WELCOME TO IFKAD 2019

Welcome to the 14th edition of IFKAD. This 2019's edition is taking place back to Matera, where for the first time our scientific knowledge-based community gathered in 2006 to start an open and interdisciplinary debate about the role and relevance of knowledge assets dynamics for the value creation mechanisms of organisational systems. Since then, our community has been growing, and IFKAD is nowadays one of the leading and most prestigious international scientific conferences focusing on the relationships between knowledge resources and organisational growth.

This year's IFKAD is supported by the University of Basilicata, the University of Rome Tre and the Chinese Culture University and it is happening in a special time for Matera, during the celebration of its appointment as European Cultural Capital. Matera is the ideal location to discuss the role of knowledge ecosystems in shaping a sustainable future as the town is developing the cultural program for the nomination of European Cultural Capital, under the label "Open Future".

Since 2006, the first edition of IFKAD was held in Matera; the world has experienced critical advances and challenges while characterised by greater complexity and multiplicity. Now, more than ever, we need scholars and practitioners who can navigate and make sense of these tensions by thinking in broad and integrative ways. Thus, during our Forum, let us imaginatively and importantly use our capabilities and voices to examine management and organisations questions that advance our understanding of the role of knowledge ecosystems for growth and a sustainable future. Indeed, the competitiveness of organisations seems more and more related to their ability to be part of knowledge ecosystems that provide the ideal conditions in terms of human, socio-cultural, and relationship capital to shape a cognitive atmosphere catalysing and supporting open innovation.

Over the past decades, management scholars from different research perspectives have extensively explained the role of knowledge as a crucial driver for the growth of organisational systems both at the micro and the macro level. Knowledge resources and dynamics represent the strategic foundations for the creation and management of any form of the firm as well as cities, local territories, regions and nations. At the 14th edition of IFKAD, by acknowledging knowledge assets as key values drivers for growth, we wish to extend our theories, findings and business discourses about the value creation dynamics of knowledge to further understand the role of knowledge ecosystems to shape a sustainable future. Today's business landscape is characterised by global and local trends that call for an extension of our understanding of the role of knowledge as a strategic resource and source of growth. Global challenges include population growth, increased diasporas, commoditization of knowledge, the pace of innovation, the digital revolution and technological advances, business model transformations, growing gig economy, while local challenges consider local development, citizen

FOREWORD

inclusiveness, employability, and quality of life. They call for a better understanding of how knowledge dynamics can properly address sustainable wealth creation, particularly through the development of knowledge ecosystems.

The mission of IFKAD is the development of research and scientific conversations aimed at contributing to theory-building as well as to the managerial practice about the role of knowledge as an organisational value-driven source. Our view is that organisations are primarily in the business of knowledge and from their capacity of managing knowledge depends on their future business sustainability and value creation capacity.

I want to extend my thank to all those colleagues and friends that every year work to make IFKAD a successful scientific event as well as a great social gathering where to meet old friends and make new once. I wish you a fruitful and inspiring conversation capable of nurturing your curiosity and scientific expertise.

Prof. Giovanni Schiuma

Abstract

The current surge of new digital technologies such as artificial intelligence, big data, blockchain, and internet of things have revitalized the interest in the effects of technological changes on organizations and individuals. Linked to this interest is also the potential for efficiency gains from automation, growth through scalability and connectivity in ecosystems offered by these technologies. Some researchers suggest that digitalization might play out differently contingent on the context in which the digitalization occurs. However, to date we have limited understanding of how the digital technologies are used and utilized and what effect they have in different knowledge domains. Consequently, there is a pressing need for more insights into the contingency factors associated with the digitalization in different industries. This paper focuses on servitization where digitization plays a crucial role in traditional manufacturing transformation from offering physical products to offering services. The transition from product- to service-oriented business models is very challenging because companies need to develop new services that are not yet in the marketplace. The utilization of digital technologies is of increasing interest as this type of manufacturing firms seek service-based strategies.

Keywords – Digitalization, digital transformation, manufacturing firms, servitization.

Paper type – Academic Research Paper

1 Introduction

There is no established framework with digitalization theory. Preliminary research offers a fragmented landscape around digitalization, often driven by an understanding from informatics. This professional perspective is more often focused on the technological complexity, and less on the understanding of the organizational complexity in which the technology is implemented and utilized. Therefore, it remains to be seen which established framework from management and organizational fields proves effective to explain particularly complex factors, such as the use of digital technologies, the commercial and organizational implications of introducing this technology and type of digital technology (i.e. artificial intelligence (AI), Internet of things (IoT), blockchain, augmented reality (AR) and virtual reality (VR) with digital ambition (digization, digital automation, digital transformation; i.e. Loebbecke & Picot, 2015). Moreover, a prerequisite condition for assessing the eligibility of different theoretical perspectives on digitalization is a further understanding of how digital technology is implemented and used in different contexts. Accordingly, this empirical paper aims at revealing how digital technologies are implemented and used in a particular context: Industrial product manufacturing firms embarking on a digitally enabled servitization strategy. Luz Martín-Peña, Díaz-Garrido, and Sánchez-López (2018) implicitly assumes a close relationship between digitalization and servitization strategies in a recent review of literature on digital business models. Moreover, harnessing digital technologies are of increasing importance as product firms organize for service led growth (Sklyar, Kowalkowski, Tronvoll, & Sörhammar, 2019). Hence, we ask: How does digitalization enable servitization? How are the technologies that are used to develop new services enacted?

While extant literature has clearly pointed out that the transition from products to services is a strategic one and requires the attention and support from top management, it is still unclear of how the actual strategy is relating the firms agility and capabilities in the digital transformation process (Bustinza, Gomes, Vendrell-Herrero, & Tarba, 2018). This is important, because this transition is likely to involve tensions and contention between product and service units (Palo et al., 2018). However, there is also likely to be ample synergies between service, enabling companies to offer entire solutions to greater customer problems (Tuli et al., 2007, Ulaga and Reinartz, 2011). This obviously requires strategic sensitivity from the company, paying attention into the differences between different type of services and the oftentimes dynamic connections between products and services. Several companies delivering technologically advanced products to the global energy and maritime sectors have experienced increased price pressure and falling margins. One way to meet these challenges for manufacturing firms is to increase the revenue from services through digitalization. Such a transition from product- to service-oriented business is called servitization (Lightfoot, Baines, & Smart, 2013). Servitization is therefore the transition manufacturing firms are within when shifting focus from tangible products to intangible services (Partanen, Kohtamäki, Parida, & Wincent, 2017). To date there exist limited empirical research addressing how digitally driven

servitization strategies in manufacturing firms are underpinned by integration and clever utilization of digital technologies.

We conducted a qualitative study with five manufacturing firms in one industrial maritime and energy cluster servicing the North Sea oil industry. In our data gathering efforts we have accessed a variety of data sources such as; visits with observation at five different production facilities, 43 in-depth semi-structured interviews with strategic decision makers, relevant customers and suppliers, as well as document studies in relation to strategic practices as well as documents studies (e.g. minutes-of-meetings, internal reports and annual reports).

The unit of analysis in this study is services where digitization plays a crucial role. Digitization is referred to as the pace of change in society driven by digital technological development (McAfee, 2009). The digitization trend consists of a number of new technologies at different stages of maturity and acceptance in the market, and these technologies will converge and create new technologies (Manyika, Chui, Bughin, Bisson, & Marrs, 2013). The consequences of digitalization for society and business can be understood in different stages (Loebbecke & Picot, 2015). Step 1 is called Digitization and refers to conversion of analogue to digital information (Negroponte, 1995). Step 2 is called digitization, which is about the process of using digital technology, where ICT is used to replace or streamline work tasks (Aron & Waller, 2014). Step 3 is referred to as digital transformation or digital switching. In this digitalization step the process development improves the organizational structure and the underlying business model, creating new markets and new business areas (Andal-Ancion, Cartwright, & Yip, 2003). These three development steps are useful as analytical tools to identify where the different service innovations are in the application of digital solutions. This can also help to develop, simplify, improve or streamline services.

Our analysis reveal that there are large variations between the companies' products and services in relation to digitization for servitization. Our study contributes to organizational studies on the role of digitalization for servitization. We found five different groups of technologies used in servitization: 1) Web-based, 2) Sensors and IoT, 3) Virtual reality and simulations, 4) Augmented reality and finally 5) Automation/Robotics. The five uses of technology are enacted in different ways and expose different commercial needs and organizational implications.

2 Theory

Servitization can strengthen companies' performance and competitiveness, especially in the long term (Visnjic, Wiengarten, & Neely, 2016); however, the transition from products to services is very challenging (Alghisi & Saccani, 2015), since they are based on different logics (Wikström, Hellström, Artto, Kujala, & Kujala, 2009). Product-oriented businesses are often characterized by standardized homogeneous solutions and volume production, while higher service orientation are characterized by heterogeneous specialized knowledge-intensive deliveries (Fisk, Brown, & Bitner, 1993) that often are customized to the specific needs of one single customer. We combine literature on

standardization and customization in services in order to identify the different strategy practices needed for different service offerings for servitization.

2.1 Strategy and servitization

Servitization relates to different functional areas in companies, and research shows that strategic management and involvement of managers are prerequisites for success (Gebauer, Fleisch, & Friedli, 2005). Since servitization both requires changes in the company's internal organization and external relationships (Alghisi & Saccani, 2015), it is likely that different types of strategy practices associated with servitization will be utilized. Recent strategy literature highlight that more companies choose completely open strategy practices to bring about tough organizational changes. However, empirical research has hitherto not explored the link between open strategy and servitization. More empirical research is needed to fill this knowledge gap. To be able to identify different types of strategy practices with servitization, we first expose theory regarding classification of industrial services before we turn to differences of customer interaction and customization.

Existing research has identified how manufacturing firms develop their service business and has classified industrial services (Parida, Sjödin, Wincent, & Kohtamäki, 2014; Partanen et al., 2017). The classification is useful for understanding how services can be divided into portfolios of services and viewing service bundling and product-service configuration. Partanen et al. (2017) set forth five dimensions or bundles of services, with a total of 15 types of services (Figure 1). This service classification can both be used to identify different service bundles and view how different bundles are used from different firms to different customer segments. Furthermore, products and services have different roles when suppliers and customers take part in the product specification or service creation, co-creating value (Vargo & Lusch, 2008). Moreover, there are different ways these services are intertwined with technology and digitization

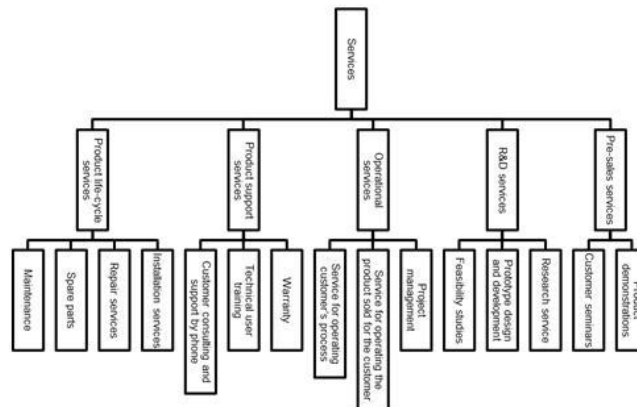

Figure 1 Dimensions of industrial services (Partanen et al., 2017)

Standardization, customization and customer interaction

To understand how customers take part in product and service creation, there are two dimensions that are often used to explain the variety: *the degree of standardization/customization* and *the degree of customer interaction* (e.g. Consoli & Elche-Hortelano, 2010; Hansen, Nohria, & Tierney, 1999; Larsson & Bowen, 1989; Løwendahl, 1997; Maister, 1993; Ramírez, 1999; Schmenner, 1986). *The degree of customization* influences the extent to which the product or service can be codified and delivered independently of specific people and locations (Hansen et al., 1999; Løwendahl, 1997; Maister, 1993). Customization means that the provided offer meets a customer's specific needs. The method of standardization is used to reduce or eliminate customized, one-time, and seldom-used processes that introduce variability while potentially adding costs and quality problems. The degree of customization influences the extent to which products and services can be commoditized (Hansen et al., 1999).

The degree of customer interaction is related to how involved the customer is during provision of the offer. Typically, the degree of customer interaction is higher for services than products. According to the literature, the quality of services is evaluated in the “moment of truth” (Normann, 1984), and services are co-produced by the customer and the service provider (Amara, Landry, & Doloreux, 2009; Bettencourt, Ostrom, Brown, & Roundtree, 2002; Ordanini & Pasini, 2008). This explanation, however, is a simplified picture of service provision (Breunig, Kvålshaugen, & Hyde, 2014). Sometimes, services are created in collaboration with the customer, and the consumption and provision go hand-in-hand. Other times, the customer is not involved in the service production at all. In such cases, the service provider receives orders from the customer and delivers the requested output. Kvålshaugen, Hyde, and Brehmer (2015) identified four generic types of services which they called standardized-provided, standardized-co-produced, customized-provided, and customized-co-produced (Figure 2).

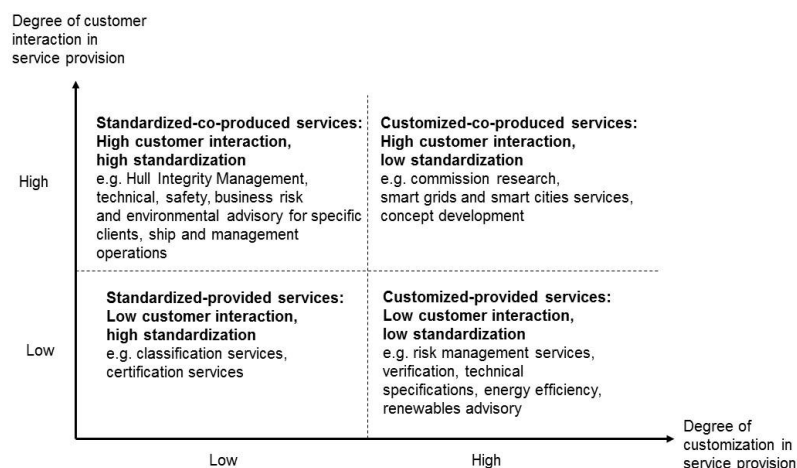

Figure 2 Customer interaction and customization (Kvålshaugen et al., 2015)

The extant literature on customer interaction and customization has so far discussed products and services in isolation, and not the bundles of products and industrial services that result from servitization processes. We believe that the relationship between customer interaction and customization are together powerful constructs to understand servitization. In order to be able to identify how companies servitize and customize their products and industrial services and their related strategizing, we therefore combine the findings from Partanen et al. (2017) regarding the different industrial service offerings, with the understanding of service customization from Kvålshaugen et al. (2015).

3 Methods

The explorative nature of our research problems warrants a qualitative approach. For the purpose, we use an embedded single-case study design aiming at building new theory (Yin, 2009). The case is an industrial cluster of equipment manufacturers within the Norwegian energy and maritime sector. Within the cluster, we have so far interviewed 43 managers from five companies from different parts of the industry value chain. The current degree of service orientation in the case organizations' business models vary, but all firms are in an ongoing process of increasing the service orientation in their business models, especially by making more extensive use of digital technologies. We collected data mainly through semi-structured, in-depth interviews with employees involved in servitization in the case organizations. The interviewed persons represented both product and service units as well as top management. The interviews varied in length between 60 and 75 minutes. All four authors of this paper participated in the interviews and at least two of the authors participated in each interview. The interview guide was discussed and developed on beforehand to secure common ground and understanding of the phenomenon at hand and the purpose of the questions. The interviews were recorded and will be transcribed. In addition, notes were taken during the interviews. We also received some information from the companies such as power point presentations and product or service brochures. Table 1 provides an overview of the cases. We analysed the interviews in an abductive manner. First, we performed a within-case analysis, trying to form an understanding of each individual company and its servitization process. Next, we did a cross-case analysis to identify possible patterns across the cases.

Table 1 An overview of the companies and the number of interviews in each of them

<i>Name</i>	<i>Offering</i>	<i>Number of interviewees</i>
Alpha	Engineering, Procurement, Fabrication, Transportation, Construction, Installation supervision, Project management (on an Engineer-to-Order basis).	8
Beta	Tailor made drilling equipment and systems, and related life-cycle services such as training and remote diagnostics and online support.	11
Gamma	Lifting equipment and related life-cycle services such as training, remote diagnostics and online support.	7
Delta	Custom-made operator chairs in small series.	7
Epsilon	Lay flat hoses. Sensoring of hoses as future prospects.	10

4 Findings

Across the five firms, there were different services that were provided and several planned services, for servitization. For each service type identified by Partanen et al. (2017), there were different services and projects using digitalization. Table 2 gives an overview of each technology used, which will be further exposed below with illustrative examples.

Table 2 Servitization and digitization

<i>Servitization/ Digitalization</i>	<i>Pre-sales services</i>	<i>R&D services</i>	<i>Operational services</i>	<i>Product support services</i>	<i>Maintenance and life-cycle services</i>
Web based	Selector		My operations app		
Sensors and IoT			Operation performance: Real time, big data for decision support		Machine prognostics; Condition based maintenance
Virtual reality and Simulations	Simulator service	BIM Modelling	Planning operations; Training	Simulator service; Location independent training; Equipment training	
Augmented reality				Digital twin	Remote repair
Automation; robots			Assist functions, CAM		

4.1 Web-based technology

The firms in our sample used web-based technology to communicate efficiently with customers during the provision of pre-sales services and operational services. The following quote from one of the managers in Epsilon illustrates the practices in this area:

«We are planning to make a web-based hose selector where the customers can choose for example the type of liquid they want to transport - Drinking water, dirt, oil, gas, compressed air – and the quality - high quality, low quality (...)»

4.2 Sensors and IoT

We found that the firms in our sample integrated sensors combined with communication technology in the equipment to a large degree. Data from these sensors were used during the provision of operational services as well as maintenance and life-cycle services. The following statement from one of the managers in Gamma illustrates how this type of data may be used to improve the customer's operational process:

«Helicopters today have health indicators monitoring their rotary equipment (...) to see for example if there are any frequencies that indicate errors. We have

a pilot project where we see if we can use this technology on cranes. We have begun to install this equipment (...). It is not a problem to make things smart.”

One of the informants in Delta also explained how they could use sensor technology to improve the customer’s use of their equipment:

«We can install sensors in the chairs. In this way they can automatically recognize the person and adjust automatically - pre-set memory setting. »

We also identified several examples on how this technology could be used to provide maintenance and life cycle services. One informant from Epsilon for example stated:

«We can install vibration meters on the looms to be able to identify when it is bad (...). This is standard equipment on wind turbines and helicopters. We can perhaps also combine this with artificial intelligence. This will enable us to provide condition-based maintenance – maintenance based on the condition of the loom (...). The customers can perhaps lease the looms instead of buying them (...). »

Another example was related to Beta. One informant stated:

«The sensors enable us to change maintenance strategy (...) From calendar-based maintenance strategy where it does not matter how much the product is used (...), to a condition-based maintenance strategy where maintenance is based on the condition of the equipment. We can do less maintenance in this way (...) When using this maintenance strategy, we get a bag of money that we have to capitalize on (...) We used to get perhaps 100 million to conduct calendar-based management every five years. But now we do not need to do this that often. So, when we get that money bag here, and only conduct maintenance based on analysis, there are margins that are amazing ...»

Our findings also suggested that this maintenance strategy is not feasible in all industries and markets. It has to be in markets that are willing to pay and where it is crucial to have such advanced data about the condition of the equipment. An informant in Epsilon for example stated:

“We might make the hose smart, especially in subsea mining. For a smart hose, there has to be willingness to pay a lot, such as for a Subsea riser. The world's toughest hose with sensors and instruments making the host costs the double. We could do that smartly. Since the subsea pump costs so much, the hose price is maybe not an issue and it matches the subsea context”

When maintenance of equipment is based on data about the condition of the equipment, ownership and sharing of data becomes an issue that need to be handled carefully and also provided some new opportunities. One informant from Beta stated:

“We need to describe how to share real-time data in the contract from the start. (...). [anonymised] is a platform that we use for making data accessible. We are early there. We are on track and the next step is to have rig data on the platform and try to get some value out of them and make them available (...). Today we collect a lot of data without having a user case (...)”

4.3 Virtual Reality

In the firms, virtual reality (VR) is both used and planned to be used in services regarding pre-sales services, R&D services, operational services and product support

services (such as training). An example from both R&D services and operational services was related to Gamma, and one informant explained:

“We want to use simulation tools to plan the operation and use it as a decision support. The fact of knowing and gain clarity about the critical phase of a big lift from a boat to the port for instance and manage to use simulations and help them make the decisions. We have made simulations of marine operations and corresponding measurements with sensors to see if we can simulate this. We can have it on the vessel and detect how this will evolve. They will use it as a decision tool and a training tool. A tool for all involved, including the captain. And we who sit on the simulation models look at how the waves will affect the operation. We can use this and manage to combine that type of service with products”

VR was mainly emphasized to plan operations and to support decision making on the use of different products. An informant described a typical context for such services.

“It's about planning and what's happening on land in relation to a heavy lift. A difficult lift, they can spend 2 years planning it. There is great potential for helping them with planning. There are extreme cases: Lifting in the borderland of what the equipment capacity can handle ... a lot of dynamics, due to sea and wind, and the equipment has its limitations and scratches when descending on the seabed and buoyancy due to the land and getting too loose, and The whole wire can snap and everything falls on the seabed and you lose the construction that costs millions. A gas module costs one billion Norwegian kroner. This involves a lot of expertise from many. And they lack a lot of information, which makes them take many assumptions, like how much flexibility is needed of our crown constructions, and there they make assumptions about which we can assist them and communicate via simulation models. This is about, for example, Subsea cranes that are on construction vessels and which will make installations on Subsea and maintain Subsea installations.”

4.4 Augmented Reality

Two of the firms also explained how they explored augmented reality (AR) for product support services and maintenance and life-cycle services through remote repair. The envisaged case is that whenever there is a problem, the person operating the machines will put on AR glasses and follow instructions from the firm about what to do. A manager from Beta explained:

“With augmented reality, as in remote repair, the rig crew calls us, and we go in digitally: We will tell the maintenance guy at the rig ‘you have to change that valve’, and all the documentation, drawings, how to put on the equipment and all the info comes up.... The business case is a reduced crew and a well-paid service, so the maintenance man only needs to be good at following instructions and using AR”

AR for servitization entail a business model where the companies are taking over part of the operations and the maintenance although at a distance. To be able to offer such services, the companies only need an internal digital twin.

“AR is low threshold, and low cost. With a digital twin in our training rooms, we can use this business model and use the digital twins internally to offer such services externally.”

4.5 Automation technology

We found that the studied firms used automation technology to provide operational services. One informant from Gamma stated:

“Today the operation of a crane is very dependent on the crane operator. We can use automation technology to make the operation more consistent. We talk about automation and assistance. An analogue is hatch parking - Automatic parking, some make it without trouble while others have problems. We can have assist functions that help the operator and make the performance less dependent on his/her skills (...). Another project we have started is to build a robot that can move vessels. It has resulted in a long-range robot and a prototype (...). We have sold this to [anonymised] (...)”

5 Concluding discussion

The analytical tools to identify the use of digital solutions together with the industrial service offerings are helpful to answer our first research question: “How does digitalization enable servitization?”. We identified several different services as described above. Most of the services are operational in Partanen et al’s (2017) categorization. Overall, the services we studied exhibit various levels of digitalization. We have categorized some of the identified services in terms of the three digitalization steps (Loebbecke & Picot, 2015) as explained in table 3.

Table 3 Examples of level of digitalization of the observed services

Step	Example of service	
0. Analog	Spare part sales	While spare parts are physical matter, their design and installation still require the effort of skilled engineers and technicians, typically on behalf of the service provider.
1. Digitization	Web-based technologies, IoT, Sensors	The web can be used to document a customer dialogue. Turning analog data into digitized in the studied context of IoT and sensors involves a human process of deciding which parameters and variables that are to be monitored and how they can be processed to yield results comparable to the human senses that are replaced. Also, eventually many decisions are still merely supported by the data that sensors provide.
2. Digitization	VR, AR, Automation	As in the previous step, technology is used to support decisions or tasks. This is most obvious in the use of AR and VR. Wherever automation is used it is still mainly used for performing limited operations and sub-tasks.
3. Digital transformation	Leasing services Performance-based contracts	These types of services already require a cultural and contractual changes in the concerned organizations as they alter their roles and responsibilities. This is, however not a result of the technology per se, but the organization uses the technology.

The second research question was, “How are the technologies that are used to develop new services enacted?”. To answer this, we follow the premises of practice theory and sociomateriality, re-interpreting the previously described technology used for services. This enables us to highlight features of embodiment.

We found five different groups of technology used services: Web based, Sensors and IoT, Automation/Robotics, Virtual reality and simulations and Augmented reality. These five different uses of technology expose how these are enacted. 1) The web based involve users to type on a keyboard for using a PC accessing the Internet or use their smart phone for accessing an app. 2) Sensors and IoT provide real time data for decision support, involving the user to thing in a different way. 3) For virtual reality and sensors, the technology enhances the user to become familiar with the equipment through training and embodiment. The technology enables the users to embody the skills of using the equipment, without actually using the equipment. For instance, to use a large crane and perform a difficult lift in rough sea and weather conditions, can be virtually trained through the simulator services. 4) The augmented reality services enhance the user to see exactly what an expert sees and without training can perform the same activities. For instance, a crew member on a rig can use AR equipment such as glasses and headphones and repair some equipment based on what is shown and told through the technology.

Abstract

Digitalisation is leading to massive change processes in organisations, which increasingly intensify the relevance of knowledge management for companies. Especially, knowledge creation and transfer are central processes for gaining and sustaining competitive advantage in a knowledge-intensive environment. Researchers identified that enablers (culture, structure, people and IT) are increasing the efficiency of these processes. Here, the people element is one of the most important factors. However, current empirical studies have focused on knowledge enablers on the organisational level. But there are no concepts for the operationalisation of knowledge enablers on individual level. The present study is addressed to fill this gap. The concept of T-shaped skills seems to be suitable for the operationalisation of the knowledge enablers. Therefore, we analysed 489 job advertisements of Scrum Masters by using a mixed-method approach (qualitative and quantitative content analysis as well as variance analysis) to shed light on the explicit T-Shaped skills. With regard to his role we assume that the Scrum Master covers and portrays the needed skills in knowledge-intensive environments. It can be stated that he fills up the key role on knowledge transfer and knowledge creation in companies. Thus, he can be seen as a knowledge enabler on

individual level. The results of the analysis were tested for group differences by using an ANOVA. There are no significant major effect for industry sectors and the company size. Thus, suggests that the T-shaped concept is static. As an implication for practitioners the present study could give an important indication for the search and selection for personalized T-shaped knowledge enablers. Further, the results can be used by companies for orientation, in particular in the development of personnel development concepts.

Keywords – Knowledge Enabler, T-shaped skills, Digitalisation, Scrum Master, Mixed Method

Paper type – Academic Research Paper

1 Introduction

In the period of “Post-Industrialisation” or “Knowledge Age”, the primary resource of organisations, especially for knowledge-intensive organisations, is moving away from classical tangible production factors towards intangible intellectual assets (Drucker, 1993). The competitive advantage of an organisation increasingly depends on being innovative and seeking complex solutions in order to adapt to a fast-changing environment. Against this background, knowledge creation and transfer are central processes for gaining and sustaining competitive advantage in a knowledge-intensive environment (knowledge is one of the core intangible assets).

Furthermore, recent developments in the corporate environment (e.g. internationalisation and digitalisation) reinforce the significance of knowledge management in organisations. In particular, digitalisation and automation are key drivers for increasing knowledge-intensive work and services (Hossain and Lassen, 2017). At the same time, progressive development of information technologies promises new possibilities to support critical knowledge processes in organisations and offers new ways for employees to transfer and create knowledge. For example, developments in artificial intelligence, virtual simulation- and virtual collaboration tools, opens up new ways and tools for networking, transferring and creating innovative knowledge among distributed individuals. However, despite these emerging opportunities, digitalisation comes with special challenges for knowledge management. That is, today’s knowledge workers have to deal with complex, dynamic and volatile working environments and with increasing amounts of knowledge resulting from digitalisation (Bennett and Lemoine, 2014).

A concept that provides guidance on how to promote effective knowledge management under these challenging conditions is the enabler approach. Following this approach certain organisational elements, particular culture, structure, people and IT (Lee and Choi, 2003), help to foster knowledge consistently through the organisation by stimulating knowledge creation and facilitating the sharing of knowledge.

Studies on the influences of knowledge enablers on effective knowledge management show, that human resources (the people element) are one of the most important factors for

enabling knowledge processes and creating knowledge (Andrawina et al., 2018; Lee and Choi, 2003).

However, people as enabling factors have rarely been considered yet. For example Lee and Choi (2003) provide a first contribution to conceptualise the people element as an enabling factor for knowledge management on an organisational level. With regards to the people element the authors use the concept of “T-shaped skills”, originally proposed by Leonard-Barton (1995). According to Lee and Choi (2003), T-shaped skills of employees are most often associated with core capability of knowledge management:

“People with T-shaped skills are extremely valuable for creating knowledge because they can integrate diverse knowledge assets. They have the ability both to combine theoretical and practical knowledge and to see how their branch of knowledge interacts with other branches. Therefore, they can expand their competence across several functional branch areas, and thus create new knowledge. T-shaped skills may enable individual specialists to have synergistic conversations with one another.” (Lee and Choi, 2003, p. 188).

Despite the encouraging conceptualisation of Lee and Choi (2003), a detailed analysis and operationalisation of T-shaped skills of individual knowledge enablers for actual working contexts are missing. The current paper contributes to close this research gap and analyses T-shaped skills of a knowledge enabler on an individual level. For this, we analysed required competencies, skills, attitudes, knowledge, experiences, education and qualification of knowledge-workers based on job advertisements of Scrum Masters. The position of the Scrum Master is responsible for ensuring the transfer and creation of knowledge in enterprises (Takpuie and Tanner, 2016). Thus, we assume that the Scrum Master can be seen as a knowledge enabler on individual level.

The key questions of the present study are:

- What are the T-shaped skills of Scrum Masters?
- Which industry and company size specifics exist?
- How to operationalise T-shaped skills on individual level?

To answer these research questions, 489 job advertisements were examined as a part of a mixed-method approach (qualitative and quantitative content analysis as well as ANOVA).

In the following, the theoretical background, consisting of the enabler approach, the T-shaped concept and the Scrum framework, will be described.

2 Theoretical Background

2.1 Enabler of Knowledge Management

Knowledge creation and knowledge transfer are central processes of creating competitive advantage in knowledge-intensive environment/digital working context. Based on several views of researchers, we define knowledge enablers as influencing factors and organizational elements that foster knowledge creation, knowledge sharing and knowledge protecting within organisations (Lee and Choi, 2003; Krogh et al., 2001).

Examples of frequently listed and examined enablers are culture, organizational structure, technology, people respective human resources (Alavi and Leidner, 2001; Gold et al., 2001; Lee and Choi, 2003; Pan and Scarborough, 1998).

Most of the current studies focus on organizational structures and processes as enabling factors (e. g. Burke and Litwin, 1992; Gold et al., 2001; Razi and Karim, 2010). In contrast, the importance of individuals has been examined rarely. However, human resources take an essential role in fostering critical knowledge processes in organizations since they build the central knowledge base (Razi and Karim, 2010). Andrawina et al. (2018) examined the influence of individual factors for enabling knowledge processes in organizations. They identified the individual factor as the most important indicator (3.27) for knowledge management in a company. Further, the individual factor is highlighted in the research model of Lee and Choi (2003). The authors state, that the people are a core/central element. Furthermore, they are the first to describe concrete features, properties and skills of individual knowledge enablers. They characterized the individual factor by T-shaped abilities. This can be attributed to a claim by Leonard-Barton (1995, p. 75): “The need for T-shaped skills surfaces anywhere problem solving is required across different deep functional knowledge bases or at the juncture of such deep knowledge with an application area. [...]. People possessing these skills are able to shape their knowledge to fit the problem at hand rather than insist that their problems appear in a particular, recognizable form. Given their wide experience in applying functional knowledge, they are capable of convergent, synergistic thinking.” In the following chapter T-shaped will be introduced further.

2.2 State of Research on T-shaped skills

T-shaped skills have already been studied for different professions (Oskam, 2009; Uhlenbrook and de Jong, 2012) and organisational units (Hansen, 2001; Hamdi et al., 2016). There are several definitions in the literature of what T-Shaped skills are, generally they refer to arrange individual abilities and their formation. Demirkan and Spohrer (2015) identified important elements of personal capabilities. According to them, T-shaped workers have deep knowledge in one area as well as a broad level of knowledge, communication skills and competences in many other areas. They also feel empathy and are critical thinkers. Demirkan and Spohrer (2015) have systematized this conglomeration. Boundary-crossing competencies are strategic thinking, people engagement, empathy, business functions, vertical industry expertise, and geographical experiences. These competencies are combined with deep knowledge in at least one discipline, business function, one system, vertical industry expertise, one culture or geographical experience (see Figure 1).

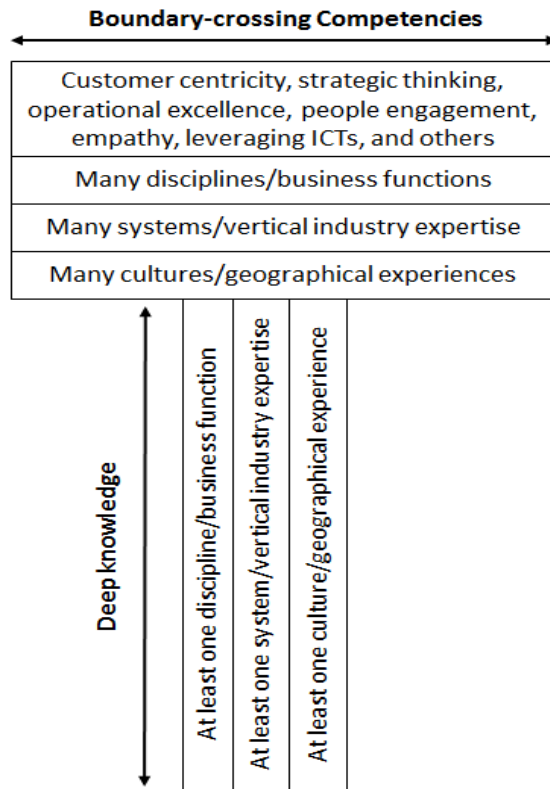

Figure 1: The T-shaped professional (Demirkan and Spohrer 2015, p. 13)

2.3 Scrum in an knowledge-intensive working environment

The focus on knowledge creation and transfer needs methods, which can increase the communication between team members and structure the process of efficient information distribution. For that agile methods are particularly suitable because they are geared towards the transfer of knowledge (Fowler and Highsmith, 2001; Boyatzis, 1998). In this context different methods are used in companies. One approach that focus on the transfer of knowledge is the Scrum framework (Boyatzis, 1998; Mirtalebi, 2017). The main principles of the Scrum method are (Lin et al., 2015):

- Mobilisation of the collective intelligence
- Ensuring efficiently teamwork with permanent feedback loops
- Mediator between relevant stakeholders
- Focus on knowledge transfer and knowledge creation in teams

Today Scrum is the most popular agile project management method (Cockburn and Highsmith, 2001; Takpuie and Tanner, 2016). Central for managing projects with this approach is a controller - called Scrum Master. According to the Scrum framework, the role of the Scrum Master is characterized as an organizer, a moderator and a process consultant for development teams (Karabulut and Ergun, 2018; Moe et al., 2010; Pfeffer

and Berchez, 2017). He “encourage[s] the team, help[s] with problems and remove[s] obstacles” (Davidson and Klemmer, 2016, p. 38). He ensures the transfer and creation of knowledge in enterprises (Takpuie and Tanner, 2016). Therefore he can be seen as an knowledge enabler on individual level. With regard to his role we used job advertisements for Scrum Masters to shed light on the explicit skills, which are requested by companies. We assume, that the T-shaped concept can be found in these job offers.

3 Methodology

We followed a mixed-method approach with a qualitative and quantitative content analysis as well as a variance analysis. The data collection (selection of job offers) will be described in detail below. On the one hand, the use of job offers is due to the fact that they are reflecting the current and future needs of companies. On the other hand, we used them because they already explicitly search for T-shaped persons. Therefore, as described above, we assume that the Scrum Master is a personalized T-shaped knowledge enabler in the digital work context.

3.1 Data collection and Sample

To achieve our research aim we analysed job postings for Scrum positions (keywords: “scrum master” or “product owner”) on a job portal, which is most used in Germany and awarded for its amount of offers, usability and search quality. The selection date was March 12th 2019. We found 556 job offers. After removing duplicates, 489 cases remained, which we included in the analysis. To cluster the industry we used the statistical classification of economic activities in the European Community (Regulation (EC) No 1893/2006). The following distribution resulted for our sample (see Figure 2 and Figure 3).

Figure 2: Distribution of companies by industries

47.4% of the posted job offers were advertised by IT companies. By comparison, these companies account for 3.8% of the total share in Germany. Manufacturing (14.9% vs. 6.7%) and financial and insurance activities (6.5% vs. 2.0%) are also over-represented in the sample. Electricity, gas, steam and air conditioning supply (3.1% vs. 2.1%), transportation and storage (3.1% vs. 3.3%) as well as administrative and support service activities (7.4% vs. 6.3%) are equally distributed. Underrepresented are accommodation and food service activities (0.2% vs. 7.1%), real estate activities (0.2% vs. 4.9%) and arts, entertainment and recreation (0.2% vs. 3.3%). The sample mainly includes companies with more than 250 employees (~88%). In Germany, only 0.4% of firms belong to this category.

Figure 3: Distribution of companies by number of employees

3.2 Methods

We evaluated our data by using an inductive qualitative and quantitative content analysis to bring together all required competencies, skills, attitudes, knowledge, experiences, education and qualification named in the job offers. Afterwards, the results of the analysis were tested for group differences by using an ANOVA. We proceeded as follows (see Table 1):

Table 1: Steps of analysis

Step	Methods	Result
(1) Generating the dataset	Collecting data from job portal	489 cases
(2) Data analysis	Inductive, qualitative content analysis and frequency analysis	289 codes with 6.095 codings
(3) Moderated workshop: (3a) Discussion and reduction of the results	Comparison of the analysis results	127 codes with 5.420 codings

(3b) Definition of the main categories	Modeling of main categories	6 main categories
(4) Modeling the T-shaped concept	Integration of the results	see Figure 4
(5) Test of group differences	Variance analysis	see p. 11

For the qualitative content analysis and frequency analysis we used MAXQDA. To judge the criteria for the quality of our research design we follow the suggestions of Neuendorf (2016) and Krippendorff (2012). First, we collected the dataset as described above. Afterwards, we subjected the data to qualitative content analysis and generate inductive codes. At that three researchers analyzed the data in parallel. The goal was to ensure the intercoder reliability of the results (Neuendorf, 2016, pp. 122). As an outcome, we received 289 codes with 6.095 codings (Step 2). In a moderated workshop we summarized the code categories and reduced the codes from 289 to 127. Codes that had less than 0.5% share of the total codings (less than 20 codings) were excluded from further analysis. As a result, we received a record of 127 codes with a total of 5.420 codings (Step 3a). The classification into the various categories was based on the standard typology of competences developed by Heyse and Erpenbeck (Heyse and Erpenbeck, 2009; Le Deist and Winterton, 2005). We defined six main categories: Competencies, Skills, Attitudes, Knowledge, Experiences, Education and Qualification (Step 3b). Subsequently, we transferred the results to the T-shaped concept (Step 4) and tested them to group differences (Step 5). Thus, we performed an analysis of variance. As the dependent variable, the codes mentioned were included in the analysis as a percentage of the total number of codes per case. As independent variables, we included first the size - measured by the number of employees- and second the industry of the company. The size of the company was described using the classes listed above (see Figure 3). The results are presented in Figure 4. The absolute and relative distribution of the codes and codings are shown more detailed in Appendix.

4 Results

According to the T-shaped concept the six identified main categories can be subdivided into boundary-crossing competencies and deep knowledge (see Figure 4). At the horizontal leg of the T, 59.7% of the main categories can be located. More than one third of the boundary-crossing competencies of the T-shaped Scrum Master consists of competencies (35.7%): specialist and methodical, social communicative, activity and action as well as personal competencies. 13.6% relates to knowledge, in particular language (German and English), project management and testified Scrum knowledge. 8.1% refer to attitudes (motivation and passion, flexibility, self-initiative, agile values, digital affinity, creative power and interest) and only 2.3% to skills (ability to motivate, empathy, creativity). At the vertical leg of the T, 40.3% of the main categories can be

classified. This deep knowledge consists of a fifth of experiences (19.8%) in agile methods, project management, Scrum, software development, agile software development, project leader, requirements management, product management, leadership, digitalisation, several industries. 14.2% can be attributed to the category education and qualification. The focus here is on study graduation and apprenticeship. 6.3% include knowledge about software / IT, agile methods, Scrum, economics and industry specifics.

Figure 4: Classification of the investigated main categories in T-shaped concept

In order to evaluate whether the main categories differ significantly between industries and company size, we conducted one-way analysis of variance. The fixed factor in the ANOVA was a six-stage variable for industry, including the following sectors: manufacturing, wholesale and retail trade; repair of motor vehicles and motorcycles, information and communication, financial and insurance activities, professional, scientific and technical activities, administrative and support service activities. The other sectors were excluded since they had too few cases (less than 20). Their inclusion would have led to systematic distortions, in particular, the criterion of variance homogeneity would have been violated. Results showed no significant major

effect for the industry sector and company size over all categories, with the exception of social competencies showing significant major effect for industries with $F(5, 422) = 2,577$ ($p = 0.026$); $r^2 = 0,018$. In sum, these results indicate that the required T-shaped skills do not differ across industries or company sizes.

5 Conclusions

What are the T-shaped skills of Scrum Masters?

We intended to create a competence portfolio for employees in knowledge-intensive work environments (knowledge enablers) in digitally driven working contexts. In doing so, we found typical competencies, skills, attitudes, knowledge, experiences, education and qualification. In the past, a strict separation between generalists and specialists has been enforced (see Cesare and Thornton, 1993; Becker and Murphy, 1992). Our findings show a combination of boundary-crossing competencies and deep knowledge of T-shaped skills of a Scrum Master as a knowledge enabler, which consists of ~60% of boundary-crossing competencies and ~40% of deep knowledge. Thus, the T-shaped concept can be found in the data. This underlines the change in requirements in knowledge-intensive and digital working environments.

The horizontal level consists of the four main categories competencies, attitudes, knowledge and skills. More than a third of this level are specialist and methodical competencies (9.5%), social communicative competencies (18.1%), activity and action competencies (2.0%) and personal competencies (6.1%). From the job offers it is noticeable that companies look for Scrum Masters with analytical and organizational skills. Next to guaranteeing an efficient teamwork with permanent feedback loops is another key role the mediation between relevant stakeholders. Thus, communication and team skills as well as interface management and problem solving skills are in the job offers in demand. The competence to act is demanded above all solution orientation. The personal competencies of the Scrum Masters are above all responsibility and independence. According to the function of the knowledge enabler on an individual level, these categories enable knowledge generation and exchange. The same results are shown in the required skills, attitudes and knowledge of the generalist: the ability to motivate, to feel empathy and to work flexibly can be found again. These competencies are important to ensure, that the Scrum Master is able to mobilise the collective intelligence. The basis for this are the required language skills (German and English) as well as training in the field of (agile) project management.

The vertical level examines the required expert or deep knowledge. In the job advertisements this is reflected in the three categories knowledge, experience, education and qualification. The sought experience (19.8% of total) consists mainly of scrum and industry experience. An important role play project management, agile methods and (agile) software development. The required education and qualification (14.2%) entails academic and professional degrees. Mainly computer science, economics and (industrial) engineering was sought. The third category consists of the required knowledge of the

Scrum Master. Especially knowledge about software and agile methods is important for the enterprises.

To summarize, the profile of Scrum Master equals the T-shaped concept. It can be stated that he fills up the key role on knowledge transfer and knowledge creation in companies. Thus, he can be seen as a knowledge enabler on individual level.

Which industry and company size specifics exist?

With regard to our second research question we performed an analysis of variance to test group differences between the industry sectors and the company size. The results show no significant major effect for both, industry sectors and the company size, over all variables except the social competency variable. There is a significant major effect for the industries financial and insurance activities, wholesale and retail trade and administrative and support service activities. In these areas social communicative skills are more important than in the others. This can be explained by the customer-centric focus of these industries. Further, the results suggest that a similar combination of T-shaped skills is required in all industries.

A first indication for the occurrence of T-shaped skills in German companies is the distribution of companies by size and industry. With regard to the enterprise size we find in our sample especially enterprises with more than 250 employees. In comparison: In Germany 98 % of enterprises have less than 50 employees (see Figure 3).

Also interesting is that mainly companies from the information and communication sector are seeking for Scrum Masters. This can be a first indication that T-shaped people are especially sought in industries with a high need for digitalisation (see Figure 2).

How to operationalise T-shaped skills on individual level?

Based on our results, it is possible to measure T-shaped skills on a dichotomous scale. This is a first step in the development of an operationalisation of T-shaped skills on an individual level. The results therefore could give companies an important indication for the search and selection for personalized T-shaped knowledge enablers. Further, they can be used by companies for orientation, in particular in the development of personnel development concepts. This is our contribution to the existing methods of the operationalisation of T-shaped skills that are currently limited to the organizational level (see Lee and Choi, 2003).

The generalizability of this study is limited. On the one hand, there is a pre-selection of companies due to the sample, for example due to the use of the chosen recruiting portal. To keep this bias to a minimal level, we used the platform which is used most in Germany and awarded for its amount of offers, usability and search quality. Further, our evaluation is based on the inductive content analysis. To increase the reliability of the data, we used the methods suggested by Neuendorf (2016), as the evaluation was conducted by three researchers independently.

This paper is a first step towards developing a scale for measuring T-shaped skills at the individual level. This is necessary to prove the importance of T-shaped enablers in companies for knowledge management. Future research should focus on a review and

further development of a scale to measure T-shaped skills at the individual level. Our study suggests that this is a static concept (based on findings with regards to industry and company size). It could be further researched whether the concept is sustainable under other influencing variables. Research on this should be given greater attention in this regard in the future.

Abstract

The process of digitalization has enhanced opportunities for exchanging economical and reliable information, consequently it has become a priority in many fields. Particularly in cultural sector digitalization can be considered a key challenge in the process of modernizing. The European Commission has studied the best ways to preserve, enrich and make available the cultural heritage for the benefit of present and future generations. On this basis was created an European platform for the management of cultural heritage called Europeana. This paper aims to analyse and assess the impact of this cultural platform through the study of digitalization process. The results show that Europeana is a tool able to create new knowledge and consolidate value chains. Moreover, from the economic perspective Europeana is able to generate welfare effects of digital cultural heritage, among them there are usage value on the one hand and indirect effects economic and social on the other hand.

Keywords – Digitalization, cultural heritage, impact assessment, Europeana

Paper type – Academic Research Paper

1 Introduction

Europe needs a new action plan in order to make the best use of information and communication technologies (ICT), this plan could contribute to accelerate economic recovery and lay the foundations for a sustainable digital future. The new action plan suggests to eliminate current obstacles to maximize the potential of ICT, making long-term investments to minimize future problems (Digital Agenda for Europe 2020).

It is widely agreed that digital technology play an important role for the innovation of cultural sector and valorization of cultural heritage. Digitalization and publication of collections online can potentially allow access to content across the globe, and as such, liberate this huge knowledge (Borowiecki and Navarrete, 2017). In this sense, digitalization is a means both for safeguarding cultural heritage for future generations and for providing access to cultural values (Marcum, 2007). Digitalization applied to cultural heritage transposes the essence of cultural objects presented in physical format into digital world and make this essence available to visitors from any place and any time in a effectively and efficiently way.

In order to reach the aim of present work among several definitions of digitalization we refer the digitalization as the process whereby by scanning or some other method of reproduction an electronic copy of a specific analogue information carrier is created (Borissova, 2018). Following these premises, the present paper aims to provide a general understanding of the digitalization phenomenon/process and its dynamics in order to better analyse and assess the impact of Europeana, the European platform for the management of cultural heritage.

2 Digitalization in Europe

The European Commission General Directorate for communications networks, content & technology has conducted extensive action to supplement Member States' cultural policy in digitalization area and online access to cultural material and digital preservation.

Digitalization turns Europe's cultural resources into an important pillar of the digital economy. Indeed, digital technologies offered huge opportunities for improving public access to different forms of cultural assets and its reuse (European Commission, 2013). Thanks to the support provided by national and international programs, in the past years, almost everywhere in Europe big efforts were put in place by public institutions and private bodies for converting the "physical cultural heritage" into "digital".

Despite the lack of information about the data on digitalization in Europe and the weak of coordination between existing ones the Report ENUMERATE Core Survey 4 provided an overall perspective on current state. This report is the fifth study of a series started in 2008 and is the second organized under the umbrella of Europeana. The participating institutions are n°983 came from n°28 countries, distinguished in four types: museum 37%, library 27%, archive/record office 21% and other type 15%. The survey was composed by five dimensions: the state of digitalization activity, the dimension and characteristics of collections, digital access, preservation strategy and expenditure (Report on ENUMERATE Core Survey 4, 2017). Highlights of the report's findings are summarized in the table 1.

Table 1: five dimensions of survey

Digital Collections - 82% of institutions have a digital collection or are engaged in digitalization activities - 42% of the institutions have digital strategy
Digitalization Activity - 59% of the institutions have born digital items - 58% of the heritage collections has been catalogued in a collection - 22% of the heritage collections has been digitally reproduced - 54% still needs to be reproduced
Digital Access - Overall institutions declare that they have 51% of their descriptive metadata online for general use - Academic research is the most important reason to provide digital access to the collection - 51% of the digital objects available on line are consulted within the institutional website, which is still the most popular channel for the institutions to provide access to their digital collections; - Channels for which a substantial growth is expected over the next two years are Social media platforms (+25%); Wikipedia (+14%); (other) aggregators (+11%) and Europeana (+5%);
Digitalization Activity - 59% of the institutions have born digital items - 58% of the heritage collections has been catalogued in a collection - 22% of the heritage collections has been digitally reproduced - 54% still needs to be reproduced
Participation - 49% of all institutions measure the use of digital collections - 90% of the institutions that do measure the use, use web statistics
Digital preservation - 27% of the institutions have a written digital preservation strategy - 45% of the institutions do not yet have a solution for long term preservation based on international standards for digital preservation

Source: our elaboration on results of “Report ENUMERATE Core Survey 4”

Although data coming from Enumerate Core Survey 4, they are useful to provide us a clearer picture of the contest but we have to consider that the sample is not representative and suffers of self-selection bias, so these results must be used under the right consideration.

3 Theoretical Framework

Digitalization of cultural content is a time-consuming process whose ultimate goal is to build a participatory social memory by connecting past, present, and future in terms of cultural heritage. Within digital networks, information is obviously physically present some-where, on a specific support, but it is also virtually present at each point of the network where it is requested (Lévy, 2002). This process has important consequence on cultural field, in particularly on production, distribution and consumption of cultural goods.

Some studies analyse the general impact of digitalization on cultural policy (Flew and Swift 2013) and on museums and libraries specifically (Navarrete2013a, b; Paolini et al.2013; Salau 2013). But this flourishing literature is until now, with a few exceptions (Borowiecki and Navarrete2015), rarely used to investigate the implications of digitalization for archives that retain data and preserve cultural heritage.

