:

RQ1. To what extent do the voluntary sustainability disclosures of Italian chemical SMEs align with the VSME requirements, and how does this alignment vary across modules, thematic areas and disclosure items?

By addressing this question, the paper contributes to the literature on SME sustainability reporting by providing empirical evidence on the degree of standard-alignment of voluntary disclosures in an environmentally relevant manufacturing sector. It also offers insights into the disclosure areas in which SMEs appear more advanced and those where alignment with the VSME remains more limited.

The remainder of the paper is structured as follows. The next section presents the research design, describing the sample selection procedure, the construction of the VSME coding grid, the scoring approach, and the quality-control process applied to document extraction. The following section reports the empirical results, examining VSME alignment at different levels of analysis, including score distribution, firm-level performance, modules, thematic areas, disclosure items, and clusters. Finally the paper then concludes by discussing the main findings, outlining the methodological limitations of the study, and identifying possible directions for future research.

2 Methodology

The empirical analysis was designed to assess the degree of alignment between the sustainability reports published by chemical Italian firms and the EFRAG Voluntary Sustainability Reporting Standard for non-listed SMEs (VSME).

The starting population was selected on the AIDA database, that is one of the main Italian databases providing corporate, financial, and economic information on firms. It was developed by Bureau van Dijk, now part of Moody's, and is widely used in academic research, economic analysis, due diligence activities, and business studies (Bureau van Dijk, 2024; Moody's, 2024). The initial sample consisted of 5,623 firms, of which 3,517 were identified as SMEs according to the European Commission classification based on the number of employees, annual turnover, and total balance sheet assets. Among these 3,517 firms, 109 were identified as having published a sustainability report or an equivalent sustainability-related disclosure document.

Given the high cost of manually collecting and coding corporate sustainability reports, a stratified sampling strategy was adopted. The sample was drawn from firms classified as having level-3 disclosure, using the relative distribution of the three clusters as the sampling criterion.

The final selected sample included 40 firms. For each firm, the relevant sustainability document was searched, downloaded where available, and stored in a structured folder. The documents included sustainability reports, impact reports, group or network sustainability reports, and sustainability-related corporat disclosures. The subsequent analysis was conducted through an AI-assisted content analysis protocol based on a VSME coding grid.

Table 1: Sampling design and final analytical dataset

Analytical step	N	Reference / percentage
Initial firm population	3517	100.00% of initial population
Firms with sustainability report / level-3 disclosure	109	3.10%
Stratified sample selected for document collection	40	36.70% of reporting firms
Reports successfully processed	33	82.50% of selected sample
Reports not included in final item-level analysis	7	17.50% of selected sample
Final firm-item observations	660	33 firms x 20 VSME items

The VSME coding grid was constructed by translating the standard into 20 disclosure items: 11 items from the Basic Module, labelled B1 to B11, and 9 items from the Comprehensive Module, labelled C1 to C9 (Table 2). Each item was assigned to one of four thematic areas: General information, Environment, Social, and Governance.

Table 2: VSME disclosure-item coding framework by module, sustainability area and coding requirement

ID Item	Module	Area	Item
B1	Basic	General information	Basis for preparation
B2	Basic	General information	Practices, policies and future initiatives for transitioning towards a more sustainable economy
B3	Basic	Environment	Energy and greenhouse gas emissions
B4	Basic	Environment	Pollution of air, water and soil
B5	Basic	Environment	Biodiversity
B6	Basic	Environment	Water
B7	Basic	Environment	Resource use, circular economy and waste management
B8	Basic	Social	Workforce - General characteristics
B9	Basic	Social	Workforce - Health and safety
B10	Basic	Social	Workforce - Remuneration, collective bargaining and training
B11	Basic	Governance	Convictions and fines for corruption and bribery
C1	Comprehensive	General information	Strategy: Business Model and Sustainability-Related Initiatives
C2	Comprehensive	General information	Description of practices, policies and future initiatives for transitioning towards a more sustainable economy
C3	Comprehensive	Environment	GHG reduction targets and climate transition
C4	Comprehensive	Environment	Climate risks
C5	Comprehensive	Social	Additional workforce characteristics
C6	Comprehensive	Social	Additional own workforce information - Human rights policies and processes
C7	Comprehensive	Social	Severe negative human rights incidents
C8	Comprehensive	Governance	Revenues from certain sectors and exclusion from EU reference benchmarks
C9	Comprehensive	Governance	Gender diversity ratio in the governance body

For each firm-item pair, the report was assessed using a three-level scoring scale: 0 indicated that the item was not covered or not aligned with the VSME requirement; 0.5 indicated partial coverage or partial alignment; and 1 indicated full coverage and substantive alignment with the VSME requirement.

As reported in Table 3, before analysing the results, a quality-control procedure was conducted on the document extraction process. Out of the 40 selected firms, 33 reports were successfully processed. Three documents were not found, two PDF files contained insufficient extractable text and were therefore likely to be scanned documents, and two reports generated extraction errors due to technical issues related to PDF encryption (Table 4). The final analytical dataset therefore consists of 33 firms and 660 firm-item observations, corresponding to 20 VSME items for each successfully processed firm.

Table 3: Quality-control results of the PDF extraction and processing phase

Status	N	Percentage of selected sample
Successfully processed	33	82.50%
PDF not found	3	7.50%
Insufficient extractable text / likely scanned PDF	2	5.00%
Extraction error	2	5.00%

Table 4: Firms excluded from the final item-level analysis

Firm name	Processing status	Reference year	Document type
AMBRO - SOL S.R.L. SOCIETA' BENEFIT , IN FORMA ABBREVIATA AMBRO - SOL S.R.L. SB	PDF not found	2024	Relazione di impatto società benefit
CROMATOS - S.R.L.	Insufficient extractable text / likely scanned PDF	2024	report ESG / bilancio di sostenibilità
EDILTECO - SOCIETA' PER AZIONI	Insufficient extractable text / likely scanned PDF	2023/2024	Bilancio di sostenibilità di gruppo
KULZER S.R.L.	Extraction error	2025	ESG report di gruppo
MERSEN ITALIA MALONNO S.R.L.	PDF not found	2024	Universal Registration Document / sustainability di gruppo

Firm name	Processing status	Reference year	Document type
SUNSTAR ITALIANA S.R.L.	PDF not found	2024	Sustainability Report di gruppo
SYMRISE S.R.L.	Extraction error	2024	Sustainability/corporate report di gruppo

3 Results Analysis

The distribution of item-level scores suggests a moderate degree of alignment with the VSME. As reported in Table 5, out of 660 firm-item observations, 141 observations received a score of 0, corresponding to 21.36% of the total; 256 observations received a score of 0.5, corresponding to 38.79%; and 263 observations received a score of 1, corresponding to 39.85%. This indicates that full alignment is observed in slightly less than 40% of the assessed disclosure items, while partial alignment is also similary frequent. Non-coverage remains substantial, but it is not the dominant outcome.

Table 5: Distribution of VSME item-level scores

Score	Interpretation	N	Percentage
0	Not covered / not aligned	141	21.36%
0.5	Partially covered / partially aligned	256	38.79%
1	Fully covered / aligned	263	39.85%

As summarized in Table 6, at the firm level, the average VSME alignment score is 0.592. The median score is 0.575, while the minimum and maximum values are 0.300 and 0.900, respectively. The standard deviation is 0.157. These results indicate a substantial degree of heterogeneity across firms in the extent to which their sustainability disclosures align with the VSME structure.

The proximity between the mean and the median suggests that the distribution of firm-level scores is not strongly driven by extreme observations. However, the relatively wide range between the lowest and highest values points to marked differences in disclosure practices within the sample. Some companies publish sustainability reports that cover only a limited subset of the VSME disclosure items, resulting in weak alignment with the standard. In these cases, sustainability information is likely to be present but fragmented, selective, or not organised according to the categories and information requirements reflected in the VSME framework.

Conversely, the firms with higher alignment scores disclose a broader and more structured set of sustainability information. Their reports appear to cover a larger number of VSME-related items and to provide information across multiple areas. Overall, the evidence suggests that, even among firms that publish a sustainability report or an equivalent sustainability-related disclosure, the degree of consistency with the VSME framework varies considerably. This confirms that the mere presence of a sustainability document does not necessarily imply comprehensive or standard-aligned reporting.

Table 6: Descriptive statistics of firm-level VSME alignment scores

Statistic	Value
Number of firms	33
Mean	0.592
Median	0.575
Minimum	0.300
25th percentile	0.500
75th percentile	0.700
Maximum	0.900
Standard deviation	0.157

The comparison between the Basic and Comprehensive Modules shows relatively similar average scores. The Basic Module has an average score of 0.588, while the Comprehensive Module has an average score of 0.598 (Table 7). This result is noteworthy because the Comprehensive Module contains more demanding disclosures, especially on climate risks, GHG targets, human rights incidents, governance diversity, and revenues from sensitive sectors. The slightly higher score for the Comprehensive Module is mainly driven by strong performance on business model, sustainability initiatives, and human-rights-policy disclosures.

Table 7: VSME alignment by module

Module	Mean score	Minimum	Maximum	Standard deviation	N firm-item observations
Basic	0.588	0.000	1.000	0.343	363
Comprehensive	0.598	0.000	1.000	0.422	297

The analysis by thematic area reveals clearer differences, as shown in Figure 1 and summarized in Table 8. General information is the most aligned area, with an average score of 0.814. This suggests that firms tend to disclose basic contextual information, business-model elements, and descriptions of sustainability initiatives relatively well. The Social area also shows a comparatively strong level of alignment, with an average score of 0.644. Environment follows with an average score of 0.511, indicating intermediate alignment. Governance is the weakest area, with an average score of 0.384. This result suggests that governance-related information, especially corruption and bribery sanctions, sensitive-sector revenues, benchmark exclusion, and board gender diversity, remains less systematically reported.

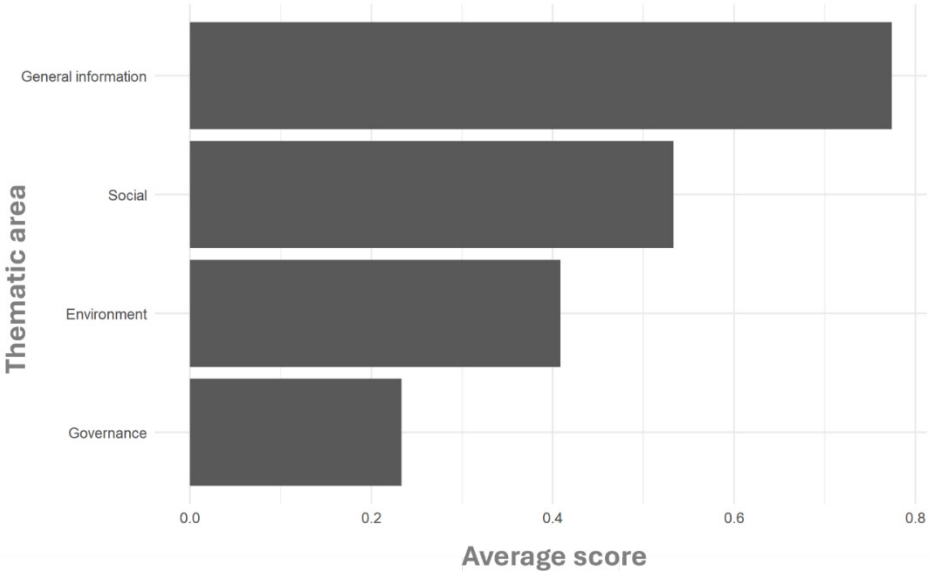

Figure 1: Average VSME alignment score by thematic area

Table 8: VSME alignment by thematic area

Area	Mean score	Minimum	Maximum	Standard deviation	N firm-item observations
General information	0.814	0.500	1.000	0.242	132
Social	0.644	0.000	1.000	0.346	198
Environment	0.511	0.000	1.000	0.362	231
Governance	0.384	0.000	1.000	0.462	99

At the item level, the strongest alignment is observed for C1, Strategy: Business Model and Sustainability-Related Initiatives, with an average score of 1.000. This means that all successfully analysed reports provide sufficient information on the firm's business model and strategic sustainability-related initiatives. High scores are also observed for C2, Description of practices, policies and future initiatives, with an average of 0.894; B2, Practices, policies and future initiatives for transitioning towards a more sustainable economy, with an average of 0.864; C6, Human rights policies and processes, with an average of 0.864; and B7, Resource use, circular economy and waste management, with an average of 0.803.

The weakest items are C8, Revenues from certain sectors and exclusion from EU reference benchmarks, with an average score of 0.121; B5, Biodiversity, with an average score of 0.212; B4, Pollution of air, water and soil, with an average score of 0.333; B11, Convictions and fines for corruption and bribery, with an average score of 0.409; and C3, GHG reduction targets and climate transition, with an average score of 0.439. These results suggest that firms are more likely to provide narrative descriptions of sustainability practices, business models, and workforce-related policies than detailed quantitative disclosures on environmental impacts, governance incidents, or climate-transition targets.

Cluster-level results should be interpreted with caution. Although the sampling strategy was designed to reflect the original cluster structure, the final successfully processed reports are concentrated in cluster 2, with

31 firms, and cluster 3, with only 2 firms. No firm from cluster 1 appears in the final processed item-level dataset. The average score for cluster 2 is 0.579, while the average score for cluster 3 is 0.800. However, given the very small number of observations in cluster 3, this comparison should be treated as descriptive only and not as evidence of statistically robust differences across clusters.

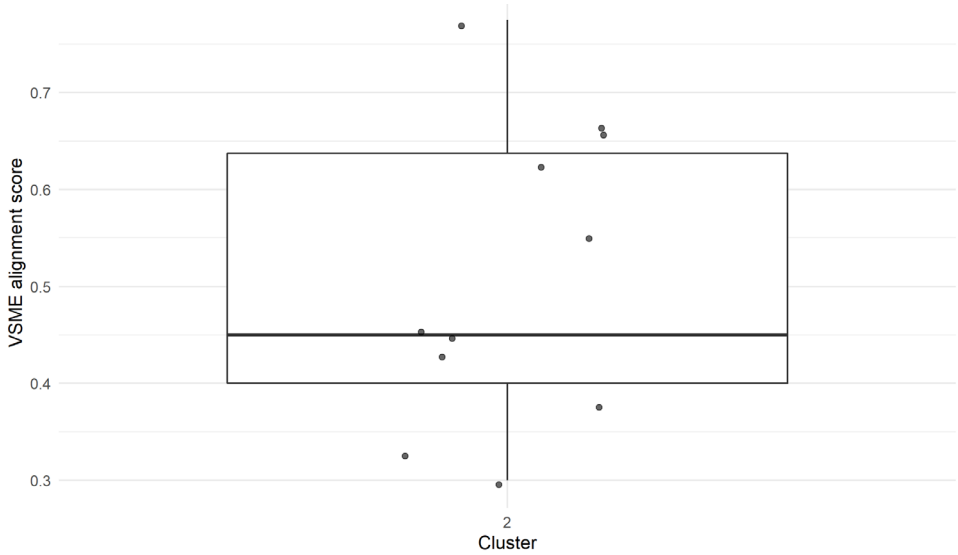

Figure2: Average VSME alignment by cluster

4 Conclusions

Overall, the results show that the analysed Italian firms disclose sustainability information in a way that is partially aligned with the VSME, but alignment is uneven across areas and items. The strongest disclosure practices concern general information, business-model descriptions, sustainability initiatives, and social policies. Conversely, the weakest areas concern governance disclosures, biodiversity, pollution, climate-transition targets, and sensitive-sector revenue information. This pattern suggests that firms are more advanced in qualitative and narrative sustainability reporting than in systematic, quantitative, and VSME-specific disclosure.

From a methodological perspective, the AI-assisted content analysis allowed the systematic coding of a relatively large number of disclosure items across multiple corporate reports. However, the analysis also highlights the importance of document availability and text-extraction quality. Seven out of the 40 selected firms could not be included in the final item-level analysis because the report was missing, technically unreadable, or insufficiently extractable. Future refinements of the analysis may therefore include manual recovery of missing or scanned reports, OCR processing for image-based PDFs, and manual validation of a subset of AI-coded observations to assess coding reliability.

5 Ethics Declaration

This study did not involve human participants, interviews, surveys, experiments, or the collection of personal data. The empirical analysis was based exclusively on publicly available corporate sustainability reports and equivalent sustainability-related disclosure documents. For this reason, no formal ethical clearance was required. All documents were analysed for academic research purposes and are reported only in aggregated form.

6 AI Declaration

This study used AI-assisted tools to support the content analysis of corporate sustainability reports. The AI tool was employed to assist in identifying and coding disclosure information according to the VSME coding grid developed for the study.

AI-assisted tools were also used during the writing process to improve the clarity, readability, grammar, and academic style of selected parts of the manuscript. The use of these tools did not replace the authors' judgement in the design of the study, the definition of the coding framework, the interpretation of the results, or the development of the conclusions.

After using these tools, the authors reviewed, edited, and validated the generated outputs and take full responsibility for the content of the submitted manuscript.

Driving Innovation and Digital Transformation in Cultural Tourism Organizations and Local Ecosystems: Final Insights of the T4Y Project

Francesco Santarsiero, Daniela Carlucci, Antonio Lerro
University of Basilicata, Potenza, Italy

Abstract

Digital transformation is increasingly presented as a necessary pathway for cultural tourism organizations, yet many local and rural ecosystems still struggle to translate digital opportunities into coherent strategies, organizational capabilities, and sustainable business model innovation. This paper presents the final insights of the T4Y research project, which developed and applied models and tools for analysing, mapping and supporting digital transformation and business model innovation in cultural tourism organizations and local ecosystems. The study is grounded in the Tech4You project and adopts an iterative, multi-method and design-oriented research approach. The research process combined an international literature review on digital transformation, digital maturity and business model innovation; an analysis of best practices; the development of a sector-specific Digital Maturity Assessment Model and related assessment tool; qualitative interviews with local stakeholders, operators and institutional actors; survey-based data collection; and participatory workshops in pilot areas in Basilicata, Southern Italy. Findings show that digital transformation in cultural tourism cannot be interpreted as a mere process of technology adoption. Rather, it emerges as a systemic capability involving seven interconnected dimensions: strategy, organization, culture, employees, tourists/customers, operations and technology. The final project insights highlight four main issues. First, digital maturity is uneven and often limited by weak strategic planning, fragmented technological infrastructures, limited use of data and discontinuous collaboration among actors. Second, business model innovation is activated when digital tools are connected to value proposition redesign, stakeholder engagement, experience innovation and territorial identity. Third, participatory tools such as assessment models, SWOT-based reflection, business model mapping and workshops act as boundary objects that transform scattered knowledge into actionable ecosystem learning. Fourth, leadership and relational capabilities are decisive for moving from isolated digital initiatives to coordinated transformation pathways. The paper contributes to knowledge management, digital transformation and tourism innovation research by framing digital maturity as an ecosystem-level knowledge capability and by offering a practical roadmap for cultural tourism organizations and policy makers.

Keywords: Cultural tourism; Digital transformation; Digital maturity; Business model innovation; Innovation ecosystems.

Paper type: Academic Research Paper

1 Introduction

Cultural tourism organizations are facing a double transformation. On the one hand, they are required to preserve, interpret and communicate cultural, historical and natural heritage in ways that remain faithful to local identity. On the other hand, they must respond to new visitor behaviours, platform-based intermediation, data-driven decision-making, sustainability pressures and the growing expectation that tourism experiences should be accessible, personalized and digitally supported. These pressures are particularly relevant in rural and peripheral territories, where cultural and natural resources can represent strong development assets, but where organizations are often small, fragmented and characterized by limited financial and managerial resources.

The debate on digital transformation has progressively moved beyond a narrow understanding of technology adoption. Digital transformation involves changes in strategy, processes, capabilities, culture, value creation logics and inter-organizational relationships (Vial, 2019; Verhoef et al., 2021). In tourism, this change is strongly connected to the smart tourism literature, which emphasizes the integration of digital infrastructures, data, stakeholders and visitor experience (Gretzel et al., 2015; Buhalis and Amaranggana, 2014). However, in cultural tourism ecosystems the adoption of digital tools does not automatically generate innovation. Digital technologies become valuable when they are embedded in organizational learning processes, shared visions and collaborative mechanisms capable of connecting individual organizations with wider territorial systems.

This paper presents the final insights of the T4Y research project, developed within the Tech4You ecosystem, with specific reference to the analysis, mapping and assessment of digital transformation and business model innovation in cultural tourism organizations. The project was designed to support local ecosystems in Basilicata, Southern Italy, by developing models and tools that could combine scientific robustness with practical usability.

Rather than producing a generic digital checklist, the project aimed to understand how cultural tourism organizations can build digital maturity, redesign their business models and activate collaborative innovation dynamics at the ecosystem level.

The paper is positioned as a synthesis and conceptual integration of the main research activities carried out during the project. It builds on previous outputs related to the Digital Maturity Assessment Model, participatory events, digital leadership and business model innovation tools, and it offers a final interpretation of what the project reveals about the digital transformation of cultural tourism ecosystems. The central research question is: How can digital transformation and business model innovation be assessed and supported in cultural tourism organizations and local ecosystems?

To address this question, the paper adopts a multi-method and design-oriented perspective. It reconstructs the development and application of a toolkit composed of a Digital Maturity Assessment Model, a survey-based assessment tool, qualitative interviews, participatory workshops, SWOT-based reflection, business model mapping and a digital transformation roadmap. The contribution is twofold. Theoretically, the paper frames digital maturity as a knowledge-based and ecosystem-level capability, rather than as an internal technological condition of individual organizations. Practically, it offers actionable insights for managers, policy makers and territorial innovation actors interested in strengthening the digital readiness and innovative capacity of cultural tourism systems.

2 Theoretical Background

2.1 Digital transformation and digital maturity in cultural tourism

Digital transformation can be understood as a process through which digital technologies trigger substantial changes in organizational strategy, structures, processes and value creation mechanisms (Bharadwaj et al., 2013; Vial, 2019). This definition is particularly important for tourism and cultural organizations because it avoids reducing digital transformation to the adoption of websites, social media profiles or isolated technological applications. The issue is not only whether an organization uses digital tools, but whether it is able to use them to rethink its relationship with visitors, partners, knowledge resources and territorial value.

Digital maturity models provide a useful way to assess this readiness. They help organizations understand their current position, identify capability gaps and define transformation priorities. However, many maturity models remain either generic or strongly technology-centred. In cultural tourism, this limitation is problematic because digitalization is closely linked to intangible resources, local knowledge, cultural narratives, stakeholder relationships and experience design. A museum, a village, a natural park, an accommodation provider or a destination management actor may all need digital capabilities, but these capabilities must be interpreted in relation to different missions, audiences and territorial roles.

For this reason, the T4Y project developed a sector-specific Digital Maturity Assessment Model structured around seven dimensions: strategy, organization, culture, employees, tourists/customers, operations and technology. These dimensions were conceived as interdependent. Strategy captures the degree to which digital transformation is connected to vision, positioning, collaboration and innovation priorities. Organization concerns structures, learning mechanisms and change management. Culture refers to digital mindset, openness to innovation and entrepreneurial orientation. Employees concern awareness, skills and continuous learning. Tourists/customers focus on digital experience, engagement and relationship management. Operations address data, analytics, resource management and process integration. Technology refers to information systems, infrastructure, security and privacy. Together, these dimensions provide an integrated perspective on digital maturity.

2.2 Business model innovation and ecosystem knowledge

Business model innovation refers to changes in the way organizations create, deliver and capture value (Teece, 2010; Foss and Saebi, 2017). In cultural tourism, business model innovation is not limited to revenue models or digital channels. It includes the redesign of value propositions, visitor journeys, partnerships, knowledge flows, cultural narratives and social impact mechanisms. Digital technologies can support these transformations, but only when they are connected to a broader understanding of value.

Cultural tourism ecosystems are characterized by interdependence. Visitors do not experience a single organization in isolation; they encounter a combination of heritage, hospitality, mobility, food, events, landscape, digital information, storytelling and community relations. Therefore, the innovation capacity of a single actor is often constrained or enabled by the maturity of the wider ecosystem. This perspective is

consistent with ecosystem theory, which highlights the role of complementary actors, shared structures and value co-creation (Adner, 2017; Jacobides et al., 2018). It also resonates with knowledge management research, which emphasizes knowledge creation, sharing and application as collective processes (Nonaka and Takeuchi, 1995; Alavi and Leidner, 2001).

From this viewpoint, digital maturity can be interpreted as a distributed knowledge capability. It depends on the ability of local actors to collect and interpret information, share experiences, align strategic priorities, learn from experimentation and transform tacit territorial knowledge into accessible and sustainable visitor experiences. The T4Y project therefore treated assessment tools and participatory workshops not merely as data collection instruments, but as knowledge translation mechanisms able to make digital transformation visible, discussable and actionable for local actors.

3 Methodology

The study is based on the research activities carried out within the Tech4You project, with a specific focus on cultural tourism organizations and local ecosystems in Basilicata. The research design was iterative, multi-method and design-oriented. Its aim was not only to observe digital transformation, but also to build, test and refine models and tools able to support organizations and territorial actors in their transformation pathways.

The first phase consisted of a literature review on digital transformation, digital maturity, business model innovation, tourism innovation and cultural tourism ecosystems. This phase supported the identification of the main theoretical constructs and informed the design of the assessment model. In parallel, an analysis of national and international best practices was carried out to understand how cultural and tourism organizations approach digital technologies, stakeholder collaboration, visitor engagement and business model redesign.

The second phase focused on tool development. The research team developed a Digital Maturity Assessment Model and a survey-based assessment tool. The tool was then refined through feedback and pilot testing, with the aim of improving clarity, internal coherence and applicability to different types of cultural tourism actors. Additional methodological tools were developed or adapted to connect digital maturity assessment with business model innovation. These included a Business Model Prism for cultural tourism, SWOT-based reflection, digital leadership prompts and workshop formats aimed at stimulating participatory discussion.

The empirical phase combined quantitative and qualitative data. Survey-based assessment was used to collect structured and comparable information on the maturity dimensions. Qualitative interviews with tourism operators, cultural organizations, institutional representatives and local stakeholders were used to interpret the reasons behind the levels of maturity observed and to explore decision-making processes, organizational capabilities, change management practices, collaboration mechanisms and leadership attitudes. Participatory workshops were organized as spaces for validation, knowledge sharing and co-creation. They allowed local actors to discuss results, identify needs and opportunities, and translate evidence into possible innovation directions.

The project covered five pilot areas, enabling a comparative reading of digital maturity and business model innovation dynamics across different territorial contexts. The analysis was conducted through descriptive synthesis, cross-case comparison and thematic interpretation. Rather than treating the data as a purely statistical exercise, the analysis aimed to identify recurring patterns and actionable insights emerging from the combination of survey results, interviews and participatory interactions. This approach is coherent with the practical and theoretical ambition of the project: to produce models and tools that are grounded in empirical evidence while remaining usable for organizations and policy makers.

Table 1: The Digital Maturity Assessment Model developed in the T4Y project

Dimension	Assessment focus	Interpretative role
Strategy	Digital vision, positioning, communication, collaboration and innovation priorities.	Clarifies whether digital transformation is part of a coherent strategic agenda rather than a set of isolated initiatives.
Organization	Structures, roles, learning mechanisms, change management and coordination processes.	Shows whether the organization can translate digital intentions into routines and responsibilities.
Culture	Digital mindset, openness to innovation, experimentation and entrepreneurial attitude.	Captures the cultural conditions that support or constrain transformation.
Employees	Digital awareness, skills, continuous learning and capability development.	Highlights the human capability base needed to use technologies effectively.

Dimension	Assessment focus	Interpretative role
Tourists/customers	Digital experience, engagement, relationship management and visitor understanding.	Connects digital maturity to experience quality and value co-creation.
Operations	Data use, analytics, KPIs, process integration, automation and resource management.	Indicates whether digital tools support operational learning and evidence-based decisions.
Technology	Information systems, infrastructure, interoperability, security and privacy.	Assesses the enabling technological foundations of transformation.

4 Findings: Final Insights from the T4Y Project

4.1 Digital maturity is multidimensional and uneven

The first final insight is that digital maturity in cultural tourism organizations is multidimensional and uneven. The project confirmed that organizations may be relatively active in some visible digital practices, such as online communication or social media use, while remaining weak in strategic planning, operational data use, integrated systems or capability development. This means that digital presence should not be confused with digital maturity. A cultural tourism organization may be visible online without having a clear digital strategy, structured visitor data, integrated processes or a shared understanding of how digital tools contribute to long-term value creation.

Across the pilot areas, the most critical issues concerned the fragmentation of digital initiatives, the limited formalization of digital objectives and the difficulty of connecting technological choices to measurable outcomes. Many actors recognized the importance of digital transformation, but this recognition did not always translate into systematic planning or investment priorities. The operational dimension was particularly relevant: data, analytics and key performance indicators were often underused, limiting the capacity of organizations to learn from visitors, monitor processes and evaluate the impact of innovation initiatives.

At the same time, the assessment revealed positive conditions on which transformation can build. Cultural tourism actors possess strong territorial knowledge, relational proximity, authenticity and awareness of the value of heritage. These resources represent a strategic basis for digital transformation, provided that they are connected to appropriate capabilities and collaborative mechanisms. Digital transformation should therefore start from existing local strengths rather than importing generic technological solutions disconnected from place-based identity.

4.2 Digital transformation becomes valuable when connected to business model innovation

The second insight concerns the relationship between digital transformation and business model innovation. The project showed that digital tools generate limited value when they are used only to improve communication or automate existing activities. Their transformative potential emerges when they support a rethinking of the organization's value proposition, visitor relationships, partnerships, internal processes and social or cultural impact.

The Business Model Prism used in the project helped actors reflect on how cultural tourism organizations create and capture value. It encouraged them to move beyond the question of which technologies to adopt and to ask why digitalization is needed, for whom value is created, which resources and partnerships are required, and how benefits can be distributed across the ecosystem. For example, digital storytelling, immersive experiences, booking platforms, data dashboards, customer relationship management tools or collaborative online maps can all be relevant. However, their value depends on whether they contribute to clearer positioning, stronger engagement, better coordination or more sustainable use of cultural and natural resources.

This finding is important because it positions business model innovation as the bridge between technological adoption and ecosystem development. In cultural tourism, the business model is often hybrid: it includes economic, cultural, social and territorial forms of value. A digital transformation roadmap should therefore avoid a narrow efficiency logic and should include questions of accessibility, inclusion, heritage interpretation, community participation and long-term sustainability.

4.3 Participatory tools act as boundary objects for ecosystem learning

The third insight concerns the role of tools. The assessment model, survey, SWOT analysis, Business Model Prism and workshop formats did not simply produce data for researchers. They functioned as boundary objects: practical artefacts that enabled different actors to discuss digital transformation using a common language. This

was particularly important in fragmented ecosystems, where organizations, institutions and stakeholders may have different priorities, vocabularies and expectations.

Participatory workshops created spaces in which local actors could interpret assessment results, compare perspectives and identify shared priorities. In this sense, the project generated not only analytical knowledge, but also relational and actionable knowledge. The workshops helped transform digital maturity from an abstract concept into a concrete topic of discussion. They also supported the emergence of needs, barriers and opportunities that would be difficult to capture through survey data alone.

This finding has implications for knowledge management. In cultural tourism ecosystems, knowledge is distributed among many actors and is often tacit, experiential and place-based. Assessment tools become useful when they help externalize this knowledge, connect it with structured evidence and translate it into decisions. The value of a maturity model is therefore not only diagnostic. It is also educational and mobilizing, because it can stimulate awareness, align actors and support the design of coordinated actions.

4.4 Leadership and relational capabilities enable the transition from projects to transformation

The fourth insight is that leadership is decisive for moving from individual digital projects to systemic transformation. Interviews and stakeholder interactions highlighted that digital transformation depends on people who are able to interpret opportunities, mobilize resources, build trust and connect actors. In many cultural tourism organizations, leadership is not only a formal managerial function. It is also a relational capability distributed across entrepreneurs, public administrators, cultural operators, associations, technology providers and community representatives.

The T4Y project highlighted the relevance of pragmatic, sustainable, facilitative, communicative, catalytic and informed leadership attitudes. Pragmatic leadership helps translate broad digital ambitions into feasible actions. Sustainable leadership connects innovation with long-term territorial value. Facilitative leadership enables participation and collaboration. Communicative leadership makes digital transformation understandable. Catalytic leadership activates change and experimentation. Informed leadership supports decisions based on evidence rather than intuition alone.

These leadership capabilities are particularly important in local ecosystems, where no single actor controls the whole visitor experience or the entire transformation process. The challenge is therefore not only to improve the digital skills of individual organizations, but to develop the capacity of the ecosystem to sense opportunities, share knowledge, coordinate initiatives and scale successful practices.

4.5 The roadmap should be progressive, situated and ecosystem-oriented

The final insight concerns the roadmap for digital transformation. The project suggests that cultural tourism organizations and local ecosystems should avoid both technological acceleration without readiness and excessive planning without experimentation. A useful roadmap should be progressive, situated and ecosystem-oriented. It should start from awareness and assessment, move towards capability building and targeted experimentation, and then consolidate practices through governance, data use and collaboration.

A first step is to map digital maturity and identify shared priorities. A second step is to strengthen basic capabilities, including digital skills, data literacy, communication practices and awareness of available technologies. A third step is to redesign selected visitor experiences and internal processes, connecting technology to business model innovation. A fourth step is to build ecosystem infrastructures, such as common data practices, shared storytelling strategies, partnership mechanisms and innovation labs or workshops. A final step is to institutionalize learning through monitoring, evaluation, governance and continuous improvement.

This roadmap is not intended as a linear recipe. Cultural tourism ecosystems differ in resources, governance arrangements, digital readiness and stakeholder relationships. The roadmap should therefore be adapted to each local context. Its main value lies in helping actors move from scattered initiatives to coherent transformation pathways.

Table 2: Final insights and implications

Final insight	Ecosystem implication	Managerial and policy implication
Digital maturity is multidimensional and uneven.	Ecosystems may show digital visibility without strategic, operational or technological integration.	Assess maturity across strategy, organization, culture, employees, tourists/customers, operations and technology before defining interventions.

Final insight	Ecosystem implication	Managerial and policy implication
Digital transformation becomes valuable when linked to business model innovation.	Technology adoption should support value proposition redesign, experience innovation and territorial value creation.	Use business model mapping to connect digital tools with value, partners, processes and impact.
Participatory tools act as boundary objects.	Shared tools help fragmented actors create a common language and transform tacit knowledge into actionable priorities.	Combine surveys, interviews, workshops and SWOT-based reflection to support collective learning.
Leadership and relational capabilities enable transformation.	No single actor can lead the whole ecosystem; transformation requires distributed leadership and trust.	Develop facilitative, communicative, pragmatic, sustainable, catalytic and informed leadership capabilities.
Roadmaps should be progressive and situated.	Transformation depends on local identity, resources and collaboration maturity.	Move from assessment to capability building, experimentation, ecosystem infrastructure and continuous evaluation.

5 Discussion

The findings offer three main contributions to the literature on knowledge management, digital transformation and cultural tourism innovation. First, the paper advances the idea that digital maturity should be understood as an ecosystem-level knowledge capability. Existing approaches often focus on the digital readiness of individual organizations. The T4Y project shows that, in cultural tourism, the transformation capacity of a single organization is deeply connected to the knowledge, resources and coordination mechanisms of the wider ecosystem. Digital maturity is therefore not only a property of internal systems; it is also a relational condition that emerges through interaction among actors.

Second, the paper contributes to the debate on business model innovation by showing that cultural tourism organizations require value frameworks that include economic, cultural, social and territorial dimensions. Digital technologies can support new forms of value creation, but they must be interpreted through the specific mission of cultural tourism: preserving heritage, enriching visitor experience, involving communities and strengthening the attractiveness and resilience of territories. This perspective extends business model innovation research by emphasizing hybrid value creation and place-based knowledge.

Third, the paper contributes methodologically by showing how assessment tools can be used not only for measurement, but also for engagement and learning. The T4Y toolkit created a bridge between academic research and territorial practice. It allowed the research team to collect structured data, while also enabling local actors to understand, discuss and use evidence. This dual function is particularly relevant for IFKAD and knowledge management scholarship because it highlights how knowledge assets can be translated into innovation dynamics through participatory and actionable devices.

The paper also contributes to the debate on the theme of intelligent knowledge for sustainable organizations. Intelligent knowledge is not limited to advanced technological systems. In local cultural tourism ecosystems, it also concerns the capacity to combine data, human judgment, cultural identity, stakeholder experience and strategic action. The T4Y project suggests that sustainable digital transformation requires hybrid knowledge processes: structured assessment, participatory interpretation, leadership, experimentation and continuous learning.

6 Practical Implications

For managers of cultural tourism organizations, the main implication is that digital transformation should be governed as an organizational and strategic process. Before investing in technologies, organizations should clarify their digital objectives, assess their capabilities and identify how digital tools can improve visitor experience, internal processes and stakeholder relationships. They should also avoid treating communication channels as the whole of digital transformation. Social media presence, websites and online promotion are important, but they represent only one part of a broader transformation journey.

For policy makers and territorial development agencies, the findings suggest the importance of ecosystem-level interventions. Many small organizations cannot develop advanced digital capabilities alone. They need shared infrastructures, training opportunities, advisory services, data practices, innovation spaces and collaborative projects. Public policies should therefore support not only funding for technologies, but also capability building, knowledge sharing and governance mechanisms that connect cultural, tourism, technological and institutional actors.

For universities and research organizations, the project demonstrates the value of engaged research. The role of the university is not only to study digital transformation from outside, but also to design tools, facilitate workshops and support evidence-based decision-making. This approach strengthens the third mission of universities and contributes to the development of territorial innovation ecosystems.

7 Conclusions

This paper presented the final insights of the T4Y project on innovation and digital transformation in cultural tourism organizations and local ecosystems. The project developed and applied a set of models and tools aimed at assessing digital maturity, supporting business model innovation and activating stakeholder engagement in pilot areas in Basilicata. The results show that digital transformation in cultural tourism is a complex and multidimensional process that cannot be reduced to technology adoption.

The main conclusion is that cultural tourism ecosystems need to develop digital maturity as a collective capability. This capability includes strategy, organization, culture, employees, tourists/customers, operations and technology, but it also requires leadership, collaboration and knowledge translation. The T4Y project showed that assessment models and participatory tools can help actors make sense of their current condition, identify gaps and design more coherent transformation pathways.

The study has limitations. The empirical work is grounded in specific local contexts in Basilicata, and the findings should be further validated in other regions and cultural tourism ecosystems. Moreover, the paper provides an integrative synthesis of project results rather than a detailed statistical analysis of each pilot area. Future research could extend the assessment model to additional contexts, develop longitudinal analyses of digital maturity evolution, integrate the tools into digital platforms or decision-support systems, and examine how artificial intelligence can support data-driven and human-centred cultural tourism innovation.

Despite these limitations, the paper offers a practical and theoretical contribution. It provides a final synthesis of the T4Y project and shows how digital transformation, business model innovation and knowledge management can be connected to support more sustainable, adaptive and collaborative cultural tourism ecosystems.

8 Acknowledgements

This paper is based on the research activities carried out within the Tech4You project - Technologies for Climate Change Adaptation and Quality of Life Improvement, code ECS_00000009, CUP C43C22000400006, with specific reference to the activities related to digital transformation and business model innovation in cultural tourism organizations and ecosystems. The authors acknowledge the contribution of all organizations, stakeholders and institutional actors involved in the project activities and participatory workshops.

9 Ethics declaration

Ethical clearance was not required for this research according to the institutional procedures applicable to the project activities. The study involved organizational and stakeholder-level data collection, interviews and participatory workshops. No sensitive personal data are reported in this paper. Participation in interviews and workshops was voluntary and the results are presented in aggregated and interpretative form.

10 AI declaration

AI tools were used to support the editorial refinement of this manuscript. The authors take full responsibility for the accuracy, validity and integrity of the research design, data collection, analysis, interpretation and final manuscript. All AI-assisted text was critically reviewed, verified and accepted by the authors.

Artificial Intelligence in Supply Chains: A Systematic Review and Knowledge Mapping of Research Trends

Benedetta Pini[1], Laura Monferdini[1], Barbara Bigliardi[1,2], Eleonora Bottani[1]
[1] University of Parma, Parma, Italy
[2] University of the Republic of San Marino, Dogana, San Marino

Abstract

Over the last decades, supply chain management has undergone a profound transformation, driven not only by rapid technological advancements but also by the increasing complexity and globalization of markets, the growing volatility of demand, and the emergence of new competitive, environmental, and institutional pressures that require greater efficiency, transparency, and adaptability. In this context, Artificial Intelligence (AI) has emerged as a key enabler of supply chain (SC) transformation, offering significant improvements in decision-making processes the optimization of the operations the enhancement of efficiency, resilience and sustainability. Despite the growing academic and managerial interest, the literature on AI in SCs remains fragmented across disciplines, sectors, and application domains.

This study aims to provide a systematic and integrated overview of the role of AI in SCs by identifying its main areas of application, emerging research trajectories, and key challenges associated with its adoption. To achieve the results, the research adopts a systematic literature review approach configured as a meta-review, focusing exclusively on review-type articles. The study adopts a systematic literature review approach configured as a meta-review, based on review articles retrieved from the Scopus database. The analysis integrates descriptive statistics with bibliometric techniques supported by VOSviewer.

The results reveal a non-uniform distribution of research, with a strong concentration in specific application domains, particularly agri-food, Supply chain-related areas such as logistics and distribution. AI applications in these domains primarily focus on demand forecasting, process optimization, traceability, and quality control. Emerging trends highlight the increasing relevance of sustainability, resilience, and digital integration, supported by complementary technologies such as blockchain, Internet of Things (IoT), and big data. At the same time, significant gaps persist, including the uneven maturity of AI applications across sectors, with some areas showing advanced implementation while others remain at an early stage. Limited technological integration, and insufficient attention to ethical and governance issues emerged.

Overall, the findings suggest that the main challenge is not the lack of interest in AI, but the need for strategies to fully exploit the potential of these technologies in managing various aspects of the SC. Based on this consideration, further research is needed to develop approaches capable of addressing the adoption of AI.

Keywords: Artificial Intelligence (AI), supply chain, Innovation, Industry 4.0 (I4.0), systematic literature review

Paper type: Academic Research Paper

1 Introduction

Over the last decades, supply chain management has undergone a profound transformation, driven by rapid technological advancements, the increasing complexity of global markets, and the emergence of new competitive, environmental, and institutional pressures (Christopher, 2022; Mentzer et al., 2001). In this evolving landscape, organizations are required to manage highly interconnected and dynamic systems, where efficiency alone is no longer sufficient. Instead, supply chains (SCs) must simultaneously ensure resilience, adaptability, transparency, and sustainability in response to growing uncertainty and disruption (Ivanov, 2019; Dubey et al., 2020).

In this context, Artificial Intelligence (AI) has progressively emerged as one of the most promising and disruptive technologies, capable of reshaping operational models, decision-making processes, and coordination mechanisms across the entire SC (Queiroz et al., 2020). AI-driven solutions enable firms to process large volumes of data, generate predictive insights, and support complex decisions in real time, thereby enhancing responsiveness and improving overall system performance (Baryannis et al., 2019). As a result, AI is increasingly recognized not merely as a technological tool, but as a strategic enabler of SC transformation.

The evolution of SCs is closely interlinked with the major stages of the industrial revolutions. The First Industrial Revolution laid the foundations for coordinating production and logistics flows through mechanization and the development of transportation infrastructures. Subsequently, the Second Industrial Revolution introduced mass production, electrification, and vertical integration, enabling SCs to expand beyond local boundaries and evolve into more structured systems (Chopra & Meindl, 2001). A major turning point occurred with the Third Industrial Revolution, characterized by the introduction of digitalization, automation, and

integrated information systems, which significantly improved efficiency, visibility, and coordination across SC processes (Efthymiou et al., 2021). Building on these developments, the Fourth Industrial Revolution, or Industry 4.0, has further accelerated this transformation by fostering interconnected, intelligent, and data-driven SCs through the integration of advanced technologies such as the Internet of Things (IoT), Big Data, blockchain, and AI (Frank et al., 2019; Ivanov et al., 2019).

In this scenario, AI plays a central role as an enabling technology for the creation, processing, and exploitation of knowledge along the SC (Sharma et al., 2024). Machine learning algorithms and predictive analytics techniques support complex decision-making processes, enhance planning capabilities, optimize inventory management and logistics flows, strengthen traceability, and improve responsiveness in uncertain and high-risk environments (Min, 2010; Baryannis et al., 2019).

More recently, the emergence of the Industry 5.0 paradigm has further expanded this perspective by placing human centricity, environmental sustainability, and system resilience at the core of industrial development. From this perspective, AI is no longer just a tool for automation, but also supportshuman–machine collaboration, circular economy practices and value creation across SCs (Longo et al., 2020; Nahavandi, 2019).

Despite growing academic and managerial interest, the adoption of AI in SCs is not without challenges. The literature highlights several critical barriers, including high implementation costs, shortages of specialized skills, difficulties in integrating AI solutions with legacy systems, and organizational resistance to change (Dwivedi et al., 2021; Kshetri, 2021). Furthermore, various ethical issues (e.g., data privacy, algorithmic bias, and transparency) may hinder the effective integration of AI into strategic processes.

Based on the above, this study aims to provide an integrated and critical overview of the state of the art on the application of AI in SCs through a systematic literature review approach. Specifically, the research is designed as a meta-review focusing exclusively on review-type articles, with the objective of synthesizing, comparing, and interpreting consolidated scientific contributions in the field (Tranfield et al., 2003).

The paper is structured as follows. Section 2 presents the objectives and the methodologies adopted in order to achieve the results, described in section 3. Finally, the conclusions along with the limitations and the future research of the study are presented.

2 Objective and Methodology

The present study aims to systematically analyze the role of AI in SCs, with the objective of understanding its main application domains, the emerging trajectories of research, and the implications arising from its adoption across different organizational and industrial contexts. More specifically, the study investigates how AI is applied along SC processes, which technological development paths are shaping the scientific debate, and how these applications relate to key issues such as sustainability, digital transformation, risk management, resilience, and ethical concerns. From this perspective, the paper seeks not only to reconstruct the current state of the literature, but also to identify the main knowledge gaps and the areas that require further theoretical and empirical investigation.

To address these objectives, the research is based on a literature analysis combining descriptive and bibliometric approaches, in order to map the structure of the field and identify the connections among its main emerging themes. This methodological choice is particularly suitable for investigating a rapidly growing and fragmented research domain, such as AI in SCs, where contributions are dispersed across different disciplines, sectors, and technological perspectives (Donthu et al., 2021; Zupic & Čater, 2015).

The literature review was designed as a *review of reviews (Grant and Booth, 2009)*, focusing exclusively on review-type articles. This choice responds to the need to provide a structured, critical, and comparative overview of an expanding body of knowledge by integrating already consolidated scientific contributions. In this way, the analysis goes beyond a mere summary of existing studies and aims instead to interpret and connect them, so as to highlight convergences, divergences, recurring thematic cores, and persistent gaps in the debate. Such an approach is particularly appropriate in a field like AI applied to SCs, which is characterized by a strong heterogeneity of perspectives, application contexts, and technologies (Tranfield et al., 2003).

The data collection process was carried out using the Scopus database, selected for its broad interdisciplinary coverage, the quality of its metadata, and the possibility of applying advanced filters to ensure rigor and transparency in the selection procedure. The corpus was built through an initial query based on the terms "*artificial intelligence*" and "*supply chain*", searched within titles, abstracts, and keywords.

This first search returned 4,419 documents. The dataset was then progressively refined according to inclusion criteria consistent with the objectives of the study. First, the search was restricted to review articles only, reducing the number of documents to 303. Second, only English-language publications were retained, which reduced the sample to 296 documents. Finally, works published in 2025 were excluded in order to avoid the

inclusion of overly recent contributions that may still be incomplete or unstable. The final corpus therefore consisted of 290 documents. The final search string was as follows:

TITLE-ABS-KEY ("artificial intelligence" AND "supply chain") AND (LIMIT-TO (DOCTYPE, "re")) AND (LIMIT-TO (LANGUAGE, "English")) AND (EXCLUDE (PUBYEAR, 2025))

Once the corpus was defined, the documents were analyzed by combining a descriptive examination of bibliographic metadata with a bibliometric analysis supported by the software VOSviewer. The descriptive analysis examine year of publication, most productive authors, top journals, and the distribution of contributions across different application domains. The bibliometric component, in turn, enabled a deeper investigation of the intellectual structure of the field through network analysis, which is particularly useful for mapping the main nodes of the literature and the relationships among them (van Eck & Waltman, 2010).

More specifically, the analysis focused on the co-occurrence of keywords, with the aim of identifying the main thematic clusters, the most central concepts, and the principal evolutionary trajectories of the scientific debate. In this sense, the integration of descriptive and bibliometric analysis allowed both a quantitative mapping of the field and a qualitative interpretation of its internal dynamics and conceptual development (Donthu et al., 2021; Zupic & Čater, 2015).

3 Results

3.1 Descriptive analysis

Figure 1 shows the trend over time in scientific publications focusing on the application of AI in SCs. The data reveal a significant increase in the number of from 2019 onward and a peak reached in 2024. This trend indicates the progressive consolidation of the topic within both academic and managerial debates, as well as the growing recognition of AI as a strategic lever for SC transformation.

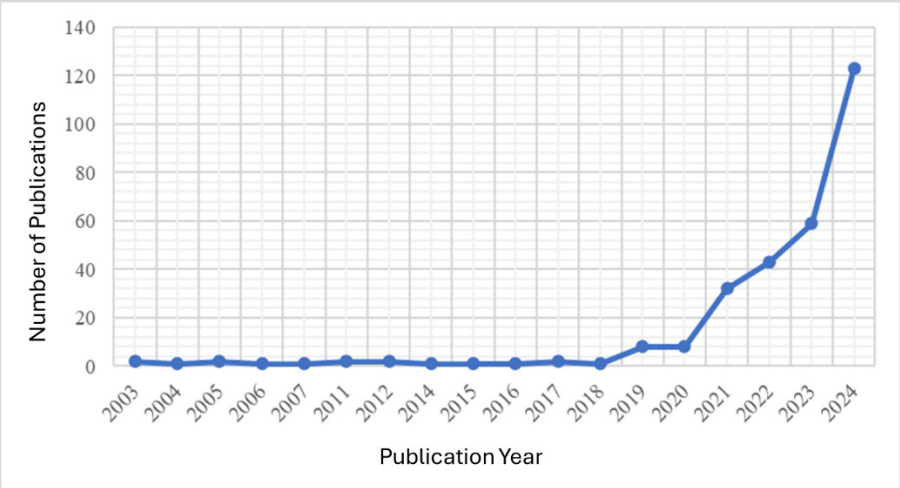

Figure 1. Number of publications by year.

The earliest contribution identified in the analyzed corpus is the article by Choy et al. (2003), which focuses on an intelligent system for supplier selection and benchmarking. This work can be considered pioneering, as it anticipated the use of AI as a support tool for decision-making processes in SC management, particularly in procurement activities. At a time when the adoption of intelligent technologies was still limited, this study had already introduced the potential of AI to improve transparency, efficiency, and objectivity in supplier evaluation decisions.

Until 2019, the annual number of publications remained relatively limited, suggesting an early stage in the development of the field, during which AI applications in SCs were still constrained by technological, infrastructural, and organizational limitations. From 2019 onward, however, the number of studies increased exponentially. This acceleration appears to be attributable to several factors. First, the rapid advancement of techniques such as machine learning, deep learning, and predictive analytics significantly expanded the application potential of AI in SC processes. Second, recent global crises, particularly the COVID-19 pandemic, highlighted the vulnerability of SCs and reinforced interest in intelligent solutions capable of improving

resilience, visibility, and predictive capacity. Finally, growing institutional and industrial support for digitalization fostered investments and experimentation in logistics and production settings.

Overall, the temporal dynamics of publications confirm that AI has evolved from an emerging topic into a consolidated research stream, becoming one of the principal drivers of digital transformation in SCs.

Figure 2 presents the main authors by number of publications, considering those with at least three contributions in the analyzed corpus.

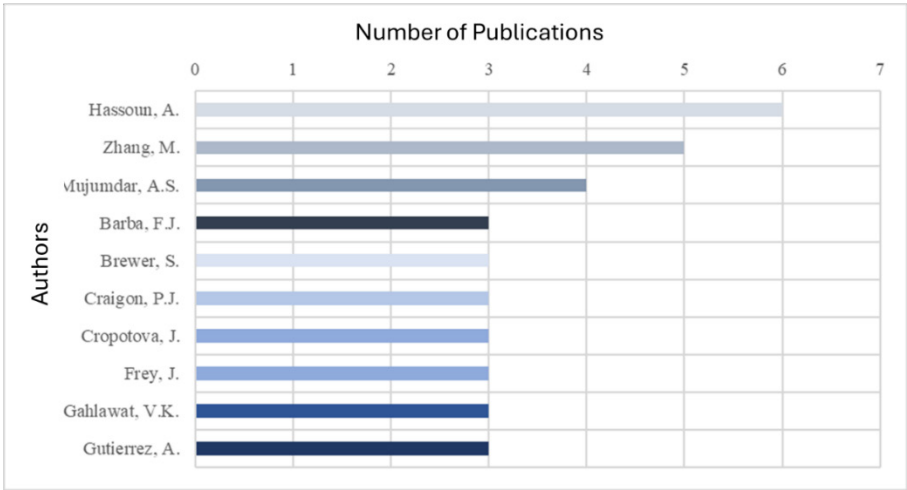

Figure 2. Top authors

The analysis reveals the presence of several particularly active scholars whose work reflects the main thematic orientations of the literature. In particular, a core group of contributions is strongly concentrated in the agri-food sector, confirming the central role of this sector in research on AI. These studies mainly explore the integration of AI, blockchain, the IoT, digital twins, and smart packaging for monitoring quality, safety, traceability, and logistics optimization in food SCs.

Alongside this stream, a second group of studies highlights the growing attention devoted to the ethical and governance implications of adopting intelligent technologies in SCs. These contributions emphasize issues such as transparency, accountability, data management, and the need for shared ethical languages among SC actors., showing that AI adoption is not only a technical matter, but also raises important social and ethical issues.

A further stream concerns the use of AI to address major challenges related to sustainability, resilience, and innovation in agri-food and manufacturing systems. In this context, digital technologies are increasingly regarded as essential tools for coping with geopolitical instability, climate change, health crises, and growing pressure toward more sustainable production models. Overall, the literature appears to be moving beyond isolated technological applications and is progressively framing AI as a cross-cutting driver of organizational transformation, sustainability, and systemic innovation.

Figure 3 shows the leading scientific journals by number of publications. The analysis highlights a strong heterogeneity of publication outlets, which reflects the interdisciplinary nature of the topic. Among the most relevant journals are *Sustainability*, *Trends in Food Science and Technology*, *International Journal of Production Research*, *Heliyon*, *Logistics*, *Computers and Electronics in Agriculture*, *Energies*, *Foods*, *IEEE Access*, and *Science of the Total Environment*. The distribution of publications across these outlets makes it possible to identify three main areas of convergence.

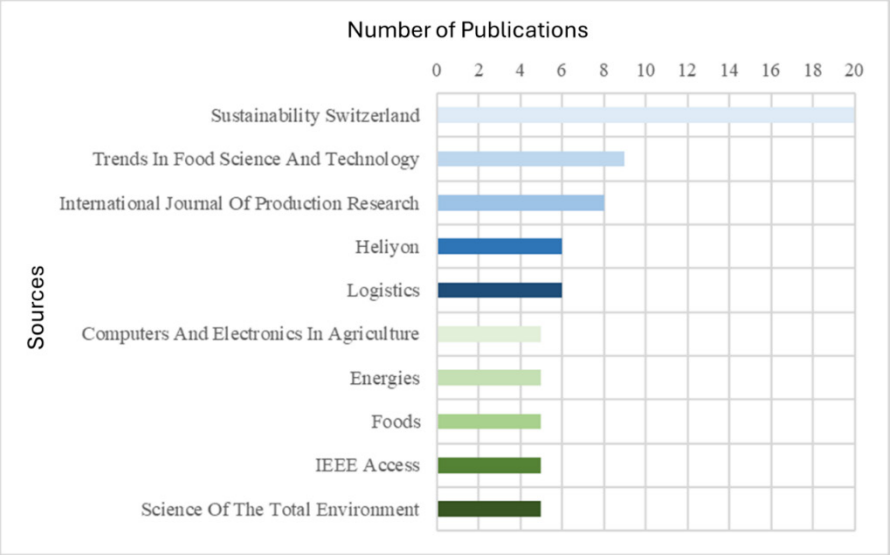

Figure 3. Top sources.

Sustainability concerns the link between technologies and environmental issues. The second (i.e., *Trends in Food Science and Technology*) is more closely related to the technological innovation in agri-food systems, where AI is studied in relation to quality, safety, traceability, and waste reduction. The third (i.e., *International Journal of Production Research*) deals with the more strictly managerial and engineering dimension, with studies focusing on process optimization, forecasting, risk management, and automation. Taken together, these journals demonstrate that research on AI in SCs lies at the intersection of management, technology, sustainability, and applied sciences.

Figure 4 presents the distribution of publications across application domains. The results show a clear predominance of the food and agriculture industry, which represents the sector with the highest number of contributions. In this domain, AI is mainly applied to quality and food safety monitoring, optimization of production and agricultural processes, waste reduction, automation in precision agriculture, and the improvement of product traceability along the SC.

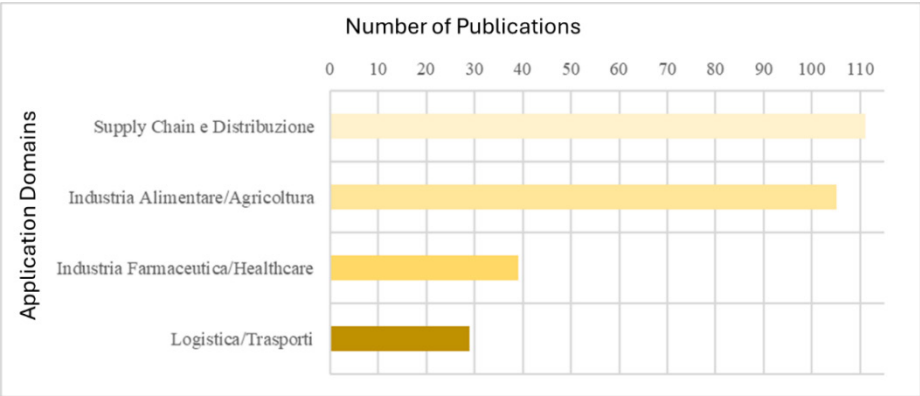

Figure 4. Main application domains.

A second particularly relevant domain concerns SC and distribution management in a broader sense. In these studies, AI is mainly employed for demand forecasting, inventory optimization, logistics flow planning, and the enhancement of transparency and resilience through integration with technologies such as blockchain and machine learning. This is followed by the pharmaceutical/healthcare and logistics/transportation areas, which also show a considerable number of contributions and growing academic interest. In these contexts, the main applications concern monitoring environmental conditions along the SC, forecasting the demand for drugs and medical devices, supporting distribution in emergency situations, and optimizing transport operations.

This analysis confirms that AI is now recognized as a strategic lever for improving efficiency, resilience, and sustainability across different industrial contexts. At the same time, it reveals a concentration of research in certain areas, whereas others remain less developed, thus suggesting opportunities for further investigation.

3.2 Network analysis

Figure 5 presents the co-occurrence map of author keywords generated through VOSviewer. In the middle of the network the terms “artificial intelligence”, “machine learning”, and “SC management” appear; these constitute the main nodes of the field’s thematic structure. This centrality is partly because these terms reflect the query used to construct the sample of papers under analysis; however, they also act as conceptual nodes capable of connecting different sub-streams of the literature.

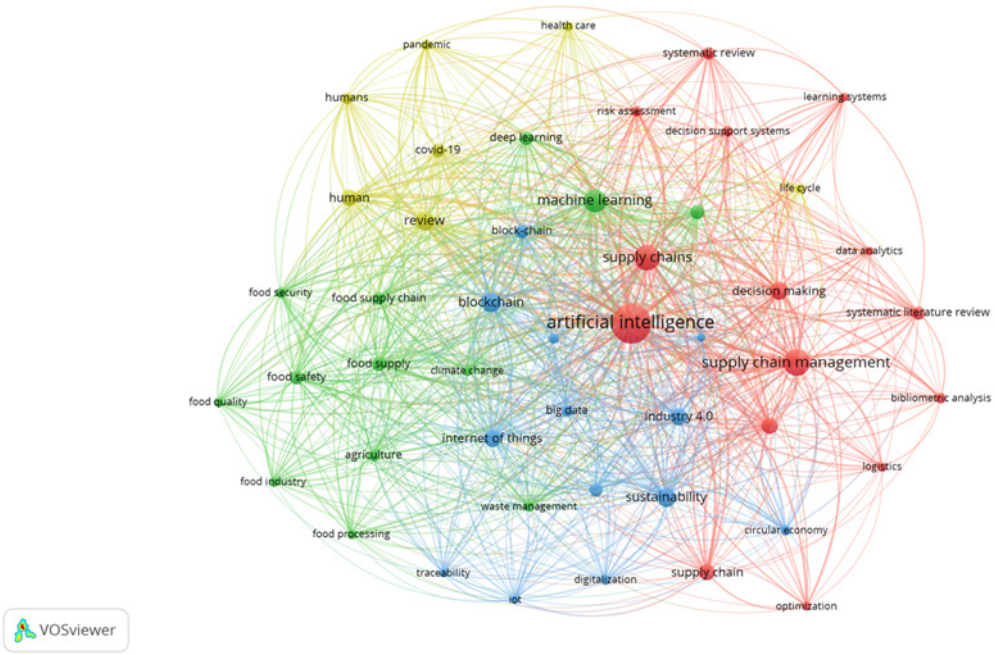

Figure 5. Co-occurence mapping of author keywords (source: VOSviewer).

Several thematic clusters are organized around these central nodes. A first cluster gathers enabling digital technologies such as IoT, blockchain, big data, and deep learning, highlighting the close relationship between AI and broader digitalization processes in SCs. From this perspective, AI does not emerge as an isolated technology, but rather as a component of an integrated digital ecosystem in which data availability, connectivity, and interoperability among systems play a fundamental role.

A second cluster concerns operational applications and the main improvement goals of SCs, with keywords such as traceability, food safety, quality control, and logistics. The proximity of these terms to the central nodes indicates that the literature mainly considers AI adoption as a lever for improving safety, transparency, reliability, and efficiency along the value chain, with particular relevance in the agri-food sector.

A third thematic core is formed by sustainability-related terms, including sustainability, environmental impact, and resource optimization. Their presence and interconnection with the technological and managerial clusters suggest that more recent research no longer interprets AI solely as a tool for improving efficiency, but increasingly as an enabling factor for sustainable, resilient, and resource-efficient SCs. In this sense, the map confirms the progressive integration of the digital agenda with the sustainability agenda.

The network also reveals a marked interdisciplinarity. Terms related to computer science, industrial engineering, logistics, food safety, and environmental studies are strongly intertwined, demonstrating that innovation in this field is rooted in the interaction among different theoretical perspectives and competencies. Keywords such as decision support systems, predictive analytics, and automation further reinforce the idea that one of AI’s main contributions to SCs lies in its ability to support decision-making, anticipate disruptions, and improve coordination across actors and activities.

Figure 6, which presents the temporal overlay visualization of keyword co-occurrences, makes it possible to reconstruct the evolution of the field over time. The terms displayed in blue-violet, corresponding to earlier streams, mainly concern the classical concepts of the discipline, such as SC management, logistics, optimization, decision support systems, and systematic review. This initial stage reflects a predominantly managerial orientation focused on operational efficiency and process optimization.

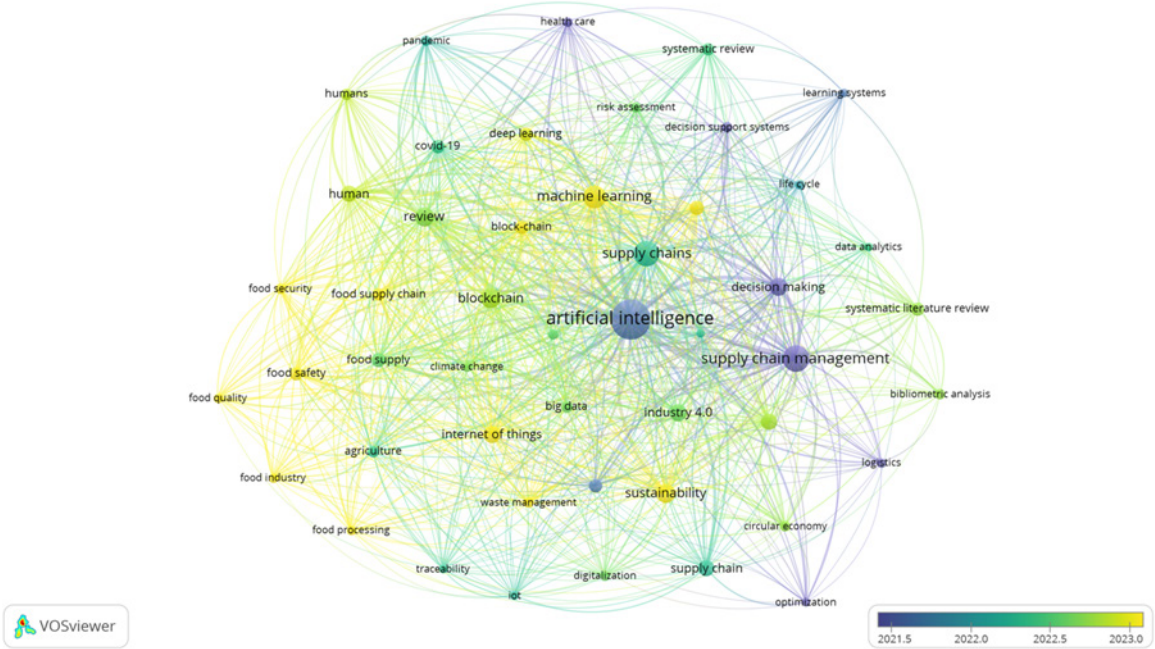

Figure 6. Network Analysis – Keywords Co-Occurrence Analysis Overlay Visualization (source: VOSviewer).

In the intermediate phase, between 2021 and 2022, terms such as artificial intelligence, machine learning, data analytics, industry 4.0, digitalization, risk assessment, and decision making become more prominent. This configuration signals a transition toward increasingly data-driven and predictive SCs, in which AI begins to be understood not merely as a tool for automation, but as a cognitive architecture supporting the analytical, learning, and adaptive capabilities of organizations.

In the most recent part of the map, highlighted in yellow, attention shifts toward themes such as sustainability, circular economy, waste management, and traceability, often associated with specific application domains, particularly agri-food. At the same time, complementary technologies such as blockchain, Internet of Things, and big data become more visible, as they are considered essential for ensuring data integrity, visibility, and reliability along the SC. The term associated with the pandemic context also remains present, having accelerated interest in resilience, digitalization, and adaptive capacity in SCs.

Overall, the temporal overlay reveals a clear evolutionary trajectory: from an initial phase centered on optimization and decision support, the field has moved toward a progressive integration of AI, machine learning, and analytics, eventually reaching a growing emphasis on sustainability, transparency, traceability, and advanced sectoral applications. AI remains the conceptual core of the field, but the most dynamic and recent themes are those that connect digitalization, sustainability, and SC governance.

4 Conclusion, Limits and Future research Agenda

This study provides a systematic and integrated overview of the role of AI in SCs through a meta-review approach supported by bibliometric techniques. The findings highlight how AI is increasingly shaping the transformation of SCs by enhancing operational efficiency, predictive capabilities, resilience, and transparency. In particular, the analysis reveals a strong concentration of research in specific application domains, such as the agri-food sector, SC and distribution management, and, more recently, healthcare and logistics.

Overall, the results confirm that AI should no longer be interpreted merely as a technological tool, but rather as a strategic enabler capable of supporting the transition toward data-driven, interconnected, and value-oriented SC models. At the same time, the literature shows a gradual shift from efficiency-oriented perspectives toward broader approaches that increasingly incorporate sustainability, traceability, and risk management. However, such evolution remains uneven and fragmented, indicating the need for further theoretical and empirical development.

From a theoretical perspective, this study contributes by systematizing a fragmented body of knowledge, identifying key thematic clusters, and reconstructing the intellectual structure and evolution of the field. From a managerial standpoint, the findings suggest that AI adoption requires not only technological investments but also organizational transformation, development of new competencies, and stronger integration across systems

and actors within the SC. A systemic perspective is therefore essential to jointly address efficiency, sustainability, and resilience.

Despite its contributions, this study presents some limitations. First, the analysis is based exclusively on review articles. While this choice ensures a high level of abstraction and allows for the synthesis of consolidated knowledge, it may limit the inclusion of recent empirical insights emerging from primary studies. Second, the use of a single database (Scopus), although comprehensive and widely recognized, may have excluded relevant contributions indexed in other databases. Thirdly, whilst the bibliometric approach is effective in identifying research patterns, groups and trajectories, it fails to fully capture the qualitative and contextual aspects of AI implementation in real-world data science contexts. Consequently, the findings should be interpreted as a structured overview rather than an exhaustive representation of all existing evidence.

The results of this study open several promising future research. First, although sustainability is increasingly present in the literature, many studies still prioritize operational efficiency and cost reduction. Future research should more deeply explore the potential of AI to address environmental challenges in a systemic way, including emission reduction, circular economy models, and resource optimization across the entire SC.

Second, the findings reveal a persistent gap in technological integration. While AI is often discussed alongside technologies such as blockchain, IoT, and big data, their actual integration in practice remains fragmented. Future studies should investigate issues related to interoperability, standardization, and scalability, which are critical for enabling fully interconnected and intelligent SCs.

Third, there is a need for more interdisciplinary research approaches. Much of the existing literature focuses on isolated aspects of SC management, whereas future research should adopt holistic perspectives that consider the interaction between technological, organizational, social, and environmental dimensions.

Another important direction concerns data availability and quality. Since AI applications are based on large volumes of reliable and structured data, future research should address challenges related to data governance, data sharing across different sectors.

Finally, greater attention should be devoted to the ethical and regulatory implications of AI adoption. Issues such as algorithmic transparency, accountability, data privacy, and the impact on employment remain underexplored but are crucial for fostering trust and ensuring responsible AI implementation.

In conclusion, the main limitation of the current research landscape does not lie in the lack of interest in AI, but rather in its uneven and fragmented development across sectors and perspectives. Future research should therefore move toward more integrated, interdisciplinary, and responsible approaches capable of aligning technological innovation with sustainability and long-term value creation.

5 Ethical Declaration

Ethical approval was not required for this study, as the research is based exclusively on secondary data and does not involve human participants, personal data, or any form of sensitive information.

6 AI Declaration

No artificial intelligence (AI) tools were used in the preparation of this manuscript.

When Lead-User Signals Mislead: Entrepreneurial Sensemaking in Sport-Tech Innovation

Abstract

This study investigates how sport-tech entrepreneurs make sense of heterogeneous lead-user signals in new product development under conditions of uncertainty. While prior research has widely emphasized the role of lead users as sources of valuable and actionable knowledge, it often assumes that user inputs reduce uncertainty by providing clear guidance for innovation. Challenging this assumption, this study draws on sensemaking theory, signaling theory, and paradox theory to conceptualize lead-user feedback as a set of ambiguous and potentially conflicting signals that require interpretation rather than direct translation into product decisions.

An exploratory sequential research design was adopted. In the first phase, survey data from 97 elite and professional athletes were analyzed using k-means cluster analysis to identify distinct configurations of lead-user signals. The analysis revealed two main profiles: (i) cautious/ambivalent users, characterized by moderate perceived usefulness combined with concerns related to usability, comfort, adaptability, and willingness to engage in co-creation; and (ii) receptive/engaged users, characterized by consistently positive evaluations across all dimensions, including performance value, usability, data reliability, and collaborative intent. These findings highlight that lead-user input is not homogeneous, but instead structured in differentiated and sometimes contradictory configurations.

In the second phase, semi-structured interviews with three sport-tech entrepreneurs were conducted to explore how these configurations are interpreted in practice. The qualitative findings show that ambivalent signals are subject to divergent interpretations: they may be framed either as remediable design issues requiring iterative refinement or as indications of deeper misalignment between the product and its target users. Conversely, positive signals are generally interpreted as validation of the product concept, although they do not eliminate uncertainty and are not always associated with immediate readiness for scaling. Across cases, decision-making emerges as an iterative and interpretive process shaped by entrepreneurs' assumptions, strategic priorities, and technical constraints.

By integrating quantitative and qualitative evidence, this study contributes to lead-user research by reframing user inputs as signals that generate both insight and ambiguity. It also advances research on entrepreneurial decision-making by highlighting the central role of sensemaking in constructing coherence among heterogeneous evaluations. From a managerial perspective, the findings suggest that the key challenge is not merely to collect user feedback, but to develop capabilities to interpret and prioritize conflicting signals in technology-driven innovation contexts.

Paper type: Academic Research Paper

1 Introduction

New digital technologies are transforming the way individuals communicate, coordinate, and interact, increasingly relying on data-rich digital infrastructures embedded in products, services, and organizational processes (Porter and Heppelmann, 2015; Cusumano et al., 2021). In the sports domain, this transformation is particularly evident in the growth of sport-tech entrepreneurship, where technology-enabled solutions are used to support training, performance monitoring, athlete engagement, and competitive advantage (Ratten et al., 2021; Ratten, 2024). Sport-tech entrepreneurs are therefore expected not only to develop innovative digital products, but also to make product development decisions in contexts characterized by technological uncertainty, rapidly evolving user needs, and complex data-driven value propositions. These conditions make sport-tech innovation a particularly challenging decision-making context. Entrepreneurs often operate under volatile, uncertain, complex, and ambiguous conditions, where action must be taken with bounded rationality, limited resources, and time pressure, rather than through fully linear optimization of clearly defined alternatives (Kotlar and Sieger, 2019; Troise et al., 2022). In sport-tech manufacturing, these challenges are amplified because product innovation often unfolds through iterative and path-dependent processes involving problem framing, prototyping, field testing, and redesign. As a result, product development decisions rarely consist of discrete choices among stable alternatives; instead, they involve successive and interdependent decisions shaped by evolving technical constraints, user feedback, and market expectations.

To reduce uncertainty in early-stage product innovation, entrepreneurs often rely on lead users. Lead users are advanced users who experience needs ahead of the mainstream market and may therefore provide valuable insights into emerging problems, product requirements, and potential solutions (von Hippel, 1986). Prior research has emphasized that involving lead users can improve the novelty and market relevance of innovation outcomes, particularly under conditions of technological uncertainty (Yin et al., 2023). However, this perspective tends to assume that lead-user inputs provide relatively clear and actionable knowledge. Less attention has been paid to situations in which lead-user feedback generates ambiguity rather than clarity, especially when entrepreneurs must translate heterogeneous user inputs into manufacturable, usable, and scalable product architectures.

This issue is especially relevant in sport-tech innovation, where user feedback may simultaneously concern performance value, usability, comfort, data reliability, adaptability, and willingness to engage in further co-creation. These signals may not always align. For instance, athletes may perceive a technology as potentially useful while also questioning its comfort, integration into training routines, adaptability to specific needs, or reliability of data outputs. In such cases, lead-user feedback does not simply reduce uncertainty; rather, it may intensify interpretive demands by exposing entrepreneurs to multiple and potentially contradictory cues.

Grounded in sensemaking theory (Weick, 1995; Maitlis, 2005), this study conceptualizes entrepreneurial decision-making in sport-tech innovation as an interpretive process through which entrepreneurs notice, select, label, and act upon heterogeneous user signals. In addition, drawing on paradox theory (Smith and Lewis, 2011), we argue that such signals may activate persistent tensions in sport-tech product development, including performance enhancement versus comfort and intrusiveness, data richness versus trust and ownership, and elite customization versus scalability. Thus, rather than treating lead-user feedback as a direct input into product decisions, this study examines how entrepreneurs make sense of differentiated lead-user signals under uncertainty.

Accordingly, the study addresses the following research question:

How do sport-tech entrepreneurs make sense of heterogeneous lead-user signals and translate them into product development decisions under uncertainty?

Empirically, the study adopts an exploratory sequential design. In the first phase, survey data from 97 elite and professional athletes are used to identify distinct configurations of lead-user signals related to perceived performance value, adoption frictions, trust in data, and collaborative intent. In the second phase, an explanatory qualitative case study of the sport-tech venture involved in the development of the evaluated technology is used to explore how these differentiated signals are interpreted in practice and how they inform product development decisions.

2 Theoretical Background

2.1 Lead users and the limits of informational clarity

Lead users are widely recognized as a valuable source of innovation-relevant knowledge, as they experience needs ahead of the mainstream market and often develop solutions that anticipate broader demand (von Hippel, 1986; Schmid et al., 2022). Engaging with such users has been shown to enhance the novelty and market relevance of new product concepts, particularly under conditions of technological uncertainty and rapid change (Yin et al., 2023). Accordingly, lead users are typically conceptualized as providers of high-quality insights that firms can leverage to guide innovation processes (Schmid et al., 2022).

This perspective, however, implicitly assumes that inputs from lead users provide relatively clear and actionable guidance. User contributions are often treated as informative cues that can be directly translated into product features or design improvements (Poblete et al., 2023). Such an assumption becomes problematic in contexts characterized by high levels of uncertainty, complexity, and time pressure, where decision-makers operate under bounded rationality (Simon, 2000; Troise et al., 2022).

In these environments, increasing the amount of available information does not necessarily reduce uncertainty. Instead, user-generated inputs may be heterogeneous, reflecting different and sometimes conflicting evaluations of the same technology (Henkens et al., 2021). As a result, lead-user inputs may contribute to ambiguity rather than clarity, reinforcing the complexity of the informational environment (Eppler and Mengis, 2004).

Despite the growing emphasis on user involvement in innovation, limited attention has been paid to the conditions under which lead-user inputs generate ambiguity rather than actionable knowledge (Venesz et al., 2022). In particular, we still lack a clear understanding of how heterogeneous and potentially contradictory user signals affect decision-making in product development contexts, especially in technology-intensive domains

such as sport-tech, where multiple product attributes must be balanced simultaneously (Porter and Heppelmann, 2015; Raff et al., 2020).

This gap calls for a shift from viewing lead users as direct sources of innovation inputs to conceptualizing their contributions as signals whose interpretation is inherently uncertain. This perspective is particularly relevant in sport-tech innovation, where technologies must simultaneously deliver performance improvements, ensure usability in physically demanding contexts, and generate reliable data, thereby creating multiple and interdependent evaluation criteria (Henkens et al., 2021).

2.2 Lead-user signals and key dimensions of evaluation

In technology-intensive contexts such as sport-tech, entrepreneurs operate under conditions of uncertainty in which decision-making cannot be reduced to linear optimization processes (Kotlar & Sieger, 2019; Troise et al., 2022). Within such environments, inputs from users are more appropriately understood as signals that capture multiple and potentially conflicting evaluations of emerging technologies, rather than as straightforward information (Connelly et al., 2011).

Building on this perspective, we conceptualize lead-user inputs along four analytical dimensions: (i) perceived performance value, (ii) adoption frictions, (iii) trust in data, and (iv) collaborative intent, which capture distinct categories of signals relevant to product development decisions. Rather than aiming at exhaustiveness, this set reflects a minimal and theoretically grounded representation of the key sources of uncertainty that entrepreneurs must address when translating user inputs into product innovation choices.

These dimensions correspond to different, non-reducible decision problems and capture distinct categories of uncertainty related to desirability, feasibility, reliability, and user involvement. Perceived performance value concerns whether a technological solution generates meaningful performance improvements and thus justifies its development (Benar et al., 2024). Adoption frictions capture constraints related to usability, comfort, and integration within training routines, shaping the feasibility of use in practice (Kim et al., 2019). Trust in data refers to the perceived reliability and credibility of technological outputs, a critical issue in data-intensive environments where decision-making depends on the validity of information (Chamorro-Koc et al., 2021). Collaborative intent captures users' willingness to engage in co-creation processes, shaping the potential for iterative learning and product refinement (Prahalad & Ramaswamy, 2004; Zhang et al., 2020).

While analytically distinct, these dimensions are empirically interdependent and do not align in a linear manner. User evaluations may combine in heterogeneous and sometimes contradictory ways, generating configurations in which high perceived value coexists with significant frictions, or willingness to collaborate emerges alongside low trust in data. Such configurations are particularly salient in sport-tech innovation, where product development involves managing persistent tensions between performance and intrusiveness, data richness and reliability, and customization and scalability (Smith & Lewis, 2011; Henkens et al., 2021).

2.3 Entrepreneurial sensemaking of lead-user signals

Lead-user signals do not translate directly into product innovation decisions. Under conditions of uncertainty, decision-making relies on interpretive processes through which entrepreneurs assign meaning to heterogeneous and potentially conflicting cues (Weick, 1995; Maitlis, 2005).

In sport-tech contexts, such signals are not self-evident but require selection and interpretation within existing cognitive frames. This becomes particularly salient when signals combine in non-linear and contradictory ways, generating configurations that do not provide clear directions for action. In these situations, ambiguity stems not from a lack of information, but from the coexistence of multiple plausible interpretations.

Entrepreneurial decision-making thus involves constructing coherence among divergent evaluations in order to define what is feasible, valuable, and scalable within a given product trajectory (Iyer et al., 2022). This perspective shifts attention from the content of user inputs to the processes through which such inputs are interpreted and enacted in decision-making. Accordingly, the study adopts a two-stage design in which configurations of lead-user signals are first identified and then examined through qualitative insights from entrepreneurs.

3 Methodology

3.1 First phase: quantitative cluster analysis

This study adopts an exploratory sequential research design to investigate how lead-user signals inform, complicate, and potentially mislead entrepreneurial sensemaking in sport-tech innovation. This design is

appropriate because the study aims first to identify heterogeneous configurations of user-generated signals and then to interpret how such signals may be used by entrepreneurs when making product development decisions under uncertainty. In line with the theoretical framing of the study, entrepreneurial decision making is not treated as a purely linear evaluation of market information, but as a sensemaking process through which decision makers interpret ambiguous and sometimes contradictory cues emerging from advanced users. The empirical setting is the sport-tech domain, where product innovation is strongly shaped by digital technologies, data-rich infrastructures, and continuous interaction with expert users.

Consistent with the theoretical framework, the survey operationalized the four analytical dimensions of lead-user signals through six empirical variables as shown in Table 1.

Table 1. Operationalization of lead-user signal dimensions.

Theoretical dimension	Empirical variabile	Reference
Perceived performance value	Perceived usefulness	Bardus et al., 2021
Adoption frictions	Usability; Comfort and ergonomics; Adaptability	Brooke, 1996
Trust in data	Data quality and reliability	Bardus et al., 2021
Collaborative intent	Willingness to engage in future co-creation	Ramaswamy and Ozcan, 2018

Perceived performance value was captured through perceived usefulness; adoption frictions were captured through usability, comfort and ergonomics, and adaptability; trust in data was captured through data quality and reliability; and collaborative intent was captured through willingness to engage in future co-creation. The use of multiple indicators for adoption frictions reflects the specific nature of sport-tech innovation, where the practical integration of technologies depends not only on ease of use, but also on bodily comfort, ergonomic fit, and adaptability to heterogeneous training routines and athletic needs.

The first phase of the study was based on a quantitative survey administered to 97 elite and professional athletes. The survey captured athletes' evaluations of a sport-tech innovation across six dimensions: perceived usefulness, usability, comfort and ergonomics, data quality and reliability, adaptability, and willingness to engage in future co-creation. These variables were selected to reflect different types of lead-user signals:

- perceived usefulness captures the expected performance value of the technology (Bardus et al., 2021);
- usability and comfort/ergonomics capture potential adoption frictions (Brooke, 1996);
- data quality and reliability capture trust-related concerns (Bardus et al., 2021);
- adaptability reflects the extent to which the technology can fit heterogeneous athletic needs (Brooke, 1996);
- and willingness to engage in future co-creation captures athletes' collaborative intent (Ramaswamy and Ozcan, 2018).

To identify distinct configurations of lead-user signals, a k-means cluster analysis was performed using SPSS software. The analysis was conducted on the six survey variables listed above, with a two-cluster solution specified. Cases were handled using listwise deletion, although no missing cases were reported in the final analysis. The use of k-means clustering is consistent with the exploratory nature of the study. Rather than testing causal relationships among variables, the aim was to classify athletes into meaningful profiles based on the pattern of their evaluations. This approach allows the study to move beyond average-level interpretations of user feedback and to examine whether lead users communicate homogeneous or differentiated signals to entrepreneurs. In this respect, the cluster analysis serves as a bridge between the quantitative and qualitative phases of the research: it identifies empirical signal configurations that can later be used to interpret how entrepreneurs make sense of user feedback during product development. The second phase of the study is qualitative and complementary. Semi-structured interviews with sport-tech entrepreneurs are used to explore how the differentiated signals emerging from the athlete survey are interpreted in practice. This phase focuses on the cognitive and interpretive processes through which entrepreneurs notice, select, label, and act upon ambiguous user inputs.

3.2 Second phase: qualitative analysis

The second phase is qualitative and complementary, and examines how entrepreneurs interpret the differentiated configurations of lead-user signals identified in the quantitative analysis. Consistent with the exploratory sequential design, the aim is not to generalize findings, but to provide process-level insights into how such signals are interpreted and translated into product development decisions under uncertainty.

Data were collected through semi-structured interviews with three sport-tech entrepreneurs directly involved in product development and commercialization (Yin, 2009). Informants were purposively selected to

ensure alignment between the user-generated signals captured in the first phase and the interpretive processes examined in the second phase. Given the exploratory nature of this phase, the goal was not theoretical saturation, but to capture variation in how similar signal configurations are interpreted.

The interview protocol focused on how entrepreneurs interpret and act upon heterogeneous user feedback, with particular attention to situations characterized by ambiguity or conflicting evaluations. Questions addressed how feedback is collected and prioritized, how different signal dimensions are interpreted, how tensions are managed, and how these interpretations inform product decisions.

Data were analyzed using an abductive thematic approach. Initial coding was guided by the four dimensions of lead-user signals, while remaining open to emergent patterns (Yin, 2009). A second level of analysis focused on sensemaking processes, examining how signals were interpreted as indicators of product validation, design limitations, adoption barriers, or ambiguity, and how interpretations varied across respondents.

This approach enables integration between the two phases: while cluster analysis identifies configurations of lead-user signals, the qualitative inquiry explains how such configurations are interpreted in practice, highlighting the role of sensemaking in entrepreneurial decision-making.

4 Results

4.1 Cluster analysis

To explore whether elite and professional athletes convey homogeneous or differentiated signals regarding sport-tech innovation, a k-means cluster analysis was conducted on six dimensions capturing athletes' evaluations of the product concept: perceived usefulness, usability, comfort and ergonomics, data quality and reliability, adaptability, and willingness to engage in future co-creation.

The two-cluster solution identified two distinct profiles of lead-user signals (Table 2). The first cluster included 33 athletes, corresponding to approximately 34% of the sample, whereas the second cluster included 64 athletes, corresponding to approximately 66% of the sample.

The first cluster can be interpreted as a group of cautious or ambivalent lead users. Athletes in this cluster reported moderate perceived usefulness of the technology, but lower evaluations on the more implementation-related dimensions. Specifically, the cluster center for perceived usefulness was 3.3, while usability was 3.0, comfort and ergonomics 2.8, data quality and reliability 3.2, adaptability 2.3, and willingness to engage in future co-creation 2.85. This profile suggests that these athletes do not reject the technology outright; rather, they recognize some potential value while simultaneously expressing reservations about its practical integration into training routines, its adaptability to specific needs, and their willingness to remain involved in future co-development activities. In this sense, their signals are not simply negative, but ambiguous: they combine moderate value recognition with concerns related to usability, comfort, adaptability, and continued collaboration.

The second cluster can instead be interpreted as a group of receptive and engaged lead users. Athletes in this cluster reported higher scores across all six dimensions. The cluster centers were 4.1 for perceived usefulness, 3.5 for usability, 3.8 for comfort and ergonomics, 3.9 for data quality and reliability, 3.4 for adaptability, and 3.60 for willingness to engage in future co-creation. This profile indicates a more favorable configuration of lead-user signals, in which the perceived performance value of the technology is accompanied by comparatively stronger evaluations of its usability, comfort, data reliability, and adaptability. Importantly, this group also showed greater willingness to participate in future co-creation, suggesting that these athletes may represent a more immediately actionable source of user knowledge for entrepreneurial product development.

Table 2. Cluster centers and profiles of lead-user signals

Variable	Cluster 1: Cautious / ambivalent lead users	Cluster 2: Receptive / engaged lead users
Perceived usefulness	3.3	4.1
Usability	3.0	3.5
Comfort and ergonomics	2.8	3.8
Data quality and reliability	3.2	3.9
Adaptability	2.3	3.4
Willingness to engage in future co-creation	2.85	3.60
N	33	64
% of sample	34.0%	66.0%

The descriptive ANOVA results show that the two clusters differ across all six dimensions. The largest difference emerged for adaptability, $F(1,95) = 64.585$, $p < .001$, followed by perceived usefulness, $F(1,95) = 42.038$, $p < .001$, comfort and ergonomics, $F(1,95) = 39.237$, $p < .001$, and data quality and reliability, $F(1,95) = 36.517$, $p < .001$. Differences were also observed for usability, $F(1,95) = 14.152$, $p < .001$, and willingness to engage in future co-creation, $F(1,95) = 10.610$, $p = .002$. However, in line with the SPSS output, these F-tests should be interpreted only descriptively, since the clusters were created to maximize between-group differences and the observed significance levels are therefore not suitable for formal hypothesis testing. Overall, the results suggest that lead-user input in sport-tech innovation is not uniform. While a majority of athletes provided broadly favorable signals, a substantial minority expressed a more ambivalent pattern, combining moderate perceived usefulness with lower evaluations of adaptability, comfort, usability, and future co-creation willingness. This finding is theoretically relevant because it qualifies the assumption that lead users necessarily reduce uncertainty for entrepreneurs. Instead, the analysis shows that lead users may generate different and partly conflicting signals: some signals point to product potential, while others reveal frictions associated with use, integration, and scalability. These configurations therefore create interpretive demands for entrepreneurs, who must decide whether cautious feedback reflects temporary product limitations, deeper adoption barriers, or valuable indications for redesign.

From a sensemaking perspective, these results indicate that entrepreneurial decision makers are not simply receiving clear market information from advanced users. Rather, they are exposed to heterogeneous cues that require interpretation, selection, and prioritization. The coexistence of receptive and ambivalent lead-user profiles may intensify the paradoxes already embedded in sport-tech manufacturing, such as the tension between performance enhancement and comfort, customization and scalability, and data richness and user trust. Therefore, the cluster analysis provides an empirical basis for the subsequent qualitative phase, where interviews with sport-tech entrepreneurs can explain how such differentiated lead-user signals are noticed, interpreted, and translated into product development decisions.

4.2 Qualitative insights: interpreting lead-user signal configurations

To complement the cluster analysis, qualitative insights were collected to explore how sport-tech entrepreneurs interpret differentiated configurations of lead-user signals in practice. The interviews focused on how decision makers make sense of heterogeneous and potentially conflicting user feedback, and how such interpretations inform product development decisions.

Consistent with the quantitative findings, entrepreneurs do not interpret lead-user signals in a uniform way. In relation to the ambivalent profile identified in Cluster 1, respondents offered partially divergent interpretations. Some entrepreneurs tended to frame moderate evaluations combined with usability and adaptability concerns as temporary and remediable issues. As noted by one informant, such feedback is often interpreted as “problems to be solved” rather than as fundamental limitations of the product. This perspective reflects an underlying assumption that perceived value justifies further refinement efforts.

However, not all respondents shared this interpretation. Another entrepreneur described similar feedback as potentially indicative of a misalignment between the product and its intended users, suggesting that such signals may reflect “non-target users” rather than correctable design issues. This divergence highlights how the same configuration of signals can support different interpretations, ranging from opportunities for incremental improvement to indications of more structural market misfit.

With respect to the more favorable profile identified in Cluster 2, entrepreneurs consistently interpreted high evaluations across dimensions as a form of validation. In some cases, this was associated with readiness for scaling, as positive feedback was seen as confirming both product value and market acceptance. In other cases, it was interpreted more cautiously as validation of the concept, still requiring further testing before broader commercialization. These findings suggest that even positive configurations do not eliminate uncertainty, but are instead incorporated into broader evaluative processes.

Ambiguity becomes particularly evident when entrepreneurs are confronted with conflicting signals within the same user feedback. Respondents frequently reported situations in which users recognized the value of a technology while simultaneously highlighting issues related to usability or comfort. In such cases, decision-making was described as iterative and contingent. One entrepreneur emphasized the need to assess whether usability constraints could limit market adoption, leading to internal discussions and case-by-case evaluations. Another highlighted the role of technical feasibility, noting that decisions often depend on whether design improvements are realistically achievable. A third respondent indicated that severe usability issues may require more radical product changes, including redesign, even when performance value is acknowledged.

These interpretations also reflect different approaches to managing trade-offs between competing product attributes. While some entrepreneurs emphasized the absence of fixed priorities, adapting decisions to perceived market needs, others described more strategic positioning choices, such as targeting specific niches when products exhibit strong performance but limited usability. In contrast, another respondent highlighted usability and comfort as primary decision criteria, even at the expense of other product attributes.

Concrete product decisions further illustrate how lead-user signals are translated into action. In one case, repeated user requests led to the addition of new features, reflecting a responsiveness to collaborative signals. In another, concerns about product size resulted in a deliberate trade-off, sacrificing some performance aspects to improve usability and compactness. In contrast, a different approach prioritized performance over design considerations, based on the assumption that usability and functionality outweigh aesthetic concerns.