According to Daniel et al (2012) cultural heritage is an expression of the legacy of physical artefacts and intangible attributes of society that are inherited from past generations, maintained in the present and bestowed for the benefit of future generations (Daniel et al., 2012). As Rizzo (2016) suggests new technologies produce a substantial change of the distribution asset model from controlled access (in a real market who does not pay the ticket price is excluded) to a network economy model (the only cost is the reduction of time for other activities). Moreover, a digital consumption could generate a learning effect, thus encouraging future (paid for) consumption so that the two consumption are not substitutes. In fact, in a recent work conducted at Louvre Museum by Evrad and Krebs (2017) is showed how the two experiences of the real and virtual visit are complementary from the point of view of interdependence and/or additional dimension of the cultural experience, but not substitutable because there is no equivalence between the digital experience and the real visit. The importance of the topic is also emphasized by Digital Agenda presented by the European Commission for the Europe 2020 strategy which sets objectives for the growth of the EU by 2020 in which proposes to better exploit the potential of information and communication technologies in order to foster innovation, economic growth and progress. One of the seven pillars proposed in fact is related to “ICT-enabled benefits for EU society” with the aim to exploit the potential offered by the use of ICTs in the area of digitalization of content through dedicated channels.

4 Research methodology

This study is based on exploratory and qualitative analysis research method developed along two stages.

In the first stage, on the desk, we used the following databases: Scopus, Elsevier, Science Direct and Springer in order to create and subsequently re-organized the findings as theoretical framework. We considered only articles which contained keywords as: digitalization, cultural heritage and impact assessment published on empirical journal, book reviews and report as for example those provided by European Commission and Strategy 2020. Finally, n°80 articles were taken into account.

The second stage, on the job, has been carried out through case study method (Yin 2002) this is particularly suitable to investigate the complex and dynamic nature of the cultural sector. Research activity has been carried out between October 2018 and March 2019. Data has been collected in three phases. The first one concerned on a detail search and analysis of information, institutional documents and publication available through the web. The second phase is based on no-participant observation of the main social channels that Europeana used as interactive tools, with the aim to better understanding how digital cultural portal communicate with the principle social media. Finally, the third phase has been focused on the data analysis in order to define the possible economic impact and value chains deriving from the platform.

4.1 The case study: Europeana's experience

The analysis begins with the study of cultural sector which look to digitalization not only as promotional tools but also and mainly as dynamic and relational platforms for the development of a proximity strategy to active cultural stakeholders (not only employee and consumers but also public/private decision-makers). This relational approach, based on interactions and cooperation between digital portal and its wide community, features the Europeana case study strongly.

Europeana is Europe's largest cultural heritage portal launched in November 2008 is co-funded by the European Commission as the most cultural and artistic institutions publicly-funded for operating as a non-profit organization.

Bakhshi and Throsby (2012) propose a generalised model of behaviour of a non-profit cultural institution composed by five objectives, two of these: objectives relating to access (making their output available for many and wide range of consumers as possible) and educational services (often through specific programmes to engage and educate young people or to enhance the learning experience of their consumers more generally) are part of the wider mission of Europeana. The simplest way to give access to the data is by opening up a digital portal; in fact Europeana project uses the same method of many institutions to make cultural data available but on a European level. On the homepage there is a research box that allows access to all the contents of Europeana (figure n°1).

Source: "Guide to using Europeana in Education"

Figure n°1: Europeana Homepage

It is possible to start the research by entering a keyword (figure n°2):

Source: "Guide to using Europeana in Education"

Figure n°2: box entering for keywords in Europeana

It is noted that in the box can appear many results, the user in fact can choose between list view or grid view and change the number of visible objects for every page.

To facilitate the search on the left side of the screen are present filters to set in order to search objectives for related contents (figures n°3):

Table n°2: Meaning search terms

Collections	As of March 2017, Art, Fashion, Music.
Media	Images, Texts, Sounds, Video, 3D Tip: by selecting ‘only items with links to media’ you get content that can be downloaded directly from Europeana.
Can I use it?	Search by license type.
Providing country	Content from institutions in specific countries.
Language	In case you search for content from a specific provider.
Institution	In case you search for content from a specific provider.

Source: our elaboration of “Guide to using Europeana in Education”

Digital collections can have multiple uses compared to those related with the portal. They can be connected, for example, with other collections, geographical points, or be accessible through mobile phones with a GPS tracker. Application Programming Interfaces (APIs) allow developers to build new tools able to ensure data access for the creation of new products and services in the light of innovation (Dietrich and Pekel, 2012). Currently Europeana platform provides access to over 50 million objects from European libraries, museums, archives, galleries and audio-visual collections. More than 3,500 cultural institutions contribute sharing their cultural content with Europeana. They range from international museum to regional archives or other smaller realities from every country member of the European Union. Among the most important institutions can be mentioned for example the Rijksmuseum in Amsterdam, the Louvre in Paris and the international libraries as British Library in London. The digital objects and collections that users can find within Europeana are not saved on a central computer, but remain available for cultural institution that hosted them on their networks. Europeana collects contextual information – or metadata – about the items, including a small picture. Users search this contextual information. Once they find what they are looking for, if they want obtained the access to full content of the item, they can click on the original site that holds

the content. It is important underline that Europeana accepts metadata about digital objects, it does not make any decisions about digitalisation. The decision about which objects are digitalized is the responsibility of organisation that holds the material. For this reason the process of digitalization by cultural institutions appears to be preeminent and useful.

4.2 Europeana vs social media

Social networks represent a significant resource available for the wider community. In accordance with the specific rules of each different platform, users can share information, opinions, knowledge and interests, but generally they can make the uses that they prefer without particular limitations. Specifically the purpose for which Europeana uses social networks is to increase access to digitalized cultural heritage and make it easily shareable. On this basis, the second phase of the present work has the aim to better understanding how Europeana communicates with the principles social media that are sponsors on its official web site: facebook, pinterest and twitter¹. The platform uses different tools to communicate their activities, projects, news and etc. but social pages have the great benefit to be more direct and easily usable allowing maximum dissemination of information, goals, mission and vision of Institution. From the analysis of these channels, realized through a non-participant observation, the following data presented in the table n.3 are emerged.

Table n°3: Official social media used by Europeana

Facebook
The Europeana Facebook page includes links for the official platform and others general information as telephone number and address. The page offers the same features as the pages of any individual, thereby, only the page's manager can post and share all types of content on its wall. The users can comment and post within the comment also photo, videos and link. Posts vary from the demonstration of appreciation through short comments or emoticons, additions of short personal experiences. Actually, the page has more than 109.061 likes, 112.101 total follower, 282 reviews, score 4,7 out of 5, 47 events advertised more than 2000 photos posted, 77 videos posted.
Pinterest
The Europeana profile includes links for the official platform and brief explanation of the content. The platform allows to create thematic virtual blackboards on numerous topics. Through Pinterest is possible to explore all the favourite categories and put the pin (that is, virtually pin) all images can be saved and categorized under a virtual theme board, called notice-board. The Europeana pinteres page have 9884 pin, 15032 followers. In the bulletin board the pins are proposed in temporal order and they are generally chosen on the basis of a specific theme or historical period.
Twitter
The Europeana twitter account includes links for the official platform and others general information. Among them it is interesting to note that Europeana is not located in a specific place in fact the location given on account is "Europe". Other general information refers to the financing source of the platform. Actually, the account has more than 35.000 follower, and more than 17.000 tweet. Moreover, in the account are present about 3.467 photos, of cultural images and public events related to cultural policies. Instead tweets refer strategic and cultural information and events but also it provides content exchange.

Source: our elaboration

¹ Although Eureopena has other profiles on other social networks, in this work are taken into account only those it advertises on the official web site

When looking at Europeana's social media analysis it is possible to observe that currently social media represents a small minority of its traffic but the statistics show that end-users that arrive at Europeana via social media *are more engaged* and more likely to share and use the content, coherently with the major *mission of Europeana that is "transform the world with culture and build and make Europe's rich heritage easier for people to use, whether for work, for learning or just for fun"*.

4.3 Impact assessment

The third and last stage of this research closes with the data analysis in order to define the possible economic and social impact generated by Europeana. Impact assessment is a very interesting but complex area of research especially in cultural field. The cultural sector generates a multiplicity of benefits (and therefore implies many costs); for this reason measuring them appear a very hard task. The problem is being able to build a hierarchy between the different benefits, which are divided in direct and indirect. The direct benefits are related to issue as for example employment or technology innovation, while indirect benefit also involve the immaterial sphere as the aesthetics, symbolism, spirituality (Trimarchi, 2004). In 2006 still Throsby proposes a possible evaluation strategy based on the willingness to pay of the people that will be greater for a cultural object that they considered particularly deserving, but he emphasizes that not all social implications can be measured monetarily. Also, Matarasso (1997) tries to shed light on the point through his famous study "Use or Ornament?" in which divided the social impact of participation in the arts into six different themes¹, relating to people as individuals or community change. This theoretical framework can be used as evaluation frameworks. Europeana is financed through a project of the European Union and as almost all projects funded by the public sector requires an evaluation scheme, as far as possible, closer to the classic economic paradigms. In order to continue to receive funding also for the years 2015-2020 Europeana in 2014 decide to evaluate the social-economic value of its action through a cost benefit analysis carried out by a research institute² of the Faculty of Economics at the University of Amsterdam. Among the results it is useful preliminary analyse the identification of users and the possible benefits that they receive by using Europeana. The results are presented in the table n.4

Table n°4: benefits by using Europeana

User Group	Benefits
Institution	Shared infrastructure leading to cost savings for stand-alone use and co-operation
General Public	Welfare/utility of visiting website or visiting virtual and offline exhibitions. Both directly via Europeana and via institutions through redirect or as a result of using Europeana inputs.

¹ Personal development, Social cohesion, Community empowerment and self-determination, Local image and identity, Imagination and vision, Health and well-being

²SEO Economic Research. Refer to <http://www.seo.nl/en/home/>

Tourism	Better access to heritage information improves position of EU for tourism
Creative industries	Database with metadata, making content accessible throughout institutions
Education and Research	Access to content for digital teaching material or cost saving on travel expenses and improvement of productivity

Source: our elaboration of “The value of Europeana”

The users group range from institution to community in a broad sense. In fact, the institution categories include: galleries, libraries, archives and museums, but also educational institutions. Instead the community is represented by general public, people inside and outside Europe who are interested in arts, culture and heritage, tourists and researchers. Finally, there is a distinct category that is Creative industries composed by institution and people, this category in fact range from publishers who make books on arts, culture, heritage or traveling guides, journalists looking for historic information, artists and designers. Regarding the benefits it is possible to distinguish two macro-categories of users, however connected among them and that fertilize each other. The first uses Europeana as any digital platform without further creation of knowledge and value (institution and tourist); the second reuses the contents to produce knowledge, value and additional services (general public, creative industries, educational institutions and researchers). Regarding the effects it is possible to make an assessment in monetary (economic) and non-monetary terms on the value of Europeana. From the first point of view the most significant benefits that the cultural platform produces are cost savings for institution and tourism. Obviously, these results referred to indirect effect that can be supposed connected with Europeana, for example the contents that can be used in order to create tools for tourism purposes. Then the economic value in generally can be associated with tourist expenditures (a better visibility of European cultural heritage which can act as a tourist attractor for international tourism) and cost-saving by institution. Regarding the last point the analysis is referred to smaller institutions, who have difficult to develop adequate digital service platforms from themselves, and helps institutions in the development of digital services which enables them to integrate their digital collections. Instead non-monetary effects are referred to: usage value, option value, existence value and social value.

Table n°5: non-monetary effect

Usage value	Option value	Existence value	Social value
Consumer or producer surplus derive from using digital cultural heritage	Option to make use of material and offered service	Contribution derived from existence of Europeana in terms of contribute to person's pride and identity	Positive effect deriving from consuming arts, culture and heritage on education, quality of life and health

Source: our elaboration by “The value of Europeana”

5 Conclusion

Europeana creates a service platform for digital cultural heritage and content from libraries, archives, galleries and museums generating spill-over effects on economic and social aspect but also in the creation process of knowledge and value chain. Based on these results it is possible to draw several conclusions about the value of Europeana. The digital platform guarantees the widest fruition of the contents and in the same time their reuse in different fields. They range from tourism to education, marketing option or simply private enjoyment. These processes act like multiplier of creativity in which the innovation deriving from digitalization promotes shared knowledge.

In the next future, in which the physical and digital world tend to merge more, Europeana ensures the preservation of the cultural collective memory through the creation of material resistant in the future. For institutions involved in the sharing process of contents with Europeana the benefits derive from an improvement of the value of their materials and this confer to them a different position in terms of visibility in the society. Through the use of social media, Europeana contributes to the exchange cultural content in a virtual society. This expansion makes the public generally interested in art, culture and heritage wider and diversified for age, social background, interests and education. Finally, from an economic perspective Europeana contributes directly to the correction of some typical market failures. First of all, it reduces transaction costs related to licensing content to third parties or creates positive external effects for copyright holders if it leads to additional licensing. Second Europeana shows that cultural products can survive to market power, without commercial purposes and even reduce costs related to finding heritage and cultural information. Also, without Europeana the fragmentation of databases used by different institutions lead to development costs and underinvest in enhancing and maintaining digital resources, its presence instead balances this underinvestment. Finally, Europeana coordinates standardization actions for digital infrastructure reducing possible operations of adaptations to standards of countries outside the Europe. The results must be considered as preliminary; further research is required to achieve deeper insights and better understanding the process of digitalization of cultural heritage. The present research in fact is to be considered as a base for insights that go in the direction of survey with privileged observers of the phenomenon and comparison with other similar platforms to discover limits and advantages.

Abstract

Using the dynamic capabilities and absorptive capacity as theoretical lenses, this paper investigates the capabilities required to exploit digital technologies in products and/or in processes. We propose that the capabilities to acquire knowledge from external sources, internal sources and manufacturing operations drive the assimilation and transformation capabilities through the formulation of a digital manufacturing strategy, which in turn determine the capability to exploit digital technologies in products and/or in processes.

This paper has adopted a quantitative survey. The respondents are from a sample of innovative SMEs of the Piedmont region, a high innovative region with a historical industrial tradition that represent a fruitful context to investigate how SMEs approach Industry 4.0.

Employing the factor analysis and structural equation modelling we found that: (1) the use of multiple external knowledge sources supports SMEs both in the introduction of product and process innovation using both operational and informational technologies; (2) the use of multiple internal knowledge sources support SMEs in the introduction of process innovation using information technologies; (3) multiple manufacturing capabilities are positively related with the introduction of digital product innovation strategies.

The sample of SMEs is limited to the Piedmont region (North Italy) which limits the generalizability to other contexts. Future research should enlarge this study in other empirical settings.

Keywords – Industry 4.0; SMEs; capabilities

Paper type – Academic Research Paper

1 Introduction

The concept of Industry 4.0 has been conceptualized as the fourth industrial revolution that refers to how a bundle of partly related digital technologies will bring major disruptions to manufacturing industries enabling major business improvements in productivity and shaping current business models (Kagermann et al., 2013).

Indeed, the digital transformation ignited by Industry 4.0 pose significant challenges for established firms (Warner and Wäger, 2018) and in particular for manufacturing SMEs given their limited financial and managerial resources, low digitalization level (Müller et al., 2018a) and low attractiveness for IT talents. Still, there is little empirical research that investigates at a company level how to deal with these challenges or has given advices on how to develop the capabilities needed to adopt Industry 4.0 (Schneider, 2018). Current studies are limited in suggesting the skills that may be required (for instance in data analytics, cyber security etc.), but fail to investigate how to develop the capabilities at a strategic level. This study aims to bridge this gap by looking at the required capabilities to master the digital manufacturing technologies. Using the dynamic capabilities and absorptive capacity as theoretical lenses, we propose that the capabilities to *acquire* knowledge from external sources, internal sources and manufacturing operations drive the *assimilation* and *transformation* of these knowledge sources through the formulation of a digital manufacturing strategy, which in turn determine the capability to *exploit* digital technologies in products and/or in processes.

2 Theoretical background

2.1 Industry 4.0

Industry 4.0 is a widely accepted term originated in Germany in 2011 to refer to the Fourth Industrial Revolution, but still lacks a generally accepted definition (Schneider, 2018). We lack a conceptualization of what actually constitutes Industry 4.0 (Schneider, 2018), despite some key design principles and technological trends are proposed. (Brettel, et al., 2014, Ghobakhloo, 2018, Hermann, et al., 2016, Kagermann, et al., 2013, Lasi, et al., 2014). Literature converges on cyber physical systems (CPS) as the main technological drivers of this industrial revolution (Li, et al., 2018, Liao, et al., 2017, Schneider, 2018). CPS are integrations of computations and physical processes with embedded computers and networks that monitor and control physical processes, usually with feedback loops where physical processes affect computations and vice versa (Wang, et al., 2015). Frequently CPS communicate over the Internet of Things, enabling further amount of Big Data related to physical systems available for analysis. Thus, technologies

such as Internet of Things, Big Data and analytics, cloud manufacturing and cybersecurity belong to the CPS domain. In addition to CPS, scholars and practitioners include in Industry 4.0 other production technologies as Additive Manufacturing, Virtual and Augment Reality, Robotics and other advanced manufacturing solution (e.g. collaborative robots, drones etc.). In line with that, in 2016, the Italian Ministry of Economic Development has delimited the scope of Industry 4.0 to nine technologies (i.e. Industrial Internet of Things, cloud computing, cybersecurity, Big Data and analytics, simulation, horizontal and vertical integration, additive manufacturing, advanced manufacturing solutions, augmented and virtual reality) and launched an industrial policy for Industry 4.0 to support firms in exploiting the opportunities of this industrial revolution. Given that firms are familiar with this national plan and following other studies on Industry 4.0 (Agostini and Filippini, 2019, Tortorella and Fettermann, 2017), we operationalize Industry 4.0 with this broad bundle of digital technologies of Industry 4.0, ranging from CPS domain to operational technologies.

2.2 SMEs and Industry 4.0

SMEs represent the backbone of many economies. In particular, in the European Union 99% of the companies are SMEs, hire between 50 and 70% of the full time equivalent of people employed and they produce over 50 % of the gross value added (Müller, et al., 2018). Therefore, SMEs require research that help them in dealing with this new industrial revolution. The academic research should not treat SMEs as small scales of their large counterparts and therefore using the same theoretical approaches in the context of Industry 4.0. Rather, it should study SMEs as a single unit of analysis considering the key challenges of these firms:

1. *low digitalization levels*: the third industrial revolution has been mostly incomplete in SMEs due to organizational and structural reasons (Buonanno, et al., 2005)
2. *limited financial resources* (Lubatkin, et al., 2006) that limit their capacity to experiment with Industry 4.0
3. *limited managerial resources* with not formalized managerial practices and centralized decision making (Cagliano, et al., 2001)

Due to these challenges, SMEs risk to be drive out of the market by more advanced competitors (Müller et al. 2018), their products becoming commoditized, or they may be relegated to the role of OEM supplier, with system integrators or who manage the data platform in control (Porter and Heppelmann, 2014). Yet, a study already acknowledges that “*the smaller SMEs are, the higher the risk that they will become victims instead of beneficiaries of this revolution*” (Sommer et al. 2015; pp 1).

Therefore, the necessity to build the required capabilities to exploit digital technologies in products and/or in processes is even higher for SMEs. Literature suggests the necessity to provide an internal integration of competencies, centralization of (already available) expertise (Agarwal and Brem, 2015) as well as strategic partnerships with other firms, industry associations and trade unions well as collaborations with higher education

institutions (Kagermann et al., 2013). Despite these exceptions, literature has not yet proposed the capabilities required by SMEs to use and implement digital technologies in products and/or processes.

2.3 Dynamic capabilities and absorptive capacity

Dynamic capabilities (DCs) have been introduced in the context of strategy as an extension of the Resource Based View (Barney, 1991) to explain how firms create, extend or modify their resources and skills in response to changing competitive environments (Kale and Singh, 2007, Teece, et al., 1997) to enhance the competitive performance of firms (Teece 2007).

Absorptive capacity has been proposed as a dynamic capability that denotes firms' ability to identify valuable external knowledge, assimilate or transform this knowledge into firm's knowledge base, and apply this new knowledge through innovation and competitive actions (Cohen and Levinthal, 1990).

The new technological revolution brought by Industry 4.0 is an *activation trigger* that lead firm to change the degree of acquisition of external knowledge (*acquisition capability*), which in turn should trigger the understanding and interpretation of these Industry 4.0-related knowledge (*assimilation capability*), the internalization of what constitute Industry 4.0 for the firm (*transformation capability*) and finally the exploitation of knowledge of Industry 4.0 (*exploitation capability*) through the use of digital technologies in products and/or in processes. We propose that the acquisition of knowledge may come from external sources as well as from internal sources in relation to internal integration and manufacturing operations capabilities. In addition, we propose that the assimilation and transformation capabilities entail the capability to formulate a digital manufacturing strategy. This reflects the capacity of the firm to integrate and internalize digital technologies within firm's boundaries, with the routines and operations currently in place.

3. Theoretical model and hypotheses development

3.1 Hypotheses development

There are several reasons which could explain the exploitation (i.e. the purposefully adoption) of digital technologies. As put forward by Cassiman and Veugelers (2006), firms may search and scan for new knowledge within and outside their boundaries. This search processes are usually complementary but bring with them significant information and knowledge which may differently impact on several performance metrics, as competitive success and cost of development (Kessler, et al., 2000), or productivity (Cassiman and Veugelers, 2006).

Following this approach, we advance that knowledge acquisition capabilities enabling the adoption of digital technologies are triggered by the use of multiple external knowledge sources (*external search depth*), the use of multiple internal knowledge

sources which denote the *internal integration* of the firm, and the presence of *multiple manufacturing capabilities*.

External factors consist in the external search depth of SMEs, namely how firms scan for new technologies within the actors of their ecosystem (Laursen and Salter, 2006). Conversely, the internal factor we identified is related with the degree of internal knowledge exchange that exists between different functional units and the manufacturing competitive priorities of SMEs (Kathuria, 2000).

The external search depth that SMEs decide to set are crucial in promoting search and scan of new technological opportunities across different business actors, but also in understanding and recognizing significant environmental shifts in the industry which may represent threats to current SME's operations.

The development of digital technologies has not achieved a high degree of maturity yet (Ganzarain and Errasti, 2016). In this vein, SMEs engaged in collaborations with actors as universities and research labs have a higher opportunity to tap into emerging technologies radically different from those currently adopted in their production process. A complementary position recognises the idea according to which the scarce development of digital technologies triggers SMEs in collaborating with actors outside their boundaries to codevelop solutions for integration within their production process (Reischauer, 2018). In this vein, the recent emergence of competence centres favouring the exchange of knowledge, ideas and technologies between universities and firms represent a significant evidence of this trend (Müller and Hopf, 2017).

Beside university-industry relationships, the openness of SMEs toward other actors may represent a trigger for the exploitation of digital technologies. For instance, customers may push both suppliers and distributors to collaborate since they have adopted digital technologies. Because of their low level of standardization, all the value-chain actors require cooperation to align their operations and this may further trigger the diffusion of the technology along the value chain.

Summarizing, it is clear that SMEs collaborating with more partners (as suppliers, distributors, universities, consultants) have superior probability to tap into different digital technologies and then to exploit them.

H1: SMEs performing external search with multiple sources have a higher degree of adoption and exploitation of digital technologies.

Literature on absorptive capacity acknowledged that, in order to assimilate, transform and exploit new external knowledge, firms need to establish ties *within units* (Jansen, et al., 2005) in addition to establish ties with external knowledge sources. Indeed, knowledge diversity facilitates both learning and innovation processes by enabling the individual to make novel associations and linkages (Cohen and Levinthal, 1990). In their study of organizational antecedents to absorptive capacity, Jansen et al. (2005) find that cross-functional interfaces (e.g. liaisons, teams etc.), and connectedness and socialization tactics enable determine the absorptive capacity of firms.

Similarly, literature on organizational knowledge creation acknowledges the importance of socialization, a process of sharing experiences that create and combine tacit

knowledge (Nonaka and Takeuchi, 1995). This literature further argue that internal integration, through for instance formal and informal communication networks, create redundancy of information, an enabling condition for knowledge creation as it facilitates the sharing of both tacit and explicit knowledge (Nonaka and Takeuchi, 1995).

H2: SMEs with a superior degree of knowledge exchange within functional units have a superior degree of adoption and exploitation of digital technologies.

In the last years, the competitive environment and the pressure of large OEMs (for which many SMEs are suppliers) have forced SMEs to shift strategic priorities from a single positioning toward hybrid positionings, which encompass the contemporary competition on multiple strategic levers (Salavou, 2015). In response to this, SMEs has adopted several managerial practices (TQM, JIT, WCM etc.) associated with world class practices (Cagliano, et al., 2001) to develop multiple manufacturing capabilities (Frohlich and Dixon, 2001). It is therefore not surprising to see SMEs competing not only on differentiation or cost-leadership strategies (Porter, 2008), but also considering as competitive levers factors such as service level (Guajardo, et al., 2015), flexibility, quality and design (Battistella, et al., 2012), and more recently on sustainability (Moore and Manring, 2009).

Firms with multiple manufacturing capability may have higher degree of adoption of digital technologies because they are continuously performing continuous improvement initiatives (e.g. quality circles, suggestions etc.) to develop continuously manufacturing capabilities. This enables them to recognize more easily opportunities to invest in digital technologies that can sustain efficiency, flexibility, quality and sustainability.

HP3: Multiple manufacturing capabilities enables the adoption and exploitation of digital technologies.

Digital technologies entail new innovation problems associated with unknown and latent customer needs, internal users and other stakeholders (Nambisan, et al., 2017). This implies that - for SMEs - knowledge related to Industry 4.0 cannot be simply acquired from the internal or external environment, but also needs to be fully integrated and shared within the firm. Such integration is crucial in enhancing the fit between operations and technologies currently adopted by the firm and those brought by Industry 4.0. We recognize that SMEs may achieve this fit through the development of a digital manufacturing strategy which allow firms to purposefully extend and modify their resource base (Helfat et al., 2007).

The digital manufacturing strategy encompasses the definition of ex-ante objectives related with the assimilation of digital technologies and enables the application of digital technologies for the development of new digital products or for the development of new processes. In this sense, we contend that:

H4: The formulation of a digital manufacturing strategy mediates the impact that external depth search, internal integration and multiple manufacturing capabilities have on the adoption and exploitation of digital technologies.

A representation of the theoretical framework is reported in Figure 1.

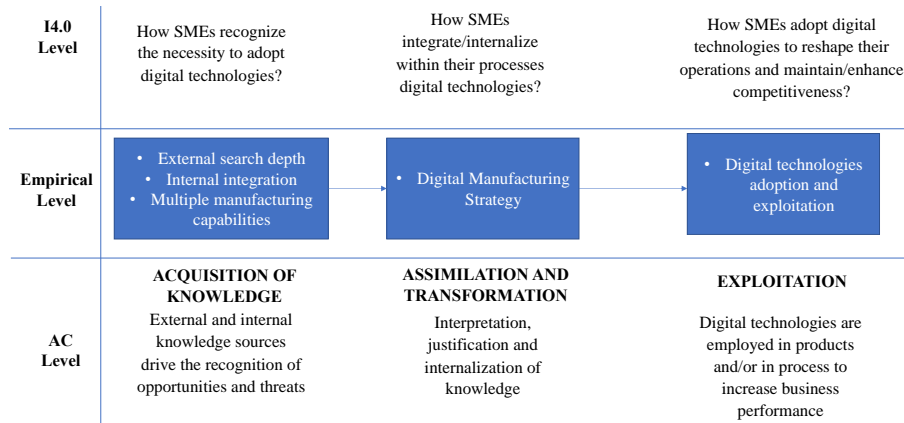

Figure 1. Representation of the theoretical framework and of the underlying hypotheses

4. Empirical methods

4.1 Data

Our empirical analysis is based on a recurrent survey of the Piedmont observatory of innovative firms. Piedmont, and Turin in particular, has long industrial tradition with a strong presence of innovative SMEs that either operates in niches in an international environment or works as supplier of large companies settled in Piedmont (e.g. FCA, Ferrero etc.). As a result, Piedmont represents an interesting setting to investigate the digital transformation of manufacturing companies

In the 2018 survey of the observatory, we include a section on Industry 4.0 which investigates current and future adoption of digital technologies, strategic opportunities, fiscal incentives adopted of the “Piano Industria 4.0” and supporting initiatives related to Industry 4.0 as well as the use of information systems (ERP, CRM etc.), considered as precursor of industry 4.0. We use questions from the other sections of the survey, not specifically related to Industry 4.0, to retrieve data on knowledge sources within and outside companies’ boundaries (suppliers, universities, distributors, customers etc) as well as for control variables (R&D expenditure, size, age etc.)

Out of 1851 email surveys, we received 367 usable responses achieving a response rate of 19,8 %. Excluding companies from non-manufacturing industries, start-ups and large companies we obtain 176 usable responses of manufacturing SMEs. Similar to other studies (Müller, et al., 2018), we consider SMEs those firms with less than 250 employees and with an annual turnover less than 50 M€. We retrieve these data from the AIDA database, a comprehensive dataset containing financial data of Italian firms.

The data analysis comprised two steps. Firstly, we used explorative factor analysis to group the digital technologies of Industry 4.0 and the other to group the strategic

opportunities driving the adoption of such different configurations. Secondly, we test the theoretical model using the structural equation modelling (SEM) technique.

4.2 Measures

Digital technologies and digital manufacturing strategy employ a 5-point Likert scale. For digital technologies the levels range from 1 indicating that there are no potential applications for the firm to 5 indicating that they already using the technology in the products and/or in processes. For digital manufacturing strategies each company was asked to indicate from 1 to 5 the importance of each investment objectives ranging from increased flexibility and efficiency to new products and services. External search depth, internal integration and multiple manufacturing capabilities were operationalized from a 5-point Likert scale into a sum of binary variables. Each variable item was coded 1 to corresponding level of 4 and 5, and 0 to corresponding to level 1, 2 and 3. In this way, we express the depth of knowledge search both internally and externally.

4.3 Control variables

We control for SMEs' innovation capability: R&D intensity, constructed as R&D expenditures to total sales. We control also for the adoption of information systems (e.g. ERP, CRM, PLM) as they are often considered precursor of Industry 4.0 (Müller, et al., 2018), constructed as a binary variable with 1 whether the firm has at least one information system adopted, 0 otherwise. Considering the high investment required by Industry 4.0, we control also for the size of investments, constructed as the total of depreciation. We control for other factors that may influence the assimilation of digital technologies namely size, age and industry.

5. Results

Table 1 and Table 2 present the results of the factor analysis regarding Industry 4.0 technologies and digital manufacturing strategies. The path coefficients of the empirical model are provided in figure 2. Table 3 reports the control variables.

5.1 Factor analysis

The first factor analysis reveals two main groups of digital technologies. The former is related to information technologies and CPS domain, while the latter is related to operational technologies. Thus, the technologies such as Internet of Things, Big Data and advanced analytics, simulation and information system integration have been grouped into a factor called *information technologies*. Virtual and augmented reality, additive manufacturing and advanced application of robotics have been grouped into a factor called *digital operational technologies*.

The second factor analysis reveals two main digital manufacturing strategies. The former strategy aims at increasing the efficiency, quality and flexibility of manufacturing processes. We called this factor *operational excellence*. The latter strategy aims at developing smart, connected products to offer new services and enter new markets. We called this factor *digital product innovation*.

5.2 Results of the empirical model

The results of SEM can be summarized as follows:

1. External knowledge search from the external ecosystem drives both the operational excellence ($\beta=0,189^{**}$) and the digital product innovation ($\beta=0,227^{***}$), driving in turn the adoption and the exploitation of both information and operational technologies. From this finding, it emerges the positive role of the ecosystem (e.g. learning factory and competence centres) that shows the potential of Industry 4.0 both for process and product innovation.
2. Internal integration drives only the operational excellence ($\beta=0,263^{***}$), driving in turn the adoption of information technologies ($\beta=0,166^{***}$). From this finding, it emerges that SMEs too focused internally may miss opportunities for product innovation, by focusing only on process innovation.
3. The capability to compete on multiple priorities drives the digital product innovation, driving in turn the adoption of both information and operational technologies. Thus, SMEs with multiple manufacturing capabilities seem to have achieved such a level of operational excellence that can exclusively focus on product innovation.
4. The digital manufacturing strategy mediates the use of external and internal knowledge sources for the adoption of digital technologies. In fact, we find non-significant direct effects among knowledge sources and the adoption of digital technologies¹.

Summarizing, we found three main patterns of adoption of Industry 4.0 by SMEs. Specifically, we find that (1) SMEs that extensively use their innovative ecosystem absorb knowledge relevant for Industry 4.0 to pursue both product and process innovation through the adoption of both information and digital operational technologies; (2) SMEs that use internal knowledge sources tend to achieve operational excellences through the

¹ Mediation analysis is not reported here but can be provide on request by the authors

use of information technologies; (3) SMEs with multiple manufacturing capabilities pursue mainly product innovation strategies using both types of technologies.

This paper contributes to the emerging literature on the antecedents of Industry 4.0 adoption (Agostini and Filippini, 2019, Müller et al., 2018b) finding that searching knowledge on multiple external sources, integrating knowledge from internal sources and multiple manufacturing capability, mediated by a digital manufacturing strategy, are positively related with Industry 4.0 adoption.

6 Limitations

This research is not free of limitations. First, our study is limited to a sample of innovative SMEs in the Piedmont region. While this offers a fruitful context to investigate Industry 4.0, given the historical industrial tradition of the region, this limit the generalizability to other contexts. Future research should enlarge this study in other empirical settings. Second, we did not control for endogeneity problems. Future research should employ tool that control for these, such as instrumental variable.

Future research should also investigate the presence of different patterns of adoption of digital technologies in SMEs. This can be verified for instance through a cluster analysis.

Abstract

This paper draws on the literature on innovation in tourism industry to investigate how the promotional tools developed by destinations – websites for information and booking, apps, e-commerce websites, tourist cards, BI and CRM software – may contribute to long-term development of accommodations in the territory. It is assessed by analysing impacts on booking channels, direct and intermediated (both online and offline), and revenue. Hypotheses are tested with a generalized linear model and an ordered logistic regression on data retrieved from 1,226 accommodations distributed in the Italian territory. Empirical results evidence the contribution of smart destinations in increasing the competitiveness of the tourism firms in the same area.

Keywords – Smart destination, Accommodation, Digital marketing, Booking channels, Revenues

Paper type – Academic Research Paper

1 Introduction

Rapid development of the Internet and wide introduction of ICTs in tourism and hospitality industry have modified the competitive landscape (Hojeghan and Esfangareh, 2011). New virtual actors, such as Online Travel Agencies (OTAs), travel metasearch engines, infomediaries (i.e. Google, Facebook) and sharing economy players, have entered the sector and gained importance. For accommodation facilities, this implies considerable complexity to manage the relationships with customers and an imbalance of power, since they largely depend on online intermediaries to reach a wide customer base,

paying commissions up to 30% of the transaction (Di Cesare, 2014; Buhalis and Law, 2008). On the other hand, the introduction of innovations has opened new possibilities of collaboration. In particular, partnerships could arise between Destination Management Organizations (DMOs) and accommodation facilities located in the same territory as they are interwoven realities (Correia and Brito, 2014; Buhalis and Molinaroli, 2003): while DMOs create and maintain the touristic demand, accommodations provide the supply.

Despite the growing interest of the literature on the topic, at our best knowledge the benefits of partnership among the industry have not been analysed with quantitative data. For this reason, the aim of this paper is to assess the effectiveness of such collaboration for accommodation facilities based on the usage of digital tools. Research draws on 1,226 accommodations located in the entire Italian territory interviewed during 2015. The empirical part uses a generalized linear model and an ordered logistic regression to measure the impact of use of digital tools developed by DMOs on revenue and booking channel management.

The rest of the paper is organized as follows. In Section 2, we present the theoretical background and research questions. Section 3 is devoted to model and data description. The empirical analysis is conducted in Section 4. Section 5 concludes.

2 Literature review

2.1 Theoretical background

The literature has largely underlined the tourism industry has been affected by a rapid change (Firoiu and Dodu, 2010) due to the introduction of the ICTs (Information and Communications Technologies) that have assumed a central role in its development and growth (Buhalis and Law, 2008). The transformation in the competitive landscape (Hojeghan and Esfangareh, 2011) led the birth of new virtual actors and the creation of new market relationships (Aldebert, Dang and Longhi, 2011) with consequently changes in the market share and bargaining power (Buhalis and Law, 2008). Above all, OTAs gained the greatest popularity, but also players who do not sell directly to the final customer but promote the tourist offers are assuming an increasingly important role (Podu, 2013). As a result, service providers experiment a more complicated management of relationships with their customers, who now interface with a large number of actors (Mihălcescu and Sion, 2011; Ruiz-Molina, Gil-Saura and Moliner-Velázquez, 2011). More specifically, in the hospitality industry, the survival of accommodation facilities is threatened by OTAs that leverage on low-cost offers and high commissions (Buhalis and Law, 2008). These changes, in addition to the fragmented nature of the tourism industry, should stimulate the many actors to develop entrepreneurial networks, supported by ICTs, for the creation and delivery of tourism products and the development of common resources (Buhalis and Molinaroli, 2003). However, the sustainability of these cooperative relationships is confined to the return gained by each single side (Berné, García-González, García-Uceda and Múgica, 2015). Common interests are expected for tourist destinations and accommodation facilities situated in the same territory since they

are related entities; such collaborations could result into positive outcome. In fact, the destination is one essential motivating factor behind the tourists' decisions, which in turns are the result of the marketing strategies adopted by its various stakeholders. Consequently, touristic enterprises have to market both their own product and the area as a single unified product. Marketing a tourist destination is often difficult to organise, since there are many actors involved, all with their own goals that have to co-exist (Grängsjö, 2003). They need to adopt innovative methods to strengthen their competitiveness. The spread of ICTs is large; they can be used both for operational and strategic objectives (Buhalis, 1998), affecting not only the volume of information exchanged, but also the value of long-term relationships (Firoiu and Dodu, 2010). In addition, the information-intensive nature of the industry should push enterprises to rely on Big Data, considered the new key source for value creation. Through datamining and statistical techniques the knowledge exploited from tourists' data can be transformed into competitive assets (Del Vecchio, Mele, Ndou and Secundo, 2018). The available technology, therefore, contributes to provide better services and offer valuable experiences for tourists and to create wealth, profit, and benefits for the organizations and destinations (Boes, Buhalis, & Inversini, 2015). Technology is the enabler to network, as internet tools are instrumental in facilitating tourist destination to develop such dynamic connections (Del Vecchio, Mele, Ndou and Secundo, 2018).

Innovative destinations, making use of websites and mobile apps, communicate with tourists with the aim to promote and raise their awareness on both the destination itself and the tourism firms (Gretzel et al., 2000). Moreover, in order to facilitate the tourist experience and increase the use of tourist services, DMOs in collaboration with the tourism destination stakeholders realize the tourist cards (Zoltan and Masiero, 2012). They are cumulative tickets that allow the tourists to access a range of services offered by destination at a total price lower than single purchases. The major benefit for service firms lies on their informative power: companies who choose to join the program have the opportunity to receive useful information to profile visitors, gain insight about their consumption behaviour and model appropriate marketing actions (Angeloni, 2015). Business Intelligence (BI) and Customer Relationship Management (CRM) software are other tools DMOs can make available to help accommodations to make a clever use of customer data and consequently develop a well-addressed communication, with relevant and personalized contents that push people to perform the desired action (Milović, 2012).

Thus, destinations assume a significant role within the tourism context as they promote the tourist offers without selling them directly to customers (Podu, 2013). Accommodation facilities could benefit from their support for both increasing sales and shifting the received bookings from intermediated channels to direct ones. Thanks to a well-managed distribution system, they can make a difference in the market, becoming leading companies instead of struggling to survive (Kotler et al., 2013).

2.2 Research objective

Despite the growing interest of the literature on the topic, empirical researches remain scarce. This paper investigates how the digital tools developed by destinations – websites

for information and booking, mobile apps, e-commerce websites, tourist cards, BI and CRM software – may contribute to long-term development of accommodations in the territory, in terms of booking channels and revenue. In specific, their contribution is considered positive if they increase revenues and favour direct bookings and diminish the intermediated ones, as they are subject to fees. Thus, following hypotheses are formulated:

Hypothesis 1. Websites for information and booking, mobile apps, e-Commerce website, tourist card and BI and CRM software will be positively associated with direct bookings.

Hypothesis 2. Websites for information and booking, mobile apps, e-Commerce website, tourist card and BI and CRM software will be negatively associated with intermediated online bookings.

Hypothesis 3. Websites for information and booking, mobile apps, e-Commerce website, tourist card and BI and CRM software will be negatively associated with intermediated offline bookings.

Hypothesis 4. Websites for information and booking, mobile apps, e-Commerce website, tourist card and BI and CRM software will be negatively associated with destination intermediated bookings.

Hypothesis 5. Websites for information and booking, mobile apps, e-Commerce website, tourist card and BI and CRM software will be positively associated with revenue.

3 Method

3.1 Model

Hypotheses are tested with two statistical models. A generalized linear model with a binomial distribution and a logit link function is used for the dependent variables related to booking channels, which are proportional. An ordered logistic regression is implemented for the variable indicating the percentage of increase and decrease of revenues compared to the previous year, which is divided into ordered classes.

3.2 Data and variables

Data are from accommodations distributed in the Italian territory, interviewed in 2015 with CAWI (Computer Assisted Web Interviewing) methodology. The survey consisted of 37 questions, in addition to the request of personal data, and has been structured into five sections: technological equipment, data management and communication with customers, promotional activities to attract new customers, reservation channels and impressions on future. 24,407 accommodation facilities have been contacted; 2,016 are the questionnaires gathered, with an 8% redemption rate. High nonresponse rate can be imputed to many causes: period of survey administration – during summer – coincided with the most work intensive months for accommodation facilities; low engagement with research study since they were contacted only by email; considerable length of the survey and complexity of some questions. Final sample, after the elimination of incomplete

questionnaires, consists of 1,226 accommodations. Panel data is statistically representative of the population of accommodation facilities situated in the country, as resulted by a comparison with the data from Italy's National Statistics Institute (Istat).

There are five dependent variables, one for each hypothesis to be tested. *Direct_bookings*, *Intermediated_online_channels*, *Intemediated_offline_channels* and *Destination_intermediated_channles* are proportional variables with values from 0 to 1, which represent the percentage of bookings coming from the related type of channel. *Direct_Bookings* are bookings received from a direct contact of the client (e.g. by email, phone, walk-in, website, app). *Intermediated_online_channels* are intermediated bookings (e.g. from OTA, metasearch) through online channels like websites and apps. *Intemediated_offline_channels* are the ones coming from traditional means, namely travel agencies and tour operators. *Destination_intermediated_channels* are bookings intermediated by DMOs. The last variable, *Revenue*, is ordinal divided into six classes, according to the percentage of increase or decrease of revenue compared to the previous year (1: < -10%; 6: > 10%). Independent variables are binary, taking value equal to 1 if the linked promotional tool provided by the destination is used by the accommodation facility. The selection of the digital tools is carried out taking into account their spread, accessibility and usability. According to this criterion we've included in the models websites, mobile apps, tourist cards and BI and CRM software. Summary statistics of the variables employed in the analysis is provided in Table 1.

Table 1 Summary statistics

Variable	Mean	Std. deviation	Min	Max
Direct_bookings	0.4520	0.2752	0	1

Nine coefficients resulted significant. In particular, one of them has a p-value of 0.000, one below 1%, two below 5% and five below 10%. The highest coefficients are related to the model with destination booking channels as dependent variable; in descending order they are the coefficients of the following variables: website for information or booking (0.76), BI and CRM software (0.61) and e-Commerce website (0.49). The odds for mobile app of having a revenue increase over 10% versus the lower categories are 1.34 greater. The odds for information/booking website, instead, indicate accommodations which use these tools are more likely to get lower revenue in comparison to previous year. Actual signs only partially correspond to expected signs for the nine significant variables. Consequently, hypotheses 1, 2 and 5 are partially confirmed. Hypothesis 3 and 4 are rejected because the significant coefficients are positive, assuming that the presence on destination's digital tools stimulates the bookings arriving from offline intermediated and destination's channels.

4.2 Discussion

Empirical results evidence the contribution of smart destinations in increasing the competitiveness of the tourism firms in the same area. In particular, accommodation facilities that are present on destination's websites (for informative and/or booking purposes) receive more direct bookings and less intermediated bookings from online channels (OTAs, metasearch engines and other third parties portals). Anyway, it is also increased the quota of intermediated bookings from traditional channels (travel agencies and tour operators). It could be the case of consumers who use the web for gathering information about the travel, but prefer to establish a face-to-face relationship with the seller in order to feel reassured with the opinion of an expert. This possibility draws attention to the omnichannel journey the tourists go through, with a mixed use of digital and traditional touchpoints along the traveling purchasing process. Tourist cards, instead, increase the percentage of direct bookings without any significant effect on intermediated ones. This highlights the mainly advertising nature of the tool: it sponsors the accommodation facilities that have joined the program. Results show smart destinations themselves become new intermediaries: the ones offer information and booking websites, e-Commerce portals and BI and CRM software address accommodation facilities a greater quota of bookings. Anyway, these platforms are often free and therefore they can still be considered a good brokerage channel. Moving to revenues, two variables result statistically significant: the presence of accommodations in information/booking destinations' websites and in destinations' mobile apps. Specifically, regarding accommodations that use the destinations' apps, they have a greater probability to experience a revenue increase. A possible explanation is that accommodation facilities that choose to join destination mobile program have at their disposal a large quantity of data that reveal precious insights on users' habits and movements. Companies then can customise their services according to customers' needs and obtain such financial benefits. Indeed, tourism industry is becoming even more customer-centric and customer satisfaction is highly rewarded, since it automatically brings to the accommodations new customers through positive reviews of their service. Instead, it is interesting to note that the probability to increase in sales over the previous year is lower for accommodations present on information or booking websites. This evidence shows that destinations' websites seem to act more as booking routers than as promotional showcases.

5 Conclusions

This paper investigated the links, in hospitality industry, between the marketing tools developed by DMOs and the distribution of bookings received through the different channels and the revenues. The models predict that a positive correlation with direct bookings and revenue may exist, while the relationship with intermediated bookings may be inversely proportional. The empirical analysis provides evidence in their favour. To our best knowledge, this is the first attempt to analyse which destination tools contribute to development of accommodations in terms of booking channels management and revenue. These two elements reflect the sustainable development perspective for

accommodation facilities for the following reasons. Appropriate channels management – i.e. direct bookings over intermediated ones – means greater presence and control towards the final consumer, strengthening of the relationships with tourists and co-creation of contextualized offers based on their needs and less dependence on third parties that apply high commissions. Money saved could be used for further investments to create new sources of revenue (e.g. potentiating marketing strategy) and/or to improve internally (e.g. technological equipment) to reduce costs in the long period. Revenue growth is equally important as it is the primary driver for company profitability: higher levels of revenues are likely to generate higher profits, if costs rise at a lower rate, to be reinvested in the business. Moreover, a positive growth rate is a good indicator of company future stability in case of bank loan request, with the possibility to achieve better financial conditions. Similarly benefits result into employees' engagement and talents' attraction. Finally, a growing business is evidence of the effectiveness in delivering value to customers, which triggers confidence into new potential buyers to obtain same benefits from the service. In addition, in accommodation facilities view, the collaboration with DMOs is also a chance to link their brand to the destination one: it is a potent way to power their image and raise consumer awareness toward their service. In fact, studies demonstrated that tourist destinations touchpoints are one of the most influential factors during inspiration and information gathering phases.

Research results confirm that, from touristic firms' perspective, DMOs who make available digital marketing tools are a good opportunity for disintermediation, reducing an excessive reliance on intermediaries. Money saved from third parties commissions can be internally invested to further develop a long-lasting growing. Although positive results emerged also in revenues analysis, there is still large space for improvements for supporting accommodations to increase their visibility and consequently their sales. Accommodations, however, should be conscious of the new consumer behaviour and adapt consequently. In their routine, people constantly switch from digital and physical activities and therefore they tend to replicate this natural behaviour in every aspect of their life, including when it comes to buy a travel service. Thus, accommodations do not have to consider distinctly offline and online anymore when reasoning about marketing strategy; they are now part of a single process that contribute to create a holistic touristic experience. Strategy should be omnichannel, in which offline and online tools are harmonized with each other.

In summary, it is now clear that collaboration between smart destinations and accommodation facilities is a win-win relationship, on which to leverage for increasing the competitiveness and the attractiveness of the tourism industry in the entire territory.

5.1 Limitation and future research

The main limitation of this study is the lack of absolute values for bookings and revenues.

Future researches could develop along various levels: i. conduct qualitative research – with interviews and focus groups – to deepen knowledge and gain insights on the relationships between accommodation facilities and DMOs located in the same territory;

ii. repeat the analysis on homogeneous groups of accommodations (e.g. hotels, farm holidays) to verify if results change since different accommodation types are targeted to people that may respond differently to marketing inputs; iii. analyse the tourist travel journey in order to provide managerial insight on the multiple touchpoints activated by tourists during the purchasing process.

Abstract

Hospitality is one of the sectors that are nowadays most heavily characterized by consumers' tendency to share online reviews on dedicated digital platforms. While most past work has focused on understanding the effect of online reviews and ratings on consumers' evaluation and purchase decisions, this research tackles the issue of what drives the sharing of certain types of online content. Specifically, we investigate the sharing of user-generated content characterized by negative emotional valence, and study the effect of two factors on the extent to which user-generated content contains negative emotions. One such factor is reviewer's expertise, while the other is hotel quality. Our analysis of 1,200 TripAdvisor reviews on Italian hotels located in three major Italian cities confirm our hypothesis that expert reviewers might share reviews containing less intense negative emotional content compared to less expert reviewers especially when the hotel is of high quality. To support our hypothesis, we build on the research on psychological antecedents of word-of-mouth behavior suggesting that expert consumers are particularly reluctant to share negative word-of-mouth to avoid projecting a negative image of themselves in social contexts, thus possibly damaging their reputation.

1 Introduction

In almost every sector, today's managers face the issue of how to fully get useful insights from the huge amount of data generated everyday by consumers, especially through digital and social media platforms. Marketing scholars have long investigated the role of User Generated Content (hereafter, UGC), which refers to media content created or produced by the general public rather than by paid professionals and primarily distributed on the Internet (Daugherty, Eastin, and Bright, 2008, p. 16).

UGC has a particularly crucial role in "information-intensive" sectors, such as tourism (Law, Buhalis, and Cobanoglu, 2014; Neirotti, Raguseo, and Paolucci, 2016; Pino et al., 2018; Vargo and Akaka, 2009), in which being able to take data-driven managerial decisions is crucial for companies that want to improve their market performance through the enhancement of the customer experience they deliver (Jackson, 2016; Phillips, Barnes, Zigan, and Schegg, 2017). Consequently, scholarly research has been dedicating a good deal of attention to understanding how contents shared by consumers online may create value in the hospitality industry, engage users and influence destination image, companies' image or tourist behavior (Gössling, Hall, and Andersson, 2018; Kim and Stepchenkova, 2015; Litvin and Dowling, 2018; Marine-Roig, Martin-Fuentes, and Daries-Ramon, 2017; Neirotti, Raguseo, and Paolucci, 2016; Ukpabi and Karjaluoto, 2018).

In this research, we focus on a more specific, though large and relevant, tourism sector such as hospitality, which certainly represents one of the sectors that has been most heavily influenced by digital media and UGC (Narangajavana, Fiol, Tena, Artola, and García, 2017; Varkaris and Neuhofer, 2017). Indeed scholars have mostly concentrated on examining the effect of UGC on outcome variables such as reputation (Dijkmans, Kerkhof, and Beukeboom, 2015), hotel room sales (Ye, Law, and Gu, 2009) and trust towards online consumer reviews (Filiari, Alguezaui, and McLeay, 2015). Scant attention, instead, has been devoted to studying the drivers of UGC, which could allow to detect predictors of reviewers' tendency to share certain types of UGC.