These findings show that lead-user signal configurations do not provide direct prescriptions for action. Instead, they require interpretation through sensemaking processes that are shaped by entrepreneurs' assumptions, strategic priorities, and technical constraints. The same configuration of signals may thus lead to different decisions, reinforcing the view that lead-user inputs contribute not only to reducing uncertainty, but also to generating ambiguity in entrepreneurial decision-making.

5 Conclusions

This study examined how sport-tech entrepreneurs make sense of heterogeneous lead-user signals and translate them into product development decisions under conditions of uncertainty. The findings show that lead-user inputs do not necessarily provide clear and actionable guidance. Instead, they are structured in differentiated and sometimes conflicting configurations, which may generate ambiguity rather than reduce it.

By combining cluster analysis with qualitative insights, the study shows that the same configurations of user signals can be interpreted in different ways, leading to different product decisions. This extends lead-user theory by framing user inputs as signals that require interpretation, rather than as direct sources of innovation-relevant knowledge. It also contributes to research on entrepreneurial decision-making by highlighting the role of sensemaking in constructing coherence among divergent evaluations, as well as to paradox theory by showing how tensions between performance, usability, data reliability, and scalability are reflected in both user feedback and decision processes.

From a managerial perspective, the results suggest that entrepreneurs should not seek consensus in user feedback, but rather develop capabilities to interpret and prioritize heterogeneous signals. Ambivalent feedback, in particular, may reveal critical constraints and opportunities for product refinement.

The study is limited by the exploratory nature of the qualitative phase and the specific sport-tech context. Future research could extend the analysis to different settings and examine how interpretive processes evolve over time.

Overall, the study highlights that in technology-driven innovation, the key challenge is not only to access user feedback, but to make sense of it under conditions of ambiguity.

6 Ethical declaration

Ethical approval was not required for this study, as the research is based exclusively on secondary data and does not involve human participants, personal data, or any form of sensitive information.

7 AI declaration

No artificial intelligence (AI) tools were used in the preparation of this manuscript.

From Intellectual Capital Statements to AI-Enhanced Strategic Knowledge Management

Manfred Bornemann, Kay Alwert
Intangible Assets Consulting GmbH, Graz, Austria

Abstract

This paper explores the Intellectual Capital Statement (ICS) “made in Germany” as a participatory method for strategic management of intangible resources in knowledge-intensive organizations. The method emerged in the early 2000s and builds on the established categories of Human Capital, Structural Capital, and Relational Capital (Edvinsson and Malone, 1997; Sveiby, 1997; Stewart, 1997). It combines qualitative assessment with moderated workshops and cause-effect modelling (Alwert et al., 2013). ICS links the diagnosis of intangible resources with strategic fields of intervention and implementation measures (Bornemann et al., 2021).

ICS aligns with knowledge management standards such as ISO 30401 (ISO, 2023) and DIN SPEC 91443 (DIN, 2020). These frameworks define system requirements and governance structures. ICS contributes a process perspective that connects assessment with strategy development through moderated dialogue and shared interpretation, which supports organizational sensemaking (Weick, 1995).

A typical ICS application centers on a facilitated workshop. Participants assess mission-critical factors and justify their evaluations. This process externalizes tacit knowledge and supports its transformation into shared understanding (Nonaka and Takeuchi, 1995). The impact matrix visualizes interdependencies between elements of Intellectual Capital and organizational outcomes (Vester, 1984). Empirical evidence from more than 1,000 applications confirms usability and transferability (BMWi, 2010).

Recent applications show how AI supports the ICS process. In the case of SBR, a medium-sized accounting service firm undergoing generational transition and staff turnover, the 2025 ICS workshop was conducted in a hybrid format with automated transcription and GPT-based summarization. AI-supported documentation produced rapid and comprehensive output, reducing cognitive load and enabling deeper reflection on improvement measures In the case of ZM-I, anonymized workshop results were analyzed with large language models to generate draft recommendations, which were refined through structured dialogue. These applications indicate efficiency gains and enhanced analytical depth while interpretation remains anchored in organizational judgement.

ICS develops further in the context of AI-supported knowledge work. Concepts such as real-time dashboards and embedded ICS agents indicate a shift toward continuous observation of Intellectual Capital. These developments require governance structures that ensure transparency and contextual sensitivity. ICS retains its role as a participatory method for organizational sensemaking and strategic transformation (Weick, 1995).

Keywords: Intellectual Capital Statement, Knowledge Management; Intangible Assets; Artificial Intelligence; Participatory Methods

Paper type: Academic Research Paper

1 Introduction

More than 30 years into the knowledge society (Drucker, 1993), at the dawn of the “age of artificial intelligence” (Bostrom, 2014), where global economies are shaped more by expertise, networks, and intangible assets than by physical goods, organizations still struggle to make the invisible visible. Strategic decisions are often based on financial metrics, historical structures, standard recipes, and individual preferences of top managers, while the dynamics caused by Intellectual Capital (IC) remain underexplored and undervalued.

1.1 Intellectual capital statements: origins and ongoing relevance

The Intellectual Capital Statement (ICS) "made in Germany" emerged as a response to this gap. Developed in the early 2000s (Alwert et al 2004 und 2013, Mertins et al 2005), it offered a practice-oriented framework to assess and develop intangible resources through an interplay of measurement, structured dialogue, participatory workshops, and visual modelling of cause-and-effect networks and has always emphasized strategic relevance and internal resonance. It helped anchor knowledge management within broader organizational development and positioned Intellectual Capital as a driver of competitive advantage.

Two decades later, ICS is still dealing with a central dilemma: How can organisations capture their collective knowledge in a credible, comprehensive, and understandable way so that it can be used for strategic management as well as for external accountability?

This question has been addressed at a normative level by recent standards for knowledge management, including ISO 30401:2018, revised in 2023, and the DIN SPEC 91443:2020 (see: DIN, 2020; ISO, 2023). Both standards provide systematic guidance for managing intangible resources, particularly for knowledge-intensive and small-to-medium-sized enterprises. While ISO 30401 establishes global principles for structured KM systems, DIN SPEC 91443 focuses on context-sensitive implementation for SMEs. The ICS, however, stands out as the only method explicitly integrating assessment and development: it identifies periodic changes and prioritizes fields of intervention, and systematically supports the implementation processes necessary to enact these changes (Bornemann et al, 2021).

1.2 Technological changes offer new opportunities

We are entering a new phase in the evolution of management: the dawning age of artificial intelligence (Brynjolfsson & McAfee, 2017; Tegmark, 2018). Language models, real-time data analytics, and predictive tools offer impressive possibilities to complement human judgment, track knowledge flows, and simulate organizational dynamics.

This article takes ICS as both a method and a perspective. We review its conceptual architecture and operational logic (Chapter 2), examine current practice through two updated case studies (Chapter 3), and explore how AI may reshape its future applications (Chapter 4). We explore how the method can remain relevant in a digitally transformed world, and whether ICS can evolve from a periodic assessment tool to a dynamic, learning-oriented system that supports strategic reflection in real time.

Our argument builds on earlier findings (Bornemann et.al, 2021) but moves beyond them. We show that ICS continues to offer value in conventional organizational settings and provides a powerful frame to reflect on the quality of knowledge governance in AI-supported environments. Case experiences suggest that AI can reduce the cognitive burden of documentation and enhance the precision of ICS outputs, without replacing the participatory essence of the method. In fact, by automating routine tasks and surfacing latent insights, AI may enable richer reflection, faster learning, and deeper insights.

More broadly, we consider ICS a potential bridge between data-driven and sensemaking practices; between planned strategy and lived behaviour; and between documentation and transformation. In an era that risks reducing knowledge to quantifiable artifacts, the ICS method reminds us that knowledge is also a social process, embedded in language and context, shaped through dialogue, and enacted in practice (Latour 2005). As such, it must be made explicit not only for reporting, but for understanding and improvement.

2 The Intellectual Capital Statement (ICS) Methodology

The Intellectual Capital Statement "made in Germany" is a structured approach to assess, visualize, and manage intangible resources. It is grounded in the theoretical frameworks of IC management and knowledge-based value creation. Drawing on the works of Edvinsson and Malone (1997), Sveiby (1997), and Stewart (1997), ICS expands the triadic structure of IC - Human, Structural, and Relational Capital - into a pragmatic, operational method. Within this triad organizational strengths, weaknesses, and development needs are analysed. Specific drivers of IC include e.g. employee competence, leadership, innovation & knowledge processes, organisational culture, IT infrastructure, external partnerships, and customer relations (Bornemann and Reinhardt, 2017).

The ICS methodology is built around a structured, participatory, and workshop-based process. At its core is a consensus-driven assessment of qualitative indicators to identify strengths and weaknesses, as well as a visual cause-effect model that links IC resources to value creation processes and strategic objectives. This approach ensures alignment with organizational priorities and stakeholder expectations.

To support this process, a dedicated software tool - the ICS Toolbox (BMWi, 2013) - has been developed. It standardizes documentation, supports strategic management, and ensures methodological consistency. The toolbox guides the process from preparation and team selection, through data collection and assessment, to the final report.

A typical ICS implementation includes the following eight steps: (1) preparatory phase with team composition, goal setting an reflection of the business model, (2) data collection from available sources, (3-5) the ICS workshop to assess the Intellectual Capital and its interplay with processes and goals, which is the core event moderated by a trained facilitator, (6) diagnosis with validation of results and feedback loops, (7) deduction of concrete actions for improvement, (8) documentation, reporting & communication. During the workshop, participants from various hierarchical levels and functions assess a set of mission-critical factors using a scale from 0% to 120%. Crucially, each assessment must be justified through structured dialogue and documented accordingly, often with narrative-rich explanations.

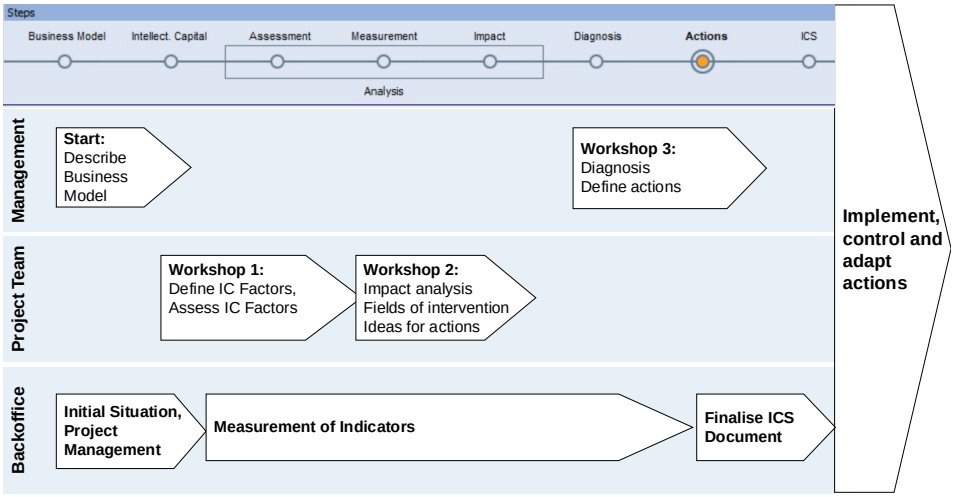

Figure 1 The implementation process of am ICS (Bornemann et al 2021)

This dialogic approach serves the following purposes: it fosters shared understanding across departments, surfaces tacit knowledge, and builds a common language for discussing intangibles. ICS is both, a reporting mechanism, and an organizational development tool. It acts as a mirror, enabling reflection and self-assessment through systemic feedback (Bornemann and Reinhardt, 2017).

A central feature of ICS is its integration of strategic goals with intangible resource assessment. This contrasts with traditional balance sheet analogues or capital inventory lists. ICS offers dynamic insights into how knowledge resources contribute to performance, agility, and long-term value creation. This is particularly relevant to all organisations, where strategic capacity and transparency are essential (Will, 2007).

The method emphasizes inclusiveness and participation, often drawing from organizational development theory (Weick, 1995). Employees become co-creators of the ICS narrative, thereby enhancing legitimacy and implementation readiness. This participatory ethos mitigates resistance and enables bottom-up commitment to actions for change. By promoting systemic thinking, ICS contributes to organizational learning and resilience (Senge, 1990).

ICS has been applied in over 1,000 cases in Germany, including manufacturing firms, public administration bodies, hospitals, and research institutions. Evaluation studies funded by the German Federal Ministry of Economics (BMWi) have confirmed the method's usability, impact, and transferability BMWi (2010).

In recent years, ICS has shown potential for adaptation in the context of digitalization. Emerging tools for automated transcription, natural language processing, and semantic analysis can support the documentation process. Likewise, AI-supported summarization and classification routines offer new ways to reduce workload and enhance consistency. These innovations are particularly relevant for ICS implementations in remote or hybrid environments.

As outlined in Bornemann, Alwert, and Will (2021), the ICS offers a unique blend of strategic clarity and operational relevance. Its structured yet adaptable design makes it particularly suitable for knowledge-intensive organizations seeking to align intangible assets with long-term value creation.

3 Reflections on Case Applications of ICS using AI-Support

The evolution of the Intellectual Capital Statement method reflects its theoretical robustness as well as its adaptability to emerging technological contexts. While original ICS practice emphasized, strategic alignment, structured dialogue and consensus-based assessments, recent implementations show how a digital focus within an ICS stimulates strategy development and how digital tools - particularly AI-assisted transcription and summarization - can meaningfully enhance the ICS process. This chapter discusses two organizations previously studied in the 2021 Journal of Intellectual Capital article (Bornemann et al, 2021) and explores their latest experiences.

3.1 Case Study: SBR (2025)

SBR, a medium-sized accounting service firm with more than 20 years of ICS experience, returned to the methodology in 2025 to reflect on recent organizational changes. While its historical ICS efforts were driven by

quality management and operational transparency (Bornemann et al., 2021), the current context introduced new dynamics: a transition in leadership to the next generation and a phase of higher-than-usual staff turnover. The ICS served as both: a retrospective reflection tool and a structured onboarding mechanism for the incoming CEO, allowing insights into the company's historical evolution and team perspectives.

For the first time, the workshop was conducted in a hybrid format via Microsoft Teams, with one remote participant. Full-session recording and automated transcription were employed - with prior consent from participants - to support documentation. Two parallel documentation strategies were evaluated:

Manual ICS Documentation: A student in her final bachelor's year documented the assessments in the ICS Toolbox, following established procedures with coaching support.

AI-Supported Documentation: The session transcript was processed using a tailored GPT model trained on ICS guidelines and reference documents. It generated summaries of IC drivers, synthesized rationales, and proposed improvement measures.

Both documentation types were available for the second workshop, where improvement strategies were discussed. Comparatively, the AI-generated report was faster, richer in detail, and more accessible in tone, while the manually prepared document, though delayed, offered precision and internal familiarity (e.g. local wording or context markers). Participants noted a reduction in stress and cognitive load through AI support, particularly during intensive sessions.

The AI model also produced a structured proposal of improvement measures, which were reviewed, discussed, and adapted by the team. This demonstrates that AI can complement human judgment. And it supported the organization's cultural commitment to transparency and engagement. The CEO endorsed the hybrid method, recognizing its potential for process efficiency and deeper insights.

3.2 Case Study: ZM-I (2025)

ZM-I group is a leading German engineering company with approximately 140 knowledge workers in seven companies. The firm plans, tests and assesses the structural frameworks of a wide range of building types as a highly knowledge intensive technical B2B service. As a medium-sized enterprise with increasingly decentralised structures, ZM-I has relied for over a decade on the Intellectual Capital Statement – Made in Germany methodology to systematically identify, steer and develop its intangible resources and manage organisational complexity.

In 2025, the IC management process was used to support a strategic reorientation in the context of the company's ongoing digital transformation. A central focus was the expansion of the digitalisation strategy initiated in 2022 through the integration of a company-wide AI strategy, aimed at aligning future developments with the demands of data-driven engineering services.

The analysis phase addressed essential technological structures, cross-location knowledge exchange and the competencies required to realise the extended strategy. The objective was to assess the organisational prerequisites for successfully implementing both digital and AI-driven initiatives.

Another advancement in the recent ICS process involved leveraging large language models (LLM) to analyze anonymized workshop outcomes, formulate summaries and generate recommendations for actions. These AI-driven suggestions were subsequently reviewed by management as well as workshop participants and incorporated as valuable input for refining the final action plan.

4 Future Scenarios and Systemic Learning in ICS Applications

Building on the adaptive and dialogic qualities of the ICS, recent discussions have begun to envision future scenarios where real-time feedback systems, augmented by artificial intelligence, transform the ICS from a periodic reflection tool into a continuous strategic monitoring interface. These developments open possibilities for integrating ICS logic into operational dashboards, supporting management with dynamically updated insights into the status of intangible resources and their relation to business outcomes.

4.1 Toward a real-time ICS dashboard

One scenario suggests a dedicated "ICS Agent" embedded within enterprise information systems. Drawing on data streams from collaborative platforms (e.g., Microsoft Teams, Google Workplace, or others), HR systems, knowledge repositories, and project management tools, the ICS Agent could autonomously collect, interpret, and visualize relevant data and indicators.

This agent would complement workshops and maintain organizational awareness between formal ICS cycles. The agent could detect emerging patterns of stress or capacity, highlight over- or underutilized competencies,

or raise alerts when strategic knowledge becomes siloed or is in risk to get lost. In this role, the ICS agent supports resilience and anticipatory learning, contributing to what Nonaka and Takeuchi (1995) describe as a knowledge-creating company.

Echoing broader trends in digital twin systems and predictive analytics, this approach envisages ICS as an integral component of the real-time management cockpit. It retains the reflective and participatory nature at the heart of ICS m.i.G., ensuring that dynamic oversight does not come at the expense of meaningful engagement.

An additional innovation concerns internal communication: Instead of distributing a final report in static form, an agentic approach could allow employees to explore results, action plans, and IC relations through dialogue. This format follows the principles of user-centred, conversational knowledge delivery, aligned with recent developments in digital workplace environments.

4.2 The ICS impact matrix as learning catalyst

Another line of development focuses on the ICS impact matrix, a cause-effect model, inspired by Frederic Vester's sensitivity model (Vester, 1984), that links intangible resources to business processes and outcomes. Historically, this matrix has been constructed through moderated team workshops, based on perceived and expected influences of IC elements.

Future systems may allow a comparison between these designed models and empirical usage patterns derived from actual process data, communication logs, and performance metrics. Such comparisons would reveal where documented logic diverges from lived organizational behaviour. This new dual-layered approach could offer two learning paths:

Adaptive Realignment: If the empirical data reflect a coherent operational logic, the designed impact model might be revised to better match actual practices, enhancing strategic realism.

Reflective Reconciliation: If the data reveal performance gaps or dysfunctional patterns, this discrepancy becomes a stimulus for dialogue and change. ICS teams can review the designed model, question misalignments, and co-create strategies to align behaviour with intention.

In both cases, the ICS evolves from a descriptive document into a generative system that surfaces contradictions and supports learning processes.

4.3 From bureaucratic routine to organizational learning

ICS has always positioned itself between strategic alignment and participatory sensemaking. Embracing AI for efficiency and for deeper diagnosis, allows organizations to turn ICS into a catalyst for transformative learning, a process that challenges individual and organizational assumptions, stimulates knowledge exchange, fosters creative responses to complex challenges, and promotes proactive change (Nonaka & Takeuchi, 1995; Senge, 1990).

This potential depends on governance choices, digital literacy, and the degree to which ICS remains anchored in shared values and collective interpretation. Technological augmentation should reinforce ICS's core purpose: to make intangible resources visible, discussable, and improvable (ISO, 2023).

Future ICS applications may include AI-supported plausibility checks across assessments. LLMs can compare argument structures underlying evaluations of Human Capital, Structural Capital, and Relational Capital and identify inconsistencies in reasoning. Similar patterns of deficits with comparable strategic relevance can be highlighted when they lead to diverging scores. Such analysis does not alter the assessment itself but supports participants in refining their justifications and aligning evaluation logic. This strengthens internal coherence and increases transparency of the ICS process.

5 Discussion and Outlook

The integration of AI into the ICS process is raises fundamental issues about the nature of knowledge work, organizational learning, and the trustworthiness of decision-making tools. As our case studies and conceptual reflections show, AI has the potential to both accelerate and deepen ICS processes, but not without new risks and unresolved challenges. In this concluding chapter, we synthesize key findings, assess opportunities and limitations, and outline implications for practice.

5.1 Efficiency gains and quality improvements

AI-supported ICS processes clearly demonstrate potential for improving efficiency. Automated transcription, summarization, and pattern recognition, especially when applied to recorded workshop dialogues, can significantly reduce the time and cognitive load required for ICS documentation. This is supported in the SBR case, where a tailored GPT model produced actionable summaries that were available the day after the ICS workshop. Beyond speed, quality improvements were also noted: participants found the AI-supported output more readable and comprehensive than traditional notes. In addition, the facilitator could focus on group dynamics rather than simultaneous documentation.

In the case of ZM-I, the interplay between ICS and AI contributed meaningful to strategy formulation, communication, and the development of enhanced improvement measures.

In future applications, AI may also enable deeper learning within ICS by linking structured outputs to behavioural data. One of the core elements of ICS is the impact matrix, which visualizes how specific IC components (e.g., staff development or IT infrastructure) affect defined business outcomes. These matrices could be validated - or challenged - by behavioural data drawn from process mining, digital workflows, or communication data. The comparison between designed models and observed practice opens another space for systemic learning and qualitative improvement. The obvious prerequisite is the explicit agreement of employees to this procedure.

Combining the ICS method with a well-trained AI agent, AI can help structure unfiltered dialogue into actionable ICS components such as drivers, impact relationships, and measures. It also can help to check if the intended and lived organisation diverge significantly. While these opportunities do not replace the need for critical review and ethical judgment, they change the balance between human interpretation and technical assistance.

5.2 Risks: distortion, bias, and convergence

Integrating AI into ICS workflows introduces risks that affect how assessments are constructed and interpreted. LLMs structure outputs along with statistical regularities, which can distort context-rich discussions and shift the emphasis of arguments. These effects influence the representation of relationships between elements of Intellectual Capital and can alter the perceived relevance of drivers.

A structural risk lies in convergence toward dominant patterns. This dynamic reduces variance in assessments and weakens the differentiation of strategic positions. ICS depends on identifying organization-specific constellations of Human Capital, Structural Capital, and Relational Capital. Convergence within AI-supported outputs can obscure these distinctions.

Bias operates across training data, prompt design, and organizational context. These influences shape how arguments are framed and how drivers are weighted within the assessment. In evaluations that relate to internal structures and performance, such effects can influence acceptance and interpretation of results.

AI-supported consistency checks introduce a secondary dynamic. Comparisons across assessments can align evaluations that differ in context or strategic relevance. Divergence in assessments often reflects relevant organizational tensions and contributes to diagnostic depth. ICS benefits from preserving these differences as part of the reflection process.

5.3 Ethical considerations and the role of AI

While AI can support the ICS process, it should not assume authority over normative judgments, such as interpreting commitment, assessing employees, or recommending cultural shifts. ICS remains a participatory tool; the danger lies in reducing it to a mechanical procedure that outputs texts with pseudo-objectivity.

A useful analogy can be drawn from education: Some researchers have compared machine learning with learning and teaching processes of humans (Moravec 1988, Tegmark 2018, Merlo & Alwert 2025). In this perspective, AI behaves like a "learning actor" rather than a mere instrument. This suggests that organizations should treat AI with the same attentiveness and respect they would give to onboarding a junior team member (Merlo & Alwert 2025): clarify expectations, training, monitor learning progress, and define boundaries of responsibility.

5.4 Outlook: a cyclical, AI-enhanced ICS

Looking ahead, the ICS could evolve from an episodic workshop model into a continuous, AI-supported knowledge management system supporting ISO 30401. Real-time ICS dashboards, intelligent agents trained on company-specific ICS profiles, and integration with strategic planning cycles are conceivable. In such scenarios,

ICS serves as documentation tool as well as a dynamic learning environment for the whole organisation and its strategic development.

Future ICS iterations may rely less on verbal workshops and more on synthesized observations from digital behaviour, yet their interpretive power will still depend on human dialogue. The ICS may thus serve as a meeting point between empirical data, shared sensemaking, and strategic transformation.

6 Acknowledgment on the Use of Artificial Intelligence

During the preparation of this article, the authors received support from artificial intelligence in selected stages of the writing process. ChatGPT-5.4 (OpenAI) were used to assist in the formulation and refinement of text passages based on preliminary drafts. ChatGPT-5.4 as well as deepL translate & write were employed to support the translation of sections originally written in German, and to improve the clarity, consistency, and readability of the manuscript, as English is not the authors' first language. ChatGPT-5.4 was also employed to assist in the formatting of references in APA style. All AI-assisted contributions were carefully reviewed, edited, and validated by the authors. The authors accept full responsibility for the accuracy, interpretation, and presentation of all content included in this article.

7 Ethics Declaration

This study did not involve experiments on human participants or animals requiring ethical approval. The case studies presented are based on organizational data and publicly available information. Where organizational or individual data were used, they were included with the explicit consent of the respective organizations. No personal or sensitive data were processed in a manner that would require formal ethical review. The authors declare no conflict of interest. No external funding was received for this study.

Innovation Orchestration through Innovation Labs: Evidence from Intellimech

Francesco Santarsiero[1], Giovanni Schiuma[1], Alessandro Massaro[1], Achille Claudio Garavelli[2]

[1] Università LUM Giuseppe Degennaro, Casamassima, Italy

[2] Politecnico di Bari, Bari, Italy

Abstract

Innovation labs are increasingly used to connect firms, universities, technology providers and local institutions around experimentation, knowledge sharing and digital transformation. However, less is known about how innovation labs orchestrate innovation when they operate not as isolated corporate laboratories, but as membership-based collaborative infrastructures serving a network of firms. This paper investigates this issue through an exploratory qualitative case study of Intellimech, an Italian private consortium for mechatronics and industrial innovation located in the Kilometro Rosso innovation district in Bergamo. Drawing on publicly available documentary evidence, including Intellimech's institutional webpages, statute, project descriptions and published case histories, the paper conceptualizes Intellimech as an innovation lab and intermediary that transforms distributed technological needs into shared learning opportunities, pre-competitive projects, open innovation initiatives and firm-level experimentation. The findings identify five orchestration mechanisms: need sensing and challenge framing; shared knowledge creation and absorptive capacity building; pre-competitive experimentation; boundary spanning across firms, universities and institutional actors; and translation of shared knowledge into firm-specific pilots and organizational routines. Examples such as AIxLAB, the Knowledge Management Cluster, Watchman, Harmony, Shop4cf/Warning and other mechatronics projects show how the lab logic can reduce the cost and uncertainty of innovation for firms while supporting knowledge circulation within a territorial ecosystem. The paper contributes to research on innovation labs, open innovation and knowledge management by showing that innovation orchestration is not limited to coordinating technological projects, but also involves the design of social, cognitive and organizational conditions that allow firms to learn collectively and innovate individually. The study also provides managerial implications for local ecosystems that seek to build sustainable innovation capacity through shared research, mentoring, training, technology scouting and pilot projects. Limitations concern the reliance on secondary public sources; future research should integrate interviews with Intellimech managers and member companies.

Keywords: innovation labs; innovation orchestration; open innovation; knowledge management; digital transformation

Paper type: Academic research paper

1 Introduction

Firms increasingly innovate in conditions of technological turbulence, knowledge dispersion and rising uncertainty. In advanced manufacturing and mechatronics, digital transformation is not merely a matter of adopting individual technologies such as artificial intelligence, robotics, industrial data platforms or sensor-based systems. It requires the capacity to identify relevant technological trajectories, translate them into business problems, mobilize complementary expertise and test solutions in realistic contexts. For many small and medium-sized enterprises, and even for larger firms facing fast technological change, this process is difficult to manage internally because knowledge is distributed across multiple actors and because experimentation involves financial, technical and organizational risks.

Against this background, innovation labs have emerged as organizational arrangements designed to support experimentation, learning and the development of new solutions. They are often discussed as physical or virtual spaces where firms, users, universities and technology providers jointly explore opportunities, prototype solutions and accelerate innovation. Yet the literature still tends to focus on innovation labs as spaces, methods or project containers, while less attention is paid to their role as orchestrators of innovation ecosystems (Schiuma and Santarsiero, 2024). This is particularly relevant when the lab does not belong to a single firm, but works as a shared infrastructure for a network of companies that contribute resources and expect access to knowledge, training, mentoring, technology scouting, open innovation opportunities and pilot projects.

This paper addresses the following research question: how can an innovation lab orchestrate innovation and knowledge processes within a network of firms and local ecosystem actors? To answer this question, the paper analyses Intellimech, a private Italian consortium for mechatronics based in Bergamo. Intellimech was founded

in 2007 and presents itself as a private consortium of large, medium-sized and small firms focused on interdisciplinary research in mechatronics for different industrial sectors. It operates at the intersection of companies, universities, technology providers and institutional actors, offering shared research, technology scouting, research and development, consulting, training and project-based experimentation (Intellimech, 2026).

The relevance of Intellimech lies in its hybrid nature. It is not simply a consultancy provider, nor merely an R&D contractor. It is a membership-based innovation infrastructure in which firms enter a network and contribute financially to a common organization that can identify needs, aggregate demand, reduce the individual cost of technological exploration and transform scattered expertise into shared innovation pathways. The statute of the consortium refers to an initial participation fee and to an annual management quota paid by members to cover operating and management costs (Intellimech, 2019). This governance logic is consistent with the idea of an innovation alliance: companies invest in a shared organizational platform that gives access to knowledge, projects and connections that would be harder to develop alone.

The paper contributes to the IFKAD debate by linking innovation labs to knowledge management and innovation orchestration. It argues that the value of a lab such as Intellimech is not only in the technologies it develops, but also in its capacity to organize knowledge flows, activate trust among heterogeneous actors, support absorptive capacity and convert exploratory activities into actionable innovation projects. The paper is structured as follows. The next section discusses the theoretical background on innovation labs, open innovation, knowledge management and orchestration. The methodology then explains the exploratory case study based on public documentary evidence. The empirical section presents Intellimech and identifies the main orchestration mechanisms. The discussion develops a conceptual model of innovation orchestration through labs and highlights theoretical and practical implications.

2 Theoretical Background

Innovation increasingly depends on the ability to connect heterogeneous knowledge sources. Open innovation theory suggests that firms should combine internal and external knowledge to accelerate innovation processes and access ideas, technologies and capabilities beyond organizational boundaries (Chesbrough, 2003; West and Bogers, 2014). This assumption is particularly relevant in complex technological domains, where no single organization possesses all the knowledge required to develop and implement new solutions. However, openness does not automatically generate innovation. External knowledge must be identified, interpreted, selected, recombined and translated into organizational action. This makes knowledge management a central component of open innovation.

From a knowledge management perspective, innovation depends on the creation, sharing, codification and application of knowledge (Nonaka and Takeuchi, 1995; Spender, 1996). In inter-organizational settings, knowledge processes are even more complex because they involve differences in language, routines, goals and absorptive capacity. Firms need mechanisms that make knowledge visible and actionable, such as workshops, assessment tools, pilot projects, roadmaps, communities of practice and shared repositories. These mechanisms can be interpreted as boundary objects: artefacts that allow actors with different backgrounds to collaborate without requiring full consensus on every detail.

Innovation labs are one way to institutionalize these mechanisms. Previous research has described innovation labs as spaces and organizational arrangements that support creativity, experimentation, prototyping and learning (Lewis and Moultrie, 2005; Magadley and Birdi, 2009). They typically combine physical infrastructure, facilitation methods, technical expertise and project-based experimentation. In their most mature form, innovation labs do not only generate ideas; they enable organizations to move from ideation to proof-of-concept, from proof-of-concept to adoption, and from adoption to organizational learning (Santarsiero et al., 2022).

The orchestration perspective helps explain how this happens. Innovation orchestration refers to the set of activities through which a focal actor mobilizes and coordinates a network of participants around innovation opportunities (Dhanaraj and Parkhe, 2006; Nambisan and Sawhney, 2011). Orchestration involves identifying opportunities, attracting partners, shaping roles, managing knowledge flows, building trust and supporting the integration of complementary resources. In innovation ecosystems, the orchestrator does not necessarily own all resources; rather, it creates the conditions under which distributed resources can be combined.

This paper integrates these streams by conceptualizing an innovation lab as an orchestration infrastructure. In this view, the lab is not only a place where innovation projects occur, but a mechanism for sensing needs, translating technological trends, building shared understanding, coordinating experiments, and supporting the diffusion of knowledge across firms. Such a view is particularly useful for membership-based labs and consortia,

where companies join a common platform to access capabilities, reduce uncertainty and participate in pre-competitive innovation activities.

3 Methodology

The paper adopts an exploratory qualitative case study design. The case study method is appropriate because the research question concerns how innovation orchestration unfolds in a real organizational and ecosystem context. The selected case, Intellimech, is theoretically relevant because it combines characteristics of an innovation lab, a private consortium, an open innovation intermediary and a territorial knowledge platform.

The empirical material consists of public documentary evidence collected from Intellimech's official website and related public documents. The evidence includes institutional pages describing the consortium, its method, technological areas, member network, research sharing, technology scouting, R&D activities, consultancy, connections with universities and institutions, and its location within the Kilometro Rosso innovation district. It also includes project and case-history pages concerning AIxLAB, the Knowledge Management Cluster, Watchman, Harmony, Shop4cf/Warning, robot-oriented applications and other mechatronics projects. The statute of the consortium was used to understand the formal governance logic of membership, participation fees and annual management quotas.

The analysis followed a qualitative document analysis procedure. First, the material was read to identify descriptive elements concerning Intellimech's mission, services, governance and ecosystem position. Second, statements and examples were coded according to innovation orchestration activities: sensing needs, selecting challenges, sharing knowledge, connecting actors, experimenting, piloting, translating solutions and supporting adoption. Third, the codes were grouped into broader orchestration mechanisms. The resulting interpretation is not intended to provide a complete internal evaluation of Intellimech, because no interviews or proprietary data were available at this stage. Rather, the paper offers an analytically grounded reading of Intellimech as a public-facing case of innovation orchestration through a lab-consortium model.

This methodological limitation also defines the contribution of the paper. Instead of claiming causal evidence, the study develops a conceptual and illustrative account that can be strengthened in future research through interviews with Intellimech managers, technical staff and member firms.

4 Case Background: Intellimech as a Lab-Consortium for Industrial Innovation

Intellimech defines itself as a private consortium of companies focused on interdisciplinary research in mechatronics (Intellimech, 2026). Its public presentation emphasizes the participation of large, medium-sized and small firms and its role in supporting applications across different industrial sectors. The consortium is located in the Kilometro Rosso innovation district in Bergamo, described as a meeting point between research and business that fosters synergies among companies, research centres, laboratories, professional services and higher education. Intellimech also has a Smart Lab at the POINT technological innovation hub in Dalmine.

The member network is heterogeneous. The public list of members includes companies from automation, electronics, energy, ICT, mechanics, construction and services, with firms such as ABB, Brembo, Dassault Systemes, Dmg Mori, Evoca Group, Fassi, Gefran, Kilometro Rosso, Lovato Electric, Oròbix, Phoenix Informatica, Siemens, SIAD Macchine Impianti, Sorint, Tesmec and many others (Intellimech, 2026). This heterogeneity is important because it creates the conditions for cross-sectoral learning. Firms with different technological backgrounds and market positions can encounter similar challenges in data management, automation, AI adoption, system integration, quality control, remote diagnostics, predictive maintenance and organizational knowledge management.

The Intellimech method starts from the needs of members and aims to transform them into innovative technological solutions. Its public description highlights problem solving, access to latest research, technology scouting and the definition of pre-competitive projects tailored to members' needs. The consortium also emphasizes the creation of a knowledge network based on cooperation, constructive confrontation and the exchange of ideas and strategies. This is central to the interpretation proposed in this paper: Intellimech works as an innovation lab because it provides structured processes through which firms can move from needs to projects, from technological trends to experimentation, and from individual problems to shared learning.

The value proposition can be read as a portfolio of orchestration services. First, Intellimech promotes shared research projects on key mechatronics topics and supports the development of pre-competitive platforms for member companies (Intellimech, 2026). Second, it carries out technology scouting to identify themes that are strategically relevant for firms and translate them into specific industrial needs. Third, it develops prototypes and manages research projects commissioned by members or third-party companies. Fourth, it participates in regional, national and European funding schemes, involving members as pilot cases. Fifth, it offers customized

consulting in mechatronics and industrial technologies. Finally, it supports training and continuous updating of technicians, which is particularly relevant in fast-changing technological domains.

This combination of activities suggests that Intellimech is more than a project provider. It can be understood as a membership-based innovation lab that transforms the economic contribution of members into shared access to knowledge, experimentation and ecosystem connections. The annual management quota described in the statute supports the functioning of the consortium, while additional projects and funded initiatives create opportunities for more focused experimentation (Intellimech, 2019). In this sense, Intellimech operates as an innovation alliance: firms do not simply buy isolated services, but participate in a collective infrastructure that can reduce uncertainty and increase innovation capacity.

5 Findings: Orchestration Mechanisms

The analysis identifies five main mechanisms through which Intellimech appears to orchestrate innovation: need sensing and challenge framing; shared knowledge creation; pre-competitive experimentation; boundary spanning; and translation into firm-level pilots and routines.

Table 1. Public evidence and orchestration mechanisms in the Intellimech case

Public evidence	Examples	Orchestration mechanism	Knowledge effect
Method and technology scouting	Needs of members; scouting of relevant themes; definition of pre-competitive projects	Need sensing and challenge framing	Transforms technological trends into shared industrial problems
Research sharing	Shared R&D projects and pre-competitive platforms	Collective agenda setting	Reduces duplication and creates common learning trajectories
R&D and funded projects	WATCHMAN, VIPS, SHOP4CF/WARNING, HARMONY	Pre-competitive experimentation	Creates demonstrators, prototypes and evidence for adoption
AIxLAB	Lovato Electric and COES experiences	Capability building and application support	Moves AI from abstract interest to firm-specific use cases
Knowledge Management Cluster	Phoenix, SIAD MI, Tesmec and other firms	Shared knowledge creation	Supports codification, organizational memory and peer learning
Kilometro Rosso and university links	Universities, research centres, institutional actors and innovation district	Boundary spanning	Combines scientific knowledge, industrial needs and territorial legitimacy

5.1 Need sensing and challenge framing

The first orchestration mechanism concerns the identification and framing of members' needs. Intellimech states that it starts from the needs of members and that the early phases of its operational approach involve technology scouting on themes considered relevant by companies. Meetings with firms are described as fundamental for selecting shared projects, because they allow broad technological domains to be translated into specific industrial requirements.

This mechanism is important because technological trends often remain too abstract for firms. AI, robotics or industrial data spaces become valuable only when they are framed in relation to concrete problems such as defect detection, quality monitoring, maintenance, logistics, worker guidance, data governance or the codification of knowledge. Intellimech performs an intermediary role by interpreting technological opportunities and connecting them to the operational language of companies. In orchestration terms, it converts scattered demand into a portfolio of possible challenges.

5.2 Shared knowledge creation and absorptive capacity building

The second mechanism is knowledge sharing. Intellimech presents itself as a network of knowledge, cooperation, constructive confrontation and exchange of ideas. The Knowledge Management Cluster provides a clear example (Intellimech, 2026). Public case histories indicate that Phoenix, SIAD Macchine Impianti and Tesmec participated in a cluster promoted by Intellimech together with ten other industrial companies. The initiative included a kick-off, shared workshops, individual meetings, periodic assessments and moments of comparison among firms.

The contents of the cluster are significant. Participating companies worked on issues such as management of non-conformities, introduction of dedicated software, standardization of project-related processes and

organizational activities. Phoenix emphasized the need to protect intangible assets and make knowledge available and resilient. SIAD described knowledge management as a way to protect, consolidate and make organizational information accessible to project actors. Tesmec connected knowledge management to operational continuity, shared memory and innovation.

This evidence suggests that Intellimech's orchestration role is not limited to technology transfer. It also concerns the design of organizational learning processes. By bringing companies together around knowledge management, the lab-consortium helps firms recognize common problems, compare practices and transform tacit issues into explicit improvement trajectories. This increases absorptive capacity: firms become better able to recognize, assimilate and apply new knowledge.

5.3 Pre-competitive experimentation and pilot projects

The third mechanism is experimentation. Intellimech promotes R&D projects and pre-competitive platforms, develops prototypes and participates in funded projects. The Watchman project illustrates this role. It aimed to develop a competence and experimentation hub for the application of AI techniques to machine vision in manufacturing, with demonstrators using deep learning to analyse images and recognize defects at the end of production processes. Intellimech acted as project leader in a partnership that included firms, a university and technology actors.

Other examples reinforce this pattern. The VIPS project concerned computer vision for quality control in small welds and included development of hardware, vision algorithms, image storage architecture and system integration. Shop4cf/Warning focused on augmented reality guidance for operators in agile production shopfloors, integrating HMI technologies, field data, enterprise data, CAD drawings and platform components to support assemblers and reduce non-conformities. Harmony, described as a regional project involving large firms, SMEs and research organizations, focuses on human-centric automation, immersive interfaces, ergonomics, human-robot collaboration and sustainable advanced manufacturing.

These examples show how Intellimech creates protected conditions for experimentation before full commercial adoption. Pre-competitive experimentation reduces the cost of learning for individual firms and creates reusable knowledge for the wider network. From an orchestration perspective, the lab designs arenas where firms can explore technologies with limited risk, observe demonstrations, participate in pilots and evaluate transferability to their own context.

5.4 Boundary spanning across firms, universities and institutions

The fourth mechanism is boundary spanning. Intellimech occupies a strategic position between companies, universities, institutions and innovation districts. Public information reports collaborations with universities including the University of Bergamo, Politecnico di Milano, University of Modena and Reggio Emilia, University of Calabria, University of Brescia and University of Pisa (Intellimech, 2026). It is also embedded in Kilometro Rosso, which is described as one of the main Italian innovation districts and as an open innovation environment with more than 80 resident partners and 2,500 employees and researchers.

This position allows Intellimech to act as a translator between different knowledge systems. Universities contribute scientific knowledge and research methods; firms contribute industrial problems and application contexts; institutional actors contribute legitimacy, funding channels and territorial development priorities; technology providers contribute tools and specialized competences. The orchestrator's role is to make these contributions combinable. It must reduce cognitive distance, create opportunities for interaction and ensure that projects remain relevant to firms while being technologically advanced.

Boundary spanning also supports the territorial dimension of innovation. Intellimech is not only a service provider for isolated firms; it contributes to a local and national industrial ecosystem by connecting companies from different sectors and by positioning them within broader innovation networks. This supports the idea that innovation labs can operate as ecosystem infrastructures rather than single-organization units.

5.5 Translation into firm-specific pilots and routines

The fifth mechanism concerns translation into firm-specific applications. AIxLAB provides a recent example. Intellimech describes AIxLAB as a laboratory designed to accompany companies through a structured path of AI exploration, learning and application. The Lovato Electric case highlights the value of combining training and practical experience to evaluate the real impact of AI in an industrial context and to compare with other companies on concrete application cases. The COES case similarly frames AIxLAB as a way to move from talking

about AI in the abstract to building something real and applicable to the firm, with areas such as internal process optimization, data analysis, decision support, logistics and embodied AI applied to production.

This mechanism is crucial because many innovation initiatives stop at awareness and inspiration. Intellimech's lab model appears to address this gap by connecting collective learning with firm-specific experimentation. Firms can participate in shared pathways and then identify applications that fit their own processes. In the Knowledge Management Cluster, this translation took the form of software implementation, standardization of project routines and management of non-conformities. In AIxLAB, it takes the form of AI applications embedded in business processes. In R&D projects, it takes the form of prototypes, demonstrators and pilots.

The contribution of the innovation lab is therefore not simply to produce technological artefacts, but to support the organizational translation required for adoption. This includes framing the problem, selecting the technology, designing the experiment, interpreting results, involving people and transforming learning into routines.

6 Discussion: A Model of Innovation Orchestration through Labs

The case suggests that innovation orchestration through a lab-consortium model can be understood as a cyclical process composed of five phases: sensing, framing, enabling, experimenting and embedding.

Sensing refers to the continuous identification of technological trends and member needs. Framing transforms broad trends into shared challenges and project opportunities. Enabling builds capabilities through training, workshops, mentoring, knowledge management tools and access to experts. Experimenting creates prototypes, demonstrators and pilots in pre-competitive or collaborative contexts. Embedding supports the translation of project learning into firm-specific routines, applications and strategic decisions.

This model extends the literature in three ways. First, it shows that an innovation lab can operate as a governance mechanism for open innovation. The lab does not only host creative sessions; it coordinates the interaction between firms, experts and institutions, helping companies select problems and organize experimentation. Second, it emphasizes the knowledge management dimension of innovation labs. Intellimech's activities around knowledge management, shared workshops, assessment and codification show that innovation orchestration involves the management of intangible assets, organizational memory and learning processes. Third, it highlights the economic and organizational sustainability of the membership-based model. The annual contribution of members supports a shared infrastructure that reduces the cost of technological exploration for individual firms while creating collective benefits.

The paper also shows that innovation labs can reconcile pre-competitive collaboration and firm-specific value creation. Companies may collaborate on generic technological themes, share learning and participate in clusters while still developing individual applications that support competitiveness. This is particularly relevant for SMEs, which may lack the resources to conduct continuous technology scouting or experimentation independently. By joining a lab-consortium, they gain access to a structured innovation environment and to the experience of other firms.

At the same time, orchestration is not neutral. It requires capabilities. The orchestrator must balance the interests of heterogeneous firms, manage confidentiality and intellectual property, select projects that are sufficiently shared but still valuable, and build trust among participants. The statute's attention to confidentiality and the protection of research results is consistent with this need (Intellimech, 2019). Without governance mechanisms, firms may be reluctant to share needs or participate in pre-competitive projects. Therefore, innovation orchestration combines technical competence, relational work and institutional design.

7 Implications

The study has implications for theory, managers and policy makers. For theory, it suggests that innovation labs should be studied not only as spaces for creativity but also as organizational platforms for knowledge orchestration. The concept of innovation orchestration helps explain how labs connect exploration, knowledge sharing and implementation. It also opens a dialogue between innovation lab research, open innovation and knowledge management.

For managers, the case highlights the value of participating in shared innovation infrastructures. Firms can benefit from technology scouting, structured learning pathways, mentoring, access to research expertise, project opportunities and comparison with peers. However, managers should not treat the lab as an external supplier only. The greatest value emerges when firms actively contribute needs, share experiences, involve internal teams and translate insights into internal projects.

For innovation lab managers, the case indicates the importance of designing a balanced portfolio of activities. Awareness events are useful, but they should be connected to workshops, assessment, pilots and implementation support. Similarly, technology projects should be complemented by knowledge management and capability-building activities. Labs that only develop prototypes risk producing isolated outputs; labs that also build routines and communities can generate more durable ecosystem effects.

For policy makers, the Intellimech case suggests that territorial innovation ecosystems can be strengthened through intermediary organizations that aggregate demand and mobilize firms around shared challenges. Public funding can support demonstration projects and experimentation hubs, but the sustainability of the ecosystem may depend on hybrid models that combine member contributions, funded projects, commissioned research and institutional partnerships.

8 Conclusions, Limitations and Future Research

This paper explored how innovation labs can orchestrate innovation in networks of firms and local ecosystems, using Intellimech as an illustrative case. The analysis suggests that Intellimech acts as a lab-consortium that enables companies to access knowledge, scouting, training, mentoring, open innovation opportunities and pilot projects. Its orchestration role unfolds through need sensing, knowledge sharing, pre-competitive experimentation, boundary spanning and translation into firm-specific routines.

The main conclusion is that the value of an innovation lab lies not only in technological experimentation, but in the organization of collective learning. Intellimech creates arenas where companies can define problems, compare experiences, access expertise and test solutions. This turns innovation from an isolated internal effort into a networked and knowledge-intensive process.

The paper has limitations. The analysis is based on public secondary evidence and does not include internal documents, interviews or direct observation. Therefore, the findings should be interpreted as an exploratory conceptualization rather than as a definitive evaluation. Future research should conduct interviews with Intellimech managers, technical staff and member firms, compare Intellimech with other innovation labs or digital innovation hubs, and examine how participation in the consortium affects firm-level innovation outcomes over time. Quantitative research could also investigate whether membership-based innovation labs increase absorptive capacity, project generation, technology adoption and business model innovation among participating firms.

Despite these limitations, the case provides a useful starting point for understanding innovation labs as orchestration infrastructures. In a context where firms must continuously navigate digital transformation and technological complexity, such infrastructures can help local ecosystems transform fragmented knowledge into coordinated innovation capacity.

Abstract

Artificial intelligence is rapidly transforming how innovation is organised within university-centred ecosystems. As AI-enabled practices diffuse across teaching, research, and collaborative activities, universities are required to redefine their governance arrangements in order to preserve transparency, accountability, and institutional legitimacy. These tensions are particularly visible in Academic Innovation Ecosystems (AIEs), where universities act as orchestrators coordinating interactions, infrastructures, and knowledge flows among diverse internal and external actors. While the literature increasingly acknowledges the relevance of responsible AI in higher education, we still lack a process-oriented understanding of how universities translate abstract principles into operational governance configurations embedded in ecosystem activities.

This study develops a conceptual model of AI governance in AIEs through qualitative document analysis grounded in abductive theorising. The empirical basis consists of official AI regulations and policy documents issued by Italian universities in response to emerging European regulatory frameworks. Out of 95 universities, 14 had adopted formal AI-related guidelines. These documents were analysed alongside institutional strategies and mission-related materials to capture how AI governance is articulated across education, research, and third-mission domains. The university is treated as the unit of analysis in its role as ecosystem orchestrator, with attention to how governance provisions shape the coordination of data and decision processes across missions.

Preliminary findings reveal a clear concentration of governance efforts around generative AI in teaching and research, whereas third-mission and administrative applications remain comparatively underdeveloped. In educational contexts, universities primarily focus on academic integrity and disclosure practices, whereas research-related provisions tend to emphasise authorship, intellectual property, and compliance with data protection norms. Across cases, regulatory references to European frameworks are present but uneven, and the operationalisation of monitoring mechanisms often remains generic rather than process-specific.

These patterns are theoretically significant because effective ecosystem orchestration depends on governance arrangements that are embedded in concrete practices rather than articulated solely as high-level principles. When AI governance remains reactive and unevenly specified across missions, the coordinating role of the university risks becoming fragmented. The proposed model advances research on innovation ecosystems by linking institutional conditions, infrastructural arrangements, and mission-specific governance choices, offering a foundation for more accountable and sustainable AI adoption within academic settings.

Paper type: Academic Research Paper

1 Introduction

Digital technologies are transforming how innovation is organized, with artificial intelligence (AI) and platform infrastructures increasingly reshaping coordination and co-creation in complex ecosystems (Rippa and Secundo, 2019).

Within universities, these transformations are reflected in the emergence of Academic Innovation Ecosystems (AIEs), where the university orchestrates interdependent activities (knowledge creation, teaching, technology transfer, and academic entrepreneurship) so that knowledge is created, translated, and diffused through aligned actors, resources, data, and rules (Angrisani et al., 2023; Rippa & Secundo, 2019). We define an AIE as a university-centered socio-technical system in which digital infrastructures, institutional arrangements, and organizational processes interact to generate innovation and societal impact. AIE constitutes a distinctive research setting that integrates educational and research activities aligned with industrial demands, while also promoting engagement initiatives. Within an AIE, each actor plays a specific role connected to the three core missions of higher education institutions (namely, education, research, and third mission - Angrisani et al., 2023). Within this system, digital platforms and data governance provide the connective infrastructure that makes

participation feasible and supports modular growth across organizational and sectoral boundaries (Jarrahi et al., 2023). They provide the technical means to connect actors, standardize information flows, and reduce transaction costs. AI operates within these platforms as a functional and cognitive layer, augmenting human capabilities by enabling data-driven discovery, automation, and decision support (Jarrahi et al., 2023). In turn, Knowledge Management (KM) processes shape how data and insights produced by AI are transformed into actionable knowledge that sustains innovation within the ecosystem.

As academic and external partners move ideas across organizational boundaries, they rely on platform infrastructures that make data legible and interactions governable; within this infrastructure, AI works alongside human expertise to surface relevant knowledge when it is needed, to keep complex information connected to its context, and to sustain the everyday conversations through which opportunities are framed and refined (Secundo et al., 2024; Jarrahi et al., 2023). In practice, this means that searches become more targeted, documents and signals are linked through shared data structures, and routine exchanges are mediated in ways that preserve traceability and accountability, so that the movement from laboratory insight to collaborative development proceeds with greater clarity and speed (Primario et al., 2024; Rippa & Secundo, 2019). Put simply, platforms and governance compose the structural "rails" of the AIE, while AI provides the functional "engine" that raises the speed and quality of knowledge movement from labs to partners and markets (Secundo et al., 2024).

Existing reviews connect AI with collaboration and decision quality, yet they stop short of mapping these capabilities onto the concrete processes through which universities coordinate technology transfer, innovation programming, and academic entrepreneurship (e.g., Secundo et al., 2024; Rippa & Secundo, 2019).

Principles often recommended for AI in knowledge-intensive settings remain only partially institutionalized in the routines that govern university–industry collaboration, leaving a visible gap between guidance and practice (Jarrahi et al., 2023). This gap is amplified by governance choices, because arrangements such as hub-and-spoke consortia allocate data access, roles, and accountability in different ways, and this allocation shapes whether AI can be scaled responsibly in academic settings (Compagnucci et al., 2025; Daymond, 2022).

In response to this gap, we adopt a process lens: we examine AIE activities process by process and interpret them through distinct categories of AI, to describe systematically which mechanisms are activated and which benefits and risks emerge for different actors and levels; from this reading, we derive practical implications for orchestration and governance that align with the platform architectures and data infrastructures characteristic of university-centred collaboration.

In response to this gap, we examine the diffusion of AI within the university environment, whose landscape is characterized by three fundamental missions: teaching, research, and the third mission. These missions fuel the innovative ecosystem of AIE, which reconfigures education and research from an innovation-oriented perspective. Therefore, understanding the extent to which AI is transforming the ecosystem orchestrated by universities requires examining how universities are approaching this revolution.

Accordingly, this study aims to address the following research question: *how do universities configure AI governance within the three missions of universities?*

By addressing this question, the paper advances the understanding of AIEs in two main ways. *First*, it offers a process-oriented framework that connects ecosystem activities with AI capabilities, providing a structured way to analyze how knowledge is mobilized and transformed across academic and external boundaries. *Second*, it translates these insights into implications for university managers and policy makers, clarifying how investments in digital infrastructures, the design of organizational roles, and the implementation of accountability mechanisms can strengthen the functioning and legitimacy of AIEs

2 Theoretical Background

2.1 Academic Innovation Ecosystems (AIEs) in AI landscape

The concept of the AIE represents a novel and transformative reimagining of the integral function that universities serve in fostering and nurturing the intricate frameworks of innovation and entrepreneurial ecosystems that are pivotal in today's rapidly evolving economic landscape. The AIE is a physical environment in which university knowledge feeds the innovation and higher education coherently with the following value proposition: the creation of knowledge to be exploited outside the boundaries of the system (Angrisani et al., 2023). This model adopts a process-oriented perspective that emphasizes the dynamic and multifaceted interconnections that exist among knowledge, innovation, and entrepreneurship, which can be conceptualized as a complex structure comprising a web of relationships that involve multiple interacting actors across various domains. The university acts as an orchestrator connecting knowledge producers with business-oriented

laboratories and professional academies, aligning research, training, and application. The innovation ecosystem, orchestrated by university, enables knowledge to be captured, transformed and applied to create value.

The substantial value that is generated as a result of such innovations is systematically captured within the business ecosystem, thereby creating opportunities for exploitation and application in the broader external environment, which often includes market dynamics and competitive landscapes. Additionally, the transfer and dissemination of knowledge can be effectively executed through the advanced educational pathways that are situated within the AIE, which are thoughtfully provided by professional academies that are committed to academic excellence and industry relevance. It emerges that AIE concept not only facilitates the flow of knowledge but also significantly contributes to the overall advancement of both academic institutions and their industrial counterparts, thereby reinforcing the interconnectedness of education and economic growth.

In the AIE, the value generated by academic knowledge is systematically translated into external opportunities for innovation and entrepreneurship through a structured technology and knowledge transfer platform (Autio and Thomas, 2014). Such platform not only facilitates the exchange of ideas and resources but also fosters collaboration, thereby enhancing the overall capacity for innovation within the ecosystem, which is increasingly deemed indispensable in a knowledge-driven economy. The technology and knowledge transfer platform is administered within the academic environment, where a structured approach is adopted to ensure that the processes involved are both efficient and effective in meeting the overarching goals of innovation and development.

In this landscape, digital technologies, most notably AI, are reshaping innovation ecosystems by shifting coordination from primarily physical and geographic connections to digital and dynamic frameworks supported by platforms (Barile et al., 2025). Secundo et al. (2025) argue that AI acts as a catalyst for the universities to handle the growing complexity and volume of knowledge assets, optimize research collaboration, and drive responsible innovation within these ecosystems. The AI is transforming how the university's missions are performed because it affects the sharing of knowledge within classroom (first mission: education), the generation of novel knowledge and technology (second mission: research), and finally the knowledge transfer practices between University-Industry-Society (third mission).

2.2 AI as an Enabler of Knowledge Management

AI has become a transformative force in KM within university-based ecosystems, fundamentally reshaping how academic communities create, capture, share, and leverage information for research, education, and institutional development (Ruano-Borbalan, 2025). Both AI and KM are tightly linked to the nature of knowledge and learning; recent advances in AI provide new foundations for transforming KM in academic ecosystems (Rezaei, 2025). There are two complementary techno-organizational orientations: (1) KM, which manages knowledge within universities, and (2) AI, a branch of computing focused on developing systems that can emulate aspects of human knowledge and learning activities. We adopt a balanced, partnership perspective in which deep-learning AI augments rather than replaces human intellect, particularly for data-intensive, repetitive, and analytically complex tasks (e.g., forecasting or anomaly detection), while humans retain primacy over open-ended, ambiguous, or morally complex decisions (Jarrahi et al., 2023). This stance aligns with scholarship emphasizing AI-enabled augmentation in knowledge work, innovation processes, and decision-making systems where AI acts as a cognitive partner (Jarrahi et al., 2023). Hence, this perspective focuses on the partnership between humans and AI and on the unique capabilities of each for KM. The dynamic nature of academic knowledge demands more adaptive and intelligent KM solutions than traditional manual or database-driven systems. In this direction, AI-driven tools facilitate knowledge discovery, retrieval, and automation, thereby enhancing organizational knowledge utilization (Secundo et al., 2025). These technologies also contribute to the development of intelligent knowledge repositories, enabling organizations to bridge human expertise with AI-driven insights for superior decision-making and innovation (Ruano-Borbalan, 2025).

To better examine AI's role in supporting KM in universities, we adopt a process-oriented perspective (following Alavi and colleagues as discussed in Rezaei, 2025) and distinguish the following core KM processes: knowledge creation; storage and retrieval; sharing and collaboration.

Concerning knowledge creation, the generation of new knowledge often involves reconfiguring and recombining existing knowledge bases as much as developing ideas from scratch. AI-driven tools facilitate knowledge discovery by automating extraction, classification, and synthesis, turning raw academic data into actionable insights. Deep-learning AI supports predictive analytics for student performance and forecasting abandonment probabilities, enabling early interventions; administrative offices can also automate standard procedures that surround teaching processes. Machine learning algorithms identify patterns in large datasets, accelerate literature reviews, and enable meta-analyses that would otherwise be prohibitively time-consuming

for human researchers. NLP can parse academic articles, theses, and reports to extract concepts, findings, and methods, and automatically summarize key insights, expanding the frontier of inquiry.

Focusing on Knowledge Storage and Retrieval, creating and maintaining organizational memory requires strategies that extract knowledge, make it explicit, and record it systematically for future use via knowledge repositories. AI systems capture and curate this knowledge, powering intelligent repositories that bridge human expertise with AI-driven insights for superior decision-making and innovation. Adaptive learning systems leverage AI to tailor course content, assignments, and assessments based on each student's unique learning style, background, and progress. This not only enhances engagement and retention but also identifies and addresses learning gaps in real time.

Lastly, Knowledge collaboration is at the heart of university-based knowledge ecosystems, involving interdisciplinary research teams, external partners, and diverse communities of practice. AI revolutionizes collaboration through (Przegalinska et al, 2025):

- Real-time synchronization: Multi-user AI research platforms allow concurrent editing, instant updates, and version control, eliminating the confusion of traditional document sharing.
- Intelligent task distribution: AI allocates research and administrative tasks based on team members' expertise and availability, improving efficiency and knowledge sharing.
- Enhanced communication: AI integrates contextual information, prior discussions, and relevant literature into virtual meetings, facilitating more effective academic interactions.
- Such systems support complex group projects, streamline research workflows, and empower students and faculty to co-create knowledge dynamically.

Harnessing AI's benefits requires to face with critical questions about governance, ethics, and responsibility (Barile et al., 2025). Institutions should develop capabilities to ensure:

- *Data security*: AI systems managing sensitive research and student data must adhere to strict privacy and compliance standards, such as GDPR.
- *Bias mitigation*: Training data and algorithms should be regularly assessed to avoid reinforcing existing inequalities or under-representing certain groups.
- *Transparent decision-making*: AI's role in academic evaluation, resource allocation, and research assessment must be transparent and explainable to stakeholders.

This prompts universities to develop frameworks for responsible AI adoption that prioritize inclusivity, accountability, and social impact.

3 Method

This study is a conceptual contribution that develops a process model of AI-enabled AIEs through a rigorous qualitative document analysis combined with abductive theory building. Our logic of inquiry privileges mechanism-centered explanation over statistical inference and follows established guidance on documentary research by treating formal documents as empirical material that can be systematically collected and analyzed with a transparent audit trail (Secundo et al., 2024; Daymond, 2022; Bowen, 2009). We proceed in two coupled streams. In the first, we conduct a structured synthesis of the pertinent literature at the intersection of AIEs, digital platforms, and AI capabilities. We document the search strings, sources, and inclusion/exclusion criteria, and we iteratively consolidate constructs and definitions to ensure conceptual coverage and reproducibility (Secundo et al., 2024). In the second stream, we build an empirical documentary corpus on the governance and use of AI within Italian higher-education institutions. The starting point is the full population of Italian universities (state, non-state, and special-regime institutions). For each institution, we collect any formal AI regulation or guideline intended to "norm" AI use (at the time of data collection, 15 such regulations were available within a population of 95 institutions), and we complement these texts with institutional strategic plans and other official policy documents. We then extend the search to each university's official website to trace the concrete presence of AI-enabled tools or initiatives connected to the university's missions.

The unit of analysis is the university as an AIE orchestrator, operationalized through mission-specific instances of AI use. For each university, we code evidence separately for (i) education and capability building (first mission), (ii) research and knowledge valorization (second mission), and (iii) third mission activities (technology transfer, engagement, and academic entrepreneurship). Data extraction is performed through a shared, predefined coding matrix used by all authors to ensure consistency. For each mission-specific entry, the coder records: the AI use scenario; the AI category; any platforms or tools mentioned; the AIE processes involved; the relevant flows (data, knowledge, resources, decisions); expected or stated benefits and risks (classified as internal vs. external and direct vs. indirect); future development trajectories; document type; target audience; ethical principles invoked; implementation or monitoring mechanisms; and formal accountability

within the organizational structure. Each coded entry must be supported by a verbatim excerpt (with page number when available) or by a stable URL, and we record document provenance, publication date, and access date to maintain an audit trail (Roundy & Asllani, 2024).

To enhance reliability, two researchers independently code an initial subset of institutions to calibrate the codebook and resolve discrepancies, after which coding proceeds with periodic peer debriefs and documented revisions of the code definitions and decision rules (Daymond, 2022). Abductive iteration is operationalized through cycles in which emerging patterns in the coded matrix are compared against the evolving conceptual categories. Finally, we synthesize the coded evidence into within-university process traces that link institutional conditions, platform arrangements, and governance choices to observed or explicitly regulated changes in AIE processes and outcomes. We then apply cross-case pattern matching across universities to identify recurrent configurations that inform the proposed process model and its associated propositions.

4 Results and Discussion

Across the corpus, the strongest concentration concerns generative AI, especially in education and research. In the coded dataset, generative AI is explicitly addressed in 10 out of 14 universities for teaching related activities and for research related activities, while explicit attention to AI in third mission domains remains rare (1 out of 14) and only partially present in administrative functions (3 out of 14).

This distribution suggests that universities are reacting first to the most visible and rapidly diffusing practices, such as student use of generative tools in learning, and researcher use in writing and synthesis, while governance implications for technology transfer and academic entrepreneurship are still underdeveloped (Secundo et al., 2025; Rippa & Secundo, 2019).

In the teaching related provisions, governance concentrates on academic integrity and assessment legitimacy, typically via disclosure expectations and guidance on acceptable support versus substitution. In the research related provisions, the emphasis shifts towards authorship and compliance with intellectual property and data protection constraints, often treating AI outputs as aids that require verification and traceable attribution. Across both missions, benefits are typically framed as efficiency and quality gains, while risks are framed around privacy, bias, and erosion of trust in evaluation processes. (Jarrahi et al., 2023; Secundo et al., 2025).

Transversally, the documents emphasize high level principles and responsibility assignment, but they vary markedly in how far they translate principles into actionable mechanisms. References to major regulatory anchors are present but not uniform, with explicit mentions of the EU AI Act (EU AI Act, 2024) appearing in 6 out of 14 cases and GDPR (European Union, 2026) or privacy frameworks in 7 out of 14. This reinforces the idea that universities are constructing legitimacy through compliance narratives, yet the operationalisation of monitoring routines often remains generic. (Compagnucci et al., 2025; Secundo et al., 2025).

From an AIE perspective, this pattern is theoretically consequential because orchestration depends on the capacity to govern flows of data, knowledge, resources, and decisions across internal units and external partners and stakeholders (Angrisani et al., 2023). When AI governance is articulated mainly as a set of generic principles, and third mission and administrative domains remain weakly specified, the university's orchestration role risks becoming reactive and irregular across ecosystem processes.

To deepen the interpretation of these findings, we analyse AI governance through the lens of the KM cycle, distinguishing between knowledge creation, storage and retrieval, sharing and collaboration, and application (Alavi & Leidner, 2001; Grant, 1996). This perspective allows us to assess whether governance mechanisms align with the transformation of underlying knowledge processes within AIEs.

AI Governance in Knowledge Creation Processes

In both teaching and research domains, AI governance concentrates primarily on the knowledge creation phase. Universities frame generative AI as a support tool for idea generation. However, regulatory provisions do not primarily focus on redesigning collaborative knowledge production processes; rather, they concentrate on safeguarding the legitimacy and integrity of outputs.

In teaching-related provisions, governance centres on academic integrity and assessment legitimacy, typically through disclosure expectations and guidance on acceptable support versus substitution. In research-related provisions, the emphasis shifts towards authorship attribution, intellectual property, and compliance with data protection norms, often treating AI outputs as aids requiring human verification and traceable responsibility. Across both missions, benefits are typically framed as efficiency and quality gains, while risks are framed around privacy, bias, and erosion of trust in evaluation processes (Jarrahi et al., 2023; Ruano-Borbalan, 2025).

From a KM perspective, this indicates that AI governance is strongly output-oriented in the creation phase. While AI is acknowledged as augmenting cognitive work, governance mechanisms largely address accountability ex post rather than redesigning the socio-technical conditions of collaborative knowledge generation (Alavi & Leidner, 2001; Jarrahi et al., 2023). In this sense, the institutional response remains corrective rather than architectonic. Accordingly, when AI governance is concentrated in knowledge creation processes and framed around output legitimacy, universities reinforce reputational protection but limit the structural redesign of collaborative knowledge production systems (*Proposition 1*).

AI Governance and Organisational Knowledge Storage and Retrieval

Although less explicitly articulated, AI-related provisions also intersect with the storage and retrieval dimension of KM. References to data governance and compliance with GDPR suggest that universities are aware of AI's implications for organisational memory and information accessibility.

However, regulatory framing in this phase is predominantly compliance-driven. Explicit references to the EU AI Act appear in 6 out of 14 cases, while GDPR or privacy frameworks are mentioned in 7 out of 14. These references reinforce the role of legal anchors in constructing institutional legitimacy (Compagnucci et al., 2025; Secundo et al., 2025).

From the perspective of the knowledge-based view of the firm, organisational performance depends on the integration and coordination of distributed knowledge (Grant, 1996). In AIEs, digital infrastructures and data governance constitute the backbone through which knowledge becomes retrievable and scalable (Angrisani et al., 2023). We therefore propose that when AI governance is predominantly anchored in regulatory compliance rather than embedded in organisational knowledge infrastructures, institutional legitimacy strengthens but systemic integration of AI into knowledge architectures remains constrained (*Proposition 2*).

AI Governance in Knowledge Sharing and Boundary-Spanning Integration

The most pronounced asymmetry emerges in the sharing and collaboration phase of the KM cycle. Explicit governance attention to AI in third-mission activities appears in only 1 out of 14 universities. Administrative applications are mentioned in 3 out of 14 cases, typically in relation to internal efficiency rather than ecosystem coordination.

This imbalance is theoretically consequential: innovation ecosystems depend on distributed knowledge integration across organisational and sectoral boundaries (Autio & Thomas, 2014; West & Bogers, 2014). AIEs, in particular, rely on orchestrated flows between research units, teaching activities, and external stakeholders (Angrisani et al., 2023). When AI governance remains inward-looking and concentrated on classroom and publication contexts, the regulatory architecture fails to address how AI may reshape inter-organisational knowledge sharing and collaborative innovation.

Recent work on AI-enabled ecosystems emphasises the transformative role of AI in coordinating open innovation processes and balancing competition and collaboration (Barile et al., 2025; Primario et al., 2024). Yet our findings indicate that formal governance provisions lag behind this potential, especially in domains directly linked to entrepreneurial and third-mission activities. In KM terms, governance attention diminishes precisely where knowledge becomes more distributed and boundary-spanning. As knowledge processes become increasingly inter-organisational, the absence of formalised AI governance mechanisms heightens the risk of fragmented ecosystem coordination (*Proposition 3*).

AI Governance in Knowledge Application and Decision Integration

Across the corpus, documents emphasise high-level principles and responsibility assignment, but they vary in how far these principles are translated into actionable mechanisms. Monitoring routines, where mentioned, often remain generic, with references to committees or advisory bodies rather than clearly embedded procedural systems.

This pattern reinforces the idea that universities are constructing legitimacy through compliance narratives, while operationalisation remains uneven. From an ecosystem perspective, orchestration depends on the capacity to govern flows of data, knowledge, resources, and decisions across internal units and external partners (Daymond et al., 2023; Angrisani et al., 2023). When AI governance is articulated mainly as a set of generic principles and remains weakly specified in third-mission and administrative domains, the university's orchestrating role risks becoming reactive and irregular across ecosystem processes. So, the greater the alignment between AI governance mechanisms and the entire KM cycle (spanning creation, storage, sharing, and application) the stronger the university's capacity to orchestrate coherent knowledge flows within Academic Innovation Ecosystems (*Proposition 4*).

Taken together, the evidence reveals an asymmetric configuration of AI governance across the KM cycle. This asymmetry suggests that AI governance in AIEs is currently shaped more by reputational risk management and regulatory alignment than by a systemic redesign of knowledge processes. As AI increasingly becomes embedded in platform architectures and data infrastructures that sustain ecosystem coordination (Roundy &

Asllani, 2024; Secundo et al., 2025), the absence of process-integrated governance may generate fragmentation in how knowledge flows are structured and legitimised across the university's three missions.

To move from descriptive evidence to analytical structuring, we organise the findings into a configurational mapping of AI governance across KM cycle and university missions (Table 1).

Table 1: AI governance across KM cycle and university missions

	University Mission		
KM Process	***Education***	***Research***	***Third Mission & Administration***
Knowledge Creation	Strong regulatory attention to generative AI use in assignments, exams, and learning activities. Focus on disclosure, academic integrity, and legitimacy of outputs.	Strong attention to generative AI in drafting, data analysis, and synthesis. Emphasis on authorship, IP, traceability, and verification.	Minimal formalisation. AI rarely addressed in venture creation, technology transfer, or entrepreneurial knowledge generation.
Knowledge Storage & Retrieval	References to data protection, repository use, and privacy compliance. Limited strategic articulation of AI-enabled learning repositories.	Attention to research data governance, GDPR compliance, and data management practices. Limited discussion of AI-driven knowledge architecture redesign.	Sparse references to institutional memory or ecosystem-level knowledge repositories. Storage framed mainly through compliance logic.
Knowledge Sharing & Collaboration	AI framed as individual support tool rather than collaborative infrastructure. Limited attention to peer-to-peer AI-mediated collaboration.	Limited governance concerning AI in inter-institutional or interdisciplinary collaboration. Collaboration governance remains generic.	Very weak formalisation of AI in university–industry collaboration, open innovation, or entrepreneurial ecosystems. Boundary-spanning knowledge flows largely unregulated.
Knowledge Application & Decision Integration	Governance focuses on acceptable use rather than integration into decision processes.	AI framed as aid in research productivity, but limited embedding into structured decision architectures.	Few references to AI in administrative decision systems. Monitoring mechanisms remain high-level and principle-based.

5 Ethics Declaration

The authors declare that they have complied with all ethical requirements. No human participants or animals were involved in the study. No conflict of interest exist.

6 AI Declaration

The authors declare that ChatGPT was used exclusively for language editing and minor stylistic revisions. The tool was not used for conceptual development, data analysis, interpretation of results, or generation of substantive content. All intellectual contributions, arguments, and conclusions remain the sole responsibility of the authors.

Controversial Advertising: Multicultural and Generational Perspectives on Knowledge and Cultural Meaning-Making

Gintarė Kriaučiūnaitė-Lazauskienė
Riga Technical University, Riga, Latvia

Abstract

Why do some advertisements inspire admiration and stick in people's minds across cultures, yet cause certain audiences to refuse to buy? This research investigates that puzzle by examining controversial advertising as a site of knowledge diversity. In this research, the perception of advertising is treated as a space in which culturally embedded unspoken knowledge and the collective construction of meaning intertwine with generational identity, thereby shaping how controversial messages are understood, interpreted, and responded to.

Twenty-two international students at Vilnius University of Applied Sciences (VIKO), Lithuania, the majority identifying as Generation Z, participated in a mixed-methods design combining focus group inquiry with a structured Likert-scale questionnaire. The sample was purposefully assembled to maximise cultural heterogeneity, with participants drawn from Morocco, Nigeria, Cameroon, Bangladesh, India, and Lithuania. The stimuli comprised five controversial advertisements drawn from Lithuanian and international contexts.

The main finding highlights what we term the "*paradox of advertising in shame-based cultures*". Students from collectivist and shame-oriented cultural backgrounds admitted that controversial advertisements attract attention and are easily memorable. However, they also emphasized that they would not want to purchase products or services from the advertised brands in their home countries. This resistance did not stem from personal indifference but was determined by communal knowledge systems that prioritise group reputation, family honour, and social conformity. Thus, the interpretation of advertising is never culturally neutral (de Mooij, 2019).

To explain this phenomenon, we present the *Cultural Knowledge Mediation Model* (CKMM). This five-stage system explains why traditional models of advertising effectiveness, such as the ELM, the AIDA hierarchy and the FCB Grid, may fail to adequately explain consumer reactions in collectivist and shame-based cultures. The model also generates three testable propositions (P1–P3) for future research.

For practitioners, the findings underscore that culturally intelligent, ethically responsible communication requires brands to engage with local knowledge ecosystems rather than assuming universal message reception. For knowledge management study, the study positions advertising reception as an under-examined knowledge-intensive phenomenon and challenges the prevailing treatment of Generation Z as a culturally homogeneous cohort.

Keywords: controversial advertising, cultural knowledge systems, generational meaning-making, knowledge diversity, social sustainability

Paper type: Academic Research Paper

1 Introduction

Consider the following scene: a group of university students from Morocco, Nigeria, India, and Lithuania sit together watching the same provocative advertisement. They all laugh; they all remember it afterwards. But ask them whether they would buy the product, and the room splits along cultural lines that no demographic variable such as age, education, digital fluency, can predict. This is not a failure of advertising effectiveness in any conventional sense but a collision between the message's intended knowledge transfer and the culturally embedded interpretive frameworks that audiences bring to the encounter.

This research examines controversial advertising communication: advertising deliberately designed to push the boundaries of social norms, raise sensitive issues, or challenge prevailing values through a knowledge management approach. This lens helps demonstrate that people do not merely react to controversial advertising. Their interpretation is based on what they already know, what they believe, and what they share with others. In this sense, the perception of controversial advertising is a process of knowledge formation. This tension forms the starting point of the research.

Organisations committed to socially sustainable communication need to know not just *whether* audiences attend to their messages, but *how* culturally diverse knowledge systems mediate the journey from attention to action – a question with direct implications for 'intelligent knowledge for sustainable organisations'.

The research reported here centres on 22 international students, predominantly Generation Z, at VIKO. Their diverse cultural backgrounds (covering North Africa, Sub-Saharan Africa, South Asia, and Eastern Europe)

presented a rare opportunity to observe how culturally distinct knowledge systems generate divergent responses to identical advertising stimuli.

2 Literature Review

2.1 Controversial advertising as a knowledge phenomenon

Controversial advertising is generally understood as commercial communication that provokes strong emotional reactions. It often employs prohibited elements such as taboo topics (religious elements, disgust, sexism) or socially sensitive contents (such as children, homeless pets) (Noland, 2021). Many studies have examined its impact on brand recognition, purchase intentions, and consumer attitudes (Machi et al., 2022; Hussain et al., 2023).

The process maps onto Nonaka and Takeuchi's (1995) SECI model of knowledge conversion. When a consumer encounters a controversial advertisement, the *Socialisation* phase activates shared tacit understandings about culturally embedded norms describing what is appropriate, what provokes shame, and what merits attention. Through Externalisation and Combination, these tacit reactions are articulated, shared and recombined with existing brand knowledge. Finally, *Internalisation* – the conversion of new explicit knowledge into personal implicit knowledge. This is a stage at which culturally embedded norms may block or facilitate brand adoption. Knowledge transfer barriers documented in organisational contexts (Argote and Ingram, 2000; Szulanski, 1996) apply with equal force to the consumer domain. Drawing on Grant's (1996) knowledge-based theory, we can understand culturally diverse audiences as possessing specialised knowledge that requires integration mechanisms which global advertising campaigns rarely provide. Table 1 (below) summarises prior empirical studies on Generation Z, advertising and multicultural knowledge practices.

Table 1: Selected empirical studies on Generation Z, advertising, and multicultural knowledge practices

Study	Context	Method / n	Ad Type	Key Finding (KM Relevance)
Li et al. (2026)	China	Qual. / n=14	Controversial sponsorship	Cultural conservatism rendered sexually suggestive content inappropriate; Gen Z transformed brand messages into memes as active sensemaking
Zulu et al. (2025)	South Africa	Quant. / n=504	Sustainable fashion	Cultural mindfulness positively influenced local brand attitudes; eco-label verification required to address trust deficits
Ali et al. (2026)	Indonesia	Quant. / n=306	Halal fashion	Religious identity more influential than product knowledge; collective norms dominated individual responses
Hu et al. (2026)	Unspec.	Exper. / n=509	CSR communication	Cultural ideology moderated CSR interpretation; intra-generational heterogeneity driven by ideology
Talesara (2025)	India	Mixed / n=115	Sustainable fashion	High environmental awareness but persistent attitude - behaviour gap; affordability as primary barrier
Fitriyana et al. (2025)	Unspec.	Qual. phenom.	Sustainability claims	Authentic narratives increased loyalty; inconsistent claims reduced purchase intent substantially
Pabian & Reformat (2025)	Poland	Qual. / n=70	Inclusive advertising	European Gen Z reported acceptance and empathy; responses distinct from Asian collectivist samples
Buckley et al. (2024)	Unspec.	Qual. / n=9	Femvertising	Identity alignment overrode inauthenticity; 'guilty displeasure' when criticising ads tied to gender identity
Sheng & Basha (2026)	China	Quant. / n=307	Short-video ads	Age/gender non-significant; content quality and algorithmic trust predicted purchase intent

2.2 Cultural knowledge systems and the dynamics of interpretation

Culture is among the most powerful yet least explicitly theorised dimensions of knowledge in management scholarship. Hofstede et al.'s (2010) foundational work established that cultural values – such as individualism and collectivism, power distance, uncertainty avoidance, long-term orientation, and indulgence/restraint – systematically shape both organisational behaviour and communicative practice. Within advertising research, De Mooij (2019) has demonstrated that these dimensions influence the acceptability and effectiveness of provocative messaging across national contexts (Kunz et al., 2025).

For the present study, the concept of *shame culture* is particularly salient. In shame-oriented cultures, conduct is calibrated predominantly by perceived group judgement and the threat of social dishonour; in guilt-oriented cultures, internal moral evaluation plays a more prominent role (Benedict, 1946; Öztek et al., 2025). work on This distinction has been further illuminated by Markus and Kitayama's (1991) influential work, and more recently by Guo et al. (2024), emphasising *interdependent self-construal*: in collectivist societies, the self is constituted through social relationships rather than autonomous individuality, and behaviour is regulated through sensitivity to others' expectations rather than through internal guilt. Hall's (1976) framework adds a further lens: shame cultures typically operate as high-context environments, where meaning is embedded in social relationships and situational cues rather than in explicit verbal content. Despite its explanatory potential, the shame–guilt dimension has received limited systematic attention in advertising research, a gap this study directly addresses.

What makes shame culture so consequential for advertising knowledge transfer is the nature of the knowledge involved. We are dealing not with mere individual preference but with what Polanyi (1966) calls *tacit knowledge* – knowledge that is deeply personal, resistant to explicit articulation, and acquired through immersion in a community of practice. For individuals from shame-culture backgrounds, such advertisements are not merely distasteful; they activate community-level knowledge systems bound up with honour, reputation and social presentation, making the interpretive act collective even when the viewer sits alone.

2.3 Generation Z: Cohort unity, cultural diversity

Generation Z (in this researched aimed from 1999-2003) has attracted significant attention from researchers as a consumer group, recognized as having grown up in the digital age characterized by high levels of media literacy and an interest in social and ethical issues (Dwivedula, 2025). Several researchers argue (Seemiller and Grace, 2019; Dolot, 2018) that this generation demonstrates greater openness to diversity, social issues, and non-normative content than previous generations.

Yet a troubling simplification pervades much of this literature: the treatment of Generation Z as a globally homogeneous group. This assumption obscures the profound cultural and geographical diversity within the cohort. As Dolot (2018) rightly cautions, generational characteristics are not culturally neutral. Rather, they reflect the specific social, educational, and familial environments in which individuals develop. For international students, who must navigate multiple cultural frameworks simultaneously, the tension between generational identity and cultural heritage becomes particularly acute.

2.4 Thematic synthesis

Four themes emerge from the nine included studies that reinforce and extend the theoretical claims above. *First*, cultural knowledge systems consistently override generational cohort characteristics as the primary determinant of advertising interpretation. Li et al. (2026) find that Chinese Gen Z rejected sexually suggestive content despite generational openness, while Ali and Rafdinal (2026) show that Indonesian religious community identity outweighed individual product knowledge as a pattern structurally analogous to the shame-culture dynamics central to this study, and consistent with Bagozzi, Verbeke and Gavino's (2003) finding that culture moderates the self-regulation of shame. *Second*, the evidence substantiates the attitude –behaviour dissociation at the heart of what we term the shame-culture paradox. Talesara (2025) demonstrates cases where stated values failed to predict purchasing behaviour. *Third*, Generation Z emerges as a knowledge-active cohort. Li et al.'s (2026) meme-making esports fans and Buckley et al.'s (2024) "guilty displeasure" among femvertising viewers both illustrate collective sensemaking. *Fourth*, the sustainability implications of culturally intelligent communication are empirically robust: Fitriyana et al. (2025) and Zulu et al. (2025) demonstrate that authentic, culturally attentive communication generates measurable gains in brand trust and loyalty.

2.5 Conceptual framework: The Cultural Knowledge Mediation Model

The theoretical strands reviewed above converge on a problem that existing models leave unresolved: why do conventional advertising effectiveness frameworks – such as the Elaboration Likelihood Model (Petty and Cacioppo, 1986), the AIDA hierarchy, the FCB Grid (Vaughn, 1980) – fail to predict advertising responses in collectivist, shame-oriented cultural contexts? These models implicitly assume culturally neutral, individual-level processing; the empirical evidence reviewed here suggests that this assumption breaks down precisely where culturally embedded knowledge systems intervene.

To address this gap, we propose the *Cultural Knowledge Mediation Model (CKMM)*, an integrative five-stage framework synthesising knowledge management theory (Nonaka and Takeuchi, 1995; Tsoukas, 1996; Grant, 1996), cross-cultural psychology (Hofstede et al., 2010; Benedict, 1946; Hall, 1976; Markus and Kitayama, 1991).

The model operates as follows (Figure 1). *Stage 1:* A controversial advertising stimulus enters the field. *Stage 2:* Before cognitive processing occurs, the stimulus passes through a *cultural knowledge* filter shaped by the audience's position on Hofstede's individualism–collectivism dimension, Benedict's shame–guilt continuum, and Hall's high–low context communication spectrum. *Stage 3:* The filtered stimulus enters the *knowledge transfer process*, theorised through Nonaka and Takeuchi's SECI model. In shame-culture contexts, the Socialisation phase activates tacit peer and elder norms, creating barriers to Internalisation of culturally misaligned brand associations. *Stage 4:* The model produces two parallel but potentially divergent outputs: cognitive responses and behavioural intent. This division is the CKMM's central departure from conventional models. *Stage 5:* All pathways converge on social sustainability outcomes: responsible brand communication, brand trust, and long-term stakeholder legitimacy.

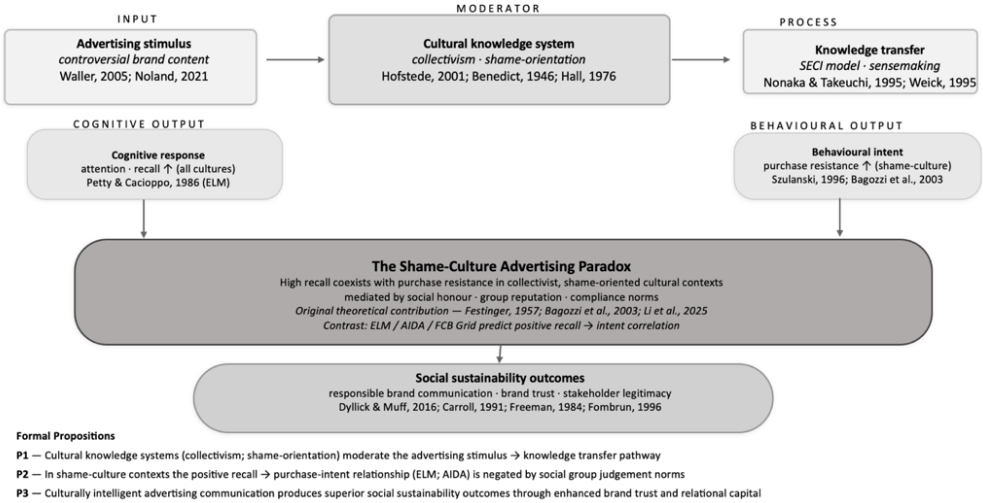

Figure 1: Cultural Knowledge Mediation Model (CKMM).
Source: Author's own conceptualisation (2026). P1–P3 = formal propositions derived from the framework.

The CKMM's central analytical contribution is the formalisation of the shame-culture advertising paradox. The paradox emerges at the bifurcation between cognitive and behavioural outputs: high recall coexists with strong purchase resistance because the knowledge transfer process is blocked by community-level knowledge systems related to honour and social compliance. This constitutes a cognitive dissonance dynamic in Festinger's (1957) terms – the individual's private receptivity is in tension with the publicly required performance of non-engagement. Here, three formal propositions follow.

P1: The more collectivist and shame-oriented an audience's cultural knowledge system, the larger the gap between advertising recall and purchase intention for controversial stimuli. P2: The recall–intention gap in P1 widens in intergenerational or public viewing contexts and narrows in private or peer-only contexts. P3: Longer exposure to individualist host cultures (acculturation) progressively attenuates the shame-culture effect.

3 Methodology

The study employed a mixed-methods design combining qualitative focus group inquiry with a supplementary quantitative questionnaire (Creswell and Creswell, 2018). This combination enables rich exploration of meaning-making processes while providing systematic attitudinal data amenable to comparison across cultural groups.

3.1 Participants

Twenty-two international students enrolled at VIKO. Participants were purposefully selected to maximise cultural diversity (voluntary), with representation from Morocco, Nigeria, Cameroon, Bangladesh, India, and Lithuania (as a comparative group). The majority identified as Generation Z (born 2001–2004, within the generational range defined in Section 2.3).

3.2 Focus group

The two focus group sessions, lasting approximately 75–90 minutes, were conducted at VIKO. Participants were shown five controversial advertisements drawn from Lithuanian and international contexts, encompassing sexually suggestive imagery, sexual wordplay in food advertising, destination marketing, and personal care campaigns. Following Krueger and Casey (2015), a semi-structured discussion guide elicited responses concerning emotional reactions, cultural values, ethical judgements, and purchase intentions. The session was in English, audio-recorded and transcribed verbatim.

3.3 Questionnaire

A short, structured questionnaire was administered after the focus group. Eight statements were measured on a five-point Likert scale (1 = Strongly disagree; 5 = Strongly agree), covering attentional capture, memorability, cultural influence on perception, generational openness, brand harm, purchase intention, and the need for cultural adaptation.

3.4 Analysis

Focus group transcripts were analysed using Braun and Clarke's (2023) reflexive thematic analysis. Initial codes were generated inductively and iteratively organised into candidate themes, with priority given to patterns relating to cultural knowledge systems, sensemaking processes, and the relationship between advertising reception and cultural identity. Questionnaire data were summarised using descriptive statistics. Integration followed a convergent parallel design (Creswell and Creswell, 2018), in which qualitative findings provide interpretive depth for quantitative patterns.

4 Findings

4.1 Attentional impact and knowledge activation

Across all cultural backgrounds, participants confirmed without exception that controversial advertising commands attention and generates enduring recall. Questionnaire data reflected this: "Controversial advertising attracts my attention" scored a mean of 4.1, and "I remember controversial ads more than regular ads" a mean of 3.9. In the focus group, participants described controversy as something that compels engagement almost involuntarily – a stimulus that activates epistemic curiosity and social debate rather than passive viewing. This foundation supports the SECI logic: schema-disrupting stimuli push audiences into the Socialisation and Externalisation phases, producing deeper processing and more durable retention than schema-confirming information.

4.2 The shame-culture advertising paradox

The most distinctive finding was a consistent pattern among participants from North African, Sub-Saharan African, and South Asian backgrounds. These students acknowledged the attentional power of controversial advertisements while simultaneously expressing firm resistance to purchasing the featured brands in their home-country contexts. Crucially, this resistance was not about personal distaste; it was about community.

A participant from Morocco described experiencing no personal discomfort with certain advertisements but explained that encountering such content alongside parents or community elders would necessitate either physical withdrawal or a deliberate performance of non-engagement. A participant from Cameroon used the phrase "you would be ashamed" to capture the contextual discomfort of encountering sexually suggestive advertising in intergenerational settings. Participants from Bangladesh and India drew explicit connections to family and caste structures as knowledge systems that define acceptable brand associations.

What we see here is the shame-culture advertising paradox: high memorability coexisting with active purchase resistance rooted in *interdependent self-construal*.

4.3 Contextual code-switching as knowledge practice

Participants exhibited considerable sophistication in modulating their responses according to social context. Several described markedly different reactions to the same advertisement depending on whether it was encountered alone, with peers, or in an intergenerational family setting. The statement "*I would act like I didn't see it*", offered by multiple participants when describing intergenerational viewing captures a widely shared strategy of contextual code-switching.

This behaviour reveals that advertising reception is not a fixed individual response but a socially situated knowledge practice. The meaning attributed to controversial content is dynamically reconstructed depending on the knowledge context in which it is encountered – precisely the kind of contextual, retrospective interpretation that Weick's (1995) sensemaking framework predicts. Consistent with Hall (1976), participants from high-context cultures derived meaning not from the advertisement's explicit content alone but from the social situation surrounding its reception.

4.4 Intra-generational diversity

While participants broadly agreed that their generation is more open to controversial advertising than older cohorts (mean = 3.7), the qualitative evidence told a more nuanced story. Participants from collectivist backgrounds displayed markedly more cautious and contextually conditional acceptance than those from more individualist settings. Generational membership supplies a shared communicative register; cultural knowledge systems supply the interpretive filters through which it operates. Generation Z's knowledge-active characteristics do not override cultural heritage; they interact with it in complex, sometimes contradictory, ways (see Table 2).

Table 2: Summary of questionnaire attitudinal items (n = 22)

Statement	Mean	SD
Controversial advertising attracts my attention	4.1	0.82
I remember controversial ads more than regular ads	3.9	0.94
Some controversial ads make me feel uncomfortable	3.8	1.05
Cultural background influences how I perceive controversial ads	4.3	0.71
My generation is more open to controversial advertising	3.7	0.98
Controversial advertising can harm a brand's image	3.6	1.02
I would stop buying from a brand after a controversial ad	3.1	1.14
Brands should adapt controversial ads for different cultures	4.4	0.68

Source: Author's own research (2026). Scale: 1 = Strongly disagree; 5 = Strongly agree.

The two highest-scoring items concerned cultural influence on perception (4.3) and the need for cultural adaptation (4.4) strengthening the qualitative evidence for the centrality of cultural knowledge systems. The comparatively lower mean for purchase discontinuation (3.1) is telling: participants recognise cultural discomfort without necessarily translating it into universal brand avoidance, a pattern consistent with the shame-culture paradox's distinction between private attitude and public behaviour. Remarkably, this item measured general boycott intention, while the paradox concerns context-specific purchase resistance in home-country and intergenerational settings, which the qualitative data capture more directly.

5 Discussion

The findings carry several implications for knowledge management theory and for the practice of global brand communication.

Controversial advertising as knowledge-intensive phenomenon. The study establishes that the effectiveness of controversial advertising cannot be understood without reference to the tacit cultural knowledge (Polanyi, 1966) that audiences bring to the interpretive encounter. The SECI model illuminates the specific failure point: in shame-culture contexts, the Socialisation phase activates community norms that block Internalisation – the stage at which brand associations would normally become embedded in individual knowledge repertoires. Organisations deploying controversial communication without mapping the tacit knowledge landscapes of their audiences risk producing what Szulanski (1996) terms 'knowledge stickiness': the message arrives but cannot be absorbed because of causal ambiguity about the brand's cultural intent and motivational barriers rooted in collective identity.

The shame-culture paradox as a structural challenge to advertising theory. Conventional advertising effectiveness models assume a positive relationship between affective engagement and purchase intention. Our findings demonstrate that this relationship is culturally conditional: in shame-culture contexts, high memorability coexists with strong purchase resistance when the advertising stimulus activates knowledge systems related to honour and social compliance. The evidence in Section 2.4 reveals this as a cross-contextual pattern: Talesara (2025) demonstrates analogous attitude–behaviour dissociations driven by economic constraints, suggesting that the paradox reflects a broader structural feature of Gen Z consumer behaviour that takes a distinctively cultural-normative form in collectivist settings.

The limits of generational framing. Much of the literature treats Generation Z as a globally homogeneous cohort; our findings complicate this picture considerably. Cultural knowledge systems, particularly those associated with collectivist, shame-oriented structures and *interdependent self-construal* (Markus and Kitayama, 1991), exert a persistent influence on advertising responses even among digitally literate, globally connected young adults. The contextual code-switching shown here, where participants reacted very differently to the same advertisement depending on the social situation as prove that the meaning of an advertisement is not fixed. Rather, it is co-constructed by the message, the audience's beliefs and knowledge, and the context in which it is encountered (Khan & Kumar, 2026; Anker, 2024).

6 Conclusions

This study has examined controversial advertising through the lens of knowledge management, revealing how culturally embedded knowledge systems and generational dynamics interact to produce diverse and sometimes paradoxical patterns of response. Its central contribution is the identification and formalisation of the *shame-culture advertising paradox*: a consistent pattern in which high attentional and memorial impact coexists with purchase resistance among individuals from collectivist, shame-oriented backgrounds. It becomes intelligible only when advertising reception is understood as a culturally mediated knowledge process, formalised here through the Cultural Knowledge Mediation Model (CKMM) and its three testable propositions.

The structured literature overview (nine included studies) provides independent cross-cultural support for the paradox and shows that analogous value–behaviour dissociations recur in economically and ideologically diverse Gen Z samples.

For practitioners, the message is clear: culturally intelligent communication is not a nicety but a necessity for brands seeking both commercial effectiveness and social legitimacy. For scholars, the study positions advertising reception as a knowledge-intensive phenomenon deserving sustained attention within KM allowance and challenges the assumption that Generation Z is a culturally unified audience.

Several limitations suggest productive future directions. The sample, while culturally diverse, is small (n = 22) and drawn from a single institutional setting, and the single, large focus group format may have amplified dominance and social-desirability effects. Replication with larger, more geographically varied samples is essential. Future work should examine how the shame-culture paradox operates across other controversial advertising categories and generational cohorts. The acculturation variable merits particular attention: Berry's (1997) framework for immigration and adaptation suggests that time spent outside one's home culture may progressively moderate the shame-culture dynamic, a hypothesis that longitudinal designs are well suited to test.

Exploring User Intentions and Behavior Towards Generative AI Adoption in Conversational Commerce

Pao-Jung Chao, Szu-Ying Lai, Chih-Chieh Chang
National Taiwan University of Science and Technology, Taipei, Taiwan

Abstract

Generative Artificial Intelligence (GenAI) is transforming retail from static e-commerce to interactive conversational commerce (C-commerce). Unlike traditional chatbots, which struggle with complex inquiries and produce formulaic responses, GenAI leverages advanced Natural Language Processing (NLP) to enable contextual awareness, personalisation, and empathetic dialogue. This paper argues that GenAI-based chatbots represent a shift toward intelligent knowledge systems capable of fostering organisational resilience and inclusive innovation.

To explore this phenomenon, we integrate three foundational frameworks: the Stimulus-Organism-Response (SOR) framework, the Technology Acceptance Model (TAM), and the Information System Success (ISS) Model. The GenAI chatbot environment serves as the external Stimulus, shaping the user's internal Organism state — comprising TAM-derived perceptions (Ease of Use, Usefulness, Risk, and Enjoyment) and ISS-derived Perceived Trust — which ultimately drives the behavioural Response (intention and actual usage).

The framework was validated through an online survey (N = 283) conducted in Taiwan, featuring a scenario-based interaction involving a hypothetical perfume purchase. Data were analysed using Partial Least Squares Structural Equation Modelling (PLS-SEM) in SmartPLS 4.0. The measurement model demonstrated strong reliability (Cronbach's α: 0.819–0.903; CR > 0.7) and convergent validity (AVE: 0.541–0.816). Seven of nine hypotheses were supported (H1, H2, H4, H5, H7, H8, H9). Behavioural intention significantly predicted actual behaviour ($\beta = 0.746$, $p < 0.001$, $R^2 = 0.556$). Intention was positively influenced by perceived usefulness ($\beta = 0.243$), perceived trust ($\beta = 0.238$), perceived enjoyment ($\beta = 0.211$), and perceived ease of use ($\beta = 0.175$). Perceived trust was driven by information quality ($\beta = 0.390$) and service quality ($\beta = 0.341$). Perceived risk and system quality showed no significant effects, suggesting that technical availability has become a baseline expectation, while trust is anchored in knowledge asset quality — response accuracy, empathy, and personalisation.

These findings support a stratified hybrid implementation strategy: deploying traditional automation for routine administrative tasks while reserving GenAI for high-empathy interactions such as product recommendations. This approach positions chatbots not merely as sales assistants but as proactive knowledge agents that cultivate customer needs and maximise organisational knowledge value.

Keywords: Generative AI, Conversational Commerce, TAM, SOR, ISS Model

Paper type: Academic Research Paper

1 Introduction

Generative Artificial Intelligence (GenAI) has emerged as a disruptive force following the launch of ChatGPT in late 2022, reaching one million users within just five days. Based on Transformer models, GenAI possesses advanced semantic understanding and contextual conversation skills. In the business landscape, this technology is poised to revolutionize conversational commerce (C-commerce), where consumer purchasing intentions are shaped through interactive dialogues.

1.1 Conversational commerce and generative AI landscape

The retail market has evolved from traditional brick-and-mortar stores to digital e-commerce, and subsequently to social commerce driven by messaging apps. C-commerce serves as a direct interface connecting customers and companies through text-based chatbots or voice assistants like Siri and Alexa. While the industry is experiencing rapid growth with a projected multi-billion dollar market value , the driving force behind this expansion is the integration of machine learning and AI to provide personalized engagement.

Unlike traditional models designed for classification, GenAI models—such as the Generative Pre-trained Transformer (GPT) family—can generate fresh, human-like content from extensive datasets. These tools exhibit contextual awareness, self-explanation capabilities, and personalization, distinguishing them from previous language models. Consequently, global retailers are increasingly integrating GenAI to optimize search results and enhance customer service.

1.2 The gap in application and research objectives

Despite the convenience of C-commerce, consumers often remain hesitant to utilize traditional chatbots. Major challenges include a perceived lack of empathy and knowledge, and an inability to handle abstract inquiries such as humor or sarcasm. Conversely, GenAI introduces new challenges, including the potential for "hallucinations" or responses that are out of context, alongside persistent concerns regarding user privacy and trust.

There is currently limited knowledge regarding the specific factors influencing the integration of GenAI-based chatbots into C-commerce. To address this gap, this study integrates the Stimulus-Organism-Response (SOR) framework, the Technology Acceptance Model (TAM), and the DeLone and McLean Information Systems Success (ISS) Model. We aim to develop a novel integrated framework to provide a comprehensive understanding of the causal factors behind behavioral intention and actual usage, while exploring how content reliability, system functionality, and service efficiency affect user trust. By achieving these objectives, this research provides meaningful insights for brand executives and developers to foster stronger customer connections through the strategic implementation of GenAI technology.

2. Literature review

This research formulates a theoretical model integrating the TAM, SOR, and DeLone and McLean ISS frameworks to examine the adoption of Generative-AI-based chatbots.

2.1 Technology acceptance model (TAM)

TAM, originally introduced by Davis (1989), evolved from social psychology theories such as the Theory of Reasoned Action (TRA) and the Theory of Planned Behavior (TPB). While extended models like TAM2 and UTAUT incorporate additional variables such as social influence and effort expectancy, TAM remains a cornerstone for understanding technology adoption. It centers on two primary drivers: perceived usefulness (PU) and perceived ease of use (PE). In the domain of e-commerce, TAM is recognized for its superior flexibility and scalability, providing a reliable framework for investigating user intentions toward AI integration and chatbot services. Consequently, TAM is employed as a foundational model for this study.

2.2 Stimulus–organism–response (SOR) framework

The SOR framework, derived from environmental psychology, posits that consumer behavior is determined by external stimuli that affect internal cognitive and affective states.

- Stimulus: Represents external environmental factors.
- Organism: Refers to the internal psychological processes of the individual.
- Response: The resulting behavioral outcome, such as approach or avoidance.

SOR is widely applied to clarify motivations and experiences in online shopping environments. This study utilizes SOR to investigate how the psychological environment created by GenAI-based chatbots (stimulus) impacts users' internal perceptions (organism) and subsequent intentions (response).

2.3 DeLone and McLean information systems success (ISS) model

The ISS model identifies critical success factors for information systems. While the original 1992 version focused on system and information quality, the updated 2003 model introduced service quality as a third essential dimension.

- System Quality: Evaluates technical success through efficiency and reliability.
- Information Quality: Measures semantic success via accuracy and relevance.
- Service Quality: Assesses overall user fulfillment and professionalism.

Previous research highlights that trust is crucial in bridging these quality dimensions with consumer attitudes. This research intends to fill the gap in how these three quality factors specifically influence users’ trust when utilizing GenAI-based chatbots in C-commerce.

3 Hypotheses Development

This study integrates the SOR, TAM, and ISS models to explore the adoption of GenAI-based chatbots. The SOR framework serves as the foundation: GenAI features act as the Stimulus, influencing users' internal Organism (perceptions derived from TAM and ISS), which ultimately leads to a behavioral Response (intention and actual usage).

3.1 Perceived factors and intentions (TAM & organism)

- H1 (Perceived Ease of Use): Previous research indicates that a user-friendly interface requiring minimal mental effort significantly enhances chatbot adoption intentions.
- H2 (Perceived Usefulness): Studies show that users' belief in a technology's potential to improve performance is a critical predictor of their intent to engage with AI-based services.
- H3 (Perceived Risk): Research suggests that concerns regarding data privacy and information accuracy can negatively impact the pursuit of desired outcomes in C-commerce.
- H4 (Perceived Enjoyment): Beyond performance, the intrinsic pleasure or interest derived from interacting with advanced AI serves as a powerful motivator for technology use.

3.2 Quality dimensions and perceived trust (ISS & organism)

- H5 (Information Quality): High standards of accuracy, relevance, and completeness are essential prerequisites for establishing user trust in conversational agents.
- H6 (System Quality): Technical success, measured through system flexibility, reliability, and response time, is hypothesized to bolster the perceived trustworthiness of the chatbot.
- H7 (Service Quality): The professionalism, promptness, and personalization of the service are critical for fostering positive attitudes and initial trust in a C-commerce context.

3.3 The path to actual behavior (response)

- H8 (Trust): In high-risk online environments, trust serves as a mechanism to reduce uncertainty, thereby positively influencing behavioral intentions.
- H9 (Behavioral Intention & Actual Behavior): Consistent with behavioral theories, a person's rational decision to use a service (intention) is the direct precursor to their actual usage behavior.

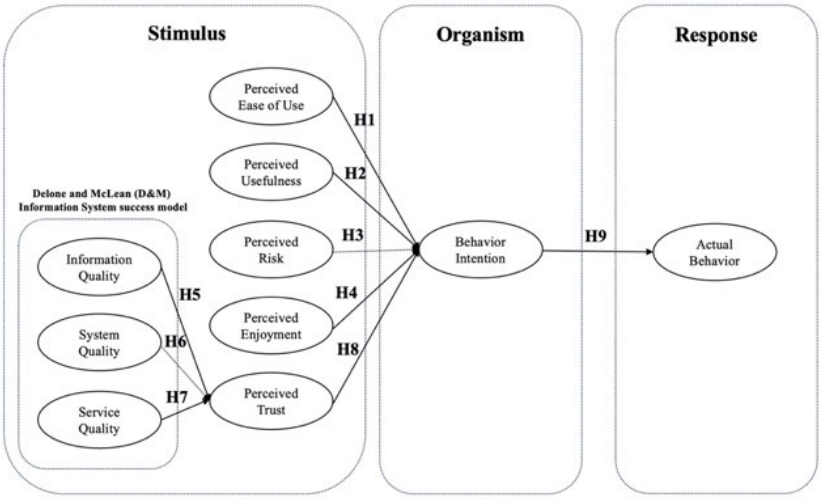

Figure 1 Research Model
Consumers' responses to Generative-AI-based chatbot in conversational commerce.

4 Research Methodology

4.1. Research design and measurement

To empirically validate the interplay between human cognition and artificial intelligence within sustainable digital ecosystems, an online survey was conducted in Taiwan between November and December 2023. The research design followed a three-phase protocol aimed at capturing the nuances of intelligent knowledge in practice. Initially, participants were introduced to the conceptual convergence of conversational commerce and Generative AI (GenAI), ensuring a foundational understanding of how these technologies reshape organizational knowledge flows. This was followed by a scenario-based simulation where participants interacted with a GenAI-driven assistant for a hypothetical perfume purchase, allowing for a direct assessment of AI's role in augmenting decision-making processes. The final phase gathered demographic data alongside assessments of theoretical

variables, using a 7-point Likert scale to capture the depth of participant agreement. To ensure cross-cultural validity, the instrument was provided in Traditional Chinese and English, with linguistic refinements made by native speakers to maintain clarity for both domestic and international respondents.

The measurement framework integrated forty-five items adapted from seminal literature to evaluate the systemic and relational dimensions of human-AI collaboration. Specifically, the study employed Davis's metrics for perceived usefulness, ease of use, and enjoyment to gauge technological acceptance, while the DeLone and McLean model provided the basis for assessing information, system, and service quality. Furthermore, constructs of perceived risk, trust, and behavioral intentions—drawing from Featherman, Pavlou, and Kasilingam—were utilized to analyze the ethical and social implications of AI integration. From a total of 283 valid responses (93 male, 190 female), the analysis demonstrated robust internal consistency, with Cronbach's alpha values ranging from 0.819 to 0.903. These results significantly exceed the reliability threshold of 0.7, confirming that the measurement model offers a reliable platform for exploring how intelligent knowledge systems can foster resilient and sustainable consumer-organizational relationships in an age of complexity.

4.2. Descriptive statistical analysis of samples

Data were collected online in November 2023 via Google Forms. After removing 10 duplicate responses, 283 valid responses were retained (275 Taiwanese; 8 foreign residents). Respondents were predominantly aged 18–25 (64.31%), followed by 26–35 (21.20%) and 36 and above (14.49%). Educationally, 49.82% held a bachelor's degree and 41.70% a master's degree. Most respondents (89.75%) used E-commerce platforms (MOMO, SHOPEE, PCHOME) as their primary shopping channel, and 70.67% shopped online 1–3 times per month. Demographic details are summarised in Table 1.

Regarding descriptive statistics, mean agreement scores across all constructs ranged from 4.37 to 6.11 on a 7-point Likert scale. Perceived Ease of Use (PE: 5.38–5.57), Perceived Usefulness (PU: 5.59–5.84), and System Quality (SSI: 5.31–6.11) received relatively higher scores, while Perceived Risk (PR: 4.42–4.78) and Service Quality (SQ: 4.37–5.25) were comparatively lower. Trust (TT: 4.78–5.16), Perceived Enjoyment (PEN: 5.06–5.14), Information Quality (IQ: 5.31–5.54), Behavioural Intention (BI: 5.15–5.46), and Actual Behaviour (AB: 5.07–5.55) all fell within a moderate-to-high range.

Table 1 Samples statistics: Demographic information of the respondents

Demographic characteristics		Frequency	Percentage
Gender	Male	93	32.86
	Female	190	67.14
Age	18-25	182	64.31
	26-35	60	21.20
	36 and above	41	14.49
Education	High School	19	6.71
	Bachelor	141	49.82
	Master	118	41.70
	PhD	5	1.77
Frequency of Online Shopping per Month	0 times	14	4.95
	1-3 times	200	70.67
	4-6 times	51	18.02
	7 times and above	18	6.36
Platform	Brand Official Website	26	9.19
	E-Commerce Platform	254	89.75
	Social Media	3	1.06
Nationality	TW	275	97.17
	Vietnam	4	1.41
	Indonesia	3	1.06
	Thailand	1	0.35

4.3. Data analysis and results

PLS-SEM was conducted using SmartPLS 4.0, an approach well-suited for complex models with non-normal data (Hair et al., 2017; Willaby et al., 2015; Hair et al., 2009). Following Anderson and Gerbing's two-step procedure, the measurement model was assessed first, followed by structural model analysis.

4.3.1 Measurement model of reliability and convergent validity

As shown in Table 2, all Cronbach's α values (0.819–0.903) and composite reliability (CR) values exceed the 0.7 threshold (Nunnally and Bernstein, 1994), confirming internal consistency. AVE values (0.541–0.816) surpass the 0.5 threshold (Fornell and Larcker, 1981; Anderson and Gerbing, 1988), and all standardised factor loadings fall between 0.610 and 0.970 (t > 1.96), demonstrating convergent validity and indicator reliability. Based on the Fornell–Larcker criterion (Table 3), the minimum square root of AVE (0.857) exceeds the highest inter-construct correlation (0.746), confirming discriminant validity (Fornell and Larcker, 1981). Overall, all constructs meet the requirements for reliability, convergent validity, and discriminant validity, and the analysis proceeds to structural model testing.

Table 2 Reliability and validity results

Constructs	Items	Factor loadings	t-value	Cronbach's α	CR	AVE
Perceived Ease of Use(PE)	PE1 <- PE	0.722	14.816	0.885	0.916	0.688

Note: The square roots of average variance extracted (AVE) are highlighted in bold.

4.3.2. Structural model

The structural model was evaluated using SmartPLS 4.0 with 5,000 bootstrap subsamples, a bias-corrected accelerated method, and a two-tailed significance level of 0.05. Model fit was confirmed by a GoF of 0.500, exceeding the 0.36 threshold (Cohen, 1988; Tenenhaus et al., 2005).

As shown in Table 4, behavioural intention was significantly influenced by perceived ease of use ($\beta = 0.175$, $p < 0.01$), perceived usefulness ($\beta = 0.243$, $p < 0.01$), perceived enjoyment ($\beta = 0.211$, $p < 0.01$), and perceived trust ($\beta = 0.238$, $p < 0.001$), supporting H1, H2, H4, and H8. Perceived risk ($\beta = -0.07$, $p > 0.05$) was non-significant, thus H3 is not supported. For perceived trust, information quality ($\beta = 0.390$, $p < 0.001$) and service quality ($\beta = 0.341$, $p < 0.001$) were significant predictors (H5, H7 supported), while system quality ($\beta = 0.022$, $p > 0.05$) was not (H6 not supported). Behavioural intention strongly predicted actual behaviour ($\beta = 0.746$, $p < 0.001$), supporting H9.

Table 5 shows moderate predictive ability for Trust and Behavioural Intention ($R^2 = 0.469$) and high predictive ability for Actual Behaviour ($R^2 = 0.556$). Effect sizes indicated a weak influence of Trust on Behavioural Intention ($f^2 = 0.067$) and a strong influence of Behavioural Intention on Actual Behaviour ($f^2 = 1.253$). No multicollinearity issues were detected. Overall, the structural model meets academic standards for explanatory power, predictive ability, and goodness of fit.

Table 4 Path Coefficients.

	Path	β	t-value	p-value	Result
H1:	PE -> BI	0.175	2.659	0.008**	Supported
H2:	PU -> BI	0.243	3.290	0.001**	Supported
H3:	PR -> BI	-0.07	1.120	0.263	Not Supported

5 Discussion

This study integrates TAM, SOR, and ISS models to examine factors influencing users' behavioural intention and actual behaviour toward GenAI-based chatbots in C-commerce. The model explains 46.9% of variance in behavioural intention and 55.6% in actual behaviour. Seven hypotheses were supported (H1, H2, H4, H5, H7, H8, H9); H3 and H6 were not supported.

Regarding H1, perceived ease of use was significant, consistent with prior research (Mahendar et al., 2023; Jan et al., 2023). GenAI chatbots offer intuitive interfaces that lower interaction barriers, expedite transactions, and strengthen users' intention to engage.

Regarding H2, perceived usefulness was supported, reinforcing TAM's core proposition (Davis, 1989; Mahendar et al., 2023; Pillai and Mukherjee, 2011). Users perceive GenAI chatbots as performance-enhancing tools that streamline the shopping process in C-commerce.

Regarding H3, perceived risk was non-significant, diverging from some prior studies (Salisbury et al., 2001; Ariffin et al., 2018; Wu et al., 2020) but aligning with others (Kasilingam, 2020; Liu et al., 2023). Possible explanations include risk normalisation among experienced online shoppers, positive ease-of-use experiences that offset privacy concerns, and the growing acceptance of AI in daily life. Nonetheless, practitioners should address transaction security and data privacy to broaden adoption.

Regarding H4, perceived enjoyment significantly influenced behavioural intention (Kasilingam, 2020; Teo et al., 1999). Unlike task-oriented traditional chatbots, GenAI systems generate contextually varied and engaging responses, creating an enjoyable conversational environment that motivates continued use.

Regarding H5, information quality positively affected perceived trust (Liu et al., 2023; Teo et al., 2008), as users expect accurate, relevant, and complete responses. GenAI's capacity to deliver personalised, context-aware answers directly strengthens trust perceptions.

Regarding H6, system quality was non-significant, consistent with findings in banking chatbot research (Nguyen et al., 2021). Users appear to treat 24/7 availability and response speed as baseline expectations rather than trust-building attributes, directing trust judgements toward response accuracy, personality, and problem-solving ability.

Regarding H7, service quality significantly enhanced perceived trust (Roh et al., 2022). GenAI's ability to comprehend user needs and respond with empathy elevates perceived service standards beyond what rule-based chatbots can offer.

Regarding H8, perceived trust positively influenced behavioural intention (Harris and Goode, 2004; Pavlou, 2003), confirming its central role in C-commerce adoption. Higher trust reduces users' motivation to switch to human agents, thereby supporting chatbot acceptance.

Regarding H9, behavioural intention was a significant positive predictor of actual behaviour ($\beta = 0.746$). Consistent with SOR theory, when users perceive the chatbot environment as useful, enjoyable, and trustworthy, the resulting internal intention translates directly into actual usage behaviour.

6 Conclusion

This study examined factors influencing consumer behavioural intention and actual behaviour toward GenAI-based chatbots in C-commerce, integrating TAM, ISS, and SOR frameworks. Findings confirm that perceived ease of use, usefulness, enjoyment, and trust drive intention, while information quality and service quality underpin trust. System quality and perceived risk were non-significant, suggesting users treat technical availability as a baseline expectation and have normalised AI-related risks through prior online shopping experience.

Practically, we advocate a stratified hybrid strategy: deploying traditional rule-based automation for routine tasks (order updates, address changes) while reserving GenAI for high-empathy interactions such as product recommendations. This positions GenAI chatbots not merely as sales assistants but as proactive agents that cultivate customer needs, enhance brand trust, and bridge the gap between automated service and human customer support.

This study has several limitations. The sample skews toward young, female participants in Taiwan, and the scope is limited to text-based GenAI. Future research should broaden demographic diversity, explore image- and voice-based AI applications, examine privacy-related concerns, and consider alternative theoretical frameworks to further advance understanding of AI adoption in digital commerce.

7 Ethics declaration

This study did not require ethical clearance as it involved anonymous online survey data with no sensitive personal information collected.

Exploring Federated Learning Adoption in Competitive and Collaborative Interorganizational Environments: A TOE-S Perspective

Tzu-Hsuan Wang, Yi-Shan Chen, Chih-Chieh Chang
Management Undergraduate Program, National Taiwan University of Science and Technology, Taipei, Taiwan

Abstract

In the current era of rapid digital transformation, financial institutions navigate a profound strategic paradox: the urgent requirement for collaborative Artificial Intelligence intelligence to combat increasingly sophisticated financial crimes versus increasingly stringent data privacy mandates that result in fragmented data silos. Federated Learning (FL) has emerged as a transformative innovation to resolve this privacy-utility trade-off, enabling decentralized machine learning where model training occurs locally on edge devices. This mechanism allows organizations to bridge critical information gaps without the risky transfer of sensitive raw data. However, the diffusion of FL within coopetitive environments—where rivals must simultaneously compete for market share and cooperate against systemic threats—remains an under-researched domain, particularly regarding the synergy between automated systems and human cognitive judgment.

This study addresses this theoretical and practical gap by investigating the socio-technical factors influencing Federated Learning adoption within the Taiwanese banking sector for collaborative fraud detection alliances. We propose an extended Technology-Organization-Environment-Support (TOE-S) framework, integrating internal leadership vision and external regulatory clarity as pivotal catalysts for innovation. A quantitative research design was employed, collecting 188 valid responses from banking professionals in Taiwan involved in anti-fraud and risk management operations. Data were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM) to evaluate the relationships between the constructs and validate the theoretical model.

The empirical results demonstrate that the proposed theoretical model possesses strong explanatory power for both adoption intention and actual usage behavior. The analysis reveals that Top Management Support and Regulatory Support are the primary predictors that exert a significant positive impact on the intention to adopt this technology. Interestingly, traditional technological hurdles, such as compatibility and complexity, as well as external competitive pressures, were found to be statistically non-significant in this context. This suggests that in highly regulated ecosystems, institutional trust and leadership mandate supersede technical considerations. The study offers a strategic roadmap for fostering resilient and sustainable financial organizations through responsible governance and inclusive innovation. The findings underscore that Federated Learning adoption should be treated as a core strategic pillar for organizational resilience rather than a mere technical Information Technology (IT) project.

Keywords: Federated Learning, Intelligent Knowledge, TOE-S Framework, Financial Fraud Detection, Coopetition

Paper type: Academic Research Paper

1 Introduction

1.1 Research Background and Intelligent Knowledge

The rapid advancement of Artificial Intelligence (AI) has empowered enterprises to automate repetitive tasks and enhance operational efficiency. In the financial sector, the synergy between human cognition and AI tools has become a cornerstone for sustainable growth. However, this evolution faces a critical bottleneck known as the Data Silo problem. Traditional machine learning requires consolidating training data into a single center, a process fraught with data leakage risks and governed by stringent regulations such as the General Data Protection Regulation (GDPR) and Taiwan's Personal Data Protection Act.

Federated Learning (FL) offers a paradigm-shifting solution by allowing model training to occur at the data source and sharing only model parameters, preserving privacy while building collective intelligence. In the context of modern knowledge management, FL represents a shift from knowledge ownership to knowledge orchestration, allowing banks to manage systemic risks through inclusive AI innovation. In Taiwan, financial fraud

cases have shown a significant upward trend, growing by nearly 30% in 2023 alone, according to the National Police Agency. This underscores the urgent need for collaborative resilience. The establishment of the Eagle Eye Anti-Fraud Alliance in 2024 represents Taiwan's first large-scale attempt at using FL for inter-bank collaboration. However, many institutions remain hesitant to adopt FL due to the complex nature of "coopetition"—a strategic state where banks must cooperate for systemic safety while remaining market rivals. This study applies an extended Technology-Organization-Environment-Support (TOE-S) framework to understand the drivers of FL adoption in this unique landscape.

2 Literature Review

2.1 Overview and Taxonomy of Federated Learning

Federated Learning (FL) is a decentralized machine learning paradigm that operates on the fundamental principle of "bringing the model to the data". The standard process involves a central coordinator distributing a global model to participants, who then perform local training on their private datasets. Only model parameters (gradients) are returned to the server for aggregation, and this cycle repeats until the model achieves optimal convergence. This mechanism effectively addresses the strategic paradox of enhancing Artificial Intelligence (AI) intelligence while adhering to stringent data privacy mandates like the General Data Protection Regulation (GDPR).

In interorganizational contexts, FL is primarily categorized into two scenarios based on data distribution. Horizontal Federated Learning (HFL) is utilized when participants share overlapping features but possess different samples, such as multiple banks collaborating to detect fraud using similar transaction record formats for different customer bases. Conversely, Vertical Federated Learning (VFL) applies to situations where participants have overlapping samples but different features, such as a bank collaborating with an e-commerce platform to assess a shared customer's creditworthiness through complementary datasets.

2.2 Theoretical Framework: From TOE to TOE-S

The Technology-Organization-Environment (TOE) framework (Tornatzky and Fleischer, 1990) is a well-established baseline for analyzing Information Technology (IT) adoption, evaluating the process through technological, organizational, and environmental contexts. While the original TOE model is robust, it often overlooks the critical role of institutional guidance in highly sensitive and regulated industries like banking. To better capture the realities of the Taiwanese financial ecosystem, this study proposes an extended TOE-S framework. By integrating the Support (S) dimension—encompassing User Support, Top Management Support, and Regulatory Support—the model provides a more comprehensive analysis of how internal leadership and external legal clarity act as the true catalysts for innovation in "coopetitive" environments.

3 Research Model and Hypothesis Development

The proposed model evaluates ten constructs across four dimensions to predict Intention to Adopt (IA) and Actual Use (AU) (See Figure 1).

Figure 1: Research Model (TOE-S Framework)

Technological and Organizational Contexts: Compatibility (COMP) reflects the alignment with an organization's values and infrastructure, while Complexity (COMX) involves the perceived implementation difficulty, particularly in complex data processes. We also consider Financial Cost (FC) for AI infrastructure and Firm Size (FS) as a proxy for resource abundance. Larger banks with higher technical compatibility are more likely to adopt FL, while high complexity and high initial costs act as significant barriers. Thus, we propose: H1: COMP(+), H2: COMX(-), H3: FC(-), and H4: FS(+) impact IA.

Environmental and Support Contexts: Competitive Pressure (CP) and Environmental Uncertainty (EU) drive innovation for survival, while Security and Privacy Regulatory Concerns (SPC) may hinder it due to compliance anxiety. Furthermore, internal User Support (US) and Top Management Support (TMS) are critical for strategic alignment, while external Regulatory Support (RS) provides institutional legitimacy. We suggest: H5: CP(+), H6: EU(+), H7: SPC(-), H8: US(+), H9: TMS(+), and H10: RS(+) impact IA.

Behavioral Outcome: Consistent with technology acceptance literature, adoption intention is a robust and direct precursor to implementation. We hypothesize H11: IA has a positive impact on AU.

4 Research Methodology

4.1 Research Design and Context

To empirically validate the TOE-S framework, this study adopted a cross-sectional quantitative design. Measurement items were adapted from validated scales (Tiwari et al., 2023; Wael Al-khatib, 2023) and refined through a pre-test with 17 experts. All indicators were measured using a 7-point Likert scale, which provides higher data variance and precise respondent mapping (Vagias, 2006). Data were collected from August to October 2024 via an anonymous online survey. To fulfill Corporate Social Responsibility (CSR) goals, a donation was made to the TFCF for each valid response, yielding 188 valid samples (89% response rate).

The demographic profile of the respondents reflects a diverse cross-section of the industry, as presented in Table 1. Notably, 48.40% are under 30 years old and 36.17% possess an Information Technology (IT) background. For data analysis, we utilized Partial Least Squares Structural Equation Modeling (PLS-SEM) via SmartPLS 4.0, following criteria by Hair et al. (2021), using a bootstrapping procedure with 5,000 resamples to ensure statistical power.

Table 1: Demographics of the respondents (n=188)

Demographics variable	**Categories**	**Frequency**	**Percent**
Gender	Male	88	46.81%
	Female	100	53.19%
Age	Less than 30 years old	91	48.40%
	31-40 years old	36	19.15%
	41-50 years old	33	17.55%
	Above 51 years old	28	14.89%
Education	Secondary school or below	5	2.66%
	Undergraduate degree	103	54.79%
	Graduate degree	73	38.83%
	Doctorate degree	7	3.72%
IT background	Posses	68	36.17%
	Lack of	120	63.83%
JOB title	Staff	129	68.62%
	Senior staff	20	10.64%
	Basic supervisor	19	10.11%
	Mid-level supervisor	4	2.13%
	Executive-level supervisor	16	8.51%
Work Experience	Less than or equal to 5 years	94	50.00%
	6-10 years	25	13.30%
	11-15 years	17	9.04%
	16-20 years	22	11.70%
	More than 21 years	30	15.96%
Demographics variable	Categories	Frequency	Percent
Firm size	500 people or less	85	45.21%
	Between 501 and 1000 people	28	14.89%
	Between 1001 and 3000 people	23	12.23%
	Between 3001 and 5000 people	9	4.79%
	Between 5001 and 7000 people	9	4.79%
	Between 7001 and 9000 people	9	4.79%
	More than 9001 people	25	13.30%
Number of IT employees	50 people or less	98	52.13%
	Between 51 and 100 people	29	15.43%
	Between 101 and 200 people	23	12.23%
	Between 201 and 400 people	17	9.04%
	More than 401 people	21	11.17%

5 Results

Reliability and validity were evaluated using criteria from Hair et al. (2011). The model demonstrated high reliability (CA and CR > 0.7) and convergent validity (AVE > 0.5). Discriminant validity was confirmed via the HTMT criterion (Henseler et al., 2015), with all values below 0.85 (See Table 2 and Table 3).

Table 2: Convergent Validity Results

Constructs	Indicators	Outer Loadings	Cronbach's alpha	Composite reliability (CR)	Average variance extracted (AVE)

	US2	0.686			
	US3	0.910			

Table 3: Discriminant Validity (HTMT)

	AU	COMP	COMX	CP	EU	FC	FS	IA	RS	SPC	TMS	US
AU												
COMP	0.746											
COMX	0.503	0.522										
CP	0.659	0.596	0.182									
EU	0.249	0.282	0.186	0.192								
FC	0.034	0.157	0.392	0.356	0.093							
FS	0.530	0.520	0.458	0.277	0.125	0.343						
IA	0.812	0.676	0.420	0.453	0.281	0.160	0.436					
RS	0.491	0.559	0.225	0.368	0.392	0.217	0.264	0.739				
SPC	0.232	0.232	0.605	0.230	0.254	0.353	0.166	0.242	0.124			
TMS	0.812	0.775	0.526	0.560	0.225	0.097	0.444	0.840	0.640	0.310		
US	0.693	0.795	0.698	0.351	0.272	0.235	0.428	0.651	0.562	0.436	0.816	

The model explained 64.4% of the variance in adoption intention (R^2= 0.644) and 52.8% in actual use (R^2= 0.528). Bootstrapping results confirmed that Top Management Support (β = 0.474, $p < 0.001$, supporting H9) and Regulatory Support (β = 0.299, $p < 0.001$, supporting H10) are the primary predictors. Furthermore, IA strongly influenced AU (β = 0.726, $p < 0.001$, supporting H11). Hypotheses H1-H8 were not supported ($p > 0.05$\$), suggesting strategic factors outweigh technical drivers (See Figure 2).

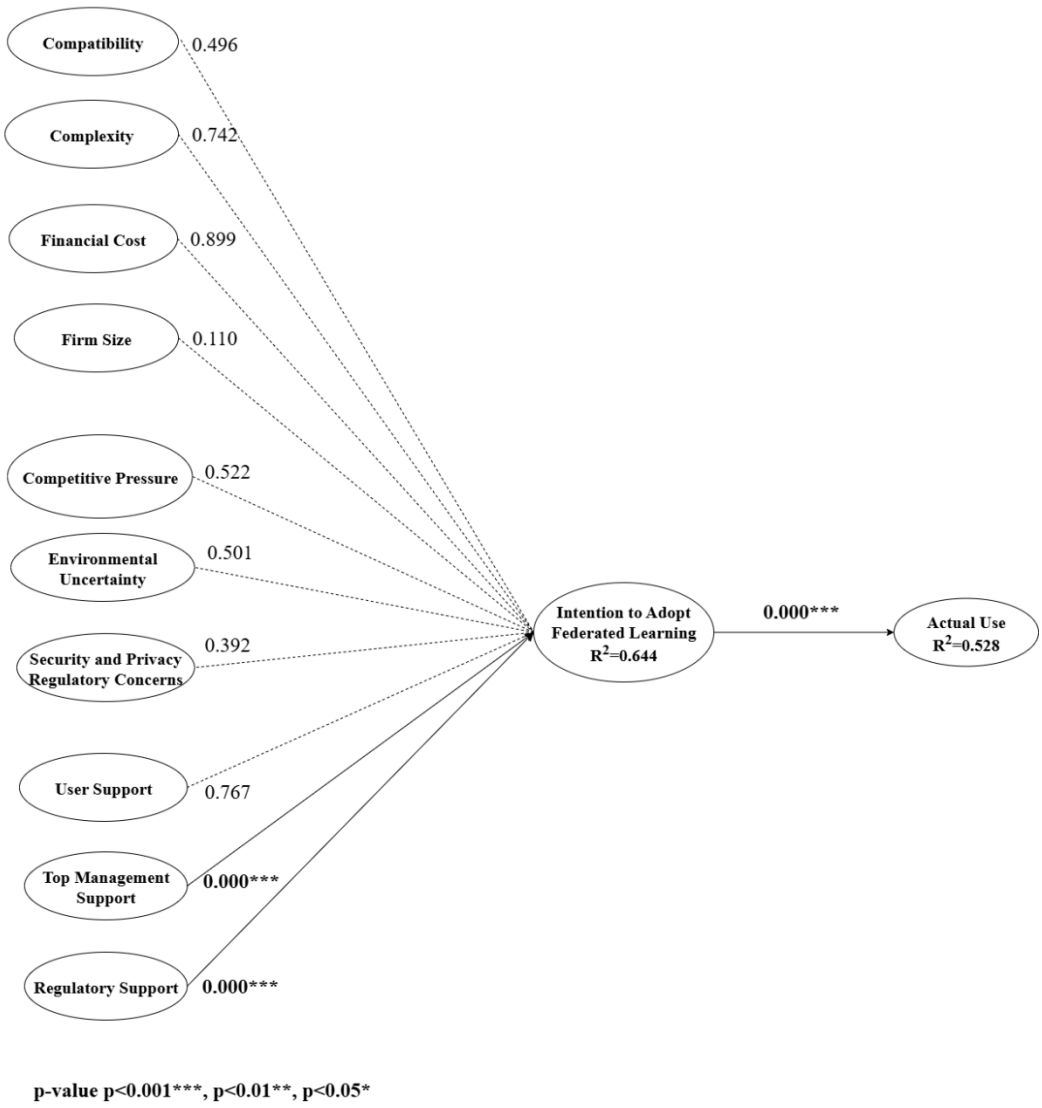

Figure 2: Structural Model Results

6 Discussion

The insignificance of Compatibility (H1) and Complexity (H2) suggests Technical-Strategic Decoupling: banking professionals view technical hurdles as solvable details once a strategic mandate is issued. Moreover, the non-significance of Competitive Pressure (H5) indicates that in Taiwan, fraud detection is viewed as a systemic responsibility rather than a source of competitive advantage. The dominance of Top Management Support and Regulatory Support confirms that innovation in coopetitive landscapes is driven by internal political will and external legal safety.

7 Implications and Conclusion

FL should be framed as a core pillar of Environmental, Social, and Governance (ESG) strategy and organizational resilience. Our findings advocate for Enabled Governance—moving beyond restrictive oversight toward fostering hybrid knowledge ecosystems through regulatory sandboxes. Federated Learning represents a critical solution for the privacy-collaboration paradox, building the collective resilience necessary to thrive in a complex digital landscape.

8 Acknowledgements

The authors express their deepest gratitude to Professor Chih-Chieh Chang for his profound guidance and trust. We also thank the members of the Fintech and AI Lab at NTUST for their support.

9 Ethics Declaration

This study did not involve sensitive human subjects or medical data; therefore, formal ethical review or Institutional Review Board (IRB) approval was not required.

10 AI Declaration

The authors utilized a Large Language Model (LLM) for the structural expansion and linguistic refinement of this manuscript. All statistical data, path coefficients, and theoretical arguments were manually verified and validated by the researchers to ensure factual accuracy and academic rigor.

Framework Development of an ESG Course Series under System Dynamics: A Comparison of TKS and KSA Perspectives

Chiung-Chuan Lo, Ya-Ping Lin
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

This study aims to develop an Environmental, Social, and Governance (ESG) course-series framework from the perspective of system dynamics and compare the differences between Task–Knowledge–Skills (TKS) and Knowledge–Skills–Abilities (KSA) in curriculum planning and learning outcome evaluation. As ESG has become an important topic in corporate governance, sustainable competitiveness, and management education, business education needs to move beyond one-way knowledge transmission toward a cumulative, practice-oriented, and assessable competence development model. This study adopts a literature-oriented conceptual modeling approach, integrating ESG education, competency models, task analysis, and system dynamics theory to develop causal loop diagrams (CLDs), stock-and-flow models, and a scenario simulation framework. The conceptual model indicates that the KSA perspective helps illustrate the long-term accumulation of ESG knowledge, analytical skills, and integrated decision-making ability. The TKS perspective helps translate ESG curriculum objectives into observable, measurable task outcomes. The conceptual scenario comparison suggests that the balanced hybrid course design best balances KSA competence growth, TKS task performance, and cognitive load control. The contribution of this research is to propose a dynamic governance framework for ESG courses, assisting business schools in curriculum design, learning assessment, and resource allocation.

Keywords: System dynamics, ESG education, TKS, KSA, curriculum design
Paper type: Academic Research Paper

1 Introduction

Environmental, Social, and Governance (ESG) has expanded from corporate sustainability disclosure and investment evaluation to a core competence area for organizational governance, strategic decision-making, and management education. Prior research shows that highly sustainability-oriented firms demonstrate distinctive organizational processes, stakeholder engagement, and long-term performance (Eccles et al., 2014), while ESG performance is also positively associated with corporate financial performance (Friede et al., 2015). Accordingly, business education should not treat ESG as a single knowledge topic, but should transform it into a cumulative, practice-oriented, and evaluable curriculum-based competence development system (Waddock & Lozano, 2013). Although ethics, corporate social responsibility (CSR), and sustainability have been gradually incorporated into global business school curricula, their integration still requires more systematic and multi-level curriculum design (Christensen et al., 2007; Setó-Pamies & Papaoikonomou, 2016).

Despite this development, three research gaps remain. First, existing ESG courses often emphasize sustainability concepts and case discussions, but pay less attention to how students progress from ESG knowledge to analytical skills, integrative abilities, and task performance. Second, learning evaluation frequently relies on static indicators, such as final examinations, questionnaires, or satisfaction surveys, which cannot adequately capture the dynamic relationships among learning engagement, project implementation, feedback, cognitive load, and competence accumulation. Third, although both Knowledge–Skills–Abilities (KSA) and Task–Knowledge–Skills (TKS) perspectives are relevant to curriculum design, their complementary roles in ESG course series have not been sufficiently examined. KSA emphasizes knowledge, skills, and abilities as the foundation of work and learning performance (Campion et al., 2011; Stevens & Campion, 1994), whereas TKS focuses on the connection among tasks, knowledge, and skills, helping translate competency requirements into actionable curriculum and performance standards (National Institute of Standards and Technology [NIST], 2021; Jonassen et al., 1998).

Based on these gaps, this study develops an ESG course-series framework from a system dynamics perspective and compares TKS and KSA in curriculum planning and learning outcome evaluation. Specifically, it clarifies the relationships among knowledge, skills, abilities, and task performance; constructs causal loop and stock-and-flow models of ESG learning outcomes; compares different curriculum design strategies; and proposes a dynamic decision-making framework for ESG curriculum governance. Methodologically, this study adopts a literature-oriented conceptual modelling approach. System dynamics is appropriate because it emphasizes feedback structures, time delays, nonlinear change, and policy simulation, which are useful for analyzing competence accumulation and learning outcomes in education systems (Sterman, 2000; Sweeney &

Sterman, 2007). Small system dynamics models can also support decision communication and scenario comparison (Ghaffarzadegan et al., 2011). This study contributes theoretically by integrating KSA, TKS, and system dynamics; methodologically by modelling ESG competence development; and practically by supporting ESG curriculum design, resource allocation, project-based learning, and competency-oriented assessment.

2 Literature review

2.1 ESG education and sustainability management competencies

ESG education has extended from corporate ethics, CSR, and sustainable development education to an important issue in business and management talent development. Existing studies have pointed out that management education must not only teach environmental, social, and governance concepts in response to sustainable transformation, but also cultivate students' systematic thinking, stakeholder analysis, strategic judgment, and problem-solving skills. Stubbs and Cocklin (2008) emphasize that sustainability education should assist business management students in changing their management mindset; Wiek et al. (2011) proposed that sustainability competencies should include systems thinking, anticipatory, normative, strategic, and interpersonal competencies. Therefore, ESG series courses should shift from a single knowledge transfer to a cross-curriculum, cross-task, and competency-oriented learning design.

2.2 KSA Competency Framework: Knowledge–Skills–Abilities

The KSA framework emphasizes the development process of learners from "knowledge" accumulation, "skill" proficiency to "ability" integration. Knowledge refers to conceptual, theoretical and institutional understanding; Skills refer to analytical, operational, and application-oriented proficiencies that can be developed through practice; Abilities refer to higher-level judgment, integration, and decision-making abilities. Campion et al. (2011) suggest that competency models can be used to define the knowledge, skills, abilities, and other attributes required for effective performance and can support training, assessment, and organizational development. When applied to ESG courses, KSA explains how students can move from ESG conceptual understanding to ESG data analysis skills, sustainability strategy integration, and governance decision-making abilities.

2.3 TKS Task-Based Competency Framework: Task–Knowledge–Skills

The TKS framework starts with a task, emphasizing first defining the specific tasks learners need to complete, and then deducing the knowledge and skills required to complete the task. This perspective is consistent with the task analysis and instructional design literature (NIST, 2021). Jonassen et al. (1998) pointed out that task analysis is an important foundation for instructional design, which can concretize learning objectives, work procedures, knowledge needs, and skill requirements. When applied to the ESG series, TKS can transform course outcomes into observable tasks such as ESG case diagnosis, sustainability report analysis, carbon emission data interpretation, stakeholder mapping, and ESG strategy proposals. This perspective helps to improve the operability and practical linkage of course assessment.

2.4 Comparison of KSA and TKS

The difference between KSA and TKS can be understood from two starting points of analysis: "ability formation" and "task performance". KSA is derived from competency modelling and job analysis research, emphasizing the knowledge, skills, and abilities required for individuals to perform effectively. In addition, abilities, skills, and task requirements can be systematically linked to explain how individual abilities and skills are translated into observable performance requirements (Fleishman et al., 1999). Campion et al. (2011) pointed out that competency models systematize the knowledge, skills, abilities, and other characteristics required for an organization or job, and support training, evaluation, and development decisions; Stevens and Campion (1994) also used team work as an example to illustrate that KSA can be used to identify individual-level competency requirements. Therefore, KSA is suitable for explaining how ESG learners can gradually develop ESG analysis skills, strategic integration skills, and sustainable decision-making skills from understanding sustainability concepts. The comparison between KSA and TKS is summarized in Table 1. This study therefore regards KSA and TKS as complementary competency frameworks rather than mutually exclusive classification tools.

Table 1. Comparison between KSA and TKS Perspectives

Dimension	KSA	TKS	ESG Course
Core logic	Focuses on the formation of learners' abilities, it emphasizes the gradual accumulation of knowledge, skills, and abilities	Focuses on task performance, first define the task, and then derive the required knowledge and skills	ESG courses need to focus on both ability development and task results
Analytical starting point	What knowledge, skills and abilities should students have?	What ESG tasks or projects should students complete?	Curriculum design can be developed in both directions based on competency goals and task requirements
Main aspects	Knowledge、Skills、Abilities	Task、Knowledge、Skills	KSA favors long-term competence development; TKS is biased towards short- and medium-term outcome verification
Knowledge definition	Basic knowledge of ESG concepts, sustainable governance, disclosure systems, stakeholder theory, etc	Expertise required to complete ESG tasks, such as ESG metrics, reporting guidelines, knowledge of carbon management	Introductory courses should establish a foundation of ESG knowledge and connect to task requirements
Skills definition	ESG data analysis, case interpretation, sustainability report analysis, problem-solving skills	Skills required to perform ESG tasks, such as data collection, metric analysis, presentations, and proposal skills	Intermediate courses can introduce data analysis, case discussions, and tool operations
Abilities / Task definition	Abilities refer to advanced integration abilities, such as strategic judgment, systems thinking, and sustainable decision-making	Tasks refer to specific observable tasks, such as ESG report analysis, carbon emission data interpretation, and sustainable strategy proposals	Advanced courses should combine project implementation with strategic integration training
Learning outcomes focus	competence accumulation, learning growth, and long-term development	Task completion, quality of results, and observable performance	Competency scales and task scoring standards can be designed at the same time
Assessment method	Pre- and post-tests, competence scales, learning process, reflection records, and ability growth curves	Project results, case reports, task performance, and performance rubrics	Mixed assessment should be adopted: competence assessment + task outcome evaluation
Advantages	It can show the phased development of ESG learners from knowledge to skills to advanced abilities	It can clearly link course activities, task requirements and performance outputs	It helps to balance the depth of the course with practical orientation
Limitations	If there is a lack of task scenarios, it may be difficult to correspond to specific course outcomes	If the design is overly task-oriented, it may overlook advanced abilities and long-term growth	Avoid focusing only on theory or task completion
Applicable course stage	It is suitable for beginner to advanced levels, especially suitable for competency maps and course sequence planning	Intermediate to advanced courses are more suitable and are especially suitable for project, practice, and outcome-oriented courses	The ESG series of courses should adopt the KSA-TKS dual-track structure
Value for ESG curriculum governance	Support long-term competence development, curriculum articulation, and competency map design	Support task design, outcome verification, and practice-oriented assessment	After integration, it can be used as a basis for ESG curriculum planning, evaluation, and resource allocation

2.5 System Dynamics and Learning Outcomes Assessment

System dynamics is suitable for analyzing educational issues with feedback, delay, and cumulative characteristics. Forrester (1961) and Sterman (2000) indicate that system dynamics describes complex system behavior through stocks, flows, and feedback loops. Learning outcomes are inherently cumulative, such as ESG

knowledge, analytical skills, decision-making ability, and task performance, which will change with learning engagement, practical experience, and feedback quality. Sweeney and Sterman (2007) also pointed out that systems thinking can help learners understand feedback, stock-flow, time delay, and nonlinear relationships. Ghaffarzadegan et al. (2011) emphasize that small system dynamic models can support policy communication and decision learning.

2.6 Literature gaps and research framework

Based on the above literature, there is still little research on ESG education that combines curriculum design, competency models, and dynamic simulations. Most studies emphasize the importance of sustainability competencies, but less explain how ESG knowledge, skills, abilities, and task performance accumulate, interact, and are moderated by constraints over time. In addition, although learning analytics research emphasizes data-based assessment and learning process tracking, it is still difficult to explain how different curriculum strategies affect long-term competence formation without causal models. Dawson et al. (2014) pointed out that the field of learning analysis has focused on understanding the learning process with data, but there is still a need for stronger theoretical and model linkages. Based on this, this study proposes a research framework of "ESG Curriculum Design–KSA/TKS Competence Formation–System Dynamics Simulation" to analyze the dynamic learning outcomes of ESG series courses using causal loop diagrams and stock-and-flow models. The research structure is summarized in Figure 1.

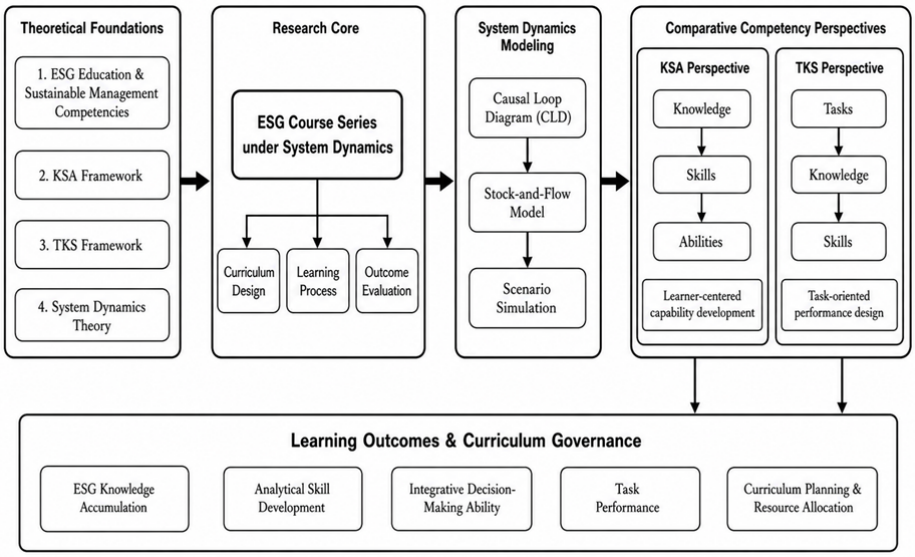

Figure 1: Research Framework of ESG Course Series under System Dynamics

3 Research methodology

3.1 Study design

This study adopts a conceptual system dynamics modeling approach, integrating ESG education, KSA competency model, TKS task analysis, and system dynamics literature to establish a dynamic analysis framework for ESG series courses. System dynamics is suitable for dealing with educational systems with feedback, delay, cumulative, and nonlinear characteristics, and can be used for scenario simulation through causal loop diagrams and stock-and-flow models (Forrester, 1961; Sterman, 2000). Sterman (2000) pointed out that system dynamics can be used as a modeling method for analyzing policy and strategic problems, and can be used to simulate complex systems and design effective policies.

The model-based results were derived through theoretical synthesis, variable mapping, causal structure identification, and conceptual scenario comparison rather than empirical parameter estimation.

3.2 Study scope and model boundaries

The boundaries of this research model are set in the ESG series of courses of the School of Business and Management, covering ESG fundamentals, sustainability report analysis, ESG data interpretation, stakeholder

analysis, case studies, and project implementation. The model does not address overall university governance or corporate ESG performance, but focuses on the process of forming students' knowledge, skills, abilities, and task performance in the curriculum.

3.3 Primary variable settings

The main stock includes ESG Knowledge Stock, ESG Analytical Skills, Integrative Decision-Making Ability, and ESG Task Performance. The main flows include Learning Engagement, Practice Intensity, Feedback Quality, and Ability Enhancement Rate. Auxiliary variables include Course Complexity, Cognitive Load, Learning Fatigue, Instructional Design Quality, and Task Difficulty. KSA variable design references competency model literature, considering knowledge, skills, and abilities as important foundations for effective performance (Campion et al., 2011); TKS, on the other hand, follows task analysis logic, deducing the required knowledge and skills from task requirements as the basis for course outcome design (Jonassen et al., 1998).

3.4 Causal loop model design

The causal loop model consists of four reinforcement loops and two equilibrium loops. R1 is the strengthening loop of "learning engagement - knowledge growth"; R2 is the "Project Implementation - Skill Growth" reinforcement loop; R3 is the "Feedback Correction - Task Performance" enhancement loop; R4 is the "Ability Integration–Decision Quality" reinforcement loop. B1 is the "cognitive load-learning fatigue" balance loop, and B2 is the "task pressure-decreased outcome quality" balance loop. This design echoes the emphasis on feedback, stock-flow, time delay, and nonlinear relationships in system dynamics (Sweeney & Sterman, 2007; Sterman, 2001).

3.5 Stock-and-flow model design

The stock-and-flow model is divided into two pathways: the KSA pathway, representing knowledge, skills, and abilities accumulation, and the TKS pathway, representing the translation of task requirements into required knowledge, required skills, and task performance. The KSA path is ESG Knowledge Stock -> ESG Analytical Skills -> Integrative Decision-Making Ability, emphasizing long-term competence accumulation. The TKS path is ESG Task Requirements -> Required Knowledge -> Required Skills -> Task Performance, emphasizing task performance and observable results. The two paths influence each other through feedback quality, implementation intensity, and cognitive load.

3.6 Scenario simulation design

Scenario simulation sets up six course strategies: S0 traditional teaching, S1 case-oriented, S2 project-oriented, S3 ESG data analysis training, S4 high-feedback intensity design, and S5 balanced hybrid course. Conceptual simulations are designed to compare the potential effects of each scenario on KSA competence growth, TKS task performance, and cognitive load. A small system dynamic model can assist in policy communication, scenario comparison, and leverage point identification, making it suitable as a decision support tool for ESG curriculum planning.

4 Research Results

4.1 ESG series curriculum structure planning results

Based on the sustainability education and curriculum design literature, this study proposes a five-stage ESG series curriculum framework of "Basic Cognition-Analysis Tools-Case Integration-Project Implementation-Reflection and Feedback". The first stage establishes ESG principles, sustainable governance, and disclosure system knowledge; the second stage introduces ESG indicators, data analysis, and sustainability performance evaluation tools; the third stage strengthens stakeholder analysis and systems thinking through corporate cases; the fourth stage develops ESG strategic integration ability through project-based application; and the fifth stage promotes reflection and revision through feedback from teachers, peers, and industry. These stages are consistent with experiential learning theory, which emphasizes learning through concrete experience, reflective observation, abstract conceptualization, and active experimentation (Kolb, 2014). This stage-based design echoes the idea that sustainability education should link competencies, pedagogies, and real-world problem-solving (Wiek et al., 2011; Lozano et al., 2017).

4.2 KSA vs. TKS Learning Outcomes Comparison Results

The KSA-based model suggests that ESG learning outcomes can be divided into three levels: knowledge accumulation, skill development, and ability integration, which are suitable for assessing students' long-term sustainable management abilities. The TKS-based model indicates that ESG course outcomes can be derived from task requirements by linking required knowledge and skills to observable task outcomes, such as ESG report analysis, carbon emission data interpretation, and sustainability strategy proposals. KSA emphasizes competence development, TKS emphasizes achievement verification; The integration of the two can prevent the competency model from remaining too abstract and task-oriented assessment from ignoring higher-order abilities. This dual-track design logic is supported by competency modeling and task analysis literature (Campion et al., 2011; Jonassen et al., 1998).

4.3 Causal loop analysis results

The causal loop model identifies four reinforcing loops and two balancing loops (Figure 2). R1 "Learning Engagement - Knowledge Growth" shows that learning engagement enhances ESG knowledge and further enhances learning confidence. R2 "Project Implementation - Skill Growth" shows that the intensity of implementation improves analytical skills and project quality. R3 "Feedback Correction - Task Performance" shows that high-quality feedback can improve student reflection and outcome correction. R4 "Ability Integration–Decision Quality" shows that knowledge and skill accumulation can improve ESG strategic judgment. In contrast, B1 "cognitive load - learning fatigue" and B2 "task pressure - decreased quality of results" indicate that excessive course intensity may inhibit learning effectiveness. This design is in line with the view of system dynamics to analyze complex systems with feedback, delay, and nonlinear relationships (Sterman, 2000; Sweeney & Sterman, 2007).

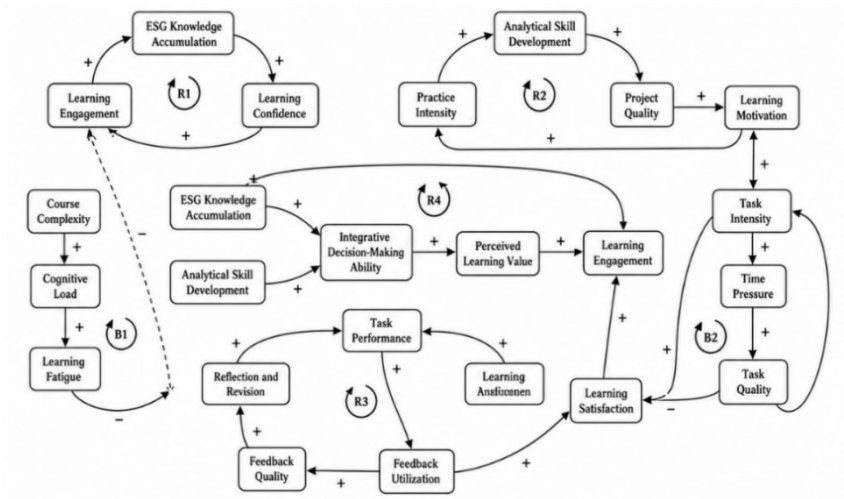

Figure 2: Causal Loop Diagram of ESG Course Series Learning System

4.3 Stock-and-flow model results

The stock-and-flow model (Figure 3) represents ESG Knowledge Stock, ESG Analytical Skills, Integrative Decision-Making Ability, and ESG Task Performance as the main stocks, while Learning Engagement, Practice Intensity, Feedback Quality, and Ability Enhancement Rate are specified as the main flows. The KSA path presents a cumulative process of "knowledge-skills-ability"; the TKS path presents a performance formation process of "task requirements-required knowledge-required skills-task performance". Both paths are moderated by cognitive load, course complexity, and feedback quality.

4.4 Scenario simulation results

The conceptual scenario comparison in Table 2 suggests that S0, the traditional lecture scenario, can steadily improve basic ESG knowledge but has limited effects on skills and task performance. Case-based learning enhances conceptual understanding and judgment, while project-based learning substantially improves TKS task performance but may increase cognitive load when feedback is insufficient. Data analytics training strengthens ESG analytical skills, and feedback-intensive design supports reflection, revision, and ability integration. Overall, the balanced hybrid course design provides the best balance among KSA competence growth, TKS task

outcomes, and manageable cognitive load. As a decision-support tool, the small system dynamics model helps compare curriculum strategies and support ESG curriculum governance (Ghaffarzadegan et al., 2011).

Table 2. Comparison of Scenario Simulation Outcomes

Scenario	KSA	TKS	Cognitive Load	Key simulation results
S0	Low to medium	Low	Low	It can steadily improve basic ESG knowledge but has limited effects on analytical skills, integrative decision-making ability, and task outcomes
S1	Medium	Medium	Low to medium	It helps students understand the context of ESG issues, stakeholder relationships, and corporate sustainability decision-making scenarios
S2	Medium to high	High	High	It improves ESG task completion and project quality but may increase time pressure and learning fatigue.
S3	High	Medium to high	Medium to high	It can strengthen ESG indicator interpretation, sustainability report analysis, and data processing skills, thereby improving KSA skill stock
S4	High	High	Medium	Through feedback from teachers, peers, and the industry, it can promote reflection and correction, task quality improvement, and integrative ability development
S5	Highest	High to very high	Medium	At the same time, it combines cases, projects, data analysis, and feedback mechanisms to balance long-term competence growth, task performance, and manageable cognitive load

5 Discussion

5.1 Theoretical implications

This study regards the ESG series of courses as a dynamic system that links competence accumulation and task performance, making up for the shortcomings of past ESG education research that focuses on course content and single-point learning assessment. The ESG and sustainability education literature points out that ESG and sustainability management education should cultivate systems thinking, strategic skills, collaboration skills, and problem-solving skills, rather than just imparting knowledge (Wiek et al., 2011; Lozano et al., 2017). Therefore, this study uses system dynamics to link competency models and curriculum design to deepen the theoretical explanatory power of ESG education.

5.2 Complementarity of KSA and TKS

KSA emphasizes the phased development of knowledge, skills, and abilities, which is suitable for explaining how ESG learners move from conceptual understanding to analysis and integrated decision-making. TKS is task-oriented, suitable for transforming ESG course outcomes into observable and evaluable task performance. The competency model literature supports the use of KSA for training, assessment, and development decision-making (Campion et al., 2011), while the task analysis literature emphasizes that instructional design needs to be developed by tasks, knowledge, and skill requirements (Jonassen et al., 1998). The integration of the two can support both competence development and outcome verification (Table 3).

Table 3: ESG Course Series Architecture under KSA and TKS

Course modules	KSA	TKS	Main activities	Learning assessment
ESG Foundation	Build ESG basic knowledge	Understand task-related ESG concepts	Lectures, readings, short case discussions	Concept test, participation, learning notes
ESG Governance and Disclosure	Develop knowledge of ESG governance and disclosure	Define sustainability report analysis tasks	Report review, materiality analysis, ESG case study	Report summary, materiality issue table
ESG Data and Analytical Tools	Strengthen ESG analytical skills	Apply required skills to data-based tasks	Indicator analysis, data interpretation, visualization	ESG data analysis report, tool-use task
ESG Case Integration	Integrate knowledge and skills into judgment	Diagnose ESG problems through cases	Case discussion, stakeholder mapping, group debate	Case diagnosis report, oral presentation

Course modules	KSA	TKS	Main activities	Learning assessment
ESG Project-Based Application	Develop integrative decision-making and problem-solving abilities	Complete ESG task outcomes	Project work, strategy proposal, industry feedback	ESG project report, proposal presentation
Reflection and Feedback	Enhance higher-order integrative abilities through revision	Improve task performance through feedback	Reflection notes, peer review, teacher feedback	Revised output, reflection report, peer assessment
Curriculum Governance and Learning Analytics	Monitor KSA competence accumulation	Track TKS task performance	Pre/post-test, portfolio review, learning analytics	KSA competence indicators, TKS task performance indicators

5.3 Curriculum governance implications

This study shows that ESG course governance should not be based solely on a single course, a single test, or satisfaction, but should be evaluated based on course series, learning journey, task outcomes, and feedback mechanisms. System dynamics emphasizes feedback, delay, and stock accumulation, which can help course designers identify the dynamic relationship between learning engagement, project implementation, cognitive load, and competence growth (Sterman, 2000; Sweeney & Sterman, 2007). Therefore, curriculum governance should focus on curriculum load allocation, feedback density, and cross-stage competence alignment (Ghaffarzadegan et al., 2011).

5.4 Practical implications

In practice, this study can assist business schools in planning ESG course maps: beginner courses to build ESG knowledge, intermediate courses to strengthen data analysis and case judgment, and advanced courses to cultivate strategic integration skills through project implementation. Small system dynamic models can also be used as a communication tool for curriculum decision-making to compare the impact of different programs such as case teaching, project orientation, data analysis training, and high-feedback design on learning outcomes (Ghaffarzadegan et al., 2011).

6 Conclusion

6.1 Research conclusions

This study constructs the ESG series curriculum structure from the perspective of system dynamics and compares the two competency perspectives of KSA and TKS. The model indicates that KSA can illustrate the long-term accumulation of ESG knowledge, skills, and higher-order abilities. TKS transforms course objectives into observable, evaluable task outcomes. Competency model research emphasizes that knowledge, skills, and abilities can be used as the basis for training, evaluation, and development decision-making (Campion et al., 2011). Sustainability education research also indicates that ESG courses should cultivate systems thinking, strategic skills, and problem-solving skills, rather than just imparting knowledge (Wiek et al., 2011). Therefore, the integration of KSA and TKS helps to balance “competence development” and “outcome validation”, echoing the dynamic curriculum governance concept proposed in the original abstract of this study.

6.2 Study limitations

This study is a conceptual model construction, and the model parameter calibration and validity test have not yet been conducted using actual student learning data. Secondly, the effectiveness of ESG courses may be affected by student background, teachers' teaching competence, curriculum resources, industry connections, and school system support, so the model results still need to be adjusted according to different educational scenarios. Furthermore, although the system dynamic model can present feedback structure and long-term trends, if there is no empirical data support, the scenario simulation results should still be regarded as decision-making aids rather than final predictions.

6.3 Future research directions

Future research can collect student learning journeys, project outcomes, feedback records, and pre- and post-test data to calibrate the stock-and-flow model and test the explanatory power of KSA and TKS indicators on ESG learning outcomes. Secondly, different course designs, such as case teaching, project-oriented, data

analysis training, and high feedback mechanisms, can be compared to the differences in long-term competence accumulation and task performance. System dynamics studies have pointed out that small models are helpful for policy communication, scenario comparison, and leverage point identification (Ghaffarzadegan et al., 2011), so ESG course governance dashboards can also be developed in the future to support course adjustment and learning early warning.

7 Declaration of Ethics

This study does not address research ethics issues.

8 Artificial Intelligence Declaration

Artificial intelligence tools were used to assist in language refinement, preliminary literature organization, and structural drafting. The authors reviewed, verified, revised, and take full responsibility for all arguments, citations, interpretations, and final content.

A System Dynamics Analysis of AI-Empowers Smart Aquaculture Technologies and Their ESG Performance Impacts

Ju-We Chen[1], Chi-Yuan Lin[2], Tsu-Erh Kuo[1]
[1] Department of Business Administration, Shih Chien University. Taipei, Taiwan
[2] Fisheries Research Institute. New Taipei City, Taiwan

Abstract

This study aims to explore the dynamic impact of Artificial Intelligence (AI)-empowered smart aquaculture technologies on environmental, social, and governance (ESG) performance. Faced with challenges in the aquaculture industry such as water quality fluctuations, overfeeding, sediment accumulation, energy consumption, and governance transparency, this study uses system dynamics (SD) as a method to construct an analysis framework of "data sensing-AI decision-making-operational control-ESG performance", focusing on three core technologies: long-term dissolved oxygen (DO) sensing, AI-empowered precision feeding, and intelligent sludge removal. The study analyzes the feedback relationship between water quality stability, fish biomass, sediment accumulation, farmer acceptance, data traceability, and ESG performance through causal loop diagrams and stock-and-flow models. The results show that AI data learning can improve decision-making quality, precision feeding can improve feed utilization efficiency and fish growth, intelligent sludge removal can reduce environmental risks, and increased automation may also bring energy load and carbon emission pressure. The scenario comparison results suggest that, compared with conventional aquaculture, a full smart aquaculture system integrating DO sensing, AI-empowered precision feeding, intelligent sludge removal, and ESG governance dashboards can generate cumulative environmental improvements, reduce labor risks, and enhance governance transparency. The main contribution of this study is to conceptualize AI-empowered smart aquaculture technologies as knowledge-intensive assets that transform sensing data, algorithmic inference, and expert rules into operational decisions and auditable ESG evidence.

Keywords: System Dynamics; Artificial Intelligence of Things (AIoT); Smart Aquaculture; ESG Performance; Precision Feeding

Paper type：Academic Research Paper

1 Introduction

The global aquaculture industry is facing multiple challenges such as improving production efficiency, environmental sustainability pressures, and governance transparency requirements. With the expansion of intensive aquaculture models, issues such as water quality fluctuations, dissolved oxygen instability, overfeeding, sediment accumulation, energy consumption, and disease risks have become important factors affecting aquaculture performance and sustainable development. Garlock et al. pointed out that the sustainability of aquaculture should not be measured solely by yield or economic benefits, but should also include comprehensive performance evaluations from environmental, economic, and social aspects. Its Aquaculture Performance Indicators also show significant differences in environmental impact, social benefits, and economic resilience between different aquaculture systems (Garlock et al., 2024). In addition, feed efficiency and the use of resources such as fishmeal and fish oil have a long-term impact on the environmental footprint of aquaculture, indicating that precision feeding and resource optimization have become key issues in the sustainable transformation of the industry (Tacon & Metian, 2008).

In recent years, artificial intelligence, Internet of Things, and sensing technologies have been rapidly introduced into aquaculture farms, gradually shifting smart aquaculture from traditional empirical management to real-time monitoring, data-driven decision-making, and automated control. Artificial Intelligence of Things (AIoT) technologies can collect real-time data such as dissolved oxygen, temperature, pH, salinity, and fish behavior through sensors, and use Artificial Intelligence (AI) models for water quality prediction, disease monitoring, and feeding decision support (Huang & Khabusi, 2025). Among them, dissolved oxygen monitoring is regarded as a core technology for maintaining fish health and water quality stability, and online intelligent dissolved oxygen detection can improve the real-time and management accuracy of environmental monitoring (Wei et al., 2019). At the same time, computer vision and fish feeding behavior recognition technologies are gradually being applied to intelligent feeding to help determine the feeding status of fish, reduce residual bait, and improve feed utilization (Xiao et al., 2025).

However, existing studies have focused on the accuracy, equipment performance, or short-term operational improvement of a single technology, and there is still a lack of integrated analysis of how AI-empowered

technologies can further impact environmental, social, and governance performance through feedback structures, time delays, and system interactions. Aquaculture is essentially a highly interdependent and complex system, and the amount of feeding affects water quality and sediment accumulation, while water quality stability affects fish growth, disease risk, and energy use. If technology performance is evaluated only based on static indicators, it is easy to overlook the cumulative and delayed nature of environmental, social, and governance (ESG) benefits. Muralidhar et al. (2023) noted that dynamic models help understand the complex interplay between environmental factors, growth, survival, and disease risk in aquaculture; Recent studies on recirculating aquaculture systems have also shown that system dynamics can be used for water quality management, resource use, and sustainability efficiency analysis (Muralidhar et al., 2023; Udayakumar et al., 2025).

Based on the above awareness, this study aims to construct a system dynamics analysis framework to explore how AI-empowered smart aquaculture technologies affect ESG performance. This study focuses on three verified core technologies: long-term dissolved oxygen sensing module, AI-empowered precision feeding system, and intelligent sludge removal technology and analyze their dynamic impacts on water quality stability, feed efficiency, sediment risk, labor load, data traceability, and governance transparency through causal loop diagrams and stock-and-flow models. The contributions of this research are threefold. First, it applies system dynamics to the analysis of AI-empowered smart aquaculture and ESG performance. Second, it transforms field-verified technical parameters into a basis for long-term sustainability-oriented scenario comparison. Third, it responds to IFKAD's focus on knowledge assets and sustainable organizations by conceptualizing AI technologies as knowledge-intensive assets embedded with sensing data, expert logic, and governance knowledge. This view also echoes the argument of Eccles et al. on corporate sustainability governance, that sustainable performance needs to be achieved through organizational processes, governance mechanisms, and long-term value creation (Eccles et al., 2014).

2 Literature Review

Artificial Intelligence of Things (AIoT) is an intelligent system that combines sensors, edge computing, data transmission, and artificial intelligence algorithms, and its core value is to transform field data into actionable decision-making knowledge in real time. In aquaculture scenarios, AIoT can continuously collect data such as dissolved oxygen, temperature, pH, salinity, water flow, fish behavior, and equipment status, and support water quality management, disease early warning, feeding judgment, and automated control through machine learning, computer vision, and predictive models. Huang and Khabusi (2025) pointed out that the main applications of AIoT in aquaculture include real-time environmental monitoring, data-driven decision-making, and automated operations, which can improve farming efficiency, sustainability, and production stability. Computer vision studies have also shown that fish monitoring can cover aspects such as fish body identification, biomass estimation, behavioral classification, and health analysis, indicating that smart aquaculture is moving from single-point monitoring to integrated intelligent management (Al-Abri et al., 2025).

The technical foundation of smart aquaculture is mainly based on three types of systems: environmental sensing, precision feeding, and automated maintenance. Dissolved oxygen is a key water quality factor affecting fish metabolism, feeding, growth, and survival, and online intelligent dissolved oxygen detection technologies can enhance real-time monitoring and dynamic management capabilities (Wei et al., 2019). In terms of feeding management, overfeeding not only causes feed waste but also increases the accumulation of residual bait, ammonia nitrogen, and sediment, thereby deteriorating water quality and increasing the risk of disease. Therefore, AI-empowered precision feeding systems can adjust the timing and amount of feeding through fish feeding behavior recognition, reducing environmental impact and improving feed utilization efficiency. Xiao et al. (2025) pointed out that computer vision has been widely used in the quantification and identification of fish feeding behavior, providing an important technical foundation for intelligent feeding. The long-term dissolved oxygen sensing, AI-empowered precision feeding, and intelligent sludge removal technologies focused in this article are the combination of core technologies that integrates environmental data, behavior interpretation, and automated maintenance into the aquaculture decision-making system.

System Dynamics (SD) provides an important method for analyzing the complex causal relationships of intelligent farming. Forrester (1961) proposed that system behavior often stems from the interaction between stocks, flows, feedback loops, and time delays; Sterman (2000) further pointed out that SD is suitable for dealing with nonlinearity, delay effects, and policy simulation problems. Aquaculture systems have typical dynamic complexities, such as feeding volume affecting fish growth and water quality load, while changes in water quality can feed back on feeding, disease risk, energy use, and maintenance needs. Muralidhar et al. (2023) pointed out that dynamic models help understand the interaction of environmental variables, biological growth, and

management interventions in coastal aquaculture. Udayakumar et al. (2025) also applied SD to water quality management in recirculating aquaculture systems, emphasizing its ability to support resource efficiency and sustainable operational analysis.

ESG governance is an important theoretical basis for evaluating the value of smart aquaculture technologies. Traditional farming performance mostly focuses on yield, cost, and income, but sustainable farming needs to incorporate environmental, social, and governance aspects at the same time. Garlock et al. (2024) analyzed 57 aquaculture systems and 88 indicators using Aquaculture Performance Indicators, pointing out that aquaculture sustainability needs to measure environmental, economic, and social outcomes at the same time, rather than just based on a single production efficiency. In this context, the environmental aspects can include water quality stability, nutrient load, sediment accumulation, energy use, and carbon emissions. The social aspect can cover labor intensity, occupational risks, farmers' acceptance and knowledge transfer; The governance aspect involves data traceability, auditability of key performance indicators, transparency in decision-making, and policy consistency. Corporate sustainability research also points out that highly sustainable organizations usually have more comprehensive governance processes, stakeholder communication, and long-term performance orientation, indicating that ESG is not an external disclosure activity, but rather a governance capability embedded in organizational processes and decision-making systems (Eccles et al., 2014).

AIoT and smart aquaculture literature explains technical feasibility, SD literature provides methods for analyzing feedback structures and delay effects, and ESG governance literature provides a sustainable performance evaluation framework. However, existing studies have mostly discussed individual technical performance, aquaculture management, or sustainability indicators, and rarely regarded AI-empowered smart aquaculture technologies as a knowledge asset embedded with sensor data, expert knowledge, and governance logic, and further analyzed its long-term dynamic impact on ESG performance. Therefore, this paper attempts to integrate AIoT, smart aquaculture, system dynamics, and ESG governance perspectives to construct an analytical framework that can explain how smart aquaculture technology generate sustainable performance through feedback loops, stock-and-flow structures, and model-based scenario analysis.

3 Research methodology

3.1 Model boundary and variables

This study adopts system dynamics (SD) to construct a dynamic analytical model of AI-empowered smart aquaculture and its impact on environmental, social, and governance (ESG) performance. SD explains system behavior through the interactions among stocks, flows, feedback loops, and time delays, and is suitable for analyzing nonlinear relationships, delayed effects, and policy scenarios (Forrester, 1961; Sterman, 2000). Following Barlas (1996), model credibility was considered through structural verification, dimensional consistency checks, extreme-condition tests, and sensitivity analysis.

The model boundary is defined as the AI-empowered smart aquaculture operation system, covering five subsystems: water quality management, feeding and fish biomass growth, sludge accumulation and environmental risk, energy and labor input, and data governance and technology adoption. The model focuses on three core technologies: long-term dissolved oxygen (DO) sensing, AI-empowered precision feeding, and intelligent sludge removal. These technologies are treated as knowledge-intensive assets that transform sensing data, algorithmic inference, and expert rules into operational decisions and auditable ESG evidence. The major stocks include water quality stability, fish biomass, sludge accumulation, farmer acceptance, data traceability, and ESG performance. The major flows include feed input rate, growth rate, mortality rate, sludge removal rate, daily energy consumption, labor input, and data accumulation rate.

Table 1. Key Variables and Model Structure

Variable	Type	ESG	Description
Water Quality Stability	Stock / Auxiliary	E	Stability of DO, pH, and water conditions
Feed Input Rate	Flow	E	Daily quantity of feed applied
Fish Biomass	Stock	E / Economic	Accumulated fish biomass and survival outcome
Sludge Accumulation	Stock	E	Sediment, residual feed, and waste accumulation
Daily Energy Consumption	Flow	E	Daily energy used by sensors, aeration, and devices
Labor Intensity	Auxiliary	S	Manual workload and maintenance burden
Farmer Acceptance	Stock	S / G	Adoption willingness and trust

Variable	Type	ESG	Description
Data Traceability	Stock	G	Accumulated auditable production and environmental data
ESG Performance	Composite Indicator	E / S / G	Integrated sustainability performance outcome

3.2 Data sources and parameter setting

The data sources are divided into three categories. First, the model incorporates field-verified parameters from the Ministry of Agriculture project, "Innovative Aquaculture Long-Term Sensing Chip and Verification of Intelligent Pollutant Discharge." The key parameters include long-term DO sensing stability exceeding seven consecutive days, AI-empowered precision feeding decision accuracy above 95%, and intelligent sludge removal coverage above 90%. Second, smart aquaculture and AIoT literature is used to support the technical logic of DO sensing, fish feeding behavior recognition, and data-driven aquaculture management. Online DO detection supports real-time water quality monitoring and risk control (Wei et al., 2019), while computer vision-based feeding behavior recognition supports AI-empowered precision feeding (Xiao et al., 2025). AIoT studies also show that real-time sensing, predictive analytics, and automated control can improve aquaculture efficiency and sustainability (Huang & Khabusi, 2025). Third, ESG and sustainable aquaculture studies are used to transform environmental, social, and governance dimensions into measurable indicators. Aquaculture sustainability should be evaluated through integrated environmental, economic, and social indicators rather than production output alone (Garlock et al., 2024).

The simulation horizon was set to 120 days, with one day as the basic time unit. Parameters were derived from field validation records, literature-based ranges, and expert judgment.

3.3 Stock-and-Flow Equations

To operationalize the stock-and-flow structure, five core equations were specified. In the following equations, t denotes the current time step and dt denotes the simulation time interval.

· Equation 1. Fish Biomass Accumulation:

$$Fish_Biomass(t)=Fish_Biomass(t-dt)+(Growth_Rate(t)-Mortality_Rate(t))\times dt$$

Fish biomass increases through growth rate and decreases through mortality rate. AI-empowered precision feeding improves feed utilization and water quality, thereby increasing growth and reducing mortality risk.

· Equation 2. Sludge Accumulation:

$$Sludge_Accumulation(t)=Sludge_Accumulation(t-dt)+(Residual_Feed_Generation(t)-Sludge_Removal_Rate(t))\times dt$$

Sludge accumulation increases with residual feed generation and decreases through intelligent sludge removal. Overfeeding increases sediment and nutrient load, while sludge removal reduces environmental risk.

· Equation 3. Water Quality Stability:

$$Water_Quality_Stability(t)=0.35DO_Stability(t)+0.25Feeding_Efficiency(t)+0.25Sludge_Reduction(t)+0.15Nutrient_Load_Reduction(t)$$

Water quality stability is determined by DO stability, feeding efficiency, sludge reduction, and nutrient load reduction.

· Equation 4. Data Traceability Accumulation:

$$Data_Traceability(t)=Data_Traceability(t-dt)+Data_Accumulation_Rate(t)\times dt$$

$$Data_Accumulation_Rate(t)=Sensor_Coverage(t)\times Data_Quality(t)\times Governance_Audit_Intensity(t)$$

Data traceability accumulates through sensor coverage, data quality, and governance audit intensity, supporting decision auditability and ESG reporting transparency.

· Equation 5. Farmer Acceptance Dynamics:

$$Farmer_Acceptance(t)=Farmer_Acceptance(t-dt)+(Trust_Building_Rate(t)-Resistance_Rate(t))\times dt$$

$$Trust_Building_Rate(t)=Decision_Accuracy(t)\times Operational_Benefit(t)\times Training_Effectiveness(t)$$

Farmer acceptance increases when AI decisions are accurate, operational benefits are observable, and training is effective; it decreases when perceived complexity or maintenance burden increases.

3.4 ESG performance calculation

ESG performance was operationalized as a composite indicator integrating environmental, social, and governance dimensions. Because the indicators are measured in different units, all variables were normalized to a 0–100 scale before aggregation. Positive indicators, such as water quality stability, farmer acceptance, and

data traceability, were normalized using min–max transformation. Negative indicators, such as sludge accumulation, energy consumption, labor intensity, and carbon emissions, were reverse-normalized.

The overall ESG performance score was calculated as:

$$ESG_Performance(t)=0.40EPI(t)+0.30SPI(t)+0.30GPI(t)$$

The environmental dimension was assigned a slightly higher weight because aquaculture sustainability is directly constrained by water quality, feeding efficiency, sludge accumulation, and energy use. The three sub-indices are:

$$EPI(t)=0.30WQS(t)+0.25FE(t)+0.20SLR(t)+0.15ER(t)+0.10CR(t)$$

$$SPI(t)=0.30LR(t)+0.25ORR(t)+0.25FA(t)+0.20KT(t)$$

$$GPI(t)=0.35DT(t)+0.25DA(t)+0.25KPI(t)+0.15PA(t)$$

where WQS denotes water quality stability, FE feeding efficiency, SLR sludge load reduction, ER energy reduction, CR carbon reduction, LR labor reduction, ORR occupational risk reduction, FA farmer acceptance, KT knowledge transfer, DT data traceability, DA decision auditability, KPI refers to key performance indicator transparency, and PA refers to policy alignment.

3.5 Scenario comparison design

The scenario comparison design includes four technology adoption pathways. S0 represents conventional aquaculture without AI-enabled smart technologies. S1 introduces long-term DO sensing to improve water quality monitoring and reduce environmental uncertainty. S2 further adds AI-empowered precision feeding to improve feed utilization, reduce residual feed, and support fish biomass growth. S3 represents the full smart aquaculture system integrating DO sensing, AI-empowered precision feeding, intelligent sludge removal, and ESG governance dashboards.

By comparing water quality stability, feed efficiency, sludge accumulation, labor intensity, farmer acceptance, data traceability, and ESG performance across the four scenarios, this study examines whether AI-empowered smart aquaculture technologies generate cumulative ESG improvements. The scenario comparison also identifies the reinforcing and balancing mechanisms through which smart aquaculture technologies transform technical performance into long-term sustainability outcomes.

4 Research Results

Based on the system dynamics model structure and scenario comparison, this study summarizes the AI-empowered smart aquaculture system into a dynamic structure of "data sensing-AI decision-making-operational control-ESG performance". Causal loop analysis shows that long-term dissolved oxygen sensing, AI-empowered precision feeding, and intelligent sludge removal are not individual equipment benefits, but jointly affect water quality stability, fish growth, environmental load, labor demand, and governance transparency through feedback mechanisms. This result echoes the view of the system dynamics literature on complex aquaculture systems, i.e., that water quality, feeding, biological metabolism, and management interventions are highly interactive, and their nonlinearity and delay effects need to be grasped through dynamic models (Muralidhar et al., 2023; Udayakumar et al., 2025).

The causal loop diagram presents two main reinforcing loops (Figure 1): R1 and R2. R1's "AI Data Learning - Decision Quality" shows that the accumulation of sensing data can improve the learning quality of AI models, thereby improving dissolved oxygen monitoring, feeding judgment, and intelligent sludge removal. After the quality of decision-making is improved, the operational data is more complete, further strengthening the AI judgment ability. AIoT research also points out that smart aquaculture can improve production stability through real-time environmental monitoring, data-driven decision-making, and automated control (Huang & Khabusi, 2025). R2's "Precision Feeding - Fish Growth" shows that improving the accuracy of AI feeding can reduce residual bait and feed waste, improve water quality, and increase fish growth and survival rates. Research on fish feeding behavior recognition also supports the use of computer vision as a technical basis for intelligent feeding decisions (Xiao et al., 2025).

The model also identifies three balancing loops: B1, B2, and B3. Balancing loop B1, “Overfeeding–Water Quality Deterioration,” shows that when feed input exceeds fish demand, residual feed and nutrient load increase, leading to lower dissolved oxygen, sediment accumulation, higher disease risk, and ultimately reduced growth performance. Balancing loop B2, “Intelligent Sludge Removal–Environmental Risk Control,” shows that sediment accumulation increases environmental risks and maintenance needs, while intelligent sludge removal systems reduce sediment load and delay water quality deterioration. Balancing loop B3, “Automation–Energy Load,” indicates that higher automation may increase electricity consumption, operational costs, and carbon emission pressure, thereby requiring energy-saving management mechanisms.

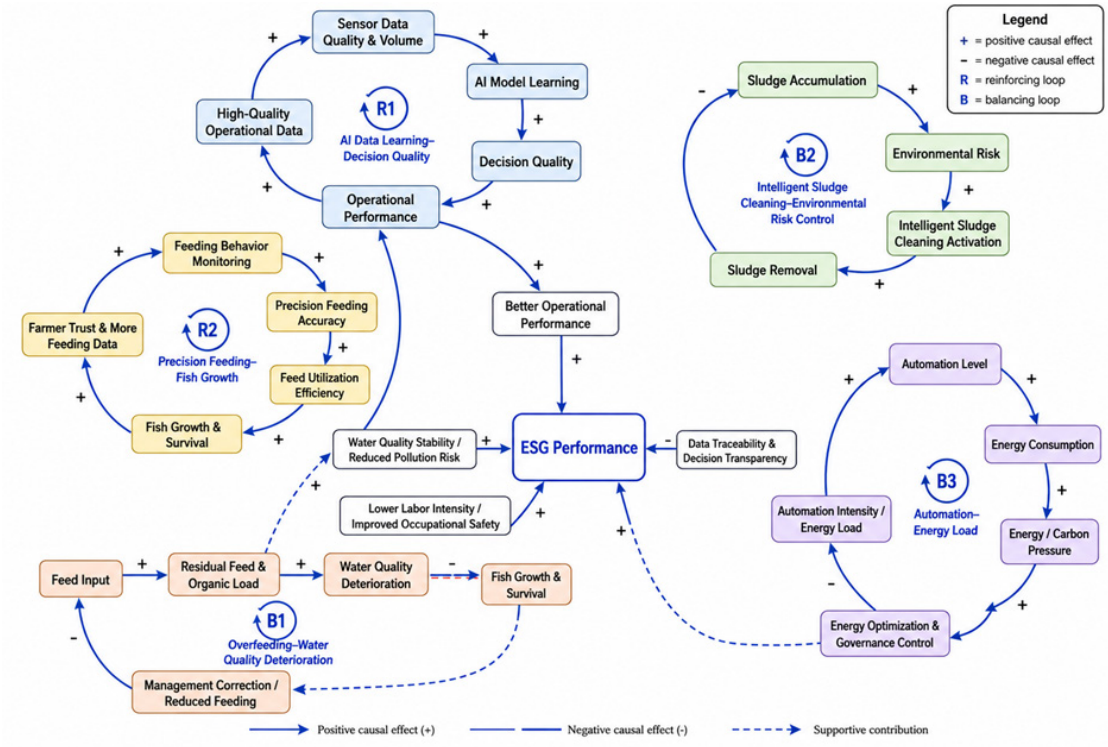

Figure 1. Causal Loop Diagram of the AI-Empowered Smart Aquaculture ESG System

In terms of stock-and-flow structure (Figure 2), this study sets "water quality stability", "fish biomass", "sediment accumulation", "farmer acceptance", "data traceability" and "ESG performance" as the main stocks. The model sets feed input rate, fish growth rate, mortality rate, intelligent sludge removal efficiency, energy consumption rate, labor input rate, and data accumulation rate as the main flows. The technical parameters of this study, including long-term dissolved oxygen sensing stability for more than seven days, AI-empowered precision feeding decision accuracy of more than 95%, and intelligent sludge removal coverage rate of more than 90%, can be used as the basis for model parameterization and scenario comparison.

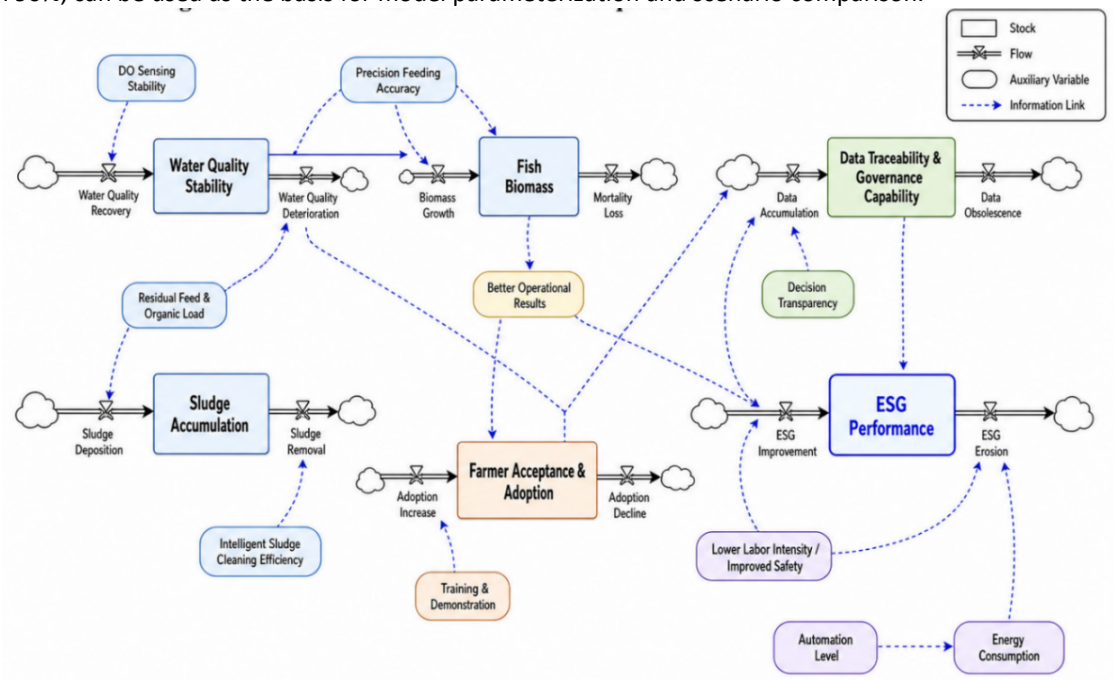

Figure 2. Stock-and-Flow Model of Smart Aquaculture ESG Performance

The model-based scenario comparison (Table 2) suggests that, under the S0 conventional aquaculture scenario, water quality fluctuations, sediment accumulation, and labor load remain relatively high, while ESG

data traceability is limited. In S1, the introduction of long-term DO sensing reduces water quality uncertainty and improves environmental monitoring capability. In S2, the addition of AI-empowered precision feeding improves feed efficiency and reduces residual feed and nutrient load. In S3, the integration of DO sensing, AI-empowered precision feeding, intelligent sludge removal, and ESG governance dashboards generates cumulative improvements in environmental, social, and governance performance. This finding is consistent with Garlock et al. (2024), who argue that aquaculture sustainability should be evaluated through integrated environmental, economic, and social indicators rather than production efficiency alone.