We investigate the effect of two UGC drivers that represent two of the most relevant elements of UGC, namely the *UGC sharer* and the *service* he/she reviews. Specifically, to capture the UGC sharer we examine the effect of reviewers' expertise, while to capture the service the UGC is about we examine the effect of the quality of the hotel reviewed. Moreover, as far as the UGC shared is concerned, we focus on UGC having emotional valence. Indeed, while it is widely known that the content shared by users often has an emotional valence (e.g. Berger and Milkman, 2012; Cervellon and Galipienzo, 2015; Munar and Jacobsen, 2014), there is, to the best of authors' knowledge, a dearth of studies examining the factors that may affect hospitality consumers' tendency to share emotional content. Therefore, we examine the effect of reviewers' expertise (measured using TripAdvisor's reviewer classification system) and hotel quality (measured through the number of "stars" the hotel has) on the extent to which UGC contains negative emotions. Operationally, we used the *Linguistic Inquiry and Word Count* software (LIWC; Pennebaker, Booth, and Francis, 2007; Pennebaker and Francis, 1996), commonly

employed for content analysis, to analyze the text of 1,200 comments posted on TripAdvisor about hotels (either 2-star or 5-star hotels) located in some of the main Italian cities in terms of international awareness and tourism (i.e., Rome, Florence, and Milan). Indeed, according to the “Top 100 City Destinations Ranking” research report published by the Euromonitor International (2017). Our analysis has been carried out through a regression model in which we used as independent variables our two focal variables, that is reviewer expertise and hotel quality, both treated as dichotomous, and as dependent variable an index of negative affect obtained from our content analysis. The reviewer expertise was considered a dichotomous variable in order to more easily study the interaction effect and to simplify the presentation of results (Farrington and Loeber, 2000).

Overall, this research sheds light on the role that one relevant UGC sharer’s characteristic (i.e., her expertise) and one relevant hotel’s characteristic (i.e., its quality) may have on the negative emotional content of comments shared online in the hospitality sector. Three are the main contributions this work makes to advancing extant knowledge. First, we contribute to the literature on tourism marketing and on the analysis of UGC in tourism and hospitality, while most previous work on UGC in tourism and hospitality has focused on the effect of UGC shared on recipients, our core focus in this research is on the determinants of UGC sharing. Second, our results contribute to the literature on social media data management in hospitality by proposing a novel conceptual framework that may help researchers and companies analyze data generated on online networks dedicated to hospitality. Third, we contribute to the UGC literature concerning hotels by analyzing the joint effect of a factor related to the online reviewer, such as her expertise, and a factor related to the product reviewed, such as the hotel quality, on the negative emotional intensity of the content shared.

2 Theoretical background

Our literature review has been the result of a systematic review process that has been conducted according to recent contributions proposed in the literature, in line with the well-established systematic literature review (SLR) approach (e.g., Centobelli et al., 2016; Denyer and Neely, 2004; Pittaway and Cope, 2007). Specifically, our systematic review started with a disciplinary stance to explore journals listed within “tourism” journal rankings. Thus, these journals citation indexes were searched systematically for papers that included the terms “hospitality,” “UGC,” “digital and social media,” “emotions” and/or “WOM” in the citation information, keywords and abstracts. All selected articles were included in a database created ad hoc for the purposes of the current research and, on the basis of the review of the abstracts of the papers selected, divided into three groups depending of their core topic (digital platforms and tourism, UGC and hospitality, emotions and WOM). Within each group, papers were then classified into three categories (A, B, C) according to their possible impact on the above-mentioned core topic. Finally, we started entirely analyzing each single article starting from the “A” papers and then moving to the “B” and “C” ones. This analysis has been firstly carried out for the “digital

platforms and tourism” group, then for the “UGC and hospitality” group and finally for the “emotions and WOM” group (please see Figure 1 for a flowchart of the methodological steps we followed and Figure 2 for a literature map that summarizes the main unit of analysis and contributions on the research topics relevant for this paper).

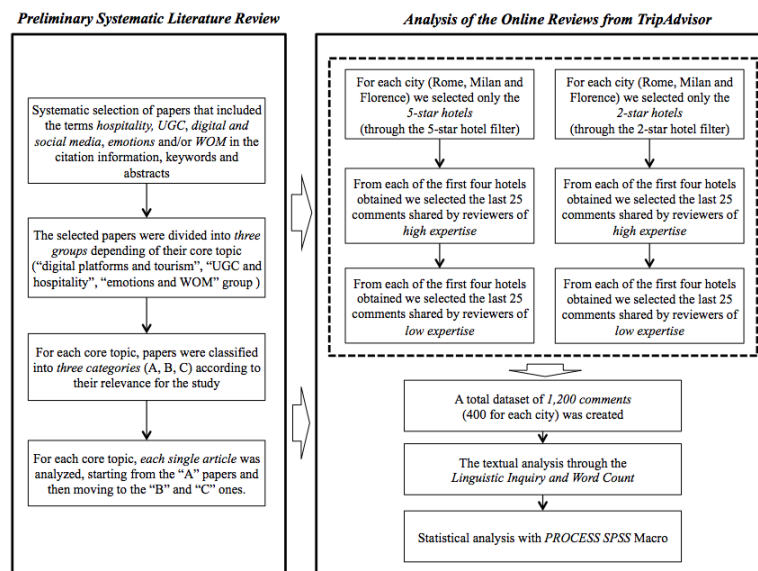

Figure 1. Flowchart summarizing the methodological procedure.

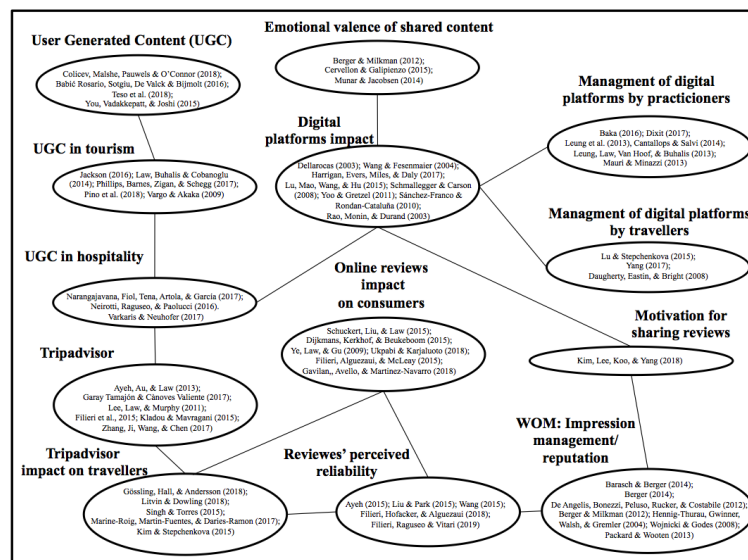

Figure 2. Literature map summarizing the main topics considered for this study.

2.1 Digital platforms in tourism

Information Technology (IT) innovations have driven the rise of digital media, which since the beginning of the new millennium have been unanimously considered as platforms of great importance for businesses in order to understand customers and respond effectively to their needs and preferences (Dellarocas, 2003), with obvious benefits for their relationship with customers (Wang and Fesenmaier, 2004). Such an influence of digital platforms on the way businesses manage their relationship with customers is particularly central in the hospitality sector (Harrigan, Evers, Miles, and Daly, 2017). Indeed, researchers have long underlined that digital media are more effective than other information sources in providing information to travelers regarding a destination (Lu, Mao, Wang, and Hu, 2015; Schmallegger and Carson, 2008; Yoo and Gretzel, 2011).

Acknowledging the importance of digital platforms in tourism and hospitality, scholars have started investigating the role of such platforms in this context and have long recognized that digital media represent one of the “mega trends” that has significantly impacted the hospitality system (Daugherty et al., 2008). In support of this belief, recent research suggests that online ratings as well as the numbers and accuracy of reviews on TripAdvisor positively influence booking transaction values (Gössling et al., 2018; Litvin and Dowling, 2018; Singh and Torres, 2015). Indeed, about 70 percent of independent travel-related bookings happen online and about 35 percent of all package tours are booked online (Schuckert, Liu, and Law, 2015).

However, even if digital platforms’ fundamental importance is nowadays well recognized by hospitality companies, many hotels are still missing a clear strategy for how to effectively respond to online reviews, thereby protecting and sustaining their reputation (Baka, 2016). This issue is particularly sensitive if we consider that reputation plays a highly central role in affecting consumers’ preferences and choices in the hospitality sectors (e.g., Rao, Monin, and Durand, 2003).

Certainly, digital platforms have changed not only the way hospitality businesses analyze the market but also the way travelers assess different alternatives. Indeed, the growth of digital platforms contribute to the dissemination of information on products and services and have become the most important source of information for travelers (Lu and Stepchenkova, 2015; Yang, 2017). Indeed, as highlighted by Daugherty et al. (2008), social media such as blogs (e.g. Twitter), UGC platforms (e.g. TripAdvisor), media sharing sites (e.g. Flickr and YouTube) or social knowledge sharing sites (e.g. Wikitravel) are today largely used by travelers to search, organize, and share their travel experiences.

In the light of this, the appropriate analysis and management of digital platforms represents today not only an opportunity to improve customers’ experience and increase their engagement with the hospitality company, but also a prerequisite for hotels’ long-term survival, especially in their facing the competition of new players born in the digital-based sharing economy (e.g., Airbnb).

2.2 Literature review on UGC in hospitality

Literature on UGC in hospitality sector has mostly focused on understanding the relationship between online reviews and consumers' purchase decisions and satisfaction judgments, on motivations to post online reviews (Schuckert et al., 2015; Kim, Lee, Koo, and Yang, 2018), on how reviews' contents could impact reputation (Dijkmans et al., 2015) and on what hospitality practitioners should do to effectively respond to online comments (Cantalops and Salvi, 2014; Leung, Law, Van Hoof, and Buhalis, 2013; Mauri and Minazzi, 2013). To illustrate, Ye et al. (2009) have showed the existence of a significant relationship between online reviews and hotel room sales, which is the most relevant business performance indicator for a hotel. Filieri et al. (2015) have investigated how factors such as quality of the information provided in the review, quality and reputation of the website in which the review is shared and customer satisfaction judgments contribute to build consumers' trust towards online consumer reviews. Gavilan, Avello, and Martinez-Navarro (2018) have investigated the influence of online reviews on hotel booking intentions by shedding light on the role that the number and the valence of reviews may have on the level of trustworthiness of the ratings. Other scholars have paid attention to motivations for sharing reviews in hospitality such as making new friends, reciprocity, feeling enjoyment in helping, desire to share narratives (Kim et al., 2018). Other motivational elements identified by the literature are represented by benefits associated to the community and personal factors, furthermore motivations seem to vary across different tipology of content creators (Munar and Jacobsen, 2014). It is interesting the study by Hennig-Thurau, Gwinner, Walsh, and Gremler (2004) investigating how motivations as social interaction and self-worth enhancing reside behind sharing and lead to WOM behavior. Even the study by Hu and Kim (2018) recognized the extremely important role of eWOM motivations in the hospitality context, identifying positive and negative motivations determining positive and negative eWOM behaviors, in this study also the role of reviewer's personality traits was explored as moderating the relation between eWOM motivations and posting behaviors. Another important work exploring motivations leading to review sharing, specifically in the context of online travels, is the one by Yoo and Gretzel (2008) that identified important underlying motivations, such as helping other travelers and need for enjoyment and self-enhancement.

Focusing instead on the perspective of travelers' adoption of UGC a very recent work of Ukpabi and Karjaluoto (2018) comprehended that the adoption may be determined by different factors related to the user, such as its profile, involvement, and enjoyment, and the content itself through its novelty, valence, and aesthetics. Even the work developed by Filieri, Raguseo, and Vitari (2019) focuses on reviews' adoption, exploring how the helpfulness of extremely negative reviews is moderated by their length, clarity and reviewer's expertise. Other scholars had pointed out that in the tourism sector users' perception of usefulness of a review is based on various factors, such as, for instance, reviewer's characteristics (e.g. her expertise), accuracy of the message and review readability (Ayeh, 2015; Liu and Park, 2015). Another key driver of travelers' tendency to rely on UGC is their perception about the credibility of the content shared (e.g. Wang, 2015).

While previous studies have certainly contributed to our understanding of the effect of UGC in hospitality much less investigated has been the issue of what might drive hospitality consumers to share UGC on digital platforms. In particular, largely uninvestigated has been the identification of conditions under which hospitality consumers might be likely to share some types of content. We tackle this issue trying to fill this literature gap by exploring how the valence of online shared content can be determined not only by reviewer characteristics but even by factors related to the object of the review.

3 Conceptualization and hypothesis development

Unlike previous work on UGC that has considered a reviewer's perceived expertise as a multidimensional construct composed of different factors such as the name of the reviewer, the number of comments she had shared online in the past and the number of replies a review has generated (Chung, Han, and Koo, 2015), in this research we employ a more objective, and perhaps simpler, definition of reviewer expertise built on the classification scheme used by well-known online platforms (namely, TripAdvisor in our case, which identifies 6 levels of reviewers' expertise) on the basis of reviewer's track records of reviews. In building our theorizing about whether and under what conditions reviewers' expertise affects the sharing of negative emotional content, we expect that an expert reviewer, compared to a less expert one, might be more concerned about potential self-image risks deriving from publishing negative comments online. WOM studies suggest that people generally tend to avoid sharing negative comments in order not to project a negative image of themselves, either as persons sharing negative things (e.g. Berger and Milkman, 2012) or as bad choosers (e.g. Hennig-Thurau, Gwinner, Walsh, and Gremler, 2004).

Importantly, moreover, we do not investigate the simple effect of reviewers' expertise, but we investigate how reviewers' expertise interacts with a product-related factor, such as the quality of the hotel reviewed. We hypothesize that expert reviewers, compared to less expert reviewers, will share online content of lower negative emotional intensity particularly when the hotel is of high (rather than low) quality. Such a hypothesis builds off past WOM research suggesting that consumers' expertise in a domain is often used as an impression management tool, whereby consumers tend either to boost their image by showing off their expertise or to protect it by avoiding sharing content that might harm their reputation as expert (e.g. Packard and Wooten, 2013). We argue such a reviewers' tendency to protect their image in a social context is stronger the higher the quality of the product or service reviewed. Indeed, grounding on the idea that high quality hotels can be considered higher-involvement goods than low quality hotels (e.g. Walls, Okumus, Wang, and Kwun, 2011), we argue that high quality hotels elicit a higher potential risk for a consumer to harm her image if she shares negative comments about her experiences.

Formally:

***Hypothesis:** UGC shared by highly expert reviewers has lower negative emotional intensity than UGC shared by lowly expert reviewers when the hotel*

reviewed is of high quality, while such a difference is less likely to be observed when the hotel reviewed is of low quality.

4 Methodology

To test our research hypothesis, we conducted our empirical analysis through the very well-known hospitality online network TripAdvisor, claiming to be the world's largest travel community, with 455 million monthly visitors, 96 million members and 600 million reviews and opinions (TripAdvisor.com, 2017).

This study focuses on TripAdvisor's reviews concerning hotels located in Italy, which represents a highly relevant country for tourism on a global basis (Guizzardi and Mazzocchi, 2010). Our dataset is composed of 1,200 comments posted on TripAdvisor regarding hotels situated in three major and highly visited Italian cities, such as Rome, Milan, and Florence. In accordance with our theorizing, we varied the quality of hotels by selecting comments regarding either 2-star (i.e. low-quality condition) or 5-star (i.e. high-quality condition) hotels. As regards the manipulation of reviewers' expertise, reviewers have been categorized on the basis of their status assigned by the TripCollective program, which recognizes users each time they contribute to TripAdvisor and classifies them.

Users' TripAdvisor level has been considered a proxy of users' expertise, whereby we identified lowly expert reviewers as level-2 reviewers and highly expert reviewers as level-5 reviewers. We collected a total of 1,200 comments (400 for each city) through an approach assuring an equal number of comments representing all four conditions emerging from crossing the two levels of reviewer expertise (high vs. low expertise) and the two levels of hotel quality level (high vs. low quality) (see Table 1 and 2 for details).

Table 1. Distribution of the selected comments on the basis of the hotel category and the level of expertise of the reviewers across the three cities considered.

Hotel category (number of stars)	Number of hotels considered	Expertise of the reviewers	Number of comments selected
<i>Rome</i>			
5	4	6	100
5	4	2	100
2	4	6	100
2	4	2	100
<i>Milan</i>			
5	4	6	100
5	4	2	100
2	4	6	100
2	4	2	100
<i>Florence</i>			
5	4	6	100
5	4	2	100
2	4	6	100
2	4	2	100
<i>Only 5- and 2-star hotels</i>	<i>48</i>	<i>Only reviewers with 6 and 2 TripCollective level</i>	<i>1,200</i>

Table 2. Name, role, operationalization and references of each of the variable used in the study.

Variables	Operationalization	References
Reviewers' expertise (Independent variable)	TripCollective program (considering the 6 levels introduced by TripAdvisor we operationalized the reviewers' expertise by using the level 2 and the level 6 as a proxy of respectively low and high expertise).	https://www.tripadvisor.com/TripCollective .
Hotel quality (Moderator)	TripAdvisor classification (we operationalized the quality of the hotel by using the number of stars reported on TripAdvisor and using 2-star hotels and 5-star hotels, located in Rome, Milan and Florence, as a proxy of respectively low and high quality level).	https://www.tripadvisor.com
Negative affect (Dependent variable)	This variable was assessed through the use of the LIWC (<i>Linguistic Inquiry and Word Count</i>) software that categorizes words related to negative emotions.	Pennebaker and Francis (1996). http://www.liwc.net .

All collected comments were put in a dataset and analyzed through a textual analysis with the purpose of determining their valence. The textual analysis was run using the LIWC software, which allows getting quantitative insights about textual comments.

In our analysis, we focused on the emotional valence of comments by using as dependent variable LIWC's measure of negative affect included in each comment.

5 Results

We employed the PROCESS SPSS Macro to analyze the data (Hayes, 2013). Specifically, we used Model 1 to test our moderation model ($R^2 = .008$), in line with the research hypothesis. Hotel quality level manipulation served as the moderator in the relationship between reviewer expertise and negative affect. The results showed a marginally significant and positive main effect of reviewer expertise (coded as 0 = low and 1 = high) on negative affect ($b = .19$, $t(1199) = 1.82$, $p = .06$) and a significant main effect of hotel quality level (coded as 0 = low and 1 = high) on negative affect ($b = .06$, $t(1199) = 2.95$, $p < .01$). Of greater importance, the interaction between the reviewer expertise and the hotel quality level resulted to be significant ($b = -.06$, $t(1199) = -2.26$, $p < .05$; see Figure 3).

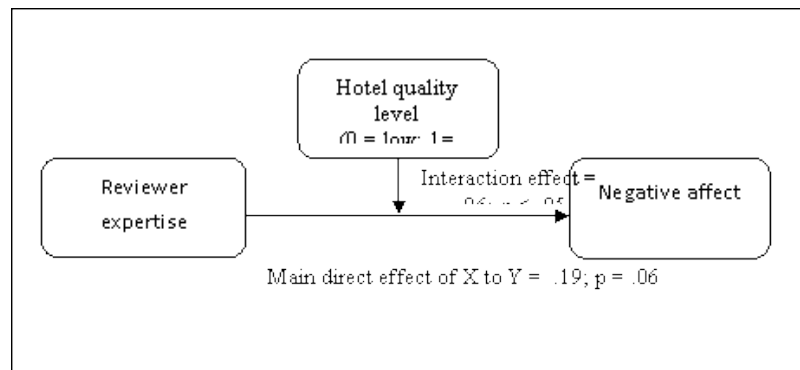

Figure 3. Conceptual model and findings

After analyzing the interaction effect of our two focal variables on negative affect, we inspected more closely such an interaction by looking at the conditional effects. Results revealed that the effect of reviewer expertise on negative affect is significant (and negative) when the review is about high-quality hotels ($b = -.12$, 95% CI: $-.24, -.00$), suggesting that in the case of luxury hotels the higher the expertise of the reviewer the lower the negative affect contained in the comment. Importantly, however, the effect of reviewer expertise on negative affect is not significant when the review is about low-quality hotels ($b = .07$, 95% CI: $-.05, .18$), suggesting that no difference in terms of negative affect contained in the UGC shared by highly versus lowly expert reviewers exists (see Figure 4). Tables 3 and 4 provide a summary of our results.

Figure 4. Negative affect as a function of the level of expertise of the reviewer and the level of quality of the hotel

Table 3. Summary of results.

Variables	Main Effects	Interaction Effect
Independent Variable (IV): reviewers' expertise (0 = low; 1 = high)	Effect of the IV on the DV: $b = .19, p = .06$	Direct effect of the interaction (IV x moderator) on the DV $b = -.06, p < .05$
Moderator: hotel quality (0 = low; 1 = high)	Effect of the moderator on the DV: $b =$.05, $p < .01$	
Dependent Variable (DV): negative affect		

Table 4. Conditional effects of reviewers' expertise on negative affect at low and high levels of hotel quality.

Hotel quality	B	S.E.	t	p
Low	.07	.06	1.14	.25
High	-.12	.06	-2.05	< .04

Note: S.E. = Standard Error

Overall, our findings provide full support to our hypothesis about the joint effect of reviewer expertise and hotel quality level on the extent to which UGC contains negative emotions. Indeed our findings indicate that the higher the expertise of the reviewer the lower the intensity of the negative emotional content shared when the hotel reviewed is of high quality. Such a tendency, moreover, seems to be particularly pronounced when the hotel the UGC shared is about is of high (versus low) quality, as hotel's high quality might enhance a reviewer's self-image concerns.

6 Conclusions and implications

The present research shows that the source of online reviews has a central role in determining the emotional content of the comments shared by reviewers on online networks dedicated to the hospitality sector. Therefore, it has potentially relevant implications for both scientific research and managerial practice. As regards theoretical implications, the present research has the merit to shed light on important, though overlooked, drivers of UGC in tourism and hospitality, related to both the UGC sharer (i.e., reviewer expertise) and the service he/she shares the review about (i.e., hotel quality). In doing so, we extend extant literature in this field by differentiating from previous studies that have mostly investigated the effects of UGC on recipients' judgments and behavior. The present study offers valuable contributions to extremely relevant domains of research as tourism marketing, social media management in the hospitality sector, and UGC concerning hotels.

As regards managerial implications, our findings can be potentially helpful to hospitality managers interested in improving their reputation on the market. For instance, they could benefit from our study by learning a methodological approach that might be useful to analyze the emotional content of online comments regarding their company

and/or their main competitors. Second, and more important, our findings suggest that expertise in online reviewing activity is a variable that could be potentially useful to target hotels' customer base.

The present research also presents some limitations that could be addressed by future studies. Indeed, our paper focuses on comments shared on TripAdvisor that is not the only one that travelers commonly use. Therefore, future research may replicate our studies considering different online platforms (e.g., hotels.com or booking.com) in order to make our findings more robust and generalizable. Moreover, our study focuses on Italy and some differences might be found through data collected in other countries. Future studies, moreover, could consider a bigger number of comments compared to our 1,200 comments. Finally, this study is based on a single hypothesis but future research may identify further hypotheses investigating potential mediators of the tested relationship, by also considering the opportunity to assess control variables that were not included in our model.

Abstract

During the last years, economies and societies have seen a continuous change inside all their aspects. In this scenario, tourism has always played an increasing crucial role in the growth of many countries and the adoption of Information Communication Technologies (ICTs) has led to several transformations in the core of this sector. Specifically, tourism has registered a tremendous growth in the diffusion of technologies which tourists interact with for searching information, communicating, generating content, transaction, and has seen the use of tools like mobile apps, social media platforms, virtual tourism communities, able to transform the tourist's travel experiences and to support tourists in discovering new attractive destinations, scheduling activities, personalizing their travel, and, more in general, making smart decisions.

Moreover, the use of ICTs has culminated with the notion of Smart Tourism Destinations (STDs), where ICT is a driver for a smart growth and for the competitiveness of a destination. Further studies have enlarged this idea, highlighting that the fundamental constructs of a STD are human capital and social capital constructs, supported and enabled by advanced ICT infrastructures.

In order to work toward the development of a smart and sustainable tourism destination, it is necessary to assess the “state of the art” of a tourism destination under different perspectives and evaluate its promptness to adopt a smart configuration. In literature several authors have considered many aspects of smart tourism and STD. Nevertheless, there is the need of investigative and holistic frameworks able to integrate all the perspectives of a STD.

Accordingly, the aim of this paper is setting up a conceptual methodological framework that integrates different levels of analysis using several dimensions characterizing a tourism destination. Such framework attempts to assess and evaluate the state of the art of a tourism destination in terms of smartness, to provide hints among the tourist actors toward the development of a sustainable tourism destination and to improve the customer perception of a destination.

Keywords – Smart Tourism, Smart Tourism Destination, Methodological framework, Smartness (*max 5 words*)

Paper type – Academic Research Paper

1 Introduction

Over the last two decades, economies and societies have seen a continuous change inside all their aspects. The daily challenge of each sector is to recognize the changes, adapt to these forces of change and exploit them as their own advantages. In particular, the expansion of the Internet and the adoption of Information Communication Technologies (ICTs), such as social media, mobile applications, recommender system and so on, have changed the global industry structure (Sigala 2018; Gretzel et al., 2015). Tourism has always played an increasing crucial role in the growth of many countries (WTTC, 2019) and the adoption of ICTs in this sector leads tourism companies and, in general, destinations to gain competitive advantage by differentiating their products and services or the fruition of their natural resources (Buhalis et al, 2019; Boes et al., 2015). In particular, the embracing of this cutting-edge technologies have led to the birth of the concept of Smart Tourism Destinations (STD), considered as a strategic way for tourism development (Jovicic , 2019; Femenia-Serra and Ivars-Baidal, 2018; Gretzel et al., 2015).

In the recent years, governments, recognizing the potential of smartness and the importance to adapt to this rapid changes, has adopted political strategies aimed at enhancing sustainable development and economic growth (Meijer and Bolívar, 2016; Cocchia, 2014; Nam and Pardo, 2011) among all the stakeholders in the tourism ecosystem.

Moreover, in the destination management new approaches are needed in order to conform to the structural changes, together with the employment of new technologies, with the aim of interacting within the stakeholders (Gretzel et al., 2015), making destinations more competitive (Wang et al., 2013; Gretzel et al., 2015), offering more personalised services to tourists and generating an enhancing tourism experience and create value (Del Vecchio et al., 2018; Weissenberg, 2017; Boes et al., 2015; Buhalis and Amaranggana, 2014; Lamsfus and Alzua-Sorzabal, 2013).

In this scenario, the definition of the “state of the art” of a destination and its promptness to shift toward a smart configuration required the definition of a methodological framework that integrate different level of desk and field analysis on the different dimensions characterizing a tourism destination.

Here it is proposed a conceptual methodological framework that integrates different levels of analysis on several features characterizing a tourism destination and delineating its promptness to adopt a smart configuration, through a focus on the major trends, challenges and opportunities, the physical and technological infrastructure, the level of cooperation culture and attitude, the level of skills and competencies of the tourism workforce and the level of institutional support.

This framework has been adopting in the NEST (Networking for Smart Tourism Development) Project. NEST is a cross-border project between Albania, Italy (Molise and Apulia) and Montenegro, aimed to sustain the competitiveness of the Ionic-Adriatic destination by empowering Tourism Enterprises (small and medium ones, SMTEs) with innovative approaches, tools and strategies that leverage on the potentialities of digital technologies, networking and collaboration.

This paper is organised as it follows. In Section 2 it is reported a brief literature review. In Section 3 the methodological framework is described. In Section 4 the results from a preliminary analysis are shown. Finally, Section 5 concludes the paper describing the implication of this study.

2 Literature review

In the recent years, Smart Tourism has become a hot topic of growing actuality among both researchers and destinations' managers (Jovicic, 2019; Del Vecchio et al., 2018; Weissenberg, 2017). This concept has been applied to describe the increasing reliance of Tourism Destinations, their industries and their tourists on emerging forms of ICT that allow for massive amounts of data to be transformed into value propositions (Xiang & Fesenmaier, 2017; Gretzel et al., 2015).

A Tourism Destination can be compared as a cluster of interrelated stakeholders embedded in a social network that interact, jointly meeting visitor needs and producing the tourism experience (Baggio et al., 2010). Recently, tourism sector registered a tremendous growth of the diffusion of search engines, new distribution channels, virtual tourism communities and numerous social media platforms that support tourists to make smart decisions (Buhalis et al., 2019; Sigala, 2018). The diffusion of mobile technology and wearable devices has further transformed the tourism experience enhancing the tourists' empowerment by bringing together information search, communication, entertainment, social networking and mobility-related functionalities (Doric et al., 2019; Tussyadiah and Zach, 2018). Moreover, tourists are shifting the competition toward the co-creation experience as a basis of value and as the future of innovation (Marasco et al., 2018; Neuhofer et al., 2015; Prahalad and Ramaswamy, 2004).

These advancement of technology in tourism has culminated with the notion of STDs, where ICT is a driver for a smart growth and for the competitiveness of a destination (Femenia-Serra and Ivars-Baidal, 2018). The STD is understood as a local tourism system characterized by advanced services, high degree of innovation and the presence of open, integrated and shared processes for enhancing the quality of life for both residents and tourists (Micera et al., 2013; Wang et al. 2013; Caragliu et al., 2009).

One of the most relevant definition of STD available in the literature is the one provided by Gretzel et al., (2015), that defines it as:

*“integrated efforts at a destination to **collect and aggregate/harness data** derived from **physical infrastructure**, social connections, **government/ organizational sources and human bodies /minds** in combination with the use of **advanced technologies** to transform that data into **on-site experiences and business value-propositions** with a clear focus on efficiency, sustainability and experience enrichment”.*

From the previous definition, it has been highlighted some of the most important key elements characterizing a Smart Destination, that have the final aim of sustainability, efficiency and experience enrichment. Moreover, all these feature can be found in the conceptual layers developed by Gretzel (2017), shown in Fig. 1, and which the analysis of the smartness of destination should be focused on.

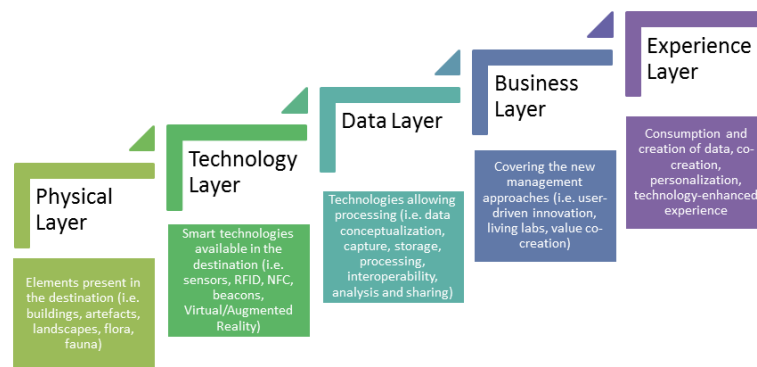

Fig. 1 Conceptual Layers of Smart Tourism (adapted from Gretzel, 2017).

Therefore, STDs can be perceived as places utilising the available technological tools and techniques are considered a means to deliver services to consumer (Helkkula et al., 2018) that enables demand and supply to co-create value, pleasure, and experiences for the tourist and wealth, profit, and benefits for the organisations and the destination (Buhalis et al., 2019; Boes et al., 2015). While many researches primarily has focused on the implementation of technology for the smartness of a tourism destination (Guo et al., 2014) and in its incorporation within the development and production of tourism processes (Wang et al., 2013), Buhalis and Amaranggana (2014) have enlarged this idea, dealing with the building of STDs as a generic framework of inherited concepts that incorporate competitiveness, sustainability, and inclusiveness bases. Boes et al. (2015) have argued that the fundamental constructs of a STD are first of all human capital, which forms the base for the leadership, entrepreneurship and innovation, and social capital constructs, and that these are supported and enabled by advanced ICT infrastructures. Moreover, ICT, people (intended as human capital, social capital and knowledge management) and leadership (meant as participatory government, policies and

regulations, change management), if intertwined and interconnected within the smart ecosystem process, can become contributors to the smartness concept and should therefore be enhanced and developed to co-create innovation (Femenia-Serra and Ivars-Baidal, 2018; Boes et al., 2016; Ndou and Petti, 2005).

Therefore, to create a STD means to have a participatory government that ensure political strategies and policies aimed at enhancing sustainable development and economic growth in the tourism sector, to have available advanced ICT infrastructure, to have access to real-time information (coming from sensors or citizens and visitors as digital footprint from their social media activities), to digitalize the core of business processes, the tourism structure to adopt technologies and improve their services, to engage both the community and the tourist participation for co-creating tourism experience, and so on.

For all these reasons, in order to work toward the development of a smart and sustainable tourism destination, it is necessary to assess the “state of the art” of a tourism destination under different perspectives and evaluate its promptness to adopt a smart configuration.

In literature several authors has considered many aspects of smart tourism and STD, in order to examine how important smart tourism technologies’ characteristics, such as information quality, interactivity, and accessibility, influence travellers’ decision making process and thus lead to their travel decision support satisfaction (Yoo et al., 2017); to investigate tourists’ preferences of smart tourism quantitatively in a tourist attraction context and give useful directions for the diagnosis of strengths and weaknesses of smart tourist attraction construction (Wang et al., 2016); to identify and clarify the employability skills deficits in rural hospitality and tourism destinations (Adeyinka-Ojo, 2018); to understand how smart cities may foster collaboration ecosystems that may improve both the standards of living and the competitiveness of urban spaces (Appio et al., 2019; Hutchison et al., 2011; Giffinger et al., 2007). Nevertheless, any studies show how to evaluate the degree of smartness of a destination.

Due to the dearth of literature in this important aspect, the aim of this paper is to set up a conceptual methodological framework that integrates different levels of analysis on the different dimensions characterizing a tourism destination and that could be used for assessing and evaluating the state of the art of a tourism destination, in terms of smartness.

3 Methodological Framework

As aforementioned, the methodological framework here proposed aims at giving support to the tourism stakeholders in order to highlight strengths and weakness and providing hints, by taking in consideration several parameters that characterize a destination, such as the presence of attractions, physical and technology infrastructures, business companies, the adoption of political tourism strategies, and tourists that contribute to the definition of tourism experiences.

In particular, for assessing the smartness of a tourism destination, it is necessary to analyse tourism destinations from two main perspectives: the *macro-environment* and the

micro-environment. Regarding the macro-environment, the investigation aims to inspect all the characteristics of a destination, the economic impacts of the sector, the main opportunities for tourism, and so on. On the other hand, in relation to the micro-environment, the attention has been focused on both business and customer perspectives, so on one hand on the tourism firms' competitiveness, their technological promptness, the diffusion/adoption of ICT tools and, simultaneously, on those tools, methodologies and approaches useful to define customers profiles, to understand and anticipate their needs, to personalize tourism offers, to co-create tourism experience and evaluate customer satisfactions.

In Fig. 2 it is portrayed the methodological framework proposed. As it can be seen, the framework is made up of three phases: the macro-environment analysis, the micro-environment analysis and, finally, the customer experience analysis. As aforementioned, the framework is based on the conceptual layers that defined a STD, as reported by Gretzel (2017), and embraces the idea that the intertwining and the interconnection between leaderships, people and ICT contribute all together to the development and growing of a STD. Moreover, the presented framework specifies what are the crucial elements for the analysis and how to perform it, pointing also out some global indicators available from different sources.

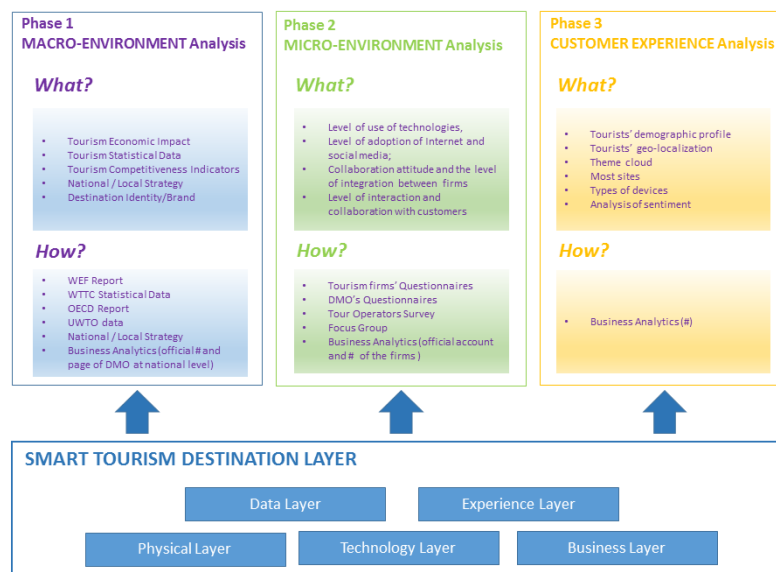

Fig. 2 Methodological Framework.

Both the macro- and micro- dimension of a tourism destination involves different layers, from the physical to the business one, passing through the adopted technologies and data layers, and are strictly related to the final destination image.

3.1 Macro-perspective analysis

The macro-dimension analysis of a destination starts from the study of the impact of the tourism sector within the economy of a country, by taking into consideration some key indicators, such as the tourism direct / indirect contribution to GDP, to employment, investment and visitors exports. Additionally, the economic impact of tourism sector is integrated with statistical information, such as the touristic flows (in terms of domestic, inbound or outbound tourism), the tourism receipts and expenditure, and other useful information about tourism enterprises, in order to describe trends and opportunities for the development of a STD.

The definition of the state of the art of tourism destination also needs to study the competitiveness of tourism destination, where destination competitiveness refers to the ability of destinations to deliver better tourist experiences and to create a better living environment for local residents and other destinations.

Understanding country competitiveness in tourism is a major consideration for policy makers and a major challenge for professionals in providing evidence to inform decision making. During the last years, various indicators have been developed by different organizations to address particular aspects of competitiveness, such as the T&T Competitiveness Index, defined by the World Travel & Tourism Council (WTTC), which is considered to adopt the most complete and modern set of indicators globally available to measure it.

Besides all these indicators, the study of destination brand or identity, which can be performed through the use of business analytics on the social media platforms, assumes an important function in this analysis, as well as the political and regional tourism strategies, which play an important role for the development of tourism destination and its competitiveness. Thus, the study of tourism strategic plan at both national and regional level, its objectives and approaches can offer useful information related to the destination at a macro-level perspective. In fact, the central argument is to see how and to what extent institutional capacity for coordination, collaboration and cooperation can be efficiently used as a governance practice (the efficiency of governance) to improve tourism destination competitiveness, helping to transform tourists needs into solutions and opportunities for a smart, inclusive and sustainable growth.

3.2 Micro-perspective analysis

In order to ameliorate the final destination image and to establish a relationship of loyalty with tourists, the different players of a touristic location have to act in an interconnected way, making available highly innovative services at the aim of making unique their experience. In this scenario, smart technologies play a crucial role in the development of STD and of the final destination image, arising from the convergence of ICTs with the tourism experience and its enhancement through personalization, context-awareness and real-time monitoring. Therefore, the micro-dimension analysis of a destination is based upon the study of the dynamic interconnection among different stakeholders for service co-creation, service exchange and value co-creation and both

social media and internet tools are instrumental in enabling firms to develop such dynamic connections, as technologies enable them to network.

To this aim, for grasping the detailed performance of the emergent features of a STD from a micro-dimension perspective, a field research methodology could be appropriate. This field research consists on gathering data regarding the promptness of the location to adopt a smart destination approach through the definition of surveys to be administered to different typologies of tourism players, such as hospitality firms (hotels, B&B, agritourist, and so on), intermediary (travel agencies, tourist guides, and so on) and Destination Management Organizations (DMO), and so on. Each question has the objective to define the level of smartness of the tourism in a specific territory in terms of its readiness and promptness for the adoption of digital technologies, creation of digital local experiences, the capacity to network and collaborate, and, mostly, to evaluate the following indicators:

- The level of use of technologies, internet and social media;
- The collaboration attitude and the level of integration with the other actors of the tourism system for creating new innovative opportunities;
- The level of interaction and collaboration with customers for experience and service co-creation.

3.3 Customer-perspective analysis

As aforementioned, one of the most fundamental layers in the touristic field is the experiential component. This layer focuses on the affective and emotional component of the consumption process. The concept of experience is strictly connected with the entertainment aspect and implies the consumer participation and interaction during the product/service creation. In other words, the contemporary tourists want to live a unique experience and are not interested anymore in purchasing a standardized product/service. So, in order to meet the new needs of the demand, the tourist destinations must give top priority to the achievement of tourist satisfaction.

Moreover, the importance of the experiential layer and the consumer satisfaction is crucial because of its great impact on future consumer intentions, loyalty and word-of-mouth communications, especially in the touristic sector.

In fact, in the era of Internet-based social media technologies, information is accessed and shared differently from the traditional way. Social networking sites have changed the way in which people plan their travels (Sigala, 2018; Gretzel et al., 2015; Hudson and Thal, 2013) and plays a key role in word-of-mouth communications and decision making processes, especially in a travel and tourism context, where tourists, sharing information on platform like TripAdvisor, Booking, Yelp and so on, help other tourists in their travel planning and influence potential travelers' decision making (Zeng and Gerritsen, 2014, Filieri and McLeay, 2014, Sparks and Browning, 2011).

The use of this data can facilitate touristic firms in knowing the needs of tourist and in planning some processes, such as advertising, sharing just in time information about attractions, catering facilities and transportation alternatives, and so on. Using the insights gained from large and complex data is important to uncover new opportunities for the business, to make decisions on the basis of numbers and analysis rather than anecdotes,

guesswork, intuition, or past experience. From the point of view of the tourists and in terms of mobile technology, having reliable real-time information always available is crucial in terms of enabling them to find their way.

In this way, Big Data Analytics strategy is also indispensable to ascertain consumer trends, travel patterns, threats, and opportunities. In particular, some of the enhancements that Big Data Analytics could bring for customer experience and business efficiency improvement are: personalizing the customer experience, helping travel companies in creating a better pricing strategy, customer analytics and improvement of services, marketing and sales optimization.

4 Preliminary Results

In the previous section it has been designed the conceptual methodological framework that has been developed in order to evaluate the state of the art of a tourism destination in terms of smartness under different perspectives, i.e. from a macro-, micro- and customer-perspective.

This framework has been adopted in the NEST Project. Primarily, in this specific context the methodological framework aims to understand in depth the level of smartness of the tourism in the context of the involved, giving an answer to the following issue:

- How to measure the impact of the tourism sector for the economy of each country covered by the project;
- How to measure the degree of e-readiness of Hospitality Firms, Intermediaries, Destination Management Organizations, through the use of questionnaires;
- How to quantify the perception of the final tourism destinations from the customer point of view.

Therefore, the adoption of this framework allows to enhance what are the major trends in each country of the context analysis, the main opportunities, the diffusion and the efficiency of both physical and technological infrastructures, if the cooperation between different tourism's actors exists and how profitable it is, if each country has different kind of support from institutions, and so on.

A preliminary analysis has been conducting under both a macro- and customer-perspective, with the aim of building the basis of a deeper analysis and of sketching out a first answer to the previously mentioned issues.

In particular, it has been investigating what is the role of travel and tourism in the economy of a country and how it contributes to the economic growth, in terms of GDP, created jobs, visitor exports (international tourism spend), domestic spending and capital investment.

Besides this macro considerations, the use of the Global Innovation Index (GII) has allowed to assess the presence of the ICT Infrastructure. The GII is an index that aims to capture the multi-dimensional facets of innovation and provide the tools that can assist in tailoring policies to promote long-term output growth, improved productivity, and job

growth¹. One of the pillar of the GII is Infrastructure, whose measure is the arithmetic mean between Information and communication technologies (ICTs), General Infrastructure and Ecological sustainability. To the aim of this analysis, it has been considered the evaluation in the field of ICTs, that is made up of four indexes: ICT access, ICT use, Government's online service, Online e-participation.

While in Fig. 3 it has been reported the trend of the ICT Infrastructure values of Albania, Italy and Montenegro in the years, from 2013 to 2018, in Fig. 4 it can be seen the details of the ICT Infrastructure pillar, as it has been reported the evaluations of the four indexes whose this pillar is made up.

Fig. 3 ICT Infrastructure values: from 2013 to 2018. Elaboration from GII 2018.

Fig. 4 ICT Infrastructure indexes for Albania, Italy and Montenegro in 2018. Elaboration from GII 2018.

¹ <https://www.globalinnovationindex.org/about-gii>

It is noticeable that the higher values are present in the Online e-participation and Government's online services. This tendency is almost justifiable by the latest European policies, aimed at simplifying procedures and bureaucracy and for this purpose adopting technological infrastructures. In general, all the indexes shows strong values and this implies that in all these countries the ICT Infrastructures are efficient, consequently it is possible to take advantages of the presence of these infrastructures and implement new services for citizens and tourists, to the aim of making "innovative" and "smart" a destination.

Behind this exploratory analysis from a macro point of view, with the help of business analytics, it has been gathered various data from social media platforms in order to analyse them and to explore the perception of the final destinations and the customer satisfaction.

After an introductory analysis on TripAdvisor, consisted in the discovery of the different activities proposed to the tourists for all the different regions and whose snapshot is shown in Fig. 5, analysing social media data from other online platforms has allowed to understand how much and how it is talked about a region, if the experience of the tourist is positive or negative, the effectiveness of the communication through the social network used.

Fig. 5 Proposed activities on TripAdvisor.

To this aim, four hashtags have been chosen in order to extract and analyse the social media data: *#Albania* for Albania, *#weareinpuglia* for Apulia, *#molise* for Molise, *#Montenegro* for Montenegro, all combined with *#tourism*. In this way, a first simple selection has been done. The tool used for the analysis is Brand24¹.

While in Fig. 6 it is reported the discussion intensity chart for the four countries, i.e. the graphic that shows the trend of the number of mentions of each related hashtag, combined with *#tourism*, in Fig. 7 it is shown the sentiment chart, that shows the trend of

¹ <https://brand24.com/>

the social sentiment analysis related to the contents. It is easy to note that the vast majority of the comments are positive for all the regions.

Fig. 6 Discussion Intensity Chart for #Albania, #molise, #weareinpuglia and #montenegro. Data elaborated with Brand24.

Fig. 7 Sentiment Chart for #Albania, #molise, #weareinpuglia and #montenegro. Data elaborated with Brand24.

This preliminary investigation through the adoption of the methodological framework here proposed has given the possibility to collect different kind of data gathered from several sources and to build the basis of a solid analysis from which it has been emerging both the strengths and weakness of each studied country, providing hints among the

tourist actors toward the development of a smart and sustainable tourism destination and the improvement of the customer perception of a destination.

5 Discussions and conclusions

In this paper it has been introduced a conceptual methodological framework that integrates different levels of analysis at a macro-, micro- and customer- level on different features that characterize a tourism destination and delineate its promptness to adopt a smart configuration.

In particular, in order to well characterize a tourism destination under the three different perspectives, several parameters, such as the presence of physical and technological infrastructures, of business companies and tourism attractions, and so on, have been included.

This framework has been adopted in the NEST (Networking for Smart Tourism Development) Project. A preliminary analysis under a macro- and customer- perspectives has allowed to highlight the efficiency of the ICT infrastructures and both the strengths and weakness of each studied country.

So this methodological framework reflects the possibility of implementing new services for citizens and tourists and attempts to provide hints among the tourist actors toward the development of a sustainable tourism destination and the improvement of the customer perception of a destination.

Finally, the ultimate perspective is to understand if the tourism destination has an ecosystem conception, by studying how much all the stakeholders are integrated within the development of the STD and the absorption of smartness by all the actors, being the country competitiveness in tourism a major consideration for policy makers and a major challenge for professionals in providing evidence to inform decision making.

Acknowledgments

This paper provides a contribution to the research related to the on-going research project NEST – Networking for smart tourism development - Project n. 96-1° call for standard project – co-financed by the European Union under the Instrument for Pre-Accession Assistance (IPA II).

Abstract

This paper aims to shed light on the link between digitization processes and market strategies in Italian museums. It is also addressed to understand how digital skills, held or accessible by the museum, do affect the organization's capability to match technological innovation and strategy.

We have adopted the multi-case study approach. A sample of Italian museums has been investigated through semi-structured interviews addressed to their managers.

Cases show how digitization processes are mainly driven by museums' accessibility to technical skills, as well as mimetic and normative isomorphism processes seem having a non-secondary role. This often brings to underestimate the required alignment between digital contents, digital skills held by the cultural organizations, and types of users.

Some early managerial implications may derive from this study. In fact, managers' awareness about the positioning of the museum can raise, as they reflect on the consistency between implemented market strategies, technologies in use, and digital skills held or accessible by the museum itself.

Keywords - Museums, digital transformation, digital skills, alignment strategy-technology-skills

Paper type - Academic Research Paper

1 Introduction

The fruition of the cultural heritage has always represented, for Italy, one of the most relevant items for the purposes of tourism development in individual cities or territories. Digitization processes can play a key-role in developing museums' ability to attract audiences and, consequently, boosting tourist flows, especially where the single museum or the local museum system represent a reference point for a tourism destination.

There is a widespread awareness that cultural organizations can benefit in many ways from the adoption of digital technologies. Collection, conservation and access to the cultural heritage in novel, accessible and attractive ways demand for digitizing museums, as well as for designing methodologies to represent, manage and exploit cultural heritage data at different levels. In Italy, as well as in many other countries, heritage organizations are currently engaged in choices regarding the adoption of digital technologies. However, either the literature or the empirical evidence suggests that not always these choices are the result of a clear perception and of a careful reflection about opportunities and limitations linked with the adoption of digital artefacts and devices.

Our paper aims to shed light on the link between digitization processes and market strategies in Italian museums housed in historical sites. Consistently with the exploratory nature of research, we adopted a qualitative approach; this has been carried out through the multi-case method. We wonder how digital skills, held or accessible by the cultural organizations, do affect the organization's capability to align technological innovation and strategy in Italian museums.

In the following paragraph we briefly illustrate the theoretical background; in section 3 we outline the research objectives and methodology; in section 4 we present the results of our analysis; and lastly, in section 5 we debate about such findings; finally, section 6 outlines the limits and the perspectives of the research.

2 Theoretical background

The general framework of reference is constituted by the relationships that exist between the firm's strategic choices, the digitization processes, and the development of digital skills. The literature review has been circumscribed to the analysis of these relationships in museums, as well as to the identification of some possible classifications and taxonomies, related to competitive strategies, technologies, as well as to the so-called "digital skills" within cultural organizations.

Research on the processes of digitization of cultural heritage, and in particular of the museums' collections, has initially privileged the analysis of technologies for the preservation of works of art, and for their remote fruition (through the Internet), and then moved on the role and the impact of digital technologies for on-site fruition. To date, two themes still seem to us insufficiently investigated in the literature: that of the relationship between choices relating to technology and the market orientation of museum institutions; as well as the question of the adequacy of digital skills and the connected degree of technology acceptance.

As regards the first issue, references to the necessary alignment between the choices of technology adoption and the market strategies of the museums are sporadic (Bertacchini & Morando, 2013; Kane, Palmer, Phillips, Kiron & Buckley, 2015; Solima & Minguzzi, 2015). Much of the research considers the introduction of digital technologies in museums as an independent variable, from which implications on organizational strategy, as well as on roles and skills, may arise. In other studies, the

analysis of the digitization process leads to the identification of alternative digital approaches (Gombault, Allal-Chérif & Décamps, 2016; Dewdney, 2018).

The topic of digital skills, on the contrary, is much more debated, but issues concerning technology acceptance are often neglected. Studies on this topic are mainly concerned with the identification of some possible classification criteria; otherwise they focus on the opportunities associated with the emergence of new roles and the evolution of existing roles within cultural organizations (Parry, Eikhof., Barnes & Kispeter, 2018).

In short, in our opinion the main gaps in the literature can be traced a) in the almost total absence of a debate about the relationship between the role of digital technologies and market strategies; b) in the lack of attention to the question of technology acceptance, both on the side of museum employees and on the users' side. A deepening in these two fields of research seems really desirable, in order to support museum organizations to pursue adequate levels of efficiency and effectiveness in the digitization processes underway.

3 Research objectives, methodology, and data collection

The first aim of our research was to assess the coherence between digital technologies in use and the competitive strategy pursued by museums. Besides, we wanted to understand how digital skills, held by the museum, do affect the organization's capability to match technological innovation and strategy.

We adopted a qualitative research design, that we carried out through the multi-case study approach. Indeed, the multi-case method makes it possible to highlight a variety of situations, even diverging from one another, with the ultimate aim of contributing to the elaboration of an explanatory theory (Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Yin, 2009).

The sample has been built according to the following criteria: a) combination of historical and artistic importance of the site and relevance of the collections housed in it; b) variety of the sample, according to the logic of multi-case method. The choice to select a sample consisting of art collections hosted in ancient palaces, castles, or villas is linked to the belief that this combination extolls the opportunities inherent in the digital technologies for on-site fruition (e.g. virtual/augmented reality devices). A significant variety of the sample was obtained by considering the following characters: ownership, year of foundation, annual number of visitors, characteristics of the collections hosted.

The main data relating to each museum are summed up in Table 1, below.

Table 1: The sample investigated

	<i>Museum</i>	<i>Place</i>	<i>Opening</i>	<i>Ownership</i>	<i>Visitors (2017)</i>	<i>Type of heritage</i>
1	National Gallery of the Marche at Palazzo Ducale	Urbino	1912	Public (government)	164.000	Renaissance painting
2	Museums at	Mantova	1881	Public	323.000	Thematic exhibitions

	Palazzo Ducale			(government)		
3	Museum at La Venaria Reale	Torino	2008	Public-private network	1.049.000	Paintings and sculptures from the 15 th to the 17 th century. Thematic exhibitions
4	Museums at Castello Sforzesco	Milano	late 1800s	Public (Municipality)	450.000	Museums of archaeological finds, wooden sculptures, ancient art, decorative arts, musical instruments. Renaissance sculptures and paintings
5	San Domenico & Palazzo Romagnoli Museums	Forlì	2005	Public (Municipality)	20.000	Frescoes and paintings from the Middle Ages. Archaeological museum (forthcoming opening)
6	Pontifical Museum Santa Casa	Loreto (AN)	late 1800s	Public (government)	20.000	Paintings and tapestries from the 15 th to the 19 th century.
7	Museums at Castello Scaligero	Malcesine (VR)	1960	Public (Municipality)	150.000	Natural history museum & museum of the Venetian galleys
8	Bali Museum	Colli al Metauro (PU)	2004	Private	50.000	Science museum

Data was collected through semi-structured interviews addressed to the managers of the museums, with the aim of drawing up deeper insight into the features of digitizing processes. Interviews were performed in the period november 2018-april 2019, either at the office of the manager or by telephone. They have lasted from thirty minutes to an hour and followed a precompiled track. However, we left managers free to investigate further points. Three main questions were posed about the following issues: type of market strategy pursued by the museum; type of digital technologies/devices in use and reasons that has pushed museums to their adoption; range of digital skills held by managers or employees in the museum, or externally accessible (at universities, museum networks, consultants,...). The data collected through the interviews were integrated with those obtained from the analysis of the museums' website. This with the aim of analyzing the main features of the museum offer, the types of services offered, and the methods of communication and interaction with the relevant public.

As regards market strategies, our reference model was that by Bakhshi & Throsby (2012, built on McCarthy & Jinnett, 2001). They distinguish between audience broadening, diversifying, or deepening; where the first refers to the "capturing a larger share of the population already known to be audiences", the second to the attraction of "new groups of consumers that do not currently attend", and the third to the "increasing and/or intensifying the engagement of audiences" (Bakhshi & Throsby, 2012: 209).

As regards digital technologies, the taxonomy proposed in Styliani, Fotis, Kostas & Petros (2009) and the distinction by Bonacini (2011) between remote fruition technologies (e.g.: website, social networks, multimedia, database) and on-site fruition technologies (e.g.: info-points, touch-screens, VR/AR devices) was used.

Lastly, we distinguished between *technical* digital skills (technological skills on solutions, platforms, programming languages, which characterize ICT roles) and *applied* digital skills (ability to use software and devices by the decision makers and the employees involved in routine tasks), following the distinction proposed by AICA & Assintel (2017).

4 Findings

The analysis of the sample of museums has led to a significant wealth of information, related on the one hand to the market strategies pursued, on the other to the digitization processes, and to the methods in which digital skills are developed or accessed.

Evidence gathered allow us to identify some common traits: among these a sufficient awareness of the potential of digital technologies in the development of the attraction capacity of the museums themselves, and the common recognition of the scarcity of financial means to support the digitization processes. Moreover, the fear that the technologies allowing remote access to collections are at the expense of the decision to visit the museum are resized from the analysis.

Below, we illustrate the results of the analysis following the outline of the interviews conducted. We will first analyze the strategic behavior of museums, then the choices of introducing digital technologies; finally, the substance of the digital skills that support the processes in place.

4.1 Market strategies

The market strategies of the museums being analyzed are mainly oriented towards increasing the number of visitors (audience broadening). This trend is present in the different types of museums, but especially in the state museums, evidently pressured by the need to reach targets concerning the number of visitors. The strategy of expanding the public is absent in the museums that have already a high number of visitors and who believe that the time has come to deepen the relation with the existing public or to approach segments of the population that are traditionally not inclined to visit museums.

The strategy is rarely clear and unambiguous. On the contrary, in most cases the will to pursue multiple strategic objectives is declared. The strategy of audience broadening is combined with others, aimed now at audience deepening, now at audience diversifying. Finally, in a couple of cases, strategies of audience deepening and diversifying are combined.

In terms of alignment between strategies and technologies, we can hypothesize that both the multiplicity of strategic objectives and the choice to focus on widening the audience with an undifferentiated approach, represent situations in which it is not easy to discern which technologies are most consistent with what strategies. On the contrary, the strategies aimed at audience deepening or diversifying may offer more precise indications about the digitization path to go.

4.2 Digital technologies

The analyzed museums highlight different combinations of remote and on-site fruition technologies; however, if we also consider the digital devices to be installed in the short term, apart from a couple of extreme situations, differences appear to be fairly limited, in relation to the high variety of the sample. At the moment, we can say that none of the analyzed museums have reached the "digital transformation" stage; however, as at least in one case (Museums at Castello Sforzesco) this goal seems to be really at hand.

As regards remote access technologies, the use of websites and social networks is almost generalized, even if their contents vary considerably; in particular, the choice of making a virtual tour possible is an exception (Museums at Castello Sforzesco), and is openly opposed in other cases. The construction of digital archives is also quite widespread, but it follows different approaches and logics from case to case.

With regard to on-site fruition technologies, touchscreen applications are the most widespread, while there is a certain hesitancy with the adoption of VR / AR instruments, that is presumably due to the challenging management of these tools. On-site fruition technologies is the category in which a more pronounced dynamic is expected in the coming years; however, this dynamic appears to be conditioned by the future availability of resources.

As for the reasons factors that have influenced the decision to adopt digital technologies, it is quite evident as the example of other museums has played an important role, together with the proposals formulated by IT consultants. These two modes often occur, regardless of the nature of ownership or the size of the museums that have been studied. It can be said with some certainty that these two factors weighed much more than the analysis of the preferences of the audience. Hence, it seems possible to state that mimetic and normative isomorphism processes constitute a powerful driver of ongoing digital transformation processes.

4.3 Digital skills

With reference to digital skills, the survey has allowed us to gather information regarding both the competences currently held, and those that are expected to be developed in the coming years. At the moment, none of the sample museums can be said to be completely self-sufficient in terms of digital skills. However, the differences from one museum to another are considerable, with regard not only to the stock of skills currently held, but also the intention to develop them in the coming years.

At one extreme we find museums that, while having at their disposal only some applied skills, that are concentrated in a few roles, do not feel the need to rebalance a situation of marked dependence on the outside (universities, software companies and digital consultancy, etc.). At the other extreme, there are museums that, despite being already in possession of some technical skills, other than the applied ones, show a clear orientation to further develop them and to make them widespread among all the roles. This in order to reduce their dependence on the outside, which does not give sufficient guarantees with regard to the development of the systems and their maintenance. Even the

simple availability of widespread applied skills seems to constitute a good result, because it is believed that an adequate level of digital literacy can favor the development of ideas and proposals to make the digital equipment of the museum more in line with the current and potential audience.

The analysis suggests that the proprietary nature of the museum can be a relevant factor for the possibility of developing a wide range of digital skills internally. From this point of view, private museums and civic museums that are part of an integrated circuit seem to be favored: in fact, for the latter, there is the possibility of developing at central level (e.g., municipality) some technical skills, without the need to develop them internally in each museum.

Table 2: Market strategy, technologies in use, and digital skills

	<i>Museum</i>	<i>Market strategy</i>	<i>Digital technologies</i>		<i>Digital skills</i>	
			<i>Off-site</i>	<i>On-site</i>	<i>Currently</i>	<i>To be developed</i>
1	National Gallery of the Marche at Palazzo Ducale (Urbino)	Audience broadening Audience deepening	Website Social networks Digital archives (under construction)	Virtual reality, Augmented reality, eye tracking technology (to be installed)	Internal, concentrated (applied) External (technical)	No change
2	Museums at Palazzo Ducale (Mantova)	Audience broadening	Website Social networks	Touchscreen station (out of order) Digital info-point	Internal, concentrated (applied) External (technical)	Development of internal skills (technical), if financial resources are available
3	Museum at La Venaria Reale (Torino)	Audience deepening	Website Social networks Digital archives Chatbots technology (to be installed)	Multimedia device	Internal, widespread (applied) External (technical)	Digital Manager to coordinate digital strategy
4	Museums at Castello Sforzesco (Milano)	Audience deepening Audience diversifying	Website Newsletter Social networks Digital archives Virtual Tour	QR code Touchscreen stations Multimedia device Virtual Reality	Internal, widespread (applied) Internal, concentrated, and external (technical)	Less use of external skills
5	San Domenico & Palazzo Romagnoli Museums (Forlì)	Audience deepening Audience broadening	Website Newsletter Social networks PatER Portal	Touchscreen stations Smartphone e tablet apps QR code (to be installed)	Internal, widespread (applied) Internal, concentrated (technical)	Deepening of internal skills (technical)
6	Pontifical Museum Santa Casa (Loreto, AN)	Audience broadening	Website Social networks (to be installed)	Touchscreen stations (to be installed)	External (applied and technical)	Deepening of internal skills (applied)

7	Museums at Castello Scaligero (Malcesine, VR)	Audience broadening Audience diversifying	Website (municipality) Digital archives	Touchscreen stations Multimedia device	Internal, widespread (applied) External (technical)	Internal development (applied), if financial resources are available
8	Bali Museum (Colli al Meatu, PU)	Audience deepening Audience diversifying	Website Newsletter Social networks Online use of astronomical observatory	QR code Multimedia device <i>(to be installed)</i>	Internal, widespread (applied) Internal, concentrated, and external (technical)	Deepening of internal skills (technical)

5 Discussion

Museums that adopt digital technologies aimed at facilitate the off-site fruition of the heritage are those in which, generally, applied skills prevail or are exclusive. These organizations focus on activation of new channels to reach the audience. To achieve this goal, they just adopt platforms (e.g. social media or websites) with a low barrier to enter, but which simply "tell" about the activities carried out in the museum (e.g. events, news, etc.). This approach can be defined as "storytellers". When the museum integrates applied skills with technical skills it can offer online access to the collections, going beyond a mere narration of the heritage (for example, through online access to the archive or virtual tours). This is an approach to the use of technology that we could call "wikipedian", because it aims to facilitate the accessibility of the heritage even to people (physically) far from the museum.

In turn, museums that choose to use technology as a tool to improve the on-site experience seem to be guided by two main options, which are linked to the type of skills (technical or applied) to which they have access.

The first option tends to use technology to spectacularize the visiting experience. Usually hardware devices (e.g. augmented reality devices) are implemented to allow visitors to access specific contents that integrate physical accessibility. Since these museums add a multimedia component to the on-site experience, this approach defines them as "entertainers". This option assumes that the museum has access to all the (technical) skills needed to implement this type of solution within the museum.

The second option, on the other hand, sees technology as a tool to facilitate the orientation of visitors within the museum, while improving the interpretation of the exposed heritage, through touchscreens or other devices that can provide those information that can improve the accessibility from a visitor perspective. Museums that adopt this approach can therefore be defined as "navigators", and they choose it when the set of accessible skills is mainly applied.

6 Conclusion

This paper represents a first attempt in understanding the phenomenon of digital transformation in the Italian museums. The variety of the analyzed sample allowed us to identify different approaches to digitization processes. Moreover, our research provided new insight in order to understand how held or accessible digital skills drives decision-making process regarding the deployment of technologies. Finally, our findings enforces our initial assumption and outlines the need of a better alignment between the choices concerning the adoption of fruition technologies, and the market orientation.

Our findings have some managerial and theoretical implications. As for the first ones, we believe that the reflections developed in the paper can help managers to choose in a more conscious way the adoption of digital technologies, evaluating in particular their sustainability over time, based on possessed and accessible skills.. Instead, as far as theoretical implications are concerned, our study contributes to strengthen the research concerning the processes of digital transformation in museums, by emphasizing the need to jointly consider the choices relating to strategy, technology and key-competences.

Among the limitations of the research we underline the fact that we have carried out only one interview for each museum. A further limitation concerns the fact that we have simply obtained a “snapshot” of the progress of digitization processes, whereas the ongoing process of digitization should benefit for a prolonged observation, in the logic of a longitudinal research.

Based on these limitations, it is possible to identify two lines of research development. On the one hand, it will be interesting to monitor how the analyzed museums proceed on the digitalisation path they have taken; on the other hand, it will be equally useful to test the conceptual model proposed through a quantitative survey on a large-sized sample, so as to identify possible correlations between some features of museums and ways of digital transformation.

Abstract

Nowadays the retail industry is changing so fast by means of digitalization processes. Digital and interactive technologies are mediating relationships and strategies among actors and modifying the way through retailers manage their value propositions. This paper applies an ecosystem perspective and represents a preliminary study about the contribution of technology to the workability, management, and survival of retail ecosystem. In particular the work compares service ecosystem features with retail industry dynamics focusing on the role of technology. A qualitative methodology has been adopted emphasizing specific focus useful to further academic research and to practitioners in order to consider retail sector as an ecosystem. Specifically, findings achieved are threefold. Firstly, this paper presents the technology as a key actor able to give a 'soul' to the ecosystem multiplying the relationships and improving the resource integration. Secondly, the work considers the relationship management as a key feature to deal with complexity and to help the retail ecosystem to survive during the time. Finally, considers the retailer as the actor able to balance the equilibrium among actors in a retail ecosystem, due to the multiplicity of actors involved and directly connected and the mutual influence they play.

Keywords – Digital technology, ecosystem, food, retailing

1 Introduction

Nowadays the digitalization process affecting people daily life is also broadly transforming many elements of the retailing industry (Hagberg *et al.*, 2017; Hagberg *et al.*, 2016) in general, and in food retail industry in particular. Digital technologies – considered in a wide sense and including interactive technologies (Huang, 2019; Poushneh, 2018) such as: Augmented Reality, Virtual Reality, Internet of Things, and so on – are mediating relationships among actors. Indeed, these technologies are modifying the way through retailers have to manage their relationships (both upstream and downstream), strategies, and their value propositions (Balaji and Roy, 2017). The widening of scholars' debate and of supply chain impact is mirrored even in the attention paid to food supply chain is growing, since they are considered as a driver of sustainability for several actors and in various perspective.

Retail sector today has a key role as sensitive and connective actor in the network of interacting actors; the cooperative retailers, retail chains, large scale distribution represent the organisations able to sense and feel the market transformation and in specific sectors, retailers are able to influence the market changing (Sansone *et al.*, 2017). Within the last years around the world, within the private labels evolution, retail sector has become an influencer (Briggs *et al.*, 2018) about customer decisions and in some cases, lifestyle and habits. This contributed in determining actors evolution and competition in this industry that involve supply chain and, in general, supply network, in particular the influences involve relationships between producers, retailers and customers.

Activities based on resource integration could be represented as belonging to systems of value founded over SMART concepts (Spohrer and Maglio, 2010a) and research streams about Service Systems in a hypothetical SMART planet (Spohrer and Maglio, 2010b) present the relevant role of technology in providing value. Each action, relation and interaction between supply networks (retail industry included) is (and it will be) managed and optimized by technology. So, technology is the main entity able to improve the opportunity of interaction between direct and indirect involved actors in systems.

Interactive technologies (Huang, 2019; Poushneh, 2018) contribute to shed the light on retail evolution direction and its use could represent elements of differentiation between chains, a relevant asset in gaining competitive advantage and a powerful tool to get realistic retail ecosystem.

2 Theoretical Background

2.1 Retail development in complex markets

Economy and world's relationships are affected by complexity due to a multiplicity of forces that act on organizations, people, politics and markets. The technology, nowadays, it is affecting the everyday life from company and customer side and it represents a key point in increasing (or reducing) complexity in relationships. Focusing on retail industry, many actors are involved in the value proposition activity. In this context value chains

and supply networks assume a role that go beyond the classic supply optimization and they become resource integrators able to contribute in generating benefits for every actor involved in the system, customer included (Groves, 2001). The traditional retail industry goals identified in providing goods, services and giving an impulse to the economy (Ilbery and Maye, 2006; Paddison and Calderwood, 2007) is aggravated by emerging roles. In particular retail sector has to stimulate and provide innovation (Pantano, 2014), integrate its knowledge within the supply network with key strategic factors such as service and technology (Kandampully, 2012) and with supply customisation looking at changes in consumption and lifestyle (De Kervenoael *et al.*, 2006; Woodliffe, 2004).

Particularly, large scale retail trade reacts to the environment stimuli adapting formats, concepts, marketing, and management approaches (Sansone *et al.*, 2017; Bruni, 2014) generating effects for industrial companies, logistics and change in consumer behaviour. The complex scenario that is affecting retail industry, customers and production needs to be studied eventually thinking to new paradigms and frameworks able to obtain more integrated perspectives and points of view. The ecosystem approach seems to be useful to the goal.

2.2 Ecosystems: a brief theoretical background in business and management

Complexity, fast communication, technologies, networks and relationships characterized this era are going to define new paradigms where could be useful to represent the actors interaction scenario in every field of interest. Considering the different outlooks in social science literature, the ecosystem seems to be a useful framework to study and interpret the actors relationships in social contexts (Moore, 1993; 2013). Different authors are working around this topic (Aarikka-Stenroos and Ritala, 2017) by multiple perspectives with a focus on business context. Literature (Aarikka-Stenroos and Ritala, 2017) is interested in describing the characteristics of interdependence and co-evolution of the business and innovation activities using ecosystem paradigm. The interdependence is represented by systemic characteristics of ecosystem and mutual dependence and continuous change of perspectives by events and activities within the ecosystem and the co-evolution is studied as ecosystem characteristic based on collaborative forces between the actors directly and indirectly involved in the ecosystem survival.

The ecosystem research branch is complex and relatively new in business marketing and management. Holmqvist and Diaz Ruiz (2017) present a contribution selecting scientific manuscripts that present three principal perspectives able to represent the same resources integration but explained by names and different points of view: a) markets (Araujo and Kjellberg, 2009); b) business networks (Cantù *et al.*, 2012); c) service ecosystems (Vargo and Akaka, 2012). They found contact points but differences in interpretation and definitions respect to these aggregations (spontaneous or finalized). Long-lasting relationships and interdependencies are identified as similar characteristics but at the same time, only the service ecosystem approach includes the customer as part of the business context management. In particular service ecosystems include the

customers as part of ecosystems and present the customer satisfaction as final purpose (Wieland *et al.*, 2015). As per (Aarikka-Stenroos *et al.*, 2017) 4 groups of researches express the ecosystem characteristics: a) competition and evolution; b) emergence and disruption; c) stable business exchange; d) value co-creation.

2.3 Ecosystem and retail

Diffusely the concept of ecosystem is applied in retail sector identifying, theoretically and practically, the wide relationships between retailers and suppliers in market contexts. Widely authors refer to retail in practical and theoretical works around ecosystems particularly following business approach (Moore, 1993; 2013) and service approaches (Aarikka-Stenroos and Ritala, 2017). Further Barile and Saviano (2014) state that a change in perspective and a new approach to retail service marketing using a service view is necessary.

Following a systemic and service approach, Sansone *et al.*, (2018) state that the ecosystem paradigm could be used to explain the latent and modern concept of retail and to express the process of interaction among a multiplicity and variety of emerging institutions through resource integrations in the retail market. Food supply chain and retailing set of actors as an ecosystem (Macfadyen *et al.*, 2015) is based on the need to consider the multiple roles and activities played to complete food retailing, moving, for instance, from the field to the table. Practitioners are aligned to scholars in defining the retail context as an ecosystem and in identifying the role of technologies as pivotal in shaping the ecosystem through changing relationships (IDC, 2016).

The retail context (food and no-food) should search for new paradigms to deep the pivots of the next steps in a future characterized by resource integration with the manufacture industry and with customers and related customer associations.

Anyway, it is still needed to understand how these actors negotiate and – when needed – counterbalance their interests when diverging. In food retail industry for instance, local farmers, big players of the food retailing industry, consumers, and all the actors surrounding the triads among the actors mentioned before (Frishammar *et al.*, 2018), should be considered in order to describe the interplay they have as a win-win game or a ‘zero-sum’ strategy. Aiming at understanding the dynamics describing how this clash takes place, a depiction of the retail ecosystem is needed and the role technology has in shaping it is the first step to be done. Technology has been considered in relation to retail ecosystem as a way to shape interactions with customers (Balaji and Roy, 2017), in different ways from a country to another (Child *et al.*, 2015), leading to industry transformation (Hänninen *et al.*, 2018).

2.4 Ecosystem and technology

Following a B2C perspective, this research is framing retail as an ecosystem, as in the pioneering consideration by Demirkan and Spohrer (2014), as they identified technology as a factor modifying society and retailing contexts, offering new solutions, and enhancing customer involvement and experiences.

The relevance in using ecosystem framework in explaining retail dynamics and the relevance of technological studies within retail evolution and customer relationships is strictly related to the fact that retail is always been an integral part of society. In retail evolution technology has always played a role as the first author of change. In particular, nowadays, the digital transformation affecting society and retail digitalization (Hagberg *et al.*, 2016; 2017) are modifying retail sector and shopping experience helping retailers to survive (Berman, 2019) and satisfy consumers needs'. On the same way, technology gained the a relevant role in customer life, stimulating customer expectations and needs (Hopping, 2000). This era is considered as the "fast era" with several example in retail context such as fast food, fast fashion, fast live in general, and in the same way the consumer is now changing faster. Nowadays, a growing number of smart consumer, digitally-connected and price-conscious are exploiting various retail channels (online and offline) to find products at the price they want (Aubrey and Judge, 2012). Fundamentally digital technologies mean as interactive technologies (Huang, 2019; Javornik, 2016; Poushneh, 2018) in the past few decades shown a significant implication for a traditional form of retail by emphasising the engagement of customers involved in the shopping process (Yadav and Pavlou 2014).

In digital technology connectivity and interactivity represent the principal features (Huang, 2019; Berman, 2019; Yim and Park, 2019) able and useful to increase the willingness to buy of customers (Poncin and Mimoun, 2014). By considering on one side the main characteristics of digital technologies such as high connectivity, interactivity, fast usage, and on the other side the expertise of consumers such as greater awareness in the use of technologies, greater shopping skills and increasingly demanding needs, emerges the necessity to consider the technology as the principal enabler of retail ecosystem.

Studies showing benefits of immersive technologies such as virtual and augmented reality are becoming numerous, specially to define main feature for the creation of innovative and efficient stores (Pantano and Servidio, 2012). The retailers awareness in the use of technology is translated in the application of a variety of systems, such as self-service technologies equipped with interactive touch screen displays, 3D virtual reality systems, mobile apps, and so on (Demirkan and Spohrer, 2014; Dennis et al., 2014; Rese et al., 2014; Pantano, 2016). Benefits come from these technologies are related with more realistic interactions, customized virtual products, augmented products and environments in order to catch the consumer's attention (Lee and Chung, 2008) both online and offline. By considering as an example an online store based on 3D virtual environments, users can explore and experience products and service directly through Internet in a more immersive and interactive manner (Lee and Chung, 2008; Liu, 2010). In the same way with the support of Augmented Reality in a physical store, for example, consumers can perform several activities such as interacting with the products, visualizing details, requesting and findings customized information able and useful to influence their final purchasing decision (Liu, 2010).

This broad overview on the relevance of technology in retailing considered as an ecosystem, is further highlighted by Finsterwalder (2018) to stress the ties linkages

among engagement, value, and actors' ties and to call for further research in order to clarify how technologies affect customers engagement in services industries. Similarly, technology can affect consumer behaviour in their decision-making process in food stores (Pantano and Priporas, 2016). Finally, in this optic the technology could be defined and also considered as the engine able to create a new vision of retail industry.

Resources integration, actors interaction and company-customer relationships are guaranteed by technology. The power balance between the role of actors within the network of relationships is regulated by technology evolution and application. The ecosystem paradigm contribute in explaining this process

3 Research Aim

The research focus is to grasp more meanings on the arising definition of retail ecosystem. In line with the theoretical background performed above, authors will compare the main features of service ecosystems with the ones of retail industry. Moreover, attention will be paid to technology in defining and identifying these key elements, since it has emerged as a relevant element in creating and steering the multiple set of interactions.

Due to the novelty of the debate on what a retail ecosystem, the attention has been drawn to how a retail ecosystem is shaped and which are the key issues framing the ongoing debate. Additionally, these key issues shaping the notions of retail ecosystem have been further investigated through the lens of new technologies to understand if and how they can support the continuous framing and reframing of ecosystems as emerged from the literature.

The literature considered in this research stems from the concept of ecosystems and moves towards the retail ecosystems. Recent contributions described ecosystems as contexts featured by the following key issues:

- complexity
- dynamicity and change
- interactions
- mutual dependence
- long-term perspective

As a consequence, the next section will be based on the parallel analysis of ecosystem literature and retail studies on the five issues above, in order to propose a path towards the understanding of retail ecosystems.

4 Findings

The overview on retail ecosystems - and more generally on the retailing operators along the supply chain - seems to mirror the same features than service ecosystem. The cross-fertilization between the two literature led us to highlight key insights in describing what retail ecosystem is.

Table 1. Ecosystem key elements' and retail studies

Key issues	Ecosystem literature	Retail studies
Complexity	The ecosystem approach is considered as suitable to analyse ecosystems, both as a feature and as a way to analyse the multiple context of interactions (Aarikka-Stenroos and Ritala, 2017)	Retail is an industry in continuous evolution causing (and getting affected by) consumption modification (Pantano and Priporas, 2016)
Dynamicity and change	The dynamicity of interactions and subsequent changes occurring in an ecosystem lead to disruption as a continuous process leading an ecosystem to be shaped and re-shaped (Aarikka-Stenroos <i>et al.</i> 2017)	The digitalization process is broadly transforming many elements of the retailing industry increasing the level of dynamicity and change approach (Hagberg <i>et al.</i> , 2016; Hagberg <i>et al.</i> , 2017)
Interactions	Multiple actors in an ecosystem are linked one another because of an intricacy of relationships with mutual influence. In such a web of relationships, technology is offering an opportunity to both manage and further advance them. (Balaji and Roy, 2017)	Retail sector has to stimulate and provide innovation (Pantano, 2014), integrate its knowledge within the supply network with key strategic factors such as service and technology (Kandampully, 2012) and with supply customisation looking at changes in consumption and lifestyle (Woodliffe, 2004; De Kervenoael <i>et al.</i> , 2006).
Mutual dependence	The interactions among actors lead to continuous change in the workability of an ecosystem and since connectivity takes place with no time and space boundaries, the influence actors can play one another is constant. (Huang, 2019)	Large scale retail trade reacts to the environment stimuli adapting formats, concepts, marketing, and management approaches (Bruni, 2014; Sansone <i>et al.</i> , 2017) generating effects for industrial companies, logistics and change in consumer behaviour
Long-term perspective	An ecosystem is evolving over time and this is due to the need to sustain the survival of the ecosystem itself and the actors shaping it. This is mirroring some more the mutual influence of actors. (Moore, 2006; Aarikka-Stenroos and Ritala, 2017)	Traditionally retail industry goal is in providing goods, services and giving an impulse to the economy during the time having a social and economic role (Ilbery and Maye, 2006; Paddison and Calderwood, 2007)

Source: Authors data elaboration

Based on the contributions highlighted in the table above (Table 1) and the key elements identified as determinants of an ecosystem, we derived the following research propositions.

RPI: Complexity describes retail ecosystems as continuously evolving, even through technological innovation

The debate on complexity derives from well-established studies on supply chain and mirrors the multiple mechanisms affecting operations in retail. An ecosystem approach deals with such a feature, since complexity is an inner feature of an ecosystem and makes actor aware of the need to consider a wide range of elements in their decision-making processes in a retail ecosystem. Technology can support these processes and the management of complexity.

RP2: Dynamicity and change depict the transformation of a retail ecosystem and digitalization supports this dynamics

In line with the previous proposition, change is constantly taking place in retail ecosystems, due to the features of all actors and the constant involvement of new ones; this is an innate feature of an open context as an ecosystem is. Thus, technologies can be helpful in tracking these changes and dealing with them, together with offering the opportunity to make this change profitable.

RP3: Multiple interactions lead to constantly rearrange a retail ecosystem; consumer behaviour, innovation and their interplay affect the set of interactions.

A wide set of interactions is the essence of a retail ecosystem, in order to favour its workability and as a way to describe what happens in such a dynamic context the intricacy of interaction makes strategies and consumption styles as constantly changing elements, leading retail ecosystems to instability. Technology can represent a way to deal with this feature and support the ecosystem's reaction to new interactions.

RP4: Actors are mutually influencing through stimuli, thus the influence in a retail ecosystem is mutual and evolving.

The above-mentioned emerging of changes due to new actors and behaviours lead a retail ecosystem to be affected because of the effects the actors can play one another. It is not a one-way process, due to the action-reaction effect. Thus, all actors are changing and adapting their behaviour because of the dependence on other actors in the ecosystem. Technology can represent a way to negotiate diverging goals and make dependence a lever to the further development of the retail ecosystem.

RP5: Time and intensity of interactions affect the perspective of a retail ecosystem, since survival is a pivotal aim for every actor and for the entire ecosystem.

Survival is a key goal for a retail ecosystem as for all ecosystems; while this is an easy to be understood feature, it is hard to deal with this goal in such a changing environment, because evolution, shaping and reshaping and new needs are affecting the inner mechanisms of a retail ecosystem. At the same time the concentration of interactions intensity automatically switches the relevance of focal nodes within the retail ecosystem. Improvements in this domain can be achieved by implementing technology and favouring social and economic results of a retail ecosystem.

5 Conclusion

This work represents a preliminary study about retail ecosystem, through the consideration of the advances in ecosystem literature and the contribution of technology to the workability, management, and survival of ecosystem.

In this first focus, the work presents the technology as a key actor able to give a 'soul' to the ecosystem and, in particular, able to keep strong relationships between the involved

actors; the management of relationships and changes is a key feature to deal with complexity - as in RP1 - and to aim at keeping alive the retail ecosystem in a long-time perspective - as in RP5 - to ensure the achievement of fruitful conditions in complex conditions depending on evolution and change. The retail ecosystem should be searching for a condition of equilibrium between actors relationships and this path stimulates continuous change in actors interactions. Interactions and their intensity affect change, thus the time perspective is something not-to-be-missed when debating and considering a retail ecosystem.

Technology works at first as a 'tool of links' but in a second level of interpretation, in particular applying the advanced technology, every device, software and technological tool gives meanings, contents and multiple connections increasing the opportunity of interaction (knowledge) between the involved actors. Each actor in the retail ecosystem has the opportunity to participate influencing the trends, the ecosystem interpretation and, of course, the ecosystem survival. The relevant role of technology emerges in retail ecosystem because it permits the emerging of ecosystem's key features through stimuli of actors dynamicity. The role of retailer is not only the simple distribution of good but it represents an intelligent actor able to manage its own activity and intervention within the ecosystem, considering that the source of ideas, insights and innovation could come from each actor directly or indirectly involved within the ecosystem (suppliers, manufacturers, customers, others). It is possible to assume that retail ecosystem should contain high number of involved actors (customer included), high levels of innovative technology, shared knowledge and low level of hierarchy between actors involved .

The 'relational weight' of each actor in the ecosystem. In some situations within the actual and modern market relationships, retailer emerges as a relevant actor in ecosystem able to influence the whole trend in terms of production, distribution, times, needs and customer knowledge. The future seems to be strongly characterized by the increasing role of retailer as an actor able to sense, feel and manage the relationship between offering and demand (Sansone *et al.* 2017) and, at the same time, the retailer should be the actor able to balance the equilibrium among actors in a retail ecosystem, due to the multiplicity of actors involved and directly connected - as in RP3 - and the mutual influence they play - as in RP4. Of course this relationship is at the base of cooperation between retailers and their partners in manufacture for private label projects but is even increasing in relationships between retailers and industrial manufacturers.

Although in traditional marketing approach the customer has always the power on the production and distribution network because the customer is the last in the chain able to choose, in technological and digital retail ecosystem it is impossible to understand 'a priori' which hands hold the power in influencing the future of consumption; the customer is always a relevant actor but in the ecosystem environment the influences in purchasing could come from retailers strategy (private label for instance in some markets has gaining over 40% in market share for sales in food retailers market) and, of course, by manufacturers; this is due to the dynamicity of the retail ecosystem - as in RP2 - and the wide set of interaction among actors, innovation, and technology - as in RP3. Digital technology represents a tool to optimize, control, diffuse knowledge and, of course to

make influence, stimulating and involving customer to co-create the value that he/she will choose. Of course the retailers have the opportunity to influence the market but the trend in value co-creation and the use of social network sites could switch parts of the influence power on the hands of other actors involved. It depends on the recognized role and awareness in the value co-creation process; this process is emerging as depending on several actors and it shapes a complex decision-making process - as in RP1 - due to the continuous changes - as in RP2 - taking place in the retail ecosystem.

Further questions should be solved in next works. For example, in terms of relationships between customers, manufacturers and retailers in terms of industrial, private label and local products. The same ecosystem is able to generate different effects for different offerings because the success in terms of sales of the different offerings (industrial products, private label products and local products) it depends by the efforts of the ecosystem's actors in generating awareness and relevance of the offerings with the interested customers. For this reason, for industrial goods the awareness is mainly generated by the industrial company and supported by the retailer in the final phase; for private label products the efforts in awareness and relevance is mainly generated by the retailer efforts in terms of strategic role of private label. Local productions, not included in private label projects and strategies are in the middle. The local productions have no strong support by the manufacturers (because often the manufacturers are small and medium enterprises not really able to manage relationships with retail ecosystem), no strong support by retailers (because at least retailer prefers to support local products in private label offerings) and a limited customer awareness. For this reason, the relevance of local productions and the representation of these offerings within the retailers assortments depends by the ecosystem's efforts in considering the integrated activity of each actor and the cooperation toward the survival of the ecosystem. Each actor should contribute in supporting the local production giving benefits to the local manufacturers (preserving the specializations and cultural identity), to the customers (that increase opportunity to choose within retail assortment) and to the retailers (they differentiate the assortments going beyond the dichotomy represented by the industrial and private label goods). That approach could represent a further set of activities that could be studied in next researches.

Ecosystem Approach in Retail Industry and Customer Role: a Service Perspective

Marcello Sansone

Department of Economics and Law
University of Cassino and Southern Lazio
Polo Folcara, 03043, Cassino (Italy)

Abstract

The evolution of the modern retail concept involves many actors and stimulates several dynamics in markets that cannot be represented only by traditional economic sectors. Retail industry is emerging as a meta-sector where production companies, agriculture, logistics, and retail are integrating their strategies and resources to have fast reaction to markets complexity and variability. Retailers stimulate the integration of many actors in the market from the production of raw material to services. Innovation in retail industry involves companies in production, distribution channels and stimulates change and evolution in consumption and demand.

Actors in retail industry are influencing, generating and using rules, languages, cultural norms, values, codes - institutions - that cause effects on the same actors involved, on markets and on the complex emerging system. Within this entangled context of actors' interaction, sharing of institutions and behaviours, following a service perspective, retail industry seems to configure a service ecosystem - retail ecosystem -.

The work contributes in explaining the emerging of retail ecosystem, the relevant institutions involved and the contribution of the customer as influencer of institutions dynamics within retail context. The relevance of ecosystem approach emerges and, although the customer represents a relevant actor, the success of the wide system comes by co-evolution of involved actors and institutions dynamics. The survival – final purpose - of the whole retail ecosystem is generated by the resource integration and mutual dependence of every involved actor.

Keywords – retail industry, survival, retail ecosystem, institutions, customer

Paper type – Academic Research Paper

1 Introduction

The economic impact of the retail industry on countries' economy is currently measured and included in the tertiary sector, with reference to the traditional division of economic activity into three main sectors: primary - extraction of raw materials and agriculture, secondary - manufacturing, - and tertiary – services (Fisher, 1939; Fourastié,

1951; Wolfe, 1955). While this distinction may be useful in terms of the real economy's organization - for instance classifying the position of companies in the market and identifying them in terms of specific functions, investments, and tax system - sometimes it is not really applicable to marketing and management regarding to understanding actors' interactions in markets, especially in times characterized by complexity, fast communication, network relationships, and interactions.

Generally retail industry is characterized by supply chains with different levels of complexity and interaction; the evolution of consumptions, markets, and actors relationships is encouraging the network and system approach (Gummesson, 2006; Espejo and Harnden, 1989; Barile, 2009) to understand the actors dynamics, interactions and the co-evolution of the multiple interactive actors involved in the process of value creation. Each marketing and management activity of companies – retail industry included - is involved in this variable market and fusion of roles, information and activities in which value is co-created by resource integration (Vargo and Lusch 2004; 2016). In this scenario the role of customer in retail industry is relevant but it is contextualised in a system of relationships and influences coming by actions and reactions of a multiplicity of integrated actors that form the retail system – farms, industrial production companies, suppliers, logistics companies, retailers, intermediaries, communication companies -.

New marketing and management paradigms are contributing to explain complex dynamics in markets, the actors' interaction and value co-creation; in fact adopting a service logic (Vargo and Lusch, 2004, 2008, 2016) the value is co-created by a wide actors interaction and resource integration, customer included. Complex markets and businesses – retail industry included – could be analysed using the ecosystem approach (Aarikka-Stenroos et al., 2017) even following a service perspective (Vargo, Wieland and Akaka, 2015). Some authors are approaching to the retail industry using the ecosystem framework (Barile and Saviano, 2014; Sansone et al. 2018) and that is generating questions around the role of actors in resource integration and around the institutions dynamics in shaping the retail ecosystem.

This work contributes in the debate explaining the emerging of retail ecosystem, the relevant institutions involved and the contribution of the customer as influencer of institutions dynamics within retail context.

2 Theoretical background

The ecosystem framework is not a novelty in literature. Moore (1993; 2013) sustains that ecosystem could be a useful framework to study and interpret the actors' relationships in social contexts. With a focus on business context, many authors are working around ecosystem framework approaching with multiple perspectives (Aarikka-Stenroos and Ritala), highlighting the ecosystem's key issues identified in complexity, interactions, dynamicity, mutual dependence. Aarikka-Stenroos *et al.* (2017) identified 4 groups of research streams expressing the ecosystem characteristics: a) competition and evolution; b) emergence and disruption; c) stable business exchange; d) value co-creation.

In particular, systemic characteristics of ecosystem stimulate the emersion of interaction and mutual dependence, change of perspectives and co-evolution between actors involved. Within the ecosystem actors resource integration is based on collaborative forces directly and indirectly involved in the ecosystem survival.

In business marketing and management studies the ecosystem research stream is relatively new; Holmqvist and Diaz Ruiz (2017) published a contribution selecting scientific manuscripts that present three principal perspectives with different points of view: a) markets (Araujo and Kjellberg, 2009); b) business networks (Cantù et al., 2012); c) service ecosystems (Vargo and Akaka, 2012). They found contact points but differences in interpretation and definitions respect to these aggregations (spontaneous or finalized). Long-lasting relationships and interdependencies are identified as similar characteristics. Between the approaches, the service ecosystem (Wieland et al., 2015) includes the customer as part of the business context management and consider value co-creation and actors' interaction at the base of actors' relationships.

Diffusely the concept of ecosystem is applied in retail sector identifying, theoretically and practically, the wide relationships between retailers and suppliers in market contexts. Widely authors refer to retail in practical and theoretical works around ecosystems particularly following business approach (Moore, 1993; 2013) and service approaches. Further Barile and Saviano (2014) state that it is necessary a change in perspective and new research in retail service marketing.

Sansone et al., (2018) present the retail concept using the ecosystem paradigm building on service and system approaches. The authors assert that through a configuration of emerging institutions the ecosystem framework contributes in explaining the multiple and variable interactions of actors within the modern retail system. Other authors (Macfadyen et al., 2015) sustain that an ecosystem emerges when a multiplicity of actors interact in food supply chain with direct or indirect relationships, sharing knowledge and protocols, bringing food from production field/plant to the customer direct consumption.

The retail context (food and no-food) should search for new paradigms to deep the pivotalsof resource integration with the manufacture industry and with customers. Anyway, it is still needed to understand how these actors negotiate and – when needed – counterbalance their interests when diverging. In food retail industry for instance, local farmers, big players of the food retailing industry, consumers, and all the actors surrounding the triads among the actors mentioned before (Frishammar et al., 2018), should be considered in order to describe the interplay they have and the real value generated by their interaction strategy. A focus on the role of customer in generating influences on retail ecosystem could contribute to the actual research debate.

3 Research aim

The work presents the institutions able to stimulate the emersion of retail ecosystem and the role of customer in generating influences in institutions dynamics and actors'

resources integration. The service perspective is adopted in identifying the retail ecosystem roots and the role of actors' interaction and institutions dynamics.

Each actor influences the retail ecosystem characterized by institutions, complexity, dynamicity, interaction and mutual dependence. Within this scenario, every actor in service ecosystem has a role and characterizes the ecosystem features; in fact in retail sector the role of customer always has been considered relevant in marketing and management strategies and it has conditioned and shaped the market approach for retailers. The retailer activities aims at satisfying the customer because he assumes a relevant role within the retail industry; in fact practitioners and researchers are focused on retailer-customer relationship searching for customer satisfaction. In contrast, within the ecosystem logic, the customer should not only represent an actor to satisfy but someone that, at the same time, gets and gives influence to institutions and to actors' activity with different levels of pressure and results. Of course the customer remains a pivotal in retail ecosystem but the ecosystem survival depends by co-evolution, integrated activity and influence of the whole system of actors involved.

The next section will present the institutions that stimulate the emerging of retail ecosystem and specific insights about the role of customer in influencing institutions dynamics and the actors' involvement in resource integration and in retail ecosystem survival.

4 Findings

Observing the relevance of consumption, the market's complexity, the development of the interactions between producers and retailers, the increasing role of the technology and the origin of relationships and interactions, it is possible to select specific institutions able to generate effects in the actors' relationships dynamic in retail ecosystem (Sansone et al. 2018). The retail ecosystem emerges as a system of actors in co-evolution that directly or indirectly interact integrating resources and co-creating value. Following a service perspective (Vargo and Lusch, 2004; 2008) every actor is influenced by other actors in the ecosystem and, within retail ecosystem, the emerging set of institutions is the result of innovation and evolution of the modern retail concept. The need to answer to market needs by actors in retail industry – from production till the retail activity – and the complex relationships between supply network players generate shared institutions between actors – customer included –.

In Table below it is possible to find the selection of institutions in retail ecosystem and for each of them, the customer influencing role of institutions dynamics is indicated.

Tab. 1: The customer's role in institutions dynamics in retail ecosystem

<i>Institutions in Retail ecosystem</i>	<i>Meaning of institutions</i>	<i>The role of customer in institutions dynamics in retail ecosystem</i>
In store value proposition management	Although this activity represents the retailer's mission, the managerial approach to the retail value	Customer benefits and, at the same time, influences the retail value proposition management in terms of purchases, requests,

	proposition could be considered an institution.	suggestions, feedbacks (demand).
Mobile applications supporting production, retail network and customer	The diffusion of use of mobile devices affects each actor and contributes in co-evolution that are working day-by-day in distribution. The institution of mobile applications affects both supply and demand.	Customer contributes to the spread of mobile applications through the frequency of applications use. The diffusion of the mobile applications increase the relevance of the customer role in increasing of institution relevance.
Relationships between manufacturer and retailer	Languages, agreements and managers that interacts each other – e.g. the trade marketing manager, buyer relationship between retailers and manufacturers – represent a shared institution that support interaction within ecosystem.	Customer is a data producer online and offline. The participation of the customer to retailers initiative for promotions and communication - for e.g. the contribution of customers in social network activity and the participation in loyalty projects – contributes in generating information that co-create value to each actor in retail ecosystem.
Private label as strategic asset	The private label assumes a strategic role that goes beyond the single use as a tool to increase margins and profit. Today the private label is a shared language and code that affects supply (retailers), production, and demand (customers).	Informed customer gives trust and a relevant role to the private label. For this reason, the private label is competing in the retail market at the same level of famous and industrial brands. That behavior encourages the retail ecosystem to make efforts in improving and developing private label strategies involving each actor in ecosystem in long term projects.
Accepted logistics practices	The logistics practices represent the core activity in retail ecosystem. The trend is to extend the sharing of solutions and information between the interacting actors. That encourages the actors co-evolution reducing complexity in actors interaction.	Every logistics practice affects the customer indirectly for retail ecosystem efficiency. Any case the last mile logistics practice – included the home delivery – have a relevant role. E-commerce encouraged the diffusion of home delivery making the customer more available to that practice. For this reason the customer is asking for new and integrated logistics practices in online and offline purchases.
Mobile communication and data exchange	Demand and supply share the habits regarding mobile communication. Rules and limits of mobile communication allow the increase in opportunities to connect the value network.	The use of mobile communication is increasing constantly and the data creation and use through mobile has overcome the traditional one. That generates strong influences in retail ecosystem in terms of communication and offerings. Every actor is affected by this evolution toward the mobile approach - from agricultural and industrial production till retailers.
E-commerce and rating systems	E-commerce and rating systems represent shared languages that involve the whole retail ecosystem. Every actor in retail ecosystem is able to use the e-commerce system and the diffusion of this practice supports the traditional retailing. From B2B to B2C - and C2C - relationships every actor finds opportunities in sharing e-commerce language. The e-commerce is linked with the rating system of reviews and comments that represent shared	The customer uses e-commerce not only as a residual choice and considers the omnichannel activity; the fast increasing of e-commerce and rating system adoption by customer increases the influence of customer on the institution and, of course, on retail ecosystem.

	codes able to give trust - or not- to the digital world.	
Sharing solutions	Sharing solutions attend to the opportunity to go beyond the single actor's activity. It is increasing the opportunity to share ideas and projects between actors in different sectors but belonging to the same ecosystem. Of course, it is possible to have different retailers belonging to the same distribution center and, at the same time, agricultural producers working with a retailer projects or a logistics provider.	Quality protocols, circular economy and shared practice in management of healthy food and practices involve the whole retail ecosystem. That creates necessity to sharing solutions, activities, tools and protocols. The customer interest in previous logics and practices is increasing and that causes an influence on this institution
Dynamic and hybrid formats and concepts	The concept of continue adaptation leads retailers to diversify the retailers value proposition integrating new and different services. The dynamic innovation is an accepted logic that is shared by the retail ecosystem.	A sophisticated customer has multiple needs for service and he is asking for continue innovation and new stimuli in value offerings. Customer induces the retailer to continuous adaptation and that dynamicity of requests generates effects to the whole retail ecosystem.

Source: Author's elaboration

The previous table presents the relevant institutions that permit to configure the retail ecosystem considering the most common and relevant practices and retail management strategies as source of information and trends. The modern retail is going beyond the mission of distribution and it is involving every economic sector in its activity, sometimes, controlling directly the process across the sectors involved – for e.g. some private label projects represent specific strategies where retailer is able to influence the production process, the logistics and the final destination of goods involving customer in loyalty relationships.

The ecosystem framework seems to efficaciously represent the dynamics of relationship in modern retail industry that are going toward smoother and soft distinctions between the actors - production, logistics, intermediaries, others - involved in different sectors within the retail industry. Every actor can integrate production activities and market strategies with retailers, starting by the sharing of rules, codes, activities – institutions - and finishing with practical projects that go beyond the classic production and distribution activities. In that way the retail ecosystem has not only the goal to distribute goods and services but it is configured as a system of value providers - co-creators - that identify and co-create lifestyles, behaviours, research projects for innovation in production and distribution and satisfaction for customers. In this relationship, customer gets and gives influence to institutions and to actors' activity with different levels of pressure and results. As explained before, the influence of the customer is sustained from one hand by technology that helps the customer to become active and influent actor in the ecosystem and from the other hand by the customer evolution in terms of knowledge and awareness about its role in the retail ecosystem. The awareness to be part of the ecosystem permits to react and participate, even searching for better opportunities achieving own satisfaction.

5 Conclusions

Ecosystem appears an alternative framework to describe the retail industry dynamics and to try to forecast trends and development of actors' interactions. Studying the retail industry relationships following an ecosystem approach gives the opportunity to shed the light on vertical and horizontal relationships between the system of actors directly and indirectly involved. Giving the ecosystem definition to the retail industry permit to consider the retail concept as something that goes beyond the mission stated in goods and service distribution. In the ecosystem approach the retail industry expresses the power of value co-creation involving actors included, otherwise, in other sectors – industrial production, agriculture, services, logistics, others -. Further, recognizing the retail ecosystem it is possible to consider the relevance of specific institutions that explain how the actors are integrating their resources and what kind of rules and languages they are using or, sometimes, creating.

Although the relevant mission for retailers remain the same – to deliver goods and services to the customer -, more specialized and sophisticated strategies contribute in giving and getting insights to customers, manufactures, logistics, data management companies and other actors involved directly or indirectly within the retail ecosystem. In this complex system of interactions actors share fundamental meanings and key issues – interaction, dynamicity, mutual dependence – and each actor in a long perspective should cooperates for ecosystem survival. The involvement of each actor in ecosystem logic is generated by the results obtainable by the cooperation and resource integration and co-evolution. The complexity of markets induces the actors in retail ecosystem to cooperate going beyond the activity within their specific sector and switching the approach toward a more inclusive and shared strategy. They should pass from the exclusive focus on own specific market/sector toward a more ecosystemic view - the retail ecosystem -, characterized by actions and reactions coming from a multiplicity of actors interconnected across the sectors.