Table 2: Scenario Comparison of ESG Performance Impacts

Scenario	Environmental impact	Social impact	Governance impact
S0 Baseline	Higher water quality fluctuation and sludge risk	Higher labor intensity	Limited traceability
S1 DO Sensing	Improved oxygen stability	Reduced monitoring burden	Better environmental records
S2 DO + AI Feeding	Lower feed waste and nutrient load	Higher farmer trust	More transparent feeding decisions
S3 Full System	Cumulative ESG improvement	Reduced labor and risk	Auditable ESG indicators

5 Discussion

The findings suggest that AI-empowered smart aquaculture technologies should not be understood merely as automated devices, but as intelligent knowledge assets embedded with sensing data, algorithmic judgement, and expert knowledge. The three technologies of long-term dissolved oxygen sensing, AI-empowered precision feeding, and intelligent sludge removal can form a dynamic cycle of "data-knowledge-action-performance" through data accumulation, feedback correction, and decision-making transparency, which echoes IFKAD's focus on knowledge assets and sustainable organizational capabilities. The three core technologies and verification parameters set in this study also support the analysis direction of this paper to transform technical performance into ESG dynamic performance.

In terms of theoretical implications, this study integrates AIoT, smart aquaculture, system dynamics, and ESG governance to make up for the limitations of previous studies that focus on single-technology accuracy or short-term operational efficiency. AIoT literature points out that smart aquaculture can improve efficiency and sustainability through real-time environmental monitoring, data-driven decision-making, and automated control. System dynamics emphasizes feedback, delay, and nonlinear relationships, which is suitable for explaining the interaction between water quality, feeding, sediment, and fish growth (Huang & Khabusi, 2025; Sterman, 2000). Therefore, the contribution of this study is to illustrate how AI-empowered smart aquaculture technologies can generate cumulative ESG benefits through system structure, rather than only a single point of efficiency improvement.

In terms of management practices, farmers should avoid treating smart devices as siloed procurement items and instead establish integrated data governance and operational decision-making processes. Long-term sensing can reduce water quality uncertainty, AI feeding can improve feed utilization and reduce residual bait, and intelligent sludge removal can suppress sediment accumulation and delayed environmental risks. This integrated management logic is consistent with the Aquaculture Sustainability Assessment study, which suggests that aquaculture performance needs to consider environmental, economic, and social outcomes rather than just yield (Garlock et al., 2024).

In terms of ESG governance, this study suggests that the governance value of AI-empowered smart aquaculture comes from data traceability, auditable decisions, and transparent disclosure of key performance indicators (KPIs). Corporate sustainability research shows that highly sustainable organizations typically have well-established governance processes, stakeholder communication, and long-term performance orientation (Eccles et al., 2014). Therefore, the ESG outcomes of smart aquaculture do not occur naturally but need to be institutionalized through standardized verification, data formats, audit mechanisms, and policy incentives.

6 Conclusion

6.1 Summary of findings

This study developed a system dynamics framework to explain how AI-empowered smart aquaculture technologies influence environmental, social, and governance (ESG) performance through feedback structures,

stock-and-flow relationships, and time-delay effects. The findings suggest that long-term dissolved oxygen (DO) sensing, AI-empowered precision feeding, and intelligent sludge removal do not create value merely as isolated technologies. Rather, they function as an integrated decision-support system that connects sensing data, algorithmic inference, operational control, and ESG performance. From a system dynamics perspective, this study shows that water quality stability, feeding efficiency, sludge accumulation, fish biomass, labor intensity, and data traceability are dynamically interrelated. This finding is consistent with prior studies emphasizing that aquaculture systems involve complex interactions among environmental variables, biological growth, water quality management, and operational interventions (Muralidhar et al., 2023; Udayakumar et al., 2025).

6.2 Theoretical contribution

Theoretically, this study contributes to the literature by integrating AIoT, smart aquaculture, system dynamics, and ESG governance into a unified analytical framework. Previous studies have shown that AIoT can support real-time environmental monitoring, data-driven decision-making, and automated aquaculture management (Huang & Khabusi, 2025), while system dynamics is particularly suitable for analyzing nonlinear relationships, feedback loops, and delayed system behavior (Forrester, 1961; Sterman, 2000). This study extends these perspectives by conceptualizing AI-empowered smart aquaculture technologies as knowledge-intensive assets. These technologies transform sensing data, algorithmic inference, and expert rules into operational decisions and auditable ESG evidence. In this sense, the study also responds to IFKAD's knowledge asset perspective by showing how intelligent technologies can support sustainable organizational capabilities and long-term value creation.

6.3 Managerial and policy implications

From a managerial and policy perspective, the findings suggest that aquaculture operators should not treat smart devices as isolated equipment investments. Instead, DO sensing, AI-empowered precision feeding, intelligent sludge removal, and ESG governance dashboards should be implemented as an integrated management architecture. Such integration can reduce water quality uncertainty, improve feed utilization, lower sludge-related environmental risks, reduce labor burden, and strengthen data traceability. This implication is consistent with aquaculture sustainability research, which argues that aquaculture performance should be evaluated through integrated environmental, economic, and social indicators rather than production output alone (Garlock et al., 2024). For policymakers, the study suggests the need to support standardized verification protocols, interoperable data formats, ESG-oriented performance indicators, and incentive mechanisms that guide farmers from technology adoption toward long-term sustainability governance. This also aligns with corporate sustainability research, which indicates that sustainable performance depends on governance processes, stakeholder communication, and long-term organizational orientation (Eccles et al., 2014).

6.4 Limitations and future research

This study has several limitations. First, the model is primarily based on conceptual system dynamics modelling, selected field-verified technical parameters, literature-based assumptions, and expert judgment. Although the model structure was examined through structural verification, dimensional consistency checks, extreme-condition tests, and sensitivity analysis, future research should incorporate longitudinal field data and cross-site empirical validation to strengthen model robustness (Barlas, 1996). Second, the ESG performance indicator in this study remains a conceptual composite measure; future studies may refine the weighting and measurement of environmental, social, and governance dimensions through expert elicitation, field calibration, or multi-criteria decision analysis. Third, future research may combine system dynamics with life-cycle assessment, cost-benefit analysis, or agent-based modelling to further evaluate the economic feasibility, environmental impacts, farmer adoption behavior, and governance value of AI-empowered smart aquaculture systems across different species, farming scales, and production environments.

7 Acknowledgements

This study forms part of the research outcomes of the Ministry of Agriculture science and technology project "Innovative Aquaculture Long-Term Sensing Chip and Verification of Intelligent Pollutant Discharge" under project number 114 Agricultural Sciences-16.1.1-Water-01. The authors gratefully acknowledge the Ministry of Agriculture for its research funding and guidance.

8 Ethics Statement

This study did not involve human subjects, personal data, or animal experimentation conducted directly by the authors. The analysis was based on aggregated technical validation parameters, literature review, and system dynamics modelling. Therefore, formal human-subject ethical approval was not required.

9 AI Declaration

ChatGPT was used to assist with language refinement, literature identification, and figure drafting. All cited references were checked by the authors for relevance to the arguments of this study. The authors remain fully responsible for the research design, analysis, interpretation, and final content of the paper.

A System Dynamics Analysis of AI-Driven Competency Development in Business Schools

Chiung-Chuan Lo
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

As artificial intelligence (AI) becomes increasingly embedded in business decision-making, analytics, marketing, finance, human resource management, and supply chain operations, business schools face growing pressure to redesign talent development models. AI adoption in business education should not be understood merely as the introduction of digital tools; rather, it represents a systemic transformation of curriculum design, learning analytics, feedback mechanisms, and competency assessment. This study develops a System Dynamics (SD) model to examine how AI-integrated learning environments influence competency development in business schools through the Knowledge, Skills, and Abilities (KSA) framework. In this model, Knowledge refers to students' accumulation of AI concepts, data analytics, management theories, and business decision-making knowledge; Skills refer to students' ability to use AI tools for data processing, case diagnosis, decision simulation, and project execution; and Abilities refer to students' higher-order capacity to integrate knowledge and skills in complex business contexts, including problem-solving, strategic judgment, cross-domain application, and responsible AI-enabled decision-making.

Methodologically, this study applies SD to construct causal loop diagrams and stock-and-flow diagrams that capture the feedback mechanisms, time delays, and nonlinear relationships underlying AI-driven competency development. Four key feedback loops are identified: the R1 Learning Accumulation Loop, which explains how AI feedback quality enhances learning engagement and knowledge acquisition; the R2 Skill Practice Loop, which illustrates how AI simulation tools and repeated practice strengthen skill development; the R3 Ability Reinforcement Loop, which shows how reflective feedback, peer interaction, project implementation, and teacher guidance deepen applied abilities; and the B1 Cognitive Load Loop, which explains how excessive course complexity and AI tool burden may increase cognitive load and learning fatigue.

This balancing mechanism is consistent with cognitive load theory, which argues that excessive task complexity consumes limited working memory resources and constrains learning effectiveness (Sweller, 1988).

Scenario-based model analysis compares three instructional designs: Traditional Teaching, AI-Assisted Learning, and AI-Integrated Experiential Learning. The findings suggest that traditional teaching supports knowledge accumulation but provides limited skill and ability development. AI-assisted learning improves knowledge acquisition and skill practice, yet may remain tool-oriented without project-based reflection. AI-integrated experiential learning produces the most balanced and sustained development across KSA by combining AI-assisted analysis, case simulation, enterprise projects, peer interaction, reflective journals, and teacher feedback. The study contributes to AI education, competency-based learning, and knowledge management (KM) by reframing business education as a dynamic, feedback-driven competency development system.

Keywords: Artificial Intelligence in Education; Business Schools; System Dynamics; KSA Framework; Competency Development.

Paper type: Academic Research Paper

1 Introduction

1.1 Background

As artificial intelligence (AI) rapidly enters the fields of corporate decision-making, business analysis, marketing management, financial technology, human resources, and supply chain management, business schools are under pressure to redefine talent cultivation models. AI not only transforms corporate knowledge creation and decision-making processes but also changes instructional design, learning analytics, personalized learning, and competency assessment methods in higher education. In recent years, AI in Education research has shown that AI has been widely used in adaptive learning, intelligent tutoring, learning prediction, intelligent assessment, and educational management, not only to improve learning efficiency but also to support learning process tracking and personalized feedback (Mahmud et al., 2025; Wang et al., 2024).

For business schools, AI-implemented courses are not just about adding digital tools but about the overall transformation of students' knowledge, skills, and abilities. AI empowerment has shifted learning from memorization and standardized tests to practical skills, knowledge application, and cognitive development

(Radu et al., 2024). Traditional courses often struggle to capture the dynamic feedback relationships among conceptual knowledge, practical skills, applied abilities, and learning performance. Therefore, this study adopts the Knowledge, Skills, and Abilities (KSA) framework to explore how AI-integrated learning environments affect student competency development in business schools (Caratozzolo et al., 2023; Faham et al., 2017).

1.2 Awareness of the problem

Existing AI education research mostly focuses on learning outcomes, learning satisfaction, personalized learning, or platform functions (Wang et al., 2024), but rarely explains from a systematic perspective how AI affects students' ability formation in the long term through feedback, delay, accumulation, and non-linear relationships. Competency-oriented education emphasizes that learning outcomes should not be limited to knowledge retention, but should be demonstrated as transferable, applicable, and measurable professional abilities (Frank et al., 2010; Voorhees, 2001). However, in AI-driven business education scenarios, students may experience a gap of "rapid knowledge acquisition" but "lack of ability deepening". While generative AI and learning analytics tools can enhance learning convenience, the lack of reflection, practice, and teacher guidance can also lead to cognitive load, tool dependence, or surface learning (Jia et al., 2025; Lee et al., 2025).

System Dynamics is suitable for dealing with such educational problems because it can analyze feedback loops, competency stock, delay effects, and balancing mechanisms. Faham et al. (2017) used system dynamics to analyze sustainability development in higher education, pointing out that student competency development involves multiple reinforcement and balancing loops, and can understand long-term change mechanisms through model simulations. Therefore, to understand the true impact of AI on business school competency development, it is necessary to move beyond single-point effectiveness evaluation and move toward dynamic system analysis.

1.3 Objectives of the study

Based on the above background and awareness of the problem, this study aims to construct a systematic dynamic model of "AI-driven business school competency development" and analyze how AI tools, learning engagement, intelligent feedback, project implementation, peer interaction, and reflective learning jointly affect KSA competency accumulation. Specifically, the objectives of this study include: first, to clarify the impact path of AI-enabled learning environment on the Knowledge, Skills, and Abilities of business school students; second, to establish causal loop diagrams and stock-and-flow diagrams to present key mechanisms such as learning accumulation, skill practice, ability reinforcement, and cognitive load; third, to compare the impact of different AI-assisted teaching strategies on students' long-term ability development, curriculum adaptability, and institutional innovation; and fourth, to put forward theoretical and practical suggestions for business schools to design AI-integrated curriculum and competency-based learning systems.

The expected contribution of this study is to integrate AI education, KSA competency framework, and System Dynamics to fill the gap in existing research that rarely deals with the dynamic mechanism of AI-driven competency development, and to reunderstand business school education as a capability development system with feedback, cumulative, and knowledge asset transformation characteristics.

2 Literature review

2.1 AI education and higher education transformation

AI in education has evolved from early computer-assisted teaching to integrated systems supporting adaptive learning, intelligent tutoring, learning analytics, prediction, assessment, and educational management. Recent studies (Wang et al., 2024) show that AI is no longer just a supporting tool but a core foundation reshaping instructional design and learning processes.

In higher education, AI enhances not only learning efficiency but also provides real-time feedback, personalized learning paths, and data-driven insights into student engagement and competency development. AI-powered intelligent assistants (Sajja et al., 2024) enable students to learn at their own pace while supporting knowledge construction and task-based learning. This shift transforms AI from a tool into a learning system, making education more dynamic and data-informed (Jia et al., 2025; Lee et al., 2025).

However, integrating AI also raises critical ethical and social concerns. Issues such as data privacy, algorithmic bias, academic integrity, and changing teacher–student roles must be addressed (Al-Zahrani & Alasmari, 2024). Therefore, AI in education should not only be evaluated by learning outcomes but also by its impact on learning interaction, competency development, and educational systems.

2.2 Business School Capability Development and AI-Driven Talent Cultivation

Business schools have traditionally focused on cultivating management knowledge, decision-making skills, and leadership capabilities. However, with the integration of AI into business operations, required competencies have expanded to include data analytics, AI tool application, digital transformation, cross-domain communication, ethical judgment as part of higher-order abilities, and complex problem-solving. Wu et al. (2026) highlight that AI reshapes business education across curriculum design, teaching methods, competency requirements, and governance, emphasizing the need for programs to align with evolving business functions.

From a competency-based perspective, learning outcomes should extend beyond knowledge acquisition to include analysis, application, and action. AI supports this shift by enabling simulated decision-making, data-driven case analysis, generative AI-assisted reporting, and real-time feedback. These tools provide students with more opportunities for practice and contextual learning, enhancing their ability to apply knowledge in real-world scenarios. However, AI integration also presents challenges, including over-reliance on tools, superficial learning, and increased cognitive load. Therefore, effective AI-enabled education must focus on how students build, transform, and internalize competencies through continuous action and reflection (Lee et al., 2025; Radu et al., 2024; Wang et al., 2024).

This study views AI-integrated learning environments as key drivers of competency development in business schools. It also argues that traditional course-based evaluation is insufficient, as it cannot capture the dynamic interaction between knowledge, skills, and performance. Instead, dynamic models are needed to better understand and assess long-term competency growth (Mahmud et al., 2025; Banihashem et al., 2022; Elsawah et al., 2022).

2.3 KSA Architecture: Knowledge, Skills, and Abilities

The KSA framework is widely used in education and talent development to describe the competencies required in professional contexts. It consists of three components: Knowledge, Skills, and Abilities. Knowledge refers to learners' understanding of concepts, theories, facts, and procedures. Skills represent the practical capability to perform tasks, use tools, analyze problems, and complete work activities. Abilities emphasize the integration of knowledge and skills in complex situations, reflecting higher-level competencies such as judgment, problem-solving, decision-making, and adaptability. Hlavac (2023) noted that KSA serves as an outcome-based framework linking education with observable performance.

In AI-driven business school education, these three components are highly interdependent. First, students must build a solid knowledge base in areas such as AI, data analytics, management theory, and digital transformation. Research suggests that AI education should be embedded within integrated competency frameworks rather than fragmented tool-based learning (Mahmud et al., 2025). Second, students need to develop practical skills, including applying AI tools for data processing, business analysis, decision simulation, and project execution. This aligns with industry demands for digital and analytical competencies (Caratozzolo et al., 2023).

Finally, Abilities are particularly critical, referring to students' capacity to apply knowledge and skills in uncertain and dynamic business environments. This includes strategic thinking, cross-domain integration, ethical judgment, and responsible decision-making. Sánchez-Ruiz et al. (2025) emphasize that AI competency must go beyond technical skills to include critical and ethical reasoning. Therefore, this study conceptualizes KSA as three core competency dimensions—Knowledge Base, Skill Set, and Abilities—essential for developing comprehensive managerial capabilities in the AI era.

2.4 System Dynamics and Educational Capacity Development

System Dynamics is well-suited for analyzing complex systems characterized by feedback loops, time delays, stock accumulation, and nonlinear changes. In education, competency development is not immediate but evolves over time through teaching input, learning interactions, practice, feedback, and reflection. Faham et al. (2017) applied SD to higher education for sustainable development and developed a model with multiple reinforcing and balancing loops to explain how students' competencies evolve over time. Similarly, Elsawah et al. (2022) emphasized that systems thinking in higher education helps students understand complex interrelationships, feedback structures, and dynamic problem situations, supporting the use of system-based approaches for analyzing educational competency development.

In this study, SD offers three key advantages. First, causal loop diagram (CLD) illustrate the relationships among AI tools, learning engagement, feedback quality, skill development, and ability formation (Sterman, 2000; Hamidi & Salavati, 2025). Second, stock-and-flow diagram (SFD) treat Knowledge Base, Skill Set, and Abilities as

dynamic competency stocks, enabling analysis of how competencies accumulate, interact, and change over time (Lin et al., 2020). Third, scenario-based model analysis allows comparison of different teaching approaches, including traditional instruction, AI-assisted learning, and AI-integrated experiential learning, and their long-term influence on competency development. In this sense, SD provides a useful methodological bridge between AI-enabled learning design and the dynamic analysis of Knowledge, Skills, and Abilities (KSA) development in business schools.

2.5 Summary: Research gaps

Existing research highlights AI's role in personalized learning, assessment, and analytics, while business education studies show that AI is reshaping required competencies. The KSA framework classifies competencies, and SD explains feedback and time-based changes. However, few studies integrate these perspectives to examine long-term competency development.

This study addresses this gap by combining KSA with SD to analyze how AI-enabled learning environments influence business students' competency growth. It focuses on dynamic processes such as learning accumulation, skill practice, ability reinforcement, and cognitive load, providing a more comprehensive understanding beyond short-term learning outcomes.

3 Research methodology

This study uses SD as the main research method, aiming to construct a dynamic model of AI-driven business school competency development. System Dynamics (SD) is suitable for analyzing complex systems with feedback loops, time delays, stock accumulation, and nonlinear changes. In educational research, SD has been applied to curriculum design, educational policy, and learning system analysis, helping researchers understand the hidden dynamic relationship between educational input and learning outcomes. Groff (2013) pointed out that education systems are highly interdependent and complex in policy, and SD can be used to analyze structural issues and future scenarios in education systems. Faham et al. (2017) also used SD to analyze sustainability development in higher education, showing that capacity development can be modeled and simulated through reinforcement and balance loops (Murthy et al., 2010).

3.1 Study design

This study adopts a research design that combines conceptual model construction and qualitative scenario-based comparison. First, based on the literature related to AI education, competency-based learning, and the KSA framework, the core variables affecting business school competency development are extracted. AI education research indicates that personalized and adaptive learning can enhance students' learning engagement, academic performance, and learning experience, especially in higher education (Du Plooy et al., 2024). Second, this study distinguishes students' competencies into three dimensions: Knowledge, Skills, and Abilities, and analyzes how AI tools, learning analytics, intelligent feedback, project implementation, peer interaction, and reflective learning affect competency accumulation. This study focuses on KSA and analyzes the expected long-term impact of AI-integrated curriculum through CLD, SFD, and qualitative scenario-based comparison.

3.2 Causal circuit diagram design

This study applies a causal loop diagram (CLD) to illustrate feedback relationships in AI-driven competency development within business schools. CLD, a key tool in System Dynamics, helps identify reinforcing and balancing loops, making it suitable for analyzing interactions among learning input, feedback quality, ability growth, and limiting factors. Prior studies (Groff, 2013; Faham et al., 2017) confirm that CLD effectively reveals hidden causal structures and dynamic mechanisms in educational systems.

The model includes four main loops. The R1 Learning Accumulation Loop shows how improved AI feedback enhances engagement and knowledge growth. The R2 Skill Practice Loop highlights how AI simulations and repeated practice strengthen skill development. The R3 Ability Reinforcement Loop explains how projects, reflection, and guidance support the integration of knowledge and skills into abilities. Finally, the B1 Cognitive Load Loop illustrates how excessive complexity and tool use may increase cognitive load, reducing engagement. This framework explains how AI influences long-term competency development through dynamic feedback processes.

3.3 Stock-and-Flow Diagram Design

In this study, the Stock-and-Flow Diagram (SFD) is used to further describe the accumulation and transformation of KSA competencies. Based on the Knowledge, Skills, and Abilities framework, the model sets three core stocks: Knowledge Base, Skill Set, and Abilities. Among them, the Knowledge Base is influenced by knowledge acquisition rate and is affected by knowledge forgetting or knowledge obsolescence. Skill Set accumulates from the skill development rate and may decline due to skill obsolescence. Abilities are formed by the ability deepening rate, which represents students' problem-solving, strategic judgment, and situational application abilities after integrating knowledge and skills. SFD can present the relationship between competency stock, flow, and time delay, which is helpful for analyzing long-term competency development (Sterman, 2000). Faham et al. (2017) also confirmed that SFD can be used to represent and, when parameterized, simulate long-term dynamics and feedback structures in higher education competency development.

3.4 Scenario design

This study compares three teaching scenarios (Table 1). Scenario 1: Traditional Teaching focuses on lectures, textbook learning, and case discussions, mainly supporting steady knowledge accumulation. Scenario 2: AI-Assisted Learning incorporates AI-based assessments, learning analytics, personalized materials, and real-time feedback to enhance learning efficiency and skill development. Scenario 3: AI-Integrated Experiential Learning combines AI tools with case simulations, corporate projects, peer interaction, reflective learning, and instructor guidance, aiming to promote comprehensive competency growth.

Table 1: Scenario Design

Scenario	Instructional Design Features	AI Level *	Expected KSA Development Logic
Scenario 1: Traditional Teaching	Teacher lectures, textbook reading, general case discussions, and final assessments	Low	Supports basic Knowledge accumulation, but provides limited opportunities for Skills practice and Abilities development
Scenario 2: AI-Assisted Learning	AI-assisted quizzes, learning analytics, personalized materials, intelligent feedback, and automated suggestions	Medium	Enhances Knowledge acquisition and Skills practice, but Abilities development may remain limited without projects and reflection
Scenario 3: AI-Integrated Experiential Learning	AI-assisted analysis, case simulations, enterprise projects, peer interaction, reflective journals, and teacher feedback	High	Promotes balanced KSA development through action, reflection, feedback, and competency transformation

* AI Level : AI Integration Level

4 Model Analysis and Scenario Comparison

This study constructs an AI-driven competency development model for business schools based on System Dynamics, and the model analysis can be divided into three part: first, proposing a competency development model with KSA as the core; second, identifying the main feedback loops in the AI-assisted learning environment; and third, comparing the expected impact of different teaching designs on students' long-term ability growth through qualitative scenario-based model analysis. Overall, the model analysis suggests that the impact of AI on business school students' ability development is not a single path or immediate effect, but is gradually formed through multiple mechanisms such as knowledge accumulation, skill implementation, reflective feedback, and ability reinforcement.

4.1 AI-driven business school capability development model

This study proposes an AI-driven business school competency development model based on the KSA framework (Knowledge, Skills, Abilities), illustrating how AI-integrated learning environments support the accumulation and transformation of student competencies. AI has been widely applied in adaptive learning, intelligent assessment, and learning analytics, enhancing personalized learning, feedback quality, and learning diagnosis (Wang et al., 2024). Furthermore, AI is reshaping business education by transforming curriculum design, competency requirements, and talent development models (Wu et al., 2026).

In this model, the Knowledge Base refers to students' understanding of AI concepts, data analytics, management theory, and digital transformation. AI-supported materials, feedback systems, and analytics help improve learning efficiency by enabling students to identify gaps and adjust their learning more quickly. This

aligns with the view that AI education should be implemented through integrated competency frameworks rather than fragmented tools (Mahmud et al., 2025).

The Skill Set represents students' ability to apply AI tools in data processing, business analysis, decision simulation, and project execution. AI simulations and generative tools provide repeated practice opportunities, allowing students to transform theoretical knowledge into practical and analytical skills. This reflects the need to align education with digital workforce competencies (Caratozzolo et al., 2023).

Abilities represent higher-level competencies, including problem-solving, strategic thinking, cross-domain collaboration, and responsible AI application in complex business contexts. Knowledge forms the foundation, skills enable application, and abilities integrate both into effective professional performance.

Overall, the model emphasizes that AI does not directly create abilities but influences competency development through three mechanisms: enhancing knowledge accumulation via feedback, strengthening skills through practice and simulation, and fostering abilities through project implementation, reflection, and guidance. Thus, AI-enabled business education should be viewed as a dynamic, long-term system of competency development rather than a tool-based or course-specific intervention.

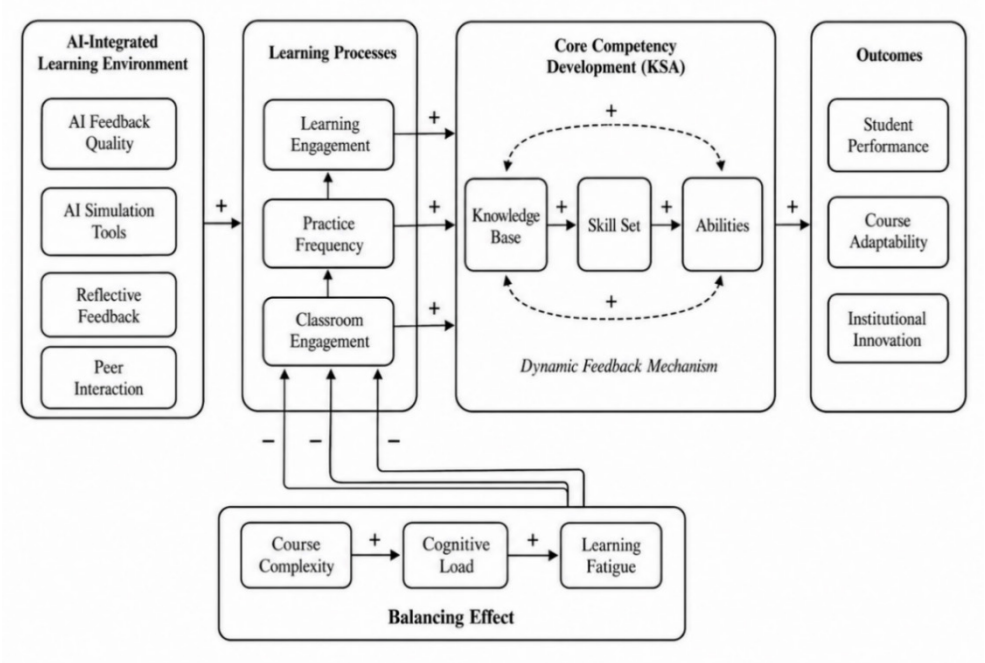

Figure 1: AI-driven business school capability development model diagram

4.2 Main feedback loop analysis

This study identifies three reinforcing loops and one balancing loop (Figure 2) to explain AI-driven competency development in business schools. The first is the R1 Learning Accumulation Loop, which highlights the positive relationship between AI feedback quality, learning engagement, and knowledge growth. AI tools—such as real-time quizzes, personalized recommendations, and learning analytics—help students identify knowledge gaps and adjust strategies, increasing engagement and accelerating knowledge acquisition. This process strengthens self-efficacy, further reinforcing continued learning and knowledge accumulation (Wang et al., 2024).

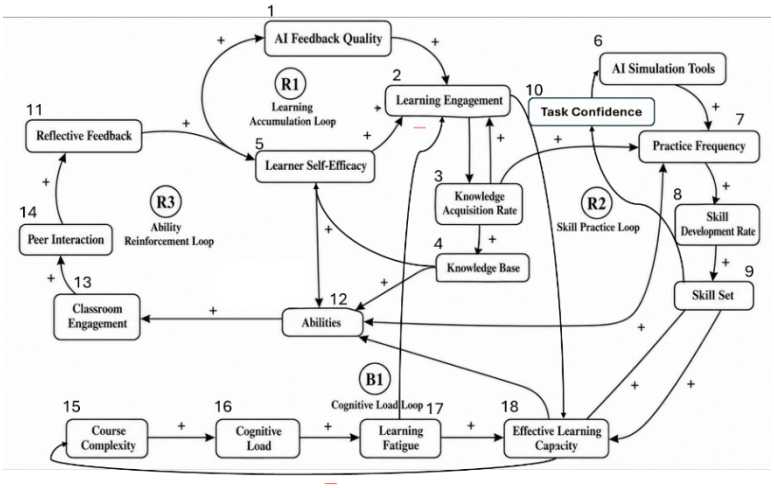

Figure 2: three reinforcing loops and one balancing loop

The second is the R2 Skill Practice Loop, which explains how AI simulation tools, repeated practice, and skill development reinforce each other. Through business simulations, data dashboards, and generative AI-assisted decision-making, students gain opportunities to apply knowledge in practical contexts. Repeated task execution enhances operational and analytical skills, aligning with research that emphasizes the role of project-based learning (PjBL) in improving competency through practice, collaboration, and reflection (Guo et al., 2020; Wu et al., 2026). The third is the R3 Ability Reinforcement Loop, focusing on the development of higher-level abilities. Through project implementation, reflective feedback, peer interaction, and teacher guidance, students integrate knowledge and skills into complex capabilities such as problem-solving, strategic thinking, and responsible AI application. This loop emphasizes that abilities are formed through continuous action and reflection rather than passive learning.

This mechanism is consistent with experiential learning and feedback research, which emphasizes that higher-order abilities emerge through experience, reflection, and feedback-supported improvement (Banihashem et al., 2022; Wijnen-Meijer et al., 2022).

Finally, the B1 Cognitive Load Loop represents a balancing mechanism. Excessive complexity in AI tools or course design may increase cognitive load and learning fatigue, reducing engagement and limiting skill and ability development. This highlights the importance of proper instructional design, including scaffolding, task segmentation, and guided support, to ensure sustainable long-term competency growth.

4.3 Scenario comparison outcomes

Based on the proposed system dynamics model, this study conducts a qualitative scenario-based model analysis (Table 2) to compare how different levels of AI integration influence students' Knowledge, Skills, and Abilities (KSA). Traditional Teaching mainly supports Knowledge accumulation through lectures, textbook reading, and case discussions, but provides limited opportunities for AI tool practice, project implementation, and ability transformation. AI-Assisted Learning improves Knowledge acquisition and Skills development through AI-assisted quizzes, learning analytics, personalized materials, and intelligent feedback; however, if learning remains tool-oriented, students' higher-order Abilities may remain limited.

Table 2: Scenario Comparison Outcomes

Scenario	Knowledge	Skills	Abilities	Overall Outcome
Traditional Teaching	Medium	Low to medium	Low	Helps students build basic knowledge, but the transformation from knowledge to skills and higher-order abilities remains insufficient
AI-Assisted Learning	High	Medium to high	Medium	Improves knowledge learning and skill development, but abilities may remain at the initial application level if learning is tool-oriented
AI-Integrated Experiential Learning	High	High	High	Produces the most balanced and sustained development across the three KSA dimensions

AI-Integrated Experiential Learning provides the strongest support for KSA development because it combines AI-assisted analysis, case simulation, enterprise projects, peer interaction, reflective journals, and teacher feedback. This scenario directly supports the R3 Ability Reinforcement Loop, in which project implementation, reflective feedback, peer collaboration, and teacher guidance help students integrate knowledge and skills into problem-solving, strategic judgment, cross-domain application, and responsible AI-enabled decision-making. Project-based learning improves higher education outcomes through practical tasks, collaboration, and reflection (Guo et al., 2020). Learning analytics strengthens feedback practices by helping students and teachers identify learning progress and competency gaps (Banihashem et al., 2022). Experiential learning also emphasizes that ability development occurs through experience, reflection, conceptualization, and active experimentation (Wijnen-Meijer et al., 2022). Therefore, AI-Integrated Experiential Learning is expected to produce the most balanced and sustainable development across the three KSA dimensions.

5 Discussion

5.1 Theoretical contributions

The main theoretical contribution of this study is the integration of AI education, the KSA competency framework, and System Dynamics to propose a dynamic model of competency development in business schools. While existing AI education research largely focuses on applications such as adaptive learning, intelligent assessment, and personalized learning (Wang et al., 2024), it rarely explains how AI influences long-term competency formation through feedback, time delays, and cumulative learning processes.

This study redefines KSA as Knowledge, Skills, and Abilities, conceptualizing them as three interdependent and evolving competency stocks rather than static categories. Drawing on Caratozzolo et al. (2023), it emphasizes that effective talent development in the digital era requires understanding how these components interact. In this model, the Knowledge Base supports understanding of AI, data analytics, and management theory; the Skill Set reflects the ability to apply AI tools in analysis and decision-making; and Abilities represent higher-order competencies such as problem-solving, strategic thinking, cross-domain integration, and responsible decision-making.

Furthermore, this study applies System Dynamics to address limitations of traditional competency research, which often overlooks feedback and temporal effects. Building on Faham et al. (2017), the model incorporates reinforcement loops (learning accumulation, skill practice, ability development) and a balancing loop (cognitive load). These illustrate that competency growth is nonlinear and influenced by factors such as feedback quality, practice frequency, reflection, and learning complexity.

Overall, this research advances AI education from a tool-oriented perspective to a dynamic framework that explains long-term competency development and knowledge accumulation.

5.2 Impact on knowledge management

From a KM perspective, this study views AI-driven business school competency development as the accumulation and transformation of educational knowledge assets. Within the KSA framework, Knowledge refers to understanding of AI, data analytics, and management concepts; Skills represent the ability to apply AI tools in analysis and decision-making; and Abilities reflect the integration of knowledge and skills into higher-level competencies such as problem-solving and strategic judgment.

AI implementation thus goes beyond tool adoption, functioning as a mechanism that converts learning data, project outputs, reflection records, and assessment results into reusable knowledge assets. Learning analytics further supports this process by collecting and visualizing data to identify learning progress, competency gaps, and improvement needs (Banihashem et al., 2022).

This knowledge management perspective aligns with IFKAD's concern with knowledge assets because students' learning traces, project outputs, competency records, and individual learning outcomes can be transformed into institutional knowledge assets that support curriculum redesign, teaching improvement, and long-term educational innovation.

5.3 Model interpretation

This research model points out that the impact of AI on business school competency development does not simply come from tool introduction, but gradually promotes the accumulation of Knowledge, Skills, and Abilities through feedback, implementation, reflection, and ability transformation mechanisms. AI feedback and learning analytics help form a knowledge base, while AI simulation tools, case studies, and project tasks can increase

practice frequency and promote skill set development. Furthermore, through project implementation, teacher guidance, and reflection activities, students can integrate knowledge and skills into abilities, demonstrating problem-solving, strategic judgment, and responsible decision-making abilities. However, if the course complexity and AI tool load are too high, it will form a cognitive load loop, reducing learning investment and inhibiting ability growth.

6 Conclusion

This study develops a systematic, dynamic model of AI-driven competency development in business schools based on the KSA framework. It argues that AI integration should not be viewed merely as the addition of digital tools, but as a feedback-driven system that enhances how competencies are accumulated, transformed, and deepened over time. AI technologies—such as adaptive learning, intelligent assessment, learner analytics, and prediction—support personalized learning and strengthen knowledge construction processes (Wang et al., 2024). The study's key theoretical contribution lies in integrating AI education, the KSA framework, and System Dynamics. Within this framework, Knowledge refers to students' understanding of AI, data analytics, management theory, and decision-making concepts. Skills represent the ability to apply AI tools for data processing, case analysis, and decision simulation. Abilities refer to higher-order competencies, including problem-solving, strategic thinking, cross-domain integration, and responsible decision-making in complex business contexts. This aligns with Caratozzolo et al. (2023), who emphasize the interconnected and dynamic nature of KSA in responding to digital transformation.

Methodologically, the study applies System Dynamics through four loops: the R1 Learning Accumulation Loop, R2 Skill Practice Loop, R3 Ability Reinforcement Loop, and B1 Cognitive Load Loop. These illustrate how AI feedback, engagement, practice, project-based learning, and cognitive load interact to influence long-term competency growth. As noted by Faham et al. (2017), System Dynamics effectively captures feedback mechanisms and time-based changes often overlooked in traditional education research. Practically, findings suggest that traditional teaching supports knowledge accumulation but has limited impact on skill and ability development. AI-assisted learning improves efficiency in knowledge acquisition and skill practice, yet without project-based tasks and reflective feedback, ability growth remains constrained. In contrast, AI-integrated experiential learning—combining simulations, real-world projects, peer interaction, and instructor guidance—promotes balanced development across KSA dimensions (Guo et al., 2020).

This study is limited by its conceptual nature and lack of large-scale empirical validation. Future research should incorporate longitudinal data, quantify model parameters, and compare different teaching scenarios. Overall, it emphasizes that AI education should focus on building sustainable, adaptive, and feedback-driven competency development systems rather than simply adopting new technologies.

7 Declarations

This study is a conceptual modeling study based on published literature and does not involve human participants, personal data, or experimental intervention. Google NotebookLM was used only to assist with literature organization and summarization. All arguments, interpretations, and final writing were reviewed and revised by the author.

Evolution of Knowledge Landscapes in AI-KM: A Longitudinal Analysis of Divergence between Term Diversity and Community Attention (2015-2024)

Hsuan-Hao Lo, Sirirat Sae Lim
National Yang Ming Chiao Tung University, Hsinchu, Taiwan

Abstract

This study adopts a longitudinal bibliometric approach combined with co-word network analysis to examine the development of the AI–KM field over the past decade. While research at the intersection of artificial intelligence (AI) and knowledge management (KM) has expanded rapidly in recent years, existing bibliometric studies have remained largely cross-sectional and descriptive, offering limited insight into how the field's knowledge structure has evolved during this period of rapid growth. Drawing on 2,857 AI–KM publications indexed in the Web of Science between 2015 and 2024, this study investigates the evolution of the field through three complementary lenses: publication growth trajectories, conceptual cluster structures, and cross-period changes in author keywords. These analyses collectively reveal the overall trajectory and structural reconfiguration of the AI–KM field, identifying the continuity of core themes, shifts in research focus, and the emergence of new topics. By adopting a longitudinal perspective, this study addresses a key limitation of prior research in capturing dynamic changes in knowledge structure and extends understanding of the AI–KM field beyond a static snapshot toward an evolutionary view. The findings provide an empirical foundation for future theory building and research agenda setting in this area.

Keywords: Artificial Intelligence, Knowledge Management, Bibliometric Analysis, Co-word Network, Science Mapping

Paper type: Academic Research Paper

1 Introduction

In recent years, the intersection of artificial intelligence (AI) and knowledge management (KM) has emerged as a rapidly growing research domain (Cantu-Ortiz, 2021). Prior bibliometric studies have begun to map the overall landscape of this interdisciplinary field. For example, Cantu-Ortiz (2021), drawing on publications from 2011 to 2019, examined research trends and future agendas in AI and KM, while Kushwaha and Maurya (2025) complemented narrative reviews by analyzing core sources, authors, institutions, and co-word relationships. Collectively, these studies suggest that the AI–KM field has maintained strong growth momentum and offer initial insights into its major research themes, leading sources, and knowledge foundations.

However, existing research remains largely cross-sectional, focusing primarily on descriptive dimensions such as publication volume, citation performance, keyword co-occurrence, thematic clustering, and author productivity. Relatively few studies have adopted a longitudinal perspective to examine how the knowledge structure of the field has evolved during its period of rapid expansion. As a result, the developmental dynamics of the field remain insufficiently understood.

This gap is particularly notable given the highly interdisciplinary nature of AI–KM, which integrates knowledge from management, information science, engineering, and organizational studies. The rapid growth of a field does not necessarily imply the stable integration of its knowledge structure. As research output increases, the variety of author keywords and conceptual labels often expands as well, creating a surface impression of thematic diversification. Yet the expansion of terminological variety does not necessarily mean that newly introduced concepts are effectively integrated into the central structure of the field. Instead, rapid growth can coincide with the consolidation of core themes, the weakening of local clusters, or an uneven pace between the expansion of concepts and the redistribution of collective attention. In short, the apparent vibrancy of the AI–KM field does not in itself indicate greater structural integration.

Against this backdrop, this study draws on the notions of term diversity and community attention as a framework for examining the evolution of the AI–KM knowledge landscape. In this study, term diversity refers to the breadth and temporal variation of author keywords used in the field, reflecting the range of conceptual vocabulary through which researchers position their work. Community attention, by contrast, refers to the relative prominence and concentration of specific keywords across the field, indicating the thematic areas that attract sustained collective focus. Although these two dimensions are related, they may evolve differently. New

terms may continue to emerge while research attention remains concentrated on a limited number of established themes. Conversely, some terms may remain prominent even as their conceptual meaning shifts over time. Tracing the relationship between these two dimensions helps reveal how the AI–KM knowledge landscape has been reconfigured during its period of rapid growth.

Building on this framework, this study combines bibliometric analysis with co-word network analysis to examine the evolution of the AI–KM knowledge landscape across multiple layers. Beyond publication growth, the analysis examines the conceptual distribution of author keywords, the structural characteristics of the co-word network, and cross-period changes in thematic composition. By integrating these layers, this study traces how conceptual linkages in the AI–KM field have formed, expanded, and reorganized over time. Accordingly, this study addresses the following questions:

1. *What stage-wise characteristics can be identified in the publication growth trajectory of the AI–KM field between 2015 and 2024?*
2. *What cluster patterns and core themes emerge in the conceptual structure formed by author keywords in this field?*
3. *How have the high-frequency author keywords of the field shifted across different developmental periods?*

This study makes three main contributions. First, it complements existing bibliometric research by adopting a longitudinal perspective, thereby extending understanding of the field beyond a static snapshot toward an evolutionary view. Second, based on publications from 2015 to 2024, it integrates descriptive analysis, co-word network analysis, and cross-period keyword comparison within a multi-layered bibliometric framework to reveal patterns in the field's structural development. Third, it provides an empirical foundation for future theory building and research agenda setting in the AI–KM domain.

2 Methodology

This study employs a quantitative research design that combines longitudinal bibliometric analysis with co-word network analysis and network structural indicators to examine the evolution of the AI–KM knowledge landscape between 2015 and 2024. These approaches have been widely used to identify research themes, map knowledge structures, and trace their long-term evolution across fields such as knowledge management, information systems, AI innovation, and digital innovation (Bernatović et al., 2022; Cobo et al., 2011; Gaviria-Marin et al., 2019). They are particularly suitable for a field such as AI–KM, characterized by rapid growth, interdisciplinary integration, and continually shifting knowledge structures.

Early literature reviews of emerging fields often relied on narrative synthesis, qualitative induction, or descriptive summaries to organize themes, theoretical foundations, and key findings (Grant & Booth, 2009). While useful for establishing an initial understanding of a field, these approaches become less effective as research output grows rapidly, making it difficult to capture structural linkages among themes, internal reorganization processes, and evolutionary changes over time. To address these limitations, later studies increasingly adopted systematic literature reviews and bibliometric methods (Donthu et al., 2021; Tranfield et al., 2003), using citations, co-word relationships, and network structures to map research themes and knowledge development over time (Cobo et al., 2011; Donthu et al., 2021).

Building on this methodological trajectory, the present study combines longitudinal bibliometric analysis and co-word network analysis to examine the developmental profile, conceptual linkages, and structural shifts of the AI–KM field.

2.1 Research Design

This study employs bibliometric analysis as its primary research method to systematically map the developmental profile, core concepts, and thematic evolution of the AI–KM field between 2015 and 2024. Compared with traditional narrative reviews, bibliometric analysis offers a more systematic, objective, and visual approach to examining the knowledge structure, conceptual distribution, and developmental patterns of a research field. To enhance the transparency and reproducibility of the research process, this study follows the methodological guidance of Donthu et al. (2021) and Öztürk et al. (2024), proceeding through data retrieval, data cleaning, network construction, analysis, and visualization.

Analytically, the study focuses on conceptual structure analysis within a science mapping framework (Hoang, 2025), using keyword co-occurrence analysis and cross-period thematic comparison as its main techniques. The former is used to identify co-occurrence relationships and thematic clusters among core concepts, while the latter is used to trace the continuity, transformation, emergence, and decline of themes across different periods.

By adopting a longitudinal perspective, this design helps reveal how knowledge in the AI–KM field has accumulated, diversified, and reorganized over time.

2.2 Data Collection

This study uses the Web of Science Core Collection (WoS) as its primary data source. WoS is well suited to longitudinal bibliometric and network analyses because of its broad interdisciplinary coverage, rigorous editorial selection and quality standards, and comprehensive citation and bibliographic records. Accordingly, it has been widely adopted as a primary data source in bibliometric research (Gaviria-Marin et al., 2019; Merigó et al., 2015; Wamba et al., 2021).

The search was conducted on January 30, 2026, and covered the period from January 1, 2015 to December 31, 2024. This period was selected because the AI–KM field has entered a phase of marked growth over the past decade, and the 2015–2024 window provides a relatively complete interval for observing the formation and expansion of its knowledge landscape. To reduce potential bias arising from the limited citation accumulation of very recent publications, records from 2025 were excluded from the core analysis.

The search query was constructed by combining AI-related and KM-related terms with the Boolean operators "OR" and "AND" and was applied to the Title (TI), Abstract (AB), and Author Keywords (AK) fields (Donthu et al., 2021; Hoang, 2025; Marzi et al., 2025). AI-related terms included *artificial intelligence*, *machine learning*, *deep learning*, and *generative AI*, while KM-related terms included *knowledge management*, *knowledge sharing*, *knowledge transfer*, and *knowledge creation*.

Document types were restricted to journal articles and conference papers, and the language was limited to English to ensure consistency, comparability, and overall research quality. The initial search returned 3,521 records. After excluding records that lacked essential information, such as publication year or author keywords, as well as non-English entries, the final dataset consisted of 2,857 publications.

2.3 Data Cleaning and Author Keyword Normalization

To improve the accuracy of the keyword co-occurrence analysis, this study conducted a systematic cleaning and normalization of the author keywords extracted from the WoS records. In the raw data, author keywords often exhibit inconsistencies in capitalization, variations between abbreviations and full forms, singular–plural differences, and synonymous expressions. Without preprocessing, the same concept may be split across multiple nodes, thereby distorting the structure of the co-word network and the formation of thematic clusters (Cobo et al., 2011; Muñoz-Leiva et al., 2012). To address these issues, a four-stage cleaning procedure was implemented, consisting of parenthetical removal, synonym consolidation, abbreviation expansion, and singular–plural unification, supplemented by a stopword list and a residual singular–plural scan to improve overall data quality.

The first stage removed parenthetical content. Some authors include supplementary notes or abbreviations in parentheses, such as "knowledge transfer (KT)." Although useful for readers, this practice creates multiple surface forms of the same concept across documents. Parenthetical content was therefore removed, standardizing such cases to a single form and reducing node fragmentation.

The second stage consolidated synonymous expressions. Terms with equivalent meanings but different spellings were merged into a unified form. For example, both "information and knowledge management" and "information & knowledge management" were standardized as "knowledge management." These merging rules were developed based on conventional usage in the domain literature and further verified through manual review to avoid over-merging concepts that differ in abstraction or scope.

The third stage expanded common abbreviations to prevent a single concept from being split across multiple nodes because of surface variation. For example, "AI" was expanded to "artificial intelligence," "LLM" to "large language model," and "CNN" to "convolutional neural network." Expansion rules were applied only when the abbreviation had a clear one-to-one mapping. In ambiguous cases, such as "RL," which may refer to either reinforcement learning or representation learning, expansion was determined case by case based on contextual cues in order to avoid erroneous merging.

The fourth stage unified singular and plural forms by mapping plurals onto their singular counterparts, such as "neural networks" to "neural network" and "large language models" to "large language model." This step is especially important in co-occurrence analysis, as singular–plural variation may underestimate the frequency of high-occurrence terms and obscure core themes.

In addition, this study compiled a stopword list to exclude overly generic terms that did not meaningfully contribute to conceptual structure analysis, such as "training," "optimization," and "feature extraction."

Although these terms appear frequently, their broad semantic scope may introduce large numbers of non-substantive linkages into the network and reduce the interpretability of thematic clusters.

Finally, to verify the quality of the cleaning process, a residual singular–plural scan was conducted on all keywords with a frequency of four or more. Variants not captured by the general rules were manually identified and added to the rule set, resulting in more than twenty additional normalization rules covering terms such as "transformers," "support vector machines," "expert systems," and "foundation models." Following this procedure, noise in the original keyword set was substantially reduced, improving the stability and interpretability of the subsequent co-occurrence and thematic structure analyses (Cobo et al., 2011; Hoang, 2025).

2.4 Data Analysis

Following the general procedures of science mapping and bibliometric analysis, the data workflow of this study comprised four stages: data retrieval, preprocessing, network extraction, and analysis and visualization. Bibliographic records meeting the search criteria were first downloaded from the WoS Core Collection. The records were then cleaned, deduplicated, and filtered to retain the fields required for analysis, including publication year, source, author and institutional information, and author keywords. Records lacking any of these fields were excluded. The final dataset served as the analytical basis of this study.

The cleaned dataset was subsequently imported into VOSviewer for network visualization and analysis. VOSviewer is widely used in bibliometric research and is particularly well suited to keyword co-occurrence analysis. Through cluster analysis and network indicators such as links and total link strength, it supports the identification of core concepts, thematic clusters, and the broader knowledge structure of a research field (Bernatović et al., 2022; Van Eck & Waltman, 2010). Using author keywords as the unit of analysis, this study conducted co-occurrence analysis to examine the relational connectivity and structural prominence of keywords within the overall conceptual network.

To examine temporal shifts in research focus, this study further compared high-frequency keywords across three developmental periods based on the growth trajectory of the field. For each period, keyword frequency was normalized as the proportion of documents containing a given keyword relative to the total number of documents in that period, and cross-period differences were calculated in percentage points. This comparison provides a basis for tracing the continuity, weakening, and emergence of themes across different stages of the AI–KM field's development, and supports the subsequent interpretation of the results.

3 Results and Discussion

This section presents the empirical results for the AI–KM field between 2015 and 2024. Following the analytical logic of bibliometric analysis and science mapping, the discussion proceeds from a descriptive overview to the conceptual structure and cross-period thematic comparison of the field.

As shown in Figure 1, the bars represent annual publications, the solid line denotes the three-year moving average, and the dashed line indicates cumulative publications. Between 2015 and 2024, the annual output of the AI–KM field exhibited a clear upward trend, increasing from 72 publications in 2015 to 782 in 2024. The cumulative curve confirms the sustained expansion of the field, while the three-year moving average indicates a marked acceleration in growth after 2022, suggesting that AI–KM research has entered a phase of rapid expansion.

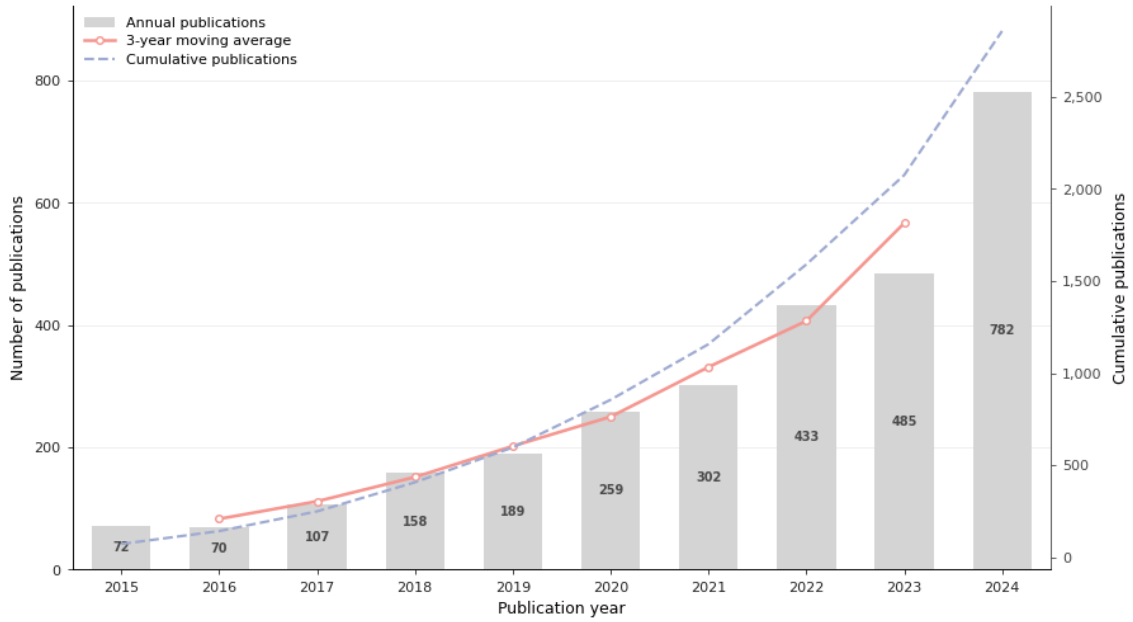

Figure 1: Annual and cumulative publication trends in AI–KM research (2015–2024

3.1 Conceptual Structure

To identify the conceptual structure of AI–KM research, this study employs co-word analysis based on author keywords. Co-word analysis captures the co-occurrence of terms within the same document and is widely used to depict conceptual linkages, thematic clusters, and knowledge structures in science mapping research (Cobo et al., 2011; Jiang et al., 2023). Although it provides a systematic way to reveal associative patterns among concepts, its results are highly sensitive to the quality, consistency, and normalization of author keywords and therefore require careful contextual interpretation (Muñoz-Leiva et al., 2012).

VOSviewer identified a total of 8,365 author keywords in the dataset. To improve the interpretability of the network and reduce noise from low-frequency terms, the minimum occurrence threshold was set at 12, resulting in 106 keywords being included in the analysis and yielding three major clusters. Based on occurrence, link count, and total link strength, the core nodes of the network include *knowledge transfer*, *deep learning*, *transfer learning*, *artificial intelligence*, *and knowledge management*, as shown in Figure 2 and summarized in Table 1.

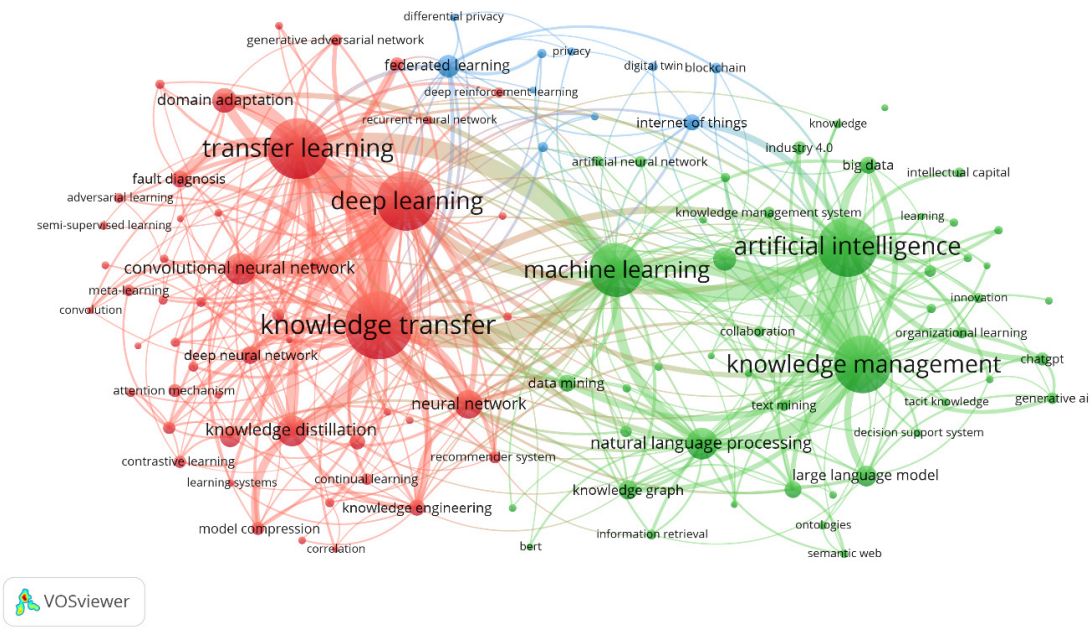

Figure 2: Conceptual structure of AI–KM research based on author keyword co-occurrence (2015–2024)

Cluster 1 centers on AI-driven knowledge transfer and learning mechanisms, with *knowledge transfer*, *transfer learning*, *deep learning*, *and knowledge distillation* as its core nodes. This cluster reflects strong scholarly attention to how knowledge is embedded in model training, transferred across domains, and operationalized through algorithmic mechanisms.

Cluster 2 constitutes the conceptual core of the AI–KM field, encompassing key nodes such as *artificial intelligence*, *knowledge management*, *machine learning*, *natural language processing*, and *knowledge sharing*. Its composition suggests that AI technologies have been broadly integrated into research on knowledge management, knowledge sharing, and semantic knowledge applications.

Cluster 3 extends toward privacy-preserving and intelligent system applications, represented by *federated learning*, *internet of things*, *blockchain*, and *data privacy*. This composition indicates that AI–KM research has also begun to **e**ngage with distributed intelligent systems and data governance concerns.

Taken together, these three clusters suggest that the AI–KM field is not organized around a single knowledge management theme. Rather, it spans technical learning mechanisms, AI-enabled knowledge management applications, and privacy-preserving and intelligent system applications.

Table 1: Major thematic clusters and top 10 keywords by occurrence in the AI–KM field

Cluster	theme label	Top 10 Author keywords by occurrence
Cluster 1	knowledge transfer and learning mechanisms	knowledge transfer (478); transfer learning (399); deep learning (385); convolutional neural network (154); knowledge distillation (132); neural network (115); domain adaptation (90); graph neural network (68); deep neural network (53); knowledge engineering (46)
Cluster 2	AI-enabled knowledge management applications	artificial intelligence (414); knowledge management (372); machine learning (332); natural language processing (134); knowledge sharing (81); large language model (68); knowledge graph (59); big data (50); ontology (49); data mining (48)
Cluster 3	Privacy-preserving and intelligent system applications	federated learning (75); internet of things (47); blockchain (23); edge computing (21); data privacy (18); digital twin (18); privacy (15); cloud computing (14); differential privacy (14); additive manufacturing (12)

3.2 Temporal Keyword Trend Analysis

To examine temporal shifts in research focus within the AI–KM field, this study adopts a cross-period keyword comparison to analyze changes in the frequency and structural composition of high-frequency keywords across different time intervals. The division of time periods should not be arbitrary, as the choice of period boundaries may affect the identification of emerging themes (Hoang, 2025). Given that the growth of AI–KM publications between 2015 and 2024 was uneven—showing marked acceleration after 2021—this study divides the observation window into three periods based on the turning points of the three-year moving average: 2015–2020 (P1), 2021–2022 (P2), and 2023–2024 (P3). To avoid interpretive bias arising from differences in corpus size across periods, Table 2 reports keyword prevalence as the proportion of documents containing each keyword relative to the total number of documents in the corresponding period.

As shown in Table 2, the research focus of the AI–KM field has evolved in clearly distinguishable stages. In P1, the most prominent keywords were *knowledge management* (18.9%), *knowledge transfer* (14.9%), *machine learning* (14.7%), *deep learning* (12.6%), and *artificial intelligence* (12.2%), indicating that research during this period was primarily built on the initial integration of established KM themes with AI-based techniques. In P2, *knowledge transfer* (18.8%) and *transfer learning* (15.5%) rose further, while *knowledge distillation* increased from 1.3% to 5.7%, reflecting a gradual shift from KM-oriented conceptual frameworks toward more technical topics centered on model transfer, knowledge compression, and representation learning. By P3, keywords such as *large language model* (5.1%), *ChatGPT* (2.1%), and *federated learning* (4.7%) had emerged rapidly, suggesting that generative AI and distributed learning have become prominent new research foci.

Building on these trends, several structural shifts merit closer discussion. The most analytically significant shift is the relative retreat of the *knowledge management* label within the field itself. As the defining term of this research domain, *knowledge management* declined from 18.9% in P1 to 8.8% in P3, a drop of 10.1 percentage points. This decline, however, does not necessarily indicate that KM research itself has receded. Rather, it can be interpreted as a shift in how researchers position their work: instead of labeling their studies directly under the broader KM umbrella, recent authors increasingly adopt more specific technical terms—such as *knowledge distillation*, *transfer learning*, and *knowledge graph*—to describe their research. In this sense, the intellectual center of gravity in AI–KM research appears to be shifting from "AI research framed around KM themes" toward "AI-based technical research that carries KM implications." This reading is consistent with

recent studies suggesting that AI is no longer merely an auxiliary tool layered onto KM processes, but has increasingly entered the core stages of knowledge creation, acquisition, sharing, and application, transforming how these activities are conducted (Jarrahi et al., 2023; Nakash & Bolisani, 2025).

Table 2: Top 20 author keywords across three developmental stages of the AI–KM field

Keyword	P1%	P2%	P3%	Δ(P2–P1)	Δ(P3–P2)	Δ(P3–P1)
knowledge transfer	14.9	18.8	15.1	+3.9	-3.7	+0.2
transfer learning	11.6	15.5	13.7	+3.9	-1.8	+2.1
deep learning	12.6	13.9	12.9	+1.3	-1.0	+0.3
artificial intelligence	12.2	14.0	12.5	+1.8	-1.5	+0.3
knowledge management	18.9	10.1	8.8	-8.8	-1.3	-10.1
machine learning	14.7	12.9	8.1	-1.8	-4.8	-6.6
knowledge distillation	1.3	5.7	6.7	+4.4	+1.0	+5.4
large language model	0.0	0.0	5.1	0.0	+5.1	+5.1
federated learning	0.4	2.3	4.7	+1.9	+2.4	+4.3

Note. Percentages were calculated by dividing the number of documents containing a given keyword by the total number of documents in each period. The total number of documents was 855 in P1 (2015–2020), 735 in P2 (2021–2022), and 1,267 in P3 (2023–2024). Percentage-point differences are reported to facilitate cross-period comparison.

By contrast, *knowledge transfer* maintained a consistently high prevalence across all three periods (14.9%, 18.8%, and 15.1%), making it the most stable bridging term in the field and suggesting that questions of how knowledge is transferred, learned, and reused remain central to AI–KM research. Yet the thematic context in which this term appears has shifted noticeably over time. In P1, *knowledge transfer* occurred predominantly alongside KM-oriented terms centered on *knowledge management*; from P2 onward, it increasingly co-occurred with machine-learning-oriented terms such as *transfer learning*, *domain adaptation*, and *knowledge distillation*. This shift suggests that a single surface term may now carry two distinct research meanings: from a management perspective, the transfer of knowledge between organizations or individuals; from a machine-learning perspective, the transfer of knowledge between models. Drawing on the notion of interdisciplinary semantic drift (Wang et al., 2023), this phenomenon can be interpreted as a gradual relocation of a concept's semantic center across disciplinary communities.

Beyond these structural changes in established vocabulary, P3 also witnessed the rapid introduction of emerging technical topics. *Large language model* and *ChatGPT* rose from 0% in the earlier periods to 5.1% and 2.1%, respectively, and *federated learning* grew from 0.4% in P1 to 4.7% in P3. The emergence of these keywords does not appear to represent a linear extension of existing themes; rather, they were introduced in conjunction with a broader paradigm shift in AI, most notably the wave of generative AI that followed the public release of ChatGPT at the end of 2022. Notably, these new terms have not displaced established core concepts such as *knowledge transfer* and *deep learning* but instead coexist with them. This pattern suggests that recent developments in the AI–KM field may be better characterized as *paradigm layering* than *paradigm replacement*: new technologies are not establishing entirely separate research traditions but appear to be absorbed into existing problem spaces and reinterpreted within the field's prior knowledge context. Taken together, the relative retreat of traditional KM labels, the semantic shift of core bridging terms, and the rapid introduction of new technical topics constitute the three principal axes along which the research focus of AI–KM has been reorganized over the past decade.

4 Conclusions

This study examined how the knowledge structure of the AI–KM field has evolved amid its rapid expansion in recent years. Drawing on 2,857 AI–KM publications indexed in the Web of Science between 2015 and 2024,

the study combined descriptive analysis, co-word network analysis, and cross-period keyword comparison to conduct a longitudinal examination across three layers: publication trajectories, conceptual structure, and temporal changes in keywords. The findings suggest that the development of the AI–KM field has not followed a single linear path. Rather, it has been characterized by the relative retreat of the traditional knowledge management label, the semantic drift of *knowledge transfer* across disciplinary communities, and the rapid emergence of technical topics such as *large language model*, *ChatGPT*, and *federated learning*.

Taken together, these patterns are better characterized as paradigm layering than as paradigm replacement. Even as the field continues to expand in scale, its core problem orientations have not been displaced by new technologies. Instead, they have continued to evolve through shifts in vocabulary, the repositioning of meaning, and the layering of new topics onto existing research concerns.

The main contribution of this study lies in complementing existing bibliometric research, which has largely focused on cross-sectional description, by adopting a longitudinal perspective. In doing so, it extends understanding of the AI–KM field from a static snapshot toward an evolutionary view and provides an empirical foundation for future theory building, research positioning, and methodological development in this area.

5 Limitations and Future Directions

This study has several methodological limitations that should be acknowledged and addressed in future research.

First, the study relies on a single data source. Although the Web of Science Core Collection offers strong advantages in indexing quality and the completeness of citation data, it may exclude relevant conference papers that are indexed only in Scopus or IEEE Xplore. Future research could integrate multiple databases to improve coverage.

Second, the use of author keywords has inherent limitations. Although author keywords provide a direct reflection of how researchers position their work, their quality depends on individual labeling practices. Some publications do not provide keywords, while others use terms that are too generic to support fine-grained analysis. Future research could combine Keyword Plus, abstract-based keyword extraction, or topic modeling to reduce reliance on author-provided keywords alone.

Third, the observed shift in the semantic center of knowledge transfer across periods is primarily inferred from differences in co-occurring vocabulary. Future research could employ word embedding models to compare the semantic positioning of the same term across different periods, thereby providing a more rigorous way to examine the presence and magnitude of interdisciplinary semantic drift.

Future research should also integrate multiple databases, abstract-based corpora, and semantic analysis methods to more precisely trace conceptual drift and structural integration across periods, thereby deepening the study of knowledge evolution in the AI–KM field.

6 AI Declaration

In preparing this paper, the author, Hsuan-Hao Lo, used ChatGPT and Claude solely to assist with English language editing. As English is not the author's first language, these tools were used to improve grammar, refine wording, and enhance overall readability. The author reviewed and revised all AI-assisted outputs and takes full responsibility for the final content of the manuscript. All data were retrieved, cleaned, analysed, and interpreted by the author; no data and statistics presented in this paper were generated by AI tools.

Embedding ESG in Strategic Management Course: A System Dynamics Approach to Experiential Learning

MeiYi Winnie Song, Ju-We Chen
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

This study aims to explore how to effectively integrate Environmental, Social, and Governance (ESG) issues into the strategic management curriculum and propose an experiential learning framework based on system dynamics (SD). Traditional strategic management courses may make it difficult for students to understand the feedback structures, time delays, nonlinear effects, and multi-objective trade-offs involved in ESG decision-making when they rely mainly on prescriptive concepts, case studies, or static analytical tools. Based on the methodology of design-based research, this study introduces causal loop diagrams, stock-and-flow diagrams, and scenario simulation activities into the undergraduate Strategic Management course, allowing students to test ESG strategy options in a simulated environment and observe the dynamic relationship between short-term financial performance, long-term environmental risks, social legitimacy, and governance mechanisms. Research data include pre- and post-course questionnaires, student reflection reports, model-building outcomes, and strategic decision-making performance. The preliminary descriptive findings indicate that experiential learning supported by system dynamics may help improve students' ESG literacy, systems thinking capability, and strategic foresight. Theoretically, this study considers ESG competencies as a dynamic knowledge capability formed through knowledge interaction, model building, and reflective practices. In terms of methods, it demonstrates the feasibility of system dynamics as a tool for management education research and curriculum design. In practice, it provides management educators with a replicable and scalable ESG strategy curriculum design framework.

Keywords: ESG Strategy; System Dynamics; Experiential Learning; Strategic Management Course; Knowledge-Based Sustainability

Paper type: Academic Research Paper

1 Introduction

As Environmental, Social, and Governance (ESG) issues have become central to corporate strategic decision-making, stakeholder management, and long-term value creation, business education must move beyond treating sustainability as a subsidiary topic of ethics or corporate social responsibility. Prior research argues that sustainability and ESG should be integrated into business and management curricula so that students can understand the relationships among sustainability strategies, organizational governance, and business performance (Beamond et al., 2026; Martínez-Bravo et al., 2024). This need is particularly evident in strategic management courses, where ESG should be framed not merely as a compliance requirement but as a strategic capability for risk identification, stakeholder response, competitive advantage, and organizational resilience. However, current ESG instruction often relies on conceptual explanation, case discussion, or indicator-based analysis, offering limited support for understanding the dynamic complexity of ESG decision-making. Sustainability education emphasizes that higher education should cultivate systems thinking, cross-domain integration, critical reflection, and future-oriented capabilities rather than only transmit static knowledge (Rieckmann, 2012; Svanström et al., 2008). To address this gap, this study proposes a system dynamics (SD)-based experiential learning approach for integrating ESG into strategic management curricula. System dynamics is suitable for analyzing feedback loops, time delays, nonlinear effects, and long-term mechanisms in sustainability issues, while experiential learning and business simulation can enhance student engagement, reflection, and attitude change in sustainable decision-making (Adib, 2024; Faham et al., 2017). Accordingly, this study aims to construct an integrated "ESG–Strategic Management–System Dynamics–Experiential Learning" curriculum framework, examine how causal loop diagrams (CLDs) and stock-and-flow diagrams (SFDs) influence students' ESG literacy, systems thinking, and strategic foresight, and explain how ESG capability can be transformed from static knowledge into actionable strategic knowledge capability. Its contributions are theoretical, methodological, and practical, offering a replicable ESG strategy curriculum design model for management education.

2 Literature Review

2.1 ESG and strategic management education

The core of ESG education is to enable students to understand that corporate sustainability is not merely associated with corporate ethics or social responsibility, but is interconnected with strategic choices, governance mechanisms, and long-term value creation. When introducing ESG into higher education, institutions should cultivate students' cross-disciplinary judgment and sustainability-oriented decision-making capabilities in the face of sustainability challenges through curriculum integration, research innovation, community engagement, leadership governance, and assessment feedback (Alenezi & Alanazi, 2024). In the context of business and management education, sustainability courses should not be limited to a single topic but should help students understand how companies transform ESG factors into strategic capabilities and organizational knowledge assets (Del Gesso & Parravicini, 2025). This also echoes the positioning of this study to integrate ESG into strategic management courses.

2.2 Experiential learning and sustainability ability development

Experiential learning provides an important teaching foundation for ESG education. Kolb (1984) argues that learning comes from a cyclical process of concrete experience, reflective observation, abstract conceptualization, and active experimentation. When applied to ESG strategy courses, students not only read corporate cases but also personally test the consequences of different sustainability strategies through simulations, team discussions, and reflection reports. Adib (2024) pointed out that business simulations incorporating sustainable decision-making can influence students' learning outcomes, satisfaction, and sustainability attitudes, indicating that experiential design helps translate ESG knowledge into decision-making understanding.

2.3 System dynamics and systems thinking

System dynamics provides a methodological basis for dealing with the complexity of ESG strategies. ESG decisions often involve feedback loops, time delays, and nonlinear effects, such as short-term cost pressures that may discourage environmental investment, but long-term environmental performance can affect brand trust and governance legitimacy. Faham et al. (2017) indicate that system dynamics can support the development of sustainability competencies in higher education by revealing the long-term behavior of sustainable systems through reinforcing and balancing feedback loops. Svanström et al. (2008) also argue that sustainable development learning outcomes should include systematic or holistic thinking, cross-perspective integration, critical thinking, and the ability to change action.

2.4 ESG capabilities from a knowledge management perspective

From the perspective of knowledge and ability, ESG literacy is not just conceptual knowledge but a dynamic ability formed by students in situational judgment, model construction, strategic simulation, and reflective practice. Rieckmann (2012) pointed out that future-oriented higher education should cultivate systematic thinking, foresight, normative, strategic and cooperative skills; Wiek et al. (2011) also consider these competencies as a core competency framework for sustainable education. Therefore, this study positions ESG education as a process of "knowledge capability generation", enabling students to transform abstract sustainability concepts into analytical, simulated, and applicable strategic management skills through experiential learning supported by system dynamics.

Existing studies have mostly discussed ESG education, experiential learning, or system dynamics separately, but rarely integrate the three in strategic management curriculum design. Therefore, this study proposes an integrated architecture of "ESG-Strategic Management-System Dynamics-Experiential Learning" (Figure 1).

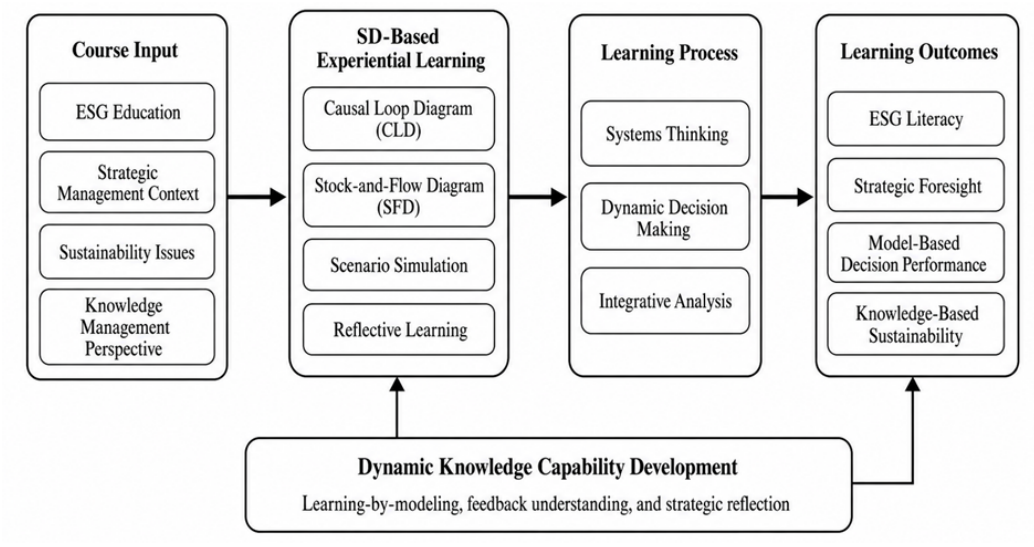

Figure 1. Research Framework of ESG-Embedded Strategic Management Learning

3 Research Methodology

This study adopts Design-Based Research (DBR) as its methodological basis. DBR connects educational theory and teaching practice through theory-informed curriculum design, teaching intervention, data collection, and iterative refinement in real educational settings. It is particularly suitable for examining innovative curricula, technology-supported learning, and complex competency development because it focuses not only on learning outcomes but also on how instructional design operates in authentic contexts (The Design-Based Research Collective, 2003; Wang & Hannafin, 2005; Anderson & Shattuck, 2012). Accordingly, this study applies DBR to examine how integrating ESG into a strategic management course through system dynamics-based experiential learning can enhance students' ESG literacy, systems thinking capability, and strategic foresight.

The research field is an undergraduate Strategic Management course. The curriculum transforms ESG issues from conceptual content into dynamic decision-making scenarios. The course intervention consists of four stages. First, students are introduced to ESG and strategic management concepts, including how ESG issues influence competitive advantage, stakeholder trust, and long-term value creation. Second, students receive system dynamics training, learning variables, causal relationships, reinforcing loops, balancing loops, time delays, system boundaries, causal loop diagrams, and stock-and-flow diagrams. Third, students construct ESG strategy models based on corporate or industry scenarios, incorporating variables such as environmental investment, carbon emissions, operating costs, brand trust, social legitimacy, governance transparency, and financial performance. Fourth, students conduct scenario simulation, decision-making, and reflection by testing alternative ESG strategies, observing long-term outcomes, and explaining decision logic, unintended consequences, and governance implications. This design aligns with the use of system dynamics for complex system modeling, policy simulation, and strategic learning (Sterman, 2000).

3.1 Data Collection

Data collection adopted a mixed-methods design to enhance the completeness and credibility of the research findings. The study was implemented in a 16-week Strategic Management course for third-year students in the Department of Business Administration, with 42 students participating. Quantitative data were collected through pre- and post-course questionnaires designed by the researchers based on relevant literature. The questionnaire measured changes in students' ESG literacy, systems thinking capability, strategic foresight, and model-based decision-making capability. Qualitative data included student reflection reports, group system dynamics model artifacts, class discussion records, and teacher observation notes. The student model artifacts were evaluated independently by two researchers using the evaluation rubric. Any scoring differences were discussed and resolved through consensus to improve the reliability of the assessment process. Faham et al. (2017) indicated that system dynamics research in sustainability education can integrate multiple data sources, including literature, questionnaires, interviews, and observations, to construct and validate sustainability-related learning models. This supports the use of mixed methods for examining complex learning processes in sustainability and ESG education.

Table 1: Mixed-method Data Sources and Descriptions

Sources	Description
Pre-course/post-course questionnaires	Evaluate changes in ESG literacy, systems thinking ability, and strategic foresight ability
Student model artifacts	Analyze the completeness and logic of students' construction of CLDs / SFDs
Simulation decision records	Examine whether students can balance short-term and long-term ESG strategy outcomes
Reflection reports	Analyze students' understanding of unintended consequences, stakeholders, and governance logic
Teacher observation records	Supplement student interaction, discussion, and learning difficulties

3.2 System dynamics model architecture

The ESG strategy learning model designed in this study includes the following variables (Table 2):

Table 2: Core Variables of ESG System Dynamics Learning Model

Variable Type	Variables
ESG input variables	Environmental Investment, Social Engagement, Governance Mechanisms
Strategy process variables	Stakeholder Trust, Operational Efficiency, ESG Integration Capability
Outcome variables	Financial Performance, Environmental Impact, Social Legitimacy, Strategic Resilience
Learning variables	ESG Literacy, Systems Thinking Capability, Strategic Foresight

The causal loop diagram (Figure 2) includes three reinforcing loops and two balancing loops: R1: ESG knowledge learning - strategy integration cycle, R2: stakeholder trust - social legitimacy cycle, R3: simulation reflection - strategic foresight cycle, B1: short-term cost pressure-ESG investment constraint cycle and B2: cognitive load - learning effectiveness regulation loop.

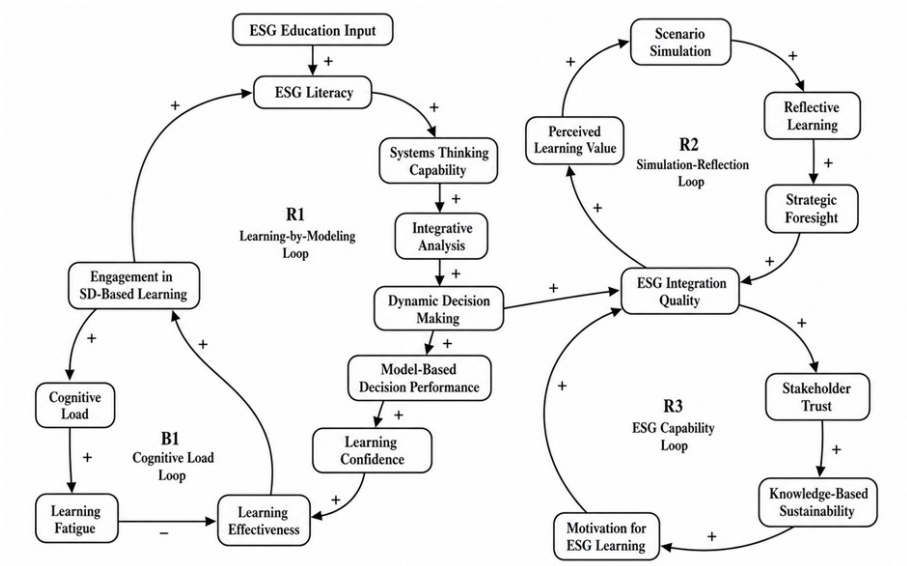

Figure 2. Causal Loop Diagram of ESG Strategic Learning System

The stock-and-flow diagram (Figure 3) shows that the main stocks are ESG Literacy, Systems Thinking Capability, Strategic Foresight, and Decision Performance.

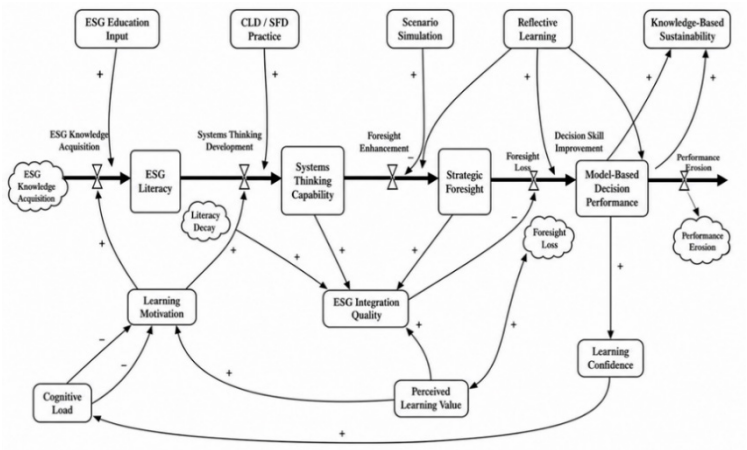

Figure 3. Stock-and-Flow Model of ESG Competence Development

3.3 Data analysis methods

In terms of analysis methods, quantitative data were first analyzed using descriptive statistics to compare pre- and post-course learning outcomes. Paired-sample tests, or the Wilcoxon signed-rank test if the data were not normally distributed, will be used in subsequent inferential analysis. Qualitative data were analyzed using thematic analysis following Braun and Clarke's (2006) procedure. Student-developed model artifacts were evaluated using scoring criteria covering variable completeness, causal logic, feedback loops, time delays, and strategic explanatory capability. This consensus-based procedure was used to enhance interpretive reliability in evaluating student-developed system dynamics models.

3.4 Summary

This research method emphasizes the cyclical process of "design–implementation–evaluation–revision" and examines how system dynamics supports ESG strategy learning through curriculum intervention and multiple data sources. This approach not only responds to the needs of sustainable competency development in management education but also helps establish a curriculum model for ESG strategy management that can be replicated, adjusted, and sustainably improved.

4 Research Results

4.1 Improvement of ESG literacy and strengthening of systems thinking capability

Based on the preliminary analysis of curriculum implementation data, the results of this study can be summarized into three aspects: learning effectiveness, model outcomes, and reflective analysis. First, in terms of learning effectiveness, students' understanding of ESG appeared to shift from "corporate social responsibility (CSR) or compliance requirements" to "strategic decision-making and long-term value creation capabilities" after the course. This result is consistent with the claim that Education for Sustainable Development (ESD) emphasizes systems thinking, cross-perspective integration, critical thinking, and change action (Svanström et al., 2008). Before class, students often use single concepts such as environmental protection, social responsibility, or governance disclosure to understand ESG. After the course, students could further explain the relationship between ESG and competitive advantage, stakeholder trust, risk governance, and financial performance. This change also echoes the emphasis on systematic, strategic, and integrated learning outcomes in sustainability assessment research (Redman et al., 2021).

4.2 Model construction results

Table 3 lists the evaluation criteria used to evaluate the system dynamics model developed by students. In addition to technical modeling quality, this evaluation criterion also evaluates ESG integration, strategy interpretation, scenario simulation, and reflective learning.

Table 3. Evaluation Rubric for Student System Dynamics Models

Construct	Beginning	Developing	Proficient	Advanced
Variable identification	Variables are vague, incomplete, or only loosely linked to ESG and strategic management.	Some ESG and strategic variables are identified, but important variables are still missing.	Key environmental, social, governance, and strategic performance variables are clearly identified.	The variables are complete, theoretically based, and highly linked to ESG strategies, stakeholder governance, and long-term value creation.
Causal logic	Causal links are unclear, inconsistent, or lack reasonable explanations.	Basic causal relationships are presented, but some links lack explanation or logical consistency.	Causal relationships are generally clear, consistent, and reasonably explained.	Causal logic is rigorous and coherent, supported by ESG, strategic management, or system dynamics perspectives.
Feedback loop structure	No feedback loops are created, or the loops are incorrectly constructed.	Some reinforcing loops or balancing loops are included, but the loop logic is not yet complete.	Reinforcing and balancing loops are correctly identified and labeled.	Feedback loops can clearly explain the dynamics of ESG, including the relationship between learning, trust, cost pressure, governance, and strategic foresight.
Stock-and-flow representation	Confusing stocks and flows, or failing to correctly distinguish between the two.	Basic stocks and flows are included, but the relationship is not yet complete.	Stocks, inflows, outflows, and auxiliary variables are appropriately presented.	Models can clearly represent the dynamic process of capability accumulation, learning decline, feedback effects, and changes over time.
Time delay and dynamic behavior	Time delay and long-term effects are not considered.	Some delay effects are mentioned, but not yet clearly integrated into the model.	Time delays and long-term outcomes are presented in key relationships.	Models can effectively explain short-term and long-term trade-offs, unintended consequences, and ESG learning trajectories.
ESG integration	ESG is only considered a general concept or a standalone issue.	ESG factors are included, but are weakly linked to strategic management.	ESG dimensions are integrated with strategic management decisions and learning outcomes.	ESG is fully embedded as a dynamic strategy system that connects governance, stakeholder trust, sustainability performance, and knowledge capabilities.
Strategic interpretation ability	The model provides only limited strategic implications.	Some strategic implications are presented, but the analysis remains descriptive.	Models can support sound ESG strategic decision interpretation.	Models generate deep strategic insights across resource allocation, stakeholder management, governance mechanisms, and long-term value creation.
Scenario simulation quality	Scenario assumptions are absent or unclear.	Scenario contexts are included, but their scope is limited and weakly connected to the model.	Scenario design is logical and can be linked to model variables.	Scenario simulations can effectively compare different ESG strategies and account for differences in long-term outcomes.
Reflective learning	Reflection is superficial or lacks relevance to model results.	Learning experiences are described, but analytical insights remain limited.	How model results changed students' understanding of ESG strategies is explained.	Reflection demonstrates deep learning, critical thinking, unintended consequences recognition, and strategic hypothesis modification skills.
Overall model consistency	The model is fragmented and difficult to understand or interpret.	The model has a basic structure, but the overall consistency is insufficient.	The model is consistent, readable, and aligned with the curriculum objectives.	The model is theoretically grounded, visually clear, analytically practical, and suitable for supporting ESG strategic decision-making.

Note. The rubric may be scored on a 1–4 scale: 1 = Beginning, 2 = Developing, 3 = Proficient, and 4 = Advanced. Total scores can be used to evaluate students' system dynamics model quality, while individual dimensions can help diagnose specific learning strengths and weaknesses.

In terms of model results, students can transform ESG strategic issues into a dynamic system with a feedback structure through causal loop diagrams and stock-and-flow diagrams. Most teams can identify the reinforcing loop of "ESG knowledge learning-strategic integration ability-decision-making quality-learning confidence" and the balancing loop of “short-term cost pressure–ESG investment willingness–sustainable performance improvement.” This indicates that system dynamics tools helped students understand time delays, nonlinear variations, and unintended consequences in sustainability issues. Faham et al. (2017) pointed out that system dynamics can help higher education identify reinforcing and balancing mechanisms in sustainability development and understand long-term behavior changes through simulation. The student-developed models in this study show similar characteristics.

4.3 Strategic Decision-Making and Reflective Performance

Table 4 summarizes the comparison of students' learning outcomes before and after taking the ESG-embedded strategic management course. The preliminary descriptive results indicate positive changes across all learning dimensions. Among them, the improvement in model-based decision-making ability is the largest descriptive improvement, indicating that the use of causal loop diagrams, stock-and-flow models, and scenario simulations helps students translate ESG knowledge into actionable strategic analysis. Additionally, improved systems thinking capability and strategic foresight indicate that students are better able to identify feedback relationships, time delays, and long-term impacts embedded in ESG-related strategic decisions. Overall, the preliminary findings suggest the potential effectiveness of system dynamics-based experiential learning in enhancing ESG literacy, integrative analytical capability, and knowledge-based sustainability competence.

Table 4. Pre- and Post-Course Learning Outcome Comparison

Dimension	Measurement focus	Pre-course mean	Post-course mean	Change	Interpretation of the results
ESG literacy	Understanding of ESG concepts, strategic relevance, and sustainability implications	3.12	4.21	+1.09	Students can better understand that ESG is a strategic management issue, not just a compliance or corporate social responsibility issue.
Systems thinking capability	The ability to identify feedback loops, time delays, causal relationships, and systemic consequences	2.95	4.08	+1.13	When students analyze ESG issues, they are better equipped to grasp their dynamics and interconnectedness.
Strategic foresight	The ability to predict long-term consequences, unintended outcomes, and stakeholder impacts	2.88	4.05	+1.17	Students are better able to evaluate short-term strategic decisions from a long-term sustainability perspective.
Model-based decision performance	The ability to use causal loop diagrams and stock-and-flow diagrams to support strategic decision-making	2.76	3.98	+1.22	Students improved in applying system dynamics models to analyze ESG strategy choices.
Integrative analytical capability	The ability to connect financial, environmental, social, and governance factors	3.01	4.14	+1.13	Students can more effectively integrate ESG aspects into strategic analysis.
Reflective learning ability	The ability to reflect on simulation results and revise strategic assumptions	3.18	4.26	+1.08	Students are more aware of the feedback effects, strategic trade-offs, and governance logic in ESG decision-making.
Knowledge-based sustainability competence	The ability to translate ESG knowledge into actionable strategic knowledge	2.91	4.10	+1.19	Through model construction and reflection, students gradually form ESG competence as a dynamic knowledge capability.

Note. Measurement scale: 1 = strongly disagree; 5 = strongly agree. These values represent preliminary descriptive results; inferential statistical testing should be conducted in subsequent analysis.

In terms of reflective analysis, the student reflection reports show that experiential learning prompts students to shift from passively accepting ESG concepts to actively examining the long-term consequences of

strategic choices. Some students pointed out that if companies only pursue short-term profits, they may reduce environmental investment and governance improvements, resulting in reputational risks and a decline in stakeholder trust. Conversely, students also recognized that stronger governance transparency and resource allocation mechanisms could support long-term strategic resilience. This is consistent with experiential learning and business simulation research. Adib (2024) indicates that business simulations incorporating sustainable decision-making can affect students' learning outcomes, satisfaction, and sustainable attitudes, and a recent review of sustainable experiential learning also pointed out that such teaching can promote the formation of students' knowledge, abilities, values, and action (Sundman et al., 2025).

5 Discussion

5.1 Integration of Preliminary Findings

Overall, three preliminary findings can be identified. First, system dynamics appears to help transform ESG from abstract concepts into visual and actionable strategic issues. Second, experiential simulations appear to support students in understanding time delays, feedback effects, and unintended consequences in ESG decision-making. Third, model building and reflective activities appear to facilitate the transformation of ESG knowledge from conceptual understanding into strategic judgment capability. These findings suggest that system dynamics-based experiential learning may provide a useful pedagogical approach for integrating ESG into strategic management education.