Analysing the institutions and the role of customer in influencing the institutions evolution and dynamics a relevant role of technology emerges. In general technology affects the service ecosystems (Maglio and Spohrer, 2008) but the actors' integration in retail ecosystem seems really characterized by technology adoption and evolution from communication to efficiency management. The same retail ecosystem is strongly characterized by the role of technology because the mentioned smoother distances between the involved actors (and sectors) are reduced thanks to the diffusion of technology in projects design, implementation and, of course, in communication and data management. More technology permits more opportunity to reduce the distances between the actors coming from different, complex and multiple sectors.

Within this context the customer can't be only considered as a subject that waits for a value offering. Customer influences the actors' interactions, ideas, projects, value propositions, times and innovation and at the same time, he is influenced by the innovation and value proposition of actors included in retail ecosystem. Although the retail ecosystem is characterized by mutual dependence and value co-creation between the

actors, the customer contributes in stimulating actions and reactions of involved actors and generates influences on institutions and institutional arrangements. Further research need understanding how to involve customer in ecosystem development and survival. Customer could better be involved in private label projects, in developing of new logistics activities, in retail formats design, in communication activities and in projects increasing efficiency and customer satisfaction.

Abstract

Starting from the theoretical framework of ecosystem in Service-Dominant Logic (S-D Logic) perspective, this conceptual study aims to understand the role of private label in the modern retail. The assumption of the work is that the literature about service ecosystem could support the analysis of retail dynamics helping to explain the relationships and interactions between manufacturer companies, copackers, retail companies, logistics, and customers; in this sense, it is possible to explain how actors' relationships in the retail ecosystem are affected by specific institutions that define actors behaviour.

The role of the private label in modern retail is analysed as institution of the retail ecosystem, in order to understand if the private label actually represents a shared language and code that affects production, retailers, customers and other actors who should recognize the growing value of private labels and could contribute to value co-creation.

The main managerial implications of the paper concern the marketing and management competences and knowledge necessary for retailers to manage an institution of increasing importance for the entire retail ecosystem, which generates economic, social and environmental value.

Keywords – retail, ecosystem, private label, institution, service ecosystem.

Paper type: Academic Research Paper

1 Introduction

The difficulty in defining the modern retail sector and in describing relationships between actors has led to the emerging of new models/ frameworks aimed at studying these topics. Among these, network and systems theories (Håkansson and Snehota, 1995; Gummesson, 2004; Espejo and Harnden, 1989; Barile, 2009) are giving specific answers to interpret the evolution of the relationships and value co-creation generation in retail industry.

Some researches (Sansone et. al, 2018) are using the Service-Dominant (S-D) Logic (Vargo and Lusch, 2004; 2008; 2016) to define the retail concept as meta-sector and to identify shared rules, languages, cultural norms, values, codes; interpreting therefore the retail as an ecosystem. This approach underlines how retail emerges as a service ecosystem, through the evolution and integration of specific institutions that affect the retail industry and the involved actors.

One of the most relevant institutions that seems to affect the retail ecosystem is the private label. Private label today plays a relevant role among the sources of competitive advantages of retailers and within the exchange economy. This trend is confirmed by the growing interest shown by scholars: they debate the strategic role of private label beyond its mere use as a tool to increase margins and profit: the definition of private labels and their evolution over time (Cristini, 1992; Fornari, 2007; Pastore et al., 2007; Castaldo et al., 2013), the determinants of success and market share (Lamey et al., 2007; Rubio, Yague, 2009; Sethuraman, Gielens, 2014), the role of the private label in retailer management policies and in the levers of the retail marketing mix (Ailawadi, Keller, 2004; Lugli, 2009; Fornari, 2009), consumer behaviour, purchase preferences and factors that influence consumer choices (Ailawadi et al., 2001; Dalli and Romani, 2003; Sprott and Shimp, 2004; De Wulf et al., 2005; Dolekoglu et al., 2008).

Based on these premises, this conceptual paper aims at analysing the role of private label in the emerging process of retail as an ecosystem; the study deeps the characteristics of the private label as an institution. It seems to summarize shared languages of interaction, codes, projects and shared strategies between actors, deeply contributing in emerging of retail ecosystem.

The paper is organized as follows: first the evolution of the private label concept in the main reference literature is discussed, then the theoretical background on ecosystems from the perspective of S-D Logic is presented, with the aim of understanding the concept of retail as ecosystem and the main institutions that characterize it.

2 Private label evolution

Over the last few years, the private label subject has attracted increasing interest from reference literature, as shown by a significant increase in research contributions; this interest is mainly aimed at justifying the growth of the private label's market share (+4% on average in Europe – with a market share in value of 39.4% across major western

markets UK, France, Germany, Greece, Italy, Spain, Netherlands) and the impact on relations upstream and downstream of the supply chain (IRI, 2018).

One of the main objectives of the research, over time, has been to define the private label concept and its role assumed within the assortment, first of all in order to understand what dynamics have given rise to the private label and the specific characteristics of each variant, as well as to understand how the objectives of retailers have changed over time (Cristini, 1992; Fornari, 2007; Pellegrini, 2008; Castaldo, et al., 2013).

In 2002, Sayman, Hoch and Raju analysed the ideal positioning of private label products, arguing that the optimal strategy for retailers is to position private label products as close as possible to the strongest of national brands; in 2004, the same authors proposed research on how the characteristics of the category affect the number and types of private labels introduced by the retailer; in 2006 Choi and Coughlan proposed reflections on private label positioning strategies in relation to the positioning of industrial brands; in 2010 Geyskens, Gielens, Gijsbrechts analysed the different positions of private labels within the range of retailers and the combined effect of the introduction of a premium, first price or mainstream line on the others.

With reference to market shares and emerging divergences in the various countries, numerous studies have been carried out in order to understand future growth prospects and developments in relation to industrial brands (Quelch, Harding, 1996) or to study the price elasticity of private label and national brand products and their consequent effects on market shares (Cotterill, Putsis, 2000). In 2007, a study looked at the success of the private label in relation to the economic situation of the reference market, empirically confirming a positive correlation between market share and economic recession (Lamey, Deleersnyder, Dekimpe, Steenkamp, 2007). In 2008, Ailawadi, Pauwels and Steenkamp proposed an econometric model aimed at understanding the relationship between the private label's market share and store loyalty, demonstrating the positive effect of all the components of behavioural trust in the store on the private label's market share.

Again, in 2012 Lamey *et al.* analyse how private label market shares vary in relation to the economic situation and the various elements of the marketing mix managed by retailer. In the same year, Gielens analyzed the effects of the introduction of private label and national brand products on their respective and reciprocal market shares and on category sales.

In this regard, Rubio and Yague (2009), compiling the previous contributions, proposed a model that summarized the determinants of the store brand's market share, outlining the market structure, demand characteristics, economic and financial objectives as well as the competitive strategy among the macro-class variables. This contribution has therefore highlighted how in recent years the choice of the retail is increasingly characterized by strategic reasons and not merely by tactics, generating the growing need for marketing skills of retailers themselves.

An important area of research is about the role of the private label in retailer management policies and in the levers of the retail marketing mix, whose contributions have focused on many aspects: the role of brand image building by retailers, focusing attention on relationships with manufacturers and the assortment of private label products

in this process (Ailawadi, Keller, 2004); on assessing the value of the private label brand with respect to the brand in general, proposing that the income differential generated by a brand with respect to that of a private brand product be a simple and objective measure of brand equity (Ailawadi, Lehmann, Neslin, 2003); in 2004, Sudhir, Talukdar analyzed the relationships between brand loyalty and store brand loyalty as well as the impact of these implications on horizontal differentiation.

The evolution of the concept and the role of the private label has had an impact on the vertical level on the supply chain, on the bargaining power that for a long time was held exclusively by industrial brands (Lugli, 2009; Fornari, 2009) and on the cross-cutting challenges that the expansion to extra-core categories opens up (Martinelli, 2012).

Private label allows brands to differentiate themselves from competitors (Spratt, Shimp, 2004 and Sudhir, Talukdar, 2004) and to enjoy greater flexibility in defining promotional policies (Nogales and Suarez, 2005). It also provides other strategic benefits, such as increasing customer traffic (Dick et al., 1995), increasing store loyalty (Cortjens and Lal, 2000; Dekimpe et al., 1997), achieving higher margins and increasing bargaining power with suppliers (Lugli, 2009; Fornari, 2009; Ailawadi et al., 2008).

3 Service ecosystem in SD-Logic perspective

At the base of S-D logic perspective there is the concept that service, as the application of one actor's resources (e.g., knowledge and skills) for the benefit of another, is the foundation of all economic and social exchange (Vargo & Lusch, 2004, 2008). More recently, Vargo and Lusch (2011) introduced within S-D logic the service-ecosystems view, conceptualizing ecosystem as *"relatively self-contained, self-adjusting system[s] of resource-integrating actors connected by shared institutional logics and mutual value creation through service exchange"* (Lusch & Vargo, 2014, p. 161), focusing on the integration of resources for connecting social and technological aspects of markets (Vargo & Akaka, 2012).

The ecosystem framework seems to be a useful to study and interpret the actors' relationships in social contexts, analysing interactions between actors within a scenario characterized by fast changes and complexity. In the ecosystem perspective, interdependence is represented by mutual dependence and co-evolution is based on collaborative forces between the actors directly and indirectly involved in the survival of the ecosystem. Moreover, the service ecosystem approach includes customers as part of ecosystems and present customer satisfaction as an end goal (Wieland et al., 2015).

In S-D Logic perspective the value creation is driven by the integration, exchange and application of resources among actors (Vargo & Lusch, 2008), so value is always co-created. Therefore, the ecosystem perspective exceeds the dualistic approach of interaction between firms and customers (Vargo & Lusch, 2011), focusing on beneficially knowledge application and overcoming a view of markets as relatively static, external entities in which value flows sequentially from value-creating firms to consumers. S-D logic extends the concept of value co-creation, emphasizing the importance of institutions (Vargo & Lusch, 2011), because for service exchange, actors depend on rules.

The S-D Logic approach supports the necessity to consider the institutions – formalized rules “such as laws, more informal norms including social expectations, values and moral codes that define appropriate behaviour, and cultural meanings including cognitive frames and schemas that encapsulate the assumptions and beliefs fundamental to make life comprehensible” (Siltalo et al., 2016) – and the institutional arrangements – set of interrelated institutions; the role and process of institutionalisation are the keys to understanding structure and functioning of the service ecosystem – as contributions to the emergence of the ecosystem.

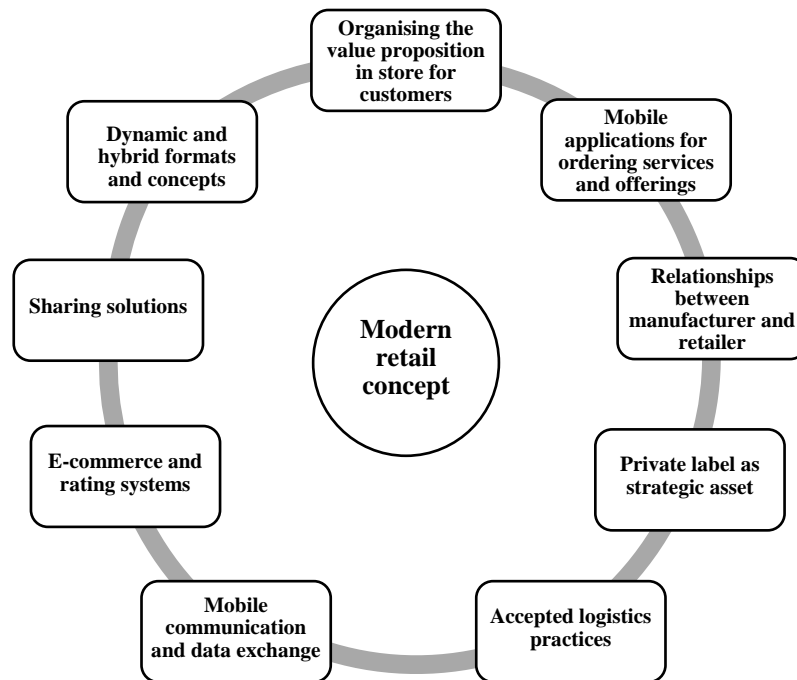

Some of these institutions are formalized (e.g. laws) and thus appear to be externally given, while others exist informally and endogenously emerge (Fujita et al., 2019). Furthermore, institutions influence the interactions among multiple actors.

In general, it is possible to assume that context is composed by networks of actors and institutional arrangement that guide actions and interactions (Vargo & Akaka, 2015).

Resource integration and service exchange among actors generate the value co-creation, involving various views on value (institutional arrangements), which determine what works and what does not work (Lusch, Vargo, & O'Brien, 2007). Therefore, the value co-creation process involves companies (manufactures or retailers), customers, influencers and it is driven by institutionalization of integrative, normative, and representational practices.

4 Retail as service ecosystem

The ecosystem framework has been applied to the retail industry with different approaches. In general, ecosystem theory has been used to analyze the relationships between retailers and suppliers following a business approach, through conceptual and empirical research (Moore, 1993; 2013). Some authors have suggested the need to study the retail system with new approaches related to service science (Barile & Saviano, 2014). Therefore, new paradigms have been proposed to analyse retail systems based on the S-D Logic perspective (Aarikka-Stenroos & Ritala, 2017; Sansone et al., 2018). In particular, Sansone et al., (2018) argue that the ecosystem framework could be useful to analyze the modern concept of retail, to understand the entangled relationships between industrial companies, agriculture, logistics, distribution and consumptions that integrate resources and exchange value belonging to the same retail system. Therefore, considering the characteristics of the modern retail concept, it is possible to define a system of institutions that affect the relationships among actors in the retail system. The relevance of consumption, the turbulence of the market, the evolution of the relationships between manufacturers and retailers, the evolution of technology, and the possible roots of relationships and interactions – knowledge, business and society, technology and culture – (Barile, 2016), give the possibility to configure some institutions that affect the dynamic of relationships between actors in the retail system (Sansone et al., 2018), as shown in Fig. 1.

Source: Sansone et al., 2018.

Fig. 1: Institutions in retail ecosystem

The interrelation of the institutions – institutional arrangements – will contribute to defining the structure and functioning of retail as service ecosystem and could be useful to interpret trends and roles of every actor in the ecosystem.

5 Private label as institution

Considering the literature contribution and the recent research, private label represents a relevant source of competitive advantage for retail companies.

In order to have an overview of the impact of private label projects in Italy, it is possible to consider the "Four Capitals" model of The European House - Ambrosetti. The model represents an integrated and multidimensional analysis system that measures the contribution generated by the private label for the country, also evaluating the structural and comparative implications, including 4 capitals: economic capital, social capital, cognitive capital, environmental capital (The European House – Ambrosetti, 2019).

The *economic capital* of the private label highlights the generation of economic value: a turnover of 10.1 billion euros, with growth in 2017 that represents about 30% in Italian food industry turnover.

Private label has impact of 10.2 billion euros on extended supply chain and that represents 0.6% of Italian GDP; in long product chain that indirectly involves 50 production and distribution sectors. In fact, the private label economic multiplier is 2.6, compared to the 2.5 of Information and Communication Technology and the 1.8 of tourism.

In Italy, the private label involves around 1,500 copacker companies, represented by Italian companies for 92%. It is interesting to highlight the long-term relationships that link retailers and copackers. Retailers prefer to establish strategic cooperation with manufacturers/copackers and for this reason 98% of contracts are more than 2 years and 47.5% go over 8 years of duration.

The *social capital* in private label economy is represented by employment aspects: 205,000 employed in the supply chain - 3% of employed in manufacturing industry and commerce in Italy; 90% of them have a permanent contract -. The private label projects stimulate employment between youngers (18%) and women employment (62%).

Furthermore, the private label social value is connected to Corporate Social Responsibility policies in modern retail, in terms of fair trade products and support for companies about social interest, in terms of supporting health, well-being, donations for charity purposes and collaborations with schools and universities.

The third aspect is *cognitive capital*, which can essentially be represented by 3 aspects: private label product *innovation*, that aims at responding to new consumption styles and to the principles of well-being and health, (private label has introduced some organic products on the market or health before the National Brands); *industrial efficiency*, through innovation and sharing of know-how; *training activities* offered by modern retailers to their employees (96%).

The last aspect is related to *environmental capital*. That is essentially represented by environmental impact of modern retail in term of energy efficiency policies and the consumption reduction for retail activities and, specifically, in private label productions: for instance, the use of sustainable raw materials for private label products (75%), the selection of copackers based on their environment respect policy (85%) and the confidence with standards of quality (95%).

This model summarizes economic, social and sustainable value of the private label and highlights that private label as institution must not be traced back only to formal or contractual relationships or to tactics of mutual interest between actors, but it seems to represent a shared code, language and way to interpret the modern retail in every step of production and distribution of goods.

The formal and contractual aspects between producers, copacker companies and retailer companies are relevant but not enough to explain the relationships and dynamics of interactions behind private label strategies.

Private label represents a project that permits the connection between numerous actors (producer of raw materials, copackers, consumers, stakeholders) who recognize the growing value of private labels, co-creating value and generating mutual benefits. Therefore, the contribution of private label in retail ecosystem seems to be relevant in

terms of influence and stimuli generated by the involved actors in ecosystem relationships.

6 Conclusions

This conceptual work aims at analysing the role of private label as institution in retail service ecosystem .

The literature about service ecosystem could support the analysis about modern retail dynamics helping to explain the relationships configuration and interactions between manufacturer companies, copackers, retail companies, logistics, and customers. Furthermore, through service ecosystem framework it is possible to explain how actors' relationships in the retail system are conditioned by specific institutions that define actors' behaviour. The interrelation of the institutions – institutional arrangements – will contribute to define the structure of retail service ecosystem and it is used to interpret trends and roles of every actor in the ecosystem. The nature of private label in modern retail context has been analysed in terms of institution and the analysis has generated opportunities to underline the role of private label in retail industry.

The value generated by private label in terms of economic capital, social capital, cognitive capital, environmental capital highlights its strategic role in the retail ecosystem. The private label seems to be a shared language and code that affects supply (retailers), production, and demand (customers) and numerous actors are starting to recognize the growing value of private labels, contributing to co-create value because they are convinced of mutual and reciprocal benefits. In particular, from the analysis it emerges that the private label could be elected as a relevant institution and involve every actor in retail ecosystem from production till final customer. Private label has a multiple role: from one hand it represents a strategic asset for retailers and by the other hand, it represents a recognized element of trust by customer side. Every actor in modern retail ecosystem seems to share the private label rules, customer included.

These results underline the implications of the strategic role of private label on knowledge management of retail companies: the preparation, organization and management of private label strategy poses organisational and management challenges and requires a marketing planning effort that involves the entire company management. The strong link between the brand and company requires full integration of marketing skills and activities in the retailing process and the need to establish supply relationships with highly qualified, more stable and long-lasting producers.

The originality of the work consists in the application of the ecosystem framework in the perspective of the S-D Logic to the modern retail, in order to study a topic of growing interest for research and companies. The main limitation is due to the conceptual nature of the paper, which therefore does not include empirical research that could be useful to better understand the relationships between actors, perhaps through in-depth interviews with the main stakeholders.

Abstract

Over the last decade, the retail sector had trouble due to the economic crisis and the growing complexity of the environment. In this context, the banking system becomes a relevant actor for accessing a critical resource such as credit. The objective of this work is to investigate the role of the legality rating, introduced by the Italian Law 62/2012 as an award-winning instrument for "virtuous" companies, in managing the relationships with bank. With this aim, this paper benefits of the systems theories and the literature on ecosystems. Primary data have been collected from 123 retailers and analysed using a qualitative approach based on the frequency distributions of the variables. Results show the main benefits provided by the legality rating that retailers claim they have had in the relationship with the banks. This paper offers an original contribution for the study of legality ratings by the business perspective and for the understanding of the retail ecosystems emersion.

Keywords: legality rating, ecosystem, retail, bank credit

1 Introduction

Since the economic/financial crisis of 2008, the need for regulatory interventions on potential illegal activities and behaviors able to affect the performance and competitiveness of companies emerged (Caputo, Pizzi, 2019). With this objective, the Italian Government introduced the legality rating aimed at stimulating the voluntary adoption of ethical, socially responsible and sustainable behaviors by enterprises. The primary purpose of this certificate is to favor enterprises, which possess it, in accessing bank credit and public financing offering a concrete opportunity for the "virtuous" enterprises to improve their reputation in relations with stakeholders. To date, this legislation has generated positive effects since the number of enterprises requesting this certificate has grown exponentially showing a great interest for the legality rating.

According to systems theories like the Viable Systems Approach (Golinelli, 2000; 2005; 2010; Barile, 2008; 2009), the General System Theory (Von Bertalanffy, 1956; 1968; Beer, 1972; Maturana and Varela, 1975; Lazlo, 1996; Meadows, 2008; Ng et al., 2012) and the Theory of Open Systems (Boulding, 1956), a system emerges because it has a governing body that relates to and interacts with supra-systems and sub-systems in order to survive over time co-creating value. This objective is reached if the relational dynamics between complex actors, albeit on the basis of constraints deriving from the relevant supra-systems, are consonant (Prahalad, Ramaswamy 2004; Vargo, Lusch, 2004; 2009; Lusch et al., 2010).

To generate effective value propositions, the relationships between interacting systems should be collaborative, communicative and conscious (Nikoomaran et al., 2013; Saren et al., 2013). During interactions the different systems should support each other and co-create value according to a shared vision defined by an entity that assumes the role of hub of this economic community, called ecosystem (Moore, 1996). Particularly, according to an ecosystems perspective, the institutional supra-system through the introduction of legal norms that regulate the interactions between systems, may favor the emergence of value co-creation paths (Vargo, Lusch, 2011). An ecosystem can emerge if certain conditions exist. These conditions could also be determined by legal rules set by an institutional supra-system (eg. the Government) with the aim of codifying the interactions between the entities that make up the ecosystem to improve and strengthen it. In this case, the dyadic relationship between the ecosystem components is enhanced by an innovative initiative developed outside the boundaries of a single organization and it is aimed at defining specific behaviors among the actors for the exchange of resources; in this context the institutional system acts as a coordination mechanism (Thornton, et al., 2012; Vargo, Akaka, 2012; Edvardsson et al., 2014; Koskela-Huotari et al., 2016; Vargo, Lusch, 2016). However, it may happen that the objective set by the legislative is not achieved compromising the emergence of the ecosystem. The study of these issues is of particular interest for the retail industry that, during the last decade, has been affected by the increasing complexity of the external environment, which compromised the effectivity of forecasting activities, and by the economic crisis, which created a reduction in consumption (Moretta Tartaglione et al., 2018). In this context, it becomes fundamental to

analyze how retailers can interact and share resources with other components of the ecosystem to which they belong in order to survive. Among the various actors, the bank is a very relevant entity as it possesses critical resources for the surviving. On the bases of these considerations, it becomes important a better understanding of the relationships between retailers and banks; with this aim we formulated the following research question: Are the relationships between retailers and banks based on an independent relational process or are they influenced by a relevant supra-system? In order to answer to this research question, this paper investigates the conditions for the emergence of the retail ecosystem, analyzing whether it is a spontaneous process or it can be determined by external factors such as norms and certifications aimed at regulating B2B relations for the valorization of the reputational equity. To achieve the objective set, this paper uses a survey administered to all the retailers possessing the legality rating in Italy to examine the opinions about the benefits in the relationships with banks generated by this award-winning instrument, issued by the Italian Competition Authority in accordance with the Law 62/2012. The primary data collected have been analyzed using a qualitative approach based on the frequency distributions of the variables.

This paper is structured as follows: after a review of the literature on the emergence of ecosystems and their role in favoring intersystemic interactions, the method used for the analysis is described; the descriptive statistics and the qualitative analysis follow. The work concludes with final considerations, managerial implications and suggestions for future research.

2 Scientific background

According to the systems theories, companies cannot be considered as “isolated” entities but they are open systems that interact with their environment in which relevant stakeholders possess the critical resources to survive (Saraceno, 1973; Golinelli, 2005). From these interactions, a complex system emerges consisting of “many independent entities and agents that behave in accordance with their objectives, and perform mutual interactions” (Fabac, 2010).

Therefore, embracing a systems perspective of the business reality, it emerges that it is able to influence the choices and behaviors of other systems as well as to be influenced in turn. As highlighted by Barile et al. (2015), a system emerges following “a process of formation of new collective entities established by the coherent behavior of interacting elements. The system is made up of many components, subject to a common plan, deliberated by a decision-maker, which allows the pursuit of specific objectives converging towards a single purpose: the survival of the system itself within the context in which it operates”. The different components support each other and co-create value according to a shared vision defined by an entity that assumes the role of hub of this constantly evolving economic community, called ecosystem (Moore, 1996). The co-evolutionary logic is also shared by Mitleton-Kelly (2003) who states that “each organisation is a fully participating agent which both influences and is influenced by the social ecosystem made up of all related businesses, consumers, and suppliers, as well as

economic, cultural, and legal institutions”. Consequently, functioning like a social ecosystem is a critical success factor for any organisation. When firms and institutions cease to function like a community or social ecosystem, they may break down (Mitleton-Kelly, 2003).

For the emergence of an ecosystem strategies and synergies are required to maximize the satisfaction of the needs and expectations of the different interacting components (Vargo, Akaka, 2012; Stam, Spigel, 2016; Taillard et al., 2016; Brown, Mason, 2017; Sansone et al., 2018) supported by the management of a culture and of advanced operating models (Davidson et al., 2015). Moreover Jacobides et al. (2018) have highlighted that ecosystems do not always "emerge" spontaneously but they can be the result of a deliberate activity by external entities.

Several authors consider the ecosystem a complex system designed by rules and regulations deriving from supra systems belonging to the external environment (Moore, 1993; Vargo, Lusch, 2011; Davidson et al., 2015; Rong et al., 2018), taking into consideration that decisions and behaviors of a single system can influence the decisions and the behaviors of the other systems also of different sectors (Gummesson, Polese, 2009; Akaka et al., 2012; Zahra, Nambisan, 2012; Barile et al., 2016). This creates mutual influences also implemented through visible and / or invisible resource flows, contracts, trusts, and vision sharing, which can lead to the expansion or decline of the ecosystem (Tsujimoto et al., 2018). For Tsujimoto et al. (2018), “within an ecosystem, each actor has different attributes, experiences, and beliefs. This path dependency creates inertia. The differences in decision principles can cause unintended results at the ecosystem level, even though each actor's decision-making and behavior is rational at a given point in time”. By sharing a positivist vision, ecosystems are considered as “a complex web of interdependent enterprises and relationships which both create and allocate business value. Business ecosystems add mutual value – the whole is greater than the sum of the individual parts. If this were not the case, there would be no incentive for organizations or individuals to participate in the system” (Davidson et al., 2015).

In an ecosystem, on the other hand, by creating a reticular situation, a co-evolutionary process is implemented in function of an innovation aimed at supporting also services to meet the expectations and needs of the customers in a way that is advantageous for the various concerned party (Moore, 1993; 2006; Iansiti, Levien, 2004; Ozcan, Eisenhardt, 2009; Adner, Kapoor, 2010; Rong, Shi, 2014; Vargo et al., 2015; Hannah, Bremner, Eisenhardt, 2016; Vargo, Lusch, 2016; Aarikka-Stenroos, Ritala, 2017; Hannah, Eisenhardt, 2018; Rong et al., 2018).

On this basis an ecosystem strategy can be implemented, according to which, each system must align with the expectations of the other systems that are part of the ecosystem itself. This must take place on the basis of the aptitude of a focused system which, having the role of a hub with respect to a network of intersystem relations, must have the capability, through the definition of specific methods of access, incentives and control, to make them converge towards a set purpose (Adner, 2016).

This need derives from the multiplicity of entities that are part of the ecosystem, from the activities that revolve around the constraints, to the rules and criteria to be able to adhere to them and which can influence the stability of the ecosystem itself (Gulati et al., 2012). Thus, according to Stam and Spigel (2016), systemic conditions are created which represent “the heart of the ecosystem and include networks of entrepreneurs, leadership, finance, talent, knowledge, and support services”.

Among these systemic conditions that interact as determinants for the success of the ecosystem, for the purposes of the present study, two decisive factors emerge: the financial capital, which represents a critical resource for the survival of many systemic entities and the state supra-system which issues also juridical norms finalized to support the economy and the relationships between the different organizations that operate in the reference territory.

On the other hand, the possibility of accessing financial resources provided by banks favors the growth of entrepreneurship in enterprises of any kind (Kerr, Nanda, 2009; Lerner, 2010; North et al., 2013; Bruton et al., 2015; Clarysse et al., 2015; Jahanmir, 2016; Stam, Spigel, 2016; Brown, Mason, 2017).

From the analysis of previous studies, some gaps of the literatures emerged:

- there are no studies that analyze the internal dynamics and the existing relationships in the ecosystem area (McGrath, 2010; Winter et al., 2017; Jacobides et al., 2018; Rong et al., 2018);
- the role of the state supra-system was analyzed only in relation to direct interventions as risk capital (Grilli, Murtinu, 2014; Harrison, 2018);
- the role of the ecosystem as a hub has been attributed to a defined private enterprise, as a leader, "platform leader", orchestrator or focal, which promotes the alignment of objectives and alliances with a large number of other partner companies, mostly sub-suppliers or suppliers of complementary products / services, aimed at maximizing its growth and development (Williamson, De Meyer, 2012; Gawer, Cusumano, 2014; Pellikka, Ali-Vehmas, 2016; Adner, 2017).

Moreover, as far as we know, there are no studies in the literature tending to analyze the existence of actual benefits generated by the legality rating on the companies that hold this certificate.

3 Method

This paper is based on a qualitative approach. To collect primary data, a semi-structured questionnaire was administered through a link to Google form to 226 retailers with a legality rating in September 19th 2017. The questionnaire includes 5 questions aimed at detecting: eventual facilities after the legality rating for the access to bank credit; the type of benefits found; the type of bank with which each retail has financial relations; the opinion about the use of the legality rating by the bank as a tool for the enterprises rewarding or simply for assessing the creditworthiness.

A total of 123 retail enterprises filled out the questionnaire, 30 of which with the legal form of a partnership and 93 of a **company**.

Table 1 – Foundation year of respondents (%)

Foundation year	Companies	Partnership
<1980	15,4	8,9
1981-2000	35,7	13
2001-2010	17,1	1,6
2011-2015 ¹	7,32	0,81
Total	75,6	24,4

Respondents have on average 201 employees, with minimum values of 1 and a maximum of 5077 units; the median value corresponds to 44 employees.

Table 2 – Turnover of respondents in million euros, year 2016 (%)

2-10	62,6
11-50	28,4
>50	9

Analyzing the type of bank with which retailers have relationships, it emerges that companies have relationships mainly with banking groups while partnership with banking groups, people's banks and co-operative banks (Tab. 3).

Table 3 – Type of banks with which respondents have relationships (%)

Type of bank	Companies	Partnership
Banking groups, people's banks, co-operative banks and other banks	2,4	1,6
Banking groups, people's banks e co-operative banks	11,3	6,5
Banking groups, people's banks e other banks	1,6	-
Banking groups, co-operative banks e other banks	0,8	-
Banking groups e people's banks	14,6	3,2
Banking groups e co-operative banks	5,7	3,2
Banking groups e other banks	1,6	-
People's banks e co-operative banks	2,4	2,4
People's banks e other banks	1,6	-
Co-operative banks e other banks	2,4	0,8
Only with banking groups	22,8	5,7
Only with people's banks	4,1	-
Only with co-operative banks	1,6	0,8
Other banks	0,8	-
Do not relate to any type of bank	1,6	-
Total	75,6	24,4

¹ According to the provisions of the legislation, the enterprises that request the rating of legality must be registered in the "Registro delle Imprese" since at least two years.

Figure 1. shows the frequency distribution of the type of banks with which retailers have relationships

The number of banks with which retailers have financial relationships is shown in Table 4.

Table 4 - Number of banks with which respondents have financial relationships

Banks	Frequency	%
0	2	1.6%
1	44	35.8%
2	47	38.2%
3	25	20.3%
4	5	4.1%
	123	100%

4 Findings and discussion

The answers show that only 30 of the 123 respondents said they have obtained benefits from the legality rating in terms of access to bank credit (Table 5).

According to the provisions of the law on legality ratings, enterprises, which stand out for compliance with high standards of legality, have the opportunity, with regard to the credit access, to be able to obtain benefits in relation to the preliminary investigation costs of the case, to the times and economic conditions of disbursement applied by the bank.

Table 6 shows the benefits that respondents claim to have obtained from the legality rating with the characteristics of retailers. Only one respondent declared that the legality rating has maximized all the benefits provided by the law. It is an enterprise established between 1981 and 2000, with a number of employees under 10 and a turnover between 2 and 10 million euros.

Table 6. Characteristics of respondents declaring to have obtained benefits by the legality rating

Figure 3 shows the frequency distributions of the variables related to the benefits obtained by retailers in terms of attribution of reward advantages and attribution of higher corporate rating.

Figure 3. Frequency distributions of the attitudes of banks towards retailers with the legality rating

From the results it emerges that only 24% of retailers interviewed found effective benefits by having obtained the legality rating when accessing bank credit, among which there are several Small and Medium Enterprises. However, only one retail company has maximized the benefits obtainable, while in the majority of cases, advantages were found only in terms of a reduced time for processing the loan procedure. However, this did not affect the confidence that retailers place on the legality rating. In fact, it is possible to highlight clearly positive perceptions in this sense, because around 40% acknowledge that the banks with which they relate concretely reward retail enterprises with a legality rating and 48% believe that the banks use this certification as one of the variables used for the

assessment of credit access. Finally, it should be noted that the companies are more inclined in this regard than the partnerships.

5 Conclusions, practical implications, limitations and future research

By introducing and regulating the legality rating, the Italian legislator has created a reward instrument that aims both to enhance the ethical and socially responsible behaviors implemented by "virtuous" companies in the long term, and to encourage a general cultural evolution in this sense. Although the rule provides that the legality rating can also be used when granting public loans and participating in tenders for the awarding of supplies / services / public works, this work focuses on access to the bank credit, which, in accordance with the provisions of the sector legislation, is in any case subject to a positive assessment of creditworthiness also for the company with a legality rating. Although there are several studies that analyze the issue of legality ratings according to the view of banks, which are required to publish data in this sense annually, this study presents significant elements of originality. On the basis of the information collected, in fact, it represents the first scientific contribution in which the business perspective is analyzed and in particular that of the retail enterprises. Moreover, this work contributes to enriching the literature on the retail ecosystem as it shows the existence of an ecosystem that emerges even if it is not always possible to design it, because relations and interactions that are difficult to hypothesize and can be schematized within specific binding regulations for the counterparts, develop.

Certainly the legal rules and therefore the constraints imposed by a relevant supra-system can support the strengthening of relationships aimed at creating shared value; however, it is undeniable that, in many cases, relations and interaction, between banks and retail companies, are governed by a relational capability dictated by a system of elements, of a different nature, that emerge: consonance between business and territory, in-depth knowledge, long term personal and trust relationships.

In conclusion, this research consolidates the thesis according to which a retail ecosystem within a B2B relational context between banks and retail companies, is not something that can be built a priori, but is something that must emerge. In this scenario, the relational elements can certainly be encouraged by certifications and rules, even if the latter are not decisive. In fact, especially in some contexts, relations between people are still fundamental, to the point that the rule is outdated by so-called institutions, in practice those rules also not written, those consolidated relationships, those customs that guarantee more than norms and certifications.

With regard to the research limitations, it is undeniable that, in order to generalize the results obtained, it would be appropriate to extend the study to include companies operating also in other economic sectors and analyze the same perceptions in relation to the possibility of accessing public funding.

With regard to future research, it is planned to deepen the analysis by repeating the administration of the questionnaire after a few years, to assess whether the data will undergo a positive or negative evolution and if the legality rating will be able to achieve

the objectives set by the legislation, while taking into account that over the years the number of companies in possession of this certificate has grown considerably. Furthermore, we intend to verify a possible correlation between the benefits obtained by retail companies with a legality rating and the level of the rating held, which increases in relation to the possession of certain requisites required by law.

Abstract

Modern Modern markets can be seen as a complex system embedding the various stakeholders in a mutually influencing network of relationship that is able to influence their decision-making processes and their value creation processes. As a consequence, modern businesses have been called to adopt a broader perspective in order to not focus their actions only on trying to maximize their economic performance, but to design them taking into account even the social and environmental impacts they have on the system as a whole; according to Zimmerman and Zeitz (2002) firms have to respond to the expectations of the various social actors operating in the same systems they are embedded into as a way to obtain the legitimacy needed to create a beneficial environment that will help them in creating a positive effect out of the system of relations the companies are part of without violating the social contract tying together all the actors in a given system (Donaldson and Dunfee, 2002). It follows that, when companies can effectively communicate to their systems' actors how they are following the principles of sustainability and somehow prove that their actions are Socially Responsible, they can get several advantages. One of the way companies have to accomplish this feat is to ask third parties to certify their actions in order to be able to print on their products one of the various Ethical Labels. Using these labels to mark their products can be used as a tool to influence the consumer in buying the company's over the competitors' one leveraging on a higher legitimacy.

In this paper, we have studied the evolution of the practice of non-financial disclosure through ethical labels that 14 coffee brands, both in Italy and in England, as a way to understand how, in different markets they have changed over a 5 year time span.

Keywords – Ethical Branding; Social Responsibility Disclosure; Legitimacy; Coffee; Modern Retailing.

Paper type – Academic Research Paper

1 Introduction

Today firms are seen as social actors in a complex systems (Boardman and Sauser, 2008). These system's actors are linked in a web of relationship, driving enterprises to take into account their activities effects on the system as a whole, not only focusing only on those actors they are in a direct relationship with but factoring in even the effects they will have on the other actors. Moreover the network structure will limit the freedom of the companies as it will propagate, and amplify, both the positive and the negative perceptions of the various actors in the system (Ekeh, 1974; Harrison and Wicks, 2013) and the companies will have to follow the social contract (Donaldson and Dunfee, 2002) they have with all the system's actors. It follows that modern companies cannot focus only on the economic performance but they have to adopt a broader vision, encompassing the social and environmental perspectives (Elkington, 1994; Passet, 1996; Sciarelli, 2012); moreover, they are more and more driven to adopt *social responsibility disclosure* (SRD) (Chauvey, *et al.*, 2015) practices to influence their stakeholders and their buying behavior (Auger *et al.*, 2008).

Several marketing scholars (Bone and Corey, 2000; Rokka and Uusitalo, 2008) have found that modern consumers prefer to consume those products they sharing values with. The product packaging, its design and its gestalt, is one of the ways companies have to communicate with their customers and to show them the values they are adopting (Wansink, Sonka, and Hasler, 2004; Silayoi and Speece, 2007).

In this paper, we report the first results of our study on how firms non financial disclosure practices using ethical labels in their products, have changed over the last 5 years. In particular, we have looked into the different approach to ethical labeling by 13 coffee brands, 10 in Italy, and 3 in the UK, both in the 2014 and in the 2018, as a way to understand how companies look at the evolution of the market.

2 Corporate Social Responsibilities, Stakeholder management, and Sustainability

As highlighted by Freeman in 1984, modern companies live in a complex world requiring them to interact with many different stakeholders not only to get access to the resources they need to carry on their activities (Pfeffer and Salancik, 1978; Frooman,

1999), but even to get a competitive advantage (Harrison, et al. 2010). Acknowledging the existence and the nature of these ties with the organization's stakeholders (Freeman, 1984; 96) is needed to define actions that can reduce the negative effects of stakeholder pressures on the company while maximizing the positive ones (Mohr, et al., 2001) as responding to these pressures in the right way is one of the keys for the companies to get the legitimacy needed to reap the maximum benefits out of the system of relations they are part of (Zimmerman and Zeitz, 2002).

Chauvey (et al. 2015) show that adopting standard SRD practices is one of the way companies can effectively obtain this legitimacy; at the same time Maak (2007) showed that the higher legitimacy is linked to the company ability to create a set of relationship with their interlocutors not only mutually beneficial but even consistent, stable over time.

It follows that companies should go beyond focusing their activities only on the economic performance but they should create value for their stakeholders, taking into account the various social and environmental constraints in order to contribute to society's advancement (Elkington, 1994; Passet, 1996; Sciarelli, 2012). Moreover the focus on sustainability should not be limited to the organization itself, but it should encompass all its value systems (Markley and Davis, 2007; Matos and Hall, 2007).

According to several authors (Hoeffler and Keller 2002; Sen and Bhattacharya, 2004, Barnett, 2007) CSR benefits are linked to the consistent responsible behavior over time as it create a set of positive perceptions that, in future, will be able to balance the eventually socially irresponsible activities (Brown and Dacin, 1997; Godfrey, 2005) with a positive corporate association.

Moreover, several authors (De Pelsmacker, et al., 2005; Lamberti and Lettieri; 2009) have found that there is a niche of consumers willing to pay a higher price to buy an asset that had been produced in a socially responsible manner; Line et al. (2002) got a similar result for ethical behavior. As a consequence, when companies are able to effectively behave in a responsible way they are able to implement a differentiation strategy, even if only for some of their product lines (Auger et al., 2003; Porter and Kramer, 2006; Carroll and Shabana, 2010).

3 Social responsibility disclosure via packaging and ethical brands

SRD activities, the various practices a company can use to disclose to the market their activities toward a sustainable society. Moreover, in the last 20 years, the SRD practices have been strongly developed (Deegan 2002; Kolk, 2003).

SRD can focus on various topics and it is usually difficult to draw a general criteria on SRD as it mostly depends on the business area the company operates (Ingram, 1978); but Branco and Rodrigues (2008) show that they usually focus on four issues: environment, human resources, products and consumers, community engagement. On a similar page, Hanss and Böhm (2012) have found that corporations have been driven by stakeholders' requests towards environmental sustainability and other issues related to social sustainability.

Even Dawkins and Lewis (2003) highlighted that market actors have an interest in getting access to this information, although other authors (Folkes and Kamins, 1999) point out that the SRD positive effects are coupled with more negative ones when the company adopts an unethical behavior.

Several authors (Nilsson, *et al.* 2004; De Pelsmacker and Janssens, 2007) have shown that insufficient transparency is one of the main SRD limitations, undermining their credibility. This risk is stronger when companies try to use SRD as a tool of brand reputation management (Neu *et al.*, 1998; Hooghiemstra, 2000) rather than as a way to help external stakeholders in understanding their social performance (Berthelot, *et al.* 2003; Dubbink, *et al.* 2008).

Even if today, companies have access to multiple media to use in their own SRD activities (Jenkins and Yakovleva, 2006), product packaging is one of the main tools company have in SRD as it does not only have a logistic and functional use (containment, protection, fragmentation, transportation, storage), but also for its role in communication process (Prendergast and Pitt, 1996). In our modern self-service economy (McDaniel and Baker, 1977), the role of packaging is becoming more and more crucial, since it is the last things consumers see before making the decision purchase (Ampuero and Vila, 2006). Pearce (1999) acknowledges that packaging becomes more relevant when the consumer has only a limited knowledge of the products and, companies can use brands, symbols or logos (Azad and Hamdavi pour, 2012) in order to communicate personal and social values (Underwood, 2003). It follows that packaging becomes more relevant in consumer relationships and some companies invest more on the design of the packaging of the product than on its advertising (Dickson, 1994).

Ethical brands, logos that companies can use to signal to stakeholders, mainly consumers, the respect of some basic principles (Font and Harris, 2004), can be used to prove if the company compliance with a given disciplinary (Teisl, *et al.* 2008).

Ethical labels, when known, help consumers in identifying more sustainable products, and, therefore, it may influence their purchasing behavior (Gallaraga Gallastegui, 2002; Hanss and Böhm, 2012). Other authors, however, stressed that the use of ethical brands faces also some critical issues, both related to their content and to the ability of consumers to fully understand their meaning. Van Amstel, *et al.* (2008) have criticized these labels as they are voluntary ones and their rules are often not enough rigid; on the same page, Gallaraga Gallastegui (2002) points out that a general lack of objective measures. On the other side, the perception of consumers of an ethical label brand is rooted on their limited knowledge of the mark's real meaning (Codron, *et al.* 2006), and on the risks of information overload when there are too many labels (Thøgersen, 2000).

4 Research Objectives and Design

The literature review highlights that a social responsible behavior can be used in corporate communication processes to influence its stakeholders and get better reactions to the firm's activities (Brown and Dacin, 1997; Godfrey, 2005). In particular, the literature review on SRD has highlighted how the packaging (Underwood, 2003) is

widely used to convey these informations as a consequence of the modern GDO self-service approach (McDaniel and Baker, 1977 Rettie and Brewer, 2000). Moreover, since the packaging communication process is implemented through trademarks, symbols and logos (Azad and Hamdavipour, 2012), it is especially suited to show off ethical labels the corporation has been certified with as a way to enable them to show consumers, and other stakeholders, that their commitment to sustainability issues is not a façade, but underlies a set of shared values (Font and Harris, 2004).

In this paper we present the preliminary results from a single sector in order to reduce the variability (Yin, 2003): ground coffee. We have chosen to focus on ground coffee as it is a commodity that is produced abroad (Catturani, et al., 2008) and it has been previously studied (De Pelsmacker, *et al.* 2005; Arnot, *et al.* 2006) have shown how, in this specific market, socially responsible business behavior actually result in a competitive advantage, a factor encouraging companies towards SRD (Mackey, *et al.* 2007).

Moreover there are several ethical certifications aimed at analyzing the sustainability of production processes and supply chains (Perna, 1998). In addition, as with all food and agricultural products, companies have the opportunity to also adopt organic farming, to further emphasize their responsible behavior towards the natural environment.

In this sector there are only few brands, helping consumers to know them and to understand them more easily (Hanss and Böhm, 2012), limiting the information overload risk (Thøgersen, 2000). The following table 1 shows the main sustainability certifications used by coffee importers on their packaging.

Table 1 – Most Used Ethical Standards in Coffee

Labels	Institution			Transparency		
	International	Private?	Coop?	Verification	Independent certified	Traceability
<i>Ecolabel</i>	YES	NO	NO	YES	YES	YES
<i>Fair Trade Label Organization</i>	YES	YES	YES	YES	NO	YES
<i>Rain Forest Alliance* **</i>	YES	YES	NO	YES	NO	NO
<i>UTZ **</i>	YES	YES	NO	YES	YES	NO

Labels	Subject			
	Supply Chain	Firm	Product	100% labeled
<i>Ecolabel</i>	YES	NO	YES	NO
<i>Fair Trade Label Organization</i>	YES	NO	YES	YES
<i>Rain Forest Alliance* **</i>	NO	YES	NO	NO
<i>UTZ **</i>	YES	YES	YES	NO

Labels	Social Performance				
	Child Labour	Freedom of union	Subcontractors	Social Development	Land Rights
<i>Ecolabel</i>	N/A	N/A	N/A	N/A	N/A
<i>Fair Trade Label Organization</i>	YES	YES	YES	YES	NO
<i>Rain Forest Alliance* **</i>	YES	YES	YES	NO	YES

<i>Ecolabel</i>	YES	NO	YES	N/A	NO
<i>Fair Trade Label Organization</i>	NO	NO	YES	NO	NO
<i>Rain Forest Alliance* **</i>	NO	NO	YES	NO	YES
<i>UTZ **</i>	YES	YES	NO	NO	NO

* A company has to follow more than 80% of the standards criteria to be certified

** Merged from december 2018, no common standard

Our analysis has been focused on two geographically distinct markets: the Italian and the English one. We looked into UK-based companies as it is an advanced market as, according to FLO data (2012), fair trade coffee has grown by about 13 times from 2001 to 2010, reaching almost 25% of the entire national market. The cases we have selected have been shown in the following Table 2. As the table shows we have analyzed 10 Italian brands (3 private labels, 3 responsible brands, and 4 traditional ones) and 3 main UK-based brands (1 responsible label and 2 private labels). Even if the number of producers is different, as shown in table 2 the number of different product label in the 2014 was similar (54 in Italy, and 47 in Uk).

Table 2 – The Cases

Mkt	Company	Brand	Abbr.	2014		2018	
				Products	Certified	Products	Certified
Italia	Alice Nero	Alcenero	AN	2	2	3	3
		Altromercato	AMA	5	5	5	5
	Altromercato	BioCaffè	AMB	2	3	4	4
		Monorigine	AMM	5	5	3	3
	Cafè do Brazil	Kimbo	KMB	6	0	10	1
		Kosè	KOSE'	2	0	2	0
	Carrefour	Normal / Classic	CRFN	5	0	5	0
		Selection	CRFS	2	2	2	2
		Bio	CRFB	-	-	1	1
	CONAD	Conad	CONAD	3	2	7	0
		Conad "Il Biologico"	CONBIO	1	1	1	1
	Coop	Coop	COOP	2	0	5	0
		FiorFiore	COOPF	1	1	1	0
		Solidal Coop	COOPS	2	2	2	2
	Ecor	Ecor	ECOR	1	1	2	2
		Natura Si	NATS	1	1	-	-
	Illy Caffè	Illy	ILLY	3	0	7	0
	Lavazza	Lavazza	LVZZ	7	0	7	0
		!Tierra!	!T!	-	-	5	5
	Passalacqua	Passalacqua	PSSL	4	0	4	0
Inghilterra	Cafedirect	Monorigine	CDM	4	4	5	5
		Organic	CDO	-	-	4	4
		Blends	CDB	6	6	5	5
	Sainsbury	Fair Trade	SBFT	11	11	7	7
		Taste the difference	SBTTF	10	10	9	9
	Tesco	Local	TSCLC	6	6	6	1
		Finest	TSCFIN	10	9	7	7

For each of these products we have looked if they were used as a media for SRD, and, as the various certification are really different, we have looked into which one they used. The factors we have studied have been reported in table 3.

Table 3 – The factors investigated

Indicator	Description	Values	
EP	Organic Product or RFA Certified	NO	YES
SP	FLO or UTZ	NO	YES
Country of Origin	Explicit definition of the Coffee Beans	NO	YES
Blend or Taste	% of Arabica Coffee Beans or a Description of Taste	NO	YES

We have not looked in the companies Social Report as many of them (mostly the Modern Distributors) even if they have a social report do not disclose their activities at the product level so the data would have been dishomogeneous with those of the packaging.

5 Discussion of Results

In the following tables 4, and 5 we report the main findings in the two years.

Table 4 – Results in the 2014

Mkt	Company	Brand	Abbr.	2014				
				Products	EP	SP	CoO	Blend or Taste
Italy	Alce Nero	Alcenero	AN	2	2	2	2	2
		Altromercato	AMA	5	0	5	0	5
	Altromercato	BioCaffè	AMB	2	2	2	0	2
		Monorigine	AMM	5	5	5	5	5
	Cafè do Brazil	Kimbo	KMB	6	0	0	0	6
		Kosè	KOSE'	2	0	0	0	2

		Natura Si	NATS	1	1	1	0	1
	Illy Caffè	Illy	ILLY	3	0	0	0	3
	Lavazza	Lavazza	LVZZ	7	0	0	0	7
		!Tierra!	ITI	-	-	-	-	-
	Passalacqua	Passalacqua	PSSL	4	0	0	0	3
UK	Cafedirect	Monorigine	CDM	4	0	4	4	4
		Organic	CDO	-	-	-	-	-
		Blends	CDB	6	0	6	0	6
	Sainsbury	Fair Trade	SBFT	11	1	11	1	11
		Taste the difference	SBTTF	10	0	10	9	10
	Tesco	Local	TSCLC	6	6	0	1	6
		Finest	TSCFIN	10	1	9	9	10

The results have been displayed graphically in the following figure 1 where we show the percentage of products disclosing the environmental and the social activities by brands.

The picture highlights the presence of four main clusters: Traditional Producers; Partially Responsible Producers; Fair-trade Producers; Ethical Producers.

The first cluster is composed by the Italian traditional producers that do not do any kind of social disclosure through the packaging, while focusing their communication on their brand. The second cluster is composed by the Italian Coop and by Tesco in UK. These big players have created specific lines to disclose their socially responsible activities overseas.

The third cluster is composed by the Fair-trade producers mostly focused on Social Performance and with a limited focus on the Environmental one.

In the last cluster (Ecor and Alce Nero in Italy) we have the two producers that are fully leveraging their CSR related activities. AltroMercato, in Italy, is in the middle ground between these last two clusters.

Figure 1 – SRD by coffee Brands in the 2014

The results in the 2018 investigation have been reported in table 5.

Table 5. – Results in the 2018

Mkt	Company	Brand	Abbr.	2018				
				Products	Env.	Social	CoO	Blend or Taste
Italy	Alce Nero	Alcenero	AN	3	3	3	3	3

	Tesco	Local	TSCLC	6	6	0	1	6
		Finest	TSCFIN	7	0	7	7	7

As before, we have represented the brands SRD in a figure (figure 2).

After 5 years the cluster of the traditional players have reacted to the market need of SRD and Cafè do Brasil, with the Italian Private label have created a different cluster with around the 20% of certified product lines.

Figure 2 - SRD by coffee brands in the 2018

Lavazza has strongly pushed toward sustainability (40% in both EP and SP). Cafédirect in Uk has joined Altrmercato to highlight a common strategy of these two fully fair-trade producers. The changes have been represented in the following table 6, and in figure 3.

Tables 6 – the change in the 5 years

		2014		2018		GAP	
		Env SRD	Social SRD	Env SRD	Social SRD	Env SRD	Social SRD
Alce Nero	AN	100%	100%	100%	100%	0%	0%

Figure 2 - SRD by coffee brands in the 2018

6 Conclusions

Our preliminary findings show that Companies in the Coffee Industry are reacting to the consumers' requests of a Behavior not only by the company but by their whole supply chain.

In particular we have found that in the 2014 there was a clear division between the two markets as in the UK there was a stronger adoption of the fair-trade label that. This label is mostly focused on the social aspects of sustainable development even if it asks companies to act for limiting the damages to the environment.

In Italy, we have found a stronger pressure towards the environmental side of CSR even if the players adopting the Ecolabel have even adopted the Fair-trade label in order to attest their behavior in the Social dimension of sustainability.

During the last years, the pressure towards sustainability have driven some of the traditional companies to create specific product lines to attract the more sensitive part of the market, with the exceptional growth of Lavazza that has decided to create a specific line so it now certifies the 40% of their product lines (not sales). Using this strategy these players have been able to play in several different segments, as shown by the increased number of product lines (from 54 to 76 in Italy).

The data show that the difference between the two market has slowly been reducing as the companies in both markets are starting to leverage SRD in both dimensions.

Our paper is just the preliminary findings to these topics, and they highlight several new directions for further analysis.

On one side, focusing on the Italian market we should focus on the effect that the new coffee caps have had toward SRD. As these products are usually sold for higher prices, they create the resources to buy more certification and to source in a more responsible way.

On the other side, we should factor in the real market effects linked to these new more sustainable product lines gathering data on the consumer perception of these labels in

order to understand if they know the differences among them or, at the very least, if they are able to discern among them.

Abstract

Purpose – The paper presents an approach helping to create a big picture view of the different information pieces involved into research. The approach is based on the use of modern visual knowledge mapping techniques. The focus of this paper is on applying systems thinking and visual metaphors for generalization of the selected research domain of management research. The visualization techniques serve not only to present the results of research analysis and to illustrate generative/analytical techniques representing the data. They are providing insight and communicative tools forming the context essential for the understanding and implementation of the research results and further discussions. Our aim is to give advice on how we can improve general understanding by using visual metaphors for different data, knowledge category and purposes. Examples for the use of this classification system for a big picture view of management research are presented. Specific examples are illustrated by concept maps, mind maps and Ishikawa diagrams.

Design/methodology/approach - This paper is considering the design science research approach and systems thinking. It is focused on the differentiated question-based aspects depending on knowledge type and the visualization techniques. We split the research knowledge domain into seven main categories of knowledge: what, what for, how to, who, where, when, and why. Each of these categories could be better presented by a different visual knowledge codification technique, enabling to create a set of diagrams for the development a big picture view of management research.

Originality/value – This research puts in evidence on the issue of big picture thinking with the use of visualization technique for the knowledge domain of management research. Different stages of research work are exploiting various complex cognitive processes. Research is a collective work and joint understanding and knowledge sharing are essential for the success. Decomposing research tasks ranging from writing a paper

to creating a grant application often results in a comprehensive set of subtasks that have complex dependencies on each other. Visual approach simplifies all the above-mentioned difficulties by creating the illustrations and simplifications of the pieces.

Practical implications – Described big picture visual approach may help young researchers and knowledge analysts to accomplish, to present and to share their results in the research community. This will also help other researchers to interpret the meanings of the concepts correctly, avoiding the cases of semantic ambiguity.

Keywords – knowledge management, visualization technique, big picture research, domain-specific KM, case study.

Paper type – Academic Research Paper

1 Introduction

In recent years, visual metaphors and images have not only become an important communication tool in academia and education to generate and uphold understanding and audience interest but also a rich resource for systems thinking and deep modelling. In this paper we discuss how well-known diagrams gathered from different business domains may be used to rethink and reconsider research in order to present which abstract concepts and objects matter to researchers to identify their ideas and to illustrate their main findings. By using mind maps and other diagrams, we explore how these visual schemes can provide deep contextual presentation of a research big picture for understanding the main ideas, principles, concepts and their relations. To facilitate analysis of the research approach we introduce visual knowledge codification tools and use them to analyze the main elements related to the study. In total, we collected some popular diagrams and used them for the research description and illustration.

However, even the simplest diagrams may cause frustration for the researchers unfamiliar with visual approach. Very few studies exist on what people do to overcome problems they encounter on the way to knowledge mapping, or how diagrams can be designed to aid people when these problems occur. In this paper, we analyze several popular diagrams (like mind maps, concept maps and Ishikawa diagram) on how researchers can implement them in order to present their current research. In particular, we identify the main categories and types of diagrams for the researchers. We analyzed the patterns of how different diagram forms and metaphors are used. We suggest some practical rather than universal solutions that may help both business school students and young researchers in their communications.

2 Research methodology

The use of graphical images, figures and maps is growing in popularity in research publications. In this paper identification and systematization of visual knowledge codification (diagramming) techniques for different management research categories and

purposes was done on the basis of the systemic literature review and interviews. A broader definition of visualization states that it is in general “a graphic representation that depicts information in a way that is conducive to acquiring insights, developing an elaborate understanding, or communicating experiences” (Lengler & Eppler, 2007). As noted by many researchers (Luther, Fiesler & Bruckman, 2013; Hahn, Chang, Kim & Kittur, 2016), decomposing tasks ranging from writing an article to creating an animated film often results in pieces that have complex dependencies on each other. Management research, as well as research in general, develops through small contributions of individuals, each of whom sees only a part of the whole big picture view. Supporting and developing management research requires a big picture view of different pieces at different scales and ensuring they all fit together. Accomplishing big picture thinking through small tasks is challenging because it means that each person can only have a limited view of the bigger picture.

Diagramming techniques were chosen to develop a big picture or visionary view of management research as they “occupy that hinterland between written text and the purely graphical. That is their strength, enabling, often through the use of graphic metaphor, the visual representation of the otherwise invisible” (Richards, 2002). A diagram serves to provide insights, develop an understanding on a specific data or topic (Iliinsky, 2010; Lengler & Eppler, 2007; Yin, 2011).

3 Tool to develop a big picture view on management research

Different stages of research work require various complex cognitive processes. The use of visual knowledge codification techniques simplifies to solve all the subtasks in decomposing research tasks in management. The suggested specification of knowledge types and diagramming techniques in management research is based on previous research and presented in Figure 1 (Kudryavtsev, Gavrilova, 2017).

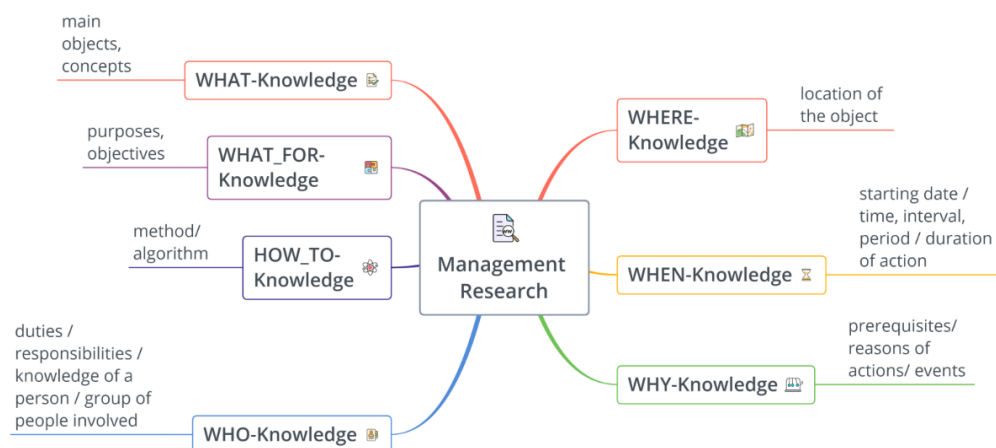

Figure 1 Description of knowledge types in management research developed from (Kudryavtsev, Gavrilova, 2017).

Specification of knowledge types described in Figure 1 helps a lot to create the set of diagrams for the big picture of management research depending on the question under consideration. This helps young researchers and knowledge analysts to find the most appropriate diagram for the presentation of the particular task; the more tasks they visualize this way – the bigger picture they get!

Visual knowledge codification techniques displayed in Figure 2 are universal techniques that can be applied to different knowledge types, but are more frequently used for “what”-knowledge. The visual approach help to inspire the researcher’s creativity and to summarise the heterogeneous pieces of information into more abstract categories.

To capture a big picture of management research, concept maps and mind maps were chosen as commonly used diagrams in scholarly research (Wheeldon & Ahlberg, 2012).

Mind maps are more flexible that concept maps in which a central governing construct is explored using groupings and/or branches (Tattersall & Vernon, 2007; Wheeldon & Ahlberg, 2012). Mind maps presented in Figure 1, 2 help to illustrate the idea of knowledge types and classification of visual knowledge codification techniques in management research, with the most important concepts of knowledge types that radiate from the central idea of management research.

Concept maps represent a technique to describe principles in management research and to represent their perceived relationships between various concepts, usually enclosed in circles or boxes (Novak & Gowin, 1984). In order to explain the conceptual structure of thesis that corresponds to WHAT-Knowledge, concept map was chosen. Linking words in the concept map help to present clear propositions on the structure of thesis described in Figure 2.

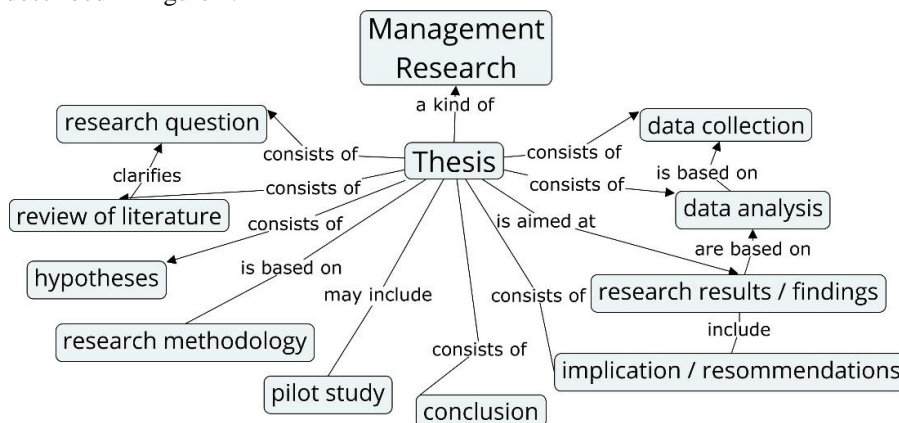

Figure 2 Concept map describing possible structure of the thesis (WHAT-knowledge example).

Cause-and-effect, or fishbone, or an Ishikawa diagram (Ishikawa, 1963; Kenett, 2007) is recommended to present WHY-knowledge, and this was chosen and created for the representation of structured literature review on visual knowledge mapping techniques (see Figure 3 for the part of it). A fishbone diagram is a graphical tool for categorizing the potential causes of a problem in order to identify its root causes. Dr. Kaoru Ishikawa, a Japanese quality control expert, introduced it to help his colleagues avoid solutions that

merely address the symptoms of a much larger problem. The design of the diagram resembles a skeleton of a fish. Fishbone diagrams are typically worked right to left, with each large “bone” of the fish branching out to include smaller bones containing more detail.

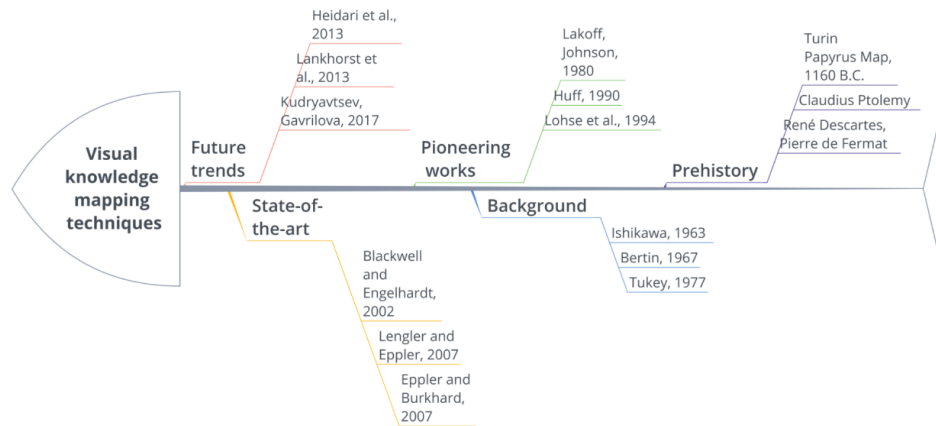

Figure 3 Fragment of Ishikawa diagram for structured literature review (WHY-knowledge example).

Sometimes such diagrams may be used for the historical view. Then the central line of Ishikawa diagram is the metaphor for time, dating back to the prehistoric period and coming to the present time, reflecting the future trends as well. Earlier works caused further development of visual knowledge mapping techniques, so structured literature review refers to WHY-Knowledge.

Usually research tasks require not only a single diagram as they depict various knowledge types; but also a set of diagrams to represent big picture, supporting the concepts presented in each of them. Supporting such work requires having a well-trained generalizing and analyzing abilities for developing the systemic view of different research aspects at different scales and ensuring they all fit together. The diagrams chosen to present research development aim at creating a big picture view of a single research or general research issues and help to avoid semantic interoperability. However, the relationships between different types of research knowledge may be presented by matrix (positioning and decision matrices, generic grid, generic scored profile, generic table) or state-space solutions, tables, profiles, checklists, taxonomy, software, and combinations thereof.

Nowadays there are a number of digital tools to support e-doodling of these diagrams. The authors use some free software to create the presented figures. But in our educational practice we use Microsoft Visio, Mind Manager, IHMC Cmap Tool, Gliffy, Trello, etc. (Capterra, 2019).

4 Conclusions

Visual knowledge codification (diagramming) techniques are widely used in research in general as well as in the management domain for collecting, organizing and summarizing different data. The paper puts in evidence on the issue of a big picture view of the different interdependent information pieces involved into research. Modern visual knowledge codification (diagramming) techniques help to capture a big picture view developing the context for the perception and realization of the research results and discussions. The paper focuses on the graphic representation of experience in the domain of management research. Especially such approach is useful in business schools and universities where students are more focused on the practical goals and underestimate the research activity. They are also unfamiliar with the business research methodology.

The study identified a visual approach that can help to create a big picture methodological view of the different information pieces (data, definitions, cases, documents, video- and audio-content, etc.) involved into research. Described diagramming techniques may help young researchers and knowledge analysts to accomplish, to present and to highlight their results either for a particular research project or for general research issues.

Concept maps provide a more structured approach to present connections to the management research concepts, with linking words depicting clear propositions. On the other hand, mind maps are more flexible tools in which a central concept is represented using groupings and/or branches. Besides, Ishikawa diagram serves a tool to explore cause and effect of a problem. The relationships between different knowledge types of management research may be presented by matrix or state-space solutions, tables, profiles, checklists, taxonomy, software, and combinations thereof.

Well-facilitated by technology media visual representation of a big picture view on management research provides additional data representation, serves an attempt towards better communication between all the stakeholders and contributes to the growing interest to the use of visual methods for business and academic purposes.

Abstract

In relation to SMEs (small and medium sized enterprises), there is a lack of managerial mechanisms to overcome environmental knowledge barriers. Some of these barriers are related to resource shortages or outdated knowledge, which can impede the utilization of Knowledge. In the following paper, we consider that if environmental knowledge barriers are present then specific knowledge management practices are required to stimulate the utilization of knowledge and, hence, provide for the assimilation of knowledge. Thus, in this paper, we focus on socializations practices as a method to counteract the problem of environmental knowledge barriers. We have analysed the relationships between environmental knowledge barriers and the SECI model using an empirical study of 87 Spanish Knowledge Intensive Business Services (commonly known as KIBS) (are services and business operations heavily reliant on professional knowledge) in SMEs, in order to identify whether the impact of environmental knowledge barriers on knowledge utilization can be mitigated through socializations practices. Our results confirm that when environmental knowledge barriers take place, the relationship between socializations practices and the utilization of Knowledge is weaker than it otherwise would be.

Keywords – Environmental knowledge barriers, Utilization of knowledge, Socializations practices.

Paper type – Academic Research Paper

1 Introduction

In recent years, small KIBS enterprises have been under pressure to innovate in order to meet modern world customers' requirements. Whilst many researchers investigated into open innovation in KIBS organisations, the main focus has been on large organisations. SMEs normally face more resource constraints than large organisations, and this could potentially influence the adoption of open innovation in SMEs. In order to create a more enabling environment for open innovation in KIBS SMEs, it is necessary to gain further insights into this domain.

The great challenge of our days is the care of the environment because the natural resource are in rapid decline (Cegarra-Navarro & Martinez, 2010; Mardani et al., 2017). Increasingly, several previous research have analysed the role of environmental sustainability in different areas such as; waste management, green product or service, climate, energy, tourism and tourist behaviour, information and communication technology, decision making, business performance and practices (Mardani et al., 2017) and other topics. In environmental issues, the principles, rules and methods are constantly questioned because rapid changes require it.

Companies are increasingly challenged to include environmental concerns in their activities. While in the past companies were considered to be mainly the source of the environmental problems, more recently they are increasingly seen as a possible solution largely thanks to their eco-innovative activity (Cainelli, De Marchi, & Grandinetti, 2015). Although, a growing number of businesses and researchers have recognised economic advantages in environmental practices, however, some companies are not implementing sustainable practices (Darnall, Henriques, & Sadorsky, 2010). The companies find barriers to applied and use environmental knowledge (Martínez-Martínez & Cegarra-Navarro, 2018; Murillo-Luna, Garcés-Ayerbe, & Rivera-Torres, 2011; Pinget, Bocquet, & Mothe, 2015; Yang & Zhang, 2017).

It should be also noted that previous studies have implicitly identified barriers to use the environmental knowledge into internal and external barriers (Chan, Okumus, & Chan, 2015; Murillo-Luna et al., 2011). The external barriers cannot always be controlled by firms (for example, legislation) however, in the internal barriers the firms could decide and act on them to modify, it seems interesting to investigate about the second type. For example, as Darnall et al., (2010) said, while smaller firms are less likely to undertake as many environmental practices as larger firms, extant literature suggests that smaller firms may be more responsive to the pressures to owners, managers or worker, in addition other stakeholder, to implement them.

In order to move towards adopting more sustainable measures, the elimination of barriers to environmental knowledge is necessary (Connell, 2010). One way people can overcome environmental knowledge barriers is by knowledge socialization practices, such practices help increase interaction between managers and organizational members that entrust them to share diverse interpretations of problems and solutions (Martínez-Martínez & Cegarra-Navarro, 2018), which serves to foster the utilization and promote the integration of heterogeneous knowledge (Cainelli et al., 2015). This study investigates

how socialization practices can mitigate or even counteract the presence of environmental knowledge barriers, along with investigating how such a process can, in turn, result in successful knowledge utilization.

This research contributes to the relevant literature in several ways. Firstly, it focus on the knowledge-intensive business services (hereafter KIBS) which makes this research unique when compared to previous studies, which have examined this problem in industrial contexts. Secondly, in the literature there are many researches on the need to use environmental knowledge but we are finding a gap between barriers to use environmental knowledge in KIBS SMEs (Castaldi, Faber, & Kishna, 2013; Pinget et al., 2015). We are focus on internal barriers of environmental knowledge in KIBS because those firms are facilitators to knowledge, research about the barriers to use environmental knowledge could be a first step to eliminate those barriers and to use environmental knowledge by KIBS. The proposed theoretical framework is presented in the following section. Details of the survey that was used to collect appropriate data to test the model are presented in section 3, results in section 4 and the conclusions, managerial implications and limitations are discussed in section 5.

2 The proposed research model

2.1. Knowledge utilization

To define knowledge utilization, we would argue that “knowledge application” is one thing and “applying knowledge” another. While knowledge application is a KM process that entails being good at transferring knowledge from one context to another (Gold, Malhotra, & Segars, 2001), applying knowledge learned to a new context may provide organizations with the incentive to improve efficiency (Senge, 1990). Put another way, while knowledge application is the capability for effective action, applying knowledge is the effective action in the business, which may involve many complex issues. This paper will therefore focus on our consideration that “knowledge utilization” is one way to apply learned knowledge to new understandings and situations to create the perception among customers that the company’s version of its product or service is somehow different and thus has added value that is not available from its competitors (Khamseh, Jolly, & Morel, 2017; Kim & Kim, 2017; Martelo-Landroguéz & Cegarra-Navarro, 2014).

2.2. Environmental knowledge utilization

As shown in Table 1, environmental knowledge (EK) has been defined in different ways. While there are authors who identify the key enablers of EK, there are others who point out the key outputs. At this point, it is also important to differentiate between reflective and formative constructs. Based on the presence of enablers versus outputs, we can find an interesting perspective about formative and reflective measurements (Rigdon, 2016). While the presence of a composite reflective EK-construct may show a high level of correlation between EK utilization issues (Cepeda-Carrion, Cegarra-Navarro, & Cillo,

2019), a composite formative EK construct may show that its EK-enablers are the ingredients to be combined to shape the construct itself (Cepeda-Carrion et al., 2019). In this study, environmental knowledge utilization is specified as a composite reflective construct given that there is a high level of correlation between indicators (Dijkstra & Henseler, 2015; Henseler, Hubona, & Ray, 2016).

Table 1. Key definitions of environmental knowledge

Definition	Source
'refers to the understanding and retention of information on ecological problems and connexions' (pp. 2)	Martínez-Martínez, Zumel-Jiménez and Cegarra-Navarro (2018)
'is a stronger predictor of private pro-environmental behavior than professional environmental knowledge' (pp. 289)	Duan and Sheng (2018)
'two constructs based on the amount of "real" (objective) and "perceived" (subjective) knowledge with regards to environmental problems and solutions' (pp. 4)	Kim, Kim and Thapa (2018)
'is technology transfer and spillovers' (pp. 382)	Ning and Wang (2018)
'is a significant predictor of environmental behaviour' (pp.86)	Myung (2017)
'shapes environmentally friendly attitudes and more responsible behaviours in relation to the surrounding environment' (pp. 385)	Paço and Lavrador (2017)
'is closer to a wide range of resources for effective action (i.e. procedural knowledge)' (pp. 283)	Martínez-Martínez, Cegarra-Navarro and García-Pérez (2015)
is a process that entails being good at transferring knowledge from one context to another (pp. 225)	Nieves and Haller, (2014)
'embedded explanatory, instrumental and evaluative knowledge, offering the "why" and "how" for the internal organisational agents (i.e. shareholders, management, and employees)' (pp. 343)	Cegarra-Navarro <i>et al.</i> (2013)
'how different approaches can work together to better steward and manage the environment and natural resources' (pp. 2)	Whyte (2013)
'as the knowledge on what people know about the environment, key relationships leading to environmental impacts, an appreciation of the 'whole systems', and collective responsibilities necessary for sustainable development' (pp. 148)	Aman, Haru and Hussein (2012)
'it relies upon the recipient actors involved (e.g. farmers, residents or visitors' (pp. 7)	Raymond <i>et al.</i> (2010)
'a key factor in the successful marketing of a product is the identification of what is important to the decision-making process' (pp.2)	Barber, Taylor and Strick (2009)
'involves what is common knowledge for society about the environment, key relationships leading to environmental aspects or impacts, and an appreciation of systems, and collective responsibilities necessary for sustainable development' (pp. 37)	Po-Shin and Li-Hsing (2009)
'are attitudes, which in turn motivate ecologically or environmentally responsible consumer behaviour' (pp. 428)	Haron, Paim and Yahaya (2005)
'a general knowledge of facts, concepts, and relationships concerning the natural environment and its major ecosystems' (pp. 48)	Fryxell and Lo (2003)
as a system that connects data, analysis and people and presents an opportunity to formalise developed ecology in a business environment (pp. 8)	Wernick (2003)
'know-how of all employees and the continuous improvements made in the company's daily practices' (pp. 292)	Boiral (2002)
'can be defined as the degree to which one express concern about ecological issues' (pp.342)	Amyx <i>et al.</i> (1994)

2.3. Internal and external barriers to use environmental knowledge

From a KM perspective, external barriers play an important role, but more important are internal barriers and the way they are overcome (Connell, 2010). According to the resource capacity theory (Wang & Byrd, 2017), while the way companies face external barriers can be a source of threats and opportunities (as shown in Table 2), the way an organization faces high innovation costs or intellectual property issues to deal with the environmental impact of the company is increasingly important in creating market value and sustainable competitive advantages. Because of this issue, we wanted to provide evidence that a socialization can play a part in overcoming some of the internal obstacles to the utilization of environmental knowledge.

Table 2. Barriers that hinder EK utilization

Internal barriers	External barriers
Financial barriers high innovation costs Shortage of qualified personnel Limited internal know-how to manage the innovation process Missing market access knowledge- to meet customer's needs- to enter foreign markets Lack of Information and knowledge about technologies Lack of intellectual property rights	Lack of efficient government support Bureaucratic hurdles- long administrative procedures- restrictive laws and regulations Lack of external partners and networking possibilities

Adapted from: (Sánchez-Polo; Cegarra-Navarro; Cillo; Wensley, 2019)

2.4. Linking environmental barriers with the effective utilization of environmental knowledge

The idea of environmental knowledge refers to the way in which companies align their strategic goals to sustainable development (Wernick, 2003). Research by Fryxell and Lo (2015) defined environmental knowledge as a general knowledge of facts, concepts, and relationships concerning the natural environment and its major ecosystems. In their research, Martínez-Martínez, Cegarra-Navarro and García-Pérez, (2015) found that the conservation of the environment becomes a key factor to be considered in the management of services business. In this regard, environmental knowledge involves what people or agents know about the environment, key relationships leading to environmental aspects or their impact, and an appreciation of systems and collective responsibilities necessary for sustainable development (Frick, Kaiser, & Wilson, 2004).

The sector of the knowledge-intensive business services (KIBS) consists mostly of SMEs (Savic, 2016). SME generate a great deal of the environmental contamination (Del Brío & Junquera, 2003). In this vein, SME tend to focus less on environmental questions than larger companies, even though they account for approximately 64% of all industrial pollution (Calogirou, Sørensen, Bjørn Larsen, & Alexopoulou, 2010). Under this framework, normative instruments for SME should be put on the nature and magnitude of the environmental contamination and that efforts should rather be directed towards the effective use of environmental knowledge (Del Brío & Junquera, 2003).

This study has selected KIBS companies since knowledge and knowledge management are the core activities of these organizations (Bettiol, Di Maria, & Grandinetti, 2012). The core of KIBS is comprised by knowledge related activities such as innovative and electronic services (Figueiredo, Neto, Quelhas, & Ferreira, 2017), or eco-innovative products and services (Cainelli et al., 2015; Marchi & Grandinetti, 2013). Although a significant majority of KIBS companies have adopted eco-innovative products and services as a way of improving customer relations (Figueiredo et al., 2017; Muller & Zenker, 2001; Scarso & Bolisani, 2012), many struggle with great challenges and barriers to implement such measures (Pinget et al., 2015).

Based on the work of (Chan et al., 2015; Connell, 2010; Murillo-Luna et al., 2011), in order to understand what hinders the utilization of environmental knowledge, the barriers may be divided into two sub-components (i.e. internal and external barriers). This study focus on internal barriers because the KIBS could decide and act on them to identify solutions (Murillo-Luna et al., 2011). Among the most common internal barriers to the effective use of technologies encompass, we might encounter the following internal barriers:

- Lack of financial resources or access to financing, they are signalled as an important environmental knowledge barriers (Azzone & Noci, 1998; Connell, 2010; Del Brío & Junquera, 2003; Delgado-Ceballos, Aragón-Correa, Ortiz-de-Mandojana, & Rueda-Manzanares, 2012; Pinget et al., 2015; Walker, Janice, Lynnaire, Calvin, & Ute, 2008). Pinget et al., (2015) said that financial barriers significantly affect companies' decisions to abandon, slow down, or not start innovative projects. In spite of, it is shows the positive relationship of environmental knowledge and business performance (Dangelico & Pontrandolfo, 2015; González-Benito & González-Benito, 2005).
- Limited human resources. It would be a barrier if they did not get involved, since the environmental knowledge is intensive in human resources (Connell, 2010; Del Brío & Junquera, 2003; Delgado-Ceballos et al., 2012; Murillo-Luna et al., 2011; Valero-Gil, Rivera-Torres, & Garcés-Ayerbe, 2017; Zaragoza-Sáez, Claver-Cortés, Marco-Lajara, & Úbeda-García, 2016), and it depends on the ability, involvement and motivation of the employees to achieve their effective application (Zilahy, 2004).
- Resistance from the organizational members. The resistance to changes or organizational inertia are less obvious barriers than financial ones, but they will be more difficult to overcome (Aquilani, Abbate, & Codini, 2017; Delgado-Ceballos et al., 2012; Gray, 2002; Kollmuss & Agyeman, 2002; Peattie & Ring, 1993; Valero-Gil et al., 2017). Besides, barrier that limits the socialization practices and acquisition of environmental knowledge (Connell, 2010; Del Brío & Junquera, 2003) .

Bearing in mind the above, it seems logical to think that the presence of environmental knowledge barriers may hinder the effective utilization of environmental knowledge (Walker et al., 2008). An example of this negative impact on the effective utilization of environmental knowledge is when internal barriers such as resistance to change or lack

financial resources make many KIBS wary of incorporating eco-effective practices into their daily routines. Therefore, this led the authors to hypothesise that:

Hypothesis 1: The presence of environmental knowledge barriers has a negative effect on knowledge utilization.

2.5. Overcoming environmental barriers by socialization

Environmental knowledge involved in environmental activities can be tacit or codified and it can be generated within the KIBS companies or be acquired from external sources such as network partners (Dominguez Gonzalez & Martins, 2017). However, explicit knowledge is not the exclusive dimension involved in environmental knowledge (Boiral, 2002). The companies need all type of environmental knowledge explicit and encoded (for example, environmental management systems as such as, ISO 14000) but the companies should not ignore or unacknowledged the implicit, subjective and tacit environmental knowledge (for example, environmental knowledge of the worker who implemented ISO 14000). The main characteristics of tacit knowledge are implicit, inarticulate or personal knowledge (Polanyi, 1962). Some companies taken their workers' environmental knowledge and turned them into the main thrust of their environmental actions (Boiral, 2002).

Environmental knowledge is not of a rigid nature. In fact, it can be acquired, distributed and utilized. Viewing the companies as a knowledge-creating entity, (Nonaka, 1994; Nonaka, Toyama, & Konno, 2000) illustrate the knowledge transformation processes that might occur within companies and develop a knowledge-use function that indicates knowledge-use capabilities of the company. In this respect, these authors try to demonstrate that the knowledge conversion process involves tacit knowledge (Nonaka et al., 2000). One of the most difficult and most interesting steps in the knowledge management process is capturing tacit knowledge (Dominguez Gonzalez & Martins, 2017). In this context it is appropriate to note that previous studies show how transactive memory systems (i.e. tacit knowledge of knowledge agents) support initiatives to increase efficiency and effectiveness in the use of environmental practices (Lewis, 2004; Martinez-Martinez, Cegarra-Navarro, Garcia-Perez, & Wensley, 2019).

So far, it may be observed that knowledge workers potentially allow end users of KIBS to gain much deeper insight into environmental issues and make more informed decisions (Figueiredo et al., 2017). Although workers often work autonomously, they also collaborate between team members, observing the team members, each team member try to analyse the other workers to bring out personal environmental knowledge (Cegarra-Navarro & Martinez, 2010; Po-Shin & Li-Hsing, 2009).

As noted above, the presence of socialization practices between company's members acquired environmental knowledge to learning from each other. They have capacity to react to and use environmental knowledge how response to external factors and by changing the ways individuals interactor come to interpreter day-to-day events related to the environment (Martínez-Martínez, Cegarra-Navarro, García-Pérez, & Moreno-Ponce, 2019).

This study recognizes “socialization” as a particularly knowledge structure through which a collaborative work of eco-innovation can be explored. Indeed, it produces emotional investment and intimate attachment among organizational members by creating social bonds and bringing a deep emotional holding power (Murillo-Luna et al., 2011; Pinget et al., 2015; Po-Shin & Li-Hsing, 2009), and it gives detailed hints how internal barriers can be overcome (Boiral, 2002; Lee & Choi, 2003; Martínez-Martínez, Cegarra-Navarro, & García-Pérez, 2017; Po-Shin & Li-Hsing, 2009). For example, the desire towards the implementation of an environmental policy forms the basis for a sense of belonging and mutual recognition, so that a high degree of trust is likely to emerge among internal and external stakeholders, which is perceived as a prerequisite for overcoming environmental barriers (Boiral, 2002). On these bases, the following hypotheses have been formulated:

Hypothesis 2: Socialization is negatively associated with the existence of environmental knowledge barriers.

Hypothesis 3: Socialization is positively associated with the utilization of knowledge.

Taking into account all of the above, this study proposes the structural model shown in Figure 1. The lower path suggests that socialization has a positive impact on the effective utilization of environmental knowledge by removing the barriers that restrict the use of environmental knowledge.

Figure 1. Theoretical model

3 Method

This research uses data from a sample of SME of KIBS. Small companies make up the vast majority of businesses in Europa (Hillary, 2004) and Spain. In 2015, on average around 99 % of European business were classified as small and medium-sized enterprises (European Commission, 2003) and the SMEs in Spain are 99,9% of the total number of companies, those are 2.3 million companies in Spain, with 10.9 million of person employed (Eurostat, 2015). The EU defines SMEs based on employee numbers, turnover

or balance sheet total and ownership. SMEs has less than 250 employees and either an annual turnover not exceeding EUR 50 million, or an annual balance sheet total not exceeding EUR 43 million, and is an independent enterprise (European Commission, 2003).

3.1 Data analysis

The proposed hypotheses were tested simultaneously using partial least squares (PLS-SEM) due to all constructs have been considered as composites (Richter, Cepeda, Roldán, & Ringle, 2016). Therefore, the total variance of all constructs is used to estimate model parameters (Hair, Hult, Ringle, Sarstedt, & Thiele, 2017; Henseler et al., 2014). The utilization of knowledge, socialization and knowledge barriers were specified as reflective indicators given that there is a high level of correlation between them (Dijkstra & Henseler, 2015; Henseler et al., 2016). Based on recent advances of PLS-SEM reporting, the first step was to examine the measures' reliability and validity.

As shown in Table 3, the fit statistics for the model indicate a reasonable data fit. The standardized root mean square residual (SRMR) value of the measurement model was 0.060 and all discrepancies were below the 95%-quantile of the bootstrap discrepancies (HI95), which suggests very good measurement model fit (Henseler et al., 2014).

Table 3. Results of the Confirmatory Composite Analysis

Overall saturated model fit evaluation	Value	Hi ₉₅	Hi ₉₉
SRMR	0.060	0.090	0.119
d _{ULS}	0.1632	0.365	0.640
d _G	0.1588	0.251	0.367

Note:

Global goodness of fit and bootstrap-based 95% and 99% quantiles (saturated model)

SRMR→ Standardized Root Mean Square Residual; d_{ULS}→ Unweighted Least Squares Discrepancy; d_G→ Geodesic Discrepancy

As shown in Table 4, all standardized loadings are greater than 0.7 and each indicator's loading has a greater loading with its constructs than with other constructs. Hence, individual items are reliable (Henseler et al., 2016).

Table 4 Factor Loadings of reflective constructs

	BAR	SOC	UK
BAR_1: Limited financial resources.	0.867	-0.259	-0.309
BAR_2: Limited human resources.	0.859	-0.253	-0.290
BAR_3: Resistance from the organizational members.	0.767	-0.177	-0.207
SOC_1: Our company stresses gathering information from suppliers and customers.	-0.314	0.863	0.514
SOC_2: Our company stresses building databases on products and service.	-0.243	0.847	0.364
SOC_3: Our company stresses planning strategies by using published literature.	-0.136	0.873	0.395

UK_1: The company (hotel) uses less polluting industrial processes and products.	-0.282	0.446	0.887
UK_2: The company (hotel) has developed a green program (waste management, control of effluents, inventory of pollution sources).	-0.317	0.402	0.858
UK_3: The company (hotel) has developed a drafting of environmental emergency plans and measures.	-0.250	0.453	0.831

Notes:

BAR= knowledge barriers. SOC = Socialization. UK = utilization of knowledge.

Discriminant validity was determined by comparing the square root of the AVE (i.e. the diagonals in Table 6) with the correlations among constructs (i.e. the lower triangle of the matrix in Table 6). On average, each construct related more strongly to its own measures than to others' (Fornell & Larcker, 1981). In addition, all the variables attain discriminant validity, since all HTMT are below the value of 0.90. The constructs correlation matrix, shared variances, means and standard deviations are shown in Table 5. As a result of this analysis, evidence of content validity, reliability and convergent validity, and discriminant validity for the constructs of the example was found.

Table 5 Descriptive Statistics

	Mean	S.D	HTMT	AVE	CA	Correlation matrix		
						1	2	3
1. Knowledge barriers	4.169	1.341				0.743		
3. Socialization	2.413	1.444	0.570	0.552	0.780	0.337	0.786	
2. Utilization of knowledge	2.907	1.474	0.779	0.619	0.830	0.405	0.600	0.778

Notes:

S.D→Standard Deviation; CA→Cronbach's Alpha; Inter correlations are presented in the lower and shady triangle of the matrix. The bold numbers on the diagonal are the square root of the Average Variance Extracted. Maximum HTMT→Heterotrait-Monotrait Ratio of Correlations.

4 Results

The PLS-SEM analysis was operationalized by two models (Hair et al., 2017; Henseler et al., 2016): (1) a measurement/*outer* model relating the manifest variables to their own latent variable; and (2), a structural/*inner* model relating some endogenous latent variables to other latent variables.

The results in Table 6 show the validity of the *outer model*. The fit statistics for the model indicate a reasonable data fit. With regard to the reliability of *knowledge barriers*, *socialization* and *the utilization of knowledge* constructs, the Dijkstra and Henseler's rho (pA) and the average variance extracted are above the common standards of 0.7 and 0.5 respectively (Dijkstra & Henseler, 2015; Henseler et al., 2016). In addition, all factor loadings from knowledge barriers, socialization and the utilization of knowledge constructs are statistically significant and greater than 0.7, with the lowest value for the item measuring "Barriers3" being "0.751".

Table 6 Measurement Outer Model Evaluation

Construct		VIF	Weight	loading	Reliability (ρ _A .. AVE ^b)
Knowledge barriers					
	Barriers1	1.692	0.453 ^{***}	0.861 ^{***}	ρ _A = 0.806 AVE=0.552
	Barriers2	1.691	0.433 ^{***}	0.853 ^{***}	
	Barriers3	1.514	0.306 ^{***}	0.751 ^{***}	
Socialization					
	Soc1	1.590	0.482 ^{***}	0.860 ^{***}	ρ _A = 0.860 AVE=0.619
	Soc2	2.244	0.350 ^{**}	0.834 ^{***}	
	Soc3	2.501	0.330 ^{***}	0.864 ^{***}	
Utilization of knowledge					
	Util1	2.173	0.396 ^{***}	0.875 ^{***}	ρ _A = 0.822 AVE=0.606
	Util2	1.965	0.377 ^{***}	0.851 ^{***}	
	Util3	1.636	0.391 ^{***}	0.832 ^{***}	

Notes:

*** <0.01

VIF → variance inflation factor; ^a Dijkstra-Henseler's rho → (ρ_A); ^b Average variance extracted → (AVE);

The results of the structural model after the PLS analysis are collected in Table 7. According to Streukens & Leroi-Werelds (2016), the use of bootstrapping (5,000 resamples) produces bootstrap confidence intervals of standardized regression coefficients. Bootstrap confidence intervals constitute a good approach for detecting path coefficients (Hayes & Scharkow, 2013). The results demonstrate that the inner model has satisfactory predictive relevance for knowledge utilization ($Q^2=0.196$) because that value is higher than 0. As Table 4 shows, the proposed model also explains the 27.7 percent of the variance in knowledge utilization (adjusted R^2). Based on Preacher and Hayes (2008), a post-hoc indirect effect analysis was carried out to test the indirect effect of independent variables on the dependent variable by way of the mediator. In doing so, a two-step procedure for testing mediation in PLS was followed: (1) we used the specific model in question with both direct and indirect paths included to perform 5000 bootstrap resampling and explicitly calculate the product of the direct paths that form the indirect path being assessed; and (2) we estimated the significance using percentile bootstrap. This generated 95% confidence intervals (CI) for the indirect relationships under study. As Table 7 shows, as the interval determined through bootstrapping does not contain the zero value, the indirect effect of socialization on the utilization of knowledge via knowledge barriers is statistically significant at a level of 0.05. Consequently, the results provided full support for both hypotheses H1, H2 and H3.

Table 7 Structural Model statistics

Direct relationship	Path coefficients	T value	Lower 5%	Upper 95%	Adjusted R^2	Significance of effect
H1: $BAR \rightarrow UK(a_1)$	-0.207***	2.354	-0.343	-0.058	0.393	Yes
H2: $SOC \rightarrow BAR(a_2)$	-0.285***	2.487	-0.451	-0.095	0.104	Yes
H3: $SOC \rightarrow UK(a_3)$	0.461***	5.014	0.320	0.622	0.393	Yes
Indirect relationship						
$SOC \rightarrow Barriers \rightarrow UK(a_1 * a_2)$	0.057**	1.781	0.009	0.115	0.393	Yes

Notes:

*** <0.01; ** <0.05

BAR= knowledge barriers. SOC = Socialization. UK = utilization of knowledge.

5 Conclusions

There is lack of research into environmental knowledge barriers and use of environmental knowledge (Cainelli et al., 2015). This research focuses on KIBS because they base their competitive advantages on the production and diffusion of knowledge. Consequently, attention is paid to solve the environmental knowledge barriers as well as to the socialization role in the use of environmental knowledge. Considering this and based on a detailed analysis, socialization practices have been found to mitigate internal barriers by informing people about the way problems can be solved.

These results support the extant literature which argues that as a result of social interaction internal and external stakeholders can help each other to use environmental knowledge (Miles, Miles, Perrone, & Edvinson, 1998), especially, in solving problems (Lundh-Snis, 2001; Tanriverdi & Iacono, 1999), which will in turn help them overcome mutual barriers (Connell, 2010; Pinget et al., 2015), and misunderstandings resulting from new environmental concerns (Cainelli et al., 2015; Gadenne & Mckeiver, 2009; Haron et al., 2005; Kabongo & Boiral, 2017). A possible explanation for this finding would be the fact that socialization mechanisms among the members of the company are necessary because produce intensively new or improved environmental knowledge, both fundamental and applied, to transform effectively the necessary part of this knowledge in productive economic or social, such as, products and services.

From a practical point of view, the overcoming environmental knowledge barriers and using environmental knowledge could mean taking a step closer to achieving eco-innovation (Cainelli et al., 2015; Marchi & Grandinetti, 2013; Zieba, Bolisani, Paiola, & Scarso, 2017). This means that KIBS managers should focus on facilitating socialization practices as a measure to environmental knowledge utilization in their companies (Muller & Zenker, 2001). In doing so, they could plan worker training or awards for workers' environmental initiatives. Furthermore, they should prepare an organizational structure that includes environmental measures.

Despite its valuable insights, the research is limited because it only analyses the KIBS companies and we know that this sector is directly affected by its action with the environment (for example, use of product or component highly environmental impacts). Other limitation is that we are research about internal barriers; future research could also be an opportunity to include external barriers. Finally, in future research the business performance and environmental behaviour should be included.

Abstract

What pushes an actor, be it an individual or an organization, to imitate the choices of others, is a theme that has fascinated scholars of several disciplines that observed this underlying dynamic in diverse phenomena. This paper provides a review on conformism across diverse research disciplines that are rarely considered altogether when conformism is addressed.

Keywords – conformism, knowledge diffusion, adoption, managerial fads, herding.

Paper type – Academic Research Paper

1 Introduction

What pushes an actor, be it an individual or an organization, to imitate the choices of others, is a theme that has fascinated scholars of several disciplines that observed this underlying dynamic in diverse phenomena. This paper provides a review on conformism across the following research disciplines: organization studies, finance and neuroscience. In relation to these areas, conformism will respectively be addressed in terms of innovation adoption and managerial fads, financial herding and brain activation.

The review will be developed across these literatures with a focus on the issue of agency, intended as the role of intentionality in human behavior and the possibility to control and design behavior and impact on reality (Frigotto, 2018; Stacey et al. 2000). Aldrich and Ruef (2006, p. 18) understand agency in terms of whether (and in what

terms) actors are free to make autonomous decisions or are driven by the context in which they are embedded up to the extreme position that sees the exogenous determination of their behavior and the illusion of control and impact on reality. Namely, by presenting the several studies on conformism, the following research question will be addressed: to what extent do actors conform i.e., display similar behaviors, i) because they rationally decide to do so i.e., as the outcome of an informed decision-making process, or, ii) because they are pushed to do so by the need to adhere to the standards of a group or coalition of other actors? In particular, contributions from neuroscience complement other streams of literature by adding to the observation and the understanding of behaviors in the organizational or financial context, also evidence on brain activation for further and more micro-level theorization of conformism.

The paper is organized as follows. In the next Section, conformism as rational decision is introduced. Then, psychological, sociological and organizational factors playing a role in conformism are presented. In Section four, conformism is addressed in terms of the determinants of financial herding. In Section five, studies on conformism from the area of neuroscience are discussed. A closing Section concludes the paper. The contribution of the paper lies in combining research areas that are rarely considered altogether when conformism is addressed.

2 The rational decision to conform

When conformism is observed in the similar behaviours of agents, researchers have often referred to its manifestation in term of herding or herd behaviour. In English the word 'herd' has three different meanings: 1. a flock of sheep or, more generally, of animals; 2. the act of grouping the animals by the shepherd, 3. the act of proceeding together performed by the animals themselves. Used metaphorically, the term refers to an association of people that adopt the so-called herd behavior or herding. Typically, when behavior is described as herding, it suggests that the observed behavior a set of subjects is not the result of an independent choice of the individuals, but an imitative reaction of the behavior of others, even when this is a harmful one, or at most the individual's response to the same external stimuli. Keynes (1930) contrasted herding with the independent choice of the individual autonomously elaborating on given information. The classical example of herding is given by the movement of the flock, moving together and appearing as a whole. However, conformism is observed everyday in various contexts for instance, in the crowd that, when facing an emergency, escapes towards the busiest, rather than the free exits.

The herd behavior is difficult to explain in the classical decision theory that was grounded in the theory of rational expectations. According to this approach, decisions are the outcome of rational reasoning applied to available information given individual preferences. Although it is recognized that human rationality is limited in different ways and further aspects besides rational ones, such as psychological or emotional ones play a role, the latter found limited room in the classical decision theory. Within a rational decision approach it is possible to explain conformism according to three alternatives:

- the imitation of the behavior of others brings advantages, at least temporarily, to the individual that performs it rationally, and the convenience to copy increases with the number of subjects making the same choice. This is called pure herding. The most famous illustration of pure herding in economics is the Keynes beauty contest organized by a newspaper that assigns a prize to the reader who will be able to guess which among six women, will win the contest. A smart reader will not vote for the most beautiful woman according to him, but he will vote for the one that he thinks will be voted by most readers. Pure herding might take the following forms:
 - i) a strategy aimed to seize positive externalities, for example, castaways on a desert island are more likely to be spotted and saved if they wave all together, so they perform the same behavior;
 - ii) a reputation strategy, for instance, when managers imitate other managers' strategies because they prefer to risk making a mistake like others, rather than being the only one to make an isolated choice (even a correct one). This form concerns a principal-agent problem, occurring when the behavior of a subject, called agent, is evaluated by another subject, known as principal, who cannot observe the information available to the agent, nor his effort.
 - iii) an informative strategy, for instance, when a foreigner in a city needs to choose a restaurant to have dinner, she observes two nearby restaurants, one with many guests and the other empty. As she ignores the quality of the two restaurants and does not want to invest time in researching, she would most likely choose to eat in the busiest restaurant. Whoever observes this decision will probably copy it, and so on. This is because she assumes that the many people who chose previously knew the quality of the restaurants.
- the individual's decision is rationally the best (at least at some point in space and time) and does not depend on the others' choice but on the individual assessment of available information. This is called spurious herding.
- conformism concerns non-rational arguments that are typical not included in the rational arguments of decision.

The problem in discerning between conformism as a rational decision (in the pure and spurious forms) and as a behavior that builds on non-rational aspects, is that it is only possible to observe behaviors and not their motivations. As a matter of fact, it is also difficult to clarify if the phenomenon of conformism is a structural element of human decision, given that it is even not possible to assess the relevance of spurious herding.

3 Psychological, sociological and organizational factors in conformism

Conformism cannot always be traced back to the rational assessment of advantages, but rather to psychological or sociological factors. This would explain why some individuals, some populations or professions are more prone to conformism, while others, in the same situations, are not. For example, in the case of a real emergency at a concert, fear and panic lead many people to the most crowded exits; the same situation during an exercise does not induce the same behavior.

Psychology studies highlighted the role of psychological traits, moods and emotions in conformism. Traits regarding the ability to socialize, such as extraversion, adherence to social norms and risk aversion, are linked to the propensity to conform (Baddeley, 2010). Conversely, Bernardo and Welch (2001) show that self-confidence is linked to the propensity to guide others and not to follow a herd behavior. However, Baddeley points out that not psychological traits but the mood, identified as a generic and superficial emotional state (positive or negative), impacts on behavior, and therefore on conformism. For example, there is evidence that the mood induced by a sunny or rainy day affects the choices of traders (Hirshleifer and Shumway, 2003). If the mood derives from external conditions such as the weather, it is however reinforced or damped by individual traits; in this perspective, herding is spurious, that is, it derives from the same external stimuli and not from imitation.

Evolutionary studies explain choices that hardly fit within a pure rational perspective with innate instincts that are the result of evolution, and that are traceable in our closest ancestors and also in other species. Fish that swim in schools display herding. In fact, such behavior produces advantages both for individuals and for the group: when attacked by a predator, they escape together, decreasing the probability of being captured, and improving their hydrodynamic efficiency.