Taken together, these findings indicate that system dynamics-supported experiential learning helps reposition ESG as a decision-making system that can be modeled, simulated, and reflected upon in strategic management courses. Students gradually develop ESG literacy, systems thinking capability, and strategic foresight capability during the learning process, and can transform sustainability concepts into knowledge and capabilities with governance logic and strategic implications. These findings are also in line with the original design of this study: through CLDs, SFDs, and simulation-based learning modules, students can understand the dynamic relationships among financial performance, environmental impact, social legitimacy, and governance mechanisms.

5.2 Implications

This study offers three implications. Theoretically, it repositions ESG education from “knowledge transfer” to “knowledge capability development.” ESG literacy is not limited to understanding ESG concepts; it also involves the ability to identify dynamic relationships among stakeholder interests, long-term risks, governance responsibilities, and value creation in strategic contexts. This aligns with sustainability education research, which argues that higher education should cultivate systems thinking, foresight, normative judgment, strategic action, and collaboration competencies (Wiek et al., 2011). Thus, ESG competence is conceptualized as a dynamic knowledge capability developed through curriculum design, model building, and reflective practice.

Methodologically, the study demonstrates that system dynamics is useful for addressing complex sustainability issues in management education. Unlike traditional ESG teaching based mainly on case reading or indicator analysis, causal loop diagrams and stock-and-flow diagrams help students visualize feedback loops, time delays, and nonlinear changes. This supports prior research showing that system dynamics can develop sustainability competencies and reveal long-term system behavior through reinforcing and balancing loops (Faham et al., 2017).

Practically, the study provides a replicable ESG strategy curriculum model. Through Design-Based Research, instructors can apply a “design–implementation–evaluation–revision” cycle to connect theory, instructional design, and classroom practice (The Design-Based Research Collective, 2003). This study further shows how sustainability-related knowledge can be structured, simulated, and transformed into actionable strategic knowledge through system dynamics-based learning.

6 Conclusion

This study proposes a curriculum design framework for integrating ESG issues into strategic management courses through experiential learning and system dynamics. The findings suggest that ESG education should move beyond concept delivery, case reading, or indicator-based analysis, because such approaches may be insufficient for cultivating the systems thinking and decision-making capabilities required to address complex sustainability challenges. By using causal loop diagrams, stock-and-flow diagrams, and scenario simulations, students can transform ESG issues into dynamic strategic systems involving feedback relationships, time delays,

trade-offs, and long-term consequences. This approach echoes sustainability education research that emphasizes systems thinking, strategic competence, and integrated problem-solving (Wiek et al., 2011), and supports the view that system dynamics can cultivate sustainability competencies in higher education (Faham et al., 2017).

The study makes three main contributions. Theoretically, it conceptualizes ESG literacy as a dynamic knowledge capability rather than static knowledge content. Through model construction, simulation-based decision-making, and reflective practice, students gradually develop sustainability-oriented judgment that can be applied to strategic contexts. Methodologically, the study demonstrates that design-based research is a useful approach for management education innovation, allowing curriculum design to respond to both theoretical development and practical teaching needs through a "design–implementation–evaluation–revision" cycle (Anderson & Shattuck, 2012). Practically, it provides management educators with a replicable ESG strategy curriculum model, positioning ESG as a core component of strategic management rather than a supplementary topic.

This study also has limitations. First, the research was conducted in a single course, and the sample size limits the generalizability of the findings. Second, learning outcomes were mainly assessed through pre- and post-course questionnaires, model artifacts, and reflection reports, making it difficult to evaluate students' long-term application of ESG capabilities in real organizational settings. Third, students' varying familiarity with system dynamics may have influenced model quality and learning performance. Future research may extend this framework to different institutions, course levels, and cross-national teaching contexts, and adopt longitudinal designs to examine the sustained development of ESG strategic capabilities. Further studies may also incorporate artificial intelligence (AI)-assisted modeling, learning analytics, and industry-based projects to explore how intelligent knowledge tools support sustainability-oriented management education.

7 Ethics Statement

This study involved course-based educational data. Students were informed of the research purpose, participation was voluntary, and non-participation did not affect course grades. All learning data were anonymized before analysis.

8 Artificial Intelligence Declaration

A System Dynamics Analysis of Career Agency Formation among Gen Z Interns: Unpacking the Contextual Mechanisms of Overseas Work-Integrated Learning

MeiYi Winnie Song , Kuan-Lun Chen
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

This study explores how career agency is formed in multiple relationship contexts when Generation Z (Gen Z) students participate in overseas internships. In the face of artificial intelligence (AI)-driven digital transformation and global labor market uncertainty, Generation Z's career development has shifted from a traditional linear employment path to a non-linear journey that emphasizes independent exploration, cross-cultural adaptation, and proactive opportunity building. Based on Work-Integrated Learning (WIL) and career agency literature, this study adopts a System Dynamics (SD) approach to construct causal loop diagrams (CLDs) and a stock-and-flow model to analyze the feedback relationships among university support, corporate mentoring, peer networks, cross-cultural pressure, career self-management, social capital, and employability capital. The proposed model suggests that career agency is not a static psychological trait, but a dynamic capability accumulated through reinforcing and balancing loops across pre-internship preparation, internship interaction, and post-internship transition. Scenario simulations indicate that program designs that integrate university support, corporate mentoring, and peer networks can best promote the simultaneous growth of career agency, social capital, and employability capital. This study contributes by connecting career development theory, WIL research, and System Dynamics (SD), while providing managerial implications for higher education institutions designing overseas internship and youth career development programs.

Keywords: Generation Z, overseas internships, career agency, Work-Integrated Learning, System Dynamics

Paper type: Academic Research Paper

1 Introduction

In the context of artificial intelligence (AI)-driven digital transformation and high uncertainty in the global labor market, the career development of Generation Z (Gen Z) college students has gradually shifted from the traditional linear employment path to a non-linear journey that emphasizes independent exploration, cross-domain mobility, and active construction opportunities. Schroth (2019) suggested that Generation Z has shown different work values and behavior patterns after entering the workplace, and organizations and educational institutions must re-understand their career expectations. Work-Integrated Learning (WIL) is regarded as an important mechanism to enhance graduates' employability, especially overseas internships can enhance students' career readiness through cross-cultural work experience, industry contact, and social networking (Jackson & Dean, 2023).

However, existing overseas internship research mostly focuses on outcome variables such as employability, cross-cultural ability, or career self-efficacy, and rarely explores how these abilities are gradually generated in the context of pre-internship preparation, internship interaction, and post-internship transfer. International students often face challenges such as language, culture, workplace norms, and insufficient support resources when participating in WIL (Vu et al., 2022), indicating that the effectiveness of overseas internships does not depend solely on individual efforts but is influenced by factors such as university systems, corporate mentoring, peer support, and cross-cultural adaptation. On the other hand, career agency and career self-management skills have been regarded as key capabilities in the face of labor market uncertainty. Relevant studies have also suggested that career competencies can be translated into career success and movement capital through job crafting, career engagement, and educational support (Akkermans & Tims, 2017; Petruzziello et al., 2022).

Based on this, this study takes the "Generation Z Overseas Internship Relationship Context" as the analysis object, adopts a System Dynamics (SD) perspective, and regards career agency as a dynamic ability accumulated through career self-management, social capital, employability capital, and institutional support in the multi-stage overseas internship process, rather than a single static psychological trait. This study therefore applies causal loop diagrams (CLDs) and stock-and-flow diagrams (SFDs) to analyze the dynamic formation of career agency in overseas WIL contexts. The research questions are as follows: (1) What relational factors affect the formation of career agency among Gen Z students during overseas internships? (2) What causal feedback relationships exist among university support, corporate mentoring, social capital, and career self-management?

(3) How do different internship support designs influence students' long-term employability and career resilience through SD mechanisms? The purpose of this study is to connect career development theory, WIL research, and System Dynamics (SD), to make up for the shortcomings of the existing literature on linear causal analysis, and to provide a dynamic decision-making basis for the design of overseas internship programs (Richardson, 2020; Patton & McMahon, 2006).

2 Literature review

2.1 Generation Z's career characteristics and work values

Growing up in a digital, platform economy, and highly uncertain labor market, Generation Z's career development has shifted from within traditional organizations to independent exploration, flexible mobility, and personalized career construction. Schroth (2019) suggested that after entering the workplace, Generation Z shows the characteristics of valuing feedback, development opportunities, work meaning, and psychological safety, and companies and higher education institutions need to re-understand their work values. Drewery et al. (2023) further found that Gen Z students' WIL experiences affect their emphasis on employer attributes and job value, indicating that internships are not just skills training but an important process in the formation of career cognition and career choice preferences.

2.2 Overseas internship and WIL

WIL is widely regarded as an important educational design to enhance the employability of college students, especially internships, workplace practice, and industry-academia cooperation can help students transform academic knowledge into workplace abilities. Jackson and Dean (2023) suggested that different types of WIL can contribute to graduate employability, but their effectiveness will be affected by program design, student participation, and the quality of workplace support. For overseas internships, WIL is more cross-cultural learning, and students must face language, life adaptation, organizational norms, and professional task challenges at the same time. A literature review by Vu et al. (2022) suggested that international students often encounter challenges such as cultural barriers, difficulties in workplace integration, and insufficient institutional support in WIL, indicating that the effectiveness of overseas internships cannot be measured solely by whether they have internship opportunities, but must be integrated into the relationship between schools, companies, peers, and cross-cultural environments. Overseas internships, as an international form of WIL, serve three functions: (1) a learning function, through which classroom knowledge is translated into practical workplace skills; (2) a career exploration function, through which students understand industries, roles, and person–career fit; and (3) a social capital function, through which employment opportunities and career resources are developed through supervisors, peers, and cross-cultural networks.

2.3 Career Agency and Career Self-Management

Career agency can be understood as an individual's ability to actively plan, adjust, and shape their career path. Akkermans and Tims (2017) suggested that career competencies can influence career success through job crafting, indicating that individuals do not passively accept the career environment but can create development opportunities through actions. Career ownership has been identified as an important factor shaping students' perceived employability (Donald et al., 2019). Petruzziello et al. (2022) also suggested that students' career investment and movement capital not only depend on personal initiative but are also influenced by the support of teaching staff. Wilhelm et al. (2024) regard career self-management behaviors as the foundation of multifaceted employability, including information search, goal setting, network building, and career monitoring. It can be seen that career agency is not a fixed personality trait, but a dynamic ability that gradually accumulates through educational support, workplace interactions, and personal reflection (Pham et al., 2023). The core concept of career agency is summarized in Table 1 of the role of this study.

Table 1. Core Concepts of Career Agency

Concept	Definition	Role in This Study
Career agency	The ability to proactively plan and shape your career	Core stock/outcome variables
Career self-management	Search for information, set goals, take action	Key process in career agency formation
Social capital	Resources formed by mentors, supervisors, peers, and cross-cultural networks	Affect employability and career confidence

Concept	Definition	Role in This Study
Employability capital	Skills, experience, resume signals, and workplace adaptability	The cumulative basis of career agency
Cross-cultural adaptation	The ability to adapt to differences in language, culture, and work norms	may promote or inhibit the effectiveness of the internship

2.4 System Dynamics (SD) and Career Development Research

A systems perspective helps compensate for the limitations of existing career and WIL research, which often relies on linear causal analysis. Patton and McMahon (2006) proposed a systematic theoretical framework for career development, emphasizing the interaction between individual, social, and environmental factors. Sterman (2002) suggested that System Dynamics (SD) is suitable for analyzing complex social systems with feedback, delay, and nonlinear characteristics. Pavlov et al. (2025) also explain that System Dynamics (SD) can understand the complex causal relationships in social and economic systems through feedback thinking. Based on this, this study treats Generation Z's overseas internships as a dynamic system, and analyzes how university support, corporate mentoring, peer networks, cross-cultural pressure, career self-management, social capital, and employability capital jointly affect the formation of career agency through causal loop diagrams and stock-and-flow models. The core idea of this study is to analyze the formation mechanism of Gen Z overseas WIL and career agency using the SD method.

3 Research methodology

3.1 Study design

This study uses System Dynamics (SD) as the main research method to analyze how career agency is gradually formed in multiple relationship contexts during the overseas internship process of Generation Z. SD is suitable for dealing with social systems with feedback, delay, cumulative, and nonlinear characteristics; Forrester (1994) suggested that System Dynamics (SD) can be used to understand and improve complex system structures, and Sterman (2000, 2002) also emphasized that model construction should combine problem definition, dynamic hypotheses, model formulation, testing, and policy simulation. Therefore, this study does not regard overseas internship as a single educational activity, but as a dynamic development system of "pre-internship preparation-internship interaction-post-internship transfer". The structure of this study design is summarized in Figure 1.

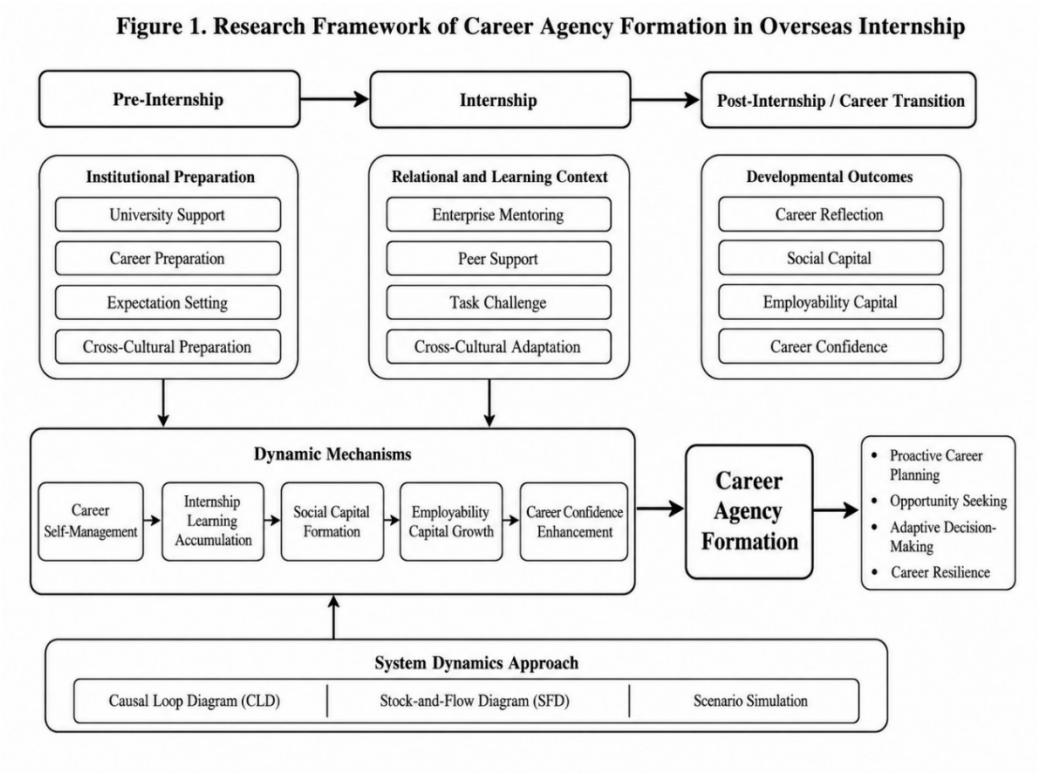

Figure 1. Research Framework of Career Agency Formation in Overseas Internship

3.2 System boundaries and analysis stages

In terms of modeling procedures, this study first extracts key variables based on WIL, career agency, and career self-management literature, and then uses a causal loop diagram (CLD) to present the positive and negative relationships between variables, and finally converts them into stock-and-flow diagrams (SFDs) to simulate the impact of different overseas internship designs on career agency formation. This study is set up to analyze the cumulative relationship between career agency, social capital and employability capital using CLDs and SFDs, and to identify leverage points for scenario simulation identification schemes. This study sets the system boundary into three phases (Table 2).

Table 2: System boundary stages

stage	Time frame	Main mechanism
Pre-internship stage	before and after application, training, and matchmaking	Career expectations, university support, language and cultural preparation
Internship stage	During overseas work and life	Corporate mentoring, task challenges, cross-cultural adaptation, peer support
Post-internship stage	Returning to the home country, employment, or entering a career program	Career reflection, resume transformation, employability accumulation, career decision-making

3.3 Variable settings

The core stock variables of this study include three items: first, career agency stock, which refers to students' cumulative ability to actively set career goals, seek resources, and adjust career paths; second, employability capital stock, including professional skills, cross-cultural abilities, work experience and resume signals; Third, social capital stock refers to the relational resources formed by university faculty, corporate mentoring, peers, and overseas workplace networks. The main flow variables include career self-management behavior, internship learning accumulation, social network formation, and career reflection. The auxiliary variables include university support quality, corporate mentor feedback, task challenge level, cross-cultural pressure, peer support, and career confidence (Table 3). This variable design echoes the view that WIL can improve employability, but its effect is affected by the type of internship, the quality of participation, and the support conditions. At the same time, career self-management behavior is also regarded as an important mechanism for maintaining and enhancing employability (Lasrado et al., 2024; Wilhelm et al., 2024).

Table 3: Core variables

Type	Variable name	Description
Stock variables	Career agency	Students' ability to actively shape career directions and actions
Stock variables	Employability Capital	Work skills, workplace experience, cross-cultural competencies, and resume signals
Stock variables	Social capital	Mentors, supervisors, peers, and workplace networking resources
Flow variables	Career self-management behavior	Goal setting, information search, career planning, and proactive action
Flow variables	Internship learning accumulation	task learning, problem solving, reflection and ability transformation
Auxiliary variables	University support quality	Pre-class training, matchmaking, counseling and crisis management
Auxiliary variables	Corporate guidance quality	Supervisor feedback, task design, and workplace support
Auxiliary variables	Cross-cultural pressure	Stress caused by differences in language, life, culture and work norms
Auxiliary variables	Career confidence	subjective beliefs about future career choices and employability

3.4 Modelling program

This study develops a literature-based exploratory SD model. Literature data are used to establish the initial variables and causal relationships. Future empirical data, including student surveys, interviews, internship reflection records, administrative data, and expert review, will be used to calibrate and validate the model.

The modelling process is as follows: 1. Key variables affecting career agency by literature extraction. 2. Establish positive and negative causal relationships between variables. 3. Draw a causal loop diagram to

distinguish between reinforcement and balancing loops. 4. Convert core cumulative variables into stock-and-flow models. 5. Set baseline scenarios and policy scenarios. and 6. Compare the impact of different overseas internship designs on career agency formation.

Scenario setting

In terms of scenario simulation, this study sets four scenarios (Table 4): baseline scenario, enhanced university support scenario, enhanced corporate mentor scenario, and integrated support scenario. The simulation period covers the transition stages before, during, and after the internship, and compares the changing trends of career agency, employability capital, and social capital in different scenarios. The planned model validation will include unit consistency testing, extreme-condition testing, behavioral reasonableness checks, and expert review to ensure that the model can reflect the main dynamic mechanisms of Generation Z's overseas internship career development.

Table 4: Scenario Setup and Expectations

Situation	Description	Expected observation
Baseline scenario	General overseas internship program	Career agency naturally accumulates, but growth is limited
Enhanced university support scenario	Increase pre-internship training and in-internship counseling	Reduce cross-cultural pressure and improve learning transformation
Enhanced corporate mentoring scenario	Improve the quality of supervisor feedback and task design	Improve job fulfillment and career confidence
Integrated support scenario	University support, corporate mentoring, and peer networks are simultaneously improved	Generate the strongest cumulative effect on career agency

4 Research results

4.1 Causal loop analysis results

Based on the System Dynamics (SD) modeling process, this study regards Generation Z's overseas internship as a dynamic system composed of "pre-internship preparation, internship interaction, and post-internship transfer". The proposed model suggests that career agency (Akkermans & Tims, 2017; Petruzziello et al., 2022; Pham et al., 2023) is not a single psychological trait, but a dynamic ability that gradually develops through feedback, accumulation, and delay effects between university support, corporate mentoring, peer networks, cross-cultural adaptation, and career self-management behaviors.

In terms of causal loop analysis (Figure 2), this study summarizes three reinforcing loops and two balancing loops. R1 is the “Career Self-Management–Career Agency” reinforcing loop: when students actively set career goals, search for information, and seek feedback, it will enhance their career confidence and self-efficacy, further promoting subsequent career actions. Akkermans and Tims (2017) suggested that career competence can be linked to subjective career success through job crafting behavior, supporting this study to consider active career action as a career agency accumulation mechanism. R2 is the "social capital-employability capital" reinforcing loop: corporate mentoring, peers, and overseas workplace networks can provide job information, emotional support, and employment opportunities, enabling students to accumulate convertible employability capital. R3 is the “Internship Learning–Career Confidence” reinforcing loop: challenging work tasks with appropriate feedback will improve problem-solving skills and career confidence, thereby prompting students to accept higher-level tasks. Jackson and Dean (2023) suggested that different types of WIL can enhance graduates' employability, but their effectiveness is closely related to participation quality and program design, supporting the emphasis on differences in internship quality in this study.

Secondly, the model also presents two balancing loops. B1 is the "cross-cultural pressure-learning inhibition" balancing loop: language barriers, life adaptation, and workplace cultural differences can increase psychological load, reduce active interaction and learning investment, and slow down the growth of career agency. A literature review by Vu et al. (2022) suggested that international students often face cultural, institutional, and workplace integration challenges in WIL, which is consistent with the stress inhibition mechanism of this model. B2 is the "Support Resources-Stress Regulation" balancing loop: university counseling, corporate mentoring, and peer support can reduce cross-cultural pressure and maintain students' internship participation and learning momentum.

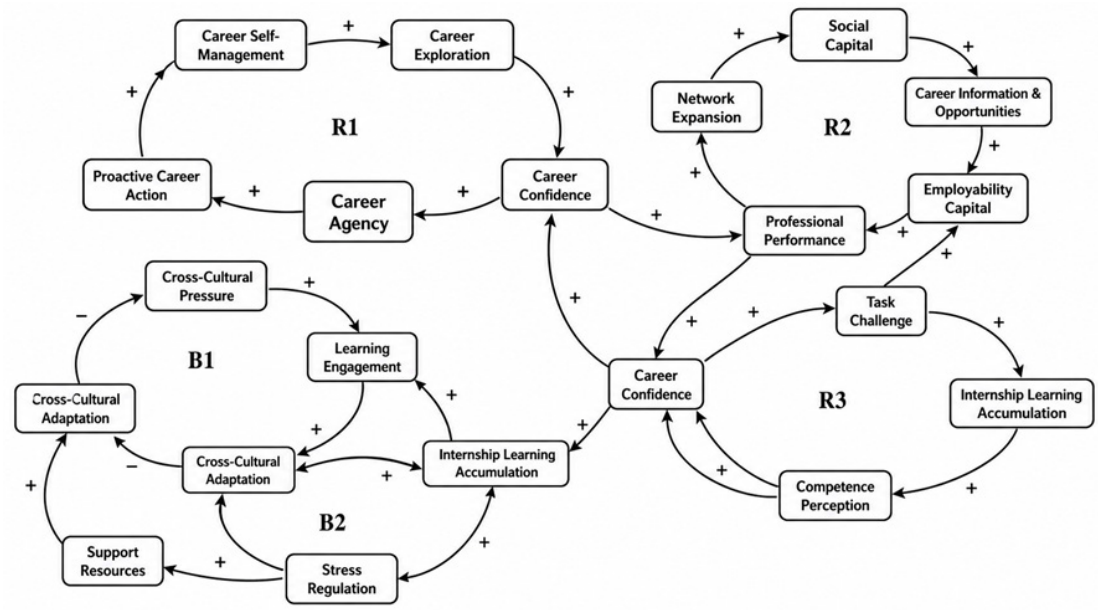

Figure 2.Causal Loop Diagram of Gen Z Overseas Internship and Career Agency Formation

4.2 Stock-and-flow model

In terms of the stock-and-flow model (Figure 3), this study sets three core stocks: career agency stock, employability capital stock, and social capital stock. The inflows into career agency include career self-management, career reflection, and proactive action experience. Outflows include career confusion, frustration, and low-quality feedback. The inflow of employability capital includes professional skills, cross-cultural competencies and internship experience; The inflow of social capital comes from mentor interaction, peer connections, and workplace networks. Luna-Reyes and Andersen (2003) suggested that qualitative data can support SD model construction and causal structure identification, so this study can further calibrate the above variable relationships through interviews and internship reflection records.

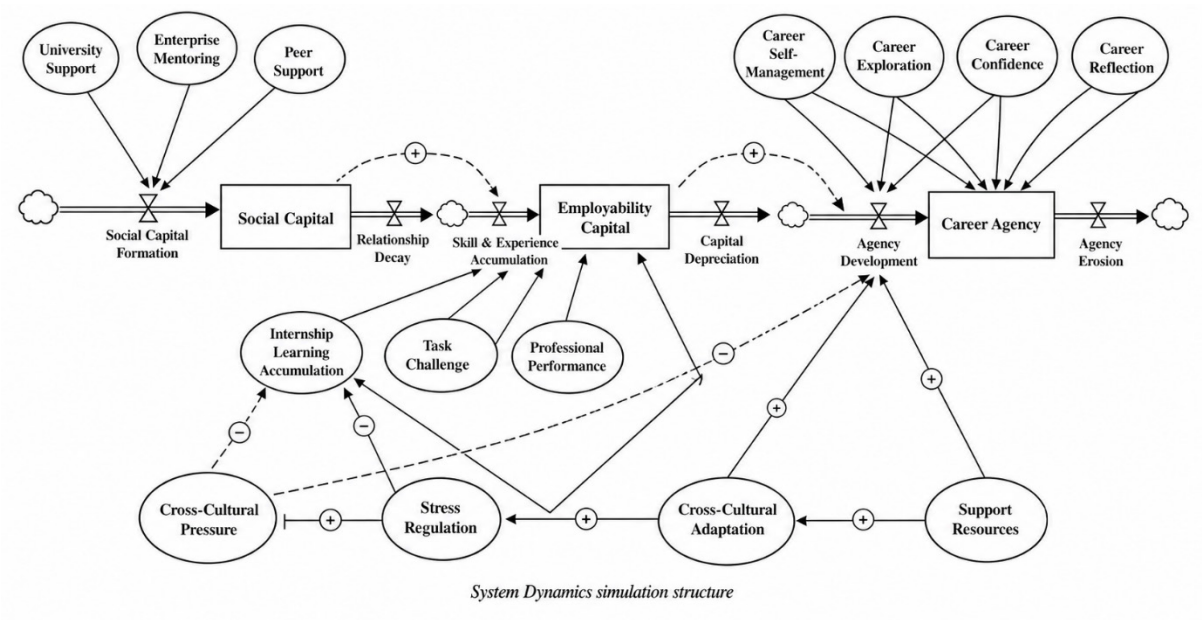

Figure 3. Stock-and-Flow Model of Career Agency Formation

4.3 Scenario simulation results

Based on the exploratory model structure, the scenario simulation (Figure 4) illustrates that under the baseline scenario, students' career agency shows a slow accumulation; Strengthening university support scenarios can reduce pre-internship uncertainty and cross-cultural pressure; strengthening the corporate

mentor scenario can improve task feedback and career confidence; In the context of integrated support, university support, corporate mentoring, and peer networks form complementary feedback, resulting in simultaneous growth of career agency, social capital, and employability capital. In terms of management implications, university overseas internship programs should not only focus on the number of dispatches, but should establish a continuous support system for pre-internship training, mentor feedback during internships, and career transformation after internships, so that overseas internships can be transformed from short-term international experience into long-term career agency development mechanisms. The scenario values are treated as illustrative assumptions and require future empirical calibration.

Table 4: Scenario simulation results

Situation	Career agency changes	Main explanation
Baseline scenario	Rise slowly	Students can naturally gain experience through internships, but the results are unstable when support is insufficient
Strengthen university support	Moderate rise	Pre-internship preparation reduces uncertainty and improves cross-cultural adaptation
Strengthen corporate mentoring	Significantly increased	High-quality tasks and feedback enhance career confidence and a sense of competence
Integrate support scenarios	Rise quickly and steadily	Universities, enterprises, and peers support each other to form a complementary feedback mechanism

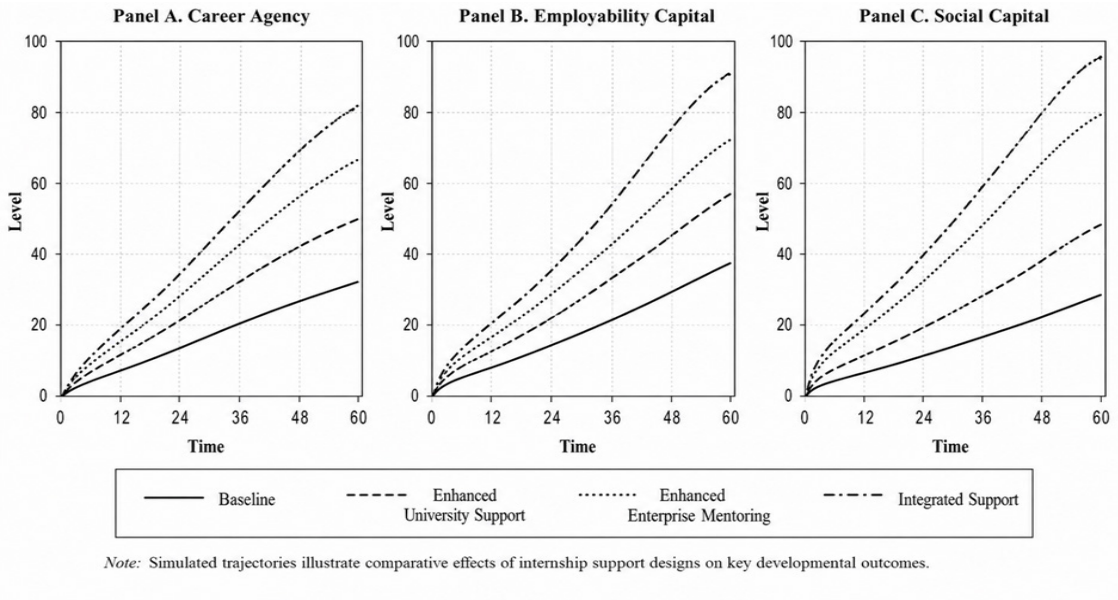

Figure 4. Scenario Simulation Results of Internship Support Designs

5 Discussion

5.1 Theoretical implications

The theoretical implications of this study are to transform the "career agency" in Generation Z's overseas internships from static psychological characteristics to dynamic abilities influenced by relationship context. Existing studies have suggested that the WIL experience of Gen Z affects their job value and career readiness (Drewery et al., 2023), and the employability agency of international graduates also needs to be formed through the combination of personal capital, social relationships, and institutional conditions (Pham et al., 2023). Therefore, this study uses System Dynamics (SD) to present the feedback relationship between career self-management, social capital, employability capital, and cross-cultural stress, which can make up for the limitations of traditional WIL research that focuses on one-way effect evaluation.

From a knowledge-management perspective, overseas internships can be viewed as structured learning systems through which experiential knowledge, relational knowledge, and career knowledge are accumulated and transformed into career agency.

5.2 Practical implications

In terms of management practice, the model-based analysis suggests that the key to the effectiveness of overseas internship programs is not the number of dispatches, but whether a continuous governance mechanism of "pre-internship preparation, internship support, and post-internship transfer" is formed. Jackson and Dean (2023) suggested that different WIL patterns may promote employability, but their effectiveness depends on program design and learning quality. Vu et al. (2022) also suggested that international students often face cultural and institutional barriers in WIL. Therefore, universities should establish cross-cultural training, corporate mentoring systems, reflective learning records, and career counseling after returning to the home country, so that overseas internships can be transformed from short-term international experience into long-term career development capital. This implication is consistent with studies on international mobility, employability agency, and Gen Z WIL experiences (Drewery et al., 2023; Pham et al., 2025).

5.3 Management and policy implications

Although ESG is not modeled as a separate stock or flow in this study, overseas internship governance reflects the social and governance dimensions of higher education sustainability and can be viewed as a concrete field in which higher education institutions fulfil their social and governance responsibilities. The introduction of ESG into higher education has been seen as an important direction for promoting sustainability paradigms and Sustainable Development Goals (SDGs) practices (Finatto et al., 2024). Therefore, overseas internship governance should emphasize equitable participation, student safety, career support, partner-institution review, learning-outcome tracking, risk management, and information transparency.

6 Conclusion

This study explores the formation mechanism of career agency in the context of overseas internship relationships of Generation Z from the perspective of System Dynamics (SD). The model-based analysis suggests that the value of overseas internships lies not only in improving short-term employability, but also in promoting the dynamic accumulation of career self-management, social capital, and employability capital through university support, corporate mentoring, peer networks, and cross-cultural adaptation. This conclusion echoes the emphasis placed on graduate employability in WIL research and complements its lack of handling feedback, delay, and nonlinear mechanisms (Jackson & Dean, 2023; Vu et al., 2022).

This study offers three preliminary contributions: first, to transform career agency from static psychological characteristics to dynamic abilities that can be accumulated through internship experience and relationship context; second, establish a causal loop and stock-and-flow structure of "career self-management-social capital-employability capital" in overseas internships; Third, it proposes a scenario simulation perspective to assist higher education institutions in comparing the long-term effects of different internship support designs. This design extends the research direction of applying CLDs and SFDs to examine the formation of career agency. Career competence and active job crafting affect individual career success, supporting this study to consider student initiative as an important mechanism for career agency growth (Akkermans & Tims, 2017).

Future research should collect longitudinal data from overseas internship students to calibrate the trajectories of career agency and employability capital, compare system structures across countries, industries, and internship types, and develop simulation-based decision-support tools for university career centers and international offices.

6 Declaration of Ethics

This study is currently based on literature-based model construction and does not involve personally identifiable human-subject data. If future surveys, interviews, or internship reflection records are collected, informed consent, confidentiality protection, and institutional ethical review will be implemented.

7 Artificial intelligence declares

AI-Empowers Smart Aquaculture: A System Dynamics-Integrated Decision-Making Architecture

Ju-We Chen, Shin-Ping Su
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

The global aquaculture industry is facing multiple challenges, including climate change, water quality risks, energy cost fluctuations, feed efficiency pressures, and increasing demands for sustainable governance. Although technologies such as artificial intelligence of things (AIoT), smart sensors, precision feeding, automated aeration, and intelligent sludge removal have been increasingly introduced into aquaculture farms, most applications remain focused on single-point monitoring, real-time warning, or device-level optimization. Limited attention has been paid to the long-term feedback relationships among water quality, feeding strategies, fish growth, energy consumption, sludge accumulation, and environmental, social, and governance (ESG) performance. Based on this, this study constructs the "AI-empowered smart aquaculture system dynamics integrated decision-making framework", which uses system dynamics as the method basis to integrate AIoT sensing data, artificial intelligence (AI) analysis signals, smart equipment information, and aquaculture management knowledge, and establishes a causal loop diagram and stock-and-flow model. The study identified four core feedback structures, including two reinforcing loops: “AI data learning–decision quality” and “precision feeding–fish growth”, as well as two balancing loops of "overfeeding - deterioration of water quality" and "aeration improvement - energy load". Further through the comparison of baseline scenarios, AIoT monitoring scenarios, and system dynamics (SD) integrated AI decision-making scenarios, this study points out that system dynamics can help managers understand time delays, nonlinear relationships, and cumulative effects, and evaluate the impact of different feeding, aeration, sludge removal, and energy control strategies on production efficiency, environmental impact, and governance transparency. The research contribution is to upgrade smart aquaculture from technology introduction to a dynamic management framework that integrates data, knowledge, decision-making, and ESG governance, and to provide a practical reference for aquaculture operators to shift from experience-oriented to model-assisted decision-making.

Keywords: AIoT, Smart Aquaculture, System Dynamics, Decision Support, ESG Governance

Paper Type: Academic Research Paper

1 Introduction

Global aquaculture is facing multiple pressures such as climate change, energy cost fluctuations, water quality risks, feed efficiency, and sustainable governance. Although aquaculture is regarded as an important industry in response to global protein demand, its production process is highly dependent on dynamic variables such as dissolved oxygen, temperature, pH, conductivity, feeding strategy, aeration energy, and waste management. Føre et al. (2018) proposed the concept of "precision fish farming", emphasizing the need to improve aquaculture operators' monitoring, control, and recording capabilities for biological production processes through sensing, control engineering, and real-time monitoring, indicating that intelligence has become an important direction for aquaculture transformation.

However, existing smart aquaculture mostly focuses on single-point equipment or real-time monitoring, such as artificial intelligence of things (AIoT) sensors, water quality monitoring, smart feeding, automatic aeration, and sludge removal equipment. Although AIoT can support real-time environmental monitoring, data-driven decision-making, and automated management, and improve operational efficiency and production stability, most applications still focus on short-term warning or equipment-level optimization, and less deal with long-term feedback, time delay, and nonlinear relationships in aquaculture systems (Huang & Khabusi, 2025). In particular, there is an interaction between feeding rate, dissolved oxygen, fish growth, sludge accumulation, energy consumption, and environmental performance, and without an integrated decision-making model, aquaculture management may still rely on empirical judgment and is difficult to translate into a traceable, simulation-ready, and governable knowledge system.

Therefore, the problem of this study is that AI-enabled smart aquaculture should not be regarded as just the introduction of sensing technology or automation equipment, but should be understood as a dynamic management framework that integrates data, knowledge, decision-making, and governance. System dynamics is suitable for analyzing complex systems with feedback, delays, and cumulative effects. Relevant studies have applied dynamic models to recirculating aquaculture systems to evaluate the impact of water quality parameters and management strategies on fish performance and system sustainability (Udayakumar et al., 2025; Kamali et

al., 2022). At the same time, the sustainable transformation of aquaculture also needs to move beyond fragmented technical issues and move towards a systematic governance approach that can address the interaction between environmental, social, and governance (Partelow et al., 2023).

Based on the above background, this study aims to construct an "AI-empowered smart aquaculture system dynamics integrated decision-making framework", integrating AIoT sensing data, AI analysis, smart equipment information, and aquaculture management knowledge into the system dynamics model to present the causal relationship between water quality stability, precision feeding, energy use, fish growth, sludge accumulation management, and environmental, social, and governance (ESG) performance. The expected contributions of this study include: first, theoretically integrating the perspectives of smart aquaculture, AI knowledge governance, and system dynamics; Second, it proposes a decision-making framework that can conduct scenario simulation and sensitivity analysis. Third, in practice, it assists aquaculture operators from experience-oriented management to data- and model-assisted decision-making, thereby improving production efficiency, environmental performance, and governance transparency.

2 Literature review

2.1 AIoT and smart aquaculture

Smart aquaculture refers to the real-time grasp of water quality, biological growth, feeding, energy, and environmental risks through sensors, the Internet of Things, artificial intelligence, automated control, and data analysis technologies. Føre et al. (2018) proposed the concept of precision fish farming (PFF), advocating the integration of control engineering, real-time sensing, and data recording into fish production systems to enhance aquaculture operators' ability to monitor, control, and record biological production processes, and reduce the dependence of traditional aquaculture on human experience and subjective judgment. This view lays an important foundation for smart aquaculture to move from "equipment automation" to "data-driven decision-making".

In recent years, the application of AIoT in aquaculture has expanded rapidly, including water quality monitoring, fish behavior identification, disease detection, precision feeding, automatic aeration, and predictive maintenance. Huang and Khabusi (2025) pointed out that AIoT combines Internet of Things (IoT), and AI algorithms to collect real-time data such as temperature, pH, dissolved oxygen, salinity, and fish behavior, and supports water quality management, disease early warning, and automated control through predictive analytics. However, existing research mostly focuses on sensing accuracy, algorithm performance, or individual equipment efficiency, and rarely further explores how multi-source data can be translated into medium- and long-term business decisions, governance capabilities, and sustainable performance of farms. Therefore, the core value of AIoT in smart aquaculture lies not only in real-time monitoring but also in the formation of knowledge assets that can be accumulated, explained, and governed.

2.2 Systemic complexity of intelligent farming decisions

Aquaculture is not a simple production process, but a complex adaptive system composed of water quality, biological growth, feed input, energy use, waste accumulation, and environmental conditions. Aquaculture managers must weigh production efficiency, fish health, energy costs, and environmental impact. For example, increasing feeding may promote fish growth in the short term, but overfeeding can also lead to increased bait residue, sludge accumulation, deterioration of water quality, and increased mortality. Increasing aeration intensity can improve dissolved oxygen, but at the same time increase energy use and carbon emissions. Kamali et al. (2022) established a dynamic model for recirculating aquaculture systems, pointing out that water quality parameters and management strategies jointly affect fish performance, and aquaculture systems need to understand the relationship between management behavior and production results through dynamic modeling.

This feature shows that smart aquaculture decisions cannot rely solely on single-point monitoring or short-term warnings, but need to deal with time delays, nonlinear relationships, and cumulative effects. For example, the impact of dissolved oxygen decline on fish health may be delayed, and the effect of sludge accumulation on water quality deterioration may not be apparent until a period of time. Without an integrated model, AIoT devices can generate a large amount of data, but it is still difficult for managers to judge the medium- and long-term effects of different decision-making solutions. Therefore, smart aquaculture needs to be further developed from "sensing-oriented" to "systematic decision-oriented".

2.3 Theoretical basis of system dynamics

System dynamics (SD) was initially developed by Forrester (1961) to analyze complex industrial and management systems with feedback structures, time delays, stock accumulation, and nonlinear behavior. Sterman (2000) pointed out that the root cause of many management problems is not a single event, but a dynamic behavior formed by the system's internal feedback structure and decision-making delays. Therefore, SD is particularly suitable for analyzing systems such as aquaculture that are affected by the interaction of biological, technological, environmental, and management factors, and transforming the "data-knowledge-decision-performance" in aquaculture systems into a simulation-ready dynamic architecture.

In smart aquaculture research, SD can make up for the shortcomings of AI and IoT's emphasis on real-time prediction. AI models can provide water quality predictions, anomaly detection, and operational recommendations, but SD can further integrate these signals into the overall feedback structure to analyze the long-term impact of different management strategies. Causal loop diagram (CLD): Shows the reinforcing and balancing loops between variables. Stock-and-Flow Diagram (SFD): Shows the stock and flow of water quality, fish biomass, energy accumulation consumption, sludge accumulation and governance capability. Recent studies have applied SD to water quality management in recirculating aquaculture systems, integrating the relationship between fish metabolism, feed input, biological filter, water exchange, aeration, and water quality parameters through models to evaluate the effects of different aquaculture densities, feeding intensities, and aeration strategies on system performance (Udayakumar et al., 2025). Therefore, SD is not only a simulation tool, but also a method of translating sensing data, management experience, and strategic assumptions into a communicative decision-making framework.

2.4 ESG governance and sustainable transformation of smart aquaculture

With the emphasis on sustainable development and ESG governance, the performance evaluation of aquaculture is no longer limited to production and revenue, but extends to water resource use, energy efficiency, carbon emissions, pollution control, food safety, social responsibility, and governance transparency. Partelow et al. (2023) point out that the sustainable transformation of aquaculture requires a greater emphasis on governance and a shift from fragmented technical issues to a systematic approach that addresses social, environmental, and institutional interactions. Therefore, the sustainable value of smart aquaculture lies not only in improving production efficiency but also in supporting traceable, verifiable, and governable operational decisions.

From an ESG perspective, the integration of AIoT with SD provides three governance functions (Table 1). First, in terms of the environment, sensing data can support water quality stability, energy efficiency, and pollution load management. Second, in terms of society, smart decision-making can reduce the risk of aquaculture failure, improve food safety, and narrow the knowledge gap among small and medium-sized aquaculture operators. Third, in terms of governance, the system model can transform decision-making basis, risk warning, and management results into traceable records, improving decision-making transparency and responsibility management capabilities. It can be seen that if AI-enabled smart aquaculture can be combined with SD, it can not only improve operational efficiency but also form an ESG-oriented knowledge governance framework.

Table 1: ESG Dimensions and System Dynamics Variables in Smart Aquaculture Governance

Dimension	Governance focus	System dynamics variables
Environmental	Water quality stability, pollution load, sludge accumulation, energy consumption, and carbon pressure are used as environmental performance metrics.	DO, pH, energy consumption, sludge accumulation
Social	Using fish survival, food safety risk reduction, production stability, and farmer knowledge as social value proxies	Fish health, mortality, and operational knowledge and ability
Governance	Using decision records, ESG dashboards, data traceability, and decision response time as governance transparency proxies	Data visualization, AI decision-making signals, and governance response speed

2.5 Literature gap

Based on the above literature, existing research has confirmed that AIoT, precision aquaculture, and automated equipment have important value for aquaculture, but there are still three gaps. First, existing research mostly focuses on a single technology or single device, and rarely integrates the dynamic relationship between water quality, feeding, energy, fish growth, and pollution accumulation. Second, AIoT research

emphasizes real-time monitoring and prediction capabilities, and less explores how data can be transformed into organizational knowledge, governance capabilities, and medium- and long-term decision support. Third, ESG research is more biased towards performance disclosure and policy discussions, and less often embeds ESG indicators into farm daily operations and scenario simulations. Therefore, this study uses system dynamics as an integrated approach to construct an AI-empowered smart aquaculture decision-making framework to respond to the research needs of smart aquaculture from technology introduction to knowledge governance and sustainable decision-making.

3 Research Methodology

This study uses SD as the main research method to construct an "AI-empowered smart aquaculture system dynamics integrated decision-making framework". System dynamics is suitable for analyzing complex management systems with feedback relationships, time delays, stock accumulation, and nonlinear behavior. Sterman (2000) pointed out that many organizational and management problems do not stem from a single event, but from dynamic behaviors formed by feedback structures and decision delays within the system. Therefore, this study uses SD to link AIoT data, smart devices, aquaculture decision-making, and ESG governance performance to make up for the shortcomings of traditional smart aquaculture research focusing on single-point monitoring and real-time control.

3.1 Study design

The modeling process of this study is divided into five steps. First, literature analysis: Define the boundaries of the system and set the research scope to the operation decision-making system of smart aquaculture farms, covering water quality management, feeding management, aeration energy, fish growth, sludge accumulation, smart equipment investment, and ESG governance. Second, carry out variable identification, based on the literature on precision fish farming and AIoT smart aquaculture, extract core variables such as dissolved oxygen, temperature, pH, feeding accuracy, fish biomass, mortality, energy consumption, and AI prediction accuracy. Føre et al. (2018) pointed out that the purpose of precision fish farming is to improve the ability of aquaculture operators to monitor, control, and record biological production processes through control engineering principles. This view provides a theoretical basis for the establishment of data-driven variables in this study (Føre et al., 2018). Third, construct a causal loop diagram (CLD) to identify the reinforcing and balancing loops between AI data learning, precision feeding, dissolved oxygen control, sludge accumulation, and management response. Fourth, establish a stock-and-flow diagram (SFD) that sets fish biomass, water quality stability, sludge accumulation, energy consumption, and governance capability as the main stocks, and uses growth rate, pollution load, sludge removal efficiency, energy regulation, and data learning rate as flows. Fifth, through scenario simulation and sensitivity analysis, compare the medium- and long-term effects of different intelligent management strategies.

3.2 Research Framework

In terms of variable design, this study divides systematic variables into six categories. The first is water quality variables, including dissolved oxygen, temperature, pH, conductivity and redox potential; the second is production variables, including fish biomass, growth rate, feed conversion rate and mortality; the third is intelligent equipment variables, including AI prediction accuracy, AIoT data quality, intelligent feeding efficiency, aeration control intensity, and sludge removal efficiency; the fourth is environmental variables, including sludge accumulation, pollution load, energy consumption and carbon emissions; the fifth is management variables, including decision-making response time, aquaculture operators' knowledge ability and system adoption; The sixth is ESG governance variables, including environmental performance, social value, and governance transparency. Kamali et al. (2022) established a dynamic model for recirculating aquaculture systems, pointing out that water quality parameters and management strategies jointly affect fish body performance, and can evaluate system behavior under different management strategies through dynamic simulation, supporting the core model structure of this study, which supports the core model structure of water quality, biological growth, and management behavior. The research structure is summarized in Table 2.

Table 2: Architecture Layers of the Proposed Decision-Making Framework

Levels	Contents	Function
Data layer	AIoT sensors, water quality meters, smart feeding, sludge removal equipment, energy equipment	Collect real-time operational data
Knowledge layer	AI analysis, water quality prediction, anomaly detection, rules of thumb	Transform data into decision-making knowledge
System dynamics layer	CLD, SFD, Scenario Simulation, Sensitivity Analysis	Analyze long-term feedback and policy effects
Governance layer	ESG indicators, decision records, risk warnings, and management dashboards	Support transparent governance and sustainable management

The data sources of this study include three categories. The first is academic literature, mainly taken from research related to smart aquaculture, AIoT, precision aquaculture, system dynamics, and ESG governance, and is used to establish variable relationships and model assumptions. The second is the data of smart aquaculture equipment, including the operation data generated by AIoT sensors, water quality monitoring equipment, intelligent feeding systems, aeration equipment, and sludge removal systems, such as dissolved oxygen, temperature, pH, feeding volume, equipment operating time, and energy consumption. The third is management and governance data, including farmer operation records, decision response time, abnormal event handling records, energy costs, and ESG performance indicators. Huang and Khabusi (2025) pointed out that AIoT can integrate sensors, AI algorithms, and automation equipment in aquaculture for water quality management, disease early warning, and decision support, indicating that multi-source data integration is an important foundation for smart aquaculture decision-making architecture. The core variables are summarized in Table 3.

Table 3: Core Variables of the Smart Aquaculture System Dynamics Model

category	Core variables	Variable description	SD role
Water quality management	Dissolved Oxygen, DO	The concentration of dissolved oxygen in the aquaculture water body for fish to breathe is a key water quality indicator that affects the health and mortality of fish.	Auxiliary variable/ state variables
Water quality management	Temperature	Water temperature affects fish metabolism, feeding behavior, dissolved oxygen requirements, and disease risk.	Auxiliary variable
Water quality management	pH	It reflects the pH state of the water body, affecting the physiological adaptation of fish, microbial action and ammonia nitrogen toxicity.	Auxiliary variable
Water quality management	Electrical Conductivity, EC	It reflects changes in water ion concentration and salinity, and can be used as a reference index for water quality changes and pollution loads.	Auxiliary variable
Water quality management	Oxidation-Reduction Potential, ORP	It reflects the redox state of water bodies, which is related to the decomposition of organic matter, microbial activities, and water quality safety.	Auxiliary variable
Production performance	Fish Biomass	The total biomass of fish in the pond is affected by growth, death, and harvest.	Stock
Production performance	Fish Growth Rate	The growth rate of fish is affected by feed efficiency, water quality stability, and fish health.	Flow
Production performance	Mortality Rate	Fish mortality is affected by low dissolved oxygen, deterioration of water quality, disease and delayed management.	Flow
Production performance	Feed Conversion Efficiency	Feed conversion efficiency refers to the efficiency of the input feed into fish growth.	Auxiliary variable
Feeding management	Feeding Amount	The amount of feed input per unit time.	Flow / Decision variable
Feeding management	Feeding Precision	The feeding system accurately feeds the fish according to the needs, behavior, and water quality conditions.	decision variable
Pollution and sludge accumulation	Feed Residue and Waste	The organic load formed by uningested feed and fish excrement.	Flow

category	Core variables	Variable description	SD role
Pollution and sludge accumulation	Sludge Accumulation	The accumulation of organic matter, residual bait and excrement at the bottom of the aquaculture pond.	Stock
Pollution and sludge accumulation	Smart Cleaning Removal	The efficiency of smart sludge removal or automatic cleaning equipment to remove sludge accumulation and contaminants.	Flow
Energy management	Aeration Intensity	The operating strength of the aeration equipment is used to improve the circulation of dissolved oxygen and water.	decision variable
Energy management	Energy Consumption	The total energy use of aeration, water circulation, monitoring, and automation equipment.	Stock
Energy management	Energy Control	Adjust the control capability of equipment operation based on water quality, dissolved oxygen demand, and energy costs.	decision variable
AI and data	AIoT Data Volume	The amount of aquaculture operation data accumulated by sensors, equipment, and management systems.	Stock / Auxiliary variable
AI and data	AI Prediction Accuracy	The accuracy of AI models in predicting water quality changes, fish growth, feeding needs, and abnormal events.	Auxiliary variable
AI and data	Anomaly Detection Capability	The ability of the system to identify abnormal water quality, equipment or fish behavior.	Auxiliary variable
Management decisions	Decision Quality	The ability of farm managers or systems to make appropriate decisions based on data and models.	Auxiliary variable
Management decisions	Decision Response Time	The time it takes to manage the execution of an action from the occurrence of an anomaly.	Auxiliary variable
Management decisions	Farmer Knowledge	Aquaculture operators' understanding and application of water quality, biological growth, equipment operation, and AI suggestions.	Stock / Soft variable
Governance and sustainability	Governance Capability	The farm's ability to institutionalize and manage data, decision-making records, risk warnings, and ESG indicators.	Stock
Governance and sustainability	ESG Dashboard	A management interface that visualizes and tracks environmental, social, and governance metrics.	Auxiliary variable
Governance and sustainability	Environmental Performance	environmental performance such as water quality stability, pollution reduction, energy efficiency and carbon emission control.	Outcome variable
Governance and sustainability	Social Value	social values such as food safety, stable production, reduced aquaculture risks, and narrowing the knowledge gap of small and medium-sized businesses.	Outcome variable
Governance and sustainability	Governance Transparency	decision-making records, data traceability, risk disclosure, and ESG reporting capabilities.	Outcome variable

Scenario simulation design is divided into three scenarios. The first is the baseline scenario, which represents traditional experiential management, which mainly relies on manual observation and aquaculture experience for feeding, aeration, and water quality treatment. The second is the AIoT monitoring scenario, which represents the introduction of sensors and smart devices, but the decision-making is still based on manual judgment. The third is the SD-integrated AI decision scenario, which represent the integration of AI prediction signals, smart device data, and system dynamics model to support feeding, aeration, sludge removal, and energy management decisions through scenario simulation. The three scenarios will compare indicators such as water quality stability, fish growth rate, mortality, feed efficiency, energy consumption, pollution load, and ESG governance transparency. Partelow et al. (2023) pointed out that the sustainable transformation of aquaculture requires a shift from fragmented technical issues to a systematic governance approach that can address interconnected sustainability issues.

Overall, this research method does not only pursue short-term prediction accuracy with AI models, but also transforms AIoT data into interpretable, simulation-ready, and governable decision-making knowledge through SD. This approach helps uncover key leverage points in smart aquaculture systems and assists aquaculture operators in assessing the long-term impact of different management strategies on production efficiency, environmental impact, and ESG governance capabilities.

4 Research results

4.1 AI empowers smart aquaculture to integrate decision-making framework

The proposed architecture integrates five layers: data acquisition, AI analytics and knowledge, system dynamics modeling, decision and governance, and operational and sustainability outcomes (Figure 1) to illustrate the dynamic relationship between AIoT data, smart devices, aquaculture management decisions, and ESG performance. The qualitative comparison suggests that the key to smart aquaculture lies not only in the introduction of sensors, AI algorithms, or automated equipment, but also in the ability to transform disparate data into interpretable, simulation-ready, and governable management knowledge. This view echoes the concept of precision fish farming proposed by Føre et al. (2018), that is, to improve the monitoring, control, and recording capabilities of aquaculture operators in biological production processes through sensing, monitoring, and control engineering.

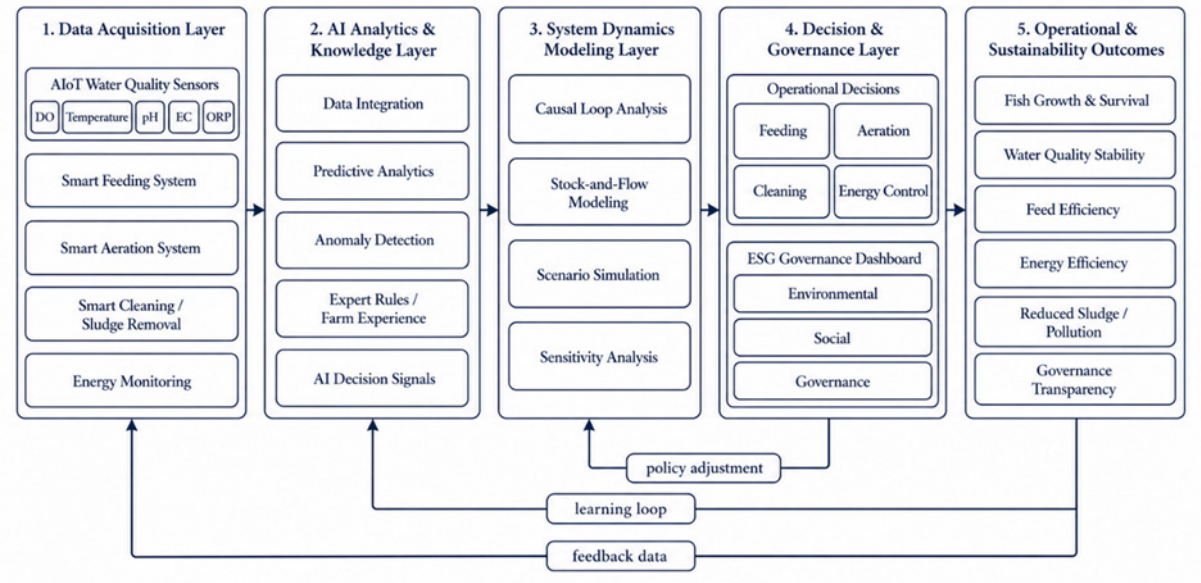

Figure 1. AI-Empowered Smart Aquaculture Decision-Making Architecture

4.2 Causal loop analysis results

The causal loop analysis identifies two reinforcing loops and two balancing loops. R1 explains how AIoT data accumulation improves AI prediction accuracy and decision quality, which further enhances aquaculture performance and technology adoption. R2 captures how precision feeding improves feed conversion efficiency, fish growth, farm revenue, and reinvestment in smart technologies. In contrast, B1 shows that overfeeding increases feed residue, sludge accumulation, water quality deterioration, and mortality risk, thereby triggering feeding adjustment. B2 indicates that aeration improves dissolved oxygen and fish survival but also increases energy consumption and carbon pressure, requiring energy-control adjustment(Figure 2).

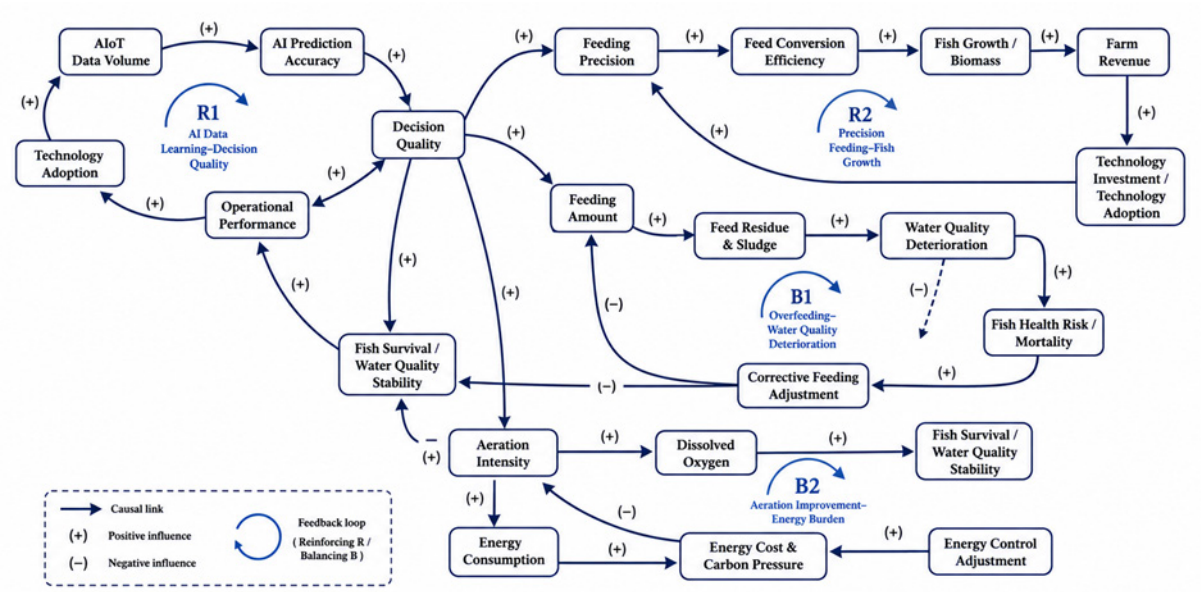

Figure 2: Causal Loop Diagram of AI-Empowered Smart Aquaculture System

4.3 Stock-and-flow model results

In terms of Stock-and-flow model, the smart aquaculture system is designed into five main stocks: fish biomass, water quality stability, sludge accumulation, energy consumption, and governance capability. Fish biomass is affected by growth rate, mortality and harvest rate; Water quality stability is affected by dissolved oxygen, pH, temperature, pollution load, and water treatment efficiency. Sludge accumulation is determined by feed residue, fish waste, and sludge removal efficiency. Energy consumption mainly comes from the operation of aeration, circulating water equipment and smart equipment; Governance capabilities are accumulated from data quality, decision-making records, AI prediction accuracy, and ESG disclosure capabilities. The dynamic model of recirculating aquaculture by Kamali et al. (2022) shows that management strategies and water quality parameters can jointly affect fish performance, and the system behavior under different strategies can be evaluated through dynamic simulation. This is consistent with the design of this study to integrate production, water quality, and management behaviors into the SFD framework.

4.4 Scenario simulation results

This study designs three qualitative scenarios to compare different smart aquaculture management logics: the baseline scenario, the AIoT monitoring scenario, and the SD-integrated AI decision scenario(Table 4). Since this research proposes a conceptual decision-making architecture rather than a calibrated numerical simulation model, the scenario comparison is presented qualitatively to illustrate how data integration and system modelling may influence production, environmental management, and ESG governance.

In the baseline scenario, aquaculture operations depend mainly on manual observation and experience-based judgment. Although flexible, this approach is constrained by delayed responses, incomplete information, and fragmented records, resulting in lower water quality stability, higher fish mortality, weaker feed and energy efficiency, greater sludge and pollution loads, and lower ESG transparency. The AIoT monitoring scenario improves real-time data collection, water quality monitoring, abnormality detection, and decision response speed through sensors and smart devices. However, without system dynamics modelling, it remains limited to short-term monitoring and warning, making it difficult to evaluate medium- and long-term effects.

The SD-integrated AI decision scenario shows the strongest expected performance. By combining AI prediction signals, AIoT sensing data, smart equipment information, and system dynamics simulation, it supports more comprehensive decisions on feeding, aeration, sludge removal, and energy control. This scenario is expected to improve water quality stability, reduce mortality, enhance feed efficiency, strengthen decision quality, and increase ESG transparency. Overall, the comparison suggests that smart aquaculture should move beyond equipment adoption toward integrated data, model-assisted decision-making, and long-term governance capability.

Table 4: Expected Scenario Comparison Results

Indicators	Baseline	AIoT Monitoring	SD-Integrated AI Decision
Water quality stability	low	Medium	High
Fish mortality	High	Medium	Low
Feed use efficiency	low	Medium	High
Energy efficiency	low	Medium	Medium-high
decision response speed	Slow	Medium	Fast
ESG transparency	low	Medium	High
LT* Governance capabilities	low	Medium	High

LT* : Long-term

4.5 Key Sensitivity Variables

Based on the qualitative scenario comparison, this study identifies three variables expected to exert strong leverage on system behavior: AI prediction accuracy, feeding precision, and aeration energy efficiency. These variables are critical because they influence decision response quality, feed conversion efficiency, water quality stability, energy costs, and carbon pressure, as summarized in Table 5.

Table 5: Key Sensitivity Variables and Expected Impacts

Key Sensitivity Variables	Impact
AI Prediction Accuracy	Improve water quality early warning, feeding decision-making and governance response
Feeding Precision	Improve feed efficiency, fish growth and reduce pollution load
Aeration Energy Efficiency	Improve dissolved oxygen stability and reduce energy costs and carbon emission pressure.

5 Discussion

This study highlights that the value of AI-empowered smart aquaculture lies in transforming fragmented operational data into decision-relevant knowledge. While AIoT sensors and smart equipment improve real-time monitoring, their managerial value remains limited if data are not connected to feedback structures, time delays, and cumulative system effects. By applying system dynamics, this study positions smart aquaculture as a knowledge-based decision system rather than a collection of isolated technologies.

From a theoretical perspective, the proposed framework extends the precision fish farming perspective by linking sensing, monitoring, and control functions with system-level learning. It shows that AI-generated data can support not only operational control but also feedback analysis, scenario learning, and strategic decision-making. This strengthens the connection between smart aquaculture, knowledge assets, and system dynamics.

From a managerial perspective, the framework suggests that aquaculture operators should move beyond experience-based responses and adopt model-assisted decision-making. For example, feeding, aeration, sludge removal, and energy-control decisions should be evaluated not only by their immediate operational effects but also by their delayed impacts on water quality, fish growth, mortality risk, energy cost, and pollution load. This helps reduce local optimization and supports more balanced operational decisions.

From an ESG governance perspective, the framework embeds environmental, social, and governance concerns into daily aquaculture operations. Water quality stability, energy consumption, pollution load, fish health, decision records, and data traceability are treated as decision variables rather than external reporting items. Therefore, AI and system dynamics integration can support sustainable governance, risk disclosure, and transparent knowledge management in smart aquaculture.

6 Conclusion

This study proposes an AI-Empowered Smart Aquaculture System Dynamics Integrated Decision-Making Framework to explain how AIoT sensing data, AI prediction signals, smart equipment information, and aquaculture management knowledge can be integrated into a system dynamics-based decision architecture. The main contribution is to reframe smart aquaculture from a technology-adoption issue into a knowledge-governance and decision-support issue. Rather than treating AIoT sensors, precision feeding, automated aeration, and sludge removal systems as isolated tools, this study connects them through causal loop analysis, stock-and-flow modeling, and qualitative scenario comparison to support medium- and long-term decision-making.

Theoretically, this study integrates AIoT-enabled smart aquaculture, precision fish farming, system dynamics, and ESG governance. It argues that AI-generated operational data should be viewed not merely as monitoring outputs, but as knowledge assets that support feedback analysis, strategic simulation, and governance transparency. Methodologically, the framework identifies two reinforcing loops and two balancing loops that clarify the dynamic relationships among water quality stability, feeding precision, fish growth, sludge accumulation, energy consumption, and ESG performance. Practically, the framework helps aquaculture operators shift from experience-based management to model-assisted decision-making.

This study is limited by its conceptual nature. The model has not yet been calibrated or validated with long-term field data, and the scenario comparison remains qualitative rather than numerical. Model assumptions may also vary across fish species, farming densities, production systems, equipment specifications, climate conditions, and operators' capabilities, which may affect generalizability.

Future research should incorporate longitudinal AIoT field data to estimate parameters, calibrate equations, and validate simulation results. Further studies may compare pond aquaculture, recirculating aquaculture systems, and offshore aquaculture to examine ESG impacts under different contexts. Future work may also develop a decision dashboard linking real-time AIoT data, system dynamics simulation, and ESG indicators as a practical decision-support tool for sustainable smart aquaculture.

7 Declaration of Ethics

This study does not involve human participants, personal data, animal experiments, or sensitive information. Therefore, no specific research ethics approval was required.

8 AI Declaration

This study used ChatGPT to assist in identifying academic references relevant to the research arguments and to support the preparation of figures. All cited references were reviewed by the authors to confirm their relevance to the study. The authors remain responsible for the accuracy, interpretation, and final content of the manuscript.

Inclusive Governance of Sport Centers: A System Dynamics Perspective

Yi-Chen Cheng, Ching-Yeh Chu
Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

This study focuses on "Inclusive Governance of Sports Centers" and explores the dynamic relationship between ESG governance, public services, and sustainable operations in urban public sports centers from the perspective of system dynamics. In recent years, the sports center has transformed from a mere venue and course service provider to an important social infrastructure that promotes public health, social participation, community connections, and access to the disadvantaged. However, in a service system that involves outsourcing operations, professional sports organizations, individual coaches, and diverse users, sports centers also face multiple tensions such as operational efficiency, service capacity, fair participation, governance transparency, and financial sustainability. This study adopts a conceptual system dynamics research design to construct a research framework, causal loop diagram, and stock flow model for inclusive governance in sports centers, and further compares five scenarios: baseline scenarios, inclusive curriculum design, capacity allocation, transparent adaptive governance, and cost pressure. The results show that there is a mutually reinforcing and constraint relationship between participation diversity, service capacity, service satisfaction, trust capital, governance capabilities, and resource reinvestment. Among them, transparent adaptive governance can best improve long-term trust and overall ESG performance. capacity configuration helps reduce congestion and improve service satisfaction; Inclusive curriculum design can enhance participation diversity, but if there is a lack of capacity support, it may have a service dilution effect. This research contribution is to integrate ESG, inclusive governance, and system dynamics into a decision support framework for public sports service governance, and to provide sports center managers and policymakers with a governance mindset that balances public value, operational sustainability, and social inclusion.

Keywords: Sports Center, Inclusive Governance, Systems Dynamics, ESG, Sustainable Sports Services

Paper type: Academic Research Paper

1 Introduction

In recent years, the role of urban sports centers has gradually transformed from mere sports venues and course service providers to important social infrastructure that promotes public health, social participation, community connections, and sustainable governance. Especially in the context of aging, health promotion, and increased awareness of ESG governance, sports centers not only need to meet the fitness needs of the general public but also respond to the participation needs of different users such as teenagers, the elderly, beginners, people with disabilities, and vulnerable groups. Existing studies have pointed out that sports participation systems involve multi-level interactions such as policies, facilities, managers, and users, and the governance goals of sports facilities are often affected by both public value and business performance (Kumar et al., 2018). The Taipei City Sports Center has the diverse operational characteristics of outsourcing operators, professional sports organizations, and individual coaches jointly providing services, so its governance issues cannot be solved by a single manager, but involve the coordination and resource allocation of multiple stakeholders.

While pursuing utilization, course revenue, and service diversification, sports centers may also face structural contradictions in inclusive governance. For example, popular hours and courses can cause crowded venues, making it more difficult for the elderly, beginners, or vulnerable groups to access services. Excessive pursuit of revenue may also compress public welfare, accessibility, and diversity of participation. Research on sports governance has pointed out that sports organizational governance not only involves internal organizational management but also encompasses multiple aspects such as institutional, political, social and stakeholder interactions (Dowling et al., 2018). The collaborative governance perspective also emphasizes that the public sector, civil society organizations, and community actors must share information, resources, and capabilities to handle public service tasks that are difficult for a single organization to accomplish independently (Shilbury et al., 2016). In addition, social inclusion research reminds that although sports participation itself contributes to social connections, increasing participation does not necessarily lead to true equity and inclusion without institutional design and environmental adjustment (Jeanes et al., 2021; Coalter, 2017）。

Based on the above awareness, this study believes that inclusive governance in sports centers should be understood as a dynamic system with feedback, delay, accumulation, and nonlinear characteristics, rather than

static institutional arrangements or single policy interventions. System dynamics emphasizes that system behavior comes from the interaction between feedback loops, stock traffic, and decision-making rules, making it suitable for analyzing long-term governance effects in complex public service systems (Sterman et al., 2015). Therefore, the purpose of this study is threefold: first, to construct a systematic dynamic analysis framework for inclusive governance in sports centers; second, identify the main causal loops between participation diversity, service capacity, satisfaction, trust, governance transparency, and resource reinvestment; Third, scenario simulation analyzes how different governance strategies affect the inclusive participation, service quality, and sustainable operation of sports centers. In this way, this study hopes to supplement the shortcomings of existing sports governance research that focuses on static analysis, and provide decision-making support perspectives for sports center managers and policymakers that take into account ESG, public value, and operational sustainability.

2 Literature review

2.1 Sports Center Governance and Public Sports Services

The sports center has the characteristics of both public services and market operations, and its governance involves not only venue management, curriculum design, and operational efficiency, but also public health, community participation, and social equity. Sports governance research points out that sports organizational governance has expanded from traditional internal management to include multi-level issues such as institutional arrangements, stakeholder coordination, accountability mechanisms, and public value creation (Dowling et al., 2018). In the scenario of Taiwan's urban sports center, the government, outsourced operators, professional sports organizations, and individual coaches jointly form a complex service system, shifting the focus of governance from a single operational performance to diversified service supply, resource allocation, and community responsiveness. Sports centers need to establish coordination mechanisms between operators, professional organizations, coaches, and diverse users to respond to the needs of inclusive governance.

2.2 Inclusive governance and social participation

Inclusive governance emphasizes that different social groups can access, use, and continue to participate in public services fairly. Although exercise is often seen as an important tool for promoting social connections and health and well-being, relevant research reminds us that sports participation itself does not necessarily lead to social inclusion. Without institutional design, resource support, and barrier to participation, the sports field may still reproduce gender, age, class, or ability differences (Coalter, 2017; Jeanes et al., 2021). Therefore, inclusive governance in sports centers should focus on accessibility, affordability, diversity of participation, and service responsiveness, and reduce the risk of exclusion of specific groups through transparent decision-making and user feedback (Table 1).

Table 1: Research Aspects of Inclusive Governance in Sports Centers

face	Description
Accessibility	venue, fees, time slots, transportation, and information accessibility
Participation diversity	Teenagers, the elderly, beginners, people with disabilities, general athletes, etc. participated in a variety of activities
Service responsiveness	Responsiveness to the needs of different groups
Stakeholder coordination	Coordination between governments, operators, coaches, communities, and users
Trust and transparency	Transparent decision-making, reasonable fees, and fair venue allocation

2.3 ESG and sustainable sports services

In recent years, sustainability has become an important topic in sports management research. Movement organizations not only need to deal with environmental impacts but also face challenges such as social responsibility, governance transparency, and stakeholder trust. The sustainable sports management literature points out that the sustainable development of the sports industry has encompassed aspects such as environmental governance, social inclusion, health promotion, and institutional accountability (Hautbois & Desbordes, 2023). When ESG is applied to sports center governance, E (Environmental) can correspond to energy saving, facility efficiency, and resource use. S (Socia) can correspond to health promotion, disadvantaged accessibility, and participation diversity; G (Governance) involves information disclosure, fair site allocation, operational accountability, and cross-departmental collaboration (Table 2). Recent ESG campaign governance

research also advocates that movement organizations need to establish actionable ESG implementation paths, rather than just making sustainability an image statement (Yu & Jeong, 2025).

Table 2: ESG is applied to ESG and observation indicators in sports centers

ESG	The meaning of sports center governance	Observable metrics
E	Energy saving, low-carbon venues, equipment maintenance, resource efficiency	energy use, carbon emissions, facility efficiency
S	Social inclusion, health promotion, access to the disadvantaged, and participation in diversity	participation rate, disadvantaged participation rate, satisfaction
G	Transparent governance, stakeholder collaboration, accountability, and resource allocation	Decision-making transparency, grievance response, and cooperation mechanisms

2.4 System dynamics and sports service governance

Systems dynamics is suitable for analyzing complex governance problems with multiple stakeholders, time delays, resource constraints, and feedback effects. Sterman et al. pointed out that system dynamics can help researchers understand cross-functional, nonlinear, and long-term cumulative management system behavior (Sterman et al., 2015). For example, increased participation may increase revenue and community trust, but if service capacity is not expanded simultaneously, it may also lead to congestion, decreased satisfaction, and user churn. Therefore, inclusive governance in sports centers should not be measured only by static performance indicators, but should be analyzed through causal loop diagrams and stock flow models to analyze the dynamic relationship between participation, capacity, trust, satisfaction, and resource reinvestment.

2.5 Literature gaps and analytical propositions

Based on the above literature, existing studies have discussed sports governance, social inclusion, sustainable sports services, and systems dynamics methods, but few have integrated the four into the dynamic model of inclusive governance in sports centers. In particular, existing research is biased towards institutional descriptions, governance principles, or performance evaluations, and rarely explains how inclusive governance is formed, strengthened, or declined through feedback loops over time. Based on this, this study proposes five analytical propositions: P1, participation in diversity enhancement will enhance community trust and public value; P2, insufficient service capacity will weaken the positive effect of participation growth on satisfaction; P3, improved governance transparency will promote user trust and continuous participation; P4, financial pressures may compress inclusive investment and improve exclusion risks; P5, adaptive governance can improve resource allocation through user feedback, thereby strengthening the sustainable service capabilities of sports centers. This integrated perspective can complement the lack of discussion of dynamic mechanisms and long-term policy effects in movement governance research (Madsen & Glebova, 2025; Shilbury et al., 2016;)。

3 Research methodology

3.1 Study design

This study adopts a conceptual system dynamics research design to construct a dynamic model of inclusive governance in the sports center, rather than a single cross-sectional causal test. System dynamics emphasizes the interaction between stock, flow, feedback loops, and time delays in social system behavior, and is suitable for analyzing the effects of multi-stakeholder, resource constraints, and policy interventions in public service governance (Forrester, 1961; Sterman, 2002). This study positions the sports center as a complex governance system that combines the government, outsourced operators, professional sports organizations, coaches and users. System dynamics is designed to understand complex system structures and dynamic behaviors, and has been widely used in the analysis of management and public policy issues.

3.2 Study scope and model boundaries

This study takes urban public sports centers as the analysis field, and the model boundaries cover three types of actors: first, the governance and operation side, including local governments, outsourcing operators, and venue managers; second, the service supply side, including professional sports organizations and individual coaches; Third, the user side, including teenagers, the elderly, beginners, regular exercisers and disadvantaged groups. The study focused on inclusive governance-related variables such as service capacity, participation

diversity, accessibility, satisfaction, trust, governance transparency, and resource reinvestment. The literature on sports governance points out that the governance of sports organizations has expanded from internal management to the integration of systems, stakeholders, and accountability, so this study regards the sports center as a multi-party collaborative governance system (Dowling et al., 2018;

Table 3: Model boundaries

category	Scope of inclusion
field	Urban public sports center
Service Providers	Outsourcing operators, professional sports organizations, and individual coaches
Users	Teenagers, the elderly, beginners, regular exercisers, and disadvantaged groups
Governance variables	Transparency, coordination, resource allocation, and feedback mechanisms
Operational variables	Service capacity, venue utilization, course supply, and financial reinvestment
Social variables	Engagement rate, participation diversity, satisfaction, trust, retention

3.3 System Dynamics Modeling Program

This study was conducted according to a five-stage modeling process: first, to define the problem scenario and illustrate the governance tension between operational efficiency, publicity and inclusive participation of sports centers; second, it proposes dynamic hypotheses to illustrate that a reinforcement or equilibrium loop may be formed between participation, trust, capacity, and resource reinvestment; third, establish a causal circuit diagram to identify the main positive and negative causal relationships; Fourth, establish a stock flow model and set inclusive participation, service capacity, trust capital and governance capabilities as core stocks; Fifth, conduct scenario simulations to compare the long-term effects of different governance strategies. Group modeling studies have also shown that system dynamics models can help stakeholders build consensus and promote organizational learning and policy commitment (Vennix, 1996).

3.4 Core variable design

The core stock of this study includes "inclusive participation stock", "service capacity stock", "trust capital stock", "governance capacity stock" and "financial resource stock". The main traffic includes new participant inflow, continuous participation flow, churn flow, capacity expansion flow, capacity depreciation flow, trust accumulation flow, and trust depletion flow. Secondary variables include service satisfaction, venue congestion, affordability, curriculum diversity, governance transparency, and inclusive investment. This design reflects that sports center governance is not a single performance variable, but an interplay between social participation, service quality, financial sustainability, and governance trust. The core variables are summarized in Table 4.

Table 4. Core Variables of Sports Center Inclusive Governance System Dynamics Model

Type	Variable name	Description
Stock	Inclusive Participation	The cumulative degree of participation of different ethnic groups
Stock	Service Capacity	Venues, courses, coaches and equipment can be serviced
Stock	Trust Capital	User trust in the governance and services of the sports center
Stock	Governance Capability	Organizational coordination, transparent decision-making, and responsiveness
Stock	Financial Resource Base	resources that can be invested in facilities, curriculum and inclusive services
Flow	Participation Inflow	New users join and engage with underprivileged groups
Flow	Retention Flow	User engagement continues
Flow	Dropout Flow	Loss due to crowding, dissatisfaction, or cost pressure
Auxiliary	Satisfaction	feelings about service quality, accessibility, and fairness
Auxiliary	Congestion	Service pressure created by demand exceeding capacity
Auxiliary	Inclusion Investment	barrier-free facilities, preferential courses, diversified curriculum design, etc

3.5 Scenario simulation design

This study plans five sets of scenarios: S0 (Baseline) is the baseline scenario, assuming that the existing capacity and governance model are maintained; S1 (Inclusive Program Design) designs scenarios for inclusive courses, adding courses that are friendly to the elderly, beginners, and disadvantaged groups; S2 (Capacity

Allocation Policy) is a capacity allocation scenario that adjusts venues and course resources according to peak and off-peak needs and group characteristics. S3 (Transparent Adaptive Governance) aims to transparently adapt to governance scenarios, strengthen information disclosure, user feedback, and stakeholder coordination; S4 (Cost-Pressure Scenario) is a cost-pressure scenario that simulates a decline in inclusive investment due to increased financial pressure. Scenario simulations will compare the long-term impact of each strategy on engagement diversity, service satisfaction, trust capital, and sustainable operations.

Table 5: Scenario simulation design

Scenario	Description	Expected effect
S0	Maintain existing governance and capacity allocation	Participation grows slowly and may be limited by capacity
S1	Increase senior, beginner, disadvantaged and family-friendly courses	Enhance participation diversity and social value
S2	Adjust capacity according to peak off-peak, group needs and site utilization	Reduce crowding and increase satisfaction
S3	Strengthen information disclosure, user feedback, and stakeholder coordination	Increase trust, retention, and re-engagement
S4	Financial pressure is rising and inclusive investment is declining	It may lead to the exclusion of vulnerabilities and a decline in trust

Model checks are based on structural rationality, variable unit consistency, extreme condition testing, and behavior pattern checking. The simulation results are not intended to predict a single value, but to compare the trends of system behavior arising from different governance strategies. Lane (2000) points out that system dynamics is not a deterministic prophetic tool, but rather a policy learning method that helps understand how structures partially shape behavior. Therefore, this study uses scenario simulation as a governance strategy comparison and management learning tool to identify possible positive loops and unexpected exclusion effects.

4 Research results

4.1 Research Framework

The results of this study present a "dynamic model of the inclusive governance system of sports centers" (Figure 1). This model takes ESG as the upper governance principle, linking public sports services, participation diversity, service capacity, user trust, and resource reinvestment. The sports center is not just a venue, but a service ecosystem composed of the government, outsourced operators, professional sports organizations, coaches and users, involving multiple operations and inclusive governance. Sports participation research also pointed out that there is a cross-sectoral linkage between public policy, facility supply, and user health, well-being, and social capital, so it is suitable for a systematic perspective (Kumar etal., 2018).

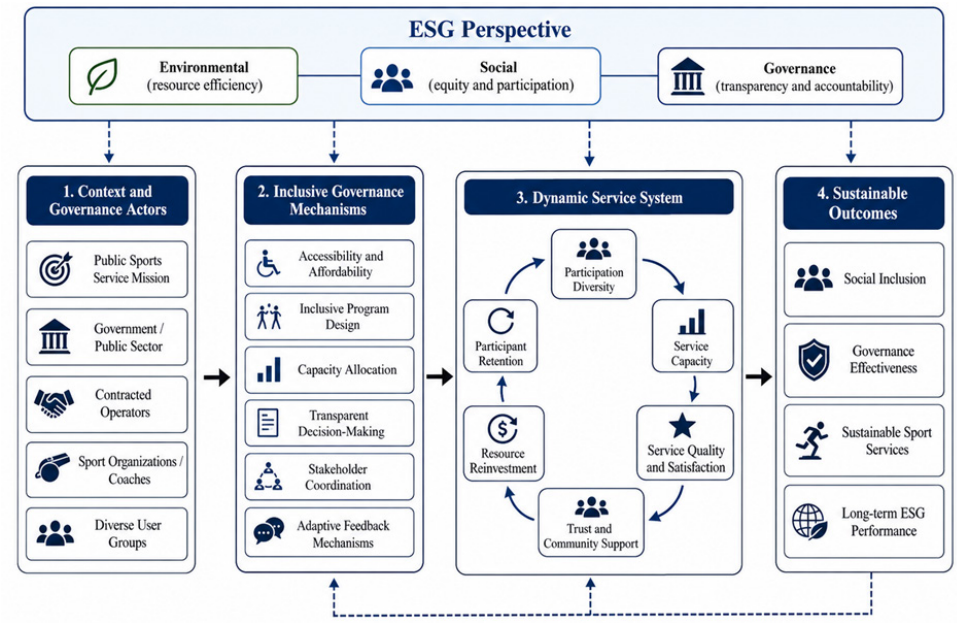

Figure 1: Research Framework of Inclusive Governance of Sports Centers

4.2 Causal circuit analysis

The causal loop diagram shows that the model in this study (Figure 2) contains three reinforcement loops and two equilibrium loops, which are summarized in Table 6。 R1 "Participation-Trust Enhancement Loop" explains that increasing participation diversity can increase community recognition and public trust, thereby promoting re-participation. R2 "Service Quality - Retention Enhancement Loop" shows that improved service quality will enhance satisfaction, retention rate, and stable revenue, allowing sports centers to have more resources to reinvest in courses and facilities. R3 "Governance Transparency - Stakeholder Support Strengthening Loop" points out that information disclosure and feedback mechanisms can enhance trust and collaboration capabilities. In contrast, the B1 "congestion-service dilution balance loop" shows that if the increase in participation exceeds capacity, it will lead to congestion, decreased satisfaction, and churn. B2 "Cost Pressure-Inclusive Investment Restriction Loop" pointed out that financial pressure may compress public welfare courses and support for the disadvantaged. This result echoes the emphasis placed in the movement governance literature on institutions, accountability, and stakeholder interaction (Dowling et al., 2018; Shilbury et al., 2016) .

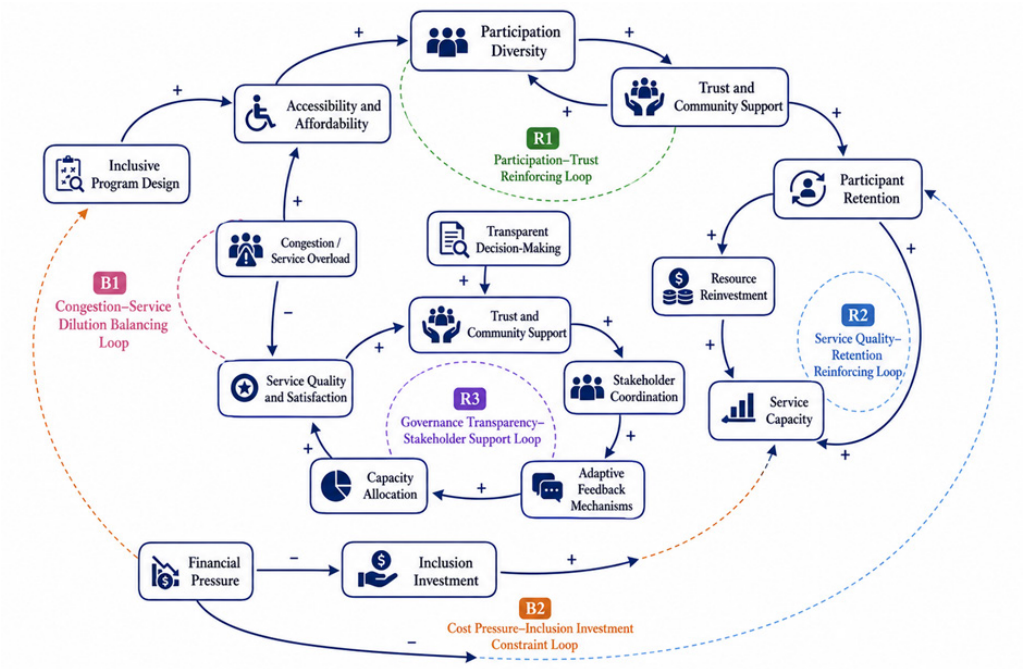

Figure 2: Causal Loop Diagram of Sports Center Inclusive Governance

Table 6: Type of Causal Loop Diagram on Sports Center Inclusive Governance

circuit	Type	Description
R1 Participation–Trust Reinforcing Loop	Strengthen the circuit	Increased participation → Increased community identity → Increased trust → increased re-participation
R2 Service Quality–Retention Reinforcing Loop	Strengthen the circuit	Service Quality Improvement → Satisfaction Improvement → Retention Rate Improvement → Stable Revenue and Reinvestment
R3 Governance Transparency–Stakeholder Support Loop	Strengthen the circuit	Increased transparency → Increased trust → Stakeholder support → Improved governance capabilities
B1 Congestion–Service Dilution Balancing Loop	Balance circuit	Increased participation → increased congestion → decreased satisfaction → inhibited participation growth
B2 Cost Pressure–Inclusion Investment Constraint Loop	Balance circuit	Increased financial pressure → Decline in inclusive investment → Decrease in disadvantaged participation → Decrease in public value

4.3 Stock flow model results

The stock flow model (Figure 3) sets "inclusive participation stock", "service capacity stock", "trust capital stock", "governance capacity stock" and "financial resource stock" as core stock. The model results show that inclusive participation is not only affected by the number of courses, but also by service capacity, affordability, course adaptation, governance transparency, and trust accumulation. When service capacity and governance capabilities increase simultaneously, participation inflow and retention flow will increase; Conversely, capacity depreciation, crowded venues, or opaque decision-making can increase churn and trust erosion. System dynamics emphasizes that the behavior of complex service systems often stems from feedback, latency, and cross-functional interactions rather than single-variable effects (Sterman et al., 2015; Sterman, 2002)。

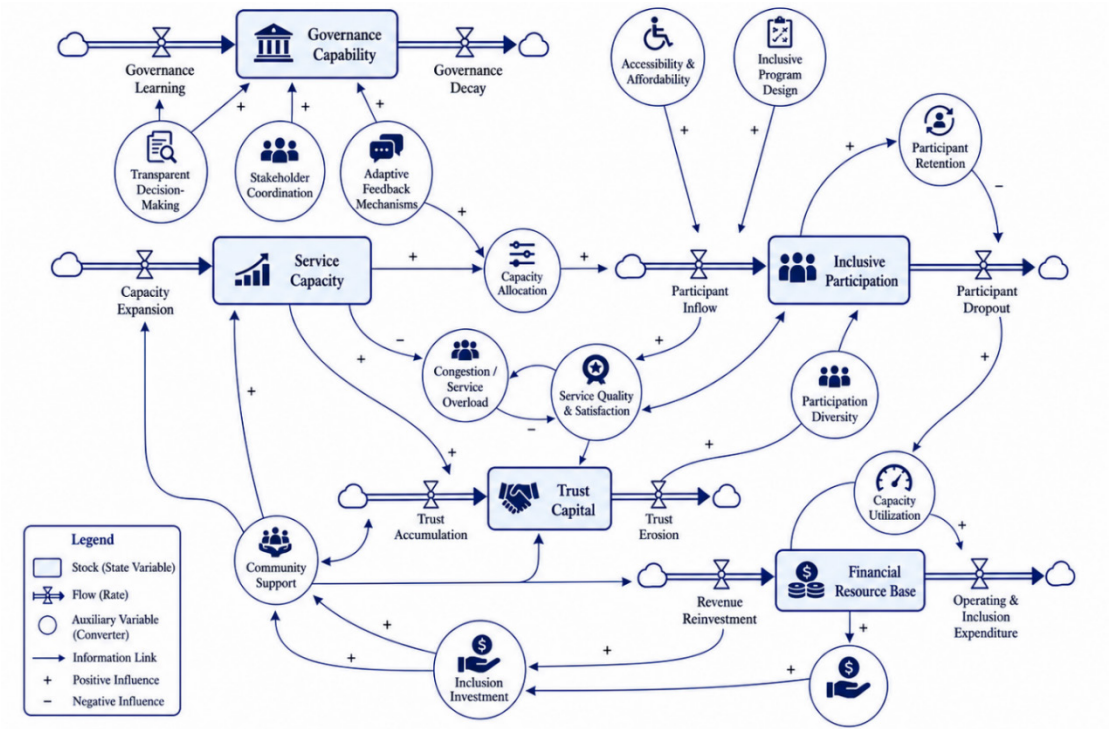

Figure 3: Stock-and-Flow Model of Inclusive Sports Center Governance

4.4 Scenario simulation results

Scenario simulations compare five governance strategies. In the S0(baseline scenario), the number of participants increases initially, but slows down later due to capacity constraints. The S1(Inclusive Program Design) is designed to increase the participation of the elderly, beginners, and disadvantaged groups, but if the capacity is not adjusted simultaneously, satisfaction may decrease. S2(Capacity Allocation) capacity configuration scenarios reduce peak congestion and improve service quality and retention. S3(Transparent Adaptive Governance) Transparently adapts to governance scenarios is the most stable for trust capital and long-term engagement, as it can continuously modify resource allocations through user feedback. The S4(Cost Pressure) cost stress scenario shows negative outcomes: inclusive investment declines, disadvantaged participation decreases, and public trust decreases. This result (Table 6) also echoes the view of social inclusion research: sports participation does not necessarily lead to inclusion, but must be supported through theoretical orientation and institutionalized design (Coalter, 2017).

Table 6: Scenario Simulation Results of Inclusive Governance Strategies

Scenario	Overall Interpretation
S0	Under the existing governance model, various indicators grew slowly, but in the later stage, due to insufficient service capacity and governance adjustment, the overall performance tended to flatten.
S1	Inclusive curriculum design is the best way to increase participation diversity, but if capacity allocation is not improved simultaneously, service satisfaction may be limited by congestion.
S2	Capacity allocation strategies can effectively reduce congestion, improve service satisfaction and retention, and significantly contribute to operational stability.

Scenario	Overall Interpretation
S3	Transparent adaptive governance performs best overall, strengthening engagement, trust, service quality, and long-term ESG governance performance at the same time.
S4	Cost stress scenarios have led to a decline in inclusive investment, worsening participation diversity, satisfaction, and trust capital.