There is also evidence of sociological factors linked to behavioral conformism that are also found in animals. Some fish, that are removed from their group, show an alteration of vital parameters and behaviors, which is interpreted as a sort of stress due to the separation from the group that plays a reassuring and calming role. Sociological studies have focused on understanding the meaning that the group has for the individual and more generally in society. It is recognized that humans often tends to place themselves in groups that approve their behavior. Important determinants of conformism are: i) the identification of the individual with the group that is, the fact that the individual recognizes himself as similar to the other members and feels he is represented by them (indicated as private acceptance); ii) the social pressure to conform (indicated as public compliance). The first element pushes the individual to operate the same choices of the group. The second pushes the the individual to replicate the choices of the group in order to be part of it.

Moreover, sociological and organizational studies suggest that when an individual belongs to a group, she builds an identity that relates herself to other individuals through a process of social construction of meanings that define what is considered relevant not only from a utilitarian, but also from an emotional perspective. Going back on the tulip bubble case, it seems impossible today that merchants and investors of the time exchanged tulip bulbs for the value of a house. Today, in fact, the value attributed to tulips appears very limited, because the demand for tulips is limited and the supply is adequate or exceeding the demand. The exchange value is very small and what is considered the intrinsic value, simply linked to the joy of enjoying the beauty of a tulip, is recognized as modest. However, in the early Seventeenth century in Holland, instead, interest in tulips became a real craze that led to the intensive search for the rarest specimens and the most amazing colors and streaks. The distance between the value

recognized today to tulips and the value attributed back then, is immense, and more precisely, it is difficult to rationally understand, if not admitting that also the concept of value is the result of a social construction. The role of the social construction of meaning is evident when bubbles burst: what leads to a sudden and unexpected refusal of a construction in which individuals believed or that individuals wanted to ride and exploit? When bubbles burst, conformism suddenly stops because the shared sensemaking collapses.

Social construction also takes place through specific languages, symbolic narratives, metaphors and tools. For example, consider that during the growth of the dotcom bubble, investor-seeking firms legitimized themselves with the number of customers and online contacts, rather than with their ability to turn these into revenues. At the same time, as the dotcom quotations grew, a rhetoric, a language and a series of indicators were developed that supported investors' confidence in the potential of the so-called new economy companies. According to Consob, the Italian national agency for the control of financial markets: "The general euphoria deriving from the concepts of "development", "progress" and "growth", associated with a cutting-edge sector such as the new economy, fueled the expectations on the future and increased the value of companies of this sector, regardless of the information expressed by traditional profitability indicators" (<http://www.consob.it/web/investor-education/la-bolla-delle-c.d.-dotcom>).

Finally, in the literature on innovation adoption, conformism has been viewed as the result of the observation of the benefits of innovation within a community of actors. This literature, mainly from the strategy area, relies on a strong belief in the agency and intentional behaviour of actors that decide according to their (bounded) rationality. In Roger's argument (1962), adopters observe the outcomes of adoption in their network of other actors and then decide whether to adopt the innovation or not. Contrasting this perspective, Abrahamson (1991) argued that innovations such as new techniques for organizing are not adopted because of their observed benefits. Adoption, instead, derives from a fascination with new and promising managerial practices, as well as from the desire to legitimate oneself into the group of reference actors that have already adopted them. They are, in fact, "managerial fads and fashions" and conformism occurs by imitation of what is done by other organizations independently from the assessments of the benefits of innovation (Abrahamson, 2013) through the so-called "bandwagon mechanism". In a similar vein, in the neo-institutional literature, conformity has been understood as a form of compliance with a perspective that is being institutionalized and that displays a logic of legitimation by a group of reference actors that lead change, rather than a logic a cost-benefit analysis (Meyer and Rowan, 1977; Di Maggio and Powell, 1983). It is not been clarified, and this goes beyond the scope that is typical of such studies, whether conformism in those cases is the result of agency, namely of an intentional action aimed at strategically exploit the behavior of a collection of agents that act similarly. The literature on organization studies building on social psychology, refers to the theories of self- and social categorization (Tajfel, 1974; Turner and Reynolds, 2011) or to the theories of similarity and attraction (Byrne, 1971) to understand conformism. In the first case, the individual feels to belong to a group and she tends to

conform to the group's behavior to stress and strengthen its membership; here, conformism is a manifestation of the affiliation to a group of agents. In the similarity-attraction paradigm, the individual is attracted by other individuals with which she shares characteristics or behaviors; here, conformism is a manifestation of the perspective shared among several agents.

4 Financial herding

In the financial literature, financial bubbles have pointed out the issue of conformity that has been debated in terms of herd behaviour. In every financial bubble, market euphoria over a specific asset leads to a boom in sales; the herd behaviour of investors can drive the price of this asset up to absurd level, as it was in the Dutch Tulip Mania of the 16th century, and in the dotcom at the end of the 90s. The financial literature has investigated to what extent a dramatic and persistent deviation of prices is due to the imitation of other investors choices independently from the estimation of the asset value, and whether investors can gain from this trend by exiting the market at the right time. When the investors' choices lead to a persistent deviation of an asset price from its intrinsic value, it is crucial to understand if herding behaviour will produce a bubble, or if such deviations will instead be rebalanced with arbitrage. Investors could identify profitable investment strategies by investigating the following issues:

- when is it profitable to be conform to others' financial choices? When is the optimal timing to make a different financial choice? The answer to these questions would help to understand when a speculative bubble is being created and to what extent it is worth riding;
- how independent from others' financial choices is the estimation of an asset value performed by the fundamental approach? The answer to this question would allow to define best practices in assets' evaluations.

Further, financial literature has investigated herding both in the portfolio composition of institutional investors and in investments' recommendation of financial analysts. Herding can arise because of reputational issues: performance evaluation of institutional investors (hereinafter referred to as manager) and analysts is usually carried out with respect to others' performance and any deviation can therefore severely damage reputation. In the following main studies on financial conformism are discussed.

The seminal model by Scharfstein and Stein (1990) shows how rationally managers mimic other managers and ignore their private information, because of reputation and career concerns. Managers are positively assessed if: 1) they made a profitable investment and 2) their portfolio composition was similar to that of others. When managers achieve the same profit, those mimicking others will be more favourable evaluated than those that behave in an opposing fashion. Unprofitable decisions are therefore not compromising the manager's career and reputation if those wrong decision are shared among others (sharing-the-blame effect): when managers follow others' decisions the market infers that all managers have been exposed to the same information (and are more likely to be smart managers). On the contrary, when a manager differs from others' behaviour, no matter

how good or bad was his investment, he is perceived as unskilled (his profit is simply the result of luck). Herding by pension funds has been tested by Lakonishok et al. (1992) by measuring the disproportionate tendency of managers to buy or sell the same asset at the same time. Results show very little herding over the all sample and more intensive herding in small stocks, possibly due to their more opaque information. Herding among mutual funds is found quite low (Wermers, 1999), but higher among growth-oriented mutual funds and in small stocks. Interestingly, any observed long-term price adjustments of those stock that have been traded by “herds” appear to be permanent, suggesting that mutual fund herding speeds the adjustment-price process and that managers end up with the same investment decisions because of their similar private information about stock’s fundamentals and not due to reputational concerns. Chevalier and Ellison (1999) relate manager’s career concerns to the desire to avoid being fired and examine how behavior differs between younger and older mutual fund’s managers. Findings point out that younger managers are less likely to deviate from others behaviour, because they are more likely to be punished (losing the job) for deviating from the herd.

Herding behavior in institutional investors could also emerge because their investment choices are based on the (same) analysts’ recommendations, which are public for a long time. Herding among financial analysts has been studied with regard to: 1) the release of forecasts of firm’s earnings and 2) the issue of investment newsletters. Trueman (1994) theoretically shows that it is not always valid to assume that earnings’ forecasts by analysts reflect their private information in an unbiased manner. When an analyst releases a forecast that is close to others’ or to his prior forecasts, the investors’ assessment of his forecasting ability increases; this enable higher fees and career progression. In the model, the issuing of an extreme forecast, although justified by private information, could be perceived simply as correction of past inaccurate estimates. As a consequence, herding behavior emerges. Empirical research investigates how herding in forecasts is linked to career opportunities and characteristics of the analysts. Hong et al. (2000) observe that less experienced analysts are more likely to be terminated for inaccurate (or deviating from the consensus) forecasts; accordingly, younger analysts herd more and revise their earnings forecasts more frequently. Clement and Tse (2005) point out the complex relation of herding and (among others) brokerage size and the number of evaluated industries: analysts with big brokerages are more likely to deviate from average forecasts (due to lower career concerns) but as the number of followed industries increases herding emerges, probably due to the analyst’s inability to develop specialized knowledge. Turning to newsletters’ release, Graham (1999) develops a model in which each analyst is tempted to ignore his private information and mimic the previous analyst’s newsletter if he has high reputation to protect and inaccurate private information. This study is the first to evaluate model’s implication by measuring analyst’s herding as the mimicking of a specific newsletter (Value Line Investment Survey, considered the market leader), and not as a statistical tendency of a high number of analysts to conform. Results corroborate the model: herding increases with newsletter reputation and poor quality of private information. Most research measure herding by estimating the deviation of each action from the mean of all actions: such measure could not be able to capture pure herding,

because it is biased by variables that similarly affect everyone's choice. Bernhardt et al. (2006) challenge the prevalent view that analysts systematically herd, by testing a model of herding in earning forecast which is robust to (among others): correlated signals among analysts, common unforecasted shocks to earnings, information arrival, systematic analyst optimism or pessimism. The authors find strong evidence against herding behavior. This stresses that to detect pure herding, empirical research needs to develop robust measures that account for common drivers.

5 Conformism in Neuroscience

Neuroscientific studies on conformism are relatively young and constitute a niche (Wu et al., 2016). While they build a discipline per se, they also provide a promising instrumentation that allows to clarify the role of psychological factors in the decision to conform, and that can thus inform other research areas. Neurosciences shed light on how the decision-making process activates and is represented in neural circuits, and this is made possible by neuroimaging tools and techniques, such as functional magnetic resonance imaging (fMRI). Berns et al. (2005) provide the first biological evidence for alterations in brain activity associated with social conformity. They show that when individuals conform judgment to that of the group specific brain areas related to perception and emotional processes are activated, and not those related to information-aware decision.

Some studies analyze whether conformism is the result of autonomous choices made by several individuals or the outcome of the adaptation to the choice of others. To understand this, they looked at whether the subjects show a different neural representation of the value associated with a stimulus, depending on whether or not they know the value given by the group to the same stimulus. Zaki et al. (2011) asked to participants to judge the attractiveness of 180 female faces by using a 7-point scale. During the first round participants were informed, on most trials, about the evaluation expressed by previous participants; however, this group ratings were generated by a pseudorandom algorithm. In the second round participants expressed a second judgment on the same faces, while they underwent fMRI scanning. Results show that attractiveness ratings were significantly influenced by social norms: participants changed their ratings to conform to those of their peers. Moreover, when the same faces are assessed for the second time, participants show a significant greater brain's response for stimuli ostensibly rated more positively by peers. Those specific brain regions (i.e. orbitofrontal cortex (OFC) and nucleus accumbens (NAcc)) respond generally to reward and when jointly activated constitute a system that learns and encodes the value of events and stimuli. These results suggest that individuals consider social consensus as intrinsically rewarding, and that they are therefore keen to conform to others. Following a similar procedure, Charpentier et al. (2014) investigate whether the response of a brain region to a specific stimulus (peers' rating) can predict subsequent brain activity to the identical stimulus, but under different circumstances (individual choice). Results show the intertemporal relationship between past and

subsequent response of the right OFC, which is observed only when individual first observe a peers' inconsistent choice.

Klucharev et al. (2009) address conformism within the framework of reinforcement learning, meaning that learning is produced through actions and the observed consequences of such actions. They observe that being in conflict with group opinion trigger a neuronal response in the rostral cingulate zone (RCZ) and in the ventral layer (VS), brain areas typically observed in neuroscientific experiments that analyse predictive errors in reinforcement learning models. these findings suggest a new role for the RCZ in social cognition: the dissimilarity of our judgements with social group norms evoke conformity via learning mechanisms.

Izuma and Adolphs (2013) stress that conformism includes a judgement on actors that could be imitated (cognitive balance), so that conformism occurs only when actors are appreciated and not despised. They reveal to participants the preferences of strongly liked or disliked groups and observe first that participants' choices conform to those of the liked people, and second that their dorsomedial prefrontal cortex (dmPFC) was activated, thus suggesting that cognitive imbalance activates the dmPFC because it represents an aversive outcome requiring subsequent adjustment. This association and later preference change remained significant even after months.

Huber et al. (2015) contextualize their neuroscientific study in finance on stocks trade. They ask participants to buy one of two stocks, subject to a different set of private (recommendation of a rating agency for one or the other stock) and social information (decisions of two fictitious stock market traders). The authors aim to explores if specific neural activation is tracked in participants that differently weight social and private information, given that conformism (in the form of informational cascades) can occur when rationally individuals decide independently of their private information. Result show that stronger individual overweighting of private information is positively correlated with activity in the inferior frontal gyrus/anterior insula, areas that have been related to higher risk aversion and risk-aversion mistakes. To avoid mistakes the participants decide to conform.

6 Conclusions

In this paper a review of the topic of conformism was elaborated across different literatures. This work displays that conformism is pervasive in observed human behavior and has been addressed within diverse disciplines. An issue that emerges across disciplines concerns the actual possibility to detect conformism by finding measures and points of reference that can show its distinctiveness with respect to other behaviors that are similar but that are simply triggered by the same set of stimuli.

Abstract

Purpose – This paper explores the role of social integration mechanisms for knowledge absorptive capacity (ACAP) in southern Brazilian firms.

Design/methodology/approach – We followed a positivist approach and we used quantitative methods. Our sample includes 125 firms from Southern Brazil. Hypotheses were tested using structural equation modelling (SEM) supported by the software ADANCO 2.0.1.

Originality/value – Our paper contributes to the knowledge-based view literature by contributing to understand ‘why’ and ‘how’ social integration mechanisms are influencing knowledge absorptive capacity in firms. Our results suggested that social integration mechanisms have a positive effect on ACAP dimensions, and that the use of teams that are cross-functional and composed by people with diverse background, is likely to improve ACAP capabilities in firms. We suggest that further studies may perform a deeper analysis about the moderation effect of social integration mechanisms on ACAP.

Practical implications – By identifying the relevance of social integration mechanisms for improving ACAP, this study brought valuable information to managers of both Brazilian firms and foreign organisations willing to establish their operations in Brazil, for the efficient allocation of firm resources for improving the innovative performance.

Keywords – Social integration mechanisms, Knowledge absorptive capacity, Knowledge management practices, Brazil.

Paper type – Academic Research Paper

1 Introduction

Innovation is an intrinsic characteristic of firms that survive (Cefis & Marsili, 2006; O'Reilly & Tushman, 2016; Schumpeter, 1942). In the last years, the nature of innovation, its antecedents and its effects have received a growing attention from scholars and practitioners (Baregheh, Rowley, & Sambrook, 2009). Several research streams (e.g. Knowledge Management) have been used by scholars to study innovation phenomenon (Crossan & Apaydin, 2010). From the knowledge management (KM) perspective, knowledge absorptive capacity (ACAP) has emerged as a key antecedent of business innovation (Davila, Durst, & Varvakis, 2018; Flatten, Greve, & Brettel, 2011).

ACAP is defined as the firm's ability to exploit external knowledge and apply it for commercial ends (Cohen & Levinthal, 1990). As a premise for ACAP, Cohen and Levinthal (1990) stated that the firm needs to have a prior related knowledge. Firms with larger and more diverse prior knowledge base are more likely to 'make the novel associations and linkages' when a new knowledge arrives, thus, improving the learning process, the innovation capability and ultimately organizational performance. The association between the prior knowledge base and the new knowledge is possible by using some mechanisms that facilitate the sharing and exploitation of knowledge, also called 'social integration mechanisms' (Todorova & Durisin, 2007; Zahra & George, 2002). Later, some scholars have focused their attention on these mechanisms and its role for ACAP (Björkman, Stahl, & Vaara, 2007; Enkel, Groemminger, & Heil, 2018; Todorova & Durisin, 2007). Despite scholars seem to converge when they affirm that a positive relationship between the use of social integration mechanisms and the firm's absorptive capacity exists, there are yet divergences when they attempt explanations about how exactly these mechanisms contribute to enhance (or to decrease) ACAP.

Empirically, the role of social integration mechanisms on ACAP have been investigated by few studies (Armstrong & Lengnick-Hall, 2013; Björkman et al., 2007; Cuervo-Cazurra & Rui, 2017; Enkel et al., 2018; Filenga, Cernas Ortiz, & Machado-da-Silva, 2016; Kallio & Bergenholtz, 2012; Vega-Jurado, Gutiérrez-Gracia, & Fernández-De-Lucio, 2008; Yao & Chang, 2017), with relevant results but not enough for a systematic understanding about how (and in what extent) these mechanisms can enhance ACAP. In one hand some authors posit that social integration mechanisms facilitates organisational process such as ACAP (Chimhanzi, 2004; Zahra & George, 2002). In the other hand, scholars point out that these mechanisms may have either a positive or a negative effect, depending of specific contingencies (Todorova & Durisin, 2007). Yet, there is no enough empirical studies for contrasting the conflicting theoretical propositions (Chimhanzi, 2004). In this context, some questions emerge: are Social

integration mechanisms really contributing to enhance firm ACAP? If that contribution exists, in what extent these mechanisms are improving ACAP? Which roles and dimensions of ACAP are more likely to be improved by the use of social integration mechanisms?

To address these research questions, we chose Brazil as it represents an under-researched context in knowledge management literature, has very distinct characteristics when compared to western countries and it is one emerging market that is becoming more and more prominent in the international arena.

2 What do we know about ACAP?

The knowledge based view of the firm (KBV) approach provides the basis for understanding organisational innovations, by considering the renovation of traditional organisational structures (e.g., empowerment, team-based structures, or strategic alliances), the importance of knowledge-based competences, and the existence of knowledge integration and application processes that leads to value creation. According to KBV, the main role of the firm is to integrate specialised knowledge resident in humans into final goods and services (Grant, 1996). To do so, Grant (1996) posits that one of the pertinent characteristics is named ‘aggregation’ of knowledge, which, in individual or organisational levels, can be explained by ACAP.

ACAP has been analysed from many research streams due to its interdisciplinary nature (Flatten et al., 2011a). Cohen and Levinthal (1990) defined ACAP as the firm’s ability to take advantage of external knowledge, in a process that includes recognising the value of the new information, assimilating, and applying this information for commercial purposes, and even for predicting the nature of future technological advances (Wesley M Cohen & Levinthal, 1994). In line with this approach, Lane et al. (2006) defined ACAP as one of the firm’s learning capabilities, because it contributes to enhance the firm knowledge base (Lane, Koka, & Pathak, 2006).

Based on Cohen and Levinthal (1990), a multidimensional definition of ACAP was proposed by Zahra and George (2002). They defined ACAP as a dynamic capability composed of a set of routines and organisational processes by which firms acquire, assimilate, transform, and explore knowledge to improve organisational skills, and consequently, to sustain and increase competitive advantage. Zahra and George (2002) emphasise the existence of four dimensions that are sequential — acquisition, assimilation, transformation, and exploitation. They also identified two processes inside ACAP: Potential – PACAP (composed by acquisition and assimilation dimensions) and Realized – RACAP (composed by transformation and exploitation dimensions). Acquisition is the ability of the firm to identify and acquire knowledge generated externally and critical to its operation. Knowledge assimilation routines allow the firm to analyse, interpret, and understand process information captured from external sources. ‘Understanding’ is the factor that promotes the assimilation of knowledge. Transformation capability facilitates the identification of opportunities by developing and refining the routines and practices that allow you to combine new knowledge with prior

knowledge base through the addition of knowledge, unlearning, or ‘bissociation,’ which occurs when the same idea is perceived by two self-consistent but incompatible backgrounds. In addition, exploitation is the ability to refine, develop, and/or change existing skills for new ones, by incorporating in the operational routines the new knowledge previously acquired, assimilated, and processed.

The ACAP model of Zahra & George (2002) has been heavily criticized (E.g. Todorova & Durisin, 2007). By using learning theory, Todorova and Durisin (2007) point out that Assimilation (part of PACAP) and Transformation (part of RACAP) are not sequential dimensions. They posit that pieces of organisational knowledge may move not only from

Assimilation to Transformation dimensions but also in the opposite direction, because they both are alternative routes to exploitation. Hence, the separation of PACAP and RACAP proposed by Zahra and George (2002) collapses. RACAP hinges entirely on PACAP, and Cohen and Levinthal (1990) say it explicitly “These abilities collectively constitute what we call a firm’s ‘absorptive capacity.’” (p. 128). Since the deconstruction of a construct that hinges upon its elements acting in an integrated fashion is perhaps not the most fruitful avenue to pursue, our study will follow the ACAP model proposed by Todorova & Durisin (2007).

3 The role of Social Integration Mechanisms for ACAP

Acquisition is recognized by Todorova and Durisin (2007) as a first component of ACAP, related to the intensity, speed and effort to gather knowledge. They cite Cohen and Levinthal (1990) and use cognitive sciences in individual learning for demonstrating that assimilation and transformation phases are alternative process, after knowledge acquisition. When the new knowledge can be slightly altered to fit and to be incorporated into the existing knowledge structures, this new knowledge is ‘assimilated’. When the new knowledge cannot be assimilated, it is transformed. The transformation is an alternative process to assimilation, and it enables firms to perceive new knowledge to some extent incompatible with prior knowledge structures, to build new ones which are capable to receive the new knowledge. Thus, it may be the transformation capability that allows firm to survive in highly competitive environments (Todorova & Durisin, 2007). Based on this, the following hypotheses are going to be tested:

H1. The assimilation of knowledge (ASS) in firms is a function of the acquisition process (ACQ).

H2. The transformation of knowledge (TRF) in firms is a function of the acquisition process (ACQ).

H3. The exploitation of knowledge (EXP) in firms is a function of the assimilation process (ASS).

H4. The exploitation of knowledge (EXP) in firms is a function of the transformation process (TRF).

Social integration mechanisms contribute to build connectedness and shared meanings (Todorova & Durisin, 2007). They favour the efficient circulation of information flows

within the firm (Fosfuri & Tribó, 2008) and they increase the interpersonal networks and make interunit knowledge transfer more intensive (Peltokorpi, 2017). For example, the use of cross-functional teams may increase innovativeness by bringing together people with different skills, backgrounds and complementary information about the same problem or opportunity (Davenport, David, & Beers, 1998; Manhães & Dávila, 2016). Informal meetings, open dialogs between employees and managers may be other forms of social integration mechanisms (Kianto & Andreeva, 2014).

Todorova and Durisin (2007) posit that the social integration mechanisms are likely to influence the four dimensions of ACAP. They posit that, depending of specific circumstances (e.g. type of new knowledge and type of knowledge processes), social integration mechanisms may have either a positive or a negative effect on those dimensions. Even more, according to Todorova and Durisin (2007), social integration mechanism may have a direct or a moderating effect on those dimensions.

The propositions of Todorova and Durisin (2007) regarding the positive or negative effects of SIM on ACAP' dimensions have not properly discussed yet, and this lack of studies is even more visible in regions beyond the boundaries of emerging countries. Thus, due its exploratory nature, this study will analyse the direct and moderations effects of SIM on ACAP' dimensions without the development of hypotheses.

4 Method

This paper follows a positivistic point of view. An analysis of the relationships between the different dimensions of ACAP and the social integration mechanisms implies a definition of a set of causal relationships that can be examined using a quantitative approach.

4.1 Sample

To address this research question, we collected the survey data in Santa Catarina State, Brazil, using scales previously validated in international context. Santa Catarina is located in the South region of Brazil, and it is responsible for 4.8% of Brazilian gross domestic product (GDP), it employs 7.8 % of the Brazilian workforce and it has the fourth highest GDP per capita (IBGE, 2014). Hofstede et al. (2010) defined the South of Brazil as "European and prosperous, is more hierarchical, less formal, more individualist, and more masculine (achievement-oriented)" (p.347).

The target enterprises were selected from a database of Industry Federation of Santa Catarina (FIESC / SC). The data was collected from November 2015 to April 2016 by mailing to companies' managers from top or middle levels in each firm. As a result of collection efforts, we collected 146 responses, representing a response rate of 9.3%. After excluding 21 responses with incomplete data or ungagged responses, we achieved a usable sample of 125 responses for further analysis.

4.2 Measures

ACAP. For measuring Potential and Realised ACAP, we used the scale developed by Flatten, Engelen, Zahra & Brettel (2011), composed by 14 items and that was built considering different research streams and models for ACAP (Todorova & Durisin, 2007; Zahra & George, 2002).

Social integration mechanisms (SIM). We measured this construct using part of the scale developed by Kianto & Andreeva (2014), because this scale contains indicators that may represent the different mechanisms, and it has a wording and structure that are well understood in Brazilian context.

Controls. We use firm size and firm age, represented by the logarithm of the number of employees and the logarithm of the number of year operating.

4.3 Analysis

In line with suggestions from Podsakoff, MacKenzie, & Podsakoff (2012) as well as benchmarking of previous studies (cf. Andreeva et al., 2017), we applied a set of remedies to control and ensure that common method bias (CMB) would not influence our results. Then, we tested our hypotheses using structural equation modelling (SEM) supported by ADANCO software, following suggestions from Henseler, Hubona, & Ray (2016). SEM allows testing causal paths between latent variables and identifying the collective strength of multiple variables (Creswell & Creswell, 2017). First, we analysed the measurement model to ensure construct reliability, convergent validity, and discriminant validity. Second, we assessed the structural model by using the following steps: we analysed the Standardized Root Mean Square Residual (SRMR), proposed by Henseler, Hubona, & Ray (2016) as a model fit assessment criterion. Then, we identified the amount of variance of dependent variables explained by the model (adjusted- R^2 values). After this, the statistical significance and the strength of path estimate between constructs were evaluated, for testing the research hypotheses. Even more, a bootstrapping procedure was performed (using 5000 bootstrap samples) in order to obtain and present confidence intervals about each construct and path in the model.

5 Results

The following section presents the application of remedies for common method bias, the results of analysis of both measurement model and structural model, for testing the developed hypotheses.

5.1 Remedies for Common Method Bias (CMB).

We used some procedural remedies suggested by Podsakoff et al. (2012). The online survey was managed and performed by FIESC, an institution that use to collect data from industries from Santa Catarina. By doing this, we provided to respondents the same data collection standards they use to deal with (e.g. ethics, privacy, communication style and channel), and we increased the probability of honest answers. We chose respondents that

were familiar with innovation and business management issues. In the statistical side, we tested a model that included additional unmeasured latent factor to represent CMB, and as suggested by Liang, Saraf, Hu, & Xue (2007), we confirmed that the loadings on the unmeasured latent factor were lower than the loadings on the construct factors. In addition, we checked that variance inflation factors (VIF) for each construct factor in each latent variable were lower than 3.3 (Kock, 2015). These procedural and statistical procedures taken together decreased the risk of CMB being a serious concern in this research. We also compared the answers of early and late respondents for testing nonresponse bias, by using discriminant analysis (J. S. Armstrong & Overton, 1977) and no significant differences were found.

5.2 Measurement model.

We confirmed good reliability in latent constructs by calculating scores (above 0.7) as recommended by Nunnally & Bernstein (1994) for Cronbach's Alpha, composite reliability, and rho A tests. The AVE scores above 0.5 for all latent variables as suggested by Fornell & Larcker (1981), and the loadings of all indicators above 0.6 (Hair, Black, Babin, Anderson, & Tatham, 2006) evidenced an adequate convergent validity (see table 1)

Table 1. Measurement test results for the variables of the study.

Constructs and Indicators		Loadings	Cronbach's Alpha	rho A	Composite Reliability	AVE
Social Integration Mechanisms (SIM)			0.842	0.854	0.888	0.615
SIM1	People from different parts of our organization interact informally with each other in a frequent manner	0.766				
SIM2	In our organization, open dialogs are common among/between employees and manager	0.781				
SIM3	In our projects, our organization uses teams consisting of people with skills and expertise from diverse fields	0.869				
SIM4	In our organization, we frequently use cross-functional teams and projects	0.820				
SIM5	In our organization, we have purposeful overlap of functional responsibilities	0.673				
Acquisition (ACQ)			0.700	0.714	0.833	0.625
AQ1	The search of relevant information concerning our industry is every-day business in our country	0.758				
AQ2	Our management motivates the employees to use information sources within our industry	0.853				
AQ3	Our management expects that the employees deal with information	0.758				

	beyond our industry					
Assimilation (ASS)			0.781	0.792	0.858	0.602
AS1	In our company ideas and concepts are communicated cross-departmental	0.765				
AS2	Our management emphasizes cross-departmental support to solve problems	0.832				
AS3	In our company there is a quick information flow, e.g., if a business unit obtains important information it communicates this information promptly to all other business units or departments	0.793				
AS4	Our company demands periodical cross-departmental meetings to interchange new developments, problems and achievements	0.709				
Transformation (TRF)			0.888	0.890	0.923	0.749
TR1	Our employees have the ability to structure and to use collected knowledge	0.844				
TR2	Our employees are used to absorb new knowledge as well as to prepare it for further purposes and to make it available.	0.907				
TR3	Our employees successfully link existing knowledge with new insights	0.857				
TR4	Our employees are able to apply new knowledge in their practical work	0.852				
Exploitation (EXP)			0.816	0.845	0.890	0.730
EX1	Our management supports the development of prototypes	0.766				
EX2	Our company regularly reconsiders technologies and adapts them accordant to new knowledge	0.914				
EX3	Our company has the ability to work more effective by adopting new technologies	0.878				

As suggested by Fornell and Larcker (1981), we assessed Discriminant validity by checking that square root of AVE in each latent construct is higher than the correlation between the construct and the other ones (see table 2). Descriptive statistics show that social integration mechanisms are widely used by firms in the sample (mean 3.76), and that acquisition and exploitation are the most representative dimensions of ACAP performed by the firms in our sample (mean 3.91).

Table 2. Descriptive statistics and correlations between variables of the study.

	Mean	ACQ	ASS	TRF	EXP	SIM	FS	FA
ACQ. Acquisition	3.91	0.79						
ASS. Assimilation	3.72	0.60	0.78					
TRF. Transformation	3.41	0.42	0.66	0.87				
EXP. Exploitation	3.91	0.50	0.55	0.46	0.85			
SIM. Social Int. Mechanisms	3.76	0.42	0.65	0.54	0.53	0.78		
FS. Firm Size	2552.58	0.05	0.12	0.05	0.11	0.07	1.00	
FA. Firm Age	35.30	0.22	0.21	0.11	0.24	0.19	0.45	1.00

* Square root of AVE in diagonal

5.3 Structural model.

The structural model presented in the figure 1, was assessed after running the bootstrapping procedure (see table 3). Our model has a good SRMR index of 0.086, below the maximum thresholds of 0.10 proposed by Henseler et al. (2016).

Table 3. Test of Hypotheses

Variables	Coef. B	p values	f ²
H1. ACQ -> ASS	0.378	0.000	0.269
H2. ACQ -> TRF	0.222	0.002	0.062
H3. ASS -> EXP	0.255	0.035	0.040
H4. TRF -> EXP	0.160	0.158	0.020
SIM -> ACQ	0.416	0.000	0.209
SIM -> ASS	0.445	0.000	0.348
SIM -> TRF	0.405	0.000	0.192
SIM -> EXP	0.259	0.008	0.057
SIMXAQU -> ASS	-0.136	0.046	0.037
SIMXAQU -> TRF	-0.123	0.053	0.020
SIMXASS -> EXP	0.102	0.491	0.004
SIMXTRF -> EXP	-0.104	0.472	0.004
Firm Size -> EXP	-0.028	0.710	0.001
Firm Age -> EXP	-0.106	0.212	0.014
			Adjusted R²
ACQ			0.166
ASS			0.557
TRF			0.336
EXP			0.340
SRMR			0.086

By analysing the adjusted-R² values, that indicate the percentage of variability accounted by predictive constructs in the model (Henseler et al., 2016), we identified that constructs in our model explain 16.6% of Acquisition, 55.7% of Assimilation, 33.6% of Transformation and 34% of Exploitation processes of ACAP in firms in the sample.

In one hand, the results provided evidence that supports the hypotheses based on Todorova and Durisin (2007) about the simultaneous nature of assimilation and transformation dimensions of ACAP. Acquisition seems to be an antecedent of Assimilation (H1) and Transformation (H2), while the dimensions of Assimilation (H3) seems to predict Exploitation dimension. The effect of Transformation on Exploitation is not significant, so H4 is not supported. Assimilation and Transformation have the lower means in the model (see table 2), and it may suggest that they are alternative dimensions, in line with Todorova and Durisin (2007).

On the other hand, the results evidenced that in firms in our sample, the use of social mechanisms have a positive effect on acquisition, assimilation, transformation and exploitation dimensions of ACAP, with effect sizes considered strong in the first three ones. As shown in table 1, the use of cross-functional teams (Dávila, North, & Varvakis, 2016) and teams composed by people with different backgrounds (Manhães & Dávila, 2016) seems to be the most important social integration mechanisms, due their correlation with this construct that influences positively the dimensions of ACAP.

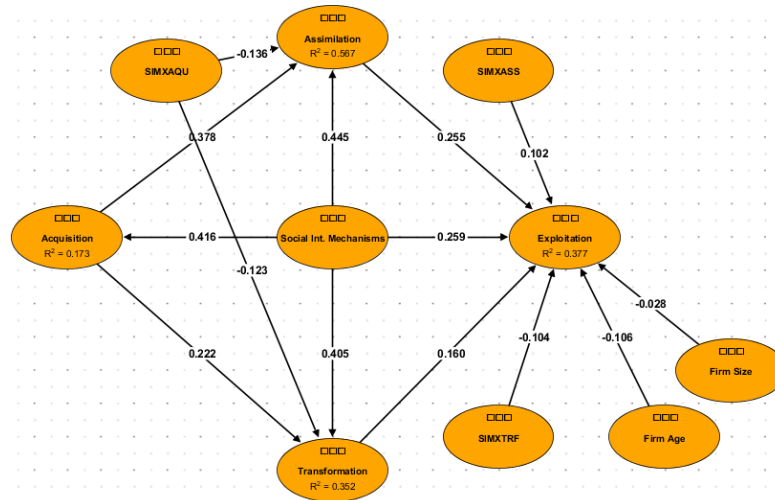

Figure 1. Path model.

Regarding moderation effects, the joint effect of social integration mechanisms and Acquisition, on Assimilation and Transformation are significant and negative, with very weak effect sizes. As Todorova and Durisin (2007) did, this can be explained by using the ‘weak-tie theory’ (Granovetter, 1977) and further developments published in studies of Hansen (2002). When the new knowledge is simple, the strong ties and use of social integration mechanisms may have a negative moderating effect on ACAP’ dimensions, by handicapping search processes. Following Hansen (2002), we may suggest that the new knowledge that Brazilian firms use to acquire is simple and not complex.

Finally, the moderating effects of firm size and firm age are not significant in our model.

6 Conclusions

This study contributed to the systematic understanding about the role of social integration mechanisms, by exploring ‘how’ these mechanisms may affect the dimensions of ACAP. In line with recent calls for deeper contextualization of the theories developed in the West (Michailova, 2011), our findings contribute to the knowledge management literature in the particular context of an emerging economy, Brazil.

By identifying the ACAP dimensions affected by social integration mechanisms, and the significance of these relationships, this study brought valuable information to managers of both Brazilian firms and foreign organisations willing to establish their operations in Brazil, for the efficient allocation of firm resources for managing knowledge and ultimately, innovation.

The moderating effects of social integration mechanisms on ACAP’ dimensions may be better explored in further studies, by including the complexity of the new knowledge that is being acquired. Other elements in the model Todorova and Durisin (2007) such as power relationships and activation triggers can be included in further research.

Abstract

Smart waste management and smart parking management are necessary improvements for civil society and significant effort how to achieve vision of smart city. Proposed innovative solutions create important knowledge to further understanding of the knowledge ecosystem in accordance to create the sustainable future. Smart trends are necessary for sustainable development and call for local and global challenges. The digital revolution and technological approaches represent unlimited source for growth. Using technological improvements and digital knowledge for innovative social solutions could significantly improve quality of life and support ecosystem. Smart devices are a key factor and ecosystem should benefit from them. Along with smart traffic, smart lighting, smart energy and smart waste management is an integral part of any smart city. There are two innovative functions of smart waste management. One is operational efficiency and second is waste reduction. Although public services and waste management companies have been around for a long time, they have implemented only limited innovations with operational efficiency, until the last few years. The other side of smart waste management deals with managing the quantity of waste created on a daily basis. Consumers and businesses create millions of tonnes of garbage every year. User friendly waste management and analytics platform could make more effective waste management. Smart waste management could simply save the costs and improve ecosystem. Another innovative approach, which is smart parking management mainly optimise parking space usage, improve the efficiency of parking operations and help traffic in city flow more freely. Smart parking designs, develops and produces outstanding leading-edge technology that enables people to manage on-street and off-street parking efficiently and cost-effectively. The first goal of the submitted article is to identify and define the key features and tools for smart waste management and smart parking management. The second goal is to examine usage of technological approaches in this area. The last aim is to draft theoretical solutions, which could be easily practically implemented into the praxis. Innovative solutions in this area will be just small step in vision of the smart city, but big improvement in quality of life. The most important contribution of the article is to highlight the necessity of smart waste management and smart parking management in contemporary world.

1 Introduction

Nowadays social processes impose requirements on innovative approaches and solutions for resolving social problems that exceed the established ways of thinking and acting. The paper contains theoretical description of smart city and innovative solutions in waste management and parking management. Smart city is a community that is sustainable, liveable and efficient. The sustainable community is one which reduces the environmental consequences of urban life and is often an output of efforts to make the city more efficient and liveable (Jurenka et al, 2019).

Smart city is created by basic infrastructure that offers a high quality of living, clean environment, renewable source of energy, and application of specific smart solutions in every day.

Smart city is a place where traditional networks and services are made more efficient with the use of digital and telecommunication technologies for the benefit of its inhabitants and business (European Commission, 2019).

The most effective definition of a smart city is a community that is efficient, liveable, and sustainable—and these three elements go hand in hand. A sustainable community is one which reduces the environmental consequences of urban life and is often an output of efforts to make the city more efficient and liveable (Charbel Aoun, 2013, Elets, 2016).

The British Standards Institution (2014) defines the term smart city as “the effective integration of human, physical and digital systems with the aim to build environment which can deliver sustainable and prosperous future for its citizens.”

Citizen-focused definitions consider smart city as friendly, clean, and with well-developed transport infrastructure. Citizen-focused definitions are also familiar words like “technology,” “connected,” “internet,” and “modern” which extend the right meaning of smart city (Centre for cities, 2014).

Basic infrastructure of smart city mainly contains well-organized and ecological urban mobility and public ways of transportation, smart waste solutions and smart waste management, citizen participation, strong information architecture with cloud solutions, safety and security systems in order to detect, analyse a prevent harmful behaviour.

Reaching of smart infrastructure is possible only in the way of applying information and communications technology (ICT) infrastructure and architecture. The availability and quality of the ICT infrastructure are important for smart cities. Indeed, smart object networks play a crucial role in building smart cities into a reality. ICT infrastructure includes wireless infrastructure (fiber-optic channels, Wi-Fi networks, wireless hotspots, kiosks) and service-oriented information systems (Jurenka et al, 2017).

The implementation of an ICT infrastructure is fundamental to a smart city’s development and depends on factors related to its availability and performance. (Hawaii International Conference on System Sciences, 2012).

2 Smart solutions

By 2050 the global population is forecast to grow to over 9 billion, 80% of which will inhabit cities. The increase in demand for all resources is unsustainable, as are traditional delivery mechanisms, which are unresponsive and too costly. To maintain quality of life expectations in the developed world, we urgently need to identify and implement innovative solutions in order to effectively manage and control human environmental interaction – particularly in cities (British Standards Institution, 2014).

Smart solutions are nowadays necessary more than ever. Smart solutions, which must be implemented in cities should focus on the following features: effective waste management, waste transformation to energy, fuel and compost, relevant public information, application of renewable source of energy, construction of green buildings, smart and safe pedestrian crossings, citizen's engagement, monitoring water quality, 100% treatment of wastewater, smart parking systems, autonomous traffic management systems, and other smart solutions.

Now more than ever, cities need to provide public services more efficiently along with supporting sustainable and long-term economic growth. The latest researches suggest that the best way to do this is becoming “smart.” This generally means to use new technologies (mainly information and communication technologies) and data to improve service delivery and address various economic, social, and environmental challenges (Jurenka et al, 2019).

As example we could point on smart transport and smart mobility initiatives, like traffic control centre, which can help the city manage traffic flows and reduce traffic jams. Real-time managing free parking spaces system, recalculating smart routes for drivers, making available bus arrival data publicly, development of new smartphones applications, special radio information systems could make commuting in the city easier.

The key components, especially of medium-sized smart cities comprises of six fundamental elements: smart people, smart mobility, smart living, smart waste management, smart economy and smart government. The aforementioned six elements are crucial for achieving the smart city goals in real meaning (Racounter, 2018).

3 Smart waste management

Based on estimates, the world cities generated 1.3 billion tonnes of waste annually. With current urbanisation and population growth rate, the global waste generation is estimated to rise to 2.2 billion tonnes by 2025. A World Bank study showed that urban areas in Asia spent USD 25 million per year on solid-waste management, and this figure will increase to USD 47 million per year (Global waste management conference, 2017).

Another prediction (Fig 1.) shows that in 2025 will be produced more than 6 million tonnes per day and in 2100 due to population growth production of the waste will rise to 11 million tonnes per day. Abovementioned predictions call for smart solutions in sector of waste management (The World Bank, European Commissions, 2018).

Fig. 1 Global predictions in waste management (NEC, 2018)

Managing waste properly is essential for building sustainable and liveable cities, but it remains a challenge for many developing countries and cities. Effective waste management is expensive, often comprising 20%–50% of municipal budgets. Operating this essential municipal service requires integrated systems that are efficient, sustainable, and socially supported (The World Bank, 2019).

Smart technologies in waste management can help optimise the budgets, municipal resources, the use of garbage trucks and improve provided services through better management. Transformation (Fig. 2) of the traditional waste management system into a smart solution could bring:

- Route optimization;
- Improvement of staff productivity;
- Measurable benefits.

Fig. 2 Transformation of waste management into a smart solution (NEC, 2018)

Benefits (Fig. 3) consist of: smart routes without traffic jams, fleet management, reducing minimum 15% operational costs, increasing of quality service, fuel savings, reducing CO2 emissions and collecting of containers only when necessary.

Fig. 3 Benefits from smart waste management (NEC, 2018)

Another solution for our future in waste management is to create complex strategy and effort in educating all people, how to reduce waste and how to correctly separated waste for effective repeatedly utilization. This important knowledge, we should transfer on children. Teach them these knowledge and habits especially in school and home. This is particularly important for municipalities, who must pay for the landfills and waste removal services. Creating strategy and our effort is fundamental to further understanding of the knowledge ecosystem, only in this way is possible to create the sustainable future.

4 Smart parking management

Nowadays almost in every medium size city arises parking problems that people must face each day. Traffic level rapidly increases with the level of population growth. The utilization of personal vehicles is increasing every year. Lots of people chooses personal vehicles than public ways of transportation. Very often is difficult and time consuming to find free parking lot in most of urban and commercial areas, particularly during the rush hours. (Rahman, S., Bhounik, P. 2019). Contemporary parking problems consist of:

- Insufficient parking lots in highly populated areas;
- Inefficient use of existing possible parking capacity;
- Struggle to find a free parking space;
- Traffic problems created due to poorly designed parking spaces;
- Problem to find your vehicle in very large parking areas;
- Some Parking spaces are inconvenient (too small) to use;
- Waste of fuel and other resources in searching for a free parking lot;
- Environmental problems due to excessive fuel exhaustion;
- Caused damages on vehicles during parking;
- Inadequate or very expensive parking price models;
- Confusing parking policies.

Smart parking is important part of smart mobility, which belongs into six key elements of each smart city. Smart parking management offers the optimization of traffic flow in the city and especially in busy neighbourhoods. Smart parking enables easier finding of free parking lot, reservation of parking space from home or car, digital payments, extension of parking time and detection of unauthorized parking.

Fig. 4 Smart parking system (Khanna, A., Anand, R., 2016)

Main purpose of smart parking (Fig. 4) solution is to reduce time to locate the available parking areas. IoT-based sensors deployed in the parking area (fixed on each parking slot) easily collect the data and simply gives a signal about which parking lot is vacant and which is occupied. Information from the sensor are analysed and send to a nearby receiver which gives a continuous live update about the availability of all the available parking slots. The collected data are broadcasted to parking information system and smartphone app for drivers. Parking spaces could be reserved through the mobile app or driver can use guidance system. (Cynthia, J. et al, 2018).

Besides the location of the parking space, the drivers will get information like the size of the parking space and even nearby public transportation information, if are needed. (Jasani, M. 2019). Smart parking solution in addition also offer reservation of parking lot, reduce the man power cost, increase the efficiency and safe environment.

Another solution for smart parking management is creating big parking places in the suburbs. This type of the parking strategy has many possibilities, how to attract people. The biggest advantage of this model would be low price, assurance of free parking space and safety location. Abovementioned solutions could by divided into mores strategies, which could reflect individual possibilities and preferences of each city. First strategy could focus on providing complimentary shuttle buses from suburb parking area to main location in the city. Second strategy could focus on providing complimentary tickets on local transport system. Third strategy could provide combination of complimentary shuttle buses and local transport system. Fourth strategy could focus on providing system

of shared bikes, which could be lend in parking areas. The fifth strategy could combine complimentary shuttle buses, complimentary local transport system and system of shared bikes together in one complex system. This suburb parking areas could offer favourable daily price and also weekly, monthly, quarterly, half yearly and yearly discounted subscription. Pricing policy will contain better price and conditions, if there will be signed longer subscription. This strategy should have own marketing campaign, web address with all information like general conditions, reservation system, time tables, price list and other important information. Own mobile app is necessary requirement and referrals bonus system is highly recommended. Mobil app could provide in easy way for their users the transportation information, time tables and best connections possibilities from parking area to their final destination and vice versa. This concept could easily solve parking problems a certain group of people, reduce traffic jams in the city, save money in long term subscription, save environment and for particular people also save time.

5 Conclusion

The future of all technologies is in personalization and in cloud organisation. Smart waste management and smart parking management could be organised from cloud operations centre, which could monitor key performance indicators in order to automatically provide services. Monitoring of public indicators could focus on taking decisions for public welfare. Cloud operations centre could offer truly integrated solution, automated regulation, and designated to meet smart city requirements in a flexible, economical and efficient way.

Smart waste management solutions could simply save the costs a improve ecosystem by using the new technological systems, which comprises of volumetric sensors inside the containers, telemetry units installed in garbage trucks and by the automatic system calculating optimized routes. Optimized routes in addition save fuel, reduce CO2 emissions and reduce operational costs.

Volumetric sensor is small sensor, which can be easily installed inside all the waste bins. Sensor measures the distance from top of the bin to the inserted amount of the waste. This technology enables to monitor real amount of the waste in containers. Smart sensors allow optimize the efficiency of waste collection. All these sensors enable to collect only full containers and exclude to pick-up empty containers.

Innovative waste solutions are fundamental for sustainable future of our world. Smart solutions are also necessary in order to build an effective circular economy, which could solve potential problems resulting from growth of population. Circular economy counts with products, that are optimized and designed for recycling and repeatedly reusing. In contemporary world national and local governments embrace the circular economy. Smart solution in waste management will help promote efficient economic growth and subsequently will minimize environmental effects.

Many cities have begun to discover how to tailor their parking solutions according to specific requirements to the actual individual needs of people. For example, Dubai has

integrated portable multi-level parking structures, in order to increase the number of cars parked in a small space.

The fundamental element of perfect parking solution is in using technological development of IoT, Big Data and Cloud Technology. The smart parking systems are still evolving. In the future could be smart parking management eco-friendly and sustainable. Smart parking solutions generally bring less maintenance cost, provide security to the parking grounds, reduce the hassle, reduce traffic jams and additional parking time fee could be remotely paid through the parking app.

The vision of smart city is not just the distant future. Important technological development has been made in the past couple of years. Innovative technologies and approaches change smart city into reality. The recent growth of Internet of Things and Cloud technologies offers great potential. Smart waste management and smart parking systems have always been the core of the smart city vision. Smart waste management and smart parking systems could easily provide real time information, make abovementioned processes effective and sustainable.

Abstract

Purpose – In the context of business, the concept of ‘peripheral vision’ is usually used to refer to instances involving detecting information that may be important for the “safe and an effective navigation of the world”. In contrast, the concept of ‘tunnel vision’ is used to refer to the situation where peripheral vision is lost and only central vision is retained with potential deleterious effects on business performance and decision-making. This study investigates how unlearning activities can counteract the presence of tunnel vision, along with how these activities can, in turn, result in the improvement of peripheral vision.

Design/methodology/approach – In this study the influence of what has been termed ‘Intentional Unlearning’ on peripheral vision as a mediating variable between focal vision and peripheral vision is investigated through an empirical study. This study used ADANCO 2.0.1 and it involved the collection and analysis of data provided by 203 bank managers.

Findings – The findings complement organizational theories of management by providing a clearer definition of tunnel-vision and provide guidance for managers as to how they may improve peripheral vision.

Originality – This study shows the need for knowledge workers to adopt procedures that will have the effect of causing them to question the familiar frameworks they use to interpret their perceptions of the external environment.

Keywords: tunnel-vision, focal vision, peripheral vision, intentional unlearning.

Paper type – Academic Research Paper

1 Introduction

Many managers believe that the key to creating sustainable competitive advantage is through the articulation of a long-term vision, translating this vision into relevant policies and making sure that these policies are implemented efficiently (Posavac, Kardes, & Joško Brakus, 2010). It can be argued that long term vision is based, in part, on two distinct sources of information: information related to core or focal perception of the organization's environment and information related to peripheral perceptions of the organization's environment. When referring to the individual, peripheral vision is more related to what is visible to the eye outside the central area of focus whereas focal vision involves what is visible in the central focal area. Focal vision typically provides information relevant to the completion of short term tasks in appropriate detail whereas peripheral vision provides information about potential changes to the environment, such as external threats, that are critical in developing long term plans and strategies (Day & Schoemaker, 2004).

The following research develops the concepts of focal and peripheral vision in the context of knowledge workers and explores both the importance of peripheral vision and the manner in which it may be augmented. Knowledge workers may be considered to be those individuals who contribute to the transformation and exchange of information. Knowledge workers make active use of the knowledge derived from information (Reinhardt, Schmidt, Sloep, & Drachsler, 2011). Thus, knowledge workers potentially rely on both focal and peripheral vision when they obtain information from which knowledge is derived to underpin their actions.

Tunnel vision represents a situation where peripheral vision is lost but focal vision is retained resulting in a constricted circular tunnel-like field of vision (Cheveleraud, 1986). It is possible to get some idea of the nature of tunnel vision by holding a card board tube (about 125 mm long) to one eye and closing the other eye. Tunnel vision makes walking and moving about difficult for the people affected it also markedly influences the individual's ability to anticipate changes in the external environment. Thus, in the context of business, as in life, peripheral vision is usually used to detect information that may be important for the "safe and an effective navigation of the world" (Day & Schoemaker, 2004). Such information may be combined with information derived from focal vision to develop appropriate organizational responses to both current and future environmental conditions. Peripheral vision may help managers focused on existing valuable customers to recognize and predict the future needs of potential customers whilst being able to use their focal vision to gather appropriate information to satisfy the needs of their current customers (Cegarra-Navarro *et al.*, 2016).