4.5 Summary of key findings

This study summarizes five key findings: First, the key to inclusive governance in sports centers is not simply to increase utilization, but to balance participation growth with service capacity. Second, trust capital is the core intermediary mechanism that connects engagement, satisfaction, and long-term retention. Third, governance transparency and user feedback can form adaptive governance capabilities. Fourth, if financial pressure takes precedence over public value, it will increase the risk of eliminating the vulnerable. Fifth, systems dynamics can integrate ESG, inclusive governance, and sports service management into a simulated decision support framework.

5 Discussion

5.1 Theoretical implications

This study regards sports centers as a "public sports service governance system" rather than a single venue management unit, supplementing the existing sports governance research that focuses on system, board of directors, or organizational performance. Movement governance research has pointed out that governance issues involve institutional arrangements, accountability, stakeholder relations, and power allocation (Dowling et al., 2018). Collaborative governance research also emphasizes the need for movement organizations to address complex public issues through cross-organizational coordination (Shilbury et al., 2016). Therefore, the theoretical implications of this study are to show that inclusive governance is not a static norm, but a dynamic process formed by participation, trust, capacity, and resource reinvestment.

5.2 ESG and system dynamics integration

This study translates ESG into a modelable governance structure: E corresponds to facility energy efficiency and resource allocation, S corresponds to participation diversity, health promotion, and social inclusion, and G corresponds to transparent decision-making, accountability, and stakeholder alignment. System dynamics emphasizes that the behavior of complex service systems often comes from feedback, delays, and cross-departmental interactions, rather than a single factor linear effect (Sterman et al., 2015). Therefore, this study uses a causal loop and stock flow model to transform ESG from an evaluation indicator into a dynamic governance mechanism.

5.3 Management implications

For sports center managers, the results show that increasing utilization does not necessarily mean governance success. If service capacity, venue configuration, and course design are not synchronized, increased participation can lead to congestion, decreased satisfaction, and user churn. Social inclusion research also points out that sports participation requires theoretical orientation and institutional support, otherwise it is difficult to naturally produce fairness and inclusion effects (Coalter, 2017). Therefore, managers should establish user feedback mechanisms, off-peak capacity adjustments, disadvantage-friendly courses, and transparent information disclosure systems.

5.4 Policy implications

For policymakers, outsourcing performance of sports centers should not be measured solely by revenue, attendance, or venue utilization, but should include indicators such as participation diversity, disadvantaged accessibility, service satisfaction, governance transparency, and community trust. This study pointed out that public sports centers should be positioned as health promotion and social inclusion infrastructure, rather than simply operating venues. This perspective also echoes the positioning of sports centers as platforms for public health, social inclusion, and community well-being.

6 Conclusion

6.1 Research conclusions

This study constructs an inclusive governance model for sports centers from the perspective of system dynamics, showing that sports centers are not only service units that provide courses and venues, but also a public sports service system composed of the government, outsourcing operators, professional organizations, coaches, and multiple users. This positioning positions the Sports Center as a platform for public health, social inclusion, and community well-being. The results point out that the key to inclusive governance lies in the dynamic balance between participation diversity, service capacity, trust capital, governance transparency, and resource reinvestment. If the governance mechanism can strengthen user feedback, capacity allocation, and disadvantaged accessibility, it will form a positive cycle of "participation-trust-re-investment"; Conversely, excessive pursuit of usage and short-term revenue can lead to congestion, decreased satisfaction, and exclusion. This finding echoes the emphasis placed on stakeholder coordination and accountability in movement governance research, and is also in line with the analytical perspective of system dynamics on feedback, delay, and cross-departmental interactions (Dowling et al., 2018; Shilbury et al., 2016; Sterman et al., 2015).

6.2 Study limitations

This study is a conceptual system dynamic model and has not yet used actual sports center operation data for parameter calibration. Different cities, outsourcing systems, charging models, and user structures may also affect the applicability of the model. In addition, this article mainly discusses the overall mechanism of inclusive governance, and there is still room for deepening the barriers to participation of subgroups such as the elderly, people with disabilities, low-income groups, or female users. Research on social inclusion in sports also reminds that sports participation does not necessarily produce natural inclusive effects and still needs to be verified through theory-oriented evaluation and institutionalized design (Coalter, 2017).

6.3 Future research suggests

Future research can collect data on the flow of people in sports centers, course registrations, satisfaction, complaints, charges, and energy usage to calibrate the stock flow model and conduct scenario simulations. Secondly, it can be combined with interviews, questionnaires, and group modeling to incorporate the perspectives of governments, operators, coaches, and users. Finally, the ESG Inclusive Governance Dashboard can be further developed as a decision-making support tool for public value, operational sustainability, and social inclusion in sports centers.

7 Ethics Statement

This study does not address research ethics issues.

[2] Department of Business Administration, Shih Chien University. Taipei, Taiwan

Abstract

This study aims to construct a smart and sustainable preschool governance model based on Environmental, Social, and Governance (ESG) principles by integrating artificial intelligence (AI)-enabled decision support and system dynamics (SD). Faced with multiple challenges such as declining birth rates, teacher stability, educational quality assurance, resource constraints, and sustainability expectations, preschools are no longer merely care and educational settings but also important early learning organizations that promote educational equity, organizational resilience, and sustainable development. This study adopts conceptual modeling and scenario-based analysis. First, ESG principles are translated into core governance variables, including environmental efficiency, social equity, teacher support, parental trust, and governance transparency. Second, causal loop diagrams (CLDs) are used to construct reinforcing and balancing loops related to AI data learning, teacher quality, governance transparency, cost pressure, and teacher workload. Third, a stock-and-flow model (SFD) is developed to explain the long-term accumulation mechanisms among educational quality, AI governance capability, ESG performance, and institutional resilience. The scenario analysis suggests that the integrated AI-enabled ESG governance scenario is expected to generate the strongest long-term improvements. The research results show that AI should not be seen as a tool to replace the education profession, but should be used as an important foundation to support knowledge management, policy simulation, and sustainable governance decision-making in preschools.

Keywords: ESG governance, artificial intelligence, system dynamics, smart preschool, sustainable education governance

Paper type: Academic Research Paper

1 Introduction

As an important field for early education and family support, preschools are facing multiple pressures such as improving education quality, the impact of declining birth rates, teacher stability, resource constraints, and sustainable governance requirements. Heckman (2006) pointed out that early ability formation has a dynamic cumulative effect, and early investment will affect subsequent educational and social outcomes. Nores and Barnett (2010) also found that early education interventions can deliver long-term benefits of cognitive, behavioral, health, and learning outcomes in different country contexts. This perspective suggests that preschool governance should not be viewed as a mere administrative issue, but should be understood as a public governance issue related to educational equity, social resilience, and sustainable development.

In recent years, sustainability and Environmental, Social, and Governance (ESG) principles have gradually expanded from corporate governance to educational organizations. Early sustainability education research indicates that preschools can cultivate children's initial understanding of nature, social responsibility, and sustainable living through games, life practices, and environmental exploration (Engdahl & Furu, 2022). Borg and Samuelsson (2022) also emphasize that young children are not merely passive recipients of sustainability education; rather, they can demonstrate agency as active learning subjects through participation and action. Recent eco-program research in preschools further points out that sustainable early childhood education should integrate ecological, social, and economic aspects rather than being limited to environmental education activities (Vodopivec & Šindic, 2025).

Existing research mostly focuses on sustainable education curricula, early childhood learning activities, or teacher attitudes, and there is still a lack of systematic models for how ESG principles translate into preschool governance indicators, resource allocation mechanisms, and long-term performance management. Although the Korean daycare ESG study found a positive correlation between ESG management and teachers' awareness of social issues and environmentally friendly education attitudes, it still favored cross-sectional empirical

evidence and less dealt with the time delay and feedback relationship between governance variables (Lim & Kim, 2025).

The application of artificial intelligence (AI) in education is expanding rapidly, and relevant research points out that AI can support personalized learning, predictive analytics, and educational decision-making, but it also involves data ethics, algorithmic bias, and governance accountability issues (Strielkowski et al., 2025; Zawacki-Richter et al., 2019). Therefore, AI should not be simplified as a teaching tool in preschools, but should be positioned as a knowledge management foundation to assist preschools in data analysis, policy simulation, and governance decision-making.

Based on the above gaps, this study extends the previous research positioning by integrating ESG governance, AI-enabled decision support, and system dynamics modeling into a smart and sustainable preschool governance framework. System dynamics is suitable for analyzing policy issues with time delays, nonlinearity, and feedback loops in education systems, and can help uncover the dynamic relationship between teacher quality, child development, resource allocation, parental trust, and governance transparency (Groff, 2013). Therefore, the purpose of this study is: first, to construct the core variables of ESG education governance in preschools; second, causal loop diagrams (CLDs) and a stock-and-flow model (SFD) are used to present the governance feedback structure; Third, AI-supported ESG policy scenarios are analyzed to assess their impact on education quality, organizational resilience, and sustainability performance.

The main questions of this study are: 1. What are the core ESG variables of the smart sustainable preschool governance system? 2. How does AI-supported data analysis improve the quality of preschool governance decision-making? 3. What reinforcing and balancing loops exist among teacher quality, parental trust, resource allocation, and child development? 4. What are the differences between different ESG policy scenarios on the long-term governance performance of preschools?

2 Literature review

2.1 ESG principles and educational governance

ESG principles were originally used to evaluate an organization's sustainability performance in environmental, social, and governance aspects, but in recent years, they have gradually extended to the field of education governance. For educational institutions, Environmental can be transformed into campus resource efficiency, energy conservation and carbon reduction, and environmental education. Social can connect educational equity, child well-being, teacher support and family participation; Governance involves transparent decision-making, budget accountability, data governance, and stakeholder communication. Higher education research points out that ESG implementation should not be limited to curriculum or image claims, but should be included in organizational governance, operation management, and sustainability performance evaluation. Research by childcare institutions also shows that ESG management can enhance the awareness of education and care workers about social issues and environmentally friendly education. Therefore, preschools can be regarded as sustainable education organizations with public responsibility, rather than mere care service units (Rosli & Azmi, 2025; Finatto et al., 2024).

Table 1: preschool governance under the ESG dimension

ESG aspect	The meaning of preschool governance	Possible variables
Environmental	Energy conservation, carbon reduction, green campus, environmental education	energy use, water resource use, and investment in green facilities
Social	Educational Equity, Child Well-being, Teacher Support, Family Engagement	affordability, disadvantaged enrollment rate, teacher satisfaction, child development
Governance	Transparent governance, data ethics, financial accountability, parental communication	Budget transparency, data governance maturity, parental trust

2.2 Sustainable Early Childhood Education and Early Learning Organization

Sustainable early childhood education emphasizes the formation of sustainable values in children's daily lives, games, environmental exploration, and social interactions. Engdahl and Furu (2022) pointed out that early childhood education is suitable as an early stage for sustainable social transformation due to its holistic, life-oriented, and child-centered nature. Borg and Samuelsson (2022) further emphasize that young children are not passive recipients of sustainable education but can demonstrate agency through participation, expression, and action. It can be seen that if preschools want to become early learning organizations, they must pay attention

to child development, teacher professionalism, family participation, and organizational learning capabilities, and upgrade sustainability from curriculum activities to organizational governance logic.

2.3 AI-powered educational governance and knowledge management

The application of AI in education has gradually expanded from personalized learning, learning analysis, and risk prediction to administrative management and governance decision-making. A systematic review by Zawacki-Richter et al. (2019) pointed out that AI education research has covered intelligent teaching systems, assessment, prediction, and support services, but it still needs to pay attention to the role of educators and ethical issues. Strielkowski et al. (2025) also point out that AI-driven adaptive learning can facilitate educational transformation, but it must be integrated with sustainability goals, accessibility, and equity. From the perspective of knowledge management, Alavi and Leidner (2001) regard information technology as an important foundation to support the creation, storage, transfer, and application of knowledge in organizations. Recent AI and knowledge management research reminds that while AI can improve knowledge processing capabilities, it also poses challenges in data quality, trust, ethics, and organizational implementation (Rezaei, 2025). Therefore, this study positions AI as a decision support and knowledge transformation tool for preschool governance, rather than an automated mechanism that replaces professional judgment by teachers and principals.

2.4 Application of System Dynamics in Educational Policy and Governance Research

Educational governance has the characteristics of multiple feedbacks, time delays, and policy trade-offs, making it suitable for system dynamics analysis. Groff (2013) pointed out that system dynamics models can help education policy researchers identify hidden system structures and simulate future policy scenarios. Kennedy (2011)'s review of the dynamic model of education policy systems also shows that system dynamics (SD) has been used for planning, resource allocation, and policy evaluation at the school, regional, and tertiary levels. Pedamallu et al. (2010) used primary education enrollment as an example to illustrate the interaction between infrastructure, teaching quality, sense of community, and educational accessibility. Therefore, the long-term dynamics of teacher quality, enrollment stability, parental trust, financial resources, and sustainable investment in preschool governance can also be presented through causal loop diagrams and stock-and-flow models.

2.5 Literature gaps and research framework derivation

In the literature review , the introduction of ESG education, sustainable early childhood education, AI education applications, and dynamic models of education systems have been discussed, but there are still three gaps: first, the indicatorization and systematic application of ESG in preschool governance are still insufficient; Second, AI education research mostly focuses on learning or teaching, and rarely explores its role in preschool governance, resource allocation, and accountability. Third, existing research on sustainability in early childhood education rarely deals with dynamic feedback between teacher quality, child development, parental trust, governance transparency, and resource constraints. Based on this, this study extends the aforementioned research positioning and constructs an integrated framework of "ESG Principles-AI Decision Support-System Dynamic Simulation" to analyze the governance mechanism and policy scenarios of smart and sustainable preschools.

3 Research methodology

3.1 Study design

This study adopts conceptual modeling and scenario simulation research design, using system dynamics as the main method to construct an AI-supported ESG preschool education governance model. System dynamics is suitable for dealing with common feedback loops, time delays, and policy trade-off problems in education governance. Groff (2013) pointed out that system dynamics models can be used in education policy design and simulation to help researchers understand the long-term behavior of complex education systems. Sterman (2000) also emphasizes that SD modeling can analyze complex organizational systems through problem definition, dynamic assumptions, model building, testing, and policy design.

ESG defines the normative governance goals, AI provides data-driven analytical and decision-support capabilities, and system dynamics offers a modeling approach for understanding feedback structures, time delays, and policy trade-offs in preschool governance.

3.2 System boundaries and units of analysis

In this study, the term "preschool" refers broadly to early childhood education and care institutions serving young children before primary schooling, including kindergartens and daycare centers where applicable. The unit of analysis is the preschool institution. Preschool principals are considered key governance actors, while the system boundaries cover educational quality, teacher professional capacity, child development, parental trust, resource allocation, environmental efficiency, governance transparency, and AI decision-support capability.

3.3 Core variable design

The core variables are organized into several categories: first, education quality, including teachers' professional ability, teacher-student interaction quality, and child development outcomes; Early education research shows that teacher professional development and teaching quality affect early childhood learning and social-emotional development (Brunsek et al., 2020). Second, social equity, including affordability, access to preschool for disadvantaged children, and family support. Third, parental trust, including home communication, information transparency and parental participation; Family engagement research points out that parent-teacher relationships have a significant impact on early education outcomes (Otero-Mayer et al., 2025). Fourth, environmental performance, including energy, water resources, and green campus investment. Fifth, governance transparency, including budget disclosure, performance disclosure, and data ethics. Sixth, AI governance capabilities, including predictive analysis, resource allocation suggestions, risk warnings, and scenario simulations. These variables are organized in Table 2.

Table 2: Core Variables of AI-empowered ESG Preschool Governance Model

category	variable	Operational definitions	ESG correspondence
Quality of education	Teacher Quality	Teachers' professional ability, stability and teaching quality	S
Child development	Child Development Outcomes	Cognitive, social-emotional and learning readiness	S
Parental trust	Parental Trust	Parents' trust in the quality, transparency, and safety of the preschool	S/G
Governance capabilities	Governance Transparency	The degree of disclosure of budget, quality, and decision-making information	G
AI capabilities	AI Decision Support Capability	Data analysis, forecasting, simulation, and decision support capabilities	G
Environmental performance	Environmental Efficiency	energy, water resources, and campus environmental efficiency	E
Financial resources	Funding Availability	income, grants, investments, and working capital	G
Accessibility	Access Equity	Disadvantaged families, affordability, and access to preschool	S

3.4 Causal Loop Diagram (CLD) Design

This study establishes a causal loop diagram (CLD) to present the reinforcing and balancing loops in the preschool governance system. Three reinforcing loops are identified: R1, the "AI Data Learning–Governance Quality Reinforcing Loop," illustrates how AI analytics capability improves decision quality and resource allocation efficiency; R2, the "Teacher Quality–Child Development Reinforcing Loop," explains how teacher professional support promotes child development and parental trust; and R3, the "Governance Transparency–Parental Trust Reinforcing Loop," shows how transparent governance strengthens parental trust and feedback data quality. In addition, two balancing loops are identified: B1, the "Cost Pressure–Sustainability Investment Constraint Balancing Loop," and B2, the "Teacher Workload–Educational Quality Regulation Balancing Loop," which reveal the policy trade-offs between ESG investment and teacher workload pressure.

3.5 Stock-and-Flow Model Design

The stock-and-flow model (SFD) defines core stocks as Teacher Professional Capacity, Educational Quality Capital, Parental Trust Capital, AI Governance Capability, ESG Performance Stock, and Institutional Resilience. Corresponding flows include teacher professional growth rate, education quality improvement rate, trust accumulation rate, AI capability building rate, ESG investment rate, and resilience improvement rate. Groff

(2013) points out that stocks represent accumulated resources or capabilities in the system, while flows represent their rate of change; both can be used to simulate the behavior of the education system.

3.6 Scenario simulation design

This study plans five scenarios (Table 3): S0 baseline scenario; S1 Green Campus and Energy Saving Investment; S2 Educational Equity & Inclusion Enrollment; S3 Budget transparency and communication with parents; Integrated ESG governance powered by S4 AI. Pedamallu et al. (2010) used SD models to analyze the relationship between basic education enrollment and infrastructure, showing that scenario simulation is useful for evaluating education policy effectiveness. In this study, AI serves as a decision support tool for predicting needs, identifying risks, and comparing policy scenarios. Relevant studies also point out that AI education applications need to take into account human-centered control, stakeholder participation, and trusted governance (Zawacki-Richter et al., 2019; Alfredo et al., 2024).

To enhance model credibility, this study applies structural validation by comparing the proposed feedback loops with prior literature on early childhood education quality, ESG-oriented educational governance, AI-enabled education, and system dynamics modeling. Since this is a conceptual modeling study, parameter calibration and empirical validation are reserved for future research.

Since this study is positioned as a conceptual system dynamics modeling study, the scenario-based analysis is qualitative and theory-driven rather than parameter-based numerical simulation.

Table 3. Scenario Design for ESG-driven Preschool Governance Simulation

Situation	Policy setting	Main interventions	Expected effect
S0 Baseline	Maintain the current governance model	No additional AI or ESG investments	The quality of education is growing slowly, but it is susceptible to cost and teacher workload
S1 Eco-efficient Investment	Strengthen energy-saving and green facilities	environmental equipment, energy-saving management	Reduce operating costs and improve environmental performance over time
S2 Inclusive Enrollment Strategy	Strengthen educational equity	Subsidies for the disadvantaged, affordable programs	Improve social performance, but increase financial pressure in the short term
S3 Transparent Budget Governance	Strengthen governance transparency	Budget disclosure, parent communication platform	Enhance parental trust and engagement
S4 AI-enabled Integrated Governance	Integrate AI, ESG, and SD simulation	Predictive analytics, real-time dashboards, policy simulations	Improve overall resilience, quality, and governance accountability

4 Research results

4.1 ESG preschool governance Framework Results

The results of this study first establish a three-tier governance framework of "ESG Principles-AI Decision Support-System Dynamic Simulation" (Figure 1). Environmental is oriented towards energy, water resources, green campuses, and environmental education; The Social aspect corresponds to educational equity, child well-being, teacher support and family participation; The governance aspect corresponds to budget transparency, data ethics, performance disclosure, and parental trust. This framework continues the three core pillars proposed in the previous summary: ESG-aligned governance indicators, system dynamics feedback structures, and AI-driven data analytics (Finatto et al., 2024). Preschools are thus defined as an early learning organization, and their governance performance depends not only on administrative efficiency but also on the long-term accumulation of educational quality, social equity, and sustainability. Engdahl and Furu (2022) pointed out that early childhood education is an important field for sustainable social transformation. ESG education research also shows that the implementation of ESG in educational institutions should cover curriculum, operations, governance, and performance evaluation.

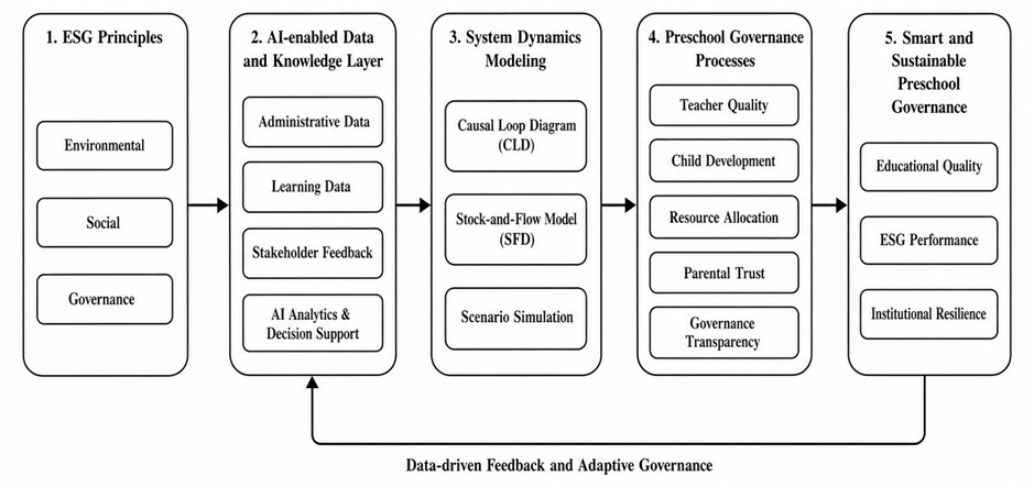

Figure 1: Research Framework of AI-empowered ESG Preschool Governance

4.2 Causal loop analysis results

The results of causal loop analysis (Figure 2) show that smart sustainable preschool governance includes at least three reinforcing loops and two balancing loops. R1, the " AI Data Learning–Governance Quality Reinforcing Loop " loop points out that after improving AI data analysis capabilities, it can improve enrollment prediction, teacher allocation, resource allocation, and risk warning, thereby improving governance quality and parental trust. The R2 " Teacher Quality–Child Development Reinforcing Loop " shows that teachers' professional support improves teaching quality, further promoting child development outcomes and parent satisfaction. R3 the " Governance Transparency–Parental Trust Reinforcing Loop " explains that budget and performance transparency can strengthen parental trust, increase parental feedback and participation, and thereby improve governance adaptability. This result echoes Alavi and Leidner's (2001) view of knowledge management systems: information technology can support knowledge creation, storage, transfer, and application.

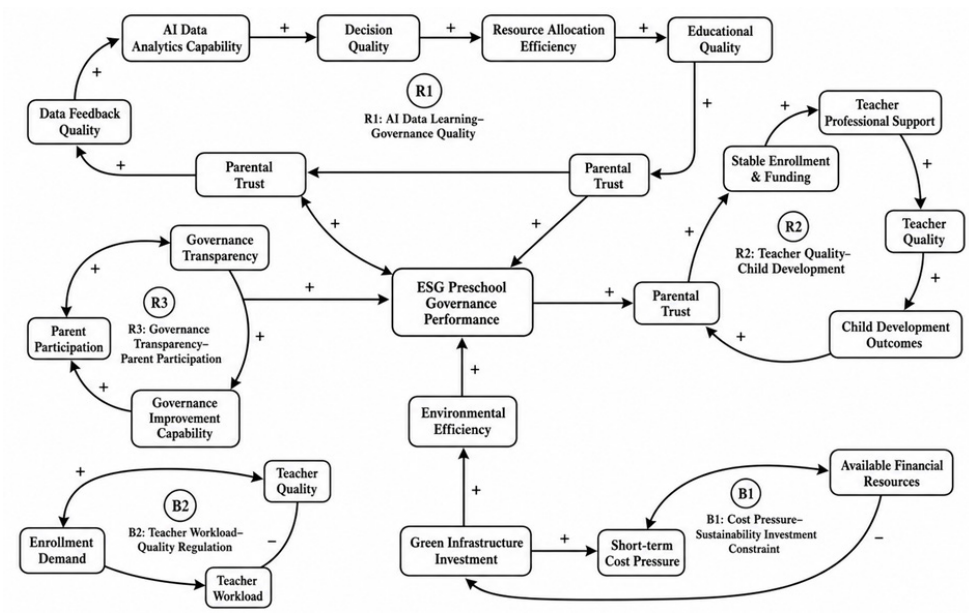

Figure 2: Causal Loop Diagram of AI-empowered ESG Preschool Governance System

At the same time, the model also reveals two restrictive structures. B1 " Cost Pressure–Sustainability Investment Constraint Balancing Loop" explains that although investment in green facilities and AI systems can improve long-term benefits, it may compress financial resources in the short term. B2 " Teacher Workload–Educational Quality Regulation Balancing Loop " pointed out that if the increase in enrollment is not synchronized with the expansion of teachers and support systems, it will increase teacher pressure and reduce the quality of education. A meta-analysis by Brunsek et al. (2020) pointed out that there is an important

association between the professional development of early childhood educators and children's outcomes, indicating that teacher competence is a key lever variable in the model.

4.3 Stock-and-Flow Model Results

The stock-and-flow model (Figure 3) decomposes preschool governance capabilities into six main stocks: Teacher Professional Capacity, Educational Quality Capital, Parental Trust Capital, AI Governance Capability, and ESG Performance Stock and Institutional Resilience. The corresponding flows include teacher professional growth rate, education quality improvement rate, trust accumulation rate, AI capability construction rate, ESG investment rate, and resilience improvement rate. This model shows that educational quality and parental trust cannot be formed quickly through short-term investment, but are gradually accumulated through teacher training, transparent governance, data feedback, and stable interaction. Groff (2013) pointed out that the system dynamics model helps to reveal hidden structures and long-term scenarios in the education policy system. Pedamallu et al. (2010) also pointed out that the quality and accessibility of basic education are influenced by the interaction of infrastructure, community conditions, and policy factors.

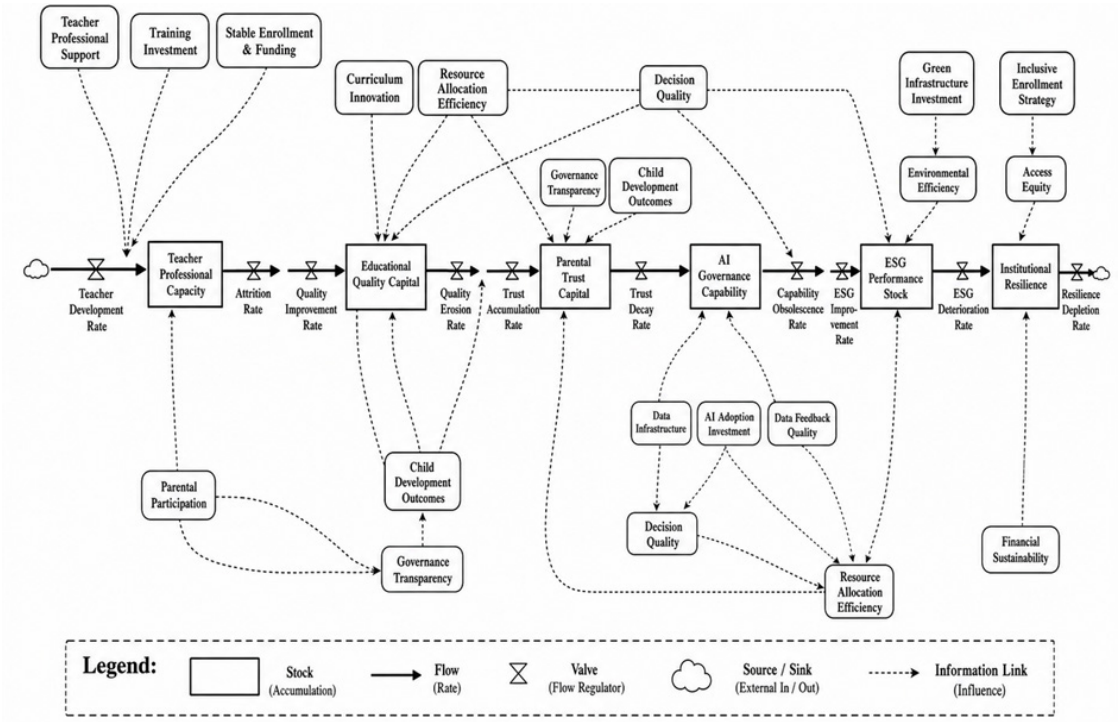

Figure 3. Stock-and-Flow Model of Smart and Sustainable Preschool Governance.

4.4 Scenario-based Analysis Results

As shown in Table 4, the scenario-based analysis suggests that under the S0 baseline scenario, education quality and parental trust only accumulate slowly, and are easily affected by teacher workload and financial constraints. S1 green campus investments can improve environmental performance, but short-term cost pressures are higher. S2 inclusive enrollment can improve educational equity, but the lack of subsidies and teacher allocation may lead to quality dilution. S3 transparent budget governance and parent communication can quickly increase trust capital. The S4 scenario "AI-Powered Integrated ESG Governance" is expected to generate the strongest long-term governance effects because it simultaneously enhances data analysis, policy forecasting, resource allocation, and performance tracking. Zawacki-Richter et al. (2019) pointed out that AI education applications have covered prediction, assessment, and support services, but they still need to incorporate educators' roles and governance ethics. Therefore, this study positions AI as a human-centered decision support rather than an automated alternative.

Table 4. Scenario-based Analysis Results of AI-enabled ESG Preschool Governance

Scenario	Scenario name	Result
S0	Baseline	Without additional policy intervention, various indicators only showed slow growth, and the overall improvement was limited.
S1	Green Infrastructure Investment	S1 is expected to primarily improve environmental and ESG-related performance, and it can moderately improve the quality of education and organizational resilience.
S2	Inclusive Enrollment Strategy	It helps improve educational equity and overall performance, but the improvement is relatively limited.
S3	Transparent Governance	The effect of improving trust in parents is the most significant, and simultaneously driving education quality and governance performance.
S4	Integrated AI-enabled ESG Governance	The integrated scenario is expected to improve all four dimensions more comprehensively than single-policy scenarios, indicating that integrating AI, ESG, and governance mechanisms can produce the strongest long-term synergies.

Summary of key findings

Overall, this study has five main findings (Table 5): First, ESG can be translated into environmental, social, and governance indicators for preschool governance; second, AI can enhance data-driven decision-making and governance knowledge transformation in preschools; third, teacher professional capacity and parental trust are core stocks of smart and sustainable preschool governance; Fourth, there is a policy trade-off between sustainable investment, educational equity and financial pressures; Fifth, a governance model that integrates AI, ESG, and system dynamics can enhance the long-term resilience and accountability of preschools more effectively than a single policy tool. Therefore, system dynamics is not only a model tool, but also a knowledge method for preschool administrators to conduct policy learning and strategy simulation (Groff, 2013; Pedamallu et al., 2010).

Table 5. Summary of Key Findings

Finding	Description
ESG can be translated into preschool governance indicators	Environmental, social, and governance goals can be operationalized in preschool management.
AI can enhance governance knowledge transformation	Administrative, learning, and stakeholder data can be converted into decision-support knowledge.
Teacher professional capacity and parental trust are core stocks	These two accumulated resources shape long-term preschool quality and legitimacy.
Sustainability investment involves policy trade-offs	Green investment, educational equity, and financial pressure interact dynamically.
Integrated AI–ESG–SD governance performs best	The integrated scenario produces stronger resilience and accountability than single-policy interventions.

5 Discussion

5.1 Theoretical contributions

The main theoretical contribution of this study is to extend ESG principles from corporate sustainability governance to preschool education governance, and to define preschools as early learning organizations that combine educational quality, social equity, and sustainability responsibilities. Existing research on early childhood sustainable education emphasizes children's participation, life practice, and environmental learning, pointing out that early childhood education is an important field for promoting sustainable social transformation. This study further elevates this perspective to the level of organizational governance, demonstrating that ESG can be used as an analytical framework for environmental management, teacher support, parental trust, and governance transparency in preschools (Engdahl & Furu, 2022).

5.2 Practical implications

In practice, this study suggests that preschool principals and education authorities can track key variables such as energy use, educational equity, teacher workload, parent engagement, and budget transparency through ESG indicator dashboards. System dynamics can help preschool leaders identify long-term feedback relationships between education quality, teacher pressure, resource allocation, and parental trust, avoiding

decision-making based solely on short-term enrollment or financial metrics. Groff (2013) pointed out that system dynamics models can reveal hidden dynamics in education policies and support future scenario design, making them suitable for preschool ESG policy simulations.

5.3 The significance of AI and ESG integration

The integration of AI and ESG is significant in transforming scattered administrative, instructional, resource-related, and parental feedback data in preschools into actionable governance knowledge. Alavi and Leidner believe that knowledge management systems can support the creation, storage, transfer, and application of organizational knowledge; AI can therefore serve as a knowledge base for ESG governance in preschools, assisting in predicting needs, allocating resources, and conducting scenario simulations (Alavi & Leidner, 2001). However, AI education applications still need to focus on educator roles, data ethics, and governance accountability, and avoid simplifying early childhood education to algorithmic management (Zawacki-Richter et al., 2019). Based on this, this study responds to the AI-driven analytics and ESG-aligned governance framework proposed in the previous summary, emphasizing that AI should be used as a human-centered decision support tool, rather than replacing the professional judgment of teachers and principals.

6 Conclusion

6.1 Research conclusions

This study constructs a preschool intelligent sustainable governance model of "ESG Principles-AI Decision Support-System Dynamic Simulation", pointing out that preschools are not only care and educational settings but also early learning organizations that cultivate sustainable literacy and social resilience. Research shows that ESG can translate into core variables such as environmental resource efficiency, educational equity, teacher support, parental trust, and governance transparency. AI can support enrollment forecasting, resource allocation, risk warning, and policy simulation, forming a data-driven governance knowledge system. The system dynamics model further reveals the long-term feedback relationship between teacher quality, child development, parental trust, financial resources, and sustainable investment, echoing the AI-driven analytics and ESG-aligned governance framework highlighted in the previous summary. Early childhood education research also points out that early education is an important field for promoting sustainable social transformation. System dynamics can assist educational administrators in analyzing hidden structures and future scenarios (Engdahl & Furu, 2022; Groff, 2013).

Overall, the study contributes an integrative governance perspective in which ESG defines the normative goals, AI enables data-driven knowledge transformation, and system dynamics supports policy learning under complexity.

6.2 Study limitations

This study is a conceptual modeling and scenario simulation study, and has not yet been used for parameter calibration and model verification based on long-term data from actual preschools. Secondly, differences in early childhood education systems, subsidy structures, teacher conditions, and ESG norms in different countries or regions may affect the extrapolation of models. Third, the introduction of AI into preschool governance involves data privacy, algorithm bias, educator roles, and accountability mechanisms, and more rigorous ethics and governance designs must be incorporated in the future. AI education research has emphasized that the role of educators and ethical risks must be paid attention to when introducing AI in educational fields, rather than just pursuing technological efficiency (Zawacki-Richter et al., 2019).

6.3 Future research directions

Future research can collect administrative, teacher, and parental feedback and sustainability performance data from multiple public and private preschools for model calibration, sensitivity analysis, and cross-case comparison. Secondly, an AI-enabled ESG dashboard can be developed to assist principals in real-time monitoring of education quality, teacher workload, resource efficiency, and parental trust. Finally, in the future, the perspectives of principals, teachers, parents, and competent authorities can also be included to examine the usability, trustworthiness, and ethical appropriateness of smart governance models in practical decision-making.

7 Declaration of Ethics

This study is based on conceptual modeling and scenario analysis. No human participants, children's personal data, or identifiable institutional records were collected. Therefore, formal ethical approval was not required at this stage. Future empirical validation involving preschool stakeholders will follow institutional ethical review procedures and data protection requirements.

8 AI Declaration

Generative AI tools were used to support language refinement, structural organization, and preliminary literature organization. The authors reviewed and verified all arguments, citations, interpretations, and final content, and take full responsibility for the accuracy and integrity of the manuscript.

How Does Knowledge Externalization Quality Shape the ESG–Financial Performance Nexus: An Explainable AI Analysis under Mandatory Disclosure Regime

Bin-Wei Hsu[1], Hsiu-Yi Lin[2]
[1] Department of Industrial Management, National Pingtung University of Science and Technology
[2] Department of Finance, National Pingtung University

Abstract

How organizations transform tacit sustainability knowledge into externally interpretable explicit information — and whether the quality of this transformation process influences capital market valuation — represents a core question that knowledge management and capital market research have yet to fully integrate. This study repositions corporate ESG (Environmental, Social, and Governance) disclosure as an institutional output of organizational knowledge externalization, further conceptualizing it as knowledge-based signals that enter market valuation mechanisms through investor interpretation. Grounded in Nonaka and Takeuchi's (1995) knowledge externalization theory and signaling theory, this study constructs a Knowledge Externalization Quality (KE Quality) indicator to measure the extent to which firms convert tacit sustainability knowledge into verifiable and comparable explicit information. Using Taiwan's mandatory ESG disclosure policy as an institutional shock, this study employs the Taiwan Economic Journal TESG database combined with financial and market data to build a longitudinal panel of 1,033 listed companies with 8,672 observations, examining how KE Quality shapes the market pricing of ESG signals. The study adopts fixed-effects OLS regression with robust standard errors, and triangulates findings through lagged specifications, Difference-in-Differences (DID) design, and XGBoost explainable AI (SHAP) analysis.

Empirical results reveal four key findings. First, KE Quality among Taiwanese firms improved significantly from 0.481 in 2016 to 0.683 in 2024, while ESG substantive scores grew only marginally (approximately 3.7%), indicating a pervasive "formal externalization" phenomenon under institutional pressure. Second, KE Quality exerts a significant positive moderating effect on market valuation (Tobin's Q; $\beta=0.033$, $p<0.01$), but has no significant impact on short-term stock returns, reflecting a temporally delayed market interpretation of ESG knowledge signals. Third, the signaling effects of Environmental (E) and Social (S) dimensions exhibit asymmetry: environmental disclosure enhances market premiums, while social disclosure compresses short-term accounting performance. Fourth, DID analysis shows that under mandatory disclosure, large firms experienced significant declines in both KE Quality (DID=−0.110, $p<0.01$) and market valuation (DID=−0.203, $p<0.01$), supporting the signal dilution hypothesis. Finally, the XGBoost model (test $R^2=0.615$) and SHAP analysis corroborate the regression findings, providing methodological triangulation. The theoretical contribution of this study lies in demonstrating that the economic value of ESG information does not derive from disclosure per se, but from the quality of its knowledge externalization signal and how institutional environments shape the interpretability and market pricing of that signal.

Keywords: Knowledge externalization; ESG disclosure; Market valuation; Signal theory; Mandatory disclosure

Paper type: Research paper

1 Introduction

When an organization's sustainability practices are codified into an ESG report, can the quality of this knowledge artifact — its completeness, verifiability, and the motivation behind its disclosure — be effectively interpreted by capital markets and reflected in firm valuation? This is among the most compelling questions that knowledge management theory can address in contemporary sustainability governance. This study positions ESG sustainability reports as institutional outputs of organizational knowledge externalization (Nonaka and Takeuchi, 1995), rather than mere information disclosure acts. Taiwan's Financial Supervisory Commission (FSC) has progressively mandated sustainability reporting since 2014, substantially expanding the mandatory scope after 2023, creating a natural experiment to observe how institutional intervention transforms the market signaling effects of knowledge externalization behavior. Over nine years, the sustainability report filing rate among Taiwan's listed firms surged from 33% to nearly 69%, yet substantive ESG score improvements lagged far behind — this gap represents the concrete manifestation of a disconnect between knowledge externalization quality and knowledge content. This study defines this as the "formal externalization" phenomenon and proceeds from this core problem.

Existing ESG research has concentrated primarily on the direct association between ESG scores and financial performance (Friede et al., 2015; Chen and Xie, 2022), or on mandatory disclosure's effects on capital markets (Krueger et al., 2024). These studies, however, treat ESG disclosure as a finished information product,

overlooking the production process itself — how organizations transform tacit sustainability knowledge into externally comparable explicit reports — which is the critical determinant of signal quality. This study's position is that ESG disclosure should be understood not as a reporting practice, but as a process of organizational knowledge externalization, where the quality of codification determines how knowledge is interpreted and priced in capital markets. Nonaka and Takeuchi (1995) established that the quality of the process by which organizations convert tacit knowledge into explicit knowledge determines the effectiveness of knowledge transfer. ESG sustainability reports are the concrete realization of this process — quality differences (voluntary vs. mandated disclosure, presence of third-party assurance, completeness of disclosure) constitute observable dimensions of knowledge codification effectiveness that should systematically influence external stakeholder valuations.

This study addresses three research questions: What is the trajectory of KE Quality evolution among Taiwanese firms during the ESG policy promotion period (2016–2024)? How does KE Quality moderate the relationship between ESG scores and financial performance, and does this moderation vary by ESG dimension and disclosure motivation? Does the financial effect of knowledge externalization behavior undergo structural change following mandatory disclosure intervention? The core theoretical contribution of this study to knowledge management literature lies in demonstrating that the market value of organizational knowledge is shaped not solely by knowledge content, but also by the quality of the knowledge externalization process under institutional constraints — a proposition that challenges the linear assumption that "more disclosure leads to higher market valuation" and establishes new boundary conditions for applying knowledge management theory in capital market contexts.

2 Literature Review

2.1 Knowledge Externalization and ESG Disclosure

Nonaka and Takeuchi (1995) established in their SECI (Socialization-Externalization-Combination-Internalization) knowledge spiral model that knowledge externalization — the conversion of tacit organizational knowledge into transmissible explicit knowledge — is a critical process whose quality directly determines the effectiveness and interpretability of knowledge transfer. In the ESG context, corporate sustainability practices (such as carbon management, labor relations, and governance mechanisms) are largely embedded in daily operations, characterized by high tacitness; the compilation of sustainability reports constitutes the institutionalized mechanism for systematically translating such tacit knowledge into externally observable information.

Established disclosure research and international reporting standards (e.g., the Global Reporting Initiative) indicate that high-quality disclosure typically exhibits completeness, comparability, and credibility (e.g., third-party assurance) — features that collectively form the basis of information interpretability and market trust. From a knowledge management perspective, these dimensions can be understood as concrete manifestations of knowledge externalization quality, reflecting the effectiveness of knowledge codification and transmission.

Signaling theory (Spence, 1973) provides a complementary framework: firms convey their internal capabilities and long-term orientation through ESG disclosure, and high-quality disclosure helps reduce information asymmetry, enabling investors to distinguish genuinely sustainable firms from those engaging in superficial compliance. In this sense, ESG disclosure can be understood as externalized knowledge signals through which investors conduct quality assessments and market valuation.

However, when disclosure transitions from voluntary to mandated, the economic implications of signals may undergo structural change. Christensen et al. (2021) indicate that mandatory disclosure regimes may erode the function of information as a differentiating signal, leading to signal dilution. In this context, markets no longer rely on "whether to disclose" as a basis for judgment, but shift toward quality differences in disclosure — making KE Quality the critical mechanism influencing market valuation. This study uses Taiwan's mandatory disclosure policy as an institutional shock and employs a Difference-in-Differences (DID) design to empirically test whether signal dilution effects exist in capital markets.

2.2 Mandatory Disclosure, ESG Quality, and Financial Performance

Existing research on ESG disclosure and corporate economic outcomes exhibits substantial heterogeneity. Friede et al. (2015), integrating more than 2,000 empirical studies, find that approximately 90% show a non-negative relationship between ESG and corporate financial performance, with most being positive, though effect sizes vary considerably across regions, industries, and measurement approaches. This result suggests that ESG

information is not a stable source of value; its economic effect depends on how markets interpret that information.

Further literature indicates that ESG information's impact on capital markets is primarily manifested in market valuation and cost of capital. Dhaliwal et al. (2011) find that voluntary non-financial disclosure helps reduce equity capital costs; Bolton and Kacperczyk (2021) demonstrate that markets price environmental risk differentially across firms, indicating that different ESG dimensions carry distinct valuation mechanisms. Investor composition also affects the transmission efficiency of ESG signals (Chen and Xie, 2022), further amplifying the heterogeneity of market responses.

On the institutional dimension, mandatory disclosure policy effects are also non-linearly positive. Krueger et al. (2024), drawing on cross-country data, find that mandatory ESG disclosure policies influence market liquidity and information environments, but effects vary substantially across firms. Christensen et al. (2021) further indicate that when disclosure becomes a regulatory obligation, firms may gravitate toward minimum compliance rather than improving information quality, thereby weakening disclosure's function as an effective signal.

Taken together, existing literature implies a core proposition that has yet to be fully examined: the market valuation effects of ESG disclosure depend not only on disclosure content, but on the quality of the knowledge externalization process, and on how institutional environments shape the interpretability of signals. This study accordingly proposes that under mandatory disclosure regimes, interfirm variation shifts from "whether to disclose" toward "disclosure quality," further shaping the pricing mechanism of ESG signals in capital markets.

2.3 Hypotheses

- *H1: During Taiwan's ESG policy promotion period (2016–2024), KE Quality shows a year-on-year upward trend, but the improvement in substantive ESG scores is smaller than the increase in disclosure behavior (formal externalization).*
- *H2: KE Quality positively moderates the effect of ESG scores on long-term market valuation (Tobin's Q), but has no significant immediate effect on short-term stock returns (market signal lag).*
- *H3: KE Quality's moderating effect on the ESG–financial performance relationship exhibits dimensional heterogeneity, with the Environmental (E) and Social (S) dimensions showing different directions and magnitudes of moderation across performance measures.*
- *H4: Voluntary early adopters exhibit significantly positive KE Quality moderation effects, while passive late adopters (firms coerced by policy) show significantly weaker or negative effects, reflecting that disclosure motivation shapes the financial effects of knowledge externalization.*

3 Methodology

3.1 Data and Sample

This study employs the Taiwan Economic Journal (TEJ) TESG Sustainability Development Index database, combined with TEJ Finance financial data and stock return data, to construct a longitudinal dataset spanning 2016 to 2024. The TESG database is structured around the SASB (Sustainability Accounting Standards Board) international framework, drawing on over 20 public information sources. Its distinctive feature is the ability to generate quantitative ESG scores even for firms that have not published sustainability reports — using external information such as ISO certifications and Ministry of Labor employment data — providing a systematic basis for comparing firms at different disclosure stages. The final sample covers 1,033 listed companies with 8,672 annual observations. Financial variables are Winsorized at the 1st and 99th percentiles; stock returns are measured using the trailing 12-month return as of each December year-end.

3.2 Variable Definitions

Knowledge Externalization Quality (KE Quality) is a composite index constructed from three equally weighted (1/3 each) conditions, ranging from 0 to 1: (1) whether a sustainability report has been published (1=yes, 0=no), reflecting the firm's willingness to voluntarily externalize knowledge; (2) whether third-party assurance has been obtained (1=yes, 0=no), reflecting the verifiability of externalized knowledge; and (3) disclosure completeness (0 to 1), standardized from TESG event radar scoring, where higher scores indicate more complete disclosure and fewer negative events. These three dimensions collectively measure the extent to which organizations effectively codify (codification) and verify (verifiability) tacit sustainability knowledge — not merely the disclosure act itself. KE Quality reflects the quality of the knowledge conversion process, while ESG scores reflect the content level of knowledge; the two are conceptually independent, and this study employs interaction terms

to capture their joint effects. Robustness analyses under five alternative weighting schemes (Analysis 10) confirm the direction and significance of interaction coefficients throughout.

Primary dependent variables include ROA (Return on Assets), ROE (Return on Equity), and Tobin's Q; stock returns serve as an additional measure of immediate signal response. Independent variables include the TESG composite score and three sub-dimension scores — Environmental (E), Social (S), and Governance (G) — all standardized. Control variables include firm size (log of total assets), debt ratio, and firm age.

Disclosure motivation grouping: based on the year of first sustainability report publication, early voluntary adopters (adopted before 2023, N=4,539 observations) and late passive adopters (joined under policy pressure after 2023, N=1,209 observations) are defined. The DID design uses paid-in capital as the treatment threshold: firms with capital ≥ NTD 2 billion form the treatment group (subject to earlier mandatory requirements, N=608 observations), while firms below this threshold form the control group. The DID event corresponds to the 2023 expansion of mandatory disclosure policy.

3.3 Analytical Methods

The primary analysis employs OLS regression incorporating year and industry fixed effects with HC1 (Heteroscedasticity-Consistent) robust standard errors. The core model specification is: Financial Performance = $\alpha + \beta_1 \times$TESG Score + $\beta_2 \times$KE Quality + $\beta_3 \times$(TESG×KE Quality) + $\beta_4 \times$Controls + Fixed Effects + ε. Robustness checks include: lagged variables (t−1) to address endogeneity, E/S/G sub-dimension robustness tests, three alternative time windows, and sensitivity analysis under five KE Quality weighting schemes.

4 Results

4.1 Descriptive Statistics

Table 1 presents descriptive statistics for core variables. The mean TESG composite score is 56.07, with E, S, and G sub-dimension scores at 57.43, 57.01, and 54.46, respectively — the governance dimension systematically lower than environmental and social. The median KE Quality is 0.333, implying that more than half of Taiwan's listed companies during the study period possessed only the disclosure completeness dimension and had not yet published sustainability reports. The distribution of early voluntary adopters (N=4,539) and late passive adopters (N=1,209) provides sufficient statistical power for the subsequent motivation heterogeneity analysis.

Table 1: Descriptive Statistics of Core Variables (2016–2024)

Variable	Mean	SD	Min	Max	Median	N
TESG Composite Score	56.07	8.58	29.89	83.73	55.62	8,672
E Score (Environmental)	57.43	12.79	26.02	92.16	55.67	8,672
S Score (Social)	57.01	11.78	26.58	91.00	56.43	8,672
G Score (Governance)	54.46	10.15	21.85	81.54	54.79	8,672
KE Quality	0.563	0.281	0.000	1.000	0.333	8,672
Has Sustainability Report	0.473	0.499	0	1	0	8,672
Has Third-party Assurance	0.277	0.447	0	1	0	8,672
ROA (%)	4.26	7.44	−22.83	27.60	3.92	8,672
ROE (%)	7.63	14.03	−48.73	48.29	7.95	8,672
Tobin's Q	1.221	0.891	0.090	5.616	0.960	8,672
Firm Size (ln)	16.25	1.65	9.76	23.35	15.98	8,672
Debt Ratio (%)	44.83	19.95	0.48	99.76	44.55	8,672
Firm Age (years)	40.32	15.85	2	80	40	8,663

4.2 Trajectory of KE Quality Over Time

Figure 1 shows that KE Quality among Taiwanese firms rose continuously from 0.481 in 2016 to 0.683 in 2024, a cumulative improvement of 42.0% over nine years. The sustainability report filing rate climbed from 33.0% to 68.9%, and the third-party assurance rate from 16.5% to 44.2%, clearly demonstrating the policy's effect. However, the TESG composite score improved only from 55.36 to 57.42 over the same period — a mere 3.7% gain, far below the increase in disclosure behavior. The comparison between the pre-policy period (2016–2022) and the post-policy period (2023–2024) shows KE Quality rising by 0.133, while substantive ESG scores improved by only 1.761 points; the gap between these two rates of improvement is statistically significant ($p<0.01$), supporting H1's formal externalization proposition.

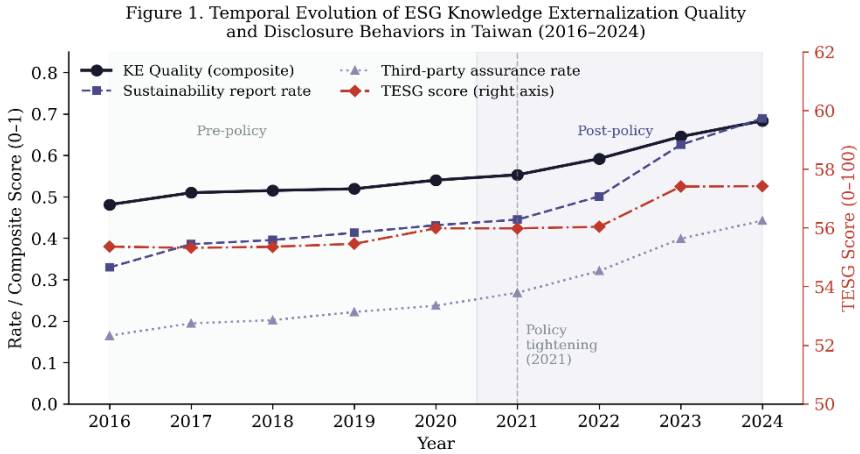

Figure 1. Annual Evolution of ESG Knowledge Externalization Quality and Disclosure Behavior among Taiwan Listed Firms (2016–2024). Left axis: KE Quality and disclosure rates (0–1); Right axis: TESG score (50–62).

4.3 Regression Results

Table 2 presents results from four regression models (DV=ROA). Model 1 shows TESG scores have a significant positive effect on ROA (β=0.616, p<0.01). Model 2, adding KE Quality, shows KE Quality itself exerts a significant negative effect on ROA (β=−0.242, p<0.05), reflecting the short-term sustainability costs borne by proactive disclosers. The core interaction term in Model 3 (TESG×KE Quality) is −0.161 (p<0.1), indicating weakly significant negative moderation — in firms with high disclosure quality, the short-term financial effect of ESG scores is partially offset. Model 4 results (moved to robustness appendix; see Section 4.6) present more pronounced policy moderation: the post-policy × KE Quality interaction is significantly negative (β=−0.397, p<0.01), representing structural weakening of KE Quality's effect on ROA after policy intervention, consistent with the formal externalization hypothesis.

Table 2: Panel Regression Results (DV=ROA)

Variable	Model 1 Baseline	Model 2 +KE Quality	Model 3 Interaction	Model 4 Policy Mod.
TESG Score β	0.616***	0.709***	0.716***	0.741***
KE Quality β	—	−0.242**	−0.216**	−0.111
Interaction (TESG×KE)	—	—	−0.161*	—
Post-policy Dummy	—	—	—	1.085***
Post-policy × KE Quality	—	—	—	−0.397***
R^2	0.177	0.178	0.178	0.168
N	8,663	8,663	8,663	8,663

****p<0.01 **p<0.05 *p<0.1. All models include year and industry fixed effects with HC1 robust standard errors. Source: This study.*

Table 3 presents the core model comparison across four dependent variables. KE Quality's moderating effect on Tobin's Q is significantly positive (β=0.033, p<0.01) and remains robust in the lagged variable model (β=0.022, p<0.05), ruling out reverse causality concerns and supporting the first part of H2. By contrast, the interaction term for short-term stock returns is not significant (β=−0.436), indicating market lag in responding to ESG disclosure quality — supporting the second part of H2.

Table 3: Core Interaction Model — Comparison Across Four Dependent Variables

DV	TESG Score β	KE Quality β	Interaction β	R^2	N
ROA	0.716***	−0.216**	−0.161*	0.178	8,663
ROE	1.332***	−0.420**	−0.194	0.145	8,663
Tobin's Q	0.068***	0.014	0.033***	0.259	8,663
Stock Return	−0.871	−0.383	−0.436	0.134	8,663

4.4 E/S/G Dimensional Heterogeneity

Table 4 presents results substituting E, S, and G sub-dimension scores for the TESG composite score, with Figure 2 displaying interaction coefficients by dimension. The Environmental (E) dimension interaction is significantly positive on Tobin's Q (β=0.050, p<0.01), indicating that transparent disclosure of environmental knowledge yields a market premium. Conversely, the Social (S) dimension interaction is significantly negative on both ROA (β=−0.327, p<0.01) and ROE (β=−0.611, p<0.01), suggesting that transparent social responsibility disclosure compresses short-term accounting performance. The Governance (G) dimension is also significantly positive on Tobin's Q (β=0.025, p<0.01). This E/S/G asymmetry in moderation directions supports H3, demonstrating that the financial effects of KE Quality are highly dependent on the type of sustainability knowledge being externalized.

Table 4: KE Quality Moderation Effects by E/S/G Sub-dimension

Dim.	DV	ESG Score β	KE Quality β	Interaction β	R^2	N
E	ROA	0.468***	−0.076	0.023	0.175	8,663
E	ROE	0.867***	−0.166	0.222	0.143	8,663
E	Tobin's Q	0.013	0.041***	0.050***	0.258	8,663
S	ROA	0.171*	0.081	−0.327***	0.174	8,663
S	ROE	0.261	0.178	−0.611***	0.141	8,663
S	Tobin's Q	0.025**	0.043***	0.005	0.256	8,663

4.5 Motivation Heterogeneity and DID Analysis

Table 5 Panel A presents motivation heterogeneity results. Early voluntary adopters show a significantly positive interaction (β=0.061, p<0.01), while late passive adopters show an interaction near zero (β=−0.009, n.s.), with KE Quality itself exhibiting a significant negative effect on Tobin's Q (β=−0.172, p<0.05). This contrast directly supports H4: disclosure motivation determines the market effects of KE Quality — voluntary disclosure functions as a signal of genuine sustainability capability with positive moderating power, whereas passive disclosure does not carry this signaling function in the eyes of the market.

Table 5 Panel B presents DID results. Using the NTD 2 billion capital threshold, treatment group firms experienced a significant decline in KE Quality (DID=−0.110, p<0.01) and a corresponding drop in Tobin's Q (DID=−0.203, p<0.01) following the 2023 policy intervention. This result appears to contradict the main regression finding that KE Quality positively moderates ESG's effect on Tobin's Q; the theoretical interpretation is addressed in Section 5.

Table 5: Motivation Heterogeneity (Panel A) and DID Analysis (Panel B)

Analysis	TESG β	KE Quality β	Interaction β	R^2 / N
Panel A: Motivation Heterogeneity (DV=Tobin's Q)				
Early voluntary (N=4,539)	0.017	0.080***	0.061***	R^2=0.312
Late passive (N=1,209)	0.047	−0.172**	−0.009	R^2=0.285
Panel B: DID Analysis (Capital Threshold ≥ NTD 2 billion)				
DV=KE Quality	−0.036***(treat)	0.089***(post)	−0.110***(DID)	R^2=0.468 / N=8,663
DV=ROA	−4.434***(treat)	1.019***(post)	−1.153**(DID)	R^2=0.175 / N=8,663
DV=Tobin's Q	0.094**(treat)	0.175***(post)	−0.203***(DID)	R^2=0.247 / N=8,672

***p<0.01 **p<0.05 *p<0.1. Panel A DV=Tobin's Q, industry fixed effects included. Panel B DID design: treat=capital≥NTD 2B, post=post-2023, DID=treat×post interaction. Source: This study.

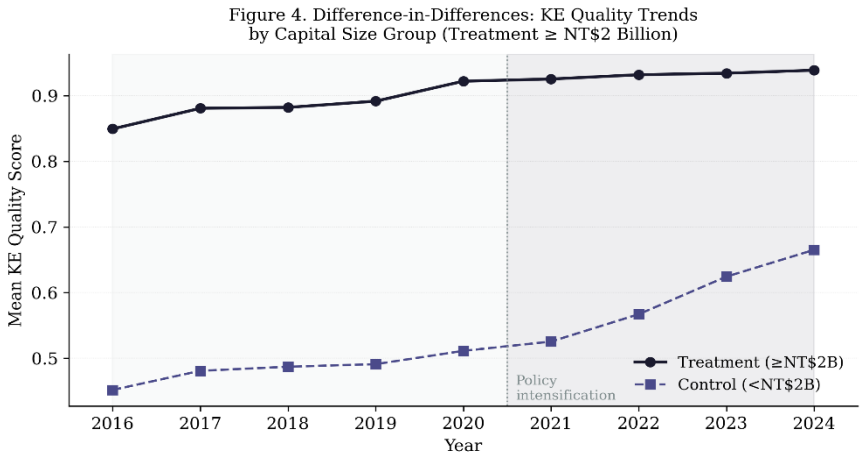

Figure 4. Difference-in-Differences Analysis: Annual KE Quality Trends by Capital Size Group (2016–2024).

4.6 Robustness Checks

This study conducts five categories of robustness checks, all supporting the main findings. First, in the lagged variable model (t−1), the Tobin's Q interaction remains significant (β=0.022, p<0.05), ruling out reverse causality. Second, across three alternative time windows (2018–2024, 2019–2024, and 2016–2022), interaction coefficients remain significant (β=0.029–0.042, p<0.01), confirming results are not period-specific. Third, all five alternative KE Quality weighting schemes yield significant interactions (β=0.031–0.036, p<0.01), demonstrating robustness of index construction. Fourth, industry heterogeneity analysis shows the moderation effect is most pronounced in chemicals/biomedical (β=0.094, p<0.1) and construction materials (β=0.094, p<0.05) sectors. Model 4 (policy moderation) is relegated to the appendix as a robustness reference due to reduced statistical

power following the post-2023 sample restriction (2,051 observations; policy_ke interaction: β=−0.263, p=0.134); causal inference for policy effects is carried by the DID design in Analysis 13.

4.7 Explainable AI Diagnostics: XGBoost and SHAP Analysis

To supplement the limitations of linear regression models and provide a nonlinear perspective, this study employs an XGBoost machine learning model to predict KE Quality, and applies SHAP (SHapley Additive exPlanations) explainable AI to diagnose the marginal contributions of each predictor. Input features include the TESG composite score, E/S/G sub-scores, firm size, debt ratio, firm age, ROA, ROE, Tobin's Q, post-policy dummy, and paid-in capital — 12 variables in total. Data are split 80/20 by year order (training: 6,930; test: 1,733) to prevent future information leakage. It is worth noting that conceptual independence does not imply empirical uncorrelatedness — firms with higher ESG content levels may also possess greater capacity for high-quality externalization; however, at the theoretical level, knowledge content (ESG scores) and knowledge externalization process quality (KE Quality) remain distinct constructs, and this distinction is a core contribution of this study.

The XGBoost model achieves R^2=0.615 and RMSE=0.183 on the test set, indicating considerable predictive power. Figure 6 presents the SHAP results: Panel A shows the feature importance bar chart, and Panel B shows the SHAP distribution plot for the top six features (red=high feature value, blue=low). SHAP analysis identifies the TESG composite score (mean SHAP=0.070) and post-policy dummy (mean SHAP=0.068) as the two most important predictors of KE Quality, with nearly equal contributions — indicating that ESG capability and institutional pressure exert roughly comparable driving forces on knowledge externalization behavior. Firm size ranks third (mean SHAP=0.063), reflecting the systematic advantage of large firms in disclosure resources and capacity.

Notably, the SHAP values for the post-policy dummy are almost entirely positive in Panel B, but taken together with DID results, this pattern is consistent with the interpretation that mandatory policy raised KE Quality's surface values without fostering genuine improvements in organizational knowledge externalization capacity — consistent with the predictions of this study's formal externalization hypothesis. Furthermore, E scores and S scores both show positive SHAP directions, but E score influence is more concentrated than S score influence, consistent with the regression finding that the environmental dimension moderation (β=0.050, p<0.01) outperforms the social dimension (β=0.005, n.s.), providing methodological triangulation. Financial performance indicators (ROA, ROE, Tobin's Q) all have mean SHAP values below 0.007, suggesting KE Quality is primarily driven by ESG characteristics and institutional environment, with limited direct association with short-term financial performance.

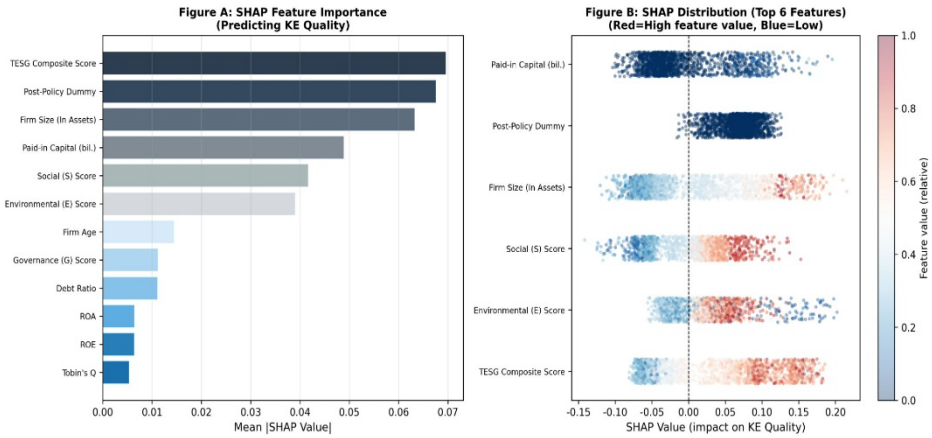

Figure 6. SHAP Explainable AI Analysis: Feature Importance (Panel A) and Distribution Plot (Panel B) for XGBoost Prediction of KE Quality.

5 Discussion

This study's most striking finding is the apparent contradiction between main regression and DID results: main regressions show that higher KE Quality amplifies ESG scores' positive effect on Tobin's Q, yet DID results show that firms subject to mandatory disclosure — large-capitalization firms — experienced simultaneous declines in KE Quality (DID=−0.110, p<0.01) and Tobin's Q (DID=−0.203, p<0.01) following the 2023 policy intervention. This contradiction points toward the signal dilution mechanism. Christensen et al. (2021) indicate

that mandatory disclosure policies may generate unintended consequences — when disclosure becomes a regulatory obligation rather than a voluntary act of knowledge sharing, markets systematically discount ESG signals from mandated disclosers, as these signals lose their differentiating function. This study's DID results directly echo this argument: among firms covered by mandatory policy, even as KE Quality values continued to improve, market valuations declined, reflecting investors' qualitative distinction between coerced and voluntary disclosure. Regarding causal inference, the DID design captures variation in regulatory exposure, but the capital threshold may simultaneously reflect firm size heterogeneity; accordingly, these results should be interpreted as policy-associated findings rather than strict causal identification. Robustness analyses with multiple thresholds (≥NTD 500M, ≥NTD 1B, ≥NTD 2B) partially mitigate this concern.

Motivation heterogeneity findings further reinforce the above interpretation. Early voluntary adopters show significantly positive KE Quality moderation ($\beta=0.061$, $p<0.01$), while the effect for late passive adopters nearly disappears ($\beta=-0.009$, n.s.), with KE Quality itself negatively associated with market valuation ($\beta=-0.172$, $p<0.05$). From the perspective of Nonaka and Takeuchi's (1995) knowledge externalization theory, voluntary disclosers' externalization behavior stems from the organization's intrinsic recognition of knowledge value, allowing externalization quality to authentically reflect sustainability capability; passive disclosers' externalization occurs under external institutional pressure, with a looser connection between quality and substantive capability, making it difficult for the market to extract useful signals.

The signal lag finding reveals a distinctive feature of Taiwan's capital market. The interaction for short-term stock returns is insignificant, while Tobin's Q interaction is significant in both full-sample and lagged variable models, indicating that market responses to ESG disclosure quality are not immediate but materialize in long-term valuation over time. This result may be associated with the incomplete maturity of Taiwan's market mechanism for processing ESG knowledge quality signals; Chen and Xie (2022) provide more general cross-market evidence that investor composition influences ESG signal transmission efficiency, offering theoretical context for this study's finding. Figure 5 visually presents this short-term versus long-term market response differential.

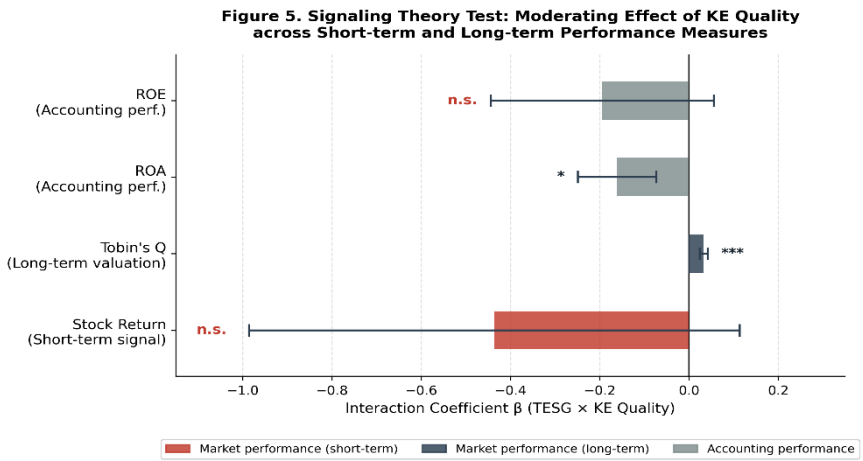

Figure 5. Signaling Theory Test: Moderating Effect of KE Quality across Short-term and Long-term Performance Measures.

6 Conclusion

This study repositions ESG sustainability disclosure as an institutional process of organizational knowledge externalization, employing Nonaka and Takeuchi's (1995) knowledge externalization theory as the core framework — combined with signaling theory and institutional theory — to systematically examine the evolution of KE Quality and its heterogeneous effects on capital market valuation during Taiwan's mandatory ESG disclosure policy period. The study's core knowledge management contributions are fourfold. First, it operationalizes KE Quality for the first time as a quantifiable composite measure of "knowledge codification effectiveness," explicitly demarcating the conceptual boundary between knowledge content (ESG scores) and knowledge externalization process quality (KE Quality), and empirically demonstrates that moderating effects vary significantly by ESG dimension (E vs. S), performance measurement dimension (market valuation vs. accounting performance vs. immediate market response), and disclosure motivation (voluntary vs. passive) — establishing specific boundary conditions for applying knowledge management theory in ESG contexts. Second, the DID design provides causal evidence for "institutional intervention distorting knowledge signals" — mandatory disclosers' KE Quality (DID=−0.110, $p<0.01$) and market valuation (DID=−0.203, $p<0.01$) both declined

following the 2023 policy, directly challenging the mainstream assumption that "more disclosure necessarily generates higher knowledge value," and providing a knowledge management interpretive framework for signal dilution theory. Third, the XGBoost explainable AI model (test R^2=0.615) and SHAP analysis constitute a diagnostic toolkit for knowledge externalization behavior, with TESG scores and policy dummy as the most important predictors — corroborating regression findings and demonstrating the methodological potential of explainable AI in knowledge management research. Fourth, the delayed market response finding indicates that Taiwan's capital market has yet to fully mature in its mechanism for interpreting ESG knowledge quality signals; the knowledge value realization pathway is primarily through long-term valuation, with short-term stock prices not yet fully reflecting differences in knowledge externalization quality.

For policymakers, this study recommends that mandatory disclosure policy be supplemented with quality incentive mechanisms rather than merely requiring formal compliance; a regulatory framework that differentiates between voluntary and passive disclosers would help preserve the differentiating value of ESG signals. For investors, when assessing corporate ESG performance, the motivational character of disclosure should be distinguished, with priority attention given to third-party assured environmental knowledge disclosure. Primary limitations include: the sample being restricted to Taiwan's listed companies, the three dimensions of KE Quality being equally weighted, and the use of static capital levels as DID grouping criteria — areas for future research to deepen.

7 Ethics Statement

This study uses publicly available commercial databases from the Taiwan Economic Journal (TEJ) and public financial disclosures from listed companies. It does not involve human subjects research and does not require Institutional Review Board approval.

8 AI Tool Usage Statement

This study used Claude (Anthropic) as an assistive tool during research design planning and initial drafting stages, for logical structuring of research design and text optimization. All statistical analyses were independently executed by the authors, and all interpretations of findings and academic judgments are the authors' responsibility.

Deepfake, Deep Scars-Protecting Children's Rights in the Age of Artificial Intelligence

Sophie Kung, Nicole Lin, Joy Hong, Peter Lee, Yaping Tsao
Taipei Municipal Zhong Shan Girls High School, Taipei, Taiwan

Abstract

This paper examines the escalating threat of AI-generated deepfake abuse against minors, focusing on the systemic dynamics that sustain and amplify these harms in the contemporary digital landscape. Adopting a systems-thinking approach, the research utilizes analytical tools such as the Iceberg Model and Causal Loop Diagrams to move beyond an event-oriented perspective of individual tragedies—such as the high-profile Elijah Heacock case—to a structural analysis of the digital environment. The methodology incorporates a comparative legislative review of frameworks in Taiwan, the United States, the European Union, and South Korea, alongside quantitative data synthesis from reporting trends provided by the National Center for Missing & Exploited Children (NCMEC) and the Internet Watch Foundation (IWF). The core analysis identifies four primary reinforcing loops that drive the deepfake crisis: the Low-Barrier Reinforcing Loop, the Anonymity–Impunity Reinforcing Loop, the Normalization–Rationalization Reinforcing Loop, and the Personalized Exploitation Reinforcing Loop. Empirical evidence indicates that AI-generated sexual exploitation is an urgent global concern, with estimates suggesting over 1.2 million children were affected by "nudified" deepfake tools in 2025 alone. The paper concludes by presenting a "Solution Landscape" that integrates technological, legal, and ethical interventions, including "Digital DNA" for content authentication and "Mandatory Empathy Windows" to introduce psychological friction in generative processes. By addressing the deep-seated structures that normalize digital harm, this research advocates for a coordinated global response to safeguard children's rights in the age of artificial intelligence.

Keywords: Deepfake technology, Child protection, Artificial intelligence, Systems thinking, Digital rights.

Paper type: Academic Research Paper.

1 Introduction

On February 28, 2025, a 16-year-old boy named Elijah Heacock took his own life after becoming the target of an AI-based sextortion scheme. Elijah had a loving family, supportive friends, and a bright future; yet a fabricated nude image of him, generated through artificial intelligence, was used to threaten, humiliate, and blackmail him. The perpetrator demanded money in exchange for not sending the image to his family and friends. Although the image was fake, the fear, shame, and emotional devastation it caused were entirely real. Elijah's death is not only a personal tragedy but also a warning of how emerging technologies can be weaponized against children and adolescents in deeply harmful ways.

Artificial intelligence has transformed modern society at an extraordinary pace, creating new possibilities across education, business, and daily life. However, AI is also a double-edged sword. Among the most alarming examples is deepfake technology, which enables the creation of highly realistic but fabricated content with minimal cost. When such technology is used against minors, the consequences are severe, violating their privacy, dignity, and basic rights. To examine this issue beyond individual incidents, this report adopts a systems-oriented approach combining structural analysis, comparative legal review, and case-based evidence.

2 Methodology and Positionality

2.1 Systems Thinking Approach

This report adopts a systems-thinking approach to examine how AI-generated deepfake abuse is produced, sustained, and intensified across digital environments. It uses analytical tools such as the Iceberg Model and Causal Loop Diagrams to identify the structural conditions, feedback processes, and psychological assumptions that underlie visible incidents. By shifting the analysis from an event-oriented perspective to a systemic one, the report traces how technological accessibility, regulatory delay, and offender motivations interact to perpetuate harm.

The research draws on three main approaches:

- **Comparative Legislative Analysis:** Examining legal and policy frameworks in Taiwan, the United States, the European Union, and South Korea to identify governance gaps.

- **Quantitative Data Synthesis:** Analyzing reporting trends and child-protection statistics from NCMEC and the IWF to assess escalation patterns.
- **Case Study Review:** Connecting system-level analysis with lived human consequences through incidents like the Elijah Heacock case and the Westfield High School case.

2.2 Positionality

The authors are three high school students from Taiwan, a society with high internet penetration. As digital natives, they occupy a dual position: they are both researchers and members of the population most exposed to AI-enabled harm. This positionality provides a unique perspective on peer-related digital risks, recognizing that these issues are intimately embedded in the everyday digital environments of young people. To ensure objectivity, the analysis is grounded in international data and cross-national cases.

3 Problem Statement

The misuse of AI-generated deepfake content has become a serious threat to children's rights. Deepfake technology first emerged in 2017 and rapidly evolved from fringe face-swapping into a broader social threat. By the 2020s, it had become increasingly linked to child sexual exploitation and financially motivated sextortion.

3.1 Historical Context

Deepfake technology transitioned from isolated incidents to systemic risks. In 2021, the Westfield High School case in New Jersey saw students use AI to generate explicit images of female classmates, highlighting the peer-to-peer nature of the threat. Between October 2021 and March 2023, the FBI received over 13,000 reports of online financial sextortion involving minors, linked to at least 20 suicides. The IWF reported action on 312,030 reports of child sexual abuse material (CSAM) in 2025, a 7% increase from 2024.

3.2 Impact and Significance

Recent European Parliament analysis indicates that pornographic material accounts for approximately 98% of deepfakes, with global sharing projected to rise to 8 million by 2025. UNICEF reports that in a survey covering 11 countries, at least 1.2 million children were estimated to have had their images "nudified" through deepfake tools in the previous year. For minors, these harms result in severe emotional consequences, including anxiety, depression, and suicidal ideation. The "permanence" of digital data means that even if a deepfake is proven false, the digital shadow can follow a victim indefinitely.

3.3 Projection and Escalation

To illustrate the possible scale of future risk, we present a scenario projection based on NCMEC reports (4,700 in 2023; 67,000 in 2024). The model applies a hypothetical annual growth rate of 150%, assumption-based on the explosive rise observed in recent years.

The projection uses the compound-growth formula: $\mathbf{N(t) = N_o(1 + r)^t}$.

Table 1: Scenario Projection of AI-Related Abuse Reports

Year	Projected Reports
2025	167,500
2026	418,750
2027	1,046,875
2028	2,617,188

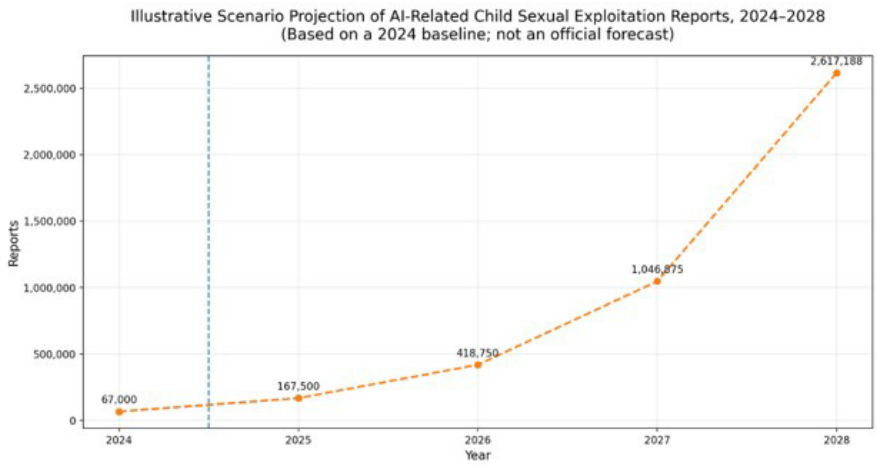

Figure 1. Illustrative scenario projection of AI-related child sexual exploitation reports, 2024–2028.

4 Systems Mapping

4.1 The Iceberg Model

To understand why this problem persists, we distinguish between visible events and underlying drivers:

- **Events:** Individual suicides, sextortion cases, and viral fake images.
- **Patterns:** Recurring trends of cross-jurisdictional offending and the rapid speed of digital circulation.
- **Structures:** Technological accessibility, fragmented legal systems, and platform anonymity.
- **Mental Models:** Harmful beliefs that "synthetic images cause no real harm" or that digital anonymity provides absolute legal protection.

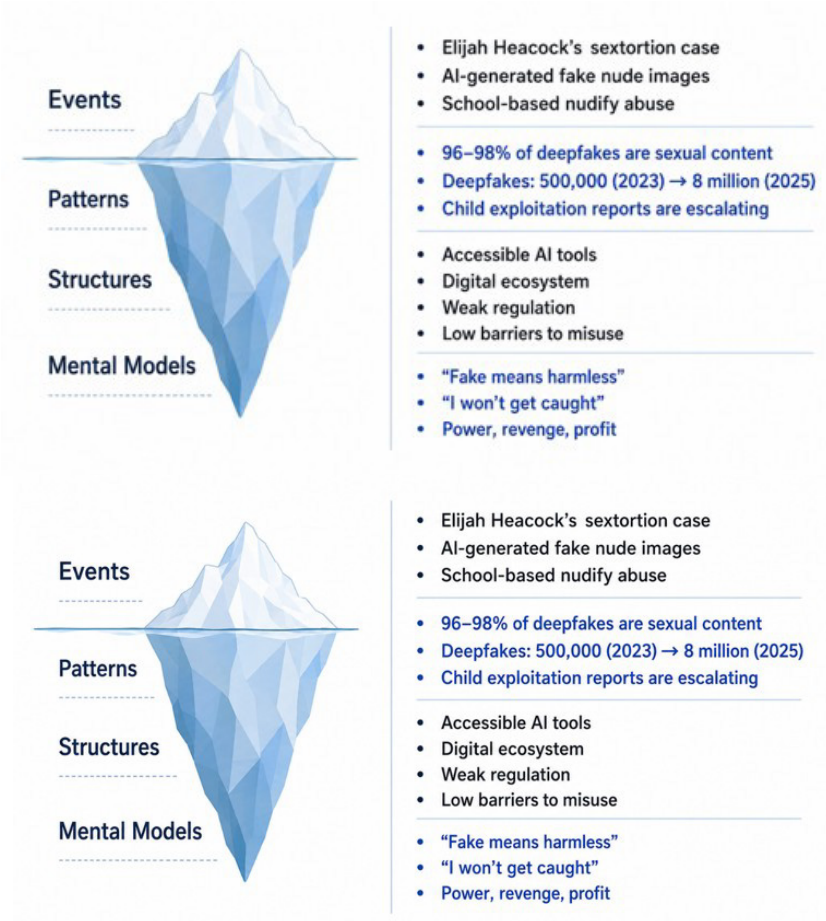

Figure 2. Iceberg model of AI-generated deepfake abuse against minors.

4.2 Causal Loop Reinforcing Logic

The deepfake crisis is driven by self-reinforcing dynamics:

- **Anonymity–Impunity Loop:** Concealment mechanisms allow offenders to obscure identities across jurisdictions. This reduces traceability, lowering the likelihood of sanctions and decreasing the psychological cost of offending.
- **Normalization–Rationalization Loop:** As more abuse occurs, desensitization follows. Increased exposure weakens moral resistance, treating abuse as routine or socially tolerated.
- **Personalized Exploitation Loop:** Reusable knowledge and access to victim-specific data increase the effectiveness of targeted abuse over time.

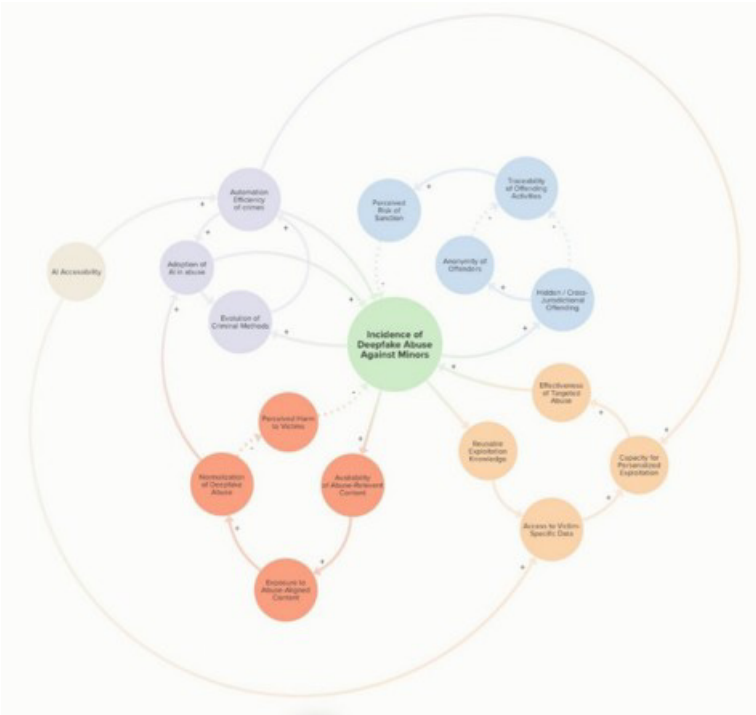

Figure 3. Causal loop diagram of the systemic dynamics sustaining AI-generated deepfake abuse against minors.

5 Comparative Legislative Analysis

5.1 Taiwan

Taiwan's **Child and Youth Sexual Exploitation Prevention Act (2024)** explicitly includes sexual imagery of minors produced through computer synthesis or other technological methods. While it recognizes synthetic content as exploitation, enforcement against overseas servers remains a primary challenge.

5.2 United States

The U.S. has introduced the **DEFIANCE Act** and the **Take It Down Act (2024)**, aiming to provide victims with civil causes of action and mandated removal from platforms. However, protection remains decentralized and varies by state.

5.3 European Union

The **EU AI Act** categorizes deepfake generation as "limited risk," requiring clear disclosure/labeling. While GDPR provides strong privacy protections, criminal law harmonization for synthetic content is still evolving.

5.4 South Korea

Following a 2024 scandal, South Korea passed a bill to criminalize the **possession or viewing** of sexually explicit deepfakes. This represents a shift toward punishing consumption to dismantle the market for synthetic abuse.

6 Solution Landscape

6.1 Solution 1: Mandatory Empathy Window

This intervention introduces psychological friction into the generative process. AI models would be required to pause and display the potential real-world harm of a prompt before generating realistic human imagery, triggering moral hesitation in the offender.

6.2 Solution 2: Digital DNA (Provenance)

Targets the Anonymity Loop by increasing traceability. Utilizing the **C2PA standard**, every generated file would contain persistent evidence of its origin, recording the tool, timestamp, and potentially user credentials.

6.3 Solution 3: Digital Bloodhound (AI Monitoring)

Leverages AI as a tool for detection rather than concealment. Specialized AI "bloodhounds" would be deployed to detect subtle pixel or movement anomalies that reveal manipulated content across platforms.

6.4 Solution 4: Jamming Signals (Image Cloaking)

Empowers individuals via tools like "Glaze" or "Nightshade," which apply invisible perturbations to images. These perturbations make raw data unusable for AI models trying to learn a person's likeness, sabotaging criminal efficiency at the source.

Table 2. Summary of proposed system-level interventions for AI-generated deepfake abuse against minors.

Solution	Core idea	Main target	Expected effect
Mandatory Empathy Window	Interrupt harmful sharing by forcing offenders to confront real human suffering before they share deepfake sexual content.	**Normalization–Rationalization Reinforcing Loop**	Reduces numbness, disrupts group-think, and weakens the belief that synthetic abuse is harmless.
Digital DNA	Embed traceable origin information into AI-generated files so content can be linked back to its source.	**Anonymity–Impunity Reinforcing Loop**	Restores accountability, increases traceability, and raises the perceived risk of sanction.
Digital Bloodhound	Use AI detection tools and real-time cross-border cooperation to identify and block harmful synthetic content.	**Anonymity–Impunity Reinforcing Loop**	Makes harmful content easier to detect and reduces offenders' ability to hide across platforms and jurisdictions.
Jamming signals	Add invisible perturbations or anti-scraping signals to personal images so AI systems cannot easily interpret or reuse them.	**Personalized Exploitation Reinforcing Loop**	Reduces the machine-readability of victim data and weakens the efficiency of personalized exploitation.

7 Feasibility and Risk Assessment

7.1 Feasibility

The C2PA standard is already supported by industry leaders like Google and Microsoft. However, a significant barrier is the **"Open-Source Gap"**. Offline, "jailbroken" models can bypass built-in empathy windows or watermarking requirements.

7.2 Privacy vs. Protection

There is an inherent tension between traceability (Digital DNA) and digital anonymity. Any solution must include strong legal guardrails to ensure these tools are not weaponized by authoritarian regimes against dissidents.

8 Conclusions

The rise of AI-generated content presents a dual crisis: unprecedented creative possibility versus systemic risks to the fundamental rights of children. Deepfake abuse is not merely a collection of isolated events, but a systemic problem driven by technological ease and legal fragmentation. Protecting the next generation requires a shift from "reactive removal" to "proactive prevention" through an integrated approach of technology (Digital DNA), law (international coordination), and social behavior (Empathy Windows).

9 Ethics declaration

This research was conducted according to ethical guidelines for child protection. All case studies (e.g., Elijah Heacock) utilize publicly available reports, and the authors have prioritized the dignity of victims throughout the process.

10 AI declaration

Generative AI tools were utilized to synthesize reporting trends and to generate conceptual diagrams (the Iceberg Model and Causal Loop Diagrams). These tools were used strictly for structural visualization and data synthesis to enhance the clarity of the systems-thinking methodology.

Sexual Violence Towards Female Domestic Migrant Workers

Kai-En Chang, Yo-Yo Chen, Yun-Hsuan Chu
Taipei Municipal Song-Shan Senior High School, Taipei, Taiwan

Abstract

In Taiwan, one of six female migrant workers has been sexually assaulted. And this phenomenon not only occurs in Taiwan but the whole world. UN WOMEN defines that nearly half of the world's 304 million international migrant workers are women (migration data portal, May 14 ,2025), crucially 765 of the 75.6 million domestic workers worldwide are female (UN women, 2025, 23 October). Because these women are primarily employed as domestic workers or caregivers, they operate within private households. This kind of private areas mean they gain less visibility and protection, exposing them to a higher risk of suffering from exploitation, abuse, or even sexual violence compared to non-female migrant domestic workers. A research by Linn et al. (2024) indicates that approximately 60 per cent of workers surveyed had experienced violence within the previous 12 months, which is markedly higher than the percentages of women who had reportedly experienced violence in their lifetime in Myanmar (20.6 per cent) and in Thailand (15.4 per cent). Our research analyses different aspects, including legislation, racial hierarchy and so on. After evaluating existing solutions' pros and cons, we came up with some potential solutions in the hope that this problem can be recognized and ameliorated.

Keywords: Systemic Power Imbalance, Human Rights Fallacy, Female domestic migrant worker, Global and Local Racial Hierarchies, Intermediary System

Paper type: Practical Paper

1 Challenges Landscape

The suffering of sexual violence stems from two dimensions: root causes, which weaken the position of female migrant workers, and perpetuating factors, which hinder resolution. Legally, linguistically, and economically disadvantaged, these workers often face societal discrimination and indifference (CEDAW, 2008). This marginalization discourages victims from seeking help and complicates the delivery of assistance.

Furthermore, the concentration of female migrant workers in private caregiving environments increases their vulnerability to harassment and rape (The Control Yuan, 2022). Seeking justice is further obstructed by the risk of job loss or deportation, alongside significant loopholes in law enforcement (AIT, 2024; 2025). This exploitation chain is often completed by intermediaries who force reconciliations and conceal abuse cases, ensuring the difficulties faced by these women remain unrecognized and unresolved (The Control Yuan, 2025).

1.1 Systemic Power Imbalance

Systemic power imbalance means one group consistently holds more economic, legal, and social power over another. Sexual violence against female migrant workers is not merely the result of individual misconduct but is rooted in systemic power imbalances shaped by patriarchal norms and reinforced by high-risk labor and

migration structures (CEDAW, 2008). As women, also as migrant workers, they are often vulnerable to exploitation (The Control Yuan, 2025). Women are often objectified, not considered as a human but as sexual value (Taiwan Taipei District Court, 2024). And as migrant workers, they are usually under the pressure of debt or the demand for a job, which puts them in a weaker position (American Institute in Taiwan, 2024). Most female migrant workers are employed as care giver, working in private homes means they receive less visibility and protection, which is likely to exposes them more to exploitation and even sexual violence by employers or other people in the household (ILO, 2011, December 15). Reporting is difficult for them too because they might lose their job, which is a risk few would take. As migrant workers, they will also have to face the barrier of language, which, combined with the dilemma they are already facing, is likely for them to bear and endure (Ministry of Health and Welfare, 2024).

1.2 Human Rights Fallacy

1.2.1 Neglect of Negative Human Rights for Migrant Workers

A prevailing bias reduces migrant workers to "labor commodities," misconstruing fundamental human rights as "extra benefits" or "privileges". When employers view workers as "private property" rather than legal

subjects, basic rights become a matter of "benevolence" rather than statutory protection. However, human dignity should never be weighed against economic profit (Rothna Begum / Human Rights Watch,2015)

The tension between Perceived Resource Costs and Legislative Prioritization can be explained through "Bounded Rationality" (Simon, 1955) and "Mental Accounting" (Thaler, 1999). Due to cognitive limits, the public often conflates essential protections with "expensive" extras, leading legislators to de-prioritize these issues in favor of more "urgent" matters. Ultimately, as Kapp (Kapp, 1950) argued, neglecting these marginalized needs forces society to pay a much higher social cost later to address crime and welfare systemic failures.

1.3 Global and Local Racial Hierarchies

The third root cause is the pervasive racial hierarchy and dehumanization inherent in global migration. Developed nations often relegate labour from developing countries to "second class" status. As Sassen (Sassen ,1991) observed, "Global Cities" depend on marginalized migrant groups while systematically excluding them from legal and social protections. In Taiwan, this manifests as a collective bias viewing citizenship as inherently superior to Southeast Asian migrants.

Such cultural bias facilitates sexual violence through Dehumanization; when workers are viewed as "disposable tools" rather than individuals, perpetrator empathy diminishes (Anderson, 2000). Furthermore, Taiwanese social discourse often "accepts" this violence as it aligns with a racialized logic placing Southeast Asian bodies at the social margins (Lan, 2006). This psychology catalyses the Social Apathy Loop, where the suffering of female workers is dismissed as a systemic "norm".

1.3.1 The Cycle of Social Apathy and Complicit Silence

Dehumanization fosters a Complicated Silence within social support systems. Due to hierarchical prejudice, the public often misclassifies abuse as a "private labour dispute" rather than a human rights violation. As Parreñas (Parreñas ,2015) notes, a "hierarchy of citizenship" creates a power vacuum at the bottom of the global care chain, where migrant workers are systematically denied full legal protection.

This apathy directly reinforces the Silence and Endurance of victims. According to a 2024 SPA survey, 1 in 6 female migrant workers in Taiwan has experienced gender-based violence, yet most remain silent (SPA, 2024). Perpetrators exploit this vulnerability by using threats of "immediate deportation" and operating under systemic impunity, emboldened by the knowledge that social biases will likely discredit the victim's voice.

1.3.2 The Visibility Trap: Low Reporting Rates and Statistical Fog

The sum of these factors results in a chronic Low Reporting Rate, creating a dangerous Visibility Trap. Official statistics often fail to reflect the true scale of the crisis because the costs of reporting—including job loss, debt bondage from high brokerage fees, and facing a judicial system lacking cultural sensitivity—far outweigh the hope of seeking justice (U.S. Department of State, 2024).

When the "visibility of actual occurrence" in official records remains low, it leads to a decline in social awareness. News media and the public encounter such information less frequently, leading to further estrangement and neglect of the issue. Without public oversight, the pressure on the government to change policy diminishes, which in turn justifies the continued existence of "high-risk labor structures." This lack of momentum for reform reinforces the original sense of racial superiority; the absence of public protest further cements the Subaltern

status of migrant workers, allowing the vicious cycle of sexual violence to continue indefinitely.

1.4 Environment of Impunity

Beyond the root causes, several perpetuating factors intertwine to form a "vicious closed loop”, ensuring that sexual violence against female migrant workers is not only possible but systematically sustained over the long term

1.4.1 Systemic Impunity and the Environment of Low Perceived Risk

The primary factor in the persistence of violence is the "low-risk environment" perceived by perpetrators. This sense of impunity stems from the failure of administrative oversight and the inefficiency of legal enforcement. An extreme example is the 2024 "Keelung Case," in which a wanted sex offender successfully passed government screening to legally hire a foreign caregiver, subsequently subjecting her to nine months of abuse—during which the local government failed to conduct a single site visit(Zeng, 2025).When perpetrators observe loose social monitoring and massive loopholes in legal execution, violent behavior persists because it is

seen as "cost-free." This environment reinforces illicit behavior and further erodes the deterrent power of the law.

1.4.2 Privacy as a Shield for Violence: The Invisibility of Domestic Space

The nature of the workspace profoundly affects the frequency of violence. As Parreñas (Parreñas, 2015) observes, employment within private domestic spaces severs social oversight. In Taiwan, this physical isolation causes violence to shift into hidden environments where public apathy treats domestic occurrences as "private matters". This concealment not only facilitates abuse but also obstructs evidence collection, fracturing judicial remedies.

Furthermore, this isolation creates a "Data & Visibility Gap." When violence remains confined to private spheres and victims remain silent, the resulting lack of official statistics misleads policymakers into believing the issue is managed. This statistical invisibility subsequently perpetuates systemic withdrawal, stratification, and continued economic oppression.

1.4.3 Hierarchy of Citizenship and the Power Vacuum

Parreñas further notes the existence of a global "hierarchy of citizenship," where the laws of developed nations often view migrant workers as "non-citizens" or merely "temporary labor"(Parreñas, 2015).In Taiwan, this hierarchy translates into a power vacuum—a dangerous space where "the law cannot reach, outsiders cannot see, and the perpetrator has the final say." Legal systems are significantly biased toward employers. Because migrant workers lack full citizenship rights and the freedom to change employers, they are trapped in a high-risk structure built on prejudice. This structural inequality grants employers' absolute power, transforming the labor-management relationship into one oppression.

1.4.4 Economic Disempowerment and the Cost of Refusal

The systemic exploitation of migrant workers significantly increases their "cost of refusal." High brokerage fees create a state of "debt bondage" from the onset of their labor in Taiwan (Workforce Development Agency, 2021). Simultaneously, these women often bear the burden of "transnational motherhood," serving as the primary economic pillars for their families back home (Parreñas, 2015).

Furthermore, Southeast Asian gender norms regarding chastity impose a "family disgrace" on victims of sexual violence, regardless of consent. This cultural stigma compels victims to choose silence to avoid familial disdain. Caught between "personal safety" and "family livelihood," workers often prioritize debt repayment over seeking justice. This induced "silence and endurance" results in low reporting rates, ultimately reinforcing the invisibility of the entire system.

1.5 Legislative Loopholes and Administrative Negligence

1.5.1 Failure of Administrative Due Process

The Control Yuan's reports highlight a critical failure in inter-agency cooperation; administrative bureaucracy often stalls case transfers, leading to "dark figures" of unreported abuse. A notable instance involved a case suppressed for two years, only surfacing via a whistleblower petition. By the investigation's conclusion, the victim had already returned home without compensation, bearing the psychological and financial scars alone.

Evidence of falsified records further underscores this systemic negligence. Municipal governments frequently fail to conduct mandatory on-site inspections, leaving discrepancies between actual and official residences unnoticed. Furthermore, bypassed departure verification procedures allow employers to forcibly deport workers before grievances are settled. These failures render the "Manpower Agency Evaluation System" futile; agencies concealing abuse have maintained "Grade B" ratings, proving the system is fundamentally disconnected from reality.

1.5.2 Legal Loopholes and Deficient Protection Mechanisms

The current legal framework lacks clear penalties for local governments regarding administrative negligence, such as mishandled case transfers or falsified records. This legislative vacuum leaves migrant workers without protection when their fundamental rights are violated. A primary concern is the "window period" during an employer transfer; although a de facto employment relationship exists, the lack of formal registration allows employers to evade statutory obligations, significantly increasing the worker's vulnerability. Furthermore, the 1955 hotline referral mechanism typically assigns cases to the authority where the employer is registered rather

than where the incident occurred. This jurisdictional ambiguity leads to bureaucratic "buck-passing," causing urgent cases to be indefinitely shelved.

1.6 Pressure from Intermediary Companies and Structural Exploitation

1.6.1 Forced Settlements: Evidence from the Keelung and Chiayi Cases

In the global labor migration system, manpower agencies act as the primary gatekeepers, controlling everything from daily life and work assignments to communication with employers. For newly arrived workers, the agency is often their sole point of contact. Due to language barriers and a lack of information, many remain unaware of alternative support channels. Even for experienced workers, agencies still wield immense power over their legal status and livelihood.

The actions of an agency can determine whether a case of sexual assault or violence is resolved or suppressed. In the Chiayi case, the agency failed to report the incident and illegally coerced the victim into a settlement. The Ombudsman's report reveals that the agency pressured the victim to accept NT$100,000 and sign a settlement agreement. By attempting to "bypass" legal procedures to minimize their own financial risks and administrative burden, the agency effectively silenced the victim and became a primary catalyst for the delay of justice. (The control Yuan, 2025, August 22)

1.6.2 International Context: The Kafala System and Total Control

In the Gulf Cooperation Council (GCC) countries, the Kafala (Sponsorship) System represents a more extreme form of labor control than Taiwan's framework. Under Kafala, employers exercise near-total authority by withholding passports and controlling visas, effectively stripping workers of their freedom of movement. Bajracharya and Sijapati (Bajracharya, R., & Sijapati, B. ,2012) report that authorities often forcibly return fleeing workers, while employers may retaliate against those escaping abuse by filing false "absconding" charges.

While Taiwan has made progress, these global comparisons underscore that systemic violations remain a persistent threat. Female migrant workers worldwide endure multifaceted exploitation—from wage discrimination to physical violence. For many, resistance remains silent and invisible, making their protection a critical human rights priority for the international community.

2 Systems Thinking Approach

2.1 Systems Map

Below is a systems map that we consolidated our challenge landscape into; we organized four loops (Figure 1)The blue one is the social cultural loop, the orange one is the institutional loop, the green one is the report procedure loop, the yellow one is the mental model loop, and the purple one is the structural dependency loop.

Figure 1: System Map

2.2 Systemic Loop Analysis

2.2.1 Socio-Cultural & Institutional Loops

The Social-Cultural Loop illustrates how racial discrimination evolves into the dehumanization and objectification of female migrant workers, fostering a "structural complicity of apathy". This environment compels victims to endure abuse in silence, leading to low reporting rates that further entrench racial biases.

Simultaneously, the Institutional Loop highlights how legislative loopholes and systemic impunity lower the perceived risk for perpetrators. The resulting physical isolation within private homes creates a "visibility gap," obstructing law enforcement and stabilizing the environment of impunity.

2.2.2 Reporting & Mental Model Loops

The Report Procedure Loop reveals a failing protection system where hotlines fail to address jurisdictional conflicts or workplace discrepancies. These failures lead to administrative delays and falsified inspection records, creating a "legal vacuum" where formal protections exist but are inaccessible. Furthermore, the Mental Model Loop identifies how intermediaries prioritize profit and employer relationships over worker safety. By forcing coerced settlements, intermediaries create severe information asymmetry, distorting evaluation systems with falsified data.

2.2.3 Structural Dependency Loop

The Structural Dependency Loop highlights how legal and financial vulnerabilities—exacerbated by debt bondage—strip workers of bargaining power. This dependency, intensified by spatial isolation and information asymmetry, makes it nearly impossible for workers to leave abusive employers, thereby increasing the probability of sustained violence. Collectively, these loops form a self-reinforcing system that perpetuates sexual violence against female migrant workers.

2.2 Iceberg Model

Below is our iceberg model (Figure 2)

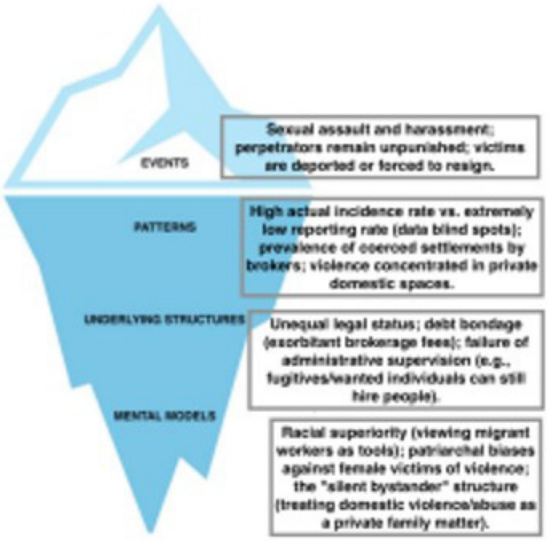

Figure 2: Iceberg Model

2.3 Stakeholders' Map

This map shows stakeholders who either exacerbate or ameliorate the problem of sexual violence towards female migrant workers (Figure 3) .

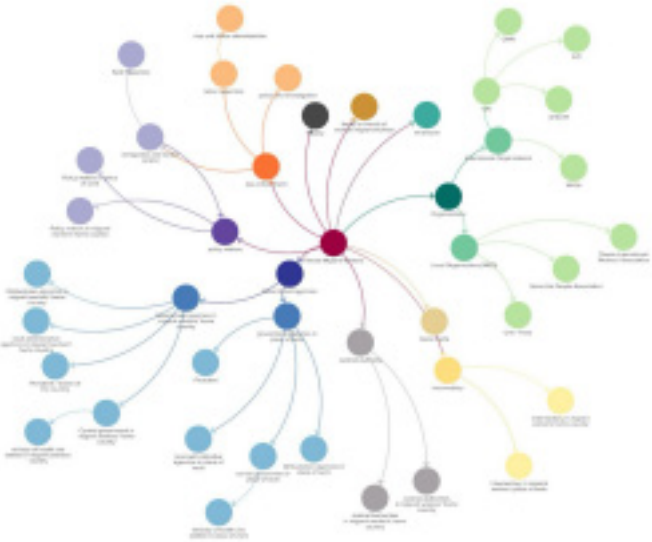

Figure 3: Stakeholders' Map

3 Solutions Landscape

3.1 Disadvantages of Existing Solutions

3.1.1 International Frameworks

- UN Resolution 78/180 (2023): While establishing vital normative protections against gender-based violence, it lacks enforcement power. Its focus on long-term "economic empowerment" overlooks the immediate crisis of debt bondage, providing "too little, too late" for workers in recruitment debt.
- 'Safe and Fair' Initiative (EU & UN, 2019): This program integrates protection into National Action Plans via technical assistance. However, its impact is limited by the host country's prioritization; if legal frameworks in service-providing nations remain weak, abuse persists. Furthermore, it fails to penetrate the entire employer-industry chain.

3.1.2 National Government (Taiwan)

Despite MOHW guidelines, structural gaps persist between mandate and capacity:

- Reactive vs. Proactive Supervision: Current policies focus on 24-hour mandatory notification post incident. This reactive measure fails to identify "pre-event" warning signs due to manpower crises and a lack of routine inspections.
- Inaccessibility in Isolated Environments: Reliance on the 1955 hotline (approx. 550 cases/year) assumes communication autonomy. It provides no intervention for victims whose phones are confiscated or movements restricted.
- • Non-standardized Interpretation: While MOHW mandates interpreters, it lacks standardized sourcing or training. Deficiencies in legal terminology and trauma-informed care often led to poor evidence collection and secondary victimization.

3.1.3 NGOs and Advocacy Gaps

- IDWF: Faced with a legal ceiling, as many host countries forbid migrant unions, stripping workers of collective bargaining power (WIEGO & IDWF, 2019).
- HRW: The Advocacy-Action Gap; international pressure often takes years to influence policy, failing to provide immediate safety for victims currently in crisis (Hafner-Burton, 2008).
- MFA: Resource Fragmentation; transnational rescue chains break if local partners lack funding or face political pressure (ILO, 2017).
- GAATW: The Complexity Trap; focuses on academic "root causes" and human trafficking definitions can be too slow for grassroots crises, causing victims of "standard" abuse to fall through the cracks (GAATW, 2007).

Table 1: Gaps and Levers of Change

Challenge	Gap	Levers of Change
Systemic Power Imbalance	• The treaty is difficult to implement because it cannot be forced, and not many countries have realized the importance of this problem. • The bind between employers and female migrant workers is hard to break.	• Reformation of law: Female migrant workers should be entitled the right to switch employers at their will. • Transparent Intermediary System: Break the information asymmetry.
Legislative Loopholes and Administrative Negligence	• Local agencies violate procedural justice through legal shortcuts and inaction, causing delays that remain systemically ignored.	• Governments should partner with NGOs to resolve staffing shortages, ensuring legal frameworks are successfully implemented. • Define clear penalties for misconduct and procedural skips to close loopholes and ensure strict enforcement.
Global and Local Racial Hierarchies	• Perpetrators operate under the "protective umbrella" of systemic impunity. • Official statistics often fail to reflect the true scale of the crisis.	• Implement stricter legislation and introduce harsher penalties. • Digital Advocacy & Awareness Campaigns: Humanizing Labor. • Inclusion of Voices: Engaging Youth and Migrant Leaders.
Environment of Impunity	• Lax social supervision and major legal loopholes reinforce the predatory behaviour of perpetrators and further weaken the deterrent power of the law. • Physical isolation further creates "blind spots" for information and data. • Structural inequality gives employers an absolute power advantage, transforming the labour relationship into one of oppression. • Migrant workers choose to endure abuse because they are burdened by debt.	• Mandatory Digital Connectivity: Legislation should prohibit employers from withholding mobile phones and ensure workers have unmonitored internet access in private spaces. • Establishing "Cyber-Safe Zones" and Peer-to-Peer Alert Systems: Government and NGOs can establish migrant worker communities or "blacklists", so workers know which employers or locations are dangerous. • Financial Support: Establish a "mutual aid fund" or introduce microloans to help migrant workers repay high-interest loans.
Human Rights Fallacy	• Public Prejudice Widespread bias and lack of awareness normalize discrimination. Without accurate understanding, the public remains indifferent to the systemic struggles migrant workers face. • A critical fallacy treats basic rights as "extra benefits." When fundamental dignity is seen as an optional privilege, it undermines the legal and moral obligation to protect workers.	• Human rights education must transcend traditional textbook instruction. Documentaries and artistic media serve as more potent catalysts for change by humanizing systemic issues through narrative storytelling. These mediums effectively bridge the empathy gap, transforming abstract concepts into relatable lived experiences that challenge public prejudice.
Loopholes of Intermediary System	• Distorted agency evaluation scores allow non-compliant companies to maintain good ratings. • For brokers, the cost of not reporting is low, so they prefer to operate in legal gray areas or illegally force settlements.	• Strict Accountability: Lower the threshold for business suspension (e.g., reducing the number of permitted non-reporting violations) to make the law stricter. • Increase penalties for failure to report.

4 Conclusions

This study employs systems thinking to deconstruct the multi-layered structural violence faced by female migrant workers in Taiwan. The analysis reveals that sexual violence is not merely a collection of isolated criminal acts, but a systemic outcome driven by the intersection of physical isolation, economic debt bondage, and socio cultural dehumanization. The self-reinforcing loops of institutional apathy and information asymmetry create a "legal vacuum" where existing protections fail to reach those in private domestic spaces.

To dismantle the systemic exploitation of migrant workers, a multi-pronged approach is required. Policymakers should shift from reactive notification to proactive inspections and ensure digital connectivity to

bridge the "visibility gap." Legal practitioners must implement trauma-informed interpretation services to prevent secondary victimization and ensure judicial accessibility. Finally, intermediaries and NGOsshould reform the brokerage system to eliminate recruitment fees, thereby reducing the financial debt that currently compels victims to endure abuse in silence.

By addressing these systemic leverage points, Taiwan can move beyond symbolic compliance toward a robust, gender-sensitive protection framework that upholds the fundamental human rights of all migrant workers.

Modern Dystopia: Social Media and Digital Fragility

Huang, Yu-En, Wu, Mei-Ling, Cheng, Hsiang-Wei
Baling High School, Taipei, Taiwan

Abstract

This practical paper investigates how social media platforms produce digital fragility through reinforcing relationships between platform incentives, algorithmic recommendations, high-stimulation interface design, and user behavior. Rather than treating excessive social media use only as a problem of individual discipline or content moderation, the paper frames it as a system-level governance challenge. The analysis focuses especially on adolescents, because peer evaluation, social belonging, and online feedback can make engagement-driven mechanisms more behaviorally influential during this developmental stage.

The paper applies a systems thinking approach to examine how social media platforms convert attention into economic value. Engagement generates behavioral data, behavioral data improves recommendation precision, and more precise recommendations increase further engagement. This circular process is strengthened by mechanisms such as infinite scroll, autoplay, push notifications, visibility metrics, and continuous recommendation feeds. To analyze these dynamics, the paper uses three systems tools: a Systems Map, an Iceberg Model, and a Stakeholders' Map. These tools show that problematic social media use is not produced by a single cause, but by the interaction of monetization models, recommendation architecture, user vulnerability, advertiser incentives, regulatory limitations, and unequal control over data and visibility.

Based on this analysis, the paper proposes a practical attention-governance framework designed to reduce cumulative exposure to high-stimulation mechanisms without regulating speech or content. The framework contains four pillars: a dual-layer protection mechanism across platform accounts and operating systems; transparent thresholds for activating protection; graduated reduction of high-stimulation mechanisms; and enforcement measures with anti-circumvention safeguards. Its core principle is to regulate mechanisms rather than content, shifting intervention from individual self-control to system design while avoiding centralized surveillance.

The paper also identifies unresolved limitations, including unauthenticated browsing, browser-level enforcement, cross-device and cross-platform circumvention, uncertainty around exact threshold values, risks of overbroad feature classification, possible misuse as content regulation, increased power for operating-system providers, and jurisdictional constraints. Overall, the paper contributes a system-informed practical framework for addressing social-media-driven digital fragility by targeting the feedback structures that sustain attention exploitation.

Keywords: System Dynamics, Social Media, Adolescents, Policy Intervention, Attention Exploitation
Paper type: Practical Paper

1 Introduction

Harms associated with excessive social media use are often framed as problems of individual discipline, digital literacy, or content moderation. This paper argues that such framing is incomplete. Social media platforms are not merely communication tools, but socio-technical systems in which business incentives, recommendation algorithms, interface design, user behavior, and regulatory limitations interact over time. For this reason, social media-related harm should be understood not only as an individual behavioral issue, but also as a system-level governance challenge. In this paper, digital fragility refers to a condition in which users' attention, autonomy, social judgment, and public discourse become increasingly vulnerable to platform systems that optimize for engagement, prediction, and retention.

In contemporary social media systems, user attention has become a measurable and economically valuable resource. Platforms are incentivized to increase engagement, extend time spent on the platform, improve advertising performance, and collect behavioral data. Recommendation systems support this process by ranking and amplifying content according to its likelihood of generating interaction. As users engage more frequently, platforms collect more behavioral data; this data improves recommendation precision; improved recommendations then increase further engagement. This creates a reinforcing feedback loop in which attention is repeatedly converted into data, and data into stronger attention capture (Zuboff, 2019; Casey, 2022; Milli et al., 2025).

In this paper, digital fragility refers to a condition in which users' attention, autonomy, social judgment, and public discourse become increasingly vulnerable to platform systems that optimize for engagement, prediction, and retention.

This issue is especially significant for adolescents. During adolescence, peer evaluation, social belonging, and social feedback often become particularly salient. Platform features such as likes, comments, follower counts, recommendation feeds, autoplay, push notifications, and infinite scrolling may therefore have a stronger behavioral influence on adolescents than on many adult users. The problem is not simply that adolescents lack

self-control, but that their developmental sensitivity can interact with platform mechanisms designed to encourage repeated use and prolonged engagement (Sherman et al., 2016; da Silva Pinho et al., 2024).

This framing also matters because many existing responses focus on symptoms rather than system structure. Education, parental guidance, screen-time reminders, and content moderation may be useful, but they do not fully address the incentives that make attention capture profitable and scalable. If the underlying system continues to reward engagement maximization, individual-level interventions may reduce some harm without changing the conditions that repeatedly reproduce it. A more effective response, therefore, requires attention to feedback loops, platform incentives, interface mechanisms, and the distribution of power between platforms, users, and regulators.

This paper adopts a systems thinking approach to examine these dynamics. It uses a Systems Map, an Iceberg Model, and a Stakeholders' Map to analyze how platform incentives, user responses, recommendation systems, data collection, and governance gaps form recurring feedback structures. Based on this analysis, the paper proposes a practical attention-governance framework that regulates high-stimulation mechanisms rather than content. It aims to reduce cumulative exposure to features such as autoplay, infinite scroll, and continuous recommendation feeds without censoring speech or creating a centralized surveillance system.

The objective of this paper is to develop a system-informed practical framework for reducing social-media-driven digital fragility by identifying the feedback structures that sustain attention capture and by proposing mechanism-based interventions that reduce cumulative exposure to high-stimulation platform features without regulating content.

2 Problem Framing

The problem examined in this paper is not simply that users spend too much time on social media. It is that social media platforms are built within incentive structures that reward repeated engagement, behavioral prediction, and long-term retention. From the platform perspective, attention is not only a sign of user interest but also a measurable resource that supports advertising exposure, data collection, and commercial value. The longer users remain active, the more opportunities platforms have to collect behavioral data, refine recommendation systems, and strengthen their position in the attention economy (Zuboff, 2019; Casey, 2022; Meta Platforms, Inc., 2025). This means that problematic use should not be understood only as an outcome of individual choice. It is also shaped by a business environment in which platforms compete to capture, retain, and monetize user attention. The term "high-stimulation mechanisms" is used here to describe interface and recommendation features that continuously supply new cues, reduce stopping points, or encourage repeated interaction, including infinite scroll, autoplay, push notifications, visibility metrics, and continuous recommendation feeds.

Recommendation systems are central to this structure. They do not merely show content in a neutral order. Instead, they rank, filter, and amplify content according to predicted interaction, such as clicks, likes, comments, shares, viewing time, and repeated visits. This means that content which is emotionally stimulating, rapidly consumable, or socially rewarding may receive greater visibility than content that is less interactive. Over time, such systems can create a feedback process in which engagement produces more data, data improves prediction, and improved prediction increases further engagement (Milli et al., 2025). Interface mechanisms such as infinite scroll, autoplay, push notifications, and continuous recommendation feeds reinforce this process by reducing natural stopping points and making repeated use easier to sustain (Rixen et al., 2023). Even when users intend to stop, the surrounding design environment may continue to provide new cues, rewards, and opportunities for re-engagement.

This platform-side dynamic interacts with user-side vulnerability. Social media is valuable because it provides communication, entertainment, information, and social connections. However, these ordinary uses can become entangled with mechanisms of social validation. Likes, comments, follower counts, and visibility metrics make social feedback immediate and measurable, linking social validation to repeated checking and potentially addictive patterns of use (Jain and Saleem, 2025). For general users, this can encourage repeated checking and prolonged participation. For adolescents, the influence may be stronger because adolescence is a period in which peer evaluation, social belonging, and social feedback often become especially important. Research on adolescent responses to social media feedback suggests that peer endorsement can influence attention, evaluation, and behavior in online environments (Sherman et al., 2016; da Silva Pinho et al., 2024). Therefore, adolescent vulnerability should not be understood as a personal weakness. Rather, it should be understood as a developmental sensitivity that may be intensified by engagement-driven platform design.

The historical development of social media has strengthened these dynamics. Earlier social media platforms were more closely associated with connecting friends, communities, and existing social networks. Content was

often presented through simpler timelines, and participation was more closely tied to known social relationships. As platforms expanded alongside smartphones, social ties became harder to leave, and engagement indicators such as likes, shares, and followers became more central to participation. In the algorithmic era, platforms increasingly shifted from chronological display toward personalized ranking and recommendation. This shift made social media less like a passive communication channel and more like an adaptive environment that continuously learns from user behavior (Nieborg and Poell, 2018; Twenge et al., 2019). As a result, the system became better at predicting what users are likely to watch, click, share, and return to.

The issue is also shaped by unequal power. Users participate in social media systems, but they do not meaningfully control the rules of visibility, ranking architecture, or data governance. Platforms possess greater access to behavioral data and greater ability to modify interface design, recommendation logic, and monetization strategies. This creates a form of data asymmetry: platforms can observe and optimize user behavior at scale, while users usually see only the final interface and have limited knowledge of how their attention is being organized. Regulators, by contrast, often face jurisdictional limits when dealing with global platforms that operate across devices, markets, and legal systems. This creates a governance gap: users experience the consequences of platform design, while platforms retain substantial control over the mechanisms that organize attention and visibility (Chan and Kwok, 2022; Königs, 2024).

For these reasons, excessive or problematic social media use should not be framed only as a failure of self-control. It emerges from the interaction of platform incentives, algorithmic recommendation, high-stimulation design, user vulnerability, competitive pressure, and weak governance capacity. This framing is important because it changes the policy question. The central issue is not only how to educate users to make better choices, but how to redesign or regulate the system conditions that repeatedly make attention capture profitable, scalable, and difficult to resist.

3 System Thinking Approach

This paper adopts a systems thinking approach because social media-related harm cannot be adequately explained through a single cause. Excessive or problematic use does not arise only from weak self-control, harmful content, platform design, or adolescent vulnerability in isolation. Rather, it emerges from the interaction of these factors over time. Systems thinking is useful in this context because it focuses on recurring patterns, feedback loops, structural incentives, and the assumptions that allow a system to reproduce similar outcomes. Instead of asking only what immediate event caused a problem, this approach asks how different parts of the system reinforce one another and why the same patterns continue to appear (Meadows, 1999; Sterman, 2001).

The analysis was conducted as a conceptual systems analysis rather than an empirical study. First, relevant literature on engagement-based ranking, adolescent social feedback, interface design, and platform governance was reviewed to identify recurring mechanisms. Second, these mechanisms were organized into system variables and actor categories. Third, causal relationships were mapped through reinforcing and balancing loops. Finally, the identified feedback structures were used to evaluate possible leverage points and develop a practical attention-governance framework.

The central system examined in this paper consists of platform companies, users, adolescents, advertisers, recommendation algorithms, interface mechanisms, operating system providers, regulators, families, educators, and civil society organizations. These actors and mechanisms do not operate independently. Platform companies design systems that maximise engagement and retention. Users respond to personalised content, social validation, and frictionless interface design. Advertisers benefit from attention and behavioral prediction. Regulators attempt to set rules, but often face jurisdictional and technical limits. Adolescents are not the only affected group, but they are especially important because social feedback and peer evaluation can be more influential during this developmental stage.

To analyze these relationships, the paper uses three systems tools: a Systems Map, an Iceberg Model and a Stakeholders' Map. The Systems Map visualizes the major variables and feedback relationships in the social media ecosystem. It shows how engagement, social validation, compulsive behavior, smartphone dependence, usage time, behavioral data and recommendation algorithms can form a reinforcing loop. In this loop, higher engagement produces more data; more data improves recommendation precision; improved recommendation increases personalized content; and more personalized content encourages further engagement. This structure helps explain why problematic use can persist even when individual users intend to reduce their screen time. The Systems Map also shows broader consequences, including polarisation, imitation, fake information and weakened meaningful public discourse. The Systems Map in Figure 1 visualizes the reinforcing relationships among engagement, behavioral data, recommendation precision and further engagement.

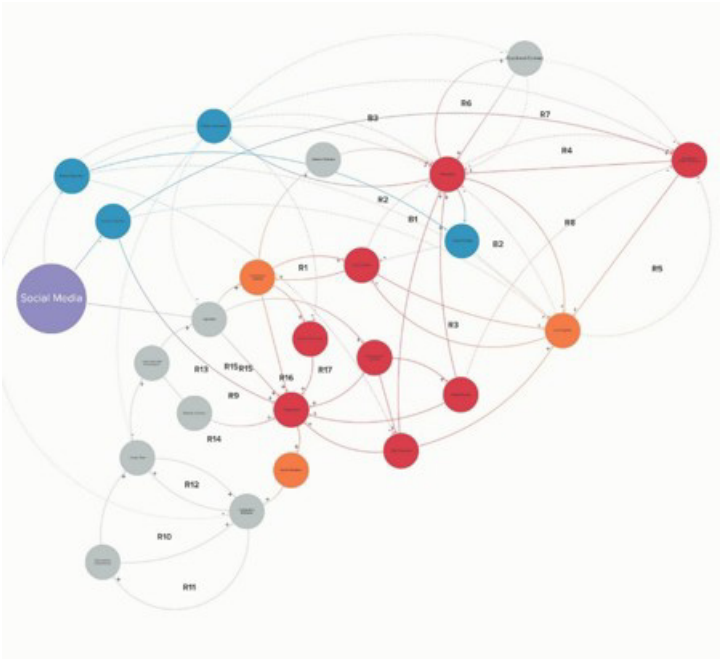

Figure 1: Systems Map
Source: Authors' Kumu systems map, available at: https://kumu.io/Ianlovesneko/cld#system-map

The Iceberg Model is used to separate visible symptoms from deeper system structures. At the event level, the issue appears as rising screen time, compulsive checking, increased phone dependence, and exposure to highly personalized content. At the pattern level, these events become recurring behaviors, such as repeated platform return, longer sessions, and growing dependence on recommendation feeds. At the structural level, the analysis identifies the mechanisms that produce those patterns, including engagement-based monetization, algorithmic ranking, infinite scroll, autoplay, push notifications, and feedback metrics. At the level of mental models, the system is supported by assumptions that constant connectivity, online visibility, and engagement growth are normal or desirable. This model is important because it prevents the analysis from stopping at surface-level symptoms. The Iceberg Model in Figure 2 separates visible symptoms from deeper patterns, structures, and mental models.

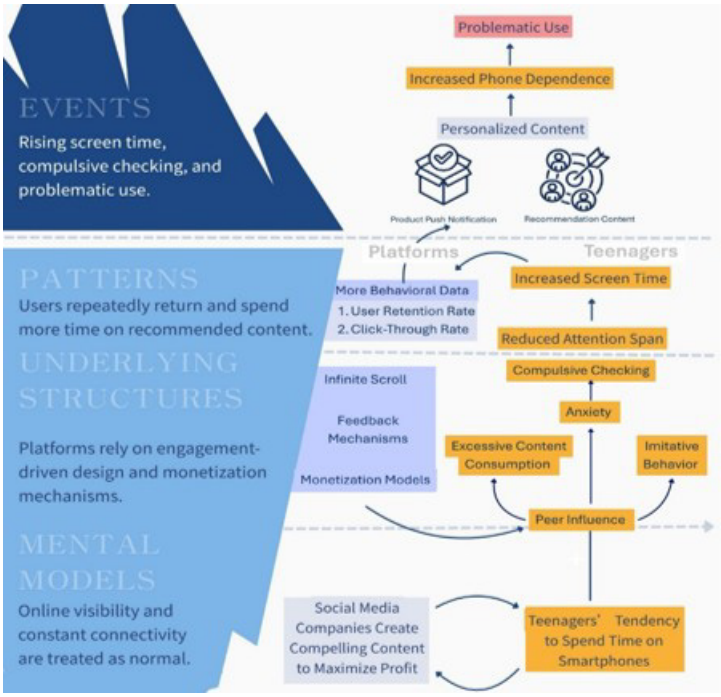

Figure 2: Iceberg Model

The Stakeholders' Map extends the analysis by identifying the actors and institutions that shape or are affected by the system. These include users, adolescents, families, educators, advertisers, platform companies, content creators, operating system providers, regulators, and civil society organizations. The map also recognises that some important forces are not human actors but structural mechanisms, such as recommendation systems, engagement metrics, and high-stimulation interface features. Treating these mechanisms as part of the stakeholder environment is useful because they influence behavior, distribute visibility, and shape decision-making even though they are not formal institutions. A full interactive version of the Stakeholders' Map is available at: https://kumu.io/Ianlovesneko/stakeholders-map

Together, these tools clarify why social media-related harm should be understood as a system-level governance problem. The Systems Map identifies reinforcing feedback loops, the Iceberg Model explains the deeper structures behind visible behavior, and the Stakeholders' Map shows the unequal distribution of influence among users, platforms, regulators, and technical infrastructures. This approach also supports the later policy analysis. If the problem is produced by reinforcing feedback structures, then effective intervention cannot rely only on education or individual discipline. It must also address the rules, information flows, and interface mechanisms that allow attention exploitation to become profitable and self-reinforcing.

4 Feedback Loops and Leverage Points

The systems thinking approach outlined in the previous section identifies that problematic social media use is sustained not by a single cause, but by recurring feedback structures. These feedback loops explain how platform incentives, user responses, algorithmic systems, and interface design interact to produce stable patterns of behavior over time. In this section, four major loops are identified: two reinforcing loops that intensify problematic use, and two balancing loops that may reduce or counteract these effects.

The first reinforcing loop (R1) can be described as the engagement loop. Higher levels of user engagement increase social validation through likes, comments, shares, and other feedback signals, which can encourage repeated checking and habit formation (Jain and Saleem, 2025). This encourages repeated checking and more frequent interaction, which can contribute to compulsive behavior and increased usage time. As usage increases, platforms collect more behavioral data, allowing recommendation systems to improve their precision. More precise recommendations then deliver more personalized and engaging content, which further increases engagement. This loop converts attention into data, and data into stronger attention capture, forming the core mechanism of the social media attention economy.

The second reinforcing loop (R2) connects personalized content, imitation, and polarisation. Recommendation systems tend to deliver content aligned with users' prior behavior and preferences. This can lead to repeated exposure to similar viewpoints, emotionally engaging material, and socially rewarded content. Such exposure may encourage imitation and strengthen belief consistency, contributing to polarisation and reducing the diversity of perspectives encountered. As users continue to interact with similar content, the system further reinforces the same pattern. Over time, this loop may weaken meaningful public discourse while increasing the visibility of highly engaging but potentially divisive material. (Avalle et al, 2024)

In contrast, two balancing loops represent mechanisms that can reduce or stabilize the system. The first balancing loop (B1) involves critical thinking and user awareness. Increased exposure to diverse perspectives, improved media literacy, and stronger critical evaluation can weaken the effects of polarisation and reduce the behavioral pull of high-stimulation content. However, this loop is relatively weak because it depends on user effort and education, while the reinforcing loops are continuously supported by platform design and economic incentives.

The second balancing loop (B2) involves external intervention, including platform-level adjustments or regulatory action. Measures such as limiting high-stimulation features, increasing transparency, or introducing friction can reduce excessive engagement and weaken the intensity of reinforcing loops. Unlike B1, this loop does not rely solely on individual behavior, but changes the conditions under which behavior occurs. However, current regulatory approaches often struggle to operate at the same scale and speed as platform-driven dynamics.

From a leverage point perspective, these loops highlight that not all interventions are equally effective. Parameter-level interventions, such as education and awareness campaigns, may support users but are unlikely to change the structural incentives that drive engagement. Stronger leverage points involve modifying information flows, feedback-loop intensity, and system rules. For example, increasing transparency in how recommendation systems operate can reduce information asymmetry. Reducing the intensity of high-stimulation mechanisms, such as autoplay and infinite scroll, can weaken reinforcing loops. Establishing

enforceable obligations and anti-circumvention rules can change the system conditions under which platforms operate.

Based on this analysis, the paper distinguishes between complementary interventions and core structural interventions. Complementary measures, such as digital literacy and critical thinking, play an important supporting role but are insufficient on their own. Core interventions must target the mechanisms that sustain reinforcing loops, particularly those related to engagement maximization, algorithmic amplification, and cross-platform attention capture. These insights provide the analytical foundation for the attention-governance framework proposed in the next section. From a systems perspective, effective interventions must target leverage points within reinforcing feedback structures rather than only addressing surface-level symptoms. Table 1 summarises the candidate interventions and their corresponding leverage levels.

Table 1: Candidate interventions by leverage level

Intervention	Target loop(s)	Meadows level	Role
Digital literacy and critical thinking	B1, R2	Supportive Information Flow	Complementary
Platform–OS feature-state reporting	R1	Level 6	Pillar 1
Threshold-triggered reduction of stimulation	R1, R2	Levels 7–8	Pillars 2–3
Legal duty and anti-circumvention	R1, B2	Level 5	Pillar 4

5 Proposed Attention-Governance Framework

Building on the feedback-loop analysis above, this paper proposes an attention-governance framework designed to reduce cumulative exposure to high-stimulation social media mechanisms. The framework does not aim to eliminate social media use, censor content, or create a centralized surveillance system. Its core principle is to regulate mechanisms rather than content.

In this paper, “high-stimulation mechanisms” refer to platform features that continuously supply algorithmically selected content, reduce natural stopping cues, or encourage repeated interaction without a deliberate user request. Examples include autoplay, infinite scroll, push notifications, and continuous recommendation feeds. These mechanisms matter because they shape how long users remain engaged, how easily they stop, and how often they return.

The first pillar is a dual-layer protection mechanism. This mechanism operates through two independent layers: a platform account layer and a device layer. The platform account layer addresses cumulative high-stimulation usage of the same account across multiple devices. The device layer addresses cross-platform usage on the same device and would be implemented through operating systems such as iOS or Android. Either layer can trigger protection independently when defined thresholds are reached. This design avoids creating a centralized cross-platform data system while still addressing platform-hopping behavior.

The second pillar is transparent and rule-based thresholds. Rather than relying only on opaque platform judgment, the framework requires clear trigger conditions for intervention, reflecting broader concerns about algorithmic transparency and ethical platform design (Hu, 2025). These may include cumulative high-stimulation usage time, continuous usage duration, late-night activity, and repeated switching between platforms. The purpose of these thresholds is not to punish users, but to define when the system should reduce stimulation. Users should also be able to understand why protection was activated and challenge incorrect triggers.

The third pillar is graduated mechanism regulation. Once thresholds are reached, platforms would progressively reduce high-stimulation features. Early intervention may involve reminders or pause screens. Stronger intervention may disable autoplay, interrupt infinite scrolling, reduce recommendation intensity, or switch users to chronological or subscription-based feeds, building on emerging research on contextual interventions during infinite scrolling (Meinhardt et al., 2025). The content itself remains accessible; what changes is the delivery mechanism. This distinction is essential because the framework aims to reduce attention exploitation without becoming content moderation or viewpoint control.

The fourth pillar is enforcement and anti-circumvention. Without enforceable duties, platforms may redesign systems to preserve engagement while appearing compliant. They may rename features, shift high-stimulation functions into alternative formats, or use notifications to pull users back into restricted environments. The framework, therefore, requires audits, compliance checks, and penalties strong enough to prevent circumvention from becoming economically rational. Protection-related data should also be used only for safety and regulatory purposes, not for advertising, commercial analysis, or recommendation optimization.

Together, these four pillars shift intervention from individual self-control to system design. Education and digital literacy remain important, but they are insufficient when the surrounding system is optimized to maximize engagement. A systems-informed policy must weaken the reinforcing loops that convert attention

into behavioral data and behavioral data into further attention capture. The proposed framework does this by changing information flows, reducing feedback-loop intensity, and creating enforceable rules around high-stimulation design.

6 Limitations and Future Refinement

This framework has several limitations that require further refinement before implementation. First, the dual-layer mechanism can reduce platform-hopping, but it cannot eliminate all forms of circumvention. Users may browse without logging in, move between browsers and apps, use multiple devices, or combine cross-device and cross-platform switching. Fully preventing these behaviors would require a centralized identity or data-sharing system, which this paper deliberately avoids because it would create serious privacy and surveillance risks. Therefore, the framework should be understood as a risk-reduction mechanism rather than a system of perfect control.

Second, exact threshold values remain uncertain. Usage time alone does not always indicate harm, because context, purpose, age, content type, and individual differences matter. For example, one user may spend time on social media for communication or learning, while another may be repeatedly exposed to high-stimulation recommendation feeds. The definition of "high-stimulation mechanisms" may also create borderline cases, such as news feeds, search results, streaming services, or educational platforms with recommendation functions. Future policy design should therefore include expert review, pilot testing, public consultation, and clear scope limitations.

Third, the framework creates governance risks. A mechanism-based system could be misused as content regulation if legal boundaries are not explicit. Device-layer enforcement may also increase the power of operating system providers such as Apple and Google, especially if they gain authority to classify or restrict platform functions. In addition, single-country implementation may face jurisdictional limits because major platforms operate across borders. These risks show that attention governance requires strong safeguards, including transparency, independent audits, appeal mechanisms, data minimization, proportional enforcement, and international coordination. These limitations do not invalidate the framework, but they show that implementation must be cautious, reviewable, and institutionally constrained.

7 Conclusion

This paper has argued that social-media-driven digital fragility should be understood as a system-level governance problem rather than only an individual behavioral issue. Excessive or problematic use does not emerge from user weakness alone. It is produced through the interaction of platform incentives, recommendation systems, high-stimulation interface design, user vulnerability, and limited regulatory capacity.

Using a systems thinking approach, the paper identified how engagement, behavioral data, recommendation precision, and further engagement form reinforcing feedback loops. It also showed that adolescents may be especially affected because online feedback, peer evaluation, and social visibility can become more influential during this developmental stage. These findings suggest that education and digital literacy remain necessary, but insufficient, if the surrounding system continues to optimize engagement and retention.

The proposed attention-governance framework responds to this problem by targeting mechanisms rather than content. Through dual-layer protection, transparent thresholds, graduated reduction of high-stimulation features, and anti-circumvention enforcement, the framework aims to reduce cumulative exposure without censoring speech or creating a centralized surveillance system.

The broader contribution of this paper is to connect systems analysis with practical policy design. By focusing on feedback structures and leverage points, it shifts the discussion from blaming users toward redesigning the conditions that shape digital behavior. Future work should test threshold design, clarify regulatory scope, and explore international coordination. Nevertheless, the central implication remains clear: meaningful intervention must address the structures that make attention exploitation scalable, profitable, and self-reinforcing.

8 Ethics declaration

This paper did not involve human participants, interviews, experiments, surveys, or the collection of personal data. The analysis was based on literature review, systems mapping, and publicly available information. Therefore, formal ethical clearance was not required.

9 AI declaration

The authors used Perplexity, ChatGPT, Claude, Microsoft Copilot, and Grammarly during the development of this paper. Perplexity was used to search for academic sources; all sources were opened, checked for DOI information and relevance to the topic, and manually reviewed before use. ChatGPT was used to translate human-written Chinese drafts into English, refine wording, generate critical questions, and support red-team debate. Claude was used for red-team critique, multi-model debate, and identifying weaknesses in the proposed framework. Microsoft Copilot was used for formatting support and layout suggestions, and Grammarly was used for grammar correction.

Some AI-assisted wording was incorporated into the paper after human review and revision. However, AI did not generate the core ideas, systems analysis, causal logic, systems maps, or policy framework. AI-generated suggestions were used only as support for language refinement, critical questioning, and presentation improvement. All final academic judgments and decisions on whether to adopt, revise, or reject AI-generated suggestions were made by the authors.

When Wetlands Disappear: What Human Development Means for Nature?

Jimmy Mao, Leticia Hsu, Sophie Yang
Taipei Digital Experimental High School (T-School), Taipei City, Taiwan, R.O.C.

Abstract

Wetlands represent some of the most productive and vital ecosystems on Earth. Despite covering approximately 6% of the global land surface, these environments—which include marshes, fens, peatlands, and various water bodies—provide indispensable ecological services, including water filtration, flood mitigation, and significant carbon sequestration. Research indicates that wetlands store more than one-third of the world's soil carbon, making them critical buffers against climate change (Mitsch and Gosselink, 2015). However, these ecosystems are currently vanishing three times faster than global forests. This study utilizes a systems-thinking methodology to analyze the drivers of wetland loss, focusing on the systemic interactions among human development, economic investment, and environmental conservation, with specific reference to the Wugu Wetlands in Taiwan.

The degradation of global wetlands has reached a critical threshold. Since 1970, an estimated 22% of the world's wetlands have been lost, primarily due to human interventions such as drainage for agriculture, urban expansion, and industrial pollution (WWF, 2024). This phenomenon, often termed the "wetland squeeze," occurs when coastal and inland habitats are trapped between rising sea levels and encroaching human infrastructure. The humanitarian implications are profound, as more than one billion people worldwide rely on wetlands for their livelihoods, including fishing, rice cultivation, and tourism (Ramsar Convention Secretariat, 2007). In Taiwan, the Wugu Wetlands serve as a primary example of this tension, where historical land-use policies have prioritized urban development over ecological preservation.

This research employs a Sustainable System Development (SSD) framework to map the complex feedback loops governing wetland exploitation. The methodology follows the strategic management and business innovation techniques outlined by Yan (2022), focusing on the identification of "reinforcing" and "balancing" loops within a system. Data were synthesized from international bodies, including the Ramsar Convention and the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES), alongside local biological data from the National Park Service of Taiwan. To process complex global and local trends, the researchers utilized artificial intelligence models to assist in the analysis of large datasets and causal relationships. The scope of the study focuses on five systemic categories: the Core exploitation-conservation balance, the Economic Loop, Community Support, Impacts on Nature, and External Factors such as climate change and international policy.

Keywords: Wetlands, Biodiversity, Systems Thinking, Human Development, Conservation

Paper type: Academic Research Paper

1 Introduction

Wetlands are defined as Areas of marshes, lagoons, peatlands, intertidal zones, and water bodies that are natural or man-made. Despite covering just 6% of the Earth's land area, these "biological kidneys" function as the planet's primary natural filtration system(Convention on Wetlands, et al., 2025). By trapping sediment and neutralizing pollutants, they provide a level of water purification that human infrastructure can rarely replicate.

But we are currently facing a "wetland squeeze" where urban expansion, agricultural development, and rising sea levels are fragmenting and drowning these vital coastal and inland buffers. When a wetland is paved over or polluted, it doesn't just disappear; it releases portions of the world's largest soil carbon store (33% of the global soil carbon) back into the atmosphere, accelerating the very climate volatility they are meant to prevent.

The collapse of these systems isn't just an environmental statistic—it is a humanitarian crisis, as more than one billion people worldwide depend directly on wetlands for their livelihoods. (IPBES, 2019) This includes the fishing and tourism sectors in Taiwan, as well as the millions of rice farmers globally. For coastal cities, the loss of wetlands means that storm surges and floods, once manageable threats, have now become catastrophic events for millions of urban residents.

This essay highlights the urgent need to connect our understanding of wetland value—estimated at up to $39 trillion in annual benefits (Convention on Wetlands, et al., 2025)—with the alarming rate of their destruction. By exploring various articles and research, we aim to uncover the complex systems surrounding wetlands and examine the links between ecological health and human security. Ultimately, we aspire to envision a hopeful future for these essential ecosystems.

2 Methodology

2.1 Research Methods

With the help of Google, Google Scholar and AI models such as Gemini and ChatGPT to help us search for websites and data related to our topic, we collected data and research studies from Ramsar, Wetland International, Global Wetland Outlook (Convention on Wetlands, 2025), and many official local government websites. By researching these gathered data and studies, we analysed wetlands' exploitation all over the world.

2.2 Research Models

Through attending a two-month systems thinking course (MIT x SSD), we've created multiple different models according to our topic. One of the models that contributed the most to our research was the causal loop diagram. Reinforcing loop, a system structure where a change in a variable sets in motion a cycle of events that amplifies or compounds the original change. Balancing loop, a self-regulating, goal-seeking structure in systems thinking that counteracts change to maintain stability and equilibrium. By understanding the different connections between elements, we are able to define which key factors we want to further explore.

Current environmental literature widely recognizes wetlands as among the most biologically diverse and productive ecosystems on Earth. Often referred to as "biological supermarkets" or the "biological kidneys" of the planet, wetlands perform irreplaceable functions. The other model we've used to solidify our understanding of this topic is the iceberg model. The model allows us to look at the problem from different views and think of other solutions.

2.3 Research Scope

Due to geographical limitations, our research is primarily based on Wugu Wetlands in Taiwan. However, we've also implemented the data given by other organizations and countries. Most of the research and studies used in this report are dated between 2022 and 2026; however, older studies remain relevant and useful despite being outdated.

3 Findings

3.1 Wetlands to the World

The definition of wetlands varies depending on what each country or organization deems important. We have compiled the different definitions of wetlands adopted by different countries and organizations (Yi-Yuan Su (蘇義淵), 2020) :

- According to the UNESCO (1971), wetlands are defined as: "areas of marsh, fen, peatland or water, whether natural or artificial, permanent or temporary, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which at low tide does not exceed six metres."
- According to the EPA(Environmental Protection Agency, the United States)(2025) the definition of a wetlands are defined as: "areas where water covers the soil, or is present either at or near the surface of the soil all year or for varying periods of time during the year, including during the growing season."
- According to the Wetland Conservation Act (Ministry of the Interior, R.O.C., 2024), wetlands are defined as "areas such as marshes, lagoons, peatlands, intertidal zones, and water bodies that are natural or man-made, permanent or temporary, static or flowing, and fresh, salty, or brackish, including sea areas where the water depth does not exceed six meters at the lowest tide."

The difference between UNESCO (1971) and the definitions in the Wetland Conservation Act (Ministry of the Interior, R.O.C., 2024) is how specific the Ramsar convention defines wetlands. We believe the reason for these differences is due to the different mass of areas each organization is in charge of and what their ultimate protection goal is. For example, the Wetland Conservation Act (Ministry of the Interior, R.O.C., 2024) is more focused on the wetland's land while the EPA (2025) is more interested in protecting the growth of plants.

3.2 Ramsar Convention on Wetlands

3.2.1 Global Standards and Local Divergence

According to the Convention on Wetlands (2025), it emphasizes a shift from reactive to proactive wetland policies that prioritize conservation, restoration, and the integration of natural capital into decision-making.

Central to these policies is alignment with the Kunming-Montreal Global Biodiversity Framework (Convention on Biological Diversity, 2022), which targets the restoration of at least 30% of degraded ecosystems and the conservation of 30% of land and waters by 2030. The Outlook outlines four primary pathways for policy transformation:

- Integrating natural capital valuation to capture the true wealth of wetland services in economic planning.
- Recognizing wetlands as global public goods essential to the hydrological cycle
- Embedding wetlands in innovative financial solutions, such as blue bonds and debt-for-nature swaps
- Scaling up nature-based solutions by unlocking a mix of public and private finance while simultaneously reforming or eliminating harmful subsidies that drive degradation.

Although the Ramsar Convention on Wetlands is reasonable and solid, we believe that there should be more flexibility on the definition of wetlands, as each country's situation and environment are unique and can't be limited to a certain continent's situation. In contrast to the Ramsar Convention on Wetlands' policies (UNESCO, 1971), Taiwan, even though not eligible to sign the policy, has set its own rules for protecting wetlands.

3.2.2 Policies on Wetlands in Taiwan

According to the Ministry of the Interior, R.O.C. (2024), it prioritizes the "no net loss" of wetland areas and functions through a hierarchy of management strategies. Specifically, the Act mandates that any development project must first seek to avoid impacting wetlands; if impacts are unavoidable, they must be minimized, and any remaining loss must be compensated through restoration or creation elsewhere. There are four main points on the Wetland Conservation Act (Ministry of the Interior, R.O.C., 2024):

- Wetland Impact Assessment: The manufacturers that plan to develop projects significantly affecting a wetland of at least national importance are required to submit a wetland impact assessment and mitigation plan.
- Graded Management: Wetlands are classified into three levels- International, National, and Local- with the highest level of protection and stricter permit requirements applied to those of International and National significance.
- Permitted Wise Use: The policy encourages "wise use", which allows for sustainable activities that do not degrade the ecological character of the wetland, such as eco-tourism, environmental education, and traditional aquaculture or agriculture.
- Ecological Compensation: If a wetland is lost or degraded due to a project of major public interest, the developer must provide compensatory wetlands that are equal to or greater in area and ecological function.

Although policies in Taiwan are yet as detailed and complete as the Ramsar Convention on Wetlands, it still has its uses on limiting the development of wetlands. Though we agree with most of the policy's ideas, we believe that the main focus shouldn't be only on the land but rather also include the animals and plants living above it.

3.3 The Biodiversity of Wetlands

3.3.1 Current State of Wetland Biodiversity

In addition to wetlands being "the Earth's kidneys", they are the home to 40% of all global species and provide ecosystem services. However, wildlife populations in freshwater ecosystems have suffered a staggering 85% decline on average since 1970, according to the Living Planet Report (World Wildlife Fund., 2024).

3.3.2 Expected State of Wetland Biodiversity

To meet global biodiversity and climate goals, the Kunming-Montreal Global Biodiversity Framework(Convention on Biological Diversity, 2022) has established ambitious targets for 2030, requiring the effective restoration of at least 30% of all degraded ecosystems and the conservation of at least 30% of land, waters, and seas. More specifically, at least 123 million hectares of wetlands will be placed under restoration while also managing 428 million hectares within protected areas or other effective area-based conservation measures. Focusing on having a biodiverse environment, in our opinion, is better as it allows us to build a resilient ecosystem that can naturally adapt to changes rather than relying on constant human intervention.

3.4 The Loss of Wetlands

3.4.1 Loss Analysis on Wetlands

Through our research, we found that roughly 6% of the Earth's surface is covered by wetlands, and approximately 35% of global terrestrial carbon is stored within them. According to the Global Wetland Outlook(Convention on Wetlands, et al., 2025), wetlands are disappearing three times faster than forests. Wetlands act as massive carbon sinks, storing organic matter in their soil and plant communities, which is critical for global climate regulation. Since 1970, about 22% of the world's wetlands have been lost due to human activities like drainage, pollution, and over-exploitation. This loss is occurring at an average rate of 0.52% per year, with fresh water ecosystems like lakes and inland marshes experiencing the most significant proportional declines.

3.5 Our Observations

Initially, we believed that measuring wetland loss by area was sufficient. However, through extensive review we found that the biodiversity of wetlands was more important and more valid. Biodiversity in freshwater wetlands plays a key role in maintaining the stability of their habitat functions. (Song et al., 2024)The biodiversity of wetlands serves as a more comprehensive indicator of the ecosystem health than mere physical size. While acreage tells us how much land remains, biodiversity reveals how well it functions.

Ultimately, we believe the global community must elevate the protection of wetland biodiversity from a niche ecological concern to a top priority. Through our research, we have come to see these environments not just as land, but as the Earth's biological infrastructure. We are concerned that focusing only on wetland size may overlook a silent crisis—the collapse of ecosystems.

4 Discussion

4.1 The Disappearing Wetlands

Since the 1700s, the expansion of human exploitation has severely damaged many natural ecosystems. Wetlands are no exception.

According to the Convention on Wetlands, et al. (2025), the Earth has lost about 1,837 million hectares of wetlands since the 1970s, which is roughly 22% of the wetlands that once existed.

However, available data in Taiwan focuses on the number of National Important Wetlands rather than their actual area, resulting in limited insight into wetland conditions.

4.2 System of Wetlands

We analyzed the system behind Wugu Wetland (New Taipei, Taiwan) and the related issues to clarify the challenges and problems within the overall wetland system. Then, we group the elements into five categories:

- The Core: the center of the system, and the critical part of the wetland system.
- The Economic Loop: a key feedback loop related to wetland exploitation.
- The Community Support: the role and actions of the community surrounding the wetland.
- Impacts on Nature: the significance of the wetlands for the natural environment.
- External factors: external factors such as government agencies, companies, and environmental organizations.

4.2.1 The Core

The core of the wetland system is formed by "Wetland Exploitation," "Wetland Area," and "Wetland Conservation". The entire system is closely linked to these three important elements.

Wetland exploitation reduces wetland area; conversely, if conservation efforts are made, wetlands can gradually recover and return to their original state.

In our case, wetland exploitation refers to constructing buildings, developing parks, or directly destroying wetlands to satisfy human needs.

Wetland conservation includes actions such as protecting the wetland environment and its wildlife, as well as implementing ecological compensation measures (Mei-Li Hsue, Hsing-Juh Lin, 2015).

4.2.2 The Economic Loop

In addition, we identified some elements and three reinforcing feedback loops linked to the "Wetland Exploitation" element, which we call the "Economic Loop". This loop is driven by economic activity, and its outcome is a change in the "Wetland Area". This destructive loop caused the wetland area to decrease rapidly.

The following statements are going to explain the details of the elements in the economic loop.

- **Company Investment:**
  Some companies invest in the exploitation of wetlands because they see them as business opportunities. As a result, they often promote wetland exploitation, which indirectly leads to wetland destruction—for example, through the construction of factories, parks, or other buildings.
- **Community Approval of Exploitation:**
  The communities surrounding wetlands sometimes approve wetland exploitation, and their level of support directly affects the extent of exploitation. Conversely, if the community doesn't support companies' development activities and prefers to preserve the environment, wetland exploitation may slow down.
- **Economic Growth:**
  Wetland exploitation can bring more economic activities and contribute to economic growth, but it also encourages further exploitation of wetlands.
  Economic growth in turn attracts more companies to invest in wetlands because of the potential financial returns.

At the same time, the perceived benefits of economic growth shape community attitudes toward wetland exploitation, making communities more likely to approve it.

The relationship among these elements creates three reinforcing feedback loops in the Economic System. These loops function as the main drivers of wetland exploitation and cause it to accelerate rapidly.

4.2.3 The Community Support

In addition to the core and the economic loop, community support is another component. The surrounding community also plays an important role in the system. Community support can have both positive and negative impacts on wetlands.

- **Community Environmental Knowledge:**
  Environmental knowledge strongly shapes the actions and attitudes of residents. With lower environmental knowledge, residents are more likely to approve of activities or policies that may lead to higher wetland exploitation. By contrast, higher environmental knowledge leads to greater support for wetland conservation.
- **Community Participation:**
  Higher levels of community participation tend to increase the willingness of residents to engage in conservation activities that would benefit the natural environment.
- **Community Identity:**
  Community identity is an important driver of community participation; residents would participate more if they think they are a part of the community.
- **Community Living Quality:**
  Living quality is a crucial concern for residents. Better living quality allows residents to live healthier and more securely. We believe that living quality is an important factor shaping community decision-making and that economic growth can improve living quality.

The community plays a key role in the system, reflecting public opinions and influencing decisions on wetland exploitation or conservation.

4.2.4 Impacts on Nature

Beyond economic activities and community support, it's important to discuss the roles of wetlands as part of the natural system.

- Wetlands provide habitats for many wildlife species. According to the Convention on Wetlands, et al. (2025), wetlands support about 40% of known species on Earth. In Taiwan, wetlands are often called "a paradise for birds," which highlights the importance of wetlands for animals, plants, and other creatures. In Taiwan, there are about 5,022 types of animals, plants, or other organisms that live in wetlands, including waterbirds, aquatic animals, aquatic plants, insects, and more. (National Park Service, MOI, R.O.C, 2026)

- Biodiversity helps maintain a stable food chain, which in turn affects the food available to humans. The plants, animals, and the environment itself form a complex web that may directly or indirectly influence human food resources. Wetland species and populations matter a lot for sustaining biodiversity.
- Wetlands have a water-purification function, which can reduce water pollution. However, water pollution caused by human activities can also destroy wetlands and hinder the water-purification function of wetlands.
- Wetlands play a regulatory role in the climate, helping to mitigate global climate change. Wetlands can modulate a high rate of greenhouse gases in the atmosphere, reducing about 60% of CH4(methane), 20% of CO2(carbon dioxide), and 6% of NO(nitrous oxide). (IPCC, 2007)

4.2.5 External Factors

Last but not least, some external factors are also taken into account to, to some extent, influence the system, such as:

- Policies:
  Some policies support companies in investing in or exploiting wetlands because governments aim to boost the economy of communities near wetlands.
- Support from non-governmental organizations (NGOs):
  Many NGOs that care about nature visit wetlands to carry out conservation work to help the wetlands recover.
  For example, in Taiwan, some NGOs have been contributing their efforts to protecting wetlands, such as the Society of Wilderness (社團法人中華民國荒野保護協會), Wetlands Taiwan (社團法人臺灣濕地保育聯盟) and the Taiwan Wetland Society (社團法人臺灣濕地學會).
- Government support:
  Some governments support NGOs or other wetland conservation initiatives in order to implement environmentally friendly policies. Since wetlands and riverside parks are publicly owned, NGOs must obtain authorization from the government before carrying out conservation activities.
- Company investment:
  Many companies invest in wetland exploitation or other forms of development because of the high land value. However, these activities can seriously damage the environment and may even completely destroy local ecosystems.
  For example, in Taiwan, Uni-President Enterprises Corporation has collaborated with the Society of Wilderness. Donation boxes have been placed in some 7-11 stores across Taiwan, not only to raise public awareness but also to support the Society of Wilderness in environmental conservation.

These factors are not part of the community or nature, but they can influence many decisions and serve as key drivers in the system.

The system map on the next page shows the overall system we identified in this issue, including the economic loop, community support, impacts on nature, and external factors.

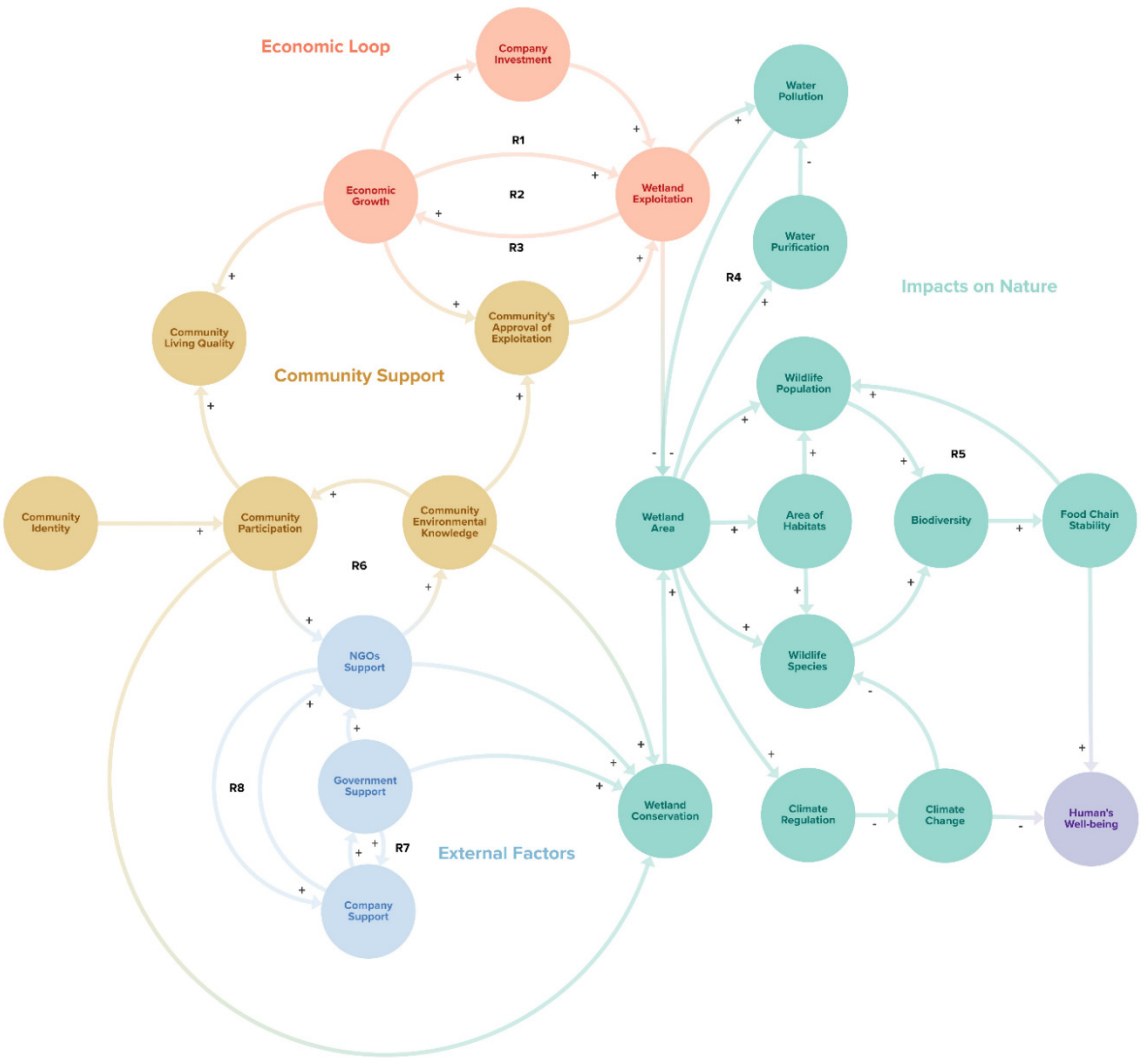

Figure 1 System Map of Wetlands with External Factors

5 Conclusion and Future Directions

5.1 Challenges

The over-development of wetlands must be addressed, but there are many complex challenges we need to confront. If we fail to tackle the following challenges, it will be very difficult to reduce wetland exploitation because of these terrible loops.

5.1.1 The Economic Loop and Community Expectation

For investors, wetlands are simply undeveloped land. If they develop the wetland, they gain financial returns, reinforcing an economic loop.

The community surrounding wetlands also benefits from economic growth and improvements in living quality, so they have little reason to oppose exploitation projects.

Governments can also gain from these exploitation projects – through taxes, economic feedback, or even votes – so policies often end up favoring investors, encouraging further wetland exploitation.

5.1.2 Climate Change

Climate change is partly due to wetland loss, but it also further accelerates wetland degradation. As wetlands disappear, we lose a crucial natural system for regulating the global climate and slowing global warming.

In addition, climate change harms human livelihoods as well as animals and plants around the world. People around the globe are increasingly concerned about climate change, which is driven not only by CO_2 emissions but also by the loss and degradation of natural ecosystems such as wetlands.

5.1.3 Water Pollution

Similarly, wetlands play a key role in purifying water quality, yet water pollution is also a major driver of ecological collapse within wetlands. As more wetlands are degraded, we not only weaken their water-purification capacity but also create a vicious cycle in which polluted water further damages the remaining wetlands and accelerates their loss.

The water pollution is also harmful for the animals, plants, and also humans. Sometimes, water pollution could cause severe diseases and even more serious ecological disasters, or ecological catastrophes.

5.1.4 Lack of Environmental Knowledge

The environmental knowledge of residents in the community is extremely important. If the community lacks sufficient environmental knowledge or awareness, residents may become the ones who damage nature—for example, by littering or feeding wild animals—and they will also be more likely to approve destructive actions such as wetland exploitation.

By contrast, if the community has sufficient environmental knowledge, residents can become protectors of the wetland. They are more likely to think critically about whether to approve development projects near wetlands, and they can participate in a wide range of wetland conservation activities that help improve and restore these ecosystems.

5.2 Suggestions

5.2.1 Implementing Natural Capital Accounting to classify wetlands practically.

We believe that governmental policies are crucial to wetland exploitation. Therefore, if we need to see changes in wetlands, close examination of policies and a shift in the current power dynamic are required.

Historically, there are countless development-oriented policies that exploit wetlands because the market value of a building was easily quantified, while the ecological services of a wetland remained "invisible" on a balance sheet.

To address over-development, Taiwan pioneered in Asia with the Wetland Conservation Act (implemented in 2015). It already classifies wetlands into "International," "National," and "Regional", three levels of importance. But to make classifying wetlands more detailed and practical, Natural Capital Accounting (NCA) should be implemented. This framework mandates that the economic value of flood mitigation, water purification, and carbon sequestration be integrated into provincial and national budgets. When the "shadow cost" of replacing a wetland with a multi-million dollar water treatment plant or sea wall is factored in, development projects that once seemed profitable are revealed as long-term economic liabilities.

By ending subsidies for coastal encroachment and prioritizing Nature-based Solutions (NbS), policies can align economic incentives with ecosystem preservation, ensuring that the "Core" wetland area is no longer a trade-off for growth, but a foundation for it.

5.2.2Implement "Citizen Science" for Community Support

To address the "Community Expectation" for quality of life, we must move beyond passive education to active community stewardship. Currently, people only care about wetlands when their own living quality has improved. We want to change it; the wetland shouldn't be a reward for a high quality of life; it should be the **engine** that produces it.

Instead of the community benefiting from the "Economic Loop" of exploitation, we must establish a system where **Wetland Health** directly drives **Local Well-being**.

We want to use citizen Science tools to gamify bio-monitoring: Citizen Science tools allow the public to voluntarily engage in scientific research. We can launch a "Community Health Dashboard," where residents can use mobile apps to log sightings of local species and assess water clarity. Through these tools, residents can access real-time data on how the wetland's "biological kidneys" are filtering their local water, cooling temperatures, and helping prevent expensive flood damage to homes. When people *understand* that a thriving wetland reduces their risks and expenses, supporting the community becomes a natural habit rooted in self-interest. And we will connect this data to local property values or "Eco-Credits." This initiative aims to create a

clear link between a thriving ecosystem and personal financial benefits, and also help residents recognize their role as stewards of the wetlands.

6 Ethics Declaration

Ethical Clearance was not required for this research.

7 AI Declaration

AI tools were employed solely for language refinement purposes and data gathering.

Montessori Education as a Human-Centered Foundation for AI Competency Development

David Coles, Tzu-Ting Hsu, Min-Ren Yan
North Star Bilingual Montessori, Taipei, Taiwan
National Chengchi University, Taipei, Taiwan

Abstract

The rapid integration of artificial intelligence (AI) is transforming how knowledge is created, interpreted, and applied within organizations. As AI increasingly automates routine and analytical tasks, sustainable competitive advantage is shifting toward distinctly human competencies, including abstraction, problem framing, adaptive learning, ethical judgment, and collaborative intelligence. These competencies shape how individuals engage with AI systems and contribute to hybrid human–machine knowledge processes (Brynjolfsson and McAfee, 2014).

From a knowledge management perspective, this shift raises a critical question: what educational foundations systematically prepare individuals for AI-mediated environments? While current discussions of AI competency emphasize technical literacy, long-term effectiveness depends on deeper cognitive and socio-ethical capacities developed through early learning experiences.

This paper proposes the Montessori–AI Capability Alignment Framework (MACAF), a three-layer conceptual model explaining how Montessori pedagogy supports the development of AI-relevant human capability. Layer 1 identifies key developmental design mechanisms embedded within Montessori education, including concrete-to-abstract progression, extended self-directed work cycles, self-correcting materials, mixed-age communities, and the teacher's role as guide. Layer 2 explains the human capabilities emerging from these mechanisms, such as structural abstraction, problem ownership, iterative reasoning, metacognitive awareness, and collaborative intelligence. Layer 3 demonstrates how these capabilities translate into AI-era organizational competencies, including algorithmic interpretation, effective human–AI interaction, iterative refinement, responsible AI use, and coordination within hybrid knowledge networks.

To illustrate the practical plausibility of the framework, the paper references North Star Bilingual Montessori School as an institutional illustration of how these mechanisms may be operationalized. Students engage in structured, real-world learning activities involving planning, collaboration, ethical decision-making, and adaptive problem solving, reflecting the formation of capabilities relevant to AI-mediated contexts.

This study contributes to knowledge management by linking developmental pedagogy with organizational capability formation. It argues that AI competency is not primarily a technical outcome, but the applied expression of human-centered cognitive and ethical development cultivated through educational design.

Keywords: Montessori education; AI competency; knowledge management; human capability; future talent development

Paper type: Conceptual Academic Paper

1 Introduction

Artificial intelligence (AI) is rapidly transforming how knowledge is generated, interpreted, and applied within contemporary organizations. As AI systems increasingly automate routine, analytical, and decision-support processes, sustainable competitive advantage is shifting toward distinctly human capabilities. In AI-mediated environments, individuals are required not only to use technological tools, but also to frame problems, interpret outputs, adapt to evolving contexts, and collaborate within hybrid human–machine systems (Brynjolfsson and McAfee, 2014).

This transformation raises important questions within knowledge management. Existing research has extensively examined how organizations create, transfer, and leverage knowledge assets (Nonaka and Takeuchi, 1995). However, comparatively less attention has been given to the developmental origins of the cognitive and socio-behavioral capacities that enable knowledge creation in the first place. Capabilities such as abstraction, adaptive learning, ethical judgment, and collaborative sense-making are not acquired instantly at the point of workforce entry. Rather, they emerge through earlier developmental experiences and learning environments.

In parallel, educational frameworks designed for the digital age emphasize similar human-centered competencies. For example, the Sustainable System Design (SSD) initiative developed by National Chengchi University (NCCU), aligned with Taiwan's 12-Year Basic Education framework, positions lifelong learning as its central objective. It is structured around autonomous action, communication and interaction, and social

participation, further elaborated into competencies such as systems thinking, adaptive innovation, ethical awareness, and collaborative engagement (NCCU, n.d.).

This convergence suggests that many competencies required for AI-mediated work represent an extension of long-recognized developmental capacities. The relevant question therefore becomes not whether these competencies matter, but how they can be systematically cultivated. While contemporary AI competency discourse often emphasizes technical literacy, such approaches risk overlooking the cognitive and socio-ethical foundations that enable meaningful AI interaction.

This paper proposes the Montessori–AI Capability Alignment Framework (MACAF), a three-layer conceptual model explaining how Montessori education functions as a developmental foundation for AI-era competency. The framework conceptualizes capability formation as a structured process linking learning environment design mechanisms, the emergence of human capabilities, and their later translation into competencies relevant to AI-mediated organizational contexts.

To clarify terminology used throughout the paper, **capabilities** refer to underlying cognitive and behavioral capacities (e.g., metacognitive awareness, iterative reasoning) that develop over time. **Competencies** refer to applied performance capacities in organizational contexts (e.g., responsible AI usage, human–AI coordination). MACAF explains how educational design mechanisms generate capabilities, which later manifest as competencies in AI-integrated work environments.

By articulating this developmental pathway, the paper advances a mechanism-based explanation of capability formation that complements existing knowledge management and AI competency perspectives. North Star Bilingual Montessori School is referenced as an institutional illustration demonstrating how such mechanisms may operate within an authentic educational setting.

2 Literature Background

2.1 AI competency and human-centered requirements

The rapid adoption of AI has led to increasing attention on the competencies required for effective participation in AI-mediated environments. While early discussions of AI competence emphasized technical skills such as programming and data analysis, recent perspectives highlight the importance of human-centered capabilities. These include abstraction, systems thinking, problem framing, adaptive learning, ethical reasoning, and collaborative intelligence (Brynjolfsson and McAfee, 2014).

In practice, the effectiveness of AI systems depends significantly on human interaction. The quality of outputs generated by AI models is shaped by the clarity of task definition, the ability to interpret results, and the capacity to iteratively refine prompts, data, and decision criteria. AI competency therefore increasingly involves higher-order cognition and judgment rather than purely technical proficiency.

2.2 Knowledge management and capability formation

Knowledge management research has long examined how organizations create, share, and apply knowledge. Nonaka and Takeuchi (1995) conceptualize knowledge creation as a dynamic process involving interactions between tacit and explicit knowledge, emphasizing human cognition, experience, and interpretation.

However, while knowledge management literature explains how knowledge is generated within organizational settings, it often assumes the presence of cognitive and socio-behavioral capabilities required for knowledge creation. In AI-mediated contexts, where organizational knowledge processes increasingly involve interaction with intelligent systems, understanding how these foundational human capabilities develop becomes particularly important.

2.3 Educational frameworks in the digital age

Educational frameworks developed in response to digital transformation increasingly emphasize transferable competencies rather than isolated subject knowledge. The SSD framework developed by NCCU provides an example of this orientation. It emphasizes lifelong learning through three core dimensions: autonomous action, communication and interaction, and social participation. These are further elaborated into competencies including systems thinking, adaptive innovation, ethical awareness, and collaborative engagement (NCCU, n.d.).

Such frameworks highlight that AI-era competencies are rooted in broader developmental capacities rather than in technical training alone. This perspective suggests that educational design should be examined as a foundational driver of long-term capability formation.

2.4 Montessori education as a developmental theory of capability formation

Montessori education offers a distinctive developmental theory grounded in the formation of human capability through interaction with a prepared environment (Montessori, 1967). Rather than viewing learning as the transmission of knowledge from teacher to student, Montessori conceptualized education as a process of self-construction emerging through purposeful activity, social interaction, and engagement with carefully designed materials. Montessori described education as “the natural process carried out by the child” through interaction with the environment (Montessori, 1967). In this view, education is understood as a process through which the individual constructs himself through interaction with the environment (Montessori, 1949).

Several core principles underpin this developmental approach. The prepared environment provides structured opportunities for exploration and independent activity. Auto-education positions the learner as an active agent in their own development, where cognitive, behavioral, and social capacities emerge through structured engagement with materials and environment. Human tendencies, including exploration, order, communication, and abstraction, are viewed as natural drivers of learning. Freedom within limits balances autonomy with responsibility, while control of error enables learners to identify and correct mistakes independently. Montessori also emphasized education for adaptation, arguing that educational systems should prepare individuals to respond effectively to changing social conditions (Montessori, 1948).

From a theoretical perspective, Montessori education can be understood as a mechanism-based developmental system. Its structural features generate recurring patterns of cognitive, behavioral, and social engagement which gradually give rise to transferable human capabilities. Key mechanisms include concrete-to-abstract progression, extended self-directed work cycles, embedded feedback through self-correcting materials, mixed-age peer learning, and the teacher's role as observer and guide. Auto-education (a term used in Montessori literature to describe aspects of the child’s self-directed learning through interaction with the environment) refers to the developmental process through which the child actively constructs cognitive, behavioral, and social capacities through purposeful interaction with a prepared environment, rather than through direct transmission of knowledge (Montessori, 1967; 1949).

These mechanisms do not directly produce isolated competencies. Instead, they shape how learners engage with experience, supporting the gradual development of independence, abstraction, concentration, adaptability, and social responsibility across contexts.

2.5 Conceptual integration and framework positioning

The preceding discussion highlights convergence across AI competency discourse, knowledge management theory, and contemporary educational frameworks. AI competency literature emphasizes human-centered abilities required for effective AI use. Knowledge management literature underscores the centrality of human interpretation in knowledge creation. Educational frameworks similarly emphasize transferable competencies that support adaptation and systems thinking.

However, these perspectives are rarely integrated into a developmental explanation of capability formation. This paper contributes by articulating a conceptual framework that links educational design mechanisms to capability development and subsequent AI-era competency expression.

3 Conceptual Framework: Montessori–AI Capability Alignment Framework (MACAF)

3.1 Framework overview

The Montessori–AI Capability Alignment Framework (MACAF) is proposed as a conceptual model explaining how educational design contributes to the formation of capabilities relevant to AI-mediated environments. Rather than treating AI competency as a set of technical skills, the framework conceptualizes AI readiness as a developmental outcome shaped by long-term patterns of cognition, behavior, and social participation.

The framework consists of three layers:

1. Developmental design mechanisms
2. Human capability formation
3. AI-era organizational competencies

These layers represent a sequential developmental process: mechanisms embedded in the learning environment shape recurring patterns of engagement, which generate capabilities that later manifest as competencies in AI-mediated organizational contexts.

3.2 Layer 1: Developmental design mechanisms

The first layer focuses on structural design mechanisms derived from Montessori developmental theory. These mechanisms operationalize principles such as the prepared environment, Auto-education, freedom within limits, and control of error. Rather than emphasizing content transmission, they shape how learners engage with knowledge, experience, and social interaction.

A key mechanism is the progression from concrete experience to abstract representation. Learners interact with physical materials that embody logical and mathematical relationships before transitioning to symbolic reasoning. This process supports the internalization of structure, allowing learners to move between levels of representation.

Extended, uninterrupted work cycles provide conditions for sustained engagement. Learners are given time to plan, execute, and reflect on their work, fostering persistence and responsibility.

Self-correcting materials introduce immediate feedback without external judgment. Errors are treated as information guiding revision, normalizing iteration and strengthening adaptive learning processes.

Mixed-age environments create opportunities for peer-based interaction. Learners observe, imitate, and teach one another, supporting perspective-taking and social responsibility. The teacher functions as observer and guide, shifting agency toward the learner.

Collectively, these mechanisms function as a developmental system through which learners gradually construct independence, concentration, abstraction, and social responsibility. Rather than directly producing competencies, they create recurring patterns of engagement that support long-term capability formation.

3.3 Layer 2: Human capability formation

The second layer explains how Montessori mechanisms generate specific human capabilities through repeated interaction. These capabilities are transferable and not confined to specific subject matter.

Concrete-to-abstract progression supports **structural abstraction**. Learners develop the ability to recognize patterns and relationships and apply them across contexts.

Sustained self-directed work cultivates **problem ownership** and intrinsic motivation, enabling learners to initiate tasks, manage time, and persist without constant external prompting.

Embedded feedback supports **iterative reasoning**, as learners become accustomed to testing approaches, revising strategies, and improving outcomes.

The teacher-as-guide structure strengthens **metacognitive awareness**, encouraging learners to monitor their thinking and adjust their approach.

Mixed-age social participation fosters **collaborative intelligence** and ethical awareness through shared responsibility, negotiation, and reciprocal teaching.

3.4 Layer 3: Translation into AI-era competencies

The third layer explains how capabilities formed in Layer 2 become operational as competencies in AI-mediated organizational contexts.

Structural abstraction supports **systems literacy** and the ability to interpret algorithmic outputs.

Problem ownership translates into effective **human–AI interaction**, as meaningful AI output depends on accurate task framing and constraint definition.

Iterative reasoning aligns with refinement cycles characteristic of AI-supported workflows.

Metacognitive awareness supports **responsible AI usage**, including critical evaluation, bias detection, and reflective judgment.

Collaborative intelligence supports coordination within **hybrid human–AI knowledge networks**, where work increasingly involves distributed collaboration mediated by AI systems.

The capabilities identified in MACAF align closely with contemporary frameworks such as SSD, suggesting that Montessori mechanisms support competency domains recognized within digital-age education discourse (NCCU, n.d.).

This translation is consistent with the NCCU Sustainable System Design (SSD) AI competency framework, which organizes AI competency across human-centred mindset, ethics of AI, AI techniques and applications, and AI system design, progressing from understanding to application and creation (Figure 1).

AI competency framework for students

COMPETENCY ASPECTS	PROGRESSION LEVELS		
	UNDERSTAND	APPLY	CREATE
Human-centred mindset	Human agency	Human accountability	Citizenship in the era of AI
Ethics of AI	Embodied ethics	Safe and responsible use	Ethics by design
AI techniques and applications	AI foundations	Application skills	Creating AI tools
AI system design	Problem scoping	Architecture design	Iteration and feedback loops

National Chengchi University (NCCU) (Year) Sustainable System Design Framework.
Figure 1: AI competency framework for students (NCCU Sustainable System Design Framework).

From a Montessori perspective, these competencies can be understood as contemporary expressions of broader developmental capacities associated with adaptation, independence, and social participation. Montessori education was not designed to prepare learners for specific technical tasks, but to cultivate flexible human capacities capable of responding to changing social conditions. Montessori emphasized that education must prepare individuals "for the conditions of modern life" (Montessori, 1948). In AI-mediated environments, these capacities acquire renewed significance.

3.5 Mechanism-based interpretation

MACAF provides a mechanism-based interpretation of capability formation. Rather than assuming competencies can be directly taught, it emphasizes that competencies emerge from long-term developmental processes shaped by structured interaction with the environment.

This shifts attention away from short-term outcome measurement and toward process explanation. It suggests that the design of learning environments may represent a foundational driver of AI-era human capability.

4 Institutional Illustration: North Star Bilingual Montessori School

4.1 Institutional context

North Star Bilingual Montessori School provides an institutional illustration of how the mechanisms articulated in MACAF may be operationalized within an authentic educational setting. The school adopts Montessori pedagogy as its core educational approach while emphasizing long-term capability development rather than short-term performance outcomes.

The practices observed at North Star reflect core Montessori principles including the prepared environment, control of error, normalization through concentration, peer learning, freedom within limits, and indirect guidance. Rather than positioning AI as a discrete subject, the school cultivates foundational cognitive, behavioral, and social capacities that align closely with the demands of AI-mediated environments.

4.2 Operationalization of developmental mechanisms

The developmental design mechanisms identified in MACAF are observable in the daily learning environment of North Star Bilingual Montessori School. The examples presented in this section are intended as illustrative demonstrations of Montessori developmental principles in practice. They are not presented as empirical evidence of AI competency outcomes, but as examples of how the mechanisms identified in Layer 1 may contribute to the capability formation described in Layer 2.

Prepared learning environments are structured to support the progression from concrete experience to abstract understanding. Learners engage with materials that embody mathematical, linguistic, and logical relationships, allowing them to internalize structural patterns prior to symbolic representation.

Extended, uninterrupted work cycles are embedded into the school schedule, providing learners with sustained periods of self-directed activity. Within these cycles, students are responsible for selecting tasks, managing time, and completing work sequences, thereby reinforcing autonomy and task ownership. For example, North Star's morning work cycle typically runs from 8:30am to 11:30am. During this uninterrupted period, students begin by writing in their journals and planning their independent work, selecting activities of their choosing while also organizing their time around scheduled presentations with guides. Learners may work individually with Montessori materials, collaborate on longer-term group projects, prepare for going-out activities, tend to the garden, or engage in practical responsibilities that support the classroom community. This sustained structure provides learners with the time and psychological space to initiate, persist, and complete meaningful work without reliance on constant external direction.

Self-correcting materials and embedded feedback structures are integrated into classroom activities. Rather than relying on external evaluation, learners receive immediate information through interaction with the task itself, encouraging revision and independent problem solving. For example, when students at North Star use command cards for the checkerboard material to complete long multiplication, they are able to check their final answer by turning over the command card to reveal the correct result. If their answer is incorrect, the child can identify the discrepancy without being judged or corrected by an adult and is encouraged to revisit the process. In many cases, the learner may attempt the problem again, seek clarification from a classmate, or return to a more familiar material such as the stamp game or bead frame to isolate the source of error before retrying the checkerboard. This structure normalizes error as part of learning and supports iterative reasoning through repeated cycles of action, feedback, and refinement.

Mixed-age classroom organization facilitates peer-based learning and creates conditions for reciprocal teaching. At North Star, classrooms typically include children aged 6, 7, 8, and 9 years old, which naturally encourages younger learners to seek guidance from older, more experienced peers. In many cases, an older child's explanation of a concept or demonstration of a material can be clearer and more accessible than an adult presentation, reinforcing and deepening the younger child's understanding. At the same time, older children often take pride in supporting younger classmates, and the act of teaching helps consolidate their own learning by requiring them to articulate steps, clarify reasoning, and model appropriate work habits. Importantly, this dynamic is not strictly hierarchical, as younger children who master a skill early may also guide older peers, demonstrating that competence is not determined solely by age. Through observation, imitation, and explanation, learners engage in admiration-based modeling and gradually transition from follower to leader, strengthening perspective-taking, social responsibility, and collaborative intelligence within the learning community.

The teacher's role is primarily that of an observer and guide rather than a central instructor. Instead of directing learning continuously, guides monitor student engagement, diagnose points of difficulty, and intervene only when necessary to restore productive independence. For example, during a fraction equivalence activity, a child may repeatedly attempt to match fraction pieces incorrectly, becoming frustrated and beginning to avoid the task. Rather than immediately correcting the child or providing the answer, the guide observes carefully to identify where the misunderstanding occurs, such as confusing the size of units or misinterpreting the relationship between parts and the whole. The guide may then offer a brief, targeted prompt or micro-presentation, such as asking the child to compare two fraction pieces directly or to rebuild the whole using different combinations, before stepping back again. This approach maintains learner agency while strengthening metacognitive awareness, as the child is encouraged to reflect on their own reasoning process and adjust strategies independently.

Through these practices, the school operationalizes the developmental mechanisms forming the first layer of MACAF.

4.3 MACAF mapping table: mechanisms to competencies

The table below summarizes the alignment between Montessori mechanisms, the capabilities they generate, and the AI-era competencies they support, using North Star as an institutional illustration.

Montessori Principle	MACAF Mechanism	Capability Generated	AI-Era Competency	North Star Illustration
Prepared Environment	Concrete-to-abstract progression	Structural abstraction	Systems literacy and algorithmic interpretation	Use of Montessori materials that embody mathematical relationships before symbolic work

Montessori Principle	MACAF Mechanism	Capability Generated	AI-Era Competency	North Star Illustration
Freedom Within Limits	Extended uninterrupted work cycle	Problem ownership and self-regulation	Effective human–AI task framing and independent execution	8:30am–11:30am work cycle with journaling, planning, independent work, projects, and going-outs
Control of Error	Self-correcting materials	Iterative reasoning	Iterative refinement in AI-supported workflows	Checkerboard multiplication with command cards and answer verification
Human Tendencies / Social Learning	Mixed-age learning community	Collaborative intelligence and ethical awareness	Coordination in hybrid human–AI knowledge networks	Peer teaching across ages 6–9 through reciprocal explanation and modeling
Auto-education / Indirect Guidance	Teacher as observer and guide	Metacognitive awareness	Responsible AI use and critical evaluation	Fraction equivalence support through observation, minimal prompting, and targeted intervention

4.4 Emergence of human capabilities

The structured implementation of these mechanisms contributes to the emergence of the capabilities described in Layer 2. Students develop pattern recognition and relational thinking through concrete materials, supporting structural abstraction. The continuity of self-directed work strengthens problem ownership, intrinsic motivation, and self-regulation. Interaction with feedback-rich materials supports iterative reasoning and adaptive learning.

The teacher-as-guide structure reinforces reflective thinking, strengthening metacognitive awareness. Participation in mixed-age communities supports the development of collaborative intelligence, communication competence, and ethical sensitivity. These capabilities emerge through sustained engagement rather than being introduced as isolated learning objectives.

4.5 Alignment with AI competency frameworks

The capabilities cultivated within this institutional illustration align with broader competency frameworks for the digital age. In particular, they correspond closely to SSD competency domains, including systems thinking, adaptive innovation, ethical awareness, and social participation (NCCU, n.d.).

This alignment suggests that Montessori developmental mechanisms are not only theoretically relevant but also consistent with contemporary competency frameworks used to define AI readiness.

4.6 Illustration interpretation

North Star illustrates how the conceptual structure of MACAF can be instantiated in a real educational setting. The school does not treat AI as a discrete technical discipline. Instead, it cultivates the foundational cognitive and social capacities required for meaningful engagement with AI-mediated environments.

This illustration should not be interpreted as empirical validation, but as an applied example demonstrating plausibility and operational coherence.

5 Discussion

5.1 Theoretical implications

This paper contributes to knowledge management by extending AI competency discourse into a developmental explanation of capability formation. While AI literature emphasizes the growing importance of human-centered competencies, and knowledge management emphasizes the role of human interpretation in knowledge creation, these perspectives are rarely linked through an explicit developmental pathway.

MACAF provides such a pathway by positioning educational design as an early-stage foundation for organizational capability. In this view, AI readiness is not simply a product of workplace training, but the applied expression of long-term developmental capability formation.

5.2 Implications for educational design

The framework suggests that educational systems seeking to prepare learners for AI-mediated environments should prioritize the design of learning conditions that cultivate transferable human capabilities. Rather than treating AI readiness as tool-based training, educational institutions may benefit from structuring environments that support autonomy, iterative feedback, reflective thinking, and collaborative responsibility.

5.3 Implications for organizations and AI-era talent development

For organizations, MACAF suggests that effective AI integration depends on workforce capabilities that cannot be developed through short-term training alone. Organizations may therefore benefit from broadening talent development approaches to include capability-focused development models that emphasize cognition, ethics, and collaborative intelligence.

5.4 Further directions

MACAF provides a foundation for future empirical investigation. Future research may examine how Montessori-aligned mechanisms influence measurable capability outcomes over time, or compare Montessori environments with alternative pedagogical systems. Further work may also refine alignment between MACAF and established competency frameworks to support policy and curriculum design.

6 Conclusion

This paper has examined how educational design contributes to the formation of capabilities relevant to AI-mediated environments. As artificial intelligence increasingly reshapes organizational knowledge processes, human-centered capacities such as abstraction, problem framing, adaptive learning, ethical awareness, and collaborative intelligence become increasingly important.

The Montessori–AI Capability Alignment Framework (MACAF) contributes a developmental perspective to knowledge management by linking Montessori educational theory to capability formation and subsequent AI-era competency expression. Grounded in principles including the prepared environment, Auto-education, control of error, human tendencies, and education for adaptation, the framework explains how long-term patterns of interaction within educational environments may give rise to capabilities that later become operational within AI-mediated contexts.

The institutional illustration of North Star Bilingual Montessori School demonstrates how Montessori mechanisms can plausibly operate in practice to cultivate transferable capabilities aligned with AI-mediated organizational requirements. Overall, the study suggests that AI readiness is not primarily a technical outcome, but the applied expression of human cognitive and ethical development cultivated through educational design.

7 Ethics Declaration

This study is conceptual in nature and does not involve human participants, personal data, or experimental procedures. The institutional illustration referenced in this paper is used solely for explanatory purposes and does not include identifiable individual data. Therefore, no ethical approval was required.

8 AI Declaration

The authors acknowledge the use of AI-assisted tools (including language models) to support language refinement and editing. All conceptual development, analysis, and academic content were developed by the authors. The authors take full responsibility for the integrity and originality of the work.

The Relationship between ESG and Firm Efficiency with the Moderating Role of Digital Transformation and Knowledge Capability

Duong Minh Tran, Wen-Min Lu
Chinese Culture University, Taipei, Taiwan

Abstract

Given the complexities of contemporary global business environment, the incorporation of environmental, social, and governance (ESG) principles into business practices has become increasingly vital. At the same time, the adoption of digital technology has accelerated the effectiveness of ESG initiatives, which has drawn increasing scholarly attention. Several empirical studies have examined the association between ESG and digital transformation, whereas others have explored the link between ESG and corporate efficiency. Nevertheless, research on the moderating effect of digital transformation on the relationship between ESG performance and firm efficiency remains limited.

National knowledge capability can be considered as one of the main drivers of digital transformation. For instance, governments may enhance digital knowledge diffusion across society by allocating national budgets to educational infrastructures, such as schools and research institutions, or they can subsidise large-scale R&D projects related to digital technology. The national investment in education may enhance digital capability of labour force, and thereby fostering the effectiveness of digital transformation process of the whole organisation.

While prior scholarly research has analysed the relationship between firm-level knowledge capability and digital transformation, little is known about whether country-level knowledge capability moderates the impact of digital transformation on the association between ESG and corporate efficiency.

Grounded in trade-off and absorptive capacity theories, this study aims to address the above-mentioned research gaps by examining how digital transformation shapes the ESG – firm efficiency relationship, while incorporating national knowledge capability as a second-order moderator. Our empirical analysis draws on a dataset of 46 technology companies listed on NASDAQ from 2019 to 2023, obtained from the London Stock Exchange Group (LSEG) and the Lens database. For digital transformation measure, textual analysis is employed, extracting technology-specific vocabularies from firms' annual reports. To examine multiple dimensions of corporate efficiency, while tackling the shortcomings of conventional data envelopment analysis (DEA), we adopt Range Directional Measures Network DEA model (RDMDEA). The results show that integrating digital transformation to ESG may undermine short-term efficiency within economies characterized by high knowledge intensity. Nonetheless, the role of digital transformation requires the application of knowledge to be realised. Subsequently, absorptive capacity should be taken into consideration through the incorporation of digital transformation into ESG initiatives, to ensure that both knowledge and digital technology can generate commercial values.

Keywords: Digital Transformation; ESG; Knowledge Capability; Corporate Efficiency; Technology.

Paper type: Academic Research Paper

1 Introduction

In recent years, business operations have increasingly adopted environmental, social, and governance (ESG) practices to fulfil regulatory requirements and stakeholder expectations. ESG initiatives, viewed strategically, foster competitive advantages and organizational legitimacy, particularly under stricter regulatory regimes (Le and Lu, 2025). Integrating ESG into corporate strategy helps enterprises build stronger stakeholder ties, enhance reputation and brand recognition, and reduce environmental and social risk exposure (Kandpal et al., 2024; Fernández et al., 2015). These positive impacts, in turn, can result in greater operational efficiency and enduring value creation (Endrikat et al., 2021; Xie et al., 2019).

In spite of the above-mentioned benefits, the association between ESG performance and firm efficiency remains ambiguous, as existing literature reports mixed results. While some studies find positive relationships (Ahmad et al., 2021; Chang et al., 2023; Pham et al., 2022), others discover negative impacts (Cao et al., 2024), as well as non-significant effects (Wanke et al., 2023; Yu et al., 2021). Hence, the inconsistencies in existing literature underscore the role of additional factors in the association between ESG and corporate efficiency.

Among these factors, digital transformation denotes the integration of digital technologies into organizational processes, which fundamentally alters and modifies firms' operations and value creation. Digital technologies allow firms to optimize resource allocation and promote green innovation (Wang and Yang, 2024). Additionally, they can improve transparency, information processing, and support more effective decision-

making, thus accelerating ESG implementation. In this regard, digital transformation reinforces ESG initiatives and improve efficiency outcomes.

Nonetheless, digital transformation entails significant investment, which requires firms to consistently acquire, integrate, apply emerging knowledge characterized by uncertainty. Empirical evidence highlights that most digital transformation initiatives are undermined by insufficient knowledge and capabilities (Xiong, 2024). The success of implementation mainly depends on firms' capacity to acquire expertise and reconfigure organizational processes (Crupi et al., 2020). These requirements impose substantial pressures on firms' internal resources and learning capacity.

Knowledge plays a pivotal role, though its effects are not consistently beneficial. Successful firms not only acquire technological knowledge but also develop the absorptive capacity to apply it within organizational processes (Chanias et al., 2019). Absorptive capacity captures an enterprise's capability to recognize, integrate, and employ external knowledge (Cohen and Levinthal, 1990). A lack of absorptive capacity may hinder firms' ability to translate knowledge into performance gains. Matarazzo et al. (2021) reveal that deficient absorptive capacity constrains digital transformation, especially when employees lack the proficiency to use new technologies. Furthermore, incorporating new knowledge into established processes is costly and time-intensive, potentially diminishing short-term efficiency (Roberts et al., 2012; Xiong, 2024).

Ultimately, these points indicate that combining ESG initiatives with digital transformation might lead to burden instead of mutual benefit. Dual investment in ESG and digitalization often creates a 'capability overload,' where firms struggle to absorb, process and effectively implement both sets of changes at once.

Building on these premises, this research investigates the impact of digital transformation (DTI) on the ESG-efficiency nexus and explores how country-level knowledge capability (KC) conditions this relationship. Despite extensive study of ESG and digital transformation as individual drivers of performance, their combined impact—particularly across both financial and non-financial efficiency metrics—remains largely underexplored.

This study adopts a range directional measures network DEA (RDMDEA) model, using a dataset of 46 NASDAQ-listed technology companies over the period 2019–2023 to analyse operational, innovation, profit, and sustainability efficiency. Additionally, we adopt textual analysis method to collect DTI data from firms' annual reports, and integrate country-level KC as a contextual moderator. Truncated regression is employed to examine the association between ESG performance, DTI, KC, and firms' efficiency.

The rest of the paper is organized as follows. Relevant literature and hypotheses development are provided in section 2, while section 3 describes the data, variables, and methodology. Section 4 presents the empirical results, and section 5 covers the conclusion with directions for further research.

2 Literature Review

2.1 ESG and Firm Efficiency

This study integrates stakeholder and trade-off theories to examine the complex relationship between ESG performance and corporate efficiency. Stakeholder relationships can be enhanced by effective ESG initiatives, which subsequently improves brand image, and reinforces access to capital, ultimately bolstering overall firm performance (Freeman, 2010; Endrikat et al., 2021; Xie et al., 2019; Malik, 2015).

Nonetheless, investment in ESG may neither generate values immediately, nor secure corporate efficiency. According to the trade-off theory, ESG initiatives consume excessive financial and organizational resources, which may dilute managerial focus on fundamental operations (Preston and O'Bannon, 1997). In capital-intensive sectors, ESG investments — which require significant expenses — can become a burden on short-term profitability and operational efficiency (Patten, 2002; Hassel et al., 2005; Friedman, 2007). Therefore, we propose the following hypothesis:

H1: In short term, ESG performance is adversely associated with corporate efficiency.

2.2 Digital Transformation as a First-Order Moderator

The Stakeholder theory asserts that firms' responses to stakeholder expectations can be more effective through digital technologies, which enhance transparency and ultimately bolster ESG performance (Xu et al., 2022).

Nevertheless, digital transformation entails substantial investments in infrastructure, systems, and operational realignment. In the early stage of digital implementation, firms encounter elevated operating expenses characterized by considerable uncertainty (Gebauer et al., 2020; Han et al., 2014). In particular, the beneficial nature of digital transformation commonly exhibits a time-lag, meaning that firms may encounter

temporary performance degradation during the transition process (Kriebel and Debener, 2019; Shakina et al., 2021). Regarding the trade-off perspective, significant resource allocation for digital transformation may constrain firms' capacity to maintain ESG investments (Li et al., 2025). Thus, we propose the second hypothesis as follows:

H2: Digital transformation significantly impacts the relationship between ESG performance and corporate efficiency.

2.3 Knowledge Capability and Absorptive Constraints

Successful digital transformation is contingent upon firms' ability to acquire, integrate, and exploit knowledge effectively. This ability is defined by absorptive capacity theory as a firm's capability to identify, assimilate, and apply external knowledge to productive ends (Cohen and Levinthal, 1990).

The organisational learning process is significantly determined by national knowledge capability of the country in which a firm operates. Robust national innovation systems accelerate knowledge creation, diffusion, and skill development, which subsequently drive digital transformation (Qi et al., 2024; Ge et al., 2023). When operating in such environments, enterprises enjoy enhanced exposure to cutting-edge knowledge and technological resources, thus boosting innovation and efficiency.

However, national knowledge capability does not automatically translate into enhanced effectiveness for all firms. As digital technologies rapidly disrupt traditional processes, firms may struggle to absorb and integrate new knowledge into their operations, especially large-scale enterprises characterized by complex systems (Guo et al., 2023; Horváth and Szabó, 2019). Developing the required capabilities for keeping pace with technological change involves extensive investments in training, systems modification, and organisational restructuring, thereby escalating costs and hampering short-term efficiency (Brunetti et al., 2020).

Surplus knowledge acquisition may induce organizational complexity and conflict between emerging and existing processes (Feliciano-Cestero et al., 2023; Zhong and Ren, 2023), which in turn diminishes returns. Under such circumstances, the integration of digital technologies within knowledge-rich environments may exacerbate efficiency pressures related to ESG commitments.

H3: Knowledge capability amplifies the negative moderating impact of digital transformation on the relationship between ESG performance and corporate efficiency.

3 Research Design

3.1 Samples and Data Collection

We gathered a dataset of technology firms listed on the NASDAQ stock exchange from diverse sources, encompassing the London Stock Exchange Group (LSEG), Lens database, and corporate annual reports from 2019 to 2023. In particular, ESG scores and financial data were drawn from LSEG, while the patent-related data, including patent applications, granted patents, and design rights, were extracted from the Patent Lens platform. Digital transformation metric was drawn from firms' annual reports by using Python to collect the digital-related words frequency, and ultimately constructing the digital transformation index (DTI) by employing Principal Component Analysis (PCA). Knowledge capability metric, which is country-level data, was obtained from The World Intellectual Property Organisation (WIPO). Samples with missing data were removed to ensure the integrity and consistency. Following the data screening and cleaning procedures, the final sample consists of 46 companies with 230 firm-year observations. The research framework of this study is depicted in figure 1.

3.2 Research Framework

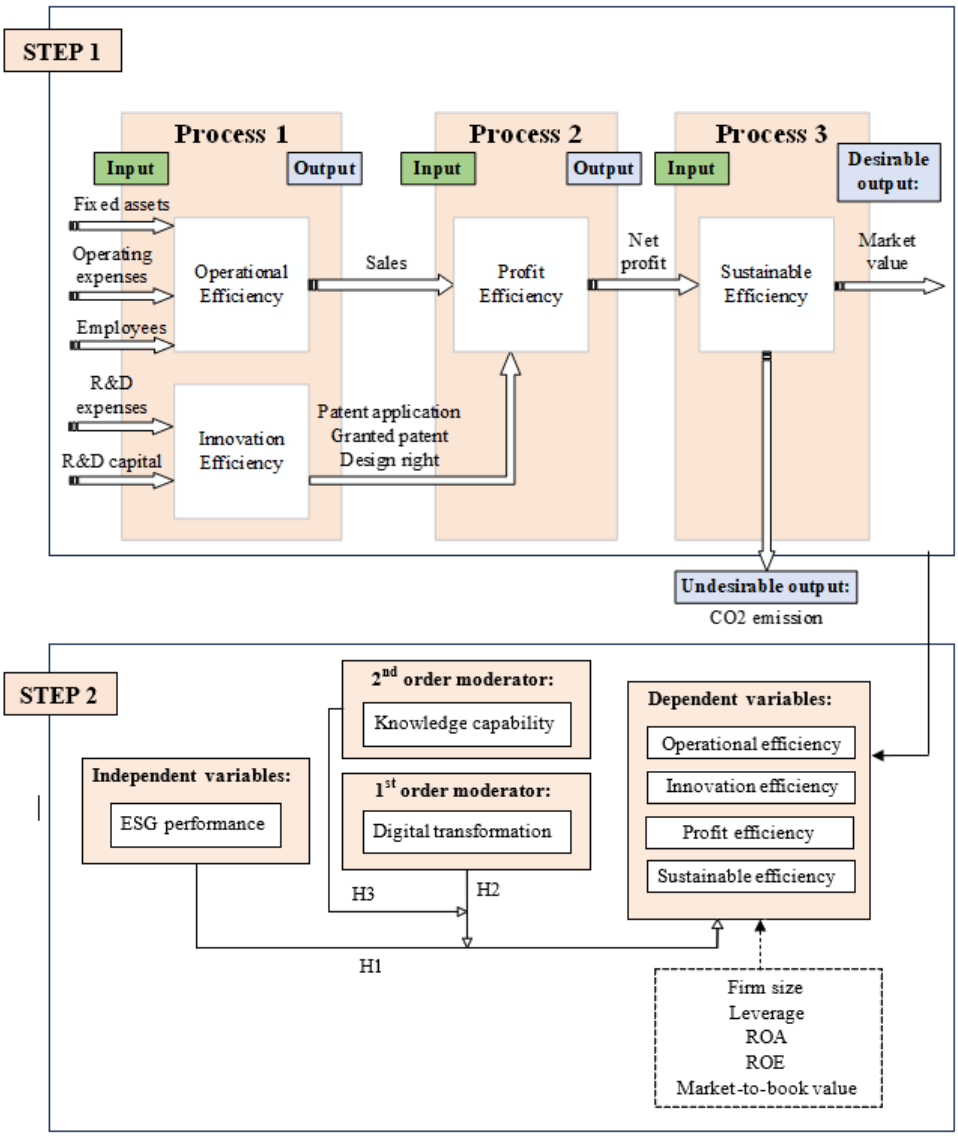

Figure 1 | Theoretical framework

4 Empirical Analysis

4.1 Descriptive Statistics Analysis:

Table 4 presents descriptive statistics and correlation matrices for the variables in RDMDEA model. We conducted the Kolmogorov–Smirnov test (K-S test), indicating that all inputs and outputs across the three processes follow nonnormal distributions with p-values below 0.01. This result suggests that inputs and outputs are valid for RDMDEA analysis since this method imposes no normality assumption.

Table 4 | Descriptive statistics and correlation matrices for RDMDEA analysis

MTBV	230	7.44	-153.79	190.54	18.21

As the hypothesis 1 proposes that the relationship between ESG performance and firm efficiencies is negative, our results in table 8 partially support H1. There are negative associations between ESG and OPE (β = -0.00267, $p < 0.01$), PE (β = -0.0275, $p < 0.05$) and SE (β = -0.00479, $p < 0.01$). Our results are in line with the

findings of Duque-Grisales and Aguilera-Caracuel (2021), Gao et al. (2025), and Fisher-Vanden and Thorburn (2011).

Regarding two-way interaction between ESG performance and moderators, the moderating effect of digital transformation on the relationship between ESG and all dimensions of efficiency (ESG x DTI) is insignificant. Hence, our findings do not provide empirical support for H2. .

Finally, with respect to the three-way interaction (ESG x DTI x KC), the analysis reveals significant negative interaction effects for OPE (β = -0.000233, p < 0.1) and SE (β = -0.000265, p < 0.05). Our previous two-way interaction result, combined with this finding, suggest that digital transformation effects can become apparent in the presence of knowledge, since the integration of digital technologies, such as big data and IoT, with multidisciplinary knowledge, offers strategic capability in business sectors (Huesig and Endres, 2019; Scuotto et al., 2017; Singh and El-Kassar, 2019). However, the result is negative, meaning that excessive country-level knowledge capability can weaken the moderating effect of digital transformation on the relationship between ESG performance and both operational and sustainable efficiencies; accordingly, our findings provide partial support for H3. (Guo et al., 2023; Feliciano-Cestero et al., 2023; Zhong and Ren, 2023).

Table 8 | Truncated regression analysis of the effect of ESG on the performance with moderators.

5 Conclusion and Recommendation

5.1 Conclusions

This study examines how ESG performance relates to corporate efficiency in the technology sector and how this relationship is shaped by digital transformation and country-level knowledge capability. Using a sample of 46 NASDAQ-listed firms over the period 2019–2023.

ESG engagement is associated with lower short-term efficiency across most dimensions, suggesting that adjustment costs and resource reallocation dominate in the early stages.

DTI, on its own, does not alter this relationship in a meaningful way. Its effect becomes more apparent only when combined with higher levels of KC. In such settings, DTI and KC jointly strengthen the negative association between ESG and efficiency.

5.2 Limitation and Further Research

This study has several limitations that provide directions for future research. First, the study uses an aggregate ESG score, which may mask differences across environmental, social, and governance dimensions. Further research could explore how these dimensions individually relate to corporate efficiency and how digital transformation and knowledge capability influence these relationships.

Second, while the textual analysis method captures firms' strategic emphasis on digitalization, it may not fully reflect the depth or effectiveness of actual digital implementation. Future research could adopt more refined measures to capture the quality and outcomes of digital transformation.

Developing an Intelligent Organizational Carbon Inventory Assistant Integrating LangChain and Large Language Models: An Empirical Study

Huang, Yan-Ping
Graduate Institute of Information and Decision Sciences, National Taipei University of Business, Taipei, Taiwan

Abstract

Continued advances in manufacturing technology have improved production precision but have also intensified resource consumption and carbon emissions, making corporate greenhouse gas (GHG) management an urgent priority. Carbon inventory is a foundational tool for this purpose, enabling firms to evaluate their carbon footprint and formulate emission-reduction strategies aligned with climate goals. In practice, however, organizations face substantial barriers when implementing carbon inventories, including difficulties in interpreting accounting standards, complex data collection, and heavy reliance on specialized expertise and external consultants. This study investigates the practices, experiences, and challenges of organizational carbon inventory and management, and examines how generative artificial intelligence can lower these knowledge barriers. Using company A—a manufacturer of medical, 3C, and automotive modification components in Taoyuan, Taiwan—as a case study, an organizational-level GHG inventory was conducted in accordance with the ISO 14064-1 standard to identify emission sources and quantify the firm's 2022 carbon footprint. Building on this inventory, the study developed a carbon-knowledge intelligent assistant by integrating the LangChain framework with a large language model (GPT-3.5), applying a retrieval-augmented generation mechanism grounded in local carbon-inventory documents, emission-factor databases, and standard operating procedures. To evaluate the system, the LangChain-integrated model was compared with standalone ChatGPT-3.5 across five representative carbon-inventory question-answering tasks. A total of 39 participants with practical experience in or active involvement with carbon inventory implementation were invited to assess both approaches in terms of knowledge accuracy and ease of understanding. The results show that the LangChain-based system consistently outperformed standalone ChatGPT-3.5, achieving an average correctness rate of 61.2% compared with 38.8%—an overall improvement of 22.4 percentage points—while also demonstrating an advantage in ease of understanding. These findings confirm that grounding a large language model in domain-specific knowledge sources markedly improves the professionalism, consistency, and reliability of generated responses in specialized applications. Overall, the study provides both empirical evidence and practical insights for organizations seeking to adopt generative artificial intelligence to strengthen their carbon inventory and carbon management practices, and it contributes to the emerging literature on applying large language models as knowledge-support tools in sustainability management.

Keywords: Autonomous AI Agent, Large Language Model, Chatbots, Intelligent Assistant, Organizational Carbon Accounting, Carbon Knowledge.

1. Research Motivation and Objectives

1.1 Research Motivation

Climate change has become one of the most pressing challenges to global sustainable development. Rising average temperatures and increasingly frequent extreme weather events threaten human societies, industry, and ecosystems. In response, the international community has established climate governance frameworks—most notably the United Nations Framework Convention on Climate Change (UNFCCC) and the Kyoto Protocol—that lay the institutional foundation for greenhouse gas mitigation and extend decarbonization responsibilities to both governments and firms.

Within this context, carbon market mechanisms are widely recognized as an effective instrument for improving the economic efficiency of emissions reduction. By enabling the trading of emission allowances, carbon markets allow firms to adopt cost-effective mitigation strategies while collectively meeting reduction targets. Their effective functioning, however, depends on accurate, consistent, and transparent emissions data, making corporate carbon inventories a critical prerequisite for both carbon management and market participation.

A corporate carbon inventory is the systematic quantification of an organization's greenhouse gas emissions over a defined period according to recognized standards. It provides essential insight into emission structures and forms the basis for reduction planning. In practice, many firms encounter significant challenges—difficulties

interpreting accounting standards, complex data collection and integration, and high demands for specialized expertise. These barriers foster heavy reliance on external consultants and limit scalability, particularly among small and medium-sized enterprises.

Recent advances in generative artificial intelligence and large language models (LLMs) offer new opportunities to support such knowledge-intensive tasks. While existing studies have mainly examined the general question-answering capabilities of LLMs, empirical research on intelligent assistants designed specifically for organizational carbon inventory and management knowledge remains limited. This study is therefore motivated by the need to integrate carbon inventory practice with generative AI in order to lower knowledge barriers, improve the accessibility and interpretability of carbon-related information, and help enterprises prepare for carbon-market participation and long-term sustainability.

1.2 Research Objectives

The primary objective of this study is to apply organizational carbon inventory methodologies to systematically analyze the carbon footprint of corporate activities and to examine their value for carbon management and sustainable-development decision-making. The study also addresses a gap in the literature by developing and empirically evaluating a carbon-knowledge question-answering system, with emphasis on how far LLMs can facilitate enterprises' understanding of carbon inventory concepts and practices.

Company A, located in Taoyuan City, serves as the case study. An organizational-level carbon inventory is conducted according to relevant standards to analyze the sources and structure of emissions and to explore the role of carbon inventory in corporate carbon management and sustainability strategy. A carbon-knowledge intelligent assistant is then developed by integrating the LangChain framework with LLMs to provide decision-support and knowledge-consultation functions. The specific aims are summarized as three phases:

Phase One: To compile and systematize key carbon-inventory terminology and greenhouse gas accounting requirements, supporting on-site investigation and preparatory activities. Phase Two: To implement a carbon-knowledge assistant integrating LangChain with a ChatGPT-based model for natural language processing, automated question answering, and text generation, and to assess its value for enterprises planning inventories. Phase Three: To conduct an experimental evaluation comparing the correctness of carbon-knowledge responses between the GPT-3.5 model integrated with LangChain and the conventional ChatGPT-3.5 model.

2. Literature Review

2.1 Organizational Carbon Inventory and Carbon Management

As global climate governance frameworks have become institutionalized, organizational-level carbon inventories have emerged as a critical foundation for corporate carbon management and sustainability decision-making. Prior studies show that systematic inventory practices allow firms to identify major emission sources and to use inventory results as a basis for reduction strategy and performance evaluation (Schaltegger & Csutora, 2012). Carbon inventories thus function not merely as compliance tools but as essential informational infrastructure for internal management and stakeholder communication.

At the international level, ISO 14064-1 is widely adopted as the core framework for organizational GHG accounting, offering explicit guidance on boundary setting, emission-source classification, and data quality to enhance the consistency, transparency, and comparability of results (ISO, 2018). Standardized procedures also strengthen the credibility of carbon information in sustainability reporting, disclosure initiatives, and carbon-market participation. Nevertheless, the literature consistently reports substantial implementation challenges, including data-collection difficulties, cross-departmental coordination costs, and the expertise required to apply accounting standards (Burritt et al., 2011; Ascui & Lovell, 2012). Small and medium-sized enterprises, lacking resources and specialized personnel, are especially constrained—highlighting the pressing need to reduce the knowledge and operational barriers associated with carbon inventory.

2.2 Generative AI and Knowledge-Oriented Question-Answering Systems

Recent advances in generative artificial intelligence (GAI) and large language models (LLMs) provide new pathways for supporting knowledge-intensive tasks. Empirical research shows that LLMs achieve near-human performance in natural language understanding, text generation, and question answering (Brown et al., 2020; OpenAI, 2023; Huang et al., 2026), and they are increasingly deployed in customer service, knowledge management, and decision support to improve information accessibility (Dwivedi et al., 2023). However, the reliability and interpretability of LLMs in domain-specific contexts remain contested (Bender et al., 2021).

Because language models generate responses probabilistically, they may produce inaccurate or inconsistent outputs when not grounded in authoritative knowledge (Ji et al., 2023). Recent work therefore emphasizes integrating LLMs with external knowledge bases to enhance the trustworthiness and stability of their outputs in professional applications.

2.3 LangChain Architecture

LangChain is an application framework designed for large language model deployment, characterized by a modular architecture that integrates language models, external data sources, and reasoning workflows to enable context-aware retrieval and task-oriented applications (Chase, 2022). It provides tools, components, and interfaces that simplify the development of LLM-supported applications such as AI chatbots, generative question-answering systems, and summarization tools. Prior research on retrieval-augmented generation (RAG) has demonstrated its potential in law, healthcare, and enterprise knowledge management, where answer consistency and knowledge traceability are critical (Lewis et al., 2020; Karpukhin et al., 2020).

As illustrated in Figure 1, the LangChain architecture forms an end-to-end pipeline that transforms local unstructured documents into context-aware LLM responses (Chase, Maass, & Gan, 2023). Document loaders extract text from local sources; text splitters divide the content into manageable chunks; each chunk is converted into vector embeddings and stored in a vector database. When a user submits a query, it is likewise embedded and compared against stored embeddings using similarity search. Relevant chunks are retrieved and combined with predefined prompt templates to construct a structured input, and the LLM then generates a response grounded in both the retrieved context and the query. This RAG process improves the relevance, accuracy, and coherence of outputs by explicitly integrating external knowledge into the inference workflow.

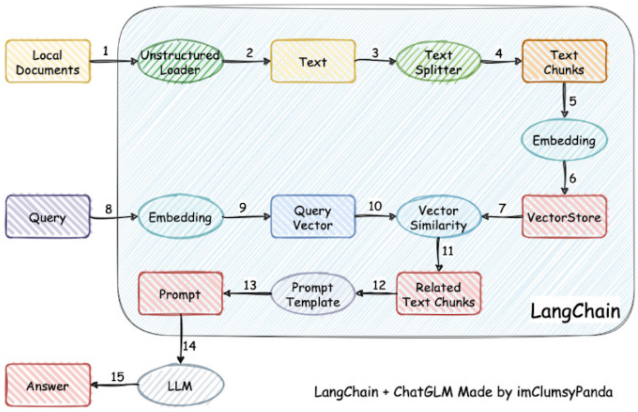

Figure 1: Algorithm architecture of LangChain (Chase et al., 2023).

Despite this potential, empirical research on intelligent carbon-knowledge assistants that integrate LangChain with LLMs remains scarce, and comparative evaluations of model architectures with respect to knowledge accuracy and perceived ease of understanding are largely absent. This study addresses that gap through an empirical design evaluating the practical effectiveness of generative-AI knowledge-support systems in organizational carbon inventory contexts.

3. Research Methodology

This chapter describes the research design and implementation in three parts: the research subject and scope, the research instruments, and the research framework and procedures.

3.1 Research Subject and Scope

The research subject is Company A, established in 2021 and engaged in developing and manufacturing medical products, 3C electronics, automotive modification components, and related parts. Its core technologies include closed-die forging of magnesium, aluminum, and lithium alloys. Responding to rising demand for lightweight materials in new-energy vehicles and unmanned transportation, the company invests in R&D to provide lightweight, high-strength, energy-efficient solutions, and it holds ISO 9001:2015 certification. Its principal markets—Europe, North America, and the United Kingdom—impose stringent environmental and sustainability requirements. Accordingly, the company has adopted measures such as rooftop ventilation to

improve heat dissipation and energy efficiency, and low-waste manufacturing under which roughly 95% of raw materials are effectively utilized and the remaining 5% recycled.

In response to the EU Carbon Border Adjustment Mechanism (CBAM), which requires carbon-content declaration for imported products from October 2023, and to proposed U.S. carbon-tariff legislation under the Clean Competition Act, Company A has begun planning carbon-inventory systems. With governmental support, it is conducting organizational-level GHG inventories and personnel training to understand its current emission profile, formulate feasible reduction pathways, meet customer and regulatory demands, and enhance competitiveness. To this end, the company convened all relevant departments to form a carbon-inventory task force, and this study provided the participating personnel with essential GHG education and training covering kick-off, organizational-boundary and emission-source identification, quantification and calculation, documentation and reporting, and internal verification.

3.2 Research Framework

After data collection and organization, this study integrates the LangChain framework with large language models to construct a question-and-answer chatbot for organizational carbon knowledge. The framework combines GHG inventory outcomes with the semantic understanding and generative capabilities of LLMs to enhance the accessibility and practical value of inventory information. The overall workflow comprises: (1) defining inventory objectives and scope; (2) identifying inventory boundaries and emission sources; (3) collecting emission-related data from internal records, government data, and third-party datasets; (4) processing data through cleaning, organization, and calibration; (5) calculating emissions using appropriate methods and emission factors; (6) importing results and documentation into LangChain, where text segmentation generates semantically meaningful chunks and keywords; and (7) using the LLM to generate a carbon-knowledge Q&A repository and an interactive chatbot.

3.2.1 Carbon Inventory Method

This study adopts the organizational carbon inventory methodology of ISO 14064-1, an international standard supporting the accurate, transparent, and consistent quantification, reporting, and verification of GHG emissions and removals. Its procedure follows a four-step process—boundary setting, source identification, calculation, and reporting—summarized in Table1.

Table 1: Four Steps of the Carbon Inventory Process

GHG Inventory Step	Description
Boundary Setting	Defines the foundation of the inventory based on organizational scale and type, activity nature, and emission profile. Boundaries are classified into organizational boundaries (the entities covered) and emission-source boundaries (the sources included).
Emission Source Identification	Identifies all direct and indirect emission sources within the boundary. Direct sources (e.g., stationary combustion, process, mobile, and fugitive emissions) are under organizational control; indirect sources (e.g., purchased energy, waste, transportation, commuting) are not.
Emission Calculation	The core step: total emissions are quantified using established GHG calculation methodologies.
Reporting	The primary output: a carbon inventory report disclosing GHG emission information to external stakeholders.

Source: Climate Change Administration, Ministry of Environment, Taiwan (2024).

3.2.2 Greenhouse Gas Emission Standards

Because many domestic enterprises are integral to international supply chains, Taiwan's Ministry of Environment revised its Greenhouse Gas Inventory Guidelines, officially released in February 2024, to provide a cross-industry reference for inventory implementation. The Guidelines correspond to Categories 1–6 of ISO 14064-1:2018, with adjustments for domestic regulatory practice. Table 2 summarizes the main correspondences between the international standard and the national Guidelines, which serve as the basis for subsequent system development and data integration.

Table 2: Comparison of Greenhouse Gas Emission Standards

Item	ISO 14064-1:2018	National GHG Inventory Guidelines
Issuing Organization	International Organization for Standardization (ISO)	Ministry of Environment, Taiwan
Scope of Application	International verification and voluntary GHG inventories	Entities regulated by the Ministry of Environment and the Financial Supervisory Commission
Classification	Scopes 1–6 (direct; energy indirect; transportation; products used; products from the organization; other indirect)	Scopes I–III, subdivided into stationary, process, mobile, fugitive, land-use, purchased energy, transportation, commuting, and product-related sources
Measurement Unit	Metric tons of CO_2 equivalent (tCO_2e)	Metric tons of CO_2 equivalent (tCO_2e)

Source: Climate Change Administration, Ministry of Environment, Taiwan (2024).

3.3 LangChain and Large Language Model Integration

This study adopts the LangChain framework (Chase et al., 2023) with OpenAI's GPT-3.5 model to construct an intelligent assistant. LangChain provides strong text-comprehension and semantic-extraction capabilities for retrieving carbon-related knowledge, while GPT-3.5 offers generative capabilities for automatically producing carbon-related question-and-answer pairs (Figure 2). The assistant is developed by (1) collecting and organizing carbon-related knowledge from government reports, journal articles, and online resources into a local PDF knowledge base; (2) using LangChain to interpret semantics and extract key information; and (3) using GPT-3.5 to generate carbon-related Q&A pairs.

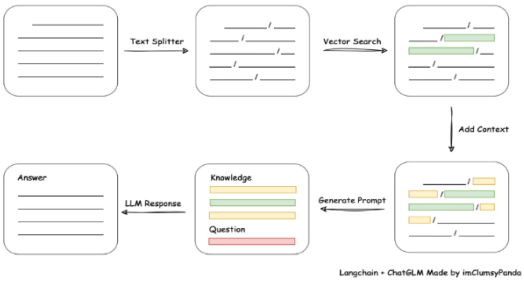

Figure 2: Workflow of LangChain and large language model integration (Chase et al., 2023).

For example, from the statement “Carbon emissions refer to greenhouse gas emissions generated by human activities,” LangChain extracts key elements (carbon emissions are GHG emissions; the source is human activities; greenhouse gases are a category of gases) and generates questions such as “What are carbon emissions?” and “How are carbon emissions generated?” GPT-3.5 then produces corresponding answers, and the resulting Q&A pairs are used to evaluate the assistant's performance.

3.4 Research Design

The evaluation design draws on the conceptual framework of the Turing Test, proposed by Alan Turing in his 1950 paper “Computing Machinery and Intelligence,” in which a human evaluator attempts to distinguish machine-generated from human responses through text-based interaction. Adapting this logic, the study adopts a comparative evaluation design in which participants interested in or engaged with carbon inventory assess responses generated by two systems—LangChain integrated with GPT-3.5, and standalone ChatGPT-3.5—both of which exhibit advanced natural-language capabilities. This Turing-Test-inspired approach examines the extent to which LLM-based carbon-knowledge assistants can produce responses perceived as accurate, natural, and professionally reliable in carbon inventory contexts.

4. Research Results

4.1 Organizational Carbon Inventory Assessment and Results

Following ISO 14064-1:2018 and the GHG Protocol (WBCSD and WRI), the study applies an operational-control approach to set the inventory boundary and consolidates Company A's GHG emissions and removals for 2022 (Figure 3). The inventory covers the company's operational boundaries and systematically identifies direct

emissions, energy-related indirect emissions, and other indirect emissions, encompassing carbon oxides and fluorinated gases per the classification of the Climate Change Administration, Ministry of Environment, Taiwan (2024).

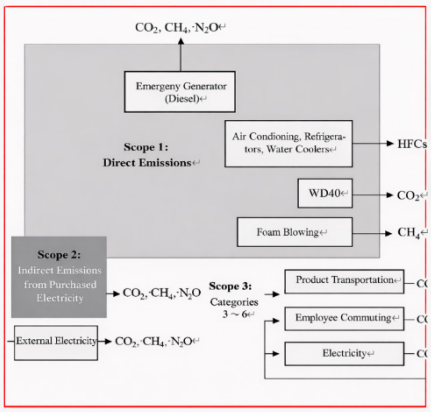

Figure3: Boundary-setting methodology for the greenhouse gas inventory.

4.1.1 Direct GHG Emission Sources (Scope 1)

Direct emissions originate from sources under the organization's operational control. For Company A, identified sources include emergency generators, lubricants (e.g., WD-40), refrigerant leakage from refrigeration and air-conditioning equipment, water dispensers, restroom septic tanks, and fire extinguishers. During the inventory year the emergency generator was neither procured nor operated, and certain equipment (the Weston cooling unit, water dispensers, R-22 and R-600a refrigerants, and ABC dry-powder fire extinguishers) was identified but excluded from quantification owing to missing charge information or applicable guidelines. Results are summarized in Table 3.

Table 3: Direct Greenhouse Gas Emissions (Scope 1)

Category	Emissions (tCO_2e)	Percentage (%)
Category 1: Direct GHG emissions and removals	2.8867	100%
1.1 Stationary combustion	0	0%
1.2 Mobile combustion	0	0%
1.3 Process emissions	0	0%
1.4 Fugitive emissions	2.8867	100%

4.1.2 Energy-Related Indirect GHG Emission Sources (Scope 2)

Company A's Scope 2 emissions derive primarily from purchased electricity supplied by Taiwan Power Company. Based on the 2022 grid emission factor of 0.495 kg CO_2e per kWh announced by the Bureau of Energy, Ministry of Economic Affairs, total Scope 2 emissions were calculated as shown in Table 4.

Table 4: Energy-Related Greenhouse Gas Emissions (Scope 2)

Category	Emissions (tCO_2e)	Percentage (%)
Category 2: Energy-related indirect GHG emissions	86.6448	100%
2.1 Purchased electricity	86.6448	100%

4.1.3 Other Indirect GHG Emission Sources (Scope 3)

Under the GHG Protocol, Scope 3 covers indirect emissions from activities such as employee commuting, upstream transportation and distribution of raw materials, and fuel- and energy-related activities. Following ISO 14064-1:2018, these are reported under Categories 3 and 4, which together amounted to 134.4287 tCO_2e (Tables 5 and 6). Company A also operates six landlord-provided window air conditioners whose R-22 refrigerant leakage falls under Category 6; these were identified but excluded from the material indirect categories per the inventory guidelines.

Table 5: Category 3 Greenhouse Gas Emissions

Category	Emissions (tCO_2e)	Percentage (%)
Category 3: Indirect GHG emissions – Transportation	118.9902	100%
3.1 Upstream transportation and distribution	108.3929	91.09%
3.3 Employee commuting	10.5973	8.91%

Table 6: Category 4 Greenhouse Gas Emissions

Category	Emissions (tCO_2e)	Percentage (%)
Category 4: Indirect GHG emissions – Use of products by the organization	15.4385	100%
4.1 Upstream purchased electricity	15.4385	100%

4.1.4 Emission Calculation and Quantification

The emission-factor approach was used to quantify emissions. Activity data were collected using the Greenhouse Gas Inventory Tool, and emission factors were obtained from the Greenhouse Gas Emission Factor Management Table (Version 6.0.4) (Ministry of Environment, 2019). Because gases differ in climate impact, emissions were converted into CO_2 equivalents using Global Warming Potential (GWP) values from the IPCC Sixth Assessment Report (AR6, 2021). The principal calculation formulas are: stationary and mobile combustion, GHG emissions = fuel consumption × emission factor × GWP; fugitive emissions from septic tanks, emissions = total working hours × septic-tank emission factor × CH_4 GWP; refrigerant leakage, emissions = annual leakage amount × GWP; purchased electricity, CO_2e = electricity consumption × emission factor (0.495 kg CO_2e/kWh); upstream transportation, emissions = vehicle emission factor ($kgCO_2e$/tkm) × cargo weight (t) × distance (km); employee commuting, emissions = transport emission factor ($kgCO_2e$/pkm) × one-way distance (km) × 2 × working days; and upstream electricity-related emissions, using the indirect factor of 0.0882 kg CO_2e/kWh (2020). Total emissions are summarized in Table 7.

Table 7: Total Greenhouse Gas Emissions of Company A in 2022

Scope	Category	Emissions tCO_2e)	Share (%)	Notes
Scope 1	Fugitive emissions	2.8867	1.29%	Stationary/mobile/process = 0
Scope 2	Purchased electricity	86.6448	38.69%	Taipower grid factor 0.495
Scope 3	Upstream transportation & distribution	108.3929	48.40%	Largest single source
Scope 3	Employee commuting	10.5973	4.73%	
Scope 3	Upstream electricity-related indirect	15.4385	6.89%	
Total		223.9602	100.00%	

4.2 Results of the Q&A Chatbot Using LangChain

An organizational carbon-inventory intelligent assistant was developed using OpenAI LLMs, Python, and LangChain to integrate domain-knowledge retrieval and question answering. Carbon-related knowledge was stored locally, and the resulting chatbot was applied within the case company to provide guidance on practical challenges (Figures 4 to 6), including: how fire extinguishers should be inventoried and which fall within the boundary; how to address data limitations for methane-generating septic tanks when design and operational records are incomplete; how to define and calculate emissions from employee business travel; and how to select appropriate emission factors, whose choice directly affects the accuracy of results. Overall, the LangChain-based chatbot provided structured explanations and practical guidance, enabling the company to conduct its inventory more systematically and confidently.

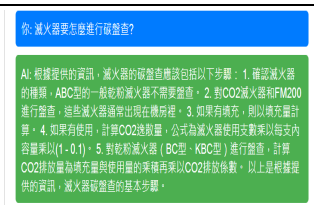

Figure 4: Fire-extinguisher inventory within the boundary.

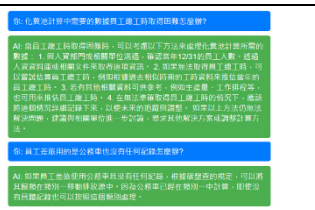

Figure 5: Practical challenges in the inventory process.

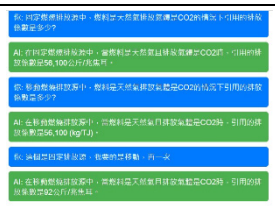

Figure 6: Emission factors used in quantification.

4.3 Questionnaire Analysis of LangChain versus ChatGPT

The experiment recruited 39 participants interested in carbon inventory or carbon-related knowledge to compare the text-generation performance of LangChain integrated with GPT-3.5 against standalone ChatGPT-3.5 across five carbon-inventory tasks; 39 valid questionnaires were collected. Female participants accounted for 69.23% (n = 27) and males 30.77% (n = 12). The largest age group was 21–30 (38.5%, n = 15), followed by 41–50 and 51+ (25.6% each). In education, 97.4% held a bachelor's degree or higher, with master's and doctoral

holders together comprising 46.1%, indicating a well-qualified sample suitable for evaluating generative-AI applications in carbon inventory.

As shown in Table 8, LangChain integrated with GPT-3.5 consistently outperformed standalone ChatGPT-3.5 across all five dimensions, with the largest gap in the general-waste inventory method (70% vs. 30%). The average correctness rate of the LangChain system was (60+61+70+58+57)/5 = 61%, compared with (40+39+30+42+43)/5 = 39% for ChatGPT-3.5—an overall improvement of 22.4 percentage points.

Table 8: Comparison of Text-Generation Correctness between LangChain and ChatGPT

System	Fire extinguisher	Septic tank	General waste	Official vehicles (no records)	Natural gas factor
LangChain + GPT-3.5	60%	61%	70%	58%	57%
ChatGPT-3.5	40%	39%	30%	42%	43%

These results indicate that integrating a knowledge-retrieval mechanism improves response accuracy by roughly 22% in professional carbon-inventory question answering. By grounding responses in local inventory documents, emission-factor databases, and standard operating procedures, retrieval-augmented generation improves consistency and reliability, making such systems well suited to domain-specific applications like carbon inventory management.

5. Conclusions

5.1 Research Summary

This study confirms that a large language model-based carbon inventory assistant is an effective means of enhancing organizational understanding of carbon-inventory knowledge. By integrating LangChain with GPT-3.5, it designed and implemented a carbon-knowledge Q&A assistant that helps organizations rapidly grasp key concepts, including definitions, calculation methods, application contexts, and managerial value. The comparative evaluation with 39 experienced participants showed that, when sufficient domain knowledge is provided, the generated responses are perceived as more acceptable and easier to understand, demonstrating the practical potential of LLMs for supporting carbon-inventory knowledge and organizational learning.

5.2 Managerial Implications

The findings offer several managerial implications. First, an LLM-based assistant reduces the learning barriers of carbon inventory by providing immediate responses on definitions, calculation methods, and applicable scopes, lessening reliance on external consultants. Second, because inventory activities span production, equipment, procurement, logistics, and administration, the assistant serves as a shared knowledge tool that improves information consistency and supports more standardized processes. Third, it functions as both a decision-support tool—giving managers timely explanations of emission sources, scopes, and regulatory guidelines—and a training resource enabling non-specialist staff to acquire fundamental knowledge. Given the time-sensitivity of inventory regulations and emission factors, management should also establish regular data updates and response validation to ensure accuracy.

5.3 Future Research Directions

Several directions emerge. At the model level, future studies may adopt more advanced LLMs to compare knowledge comprehension, terminology handling, and response quality. Regarding knowledge sources, integrating additional structured and unstructured data—international emission databases, industry-specific factors, and regulatory documents—with automated update mechanisms would improve accuracy as standards are revised. At the functionality level, the assistant could extend beyond basic Q&A to incorporate emission-calculation modules, scenario simulation, and reduction-strategy recommendations. Finally, more comprehensive empirical evaluations using quantitative indicators and longitudinal studies across organizations of different sizes and industries would clarify the long-term impact of LLM adoption on carbon-management maturity.

6 Acknowledgements

The author thanks Engineer Lin Feng-Yu for technical support that made the successful completion of this study possible.

7 Ethics declaration

This research involved an anonymous questionnaire in which 39 adult participants voluntarily evaluated the accuracy and ease of understanding of system-generated responses. No personally identifiable, sensitive, or health-related data were collected, and participation was voluntary and anonymous. Under the applicable institutional guidelines, this type of low-risk, non-interventional survey did not require formal ethics committee clearance.

8 AI declaration

Generative AI tools form the subject of this study; the LangChain-integrated GPT-3.5 system and ChatGPT-3.5 were used as research instruments, and their outputs were evaluated by human participants as described in the methodology. All research design, data collection, analysis, interpretation, and conclusions are the author's own, and the author reviewed and verified all content to ensure its accuracy and integrity.

Developing a Two-Dimensional Portfolio Matrix of Innovation and Profitability: Evidence from Solar Energy Firms

Huang, Yan-Ping[1] Huang, Shyh-Fang[2]
[1]Graduate Institute of Information and Decision Sciences, National Taipei University of Business, Taipei, Taiwan
[2]Department of Computer Science and Information Engineering, Minghsin University of Science and Technology, Taiwan

Abstract

Amid escalating global challenges such as climate change and resource depletion, the transition toward sustainable energy systems has become a critical priority. Solar energy, as a representative clean energy source, plays a pivotal role in reducing carbon emissions, enhancing energy security, and supporting corporate sustainability and environmental, social, and governance (ESG) performance. As the solar industry expands, competition among firms has intensified, making it increasingly important to balance technological innovation with market profitability to sustain long-term competitive advantage. While prior research has predominantly examined innovation and financial performance separately, limited attention has been given to their joint strategic implications, and few analytical tools simultaneously capture innovation, profitability, and sustainability, particularly within the solar energy sector. To address this gap, this study develops a Patent and Gross Margin Portfolio Management (PGMPM) model that integrates patent-based innovation indicators with profitability measures, providing a unified two-dimensional framework for evaluating firm-level strategic positioning. Using panel data from eight leading domestic and international solar energy firms over the period 2000–2024—drawing patent information from the LexisNexis database and financial data from the Datastream database—this study empirically examines the interaction between technological capability and financial performance. Firms are positioned within the portfolio matrix according to their patent counts and average gross margins, and their strategic profiles are analysed across the upstream, midstream, and downstream segments of the solar value chain. The results reveal substantial heterogeneity in firms' innovation–profitability profiles and demonstrate that firms achieving a balanced alignment between innovation and profitability exhibit stronger competitiveness and sustainability performance, whereas firms weak on both dimensions face significant strategic risk. The findings further highlight the strategic importance of patent portfolio management in enhancing ESG-related outcomes and long-term value creation. This study contributes to the literature by bridging innovation and profitability perspectives within a portfolio matrix framework and extending its application to the renewable energy sector. The proposed model offers actionable insights for strategic decision-making and supports the sustainable development of the solar energy industry, providing practical guidance for firms, policymakers, and industry stakeholders seeking to strengthen both technological and financial resilience.

Paper type: Practical Paper

1. Introduction

Given the rapid depletion of fossil fuels, the development of renewable energy has become a strategic priority for governments and enterprises worldwide. According to the World Nuclear Association, recoverable oil reserves are estimated to last around 40 years, natural gas around 62 years, and coal around 216 years. As a result, countries have begun actively pursuing renewable sources to replace traditional fossil fuels, and studies increasingly examine green IT scheduling for renewable energy (Gu et al., 2018) and the economical operation of cloud data centres through energy trading with the power grid (Grange et al., 2018). Under the Renewable Energy Development Act (REDA), renewable energy includes solar, biomass, geothermal, ocean, wind, non-pumped hydropower, and energy recovered from waste. Among these, solar energy offers the greatest potential: the sun is a permanent, inexhaustible source of heat, and roughly 15 minutes of sunlight reaching the Earth's surface could, in principle, meet global energy demand for a full year.

Amid escalating challenges such as climate change and resource depletion, the solar energy industry has emerged as a key low-carbon sector. As the industry expands, however, competition has intensified, making it increasingly critical for firms to balance technological innovation with market profitability to sustain long-term competitive advantage. Existing studies have largely focused on single dimensions—using patent data to measure innovation capability, or financial indicators to evaluate performance—with limited effort to integrate these perspectives into a unified framework. With the growing importance of environmental, social, and

governance (ESG) considerations, firms are now expected to achieve not only technological and financial performance but also sustainable and socially responsible outcomes. Nevertheless, few analytical tools simultaneously capture innovation, profitability, and sustainability, particularly in the solar energy context.

To address this gap, this study proposes a two-dimensional portfolio matrix integrating innovation and profitability by combining patent-based indicators with gross-margin measures. Using the solar energy industry as the empirical context, the study analyses eight solar energy companies with the Patent and Gross Margin Portfolio Management (PGMPM) model, which combines firms' gross margins with their patent counts in a product-portfolio-management framework. The specific objectives are: (1) to analyse the current status of patent development in the global solar energy industry and examine the patent deployment strategies of major firms; (2) to apply the patent strategic matrix to assess firms' relative positions in technological innovation and market share; and (3) to explore how patent strategies influence corporate performance in environmental sustainability and green competitiveness, and to propose recommendations for future development.

This paper applies a correlational case-study design to eight listed domestic and foreign solar power firms, using the PGMPM business matrix to analyse the gross margins and patent counts of their products, to probe each firm's competitive advantage, and to derive policy recommendations. The implementation comprises: an introduction outlining research motives, objectives, and process; a literature discussion covering the solar cell industry and Ohmae's product-portfolio matrix; the proposal of the research framework and an overview of the domestic and international industry; the case study describing the solar cell industry and the PGMPM matrix calculations; and conclusions summarising implications for research management and strategic policy in the solar cell industry.

2. Literature Review

2.1 Patent Analysis

Citation-based patent analysis has been widely adopted (Albert et al., 1991; Breitzman & Thomas, 2002), using past patents as references for future ones, though it may underestimate newer patents that are cited less—a problem that worsens in fast-moving industries with short technology life-cycles. Analyses of solar energy patents have applied network and visual analysis (Kajikawa & Takeda, 2009), keyword-based approaches (Yoon & Park, 2004; Noh et al., 2015), high-tech trend analysis (Rafols & Meyer, 2010), and property–function analysis (Yoon & Kim, 2012), as well as technology-strategy studies of solar materials and cells (Torben et al., 2010; Wu & Mathews, 2012; Tseng et al., 2011).

In innovation research, patents are commonly used to measure firms' technological capabilities and knowledge accumulation, capturing not only innovation outputs but also technological quality, knowledge impact, and competitive positioning. Scholars increasingly argue that patent evaluation should extend beyond financial valuation to incorporate non-financial dimensions such as technological relevance and strategic implications, and multidimensional frameworks have been proposed to strengthen patent analysis in strategic decision-making (Lawson-Drackey, 2012). Patent-based analyses also distinguish between component and architectural knowledge, offering insight into the breadth and depth of technological development (Meunier & Bellais, 2019), and enable the identification of technological trajectories and lifecycle stages for forecasting and planning (Lee et al., 2024; Coccia & Roshani, 2025).

At the firm level, technological capabilities proxied by patents can enhance investment efficiency, improve resource allocation, and reduce information asymmetry (Li et al., 2025), and patent texts help explain firm market value and predict future earnings (Zheng, 2025). The relationship is not always linear, however; innovation may introduce uncertainty and, under certain conditions, even lead to overvaluation (Doruk, 2025). With advances in artificial intelligence, machine learning, semantic analysis, and text mining are increasingly applied to identify technological topics and innovation patterns—for example, vector-space and semantic methods that assess technological relevance (Huang & Lin, 2018), and multi-source approaches combining patents with web news to forecast emerging trends (Li et al., 2025).

In the solar energy sector—technology-intensive and policy-driven—innovation depends heavily on continuous R&D and patent deployment. Patent data have been used to analyse technological trends and knowledge flows in solar technologies (Chen & Pham, 2014), while government policy, technological capability, and market demand are considered key drivers of industry development (Wang & Wang, 2020), and global competition requires firms to balance innovation investment with cost efficiency (Guo et al., 2025). Meanwhile, ESG factors have emerged as critical determinants of firm performance: ESG affects stock returns, risk, and investment decisions (Teja & Liu, 2024); integrating ESG into predictive models improves accuracy (Park et al., 2024); ESG has evolved from a compliance requirement into a source of competitive advantage (Xing et al.,

2025); and ESG controversies can reduce firm value, moderated by governance mechanisms such as board diversity and independence (Brinette et al., 2024). Overall, most studies address a single dimension and rarely integrate innovation, profitability, and sustainability into one framework—the gap this study addresses through a two-dimensional portfolio matrix applied to the global solar energy industry.

2.2 Product Portfolio Management

Kenichi Ohmae's Product Portfolio Management (PPM) business matrix combines the Boston Consulting Group (BCG) matrix and the GE–McKinsey matrix. The BCG matrix, designed by Bruce Henderson in 1970, helps firms assess an existing product line and allocate cash efficiently (Hax & Majluf, 1983; Hill & Jones, 1995); its horizontal axis represents relative market share and its vertical axis market growth rate, yielding four product types—Question Marks, Stars, Cash Cows, and Dogs. In the PPM career matrix, the horizontal axis represents company strength (divided into three levels) and the vertical axis the attractiveness of the external industry (also three levels). The company-strength and external-environment variables are summarised in Table 1.

Table 1: Company strength variables and indicators of external environment variables

Company strength	External environment
1. Competitiveness: market share 2. Profits: profit margin, cash flow 3. Resources: financial and human resources, raw materials, downstream management 4. Technical: patented and unique technology, quality and design 5. Marketing: brand, regular customers, promotion, marketing dominance	1. Surrounding environment: social, environmental, legal, political, organizational, industry-intensive 2. Profits: industry profit tendency and profitability 3. Competition status: occupancy, capacity, entry difficulty, vertical integration, service and price elasticity 4. Market: size, growth rate, stability, level of detail

Source: Kenichi Ohmae, corporate consultant.

Beyond power generation, solar cells are widely used in consumer, communication, and signalling products (Mary, 1991; Pilkington et al., 2002). The commercial development of solar energy is regarded as an important trend internationally: the European Union, Japan, and the United States have prioritised solar and other renewables as a safe post-2030 energy supply, and solar power is projected to exceed 10% of world electricity supply by 2030 and 20% by 2050. Most major countries promote renewables through tax concessions, equipment subsidies, and preferential feed-in tariffs, using public funds to accelerate R&D and build enabling infrastructure. Although the 2008 US subprime crisis and the subsequent European debt crisis depressed markets and disrupted the industry, the global solar market has continued to advance and grow over the long term.

3. Methodology

This study uses Patent and Gross Margin Portfolio Management (PGMPM) matrix analysis to investigate the solar cell industry and profile the case firms. The PGMPM business matrix combines patent analysis with product portfolio management to evaluate the priority of patent value and firm performance, identify risks and opportunities, prioritise products, and optimise the portfolio, thereby supporting strategies to achieve target revenue and profitability. The PGMPM algorithm takes as input (i) patent sets and (ii) the gross-margin portfolio, and outputs a characteristic rule set generalised from the input, through four steps: (1) collect the patent-set data; (2) perform the PGMPM model—beginning from the basic patent sets, for each attribute in the gross-margin portfolio, selectively generalise attributes and merge identical rules; (3) describe the solar cell industry and compute the PGMPM business matrix; and (4) summarise the conclusions and recommendations for strategic policy in the solar cell industry.

The PGMPM framework provides the foundation for a case study of the solar energy industry. The case firms are listed companies whose solar cell patent information is registered in the LexisNexis database, while their financial statements are obtained from the Datastream database. The eight firms examined are Sino-American Silicon, NEO Solar Power, KYOCERA, Evergreen Solar, BP Solar, Wacker Chemie, Q-Cells, and KANEKA. Sino-American Silicon and NEO Solar Power are professional wafer-material suppliers focused on solar plant development and production; KYOCERA extended from high-precision ceramics into solar cells as a diversified high-tech enterprise; Evergreen Solar is a US solar cell manufacturer; BP Solar is a leading global solar company; Wacker Chemie operates in organic silicon, semiconductors, and chemical polymerisation; Q-Cells is a leading

solar panel manufacturer; and KANEKA mainly produces chemicals, functional resins, and electronic components. Profiles of the firms are summarised in Table 2.

Table 2: Information on the various solar companies

Company	Profile
Sino-American Silicon	Professional wafer-material supplier.
NEO Solar Power	Solar energy R&D and production plant, established in 2005.
KYOCERA	Former high-precision ceramic factory, now extended into solar cells as a diversified high-tech enterprise.
Evergreen Solar	US solar cell manufacturer.
BP Solar	One of the world's leading solar companies.
Wacker Chemie	Global chemical company operating in organic silicon, semiconductors, and chemical polymerisation.
Q-Cells	Leading solar panel manufacturer.
KANEKA	Mainly produces chemicals (PVC), functional resin, and electronic components.

4. Solar Power Plant PGMPM Business Matrix Analysis

The solar cell industry can be divided into upstream, midstream, and downstream segments. The upstream processes materials: after obtaining silicon from suppliers, a crystal-growth furnace produces a silicon ingot, which a precision cutting machine slices into wafers. The midstream focuses on solar cell components (PV cells), and the downstream on product applications, including PV modules and assembled solar systems. The eight firms were analysed with the PGMPM matrix, where the horizontal axis represents company strength (proxied by total patent count from LexisNexis) and the vertical axis the external environment (proxied by the average gross-margin ranking over 2000–2024, from Datastream). Firm rankings are shown in Table 3.

Table 3: Companies' gross margins and number of patents

Company	Avg. gross margin	Margin rank	Patents (upper/mid/lower)	Patent rank (total)
Sino-American Silicon	26.37%	2	0 / 22 / 19	1 (41)
NEO Solar Power	27.62%	1	8 / 15 / 8	2 (31)
KYOCERA	15.26%	6	0 / 21 / 4	3 (25)
Evergreen Solar	-40.99%	8	11 / 7 / 6	4 (24)
BP Solar	20.86%	4	14 / 6 / 1	5 (21)
Wacker Chemie	15.85%	5	1 / 7 / 6	6 (14)
Q-Cells	26.33%	3	13 / 0 / 0	7 (13)
KANEKA	10.28%	7	0 / 7 / 1	8 (8)

Plotting each firm by its total patent count and average gross margin yields the solar energy PGMPM business matrix shown in Figure 1. NEO Solar Power and Sino-American Silicon combine relatively high patent counts with strong gross margins, placing them in a favourable position; their strategy is to adhere to advantages, expand industrial scale, and selectively increase investment in response to future trends. Sino-American Silicon, as a professional foundry, relies mainly on order volume, so the pressure for new technology is less acute; actively developing new technology would enhance its competitiveness and reduce order dependence. Wacker Chemie shows good industry attractiveness but a low patent count; as an upstream raw-material supplier, its investment plan—spending EUR 200 million to expand polysilicon production and fund new R&D, targeting about 22,000 metric tons (roughly 13% of global production)—can be read as an attempt to dominate the upstream.

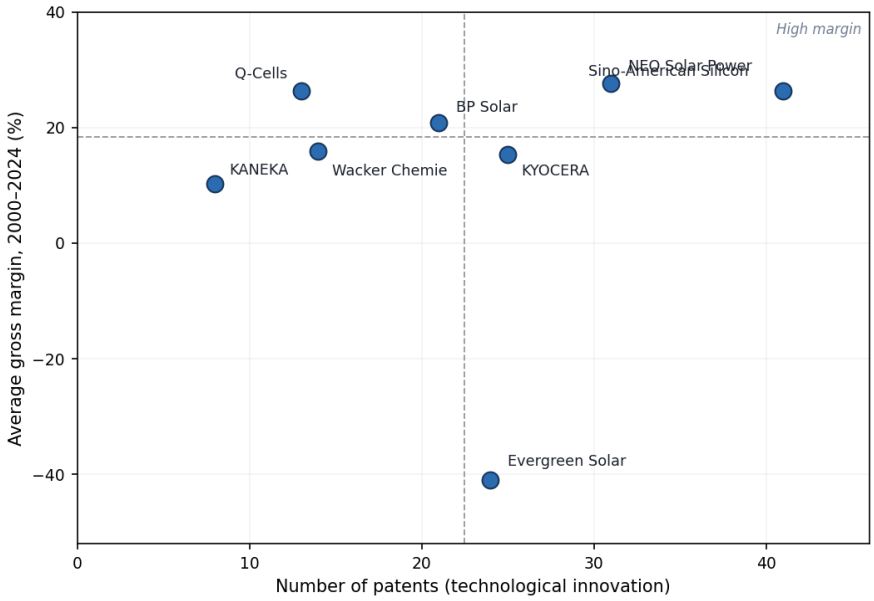

Figure 1: The solar energy PGMPM business matrix

NEO Solar Power, BP Solar, and Q-Cells rank in the middle for patent count. NEO Solar Power's gross margin is below the eight-firm average; consistent with the matrix, its feasible strategies are to eliminate risk and increase profits. Established at the end of 2005, its market share is still limited, suggesting a need for closer cooperation with other manufacturers. BP Solar and Q-Cells sit in the middle of the matrix, making them the most flexible and able to adjust to circumstances; the BP oil-spill incident, which cost the company more than USD 400 billion, illustrates such exposure, and although its revenue has recovered it has not returned to prior levels.

Evergreen Solar has recorded significant losses over the past decade; following a net loss of about USD 12.5 million, it announced plant shutdowns and layoffs and later warned of a funding shortage driven by declining orders, raising bankruptcy risk. Its position corresponds to revenue maximisation under the matrix—where cash cows can no longer generate profit—implying it is likely to divest plants or exit. KYOCERA and KANEKA, by contrast, occupy strong positions: KYOCERA began developing solar cells in 1975, reaching single-crystal cell efficiency of 19.5% and substantial annual output, and expanded production capacity internationally, while KANEKA invested heavily in Hyogo Prefecture targeting 1 GW capacity. Both firms diversified into solar from other industries—precision ceramics and chemicals respectively—reflecting a standard growth-investment strategy anchored on scale advantage.

Value-chain analysis of the patent statistics shows that Sino-American Silicon and Wacker Chemie focus upstream: both aim to improve silicon purity, but Sino-American Silicon emphasises equipment efficiency (crystal-pulling and growth furnaces) to produce high-quality silicon rods, while Wacker Chemie focuses on purifying and processing monocrystalline silicon, which is more complex but yields higher generation efficiency. Evergreen Solar and KYOCERA hold upstream patents in silicon wafers and ingots. The remaining firms concentrate on midstream and downstream stages—PV components and module packaging: KANEKA develops next-generation thin-film cell materials; KYOCERA, Evergreen Solar, and NEO Solar Power hold electrode-improvement patents; BP Solar develops amorphous-silicon and dye-sensitised cells; and Q-Cells holds back-contact cell technology that increases the light-absorbing area for higher efficiency than conventional front-electrode designs. KYOCERA and BP Solar also hold chemical-vapour-deposition patents for anti-reflective and reflective coatings that improve sunlight absorption. Downstream, KANEKA offers the most complete capability from module to package testing, while KYOCERA holds a distinctive patent for solar-tracking devices. Although these data do not by themselves prove that Taiwan's R&D lags other countries, they indicate that domestic capabilities still need strengthening through systematic patent analysis to inform strategy, market direction, and talent development.

5. Conclusions and Suggestions

5.1 Solar Cell Energy Industry Strategy Management

As the world promotes energy-saving technology, solar energy has become a major player in the green energy industry. Taiwan's well-developed foundry sector remains an important revenue source for many small and medium enterprises, but the industry should transform toward a knowledge-based model, which requires cooperation among production, government, academia, and research to train technical personnel—supported, for example, by the Ministry of Education's green-technology talent-cultivation programme. Technology and marketing are further levers: the cost of producing 1 W of capacity remains high even with subsidies, and cells must last more than 20 years to balance costs. Upgrading technology—through transfer of foreign technology or domestic development of high-conversion cells—and changing marketing strategies to increase installations in public facilities and residential roofs are therefore essential. In the future, solar products must be diversified, reach high value, and promote environmental protection; improving conversion efficiency and subsidising production capacity remain the most important issues for both the industry and government.

5.2 Management Implications and Future Research

This study makes two contributions. First, it proposes the PGMPM model, which combines patent analysis with gross-margin portfolio management to obtain, integrate, accumulate, transfer, and innovate an industry's knowledge value. Second, it applies the model to the solar energy industry to integrate the major value attributes of the sector. In the internal-environment analysis, the industry maintains good policy convergence, but industry consolidation and marketing still have room for improvement; achieving cluster efficiency requires a strong value chain that combines government and industry and emphasises the layout of technology patents. In the external-environment analysis, Europe, the United States, and Japan each present clear solar strategies and development visions; Taiwan now offers renewable-energy subsidies, feed-in tariffs, equipment subsidies, low-interest loans, and tax relief, signalling policy commitment, but the industry still lacks horizontal and vertical integration.

Based on the analysis, recommendations for the solar energy industry fall into six directions: (1) government and private enterprises should jointly create green-energy employment, integrate industry and market planning with policy, expand financing channels, establish an industrial development investment fund, and build a national quality-supervision mechanism; (2) strengthen patents, technology research, and forecasting in key scientific fields to shape manufacturers' advantages and master dominant specifications; (3) overcome reliance on rare metals such as germanium and improve conversion efficiency, with academia and industry cooperating to reduce R&D costs; (4) use lens-based light concentration to improve generation efficiency and reduce cost while enhancing device capacity and durability; (5) promote cluster efficiency and a sound value chain that combines upstream, midstream, and downstream strengths, supported by new energy resources, geographic information systems, and personnel training; and (6) focus on policy integration, industrial integration, and marketing, learning from and cooperating with Europe, the United States, and Japan to pursue multiple strategic layouts and global promotion.

Legal Risk Management of Business Owners from the Perspective of Choice-of-Law Rules: A Research Focus On the Impact of Environmental Change on Food Safety

Chang, Che-Wei, Hung, Yu-Chun, Tsai, Pei-Fen
Asia University, Taiwan (R.O.C.)

Abstract

Different choice-of-law rules give rise to vastly different corporate liabilities. This article investigates the management of liability risks and cost controls for multinational enterprises (MNEs) or International Trading Company, specifically addressing how such entities can preemptively mitigate the disparate legal exposures arising from the divergence of conflict-of-law rules. The core of this research focuses on tortious liability for damages stemming from food safety and hygiene crises precipitated by environmental transformations, examining the strategic navigation of applicable legal frameworks to ensure institutional stability.

The Rome II Regulation establishes a unified framework for choice-of-law rules regarding non-contractual obligations (torts) across all EU Member States. Specifically, Article 7 stipulates the choice-of-law regime for environmental damage, which consequently subjects enterprises to varying liability risks depending on the applicable governing law. Regarding the legal framework in Taiwan, the relevant choice-of-law rules are stipulated in Articles 26 of the Act Governing the Application of Laws in Civil Matters Involving Foreign Elements. Unlike the EU framework, Taiwanese law currently lacks a specialized provision for environmental torts, thereby mandating that such cases be governed by general tortious choice-of-law rules.

Due to these diverging protective purposes and developmental trajectories, the stringency of these frameworks varies significantly. In specific food safety cases, the application of EU law under choice-of-law rules substantially increases the probability of successful claims by victims. Consequently, when EU law is applicable, business owners must engage in quality control standards commensurately elevated to manage legal obligations effectively.

If managerial duties are governed by Taiwanese law, which aligns with United Nations standards, an additive may be permitted in the absence of conclusive evidence of harm. That is, as long as the product does not pose an 'unreasonable' or 'unacceptable' risk to public health under reasonably foreseeable and normal conditions of use, the addition of such a substance will generally not be unlawful.

Multinational Corporation or International Trading Company must anticipate applicable choice-of-law outcomes. When EU law applies, enterprises cannot rely on permissive local standards; they must proactively elevate internal quality controls and supply chain standards to satisfy strict precautionary requirements and mitigate potential compensation claims.

Herefore, multinational enterprises or international trading companies must anticipate applicable choice-of-law outcomes to serve as control standards for internal quality assurance and supply chain management.

Keywords: Conflict-Of-Law Rules, Legal Risk Management, Environmental Change, Food Safety, Tortious Liability

Paper type: an Academic Research Paper

1 Research Subjects and Scope

This study examines how enterprises can proactively mitigate legal risks of tort liability for damages when environmental pollution, or environmental changes caused by climate change, give rise to food safety issues. [1] Because tortious conduct encompasses a wide range of circumstances, and to facilitate analysis of the relationship between choice-of-law rules and the liabilities of transnational enterprises, the study confines its scope to the impact of environmental and climatic changes on food hygiene and safety.

Corporate rights and obligations concerning food hygiene and safety can be categorized primarily under three regimes: EU standards, United Nations standards, and US standards. Taiwan tends to align more closely with UN and US frameworks. This article therefore delineates the principal differences among these three regimes and examines how the liability of corporate actors shifts when choice-of-law rules select a particular national or supranational governing law and its corresponding substantive rules are applied.

2 Food Additives and Case Studies

Suppose a European tourist visiting the United States purchases and consumes a food product that was manufactured in Taiwan and exported to the U.S. After ingestion, the tourist experiences itching and

[1] *For reasons related to the study's theoretical framework and word-count constraints, this research is limited to tort liability and does not address damages arising from contractual obligations.*

gastrointestinal inflammation. Examination of the product's ingredients raises suspicion that the adverse reaction was caused by the artificial colorant titanium dioxide (Titanium Dioxide, E171/INS 171). The tourist then brings a tort claim seeking damages, including medical expenses, compensation for emotional distress, transportation costs for medical consultations, and lost earnings due to time off work for treatment.

Whether titanium dioxide (Titanium Dioxide, E171/INS 171) may be lawfully used as a food additive is currently one of the most significant points of international disagreement. In 2022 the EU concluded that titanium dioxide could not be excluded as causing DNA damage, identifying a potential genotoxic risk and expressing concern that particle accumulation might induce genotoxic effects or chronic intestinal inflammation, and consequently enacted a comprehensive ban[1]. By contrast, the Joint FAO/WHO Expert Committee on Food Additives (JECFA) assessed that the available data remain insufficient to demonstrate an immediate hazard to humans; accordingly, the Codex Alimentarius Commission (CAC) lists titanium dioxide as an authorized white pigment in the General Standard for Food Additives (GSFA). In Taiwan, under the Ministry of Health and Welfare—Taiwan Food and Drug Administration (TFDA)'s Standards for the Scope of Use, Maximum Limits and Specifications of Food Additives, titanium dioxide is classified as a Category IX colorant and may be used in various foodstuffs as needed within appropriate limits; however, it is expressly prohibited from use in certain unprocessed foods, including fresh meats, fresh seafood, fresh legumes, fresh vegetables, fresh fruits, miso, soy sauce, kelp, nori, and tea[2]. If meat becomes discolored and turns gray, the addition of titanium dioxide can make it appear redder; likewise, tofu skin or surimi products may incorporate titanium dioxide to mask inferior raw materials. Soy sauce's color should derive from fermentation and caramelization, and tea from the natural hue of the leaves; permitting titanium dioxide would undermine these traditional color characteristics, risk misleading consumers, and could result in purchases of stale or poor-quality foods. Accordingly, on 23 March 2026 the authorities issued a draft "Analytical Methods and Specifications for Titanium Dioxide as a Food Additive," [3]indicating governmental efforts to strengthen monitoring of the substance's purity and composition, although this measure does not amount to an outright ban.

The EFSA assessment indicates that occurrences of typical food-allergic reactions to titanium dioxide (e.g., urticaria or respiratory difficulties) are exceedingly rare[4]. A 2024 study investigating the impact of titanium dioxide on the intestinal barrier reported that long-term ingestion of micrometer- or nanometer-sized titanium dioxide may damage the intestinal mucosa. When the gut barrier is compromised (so-called "leaky gut")[5], systemic inflammatory responses may be heightened, potentially exacerbating preexisting conditions; although clinical case reports are limited, their scarcity does not imply absence of risk.

3 Liability of Product Manufacturers

3.1 Legal Nature and Classification

In the case described above, the sale arises from a contract between the retail merchant that sold the product and the consumer; the product manufacturer has no contractual relationship with the buyer. Accordingly, any recovery sought against the manufacturer should be grounded in tort law, and the legal characterization of the claim is one of manufacturer liability in tort.

The product was manufactured by a Taiwanese company whose principal is a national of the Republic of China. The food, produced in Taiwan, was imported into and complied with U.S. food regulations. A European consumer who returns to Europe and then consumes the Taiwan-made product purchased in the United States and subsequently seeks medical treatment may have been harmed for various reasons: a defect intrinsic to the product; deterioration during prolonged transport or storage after leaving the U.S. and en route to Europe due to changes in climate and environment; or a post-consumption interaction between the product and other foods

[5] "The disruption of the intestinal epithelial barrier allows for the translocation of pro-inflammatory cytokines into the systemic circulation... which can potentially exacerbate pre-existing skin conditions such as chronic urticaria or atopic dermatitis by lowering the degranulation threshold of skin mast cells." Niqhat Fatma Rizvi, Anoop Kumar, Rashmi Chandra, and Shoebul Haque (2024), Synthetic Food Colourants: Applications, Regulatory Perspectives, and Potential Health Implications, World Journal of Biology Pharmacy and Health Sciences (WJBPHS), Vol.17, No. 1, January, p.63. See DOI: 10.30574/wjbphs.2024.17.1.0068 (as available on 18.5.2026)

producing a chain reaction in the body despite the product itself remaining unspoiled. These distinct causal scenarios give rise to different patterns of corporate liability, and litigation brought in European courts versus courts of the Republic of China may produce divergent outcomes (discussed further below).

In cross-border disputes, the initial decision is which court will hear the case—i.e., the choice of international jurisdiction. Once jurisdiction is established, the next step is to determine the applicable law. In tort cases, and to avoid divergences among national substantive rules, the EU adopted unified choice-of-law rules for non-contractual obligations known as Rome II (Regulation (EC) No. 864/2007, commonly referred to as Rome II).

If the plaintiff files suit in Taiwan on the basis that the defendant manufacturer is Taiwanese, the choice-of-law instrument applied by Taiwanese courts is the Act Governing the Choice of Law in Civil Matters Involving Foreign Elements.

3.2 Corporate Liability under the EU Choice-of-Law Rules

Under the Brussels I Recast (Regulation (EU) No 1215/2012) [1], the courts of the place where the tort was committed—including both the place of the harmful event and the place where the damage occurred[2]—are competent to exercise international jurisdiction.

For the benefit of Taiwanese business owners in understanding that corporate liability in transnational cases depends on choice-of-law rules—and that different rules may yield divergent liabilities—this paper outlines the choice-of-law provisions most commonly applied to manufacturers' torts: Article 5 of Rome II for product-related non-contractual obligations, and Article 7 of Rome II for torts arising from changes in climate or the environment.

3.2.1 Corporate Liability for Environmental Damage under the Choice-of-Law Rule of Article 7 of Rome II

Article 7 (Environmental damage) of Rome II: "The law applicable to a non-contractual obligation arising out of environmental damage or damage sustained by persons or property as a result of such damage shall be the law determined pursuant to Article 4(1), unless the person seeking compensation for damage chooses to base his or her claim on the law of the country in which the event giving rise to the damage occurred." If, pursuant to Article 4(1), the law of the country where the damage occurred is to be applied, then the governing law is determined solely by the place of the damage regardless of the country in which the factual cause of the damage arose or where any consequential or indirect effects occurred. Applying this to the present case, EU law would govern. Because the inclusion of titanium dioxide in the product contravenes EU food regulations, the manufacturer should be held liable for the harm suffered by the consumer, an outcome that is unfavorable to the manufacturer.

Article 7 of Rome II also provides an alternative choice-of-law criterion: the law of the country in which the event giving rise to the damage occurred. Accordingly, the defendant may contend that the applicable law in this case should be that of the United States because the product was originally acquired there and the causal event giving rise to the damage occurred there; thus U.S. law, rather than EU law, should govern. Under U.S. law the use of titanium dioxide is lawful, so the mere inclusion of titanium dioxide would not, per se, give rise to legal liability. Liability would instead depend on whether environmental or climatic changes led to product deterioration that caused the consumer's illness, an issue requiring factual and expert inquiry. Moreover, under both the Second[3] and Third[4] Restatements, the predicate for liability is a product defect, which is understood to include manufacturing defects, design defects, and defects arising from inadequate instructions or warnings.[5] Accordingly, if a manufacturer or commercial operator can demonstrate that the product was not defective, the requisite elements for tort liability are lacking and no compensation is owing to the plaintiff. The defendant may further argue that, if the harm resulted from improper storage during long-distance transportation, customs detention, or the plaintiff's own mishandling, the risk should be borne by the plaintiff.

---

[1] Regulation (EU) No 1215/2012 of the European Parliament and of the Council of 12 December 2012 on jurisdiction and the recognition and enforcement of judgments in civil and commercial matters (Brussels I Recast), OJ L 351/1, 2012.

[2] The three principal provisions of the Brussels I Regulation are: (1) the defendant's domicile rule (Article 4); (2) the tort venue rule, encompassing both the place of the wrongful act and the place where the damage occurred (Article 7); and (3) consumer-protection jurisdiction (Articles 17–19).

[3] Article 402A of Restatement (Second) of Torts: "Special Liability of Seller of Product for Physical Harm to User or Consumer (1) One who sells any product in a defective condition unreasonably dangerous to the user or consumer or to his property is subject to liability for physical harm thereby caused to the ultimate user or consumer, or to his property,....."

[4] Article 1 of Restatement (Third) of Torts: Products Liability : "Liability of Commercial Product Seller for Harm Caused by Defective Products-One engaged in the business of selling or otherwise distributing products who sells or distributes a defective product is subject to liability for harm to persons or property caused by the defect."

[5] Article 2 of Restatement (Third) of Torts: Products Liability: "Categories of Product Defect -A product is defective when, at the time of sale or distribution, it contains a manufacturing defect, is defective in design, or is defective because of inadequate instructions or warnings."

3.3.2 Corporate Liability under the Choice-of-Law Rule of Article 5(1) main paragraph of Rome II

It is important to note the Article 5(1) textual proviso—"subject to Article 4(2)"—which reflects that Article 5(1) applies where the liable party and the victim are not both habitually resident in the same country at the time the damage occurs. If the manufacturer or liable party is not domiciled or habitually resident in an EU Member State, the assumptions underpinning Article 5(1) main paragraph may not be met, and the special rule set out in the proviso to Article 5(1) must be applied instead.

3.3.3 Corporate Liability under the Proviso to Article 5(1) of Rome II

According to the proviso to Article 5i of Rome II :"However, the law applicable shall be the law of the country in which the person claimed to be liable is habitually resident if he or she could not reasonably foresee the marketing of the product, or a product of the same type, in the country the law of which is applicable under (a), (b) or (c)." In other words, If the producer could reasonably have foreseen that the product might be brought into use in the EU, and the producer's habitual residence is in an EU Member State, the law of that Member State will apply and the producer will be liable for adverse health effects resulting from the addition.

The capacity to foresee and the fact of having foreseen must be clearly distinguished. Legal responsibility attaches to the capacity to foresee: if a defendant lacked that capacity, it should not be reproached; if the defendant possessed that capacity, then irrespective of whether actual foresight occurred, the defendant is obliged to implement measures commensurate with that foresight, and failure to act gives rise to liability. Whether the capacity to foresee existed is a matter for judicial appraisal, and accordingly the producer faces a risk of being ordered to pay damages.

3.3.4 Corporate Liability under the Choice-of-Law Rule of Article 5(2) of Rome II

According to Article 5 of Rome II: " 2.Where it is clear from all the circumstances of the case that the tort/delict is manifestly more closely connected with a country other than that indicated in paragraph 1, the law of that other country shall apply. A manifestly closer connection with another country might be based in particular on a pre-existing relationship between the parties, such as a contract, that is closely connected with the tort/delict in question.", based on a "manifestly closer connection" with another country, a company can argue that its products were manufactured in Taiwan and sold in the United States, thus establishing a close connection with Taiwan or the United States. The EU connection is merely an isolated incident, therefore Taiwanese or US law, rather than EU law, should apply.

In this case, EU consumers brought the goods back from the US and the product spoiled due to local climate or environment, resulting in health problems, then the consumer's actions constitute an intervention or processing that caused product damage. Even if the court finds the company liable, the manufacturer can argue that the plaintiff's negligence should be offset when calculating damages to reduce its liability.

3.3 Corporate Legal Liability under Taiwan's Choice-of-Law Rules

3.3.1 Corporate Liability under the Main Paragraph of Article 26 of the Act Governing the Choice of Law in Civil Matters Involving Foreign Elements

If this case is litigated in Taiwan, the Taiwanese court will apply Article 26 of Act Governing the Choice of Law in Civil Matters Involving Foreign Elements: "Where an injury has resulted from an ordinary use or consumption of an article of commerce, the legal relationship between the injured person and the manufacturer is governed by the national law of the latter. However, where the manufacturer has agreed in advance or where the manufacturer could have foreseen that the article would be sold in a place whose law is one of the three mentioned below, the law of that place is applied, if the injured person chooses that law as the applicable law: a. The law of the place of injury; b. The law of the place where the injured person purchased the article; and c. The national law of the injured person." Under that provision, where the applicable law is "the law of the country of the manufacturer," if the manufacturer is a national of the Republic of China (Taiwan) Taiwanese civil law and related statutes apply. The addition of titanium dioxide would therefore be lawful and not by itself actionable.

However, if consumption of the food causes adverse health effects, liability may arise pursuant to Article 191-1 of the Civil Code[1], a manufacturer or commercial enterprise should be held liable for damages unless it

[1] *Article 191-1 of the Civil Code : "The manufacturer is liable for the injury to another arising from the common use or consumption of his merchandise, unless there is no defectiveness in the production, manufacture, process, or design of the merchandise, or the injury is not caused by the defectiveness, or the manufacturer has exercised reasonable care to prevent the injury.*

can demonstrate that the product's production, manufacture, processing, or design was free of defect, that the harm did not result from such a defect, or that it exercised due care reasonably necessary to prevent the harm. Further details are discussed below.

3.3.2 Corporate Liability under the Proviso to Article 26 of the Act Governing the Choice of Law in Civil Matters Involving Foreign Elements

If the proviso to Article 26 of the Act Governing the Choice of Law in Civil Matters Involving Foreign Elements applies, several potential choice-of-law rules may be invoked: (1) the law of the place where the damage occurred — in this case, applicable EU regulations, with conclusions as described above; (2) the law of the place where the victim purchased the product — in this case, U.S. law, with corporate liability as described above; and (3) the law of the victim's country of nationality — in this case, an EU Member State's law, under which the question of the manufacturer's liability will be assessed according to relevant EU norms, potentially resulting in significantly greater corporate responsibility and damages.

4 Corporate Liability Interlinked with Causation and the Burden of Proof

4.1.Causation and Strict Liability

After 1985, Directive 85/374/EEC enshrined the strict liability principle: victims need not prove the manufacturer's fault, but only a causal link between a product defect and the damage sustained; manufacturers are therefore liable for harm caused by defective products. This principle has been fully transposed into the domestic laws of all EU Member States. Consequently, absent a demonstrable lack of causal connection between the product and the consumer's health impairment, manufacturers will generally be held liable; they cannot avoid liability merely by invoking the absence of fault, although they may be exonerated if post-incident expert evidence establishes no causal relation to the product.

4.2. Legal Liability Arising from the Allocation of the Burden of Proof

4.2.1 Burden-of-Proof Rules in the European Union

The Product Liability Directive (Directive (EU) 2024/2853) [1], adopted in 2024, introduced a presumption-of-proof mechanism particularly tailored to situations of pronounced information asymmetry within the food supply chain[2]. The measure is intended to address victims' inability to prove highly technical causal links: under the traditional regime, plaintiffs must demonstrate the existence of a product defect, a burden that is especially onerous in transnational food chains because critical production processes, testing data, and internal quality-control records are typically controlled by corporations[3]. Consequently, the Directive permits provisional presumptions that a product is defective, or that a defect is causally linked to the harm, thereby increasing victims' prospects of prevailing in litigation.[4]

Accordingly, applying the Product Liability Directive (Directive (EU) 2024/2853) through choice-of-law rules would effectuate a reversal of the evidentiary burden, relieving consumers of the obligation to prove causation—a result that benefits consumers and disadvantages producers. Although the Directive primarily targets businesses that market products to, or whose products circulate within[5], EU Member States, its rationale is intended to inform domestic tort law across the Member States. Although the Directive applies to businesses that market products to EU Member States or whose products circulate within EU Member States, its spirit has become the basis for the allocation of the burden of proof in product liability cases.

The manufacturer mentioned in the preceding paragraph is the person who produces, manufactures, or processes the merchandise. Those, who attach the merchandise with the service mark, or other characters, signs to the extent enough to show it was produced, manufactured, or processed by them, shall be deemed to be the manufacturer.

If the production, manufacture, process, or design of the merchandise is inconsistent with the contents of its manual or advertisement, it is deemed to be defective.

The importer shall be as liable for the injury as the manufacturer."

[1] The revised Product Liability Directive (Directive on liability for defective products) was adopted by the European Parliament and the Council of the European Union on 23 October 2024 and published on 18 November 2024; it entered into force on the twentieth day following publication and is therefore currently in effect. See Taipei Economic and Trade Office in Surabaya, "EU Revision of the Product Liability Directive: Overview," 29 November 2024, p. 1, available at https://reurl.cc/9bQgQx. (as available on 18.5.2026)

4.2.2 Burden-of-Proof Rules in Taiwan's Jurisdiction

The presumption of causation and allocation of the burden of proof for product liability in our country are provided in Civil Code Article 191-1. If a manufacturer cannot prove that the production, manufacture, processing or design was free of defects, or that the damage was not caused by such a defect, or that it exercised due care to prevent the damage, then even if the manufacturer establishes that the addition of titanium dioxide was lawful under Taiwanese regulations, it will still be liable for compensation for health damage resulting from consumption.

4.2.3 Comparative Analysis of the Burden of Proof for Product Causation: EU versus Taiwan

From the foregoing food-safety provisions, it is evident that presumptions of causation and the burden of proof have been shifted onto manufacturers in both the EU and Taiwan; on this point the rules are the same and there is no divergence.

At present, both the EU and Taiwan regulate causation in product cases as a substantive matter by adopting a presumption-based liability regime. Thus, where harm arises from the normal use of a product—such as adverse health effects following consumption—the plaintiff need only demonstrate that the injury originated from the product, upon which the manufacturer is required to assume liability for damages. This,if the product was not used normally, the consumer bears responsibility.

If a manufacturer seeks to avoid liability for damages, it must adduce evidence that the adverse outcome resulted from climatic and environmental changes in Europe—such as food spoilage or the induction of unhealthy or allergic reactions following ingestion of additives—rather than from defects in the product's manufacture, formulation, or design. For example, titanium dioxide particles ingested in the European diet readily adsorb particulates in the gastrointestinal tract; climate change—by warming and acidifying the oceans (ocean acidification, OA)[1] and provoking alternating extremes of intense rainfall and drought—alters river runoff dynamics. During drought, heavy metals in soils and sediments may oxidize, and subsequent heavy rains can wash these mobilized metals into the sea in large quantities, thereby changing coastal salinity and pH.[2] When the oceans absorb excess carbon dioxide, seawater pH declines; in such more acidic conditions, heavy metals previously sequestered in marine sediments (e.g., cadmium [Cd], lead [Pb], mercury [Hg], arsenic [As]) undergo speciation changes, shifting from stable bound forms to more labile ionic forms, which are readily taken up by lower marine organisms such as algae and bivalves[3], and this leads marine organisms to accumulate greater loads of microplastics and heavy metals, producing the so-called "Trojan horse" effect[4]. This amplifies the bioaccumulation and biomagnification of toxins within the food web, increasing the risk that, when humans consume seafood, titanium dioxide particles enhance the uptake of marine pollutants and thereby raise the incidence of gastrointestinal inflammation or allergic reactions.[5] If such adverse outcomes stem from environmental contamination and consumer dietary practices rather than from spoilage or manufacturing defects in the food itself, the duty of care for safe consumption rests with the consumer. Given that the EU prohibits the use of titanium dioxide as a food additive, European consumers are expected to possess baseline knowledge and prudence; when purchasing or consuming foods legally containing titanium dioxide in other jurisdictions, they should avoid mixing such products in ways that could precipitate health risks. Consumption choices are therefore matters of individual autonomy and risk-bearing, not the responsibility of manufacturers.

4.2.4 Burden of Proof Where Physical Evidence Has Been Lost

If a victim requires physical evidence beyond proof of causation—for example, where the consumed product was discarded after the victim lost consciousness and thus cannot be produced—manufacturers and other actors in the supply chain have no inherent obligation to supply such items under ordinary rules. Under the 2024 Product Liability Directive, however, a court may compel the provision of relevant materials. To prevent plaintiffs from using such measures to obtain internal product information they otherwise could not access, plaintiffs should first establish prima facie evidence that the injury originated from the product—for instance, medical

[5] For example, research has also reported that titanium dioxide nanoparticles exacerbate the bioaccumulation and toxicity of cadmium in mussels; see Canesi, L., et al., "Titanium dioxide nanoparticles aggravate the bioaccumulation and toxicity of cadmium in Mytilus galloprovincialis," Science of the Total Environment, 466, 2014, pp. 631–637.

records documenting treatment, clinical injury reports, purchase receipts, witness testimony, or widely reported instances of similar defects associated with the same product model on the market.

5 Conclusion (Management Recommendations For Business Owners)

In the EU, product liability arising from environmental change is governed by Article 7 of Rome II, under which the applicable law may be either the law of the country where the damage occurs or the law of the country in which the event giving rise to the damage occurs. In this case, the application of different connecting factors yields divergent outcomes: under the former the producer would be liable, whereas under the latter the producer would not be liable. Ordinary product-related torts are governed by Article 5 of Rome II, which applies either the law of the habitual residence (lex domicilei) or the rule of the manifestly closest connection.

When an action is brought before Taiwanese courts, Article 26 of the Act on the Application of Laws to Foreign-related Civil Relations governs choice of law: where the rule prescribes application of the law of the manufacturer's country, Taiwanese substantive civil law applies in the present case. However, if the proviso to Article 26 is applicable, the law of the place where the damage occurred or the law of the victim's nationality may instead lead to application of the relevant EU tort laws; and where the law of the place where the plaintiff purchased the product is the connecting factor, U.S. law may be applied. Thus, different applicable laws yield divergent outcomes as to corporate liability and damages.

Based on the foregoing analysis of this case, manufacturers and marketers must reassess their practices. With global travel and tourism facilitating the movement of consumers across jurisdictions, even where an ingredient is legally permitted in the jurisdiction of production or sale, R&D and production teams should proactively design formulations to meet the strictest international standards. This approach accords with the precautionary principle in risk governance: "Where there are plausible grounds for concern that a potentially dangerous effect on the environment or human health may be inconsistent with the high level of protection chosen, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation." Although compliance with stricter standards may raise production costs, those expenses are likely modest compared with potential liability awards (some of which can be enormous).

Concurrently, firms should implement Failure Mode and Effects Analysis (FMEA) during the food design stage, incorporating long-term cumulative toxicity risks into the FMEA assessment matrix. By applying Risk Priority Numbers (RPNs) to quantify subjective concerns, organizations can render latent risks visible and thereby inform managerial decision-making and remedial action.

Moreover, manufacturers should attend to principles of information symmetry and conspicuous notice. They should employ internationally recognized warning icons and prominently display in bold on product packaging the following: "This product is intended for sale and consumption only within [specified country/region]. Any risks arising from transporting and storing the product outside the authorized territory are the responsibility of the holder." Although such warnings will not entirely absolve legal liability, they constitute important evidence in litigation that the manufacturer fulfilled its duty to inform.

It is recommended that firms establish blockchain-grade traceability systems. When a product issue arises—such as the additive dispute described above—companies must be able, within minutes, to leverage their ERP (Enterprise Resource Planning) systems to trace a batch's raw-material suppliers, the specific production line that manufactured it, and the distributors to whom it was sold. Such capability permits containment of harm to discrete batches and enables precise attribution of responsibility in litigation.

Unforeseen events often occur beyond reasonable expectations. Accordingly, firms should transfer risk where appropriate by obtaining adequate insurance so that potential awards are shared with insurers. They should also establish a Product Launch Review Committee composed of R&D, Quality Assurance, Marketing, and Legal functions to identify and mitigate regulatory and corporate risks across jurisdictions, thereby enabling proactive prevention. In addition, companies ought to set aside dedicated legal and recall reserves to ensure that cash flow remains solvent when facing class actions or cross-border litigation.