In the same way that optometrists are able to assist patients in counteracting the loss of peripheral vision in cases of tunnel vision with special exercises (Wiegand, 1999), knowledge workers can counteract tunnel vision, potentially leading to flawed decision-making and planning, through developing and enhancing peripheral vision through the updating of procedures, standards, and knowledge (Posavac *et al.*, 2010). In prior research it has been argued that such updating of procedures, standards and knowledge (generally

referred to as knowledge and knowledge structures) involves intentional unlearning. Intentional unlearning is the act of putting aside knowledge and knowledge structures that are not appropriate for use in a given context (Fernandez & Sune, 2009). By putting aside outdated knowledge and knowledge structures and updating their knowledge and knowledge structures, both individuals and organisations may be empowered in their efforts to expand the field of vision beyond what occurs in their focal vision (Day & Schoemaker, 2004; McWilliam, 2005). In addition to implementing specific procedures supporting the removal of knowledge, unlearning may also be facilitated through the creation of an 'unlearning context'.

This study investigates how unlearning activities can counteract the presence of tunnel vision, along with investigating how these activities can, in turn, result in the improvement of peripheral vision. The research approach adopted involves carrying out an empirical investigation involving data provided by 203 bank managers. The paper is structured as follows. First, the conceptual framework and hypotheses are presented. Then, the methodology used and the results obtained are explained. Finally, a discussion of the implications and limitations of the research is presented.

2 Theoretical background and research model

From the point of view of a company, focal vision may be considered to relate to the ability of managers to focus on identifying the needs and wants of existing valuable customers (Sard, 2000). Thus, well-developed focal vision provides managers with focus and direction for setting relatively short-term operational goals relating to serving these existing customers. In addition, knowing specifically what valuable customers want enables managers to build and deliver precise solutions to meet these valuable customers' needs (Sherden, 1994). Good focal vision also guides managers in making decisions and establishing what the organisation does best (Sard, 2000).

Despite the above benefits, it should be noted, however, that focal vision has inevitable drawbacks. As it is shown in Figure 1, in the case of the human eye, focal vision addresses perceptions in the central two degrees of vision. This means that although focal vision offers the sharpest view, it also represents a very narrow view of the external visual environment (Luo & Peli, 2006). In a business context this could lead to the company ignoring external factors when making decisions that are significant for potential customers (Day & Schoemaker, 2006). Essentially there is a trade-off between the fine details and accuracy of focal vision and the much less detailed by far more extensive peripheral vision. As pointed out by Miller (1982), current models of professionalism perpetuate a very narrow perspective, with a lack of openness to other specializations or bases of expertise that promotes a form of blindness which is typically unsustainable given the complexity of organizational problems and the scope needed for their solution. It may also be noted that the development of expertise typically leads to the development of focused attention to a relatively small number of perceptual cues in problem solving. Although extremely valuable in addressing complexity it has been observed that this may lead to what has been termed the 'garden path' phenomenon

(Johnson & Thompson, 1981) where an expert is misled as a result of focusing on a small number of cues rather than perceiving the richness of the problem.

As it is shown in Figure 1, peripheral vision encompasses what is potentially visible outside the central area of focus (Chevaleraud, 1986). As noted above, in the context of ‘company vision’, focal vision is also potentially very narrow and it usually focuses on a small subset of valuable customers, while a company’s peripheral vision potentially involves a much larger visual field (Cegarra-Navarro *et al.*, 2016). It has been noted that companies utilising peripheral vision are often very successful (Day & Schoemaker, 2006). Furthermore, being unaware of peripheral signals can result in the erosion of the firm’s competitive position as new competitors enter the fray and new products invade the marketplace but are not perceived or their importance un-assessed or under-assessed (Day & Schoemaker, 2006; Mathur, Gehrmann, & Atchison, 2013).

Fairclough (2005) further asserts that when organisations ignore the events unfolding on the periphery of their business, they usually experience significant costs and risks. In contrast to peripheral vision, tunnel vision is a condition in which you can see things that are straight ahead of you but not to the side (Wiegand, 1999). As Cegarra-Navarro *et al.* (2017) have pointed out, tunnel vision is the loss of peripheral vision, which means that knowledge workers who lose their peripheral vision may have difficulty recognizing and understanding potential customers needs leading to failure to develop products and services targeted to potential customers (Day & Schoemaker, 2006; Haeckel, 2004). It may be further observed that Christensen’s work on disruptive innovation (Christensen, 2016) identifies examples of major organizations that have failed as a result of their concentrating on existing customers and failing to interpret correctly information concerning emerging technologies that although not directly related to their core technologies and competencies are more effective in addressing the needs to existing and potential customers.

What the above considerations potentially mean for knowledge workers is that the overuse of focal vision may lead to “tunnel vision effects” which may limit the scope for detecting, in particular, investment and marketing opportunities (Posavac *et al.*, 2010). In this study the overuse of focal vision within the context of organisations is defined as “tunnel vision”. As suggested by some researchers, managers are able to develop what may be considered to be limited background visual perceptions in their visual field (but maintain sharp focus on a narrow visual field). Thus, they can maintain both focal vision and peripheral vision simultaneously. This strategy avoids the pitfalls of tunnel vision (Posavac *et al.*, 2010). Thus the development of such background perceptions, blurred and limited though they are, is likely to have a positive effect on employees and, in particular, knowledge workers’ ability to detect market trends and weak signals beyond the strong signals relating to current necessities of valuable customers (Cegarra-Navarro *et al.*, 2016; Day & Schoemaker, 2006).

Fairclough (2005) further asserts that when organizations ignore the events unfolding on the periphery of their business, they usually experience significant costs and risks. For example, when Blackberry (formerly RIM) ignored the “touchscreen interface” in the belief that its valuable customers would always prefer their “tactile keyboard”, it was

misaligned its organisation around a strategic dead-end. The result was that Blackberry experienced a significant decline in business and became, essentially, a minor competitor in the smart phone business. Furthermore, both focal and peripheral visions are necessary to update the strategic thinking over the course of the company lifetime (Haeckel, 2004; Cegarra-Navarro *et al.*, 2017).

Figure 1: Focal vs Peripheral Visions

This paper focuses on the role of intentional unlearning in counteracting tunnel vision and supporting peripheral vision in an organizational context. If we extrapolate the above practices to the context of business, then it could be considered that intentional unlearning offers an excellent opportunity to overcome some of the above problems and thus to ‘see beyond’ the central two degrees of vision. Since intentional unlearning is a process that explicitly addresses the need to adapt to discrepancies between currently validated knowledge and the existing body of organizational knowledge (Wensley & Navarro, 2015) this process can be used to broaden our vision (Coombs, Hislop, Holland, Bosley, & Manful, 2013). Intentional unlearning is comprised of a set of action rules that prepare the ground for the creation and application of new knowledge and new knowledge structures (Cegarra-Navarro, Wensley, & Polo, 2014). As suggested by Aledo Ruíz *et al.* (2017), “intentional unlearning” is thus a set of actions that take place when people need to update knowledge and knowledge structures (e.g. routines, processes or protocols) that over time have become obsolete.

Based on the work of Cegarra-Navarro *et al.* (2014), awareness, relinquishing and relearning contribute to create ‘room’ for new knowledge, which in turn enables individuals to identify mistakes (Srithika & Bhattacharyya, 2009), errors or inappropriate or incorrect assumptions which may require the recognition of the restrictive nature of tunnel vision and the realisation of the power of peripheral vision (Cegarra-Navarro *et al.*, 2017; Zhao, Lu, & Wang, 2013).

Figure 2 provides a description of the hypotheses examined in this study. The first two hypotheses assume that the positive influence of tunnel vision on peripheral vision is indirect and is mediated by the presence of intentional unlearning. Therefore, the first hypothesis considers that intentional unlearning has a positive impact by removing the constraints of tunnel vision, the ‘blinkers/blinders’ that restrict and attenuate peripheral perception, and the second hypothesis considers that “intentional unlearning” is a necessary prior task in the acquisition of new knowledge that is not compatible with

current vision in different contexts and situations, thus realising the power of peripheral vision. The third hypothesis of the model relates to the direct effect of tunnel vision on peripheral vision, which is expected to enhance efficiency through the reduction of the cost of search and acquisition of weak signals. In other words, knowledge workers who have developed effective tunnel vision and are able to understand valuable customers are more likely to understand and adopt new ideas if these can improve their relationship with new and potential customers.

.Figure 2: The Proposed Theoretical Model

3 Methodology

3.1 Data Collection

This research contributes to better understand the peripheral vision of knowledge workers. To achieve this, it was seen necessary to collect data from bank managers. As previously stated by authors such as Cegarra-Navarro *et al.* (2017), bank managers have a relevant and important role to play and must have expert knowledge of every aspect of the business in order to give their customers greater service. Before conducting the surveys, managers from 690 bank branches of a major Spanish bank were informed of the objectives of the research and were also invited to participate in the study. A total of 203 managers out of the 690 initially contacted agreed to participate in the study, on the assumption that they had at least six or more employees under their own direct responsibility. The survey was administered over a period of two months, from early January to early March 2016, with a factor of error of 5.77% for $p=q=50\%$ and a reliability level of 95.5%. The response rate of 29.42% is greater than the average response rate of 15 to 25 percent suggested by Menon, Bharadwaj and Howell (1996) for surveys involving senior management.

3.2. Measures

Focal vision (FV) was measured by using four indicators initially proposed by Cegarra-Navarro *et al.* (2017). The authors adopted questions focusing on the way management faced up to change, actively introduced it into the company through projects, and fostered collaboration with profitable customers of the organisation.

Intentional unlearning is assessed through items relating to awareness, relinquishing and relearning as three reflective dimensions (Aledo Ruíz *et al.*, 2017). Awareness items recognize the support of policies and rules that encourage problems identification and the identification and investigation of mistakes. The relinquishing scale focuses on employees' ways of thinking and behaviours that guide new ways of performing tasks. Finally, relearning items describe how management faces up change, collaborates with other organization members, and introduces changes into the company through projects.

Previous studies by Day and Schoemaker (2006) provide guidance in developing items to measure peripheral vision (PV). Four items assessed the importance of 'peripheral vision' for cognitively-aware managers in relation to the enhancement of technical, administrative and social strategies due to a better understanding of the information available to potential customers.

All the selected items are shown in the Appendix.

3.3. Data Analysis

The data collected was analysed using ADANCO 2.0.1 Professional for Windows (<http://www.composite-modeling.com/>) (Dijkstra & Henseler, 2015). Intentional unlearning (IU) was operationalised as a second-order construct with three dimensions. It should be noted here that "awareness, relinquishing and relearning" capture different theme with respect to type of activity and values. Therefore, the relationships between the unlearning process and its three steps represent a second-order refractive-formative type. Following the Becker *et al.* (2012) guideline, the analysis was conducted on two levels of the first-order constructs and second-order constructs level.

An examination of the results in Table 1 shows that all first-order factor loadings and second-order factor weights were significant. In addition, all Dijkstra and Henseler's ρ are greater than 0.8, the scores for the average variance extracted (AVE) surpass the threshold of 0.5 for composites' unidimensionality, and all HTMT are below the value of 0.90, thereby providing evidence that IU is a multifaceted construct construed from awareness, relinquishing and relearning.

Table 1 Second-order confirmatory factor analysis of Intentional Unlearning

First-order construct				Second-order construct			
	Indicator	Loading	t-value	Reliability (ρ_A^a , AVE ^b)	Weight	t-value	Maximum HTMT
Awa	Awa1	0.800	18.141	$\rho_A = 0.869$ AVE=0.683	0.466	18.552	0.746
	Awa2	0.887	33.098				
	Awa3	0.788	17.474				
Relinq	Relinq1	0.707	12.116	$\rho_A = 0.824$ AVE=0.598	0.448	15.539	0.746
	Relinq2	0.858	26.715				
	Relinq3	0.748	15.371				
Rel	Rel1	0.726	12.524	$\rho_A = 0.802$ AVE=0.568	0.425	16.625	0.679
	Rel2	0.821	16.872				
	Rel3	0.710	11.981				

Discriminant validity was determined by comparing the square root of the AVE (i.e. the diagonals in Table 3) with the correlations among constructs (i.e. the lower triangle of

the matrix in Table 3). On average, each construct related more strongly to its own measures than to others' (Fornell & Larcker, 1981). The constructs correlation matrix, shared variances, means and standard deviations are shown in Table 2. As a result of this analysis, evidence of content validity, reliability and convergent validity, and discriminant validity for the constructs of the example was found.

Table 2 Construct correlation matrix

	Mean	S.D	CA	Correlation matrix		
				1	2	3
1. Focal Vision	4.420	1.200	0.900	0.833		
3. Peripheral Vision	4.315	1.248	0.889	0.728	0.818	
2. Intentional Unlearning	0.000	0.808	0.861	0.358	0.518	n.a

Notes:

S.D. = Standard Deviation; CA = Cronbach's Alpha; Intercorrelations are presented in the lower and shady triangle of the matrix. The bold numbers on the diagonal are the square root of the Average Variance Extracted. n.a→ not applicable.

4 Results

The results of the *structural model* after the PLS analysis are collected in Table 3. According to Streukens & Leroi-Werelds (2016), The results demonstrate that the inner model has satisfactory predictive relevance for Peripheral Vision ($Q^2 = 0.46$) because that value is higher than 0. As Table 5 shows, the proposed model also explains the 72 percent of the variance in Peripheral Vision (R^2). Based on Preacher and Hayes (2008), a post-hoc indirect effect analysis was carried out to test the indirect effect of independent variables on the dependent variable by way of the mediator. As Table 3 shows, as the interval determined through bootstrapping does not contain the zero value, the indirect effect of Focal Vision on Peripheral Vision via the Intentional Unlearning is statistically insignificant. Consequently, the results provided full support for both hypotheses H1, H2 and H3.

Table 3 Structural Model statistics

<i>Direct relationship</i>	Path coefficients	T value	Lower 5%	Upper 95%	Adjusted R^2	Supported
<i>H1: FV → IU (a_1)</i>	0.378 ^{***}	3.143	0.234	0.553	0.139	Yes
<i>H2: IU → PV (a_2)</i>	0.280 ^{**}	2.282	0.039	0.472	0.720	Yes
<i>H3: FV → PV (a_3)</i>	0.810 ^{***}	9.116	0.471	0.945	0.720	Yes
<i>Indirect relationship</i>						
<i>FV → IU → PV ($a_1 * a_2$)</i>	0.106 ^{**}	2.797	0.02	0.178	0.720	Yes

Notes:

*** <0.01; ** <0.05;

FV= Focal Vision. IU= Intentional Unlearning. PV= Peripheral Vision.

5 Conclusions

This research has addressed an issue of significant importance for business and raised awareness of the importance of carrying out further research to understand the many ramifications of the interaction between focal and peripheral vision and organizational

learning. There are extensive opportunities for research and practice addressing the concepts of peripheral vision, focal vision and intentional unlearning in domains currently driving socio-economic development. The findings of this research complement organizational theories of management with a conceptual framework that more clearly articulates the concepts of peripheral and focal vision and indicates how they may be used as a basis for improving peripheral vision in organizations resulting, it may be argued, in improved organizational agility.

The results of this study indicate that peripheral vision relies on both the direct and indirect effects of focal vision. Therefore, this research highlights the importance of encouraging knowledge workers to question and assess the validity of the knowledge derived from their focal vision (e.g. routines and procedures that they regularly follow). However, the ability of an organisation to unlearn and revised its knowledge and knowledge structures as result of its relationships with valuable customers and the external environment is a subject which has generally been overlooked in the extant literature. In terms of managerial implications, this work points to intentional unlearning as a mechanism for updating the knowledge and knowledge structures derived from their focal vision by identifying and putting in place new rules which can lead to new learning processes.

Despite its valuable insights, the research has limitations mainly derived from the analysis of a financial institution which is likely to be directly affected by its interaction with the dynamic environment in which it operates. Having addressed some of the limitations associated with self-report surveys, it has been confirmed that common method biases are very difficult to quantify on any self-report study. Thus, further research could be undertaken to triangulate our findings through interviews and observational case studies. It should also be acknowledged that the authors have assumed that peripheral vision focuses mainly on the understanding of needs and preferences of certain potential customers. In other words, we have not considered the possibility offered by peripheral vision that would enhance the understanding of other stakeholders of the financial institution. This assumption is currently being explored. Future research will therefore focus on carrying out more extensive empirical testing of the model proposed in this study with an aim to establish its validity and impact on organisational management and organisational performance. In addition, future research will focus on carrying out more extensive empirical testing of this model in other sectors, as well as the analysis of the “social performance” of organisations.

Appendix: Questionnaire items

Peripheral Vision: with respect to your organisation, indicate the extent to which you agree or disagree (1= strongly disagree and 7= strongly agree):
PV1: Managers seem to be open to new ideas of potential customers. PV2: Management has tried to initiate innovations focused on potential customers. PV3: Managers adopt the suggestions of peripheral customers in the form of new routines and processes. PV4: Managers are prone to collaborate with other companies and to solve potential customers' problems together. (Source: Day and Schoemaker 2006)
Awareness: with respect to your current position indicate the degree of agreement or disagreement (1= strongly disagree and 7= strongly agree):
Awa1: Employees try to reflect and learn from their own mistakes. Awa2: Employees are able to see mistakes from my colleagues. Awa3: Employees are able to listen to my customers (e.g. complaints, suggestions). (Source: Aledo <i>et al.</i> , 2017)
Relinquishing: with respect to your current position indicate the degree of agreement or disagreement (1= strongly disagree and 7= strongly agree):
Relinq1: Individuals recognise forms of reasoning or arriving to solutions as inadequate. Relinq2: New situations have helped individuals change their behaviours Relinq3: New situations have helped individuals change their thoughts and attitudes. (Source: Aledo <i>et al.</i> , 2017)
Relearning: with respect to your organization indicate the degree of agreement or disagreement (1= strongly disagree and 7= strongly agree):
Rel1: Managers adopt the suggestions of personnel in the form of new routines and processes Rel2: Managers are prone to collaborate with members of the organization and to solve problems together Rel3: Managers are concerned with the fact that the manner of answering before unforeseen circumstances will be known by all. (Source: Aledo <i>et al.</i> , 2017)

Focal Vision: with respect to your organisation, indicate the extent to which you agree or disagree (1= strongly disagree and 7= strongly agree):
<p>FV1: Managers seem to be open to new ideas of valuable customers.</p> <p>FV2: Management has tried to initiate innovations focused on valuable customers.</p> <p>FV3: Managers adopt the suggestions of valuable customers in the form of new routines and processes.</p> <p>FV4: Managers are prone to collaborate with other companies and to solve valuable customers' problems together.</p> <p>(Source: Day and Schoemaker 2006)</p>

Requirements of Implementing Knowledge Management System in Crisis Management (Case Study: Crisis Management in Chabahar Municipality)

Abstract

While numerous management theories and technologies have been established to help managers address the challenges they routinely encounter, there are always sudden problems for which organizations are often unprepared. These low frequency and high consequence challenges are commonly defined as crises. The main characteristics of crises are uncertainty and ambiguity which threaten the productivity of an organization. For organizations to prosper and survive, they must act strategically in allocating their key resources and perform effectively and efficiently. This is especially true when dealing with crises. Unfortunately, one of the most valuable resources that organizations possess, knowledge, has been largely ignored in the CM literature. To address this deficiency, this study discusses about a knowledge management system (KMS) which helps organizations better managing of a crisis. This KMS possesses several requirements which aim to develop a strategic alignment framework that seeks to align CMS with knowledge strategy.

The use of collaborative networks regarding to the process of acquiring, sharing, and storing their knowledge is necessarily complex and also complicated for the managers. In regard to published related research works, despite the contributions of these CM studies, very limited research has been explicitly investigated the requirements of implementing KM strategies and system in a CM perspective. In order to fill this gap, our model of identifying KMS requirements will be designed and presented.

Therefore, this study aims to present the requirements of implementing knowledge management system in crisis management; a new trend which is not widely studied in research works. Knowledge management system will be helpful for managers to confront with internal and external crises effectively while it will support organizations not only to manage their knowledge but also in applying knowledge strategies properly.

This study has conceptualized the required process and elements of knowledge management system implementation through semi-structured in-depth interviews with a focus expert group selected from Chabahar municipality. Semi-structured, in-depth

interviews are utilized extensively as interviewing format possibly with a group in designing new models or processes. Recognizing focus group respondents was done through snowball sampling method. Snowball sampling is where research participants recruit other participants for a test or study. Content analysis method is used to analyze the interviews as a research technique used to make replicable and valid inferences by interpreting and coding textual material.

Chabahar municipality (at the south of Balouchestan, Iran) has been selected as a case study. Chabahar is a strategic port not only for Iran but also for India and China. Because hug amount of foreign investment in Chabahar, it is now the only sanction-except city of Iran. The strategic nature of this port confronts this port with several crises which should be managed and solved by its municipality. This organization, the same as other municipalities, is encountered with various crises during the year including natural crises like flood and human crises like social protest and even shooting in urban area. In order to achieve practical solution to implement knowledge management system, this organization is selected as a case study. The result is a seven-dimension-model that presents the requirements of implementing a KM system in organizations, extracted by using a case study. These dimensions are as following:

- 1. determine a crisis phase*
- 2. determine sensitive factors*
- 3. identify stakeholders*
- 4. data gathering*
- 5. data verification*
- 6. data analysis*
- 7. Knowledge management*

Keywords – crisis management, knowledge management, knowledge management system, Chabahar city of Iran, flood

Paper type – Practical Paper

1 Introduction

While numerous management theories and technologies have been established to help managers address the challenges they routinely encounter, there are always sudden problems for which organizations are often unprepared. These low frequency and high consequence challenges are commonly defined as crises. The main characteristics of crises are uncertainty and ambiguity which threaten the productivity of an organization.

crisis management (CM) can be described as a set of ongoing, systematic, and interrelated processes for identifying, analysing, treating and learning about various crises which an organization have been encountered or will be encountered with, in the future (Wang & Belardo, 2009). Crisis management applies management strategies and practices not only to prevent the crisis and decrease the negative effects of that but also to manage recovery and learning processes from crisis. In the other word, CM strategies

(CMS) emphasis on addressing the question of what organizations should consider in order to make appropriate decisions for managing crises (Wang & Belardo, 2009).

In other hand, for organizations to prosper and survive, they must act strategically in allocating their key resources and perform effectively and efficiently. This is especially true when dealing with crises. Unfortunately, one of the most valuable resources that organizations possess, knowledge, has been largely ignored in the CM literature (Haghani and Gharibpour, 2018). To address this deficiency, this study discusses about a knowledge management system (KMS) which helps organizations better managing of a crisis.

This KMS possesses several requirements which aim to develop a strategic alignment framework that seeks to align CMS with knowledge strategy.

The main aim of this study is to extract the requirements of knowledge management system in a municipality, as a center of commands, at the time of crisis. The crises which a municipality is faced with, will not only be limited to organizational and financial crises but it also covers all urban and natural ones. The specific nature of municipality and its responsibility to overcome all internal and external crises encouraged us to consider this kind special of organization as a case study as it mostly required a knowledge management system. To determine and conceptualize the requirements of implementing KMS in the municipality, Chabahar municipality in Iran is selected as it confronts with annual destructive Floods.

2 Knowledge management and its use in crisis management

Using Knowledge Management (KM) concepts to perform Crisis Management (CM) in the existing CM literature has been studied, in a very implicit way, and it has been categorized by Wang and Belardo (2009) into three main groups: “The first category addresses the importance of KM in terms of helping organizations acquire critical knowledge for managing crises through effective learning processes. The second category concerns the issue of recognizing the strengths and weaknesses of an organization’s KM capabilities. Studies in this category address the importance of the application of various technologies and methods to facilitate knowledge acquisition, sharing, distribution and storage. The third category concerns the sources of critical knowledge which can enhance the effectiveness of CM efforts. Studies in this category emphasize the need to develop efficient and effective means of locating and acquiring knowledge critical for managing crises”.

They believe while CM various frameworks provide valuable guidelines for organizing the crises within the organizations, they typically not include knowledge-based resources, such as the crisis management knowledge and experience of employees.

If we consider crisis as an “unusual event of overwhelmingly negative significance that carries a high level of risk, harm and opportunity for further loss (Fink, 1986)”, then we need an “IT (Information Technology)-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application (Alavi & Leidner, 2001)” which is described as a knowledge management

system (KMS). It is a main requirement of effective managing crisis while having two aspects: soft and hard.

In the other word, managing KM processes and implementing KM system can help managers to proactively respond to a highly turbulent environment and will benefit an organization (Burnell et al., 2004) while this is more significant for organizations that plan and prepare for emergencies and crisis response situations (Kostman, 2004), such as municipalities.

Moreover, a crucial element in managing crises over time by an organization concerns the constantly increasing volume of available data and knowledge. In CM, stakeholders are facing an increasing number of data sources, including non-dedicated ones. Practices, tools and usages regarding knowledge management in crisis contexts are not appropriate to this situation anymore and must be adapted (Benaben et al., 2016). Initiating suitable knowledge strategies and implementing a knowledge management system is the best way of overcoming this challenge. It seems more important when we find that CM is always performed by various types of stakeholders (to support all the involved multi-dimensional treatment actions), engaged in collaborative networks, inside or outside of an organization (Benaben et al., 2016). The use of collaborative networks regarding to the process of acquiring, sharing, and storing their knowledge is necessarily complex and also complicated for the managers.

Jennex and Raman (2009) investigate the role and relevance of knowledge management (and knowledge management systems therein) in support of crisis response. They present why crisis response efforts within an organizational context, might benefit from knowledge management initiatives and provide specific examples of how knowledge management efforts have supported crisis response in the past.

Shaw et al. (2007) found that the response to the crisis was to recognise the importance of the people and their knowledge to the organisation, and to build a strategy which employs all knowledge workers in the process of managing crises.

Their paper determines the importance of building a knowledge management strategy during times of crisis and draws out important lessons for organisations facing crisis.

In their book, Shankar and her colleagues (2008) criticized the traditional knowledge management process and tools, and suggested technology-based knowledge management. They believe that while traditional knowledge management techniques are being employed in government agencies responsible for disaster management, but many new technologies and practices, particularly the Internet and Web 2.0, are providing opportunities for individuals, responders, and trainers to share what they know and to acquire needed information, and prepare for the next crisis. They discuss that “although the Internet is already in extensive use in disaster management, knowledge management will only be effected if top-down and bottoms-up approaches to information gathering, organization, and dissemination are implemented”.

In regard to published related research works, despite the contributions of these CM studies, very limited research has been explicitly investigated the requirements of implementing KM strategies and system in CM perspective. In order to fill this gap, the following model of identifying KMS requirements will be designed and presented.

3 Identifying the requirements of implementing KM system in CM

In order to identify the requirements of KMS for supporting managers in CM, the following preconditions are assumed and obtained:

1. We reviewed all published related research works which can be helpful in recognizing different elements and process of CM or KM. The results show that Benaben et al. (2016) metamodel can be used in this study because of its comprehensiveness however, it is not empirically tested.
2. We reviewed all accessible reports published by organizations during or after crisis. Some of them were helpful as they implied the process of KM in the crisis time.
3. We further looked forward an empirical way to extract the KMS requirements, in a way that ensures managers to implement these requirements as well as the KMS. We finally concluded that interviews with the group of experts, in both KM and CM can be the best way.
4. For interviews with a group of experts (focus group), we consider municipality as an organization which confronts with various external and internal crises. To better understanding the elements and requirements of KMS, the natural crises such as earthquakes, floods, wildfires or typhons which involve different stakeholders such as government, NGOs, Red Crescent and citizens seem more useful.
5. Therefore, we recognized a group of experts (focus group) in a municipality of Chabahar (at the south of Iran), who had been faced with the latest annually floods in Balouchestan, Iran.

Chabahar is a free-port and free-trade-zone which recognized as the Iran's southernmost city. Due to its free trade zone status, the city has increased in significance in international trade. In the past years, this city has known as a strategic zone as it is Iran's closest and best access point to the Indian Ocean. Because of Chinese and Indians investment in this city's urban and marine infrastructure, this is the only city of Iran which is except from US sanctions (Haghani and Gharibpour, 2018).

While this city is developing in various aspects (financial, economic, marine, trade, industrial) its wild and unique nature causes natural disaster in each year which require a knowledge-based crises management to decrease financial and human losses. Floods and drought are at the top of them. Floods and drought are often two sides of the same coin. In certain places, they damage soil, watersystems and ecosystems in repeating cycles that exacerbate each other's impact. In Chabahar, during the dry season, any rain passes straight through what are often degraded soils, leaving crops to wither in the sun. Instead, farmers, firms and factories rely on wells that tap underground reservoirs (Haghani and Gharibpour, 2018). But this resource is quickly depleted because most monsoon rainfall runs uncontrollably off the land, without replenishing the underlying water. When flooding occurs, it is traditional to divert water away from inundated floodplains to protect people and reduce damage to homes, farms, businesses and infrastructure. But by

then, it is often already too late — and the following year the story will repeat itself (<http://SCIDEV.NET>).

Devastating floods in 2018, 2017, 2016 and 2015 affected more than 3.5 million people in Chabahar zone; leaving a lot of them in need of humanitarian assistance, more than 100 dead, and around 1500 injured. Across all affected areas, 5000 houses are destroyed, another 30,000 damaged.

The most disappointing point is repeating this deadly story without basic steps in managing these disasters over years. A knowledge management system provides a basis to manage them (Haghani and Gharibpour, 2018).

Regarding to new climate of Iran, these scientific works are more essential than any other times: during the past month (in March and April, 2019), Iran has been continuously hit by heavy rain that have led to flooding of almost all its 31 provinces, affecting more than 2,000 cities and villages.

Therefore, we selected this qualitative research methodology as it is suitable when the researcher investigates new field of study or intends to ascertain and theorize prominent issues.

Applying semi-structured, in-depth interviews assisted us to extract information through pre-set open-ended questions. Semi-structured, in-depth interviews are utilized extensively as interviewing format possibly with a group in designing new models or processes.

Recognizing focus group respondents was done through snowball sampling method. Snowball sampling is where research participants recruit other participants for a test or study.

Content analysis method is used to analyze the interviews. Content analysis is a research technique used to make replicable and valid inferences by interpreting and coding textual material.

4 Results

The following steps are presented as the results of content analysis of all interviews with 15-member- focus group. These steps are the main requirements of implementing KMS in a public organization like municipality to manage crisis with the support of KMS.

In these steps we assumed that an organization doesn't have a KMS as well as KM strategies.

First step: determine a crisis phase

- Each crisis has 5 phases which are: prevention, preparation, response, recovery, and learning).
- The feature of KMS is different regarding to each phase.

Second step: determine sensitive factors

- For each crisis phases, we have to identify some sensitive factors.
- Data and information will be extracted based on these sensitive factors in each phase.

- A group of experts are the best references of determining these factors.
- Third step: identify stakeholders
- In each phase of crisis, different stakeholders are playing roles. It is important to recognize all these stakeholders and their roles.
 - These stakeholders should be ranked regarding to their power and effect on crisis as well as their closeness and relation to the crisis.
- Forth step: data gathering
- Data should be gathered through all stakeholders regarding to their ranks.
 - Data should be categorized through its types and levels.
 - Data should be screened regarding to the sensitive factors.
- Fifth step: data verification
- All extracted selected data should be verified in this step.
 - The group of experts are the best source of verifying data.
 - Then data should be ranked to ensure better uses.
- Sixth step: data analysis
- Prepared data should be analysed in this step by KM expert.
 - The users of each data category should be determined.
 - All data and analysis process are done and stored in KM system.
- Seventh step: Knowledge management
- Knowledge should be acquired from prepared and stored data.
 - Knowledge should be stored in KM system.
 - Knowledge should be shared with all stakeholders by KM system.
 - Knowledge should be applied by all stakeholders.

This framework presents the requirements of implementing a KM system in organizations which are extracted from deep interviews. The results also indicate that all experts insisted on employing knowledge management system to better crisis management in the future years. This seven-step framework is necessary to be applied not only in Chabahar but in other city of Iran to decrease the effects of recent devastating floods which will be repeated because of climate changes.

Abstract

This paper addresses the topic of knowledge discovery from data in the context of Arts. In particular, the paper aims to examine the “distant listening” approach to uncover and interpret patterns and rules behind archaeology-inspired music. This approach employs quantitative data mining and graphical visualisation tools to identify and present discovered patterns in music data. For the purpose of the current study, a set of classical music pieces motivated by UNESCO-listed world heritage 'stecci' was collected and used as a source of arts data. The collected data were stored in a spreadsheet file and then analysed using Palladio software for network analysis and visualisation. The resulting relational graph enabled easy visual exploration of associations between stecci and musical forms and styles inspired by these archaeological artefacts. However, these findings need to be interpreted with caution due to present limitations. Further research is necessary that would replicate and extend current study to other contexts and questions.

Keywords –Knowledge Management, Knowledge Discovery from Data, Distant Listening, Arts, Classical Music

Paper type – Academic Research Paper

1 Introduction

The purpose of this paper is to address the topic of knowledge discovery from data in the context of Arts. With rapidly increasing quantities of arts data, there is a growing need for novel knowledge management (KM) methods and applications for analysing and presenting such big data. Knowledge discovery from data (KDD) is one such promising approach that involves the non-trivial process of identifying valid, novel, useful and understandable patterns in data (Fayyad et al., 1996). The uncovered patterns in the form of clusters, categories, associations or trends are usually described and presented in a visual mode understandable by humans. A plethora of data mining and visualisation tools are available to choose from for the purposes of knowledge discovery and presentation (Liu, 2018). Most recently, these have become an important part of a humanist's virtual knowledge space architecture (Handzic and Heuvel, 2018).

In the context of Arts, Moretti (2013) introduced the idea of KDD into literature under the term 'distant reading'. In this study, a similar 'distant listening' approach is suggested in the attempt to uncover the patterns and rules behind music. Essentially, the term 'distant listening' denotes the process of knowledge discovery from musical data using quantitative data mining and graphical visualisation tools.

The focus of the current study is on distant listening of classical music inspired by archaeology. The study was carried out in a specific context of Bosnia and Herzegovina. Arts data selected for the examination included classical music pieces motivated by UNESCO-listed world heritage 'stecci' (Nomination 1504, 2016).

The paper is structured as follows: after this brief introduction, section 2 reviews selected literature on relevant concepts (e.g. knowledge discovery, visualisation, archaeology in arts, stecci) and develops related objectives and research questions for the current study. Next, section 3 describes a case study methodology used for empirical examination. Then, section 4 presents a summary of the main findings, their implications for research and practice, current limitations and future research directions. The paper concludes with a brief summary and research contributions to the body of knowledge given in section 5.

2 Literature review

2.1 Knowledge discovery and visualisation

The growing number of digitised, as well as digitally born data is becoming an increasingly important source of new knowledge. Hence, one of the main KM issues is concerned with the discovery of knowledge that is 'hidden' in these data (Fayyad et al. 1996), and the utilisation of the extracted knowledge to support work-related activities. Two main goals of knowledge discovery include description and prediction. Whereas description is concerned with identifying patterns for the purpose of presenting them to users in an easy-to-understand form, prediction focuses on the patterns being 'mined' for the purpose of predicting future values for the variables in question.

Various data mining and knowledge discovery technologies can look for hidden patterns in groups of data to discover previously unknown trends or relationships. These applications often use complex and sophisticated algorithms to discover knowledge. In addition to trend and association analysis, clustering and classification, the current research efforts in these areas also include the use of intelligent agents (Blanning, 2000).

Making knowledge visible so that it can be better accessed, discussed, valued or generally managed is another long-standing objective in knowledge management (Eppler and Burkhard, 2007). Visualisation formats range from structured text and tables, through heuristic sketches, conceptual diagrams, visual metaphors, knowledge maps, to interactive visualisations and animations. Numerous digital tools have been developed applying different graphic means and advanced digital technologies. A list of some of the most popular general-purpose, as well as some special-purpose visualisation tools is maintained online by Liu (2018).

Eppler and Burkhard, (2007) suggest that for the effective creation and transfer of knowledge through visualisation, at least five questions should be considered with regard to knowledge visualisation: what (content), why (purpose), who (target group), where (context) and how (format). Findings from a summary of various application examples indicate the way different visualisation formats can be used to facilitate different KM tasks. Overall, these preliminary findings reveal that knowledge visualisations are particularly suited for knowledge creation and transfer.

2.2 Archaeology in Arts

Artists often find stimulation and subject matter in archaeological procedures, sites and artefacts. It is widely recognised that they can create new and enriched ways of perceiving material remains and provide new interpretive models for archaeologists to explain the past. In general, artists are considered as makers of new worlds and archaeologists as makers of past worlds. Russell and Cochrane (2014) argue that conversations and collaborations between these two groups (artists and archaeologists) are needed in order to encourage the creative interplay between different approaches and to contribute to our understanding of the world.

Lauzikas et al. (2018) note that archaeological and material cultural heritage enjoys a particular status in public as “the locus for the expression and negotiation of regional, national and intranational cultural identities, for public policy regarding the preservation and management of cultural resources, and for education, tourism, leisure and well-being”. Furthermore, Handzic and Carlucci (2019) claim that cultural knowledge rooted in heritage can be communicated through arts. While capturing artists’ imagination, heritage can become an instrument for conveying knowledge of the most important aspects of a specific culture.

2.3 Study objectives

In view of the above, of special interest to this study is KDD goal of description including identification and presentation of existing associations between archaeology and arts in a specific context of steci-inspired music.

Stecci ('standing stones') are monumental tombstones found in necropolises spread across the territory of the medieval Bosnian Kingdom. Today, there are over 3000 known necropolises with over 70 thousand tombstones. Out of these, 28 are listed on the UNESCO world heritage list (Nomination 1504, 2016). Contemporary Bosnian artists often engage with stecci (archaeological artefacts) in order to express their national cultural identity.

Therefore, the main objective of this exploratory study is to examine the potential of network analysis and graphical visualisation as KM tools to support discovery and interpretation of important and interesting relationships between stecci and music pieces inspired by these archaeological artefacts.

3 Research method

An exploratory case study (Yin, 2003) was selected as the most appropriate method for the current investigation due to the general lack of prior research on the issue of interest. In principle, a case study is recommended for answering "how" types of questions such as: how can knowledge discovery tools for network analysis and visualisation facilitate understanding of the musical knowledge domain under investigation.

For the purpose of the current study, a set of musical pieces motivated by UNESCO-listed world heritage 'stecci' (Nomination 1504, 2016) was collected and used as a source of arts data. Firstly, each piece, listed by its title, composer, genre and significant features was stored in a spreadsheet file for further quantitative analysis and visualisation. Then, network analysis with graphical presentation was applied, using a Palladio software tool developed by Stanford Humanities Center (2017), to enable visual exploration of existing associations between stecci monuments and musical forms and styles inspired by these archaeological artefacts.

4 Main findings

4.1 Summary of main findings

The analysis performed on collected data revealed an unexpected result that all music pieces under study were inspired by stecci only indirectly through the poetry of a famous Bosnian literary artist Mak Dizdar. Accordingly, related vocal compositions (with or without instruments) dominate the music space presented in Figure 1. These are followed by some instrumental and dramatic works. The figure also indicates Vojin Komadina as the most prolific and diverse composer.

Overall, these results recognise the crucial role of Dizdar's poetry in giving stecci 'stone sleepers' a voice and turning them into 'stone speakers' of national cultural identity. Their musical awakening is manifested in a variety of vocal, instrumental and dramatic works of Bosnian composers.

Generally, these composers communicate with Dizdar's poetry in two ways. In the first way, the composer creates music in order to enhance the particularly important poetic moments and layers in a poem. Such an approach is evident in vocal compositions by Vlado Milosevic, Vojin Komadina, Rada Nuic, Ramiz Tahiri, Teodor Romanic, Asim Horozic, and Ivan Cavlovic.

In the second way, a poem serves as an inspiration for the composition. Here, communication with poetic text goes beyond the basic to the imaginary layer of associative schemes (i.e. all that the work activates in the listener). Instrumental works by Vlado Milosevic and Vojin Komadina are good representatives of this approach. Both of them offer musical answers to Dizdar's poetry that recover lost memory and restore the sense of spatial and temporal belonging.

Figure 1: Results of network analysis and visualisation of music inspired by stecci

With respect to dramatic forms, 'kolo' (circle dance) serves as an inspiration for two choreographic works. In the case of musical theatre by Belma Beslic-Gal, Dizdar's poem is a starting conceptual moment for deconstruction. Her kolo is not a standard dance, but rather a magic circle in which she sees people living and which they cannot leave, except perhaps when they die. Furthermore, Dizdar's kolo is a textual foundation for a choreographic suite by Vojin Komadina. that represents an apotheosis of dance. In national mythology, the circle dance is believed to guide souls to another, everlasting world.

In summary, the applied KM initiatives (network analysis and graphical visualisation) enabled quick and easy creation of the wholistic picture of the music space under study and achievement of the learning outcomes described above.

4.2 Implications for research and practice

This study makes two important contributions to research: (i) it opens up a new line of interdisciplinary research that should benefit both KM and the Arts; and (ii) it provides preliminary empirical evidence of the value of such collaboration in a specific musical context.

With respect to the first point Handzic (2017) of argument for the field of KM to survive and grow, it needs to expand its realm. Humanities offer an interesting new context for such expansion. This has been recognised by some scholars and a number of so-called “digital” humanities projects have been initiated worldwide (Handzic and Heuvel, 2018).

With respect to point 2, in the specific case of archaeology-inspired music, the study showed how KM initiatives, such as network analysis and graphical visualisation could help to create a 'big picture' of the examined knowledge domain, provide insight and improve its understanding. In addition to such generic value, the identified specific relationships between stecci and classical music could serve as an indicator of the enduring Bosnian cultural identity.

For practice, the study implies that the increased scale of big arts data may offer new and exciting possibilities and challenges for KM practice in the Arts. Thus, KM may change the way musicologists and other arts scholars interact with their data and share their insights. Essentially, the study suggests that the network analysis and graphical visuals work well together to reveal important relationships.

4.3 Limitations and future directions

However, these implications should be considered in light of the current methodological and contextual limitations. Thus, the applied network analysis and visualisation tool was subjectively selected by the researcher. Other tools of varying levels of functionality and usability could provide different levels of support. Furthermore, a sample of classical music pieces for the study was small. A larger sample size and other music genres could have provided a wider variety of findings. Finally, the study was conducted in the context of Bosnia and Herzegovina, so the question arises if current results would hold in other communities.

These limitations of the current research can be addressed by further study replications and methodological triangulation of research with different tools in order to verify and generalise current findings. In addition, future research may extend current study to other contexts and research questions of common interest to the field of knowledge management and different arts disciplines.

5 Conclusions

This paper pushes KM research beyond the traditional organisational settings into the realm of Arts. Following the suggested need for KM expansion (Handzic 2017), the current study showed that Arts could offer an interesting new context for such development.

In summary, the preliminary study findings provided empirical evidence of the value of collaboration between KM and Arts in a specific musical context. Specifically, they showed how network analysis and graphical visualisation could facilitate user exploration of the relationships between stecci and music pieces inspired by these monuments.

Overall, these findings imply that KM technology has the potential to change the way Arts scholars interact with their data and share their insights. On the other hand, the increasing availability of digital arts data may offer KM professionals an opportunity to develop new methods and applications in order to deal effectively with the challenges of analysing and presenting such data.

However, these conclusions need to be interpreted with caution due to a number of limiting contextual and methodological factors. Future research is recommended to address these limitations and extend current research to other KM initiatives and their applications in other Arts disciplines.

Abstract

This manuscript investigates how Business Analytics (BA) may be practically exploited within the Knowledge Management process or activities to improve decision making. In particular, we developed a case study within a European private hospital in which we applied Process Mining – an emerging type of BA – to a six-month event dataset of the emergency department hip fracture diagnosis process for identifying delays linked to knowledge sharing issues. The evidences showed that, in over one case out of three, knowledge-sharing-related issues hindered the hospital in complying with the emergency department time targets and led to inefficient decision making. Hence, we proposed two preliminary solutions that may cope with such issues and that might decrease the patient's Length of Stay and reduce the corresponding costs.

Keywords – Knowledge sharing; healthcare; process mining; business analytics.

Paper type – Academic Research Paper

1 Introduction

Process Mining (PM) is a kind of business analytics for business process diagnosis and enhancement (van der Aalst, 2016) that can be exploited within the Big Data (BD) environment too (Maldonado-Mahauad *et al.*, 2018). With this aim, PM encompasses a set of techniques for the semi-automatic analysis of event data extracted the event logs

largely available in today's Information Systems (ISs). Probing event data through PM allows to model the actual behaviour of an IS-supported business process, to check its conformance against a reference model, or to analyse its performances from different perspectives.

PM has been framed within the process-oriented Knowledge Management (KM) scope to evaluate the knowledge-based business processes and to probe their evolution (Jung, Choi and Song, 2007). Nonetheless, the scientific literature has not deepened how analytics, such as PM, may be practically applied within KM process or activities. More in particular, Pauleen and Wang (2017) have called for more research investigating how KM may operationally use analytics to improve decision making.

Accordingly, this paper aims at answering this call. In so doing, we developed a case study in which we exploited PM to enable a more efficient (*i.e.* faster) Knowledge Sharing (KS) in a European private hospital. We chose the healthcare environment because it is knowledge-intensive (Di Ciccio, Marrella and Russo, 2015) and complex, *i.e.* it is characterized by: (I) autonomous and opinionated people that modify their behaviour to improve outcomes related to their own perspective and objective; (II) interconnected practices, processes, and behaviours; and (III) behaviours and activities that continually change and evolve over time (Antonacci *et al.*, 2018; Glouberman and Mintzberg, 2001; Reed *et al.*, 2018). In such an environment, a more punctual sharing of the medical knowledge (*e.g.* the content of the Electronic Medical Records – EMRs) is of utmost importance because it can affect the overall management efficiency in making decisions (*cf.* O'Malley, Grossman, Cohen, Kemper, & Pham, 2010).

In detail, we applied PM to one year of event data, extracted from the Emergency Department (ED) Information System, concerning the diagnosis and treatment process of patients affected by hip fracture – a very challenging clinical process involving different medical specialties. These analyses were conducted through Disco[®], a commercial PM tool. In a first phase, we discovered the control flow in the ED Information System, *i.e.* the actual sequence of activities belonging to the executed process. In a second phase, we enriched the control flow with time and frequency performances extracted from the event log. In the third phase, we analysed these results with the support from the Emergency Department (ED) staff to identify those process weaknesses related to a low-efficient KS.

The results highlighted some process issues (*e.g.* excessive waiting time before receiving the outcome about the diagnosis) due to inefficiencies in the EMRs sharing. Hence, we proposed a set of solutions to tackle the KS inefficiencies, for instance the automatic submission of the X-ray diagnosis from the Rx unit to the orthopaedist once the medical examination has finished. These knowledge-sharing-related solutions may enable a better decision-making on two different levels. First, they may permit faster diagnosis & treatment cycles, which may positively impact on patient care and satisfaction. Second, they may lead to the reengineering of the information flow within the process according to more objective, data-driven evidences.

The remainder of this manuscript is structured as follows: Section 2 details the research design; Section 3 outlines the results, which are discussed in Section 4; finally, Section 5 presents the conclusions.

2 Research Design

The research design relied on a case study developed in a mid-sized European private hospital. According to the roadmap by Yin (2013), we designed and developed a descriptive case study for (I) gathering the data needed to investigate the KS dynamics, (II) collecting the event data for the PM application, and (III) involving the hospital staff in interpreting the findings. This methodology fits our research purposes because they did not require any control over the behavioral events while focusing on contemporary events (Yin, 2013). Furthermore, it is consistent with the need to collect domain knowledge when harnessing business analytics (Waller and Fawcett, 2013). The case design was *single-case* because its descriptive nature did not require any replication or analytic generalization. The rationale of the single case was the *common case* for capturing "*the circumstances and conditions of an everyday situation*" (Yin, 2013, p. 52).

Among the business processes managed within the hospital, we focused on the hip fracture diagnosis & treatment because it is a process for which time-related KS activities may strongly affect the overall time performance. Indeed, it is not by chance that national and international clinical guidelines suggesting target thresholds for time performance process indicators have been developed (Mainz, 2003; Donabedian 1966, 1988), and PM may enable improvements in such time performances. We focused on the ED diagnosis aspect of the process because, in the ED, KS efficiency is felt as an urgent issue since it is often required for rapid decision making.

Within the ED hip fracture diagnosis activities, we applied PM as it allows to define the process flows executed by the ED Information System and to quantify the time performances of the related information exchange (Mans, van der Aalst, and Vanwersch 2015). Based on the PM evidences, which steered the identification of the KS inefficiencies, we proposed two solutions for fixing the detected issues.

In the following sections, we detail the case study (2.1) and the PM application (2.2).

2.1 The case study

The European private hospital which the case study was developed in can host up to 1000 patients across 28 departments and it provides over 4000 different diagnostic and therapeutic services. In the last years, on average, it has registered almost 60,000 hospitalizations and 1.5 million outpatient treatments. Since the first half of nineties, the hospital has established research relationships with different universities and it has been officially recognized as a research institute by the National Health Authority. Encouraged by the remarkable performance, in 2012 the top management approved a long-term development plan that is still on-going. Currently, this plan is focusing on the further digitalization of care processes, particularly those concerning the Emergency, Cardiology, and Orthopaedics departments, and on innovative treatments for genetic diseases.

The hospital IS architecture includes several Health Information Systems (HISs) that support the main health care processes. The most specialized departments are backed up by ad hoc information systems that manage the corresponding EMR flows. In particular, the ED Information System interacts with several other HISs because its health care services are heterogeneous. Yet, currently, the ED Information System lacks complete integration with the other ISs and this hampers the inter-departmental data and knowledge sharing activities.

According to the international guidelines previously cited, the hospital defined specific time thresholds for completing the diagnosis activities concerning the hip fracture cases. In detail, the related Lab Tests should not overrun 60 mins, while the X-ray activities should not require more than 90 mins. These thresholds were considered as a reference for the interpretation of the findings from the PM application, which is detailed in the following section.

2.2 The Process Mining application

The PM application was structured into three sequential phases:

- **Data collection and preparation.** The event data concerning the hip fracture diagnosis process, collected from the ED IS, were extracted and pre-processed. The collected data regarded the registration of six months of activities performed by the ED staff. Incomplete data were removed, leading to an 82-patient dataset.
- **Process discovery.** By leveraging the event dataset, we applied PM to discover the process flow (*i.e.*, the actual business blueprint) of the process under investigation. The discovery activity was performed through Disco[®], a widespread PM tool (van der Aalst 2016). Since the dataset included the timestamp of all the events, we were able to evaluate the time performance of each activity and of each information exchange involved into the process.
- **Process analysis.** Among the 82 cases, we identified the most relevant delays in the information exchange involved in the process. The relevance of the delays was evaluated against the targets, set by the hospital, for such exchanges. The detected delays were discussed together with the ED staff and the top management of the hospital to further probe their nature and the events that likely caused such deviations. Two main causes were identified, and a solution for both of them was suggested. The feasibility of the proposed solutions was evaluated along with the case respondents and a possible intervention was then formulated.

3 Results

Figure 1 depicts the discovered ED flow of the hip fracture patients. The boxes specify the activities, which are linked to each other by arrows representing the transition from an activity to the following one. The numbers detail the case frequency, *i.e.* the number of occurrences out of the 82 cases. The more an arrow is thick and the more a box is dark, the more their case frequency is high. The overall mean and median Length of

Stay (LoS) are 2.7 h and 1.78 h, respectively. Table 1 describes the activities of the analysed process.

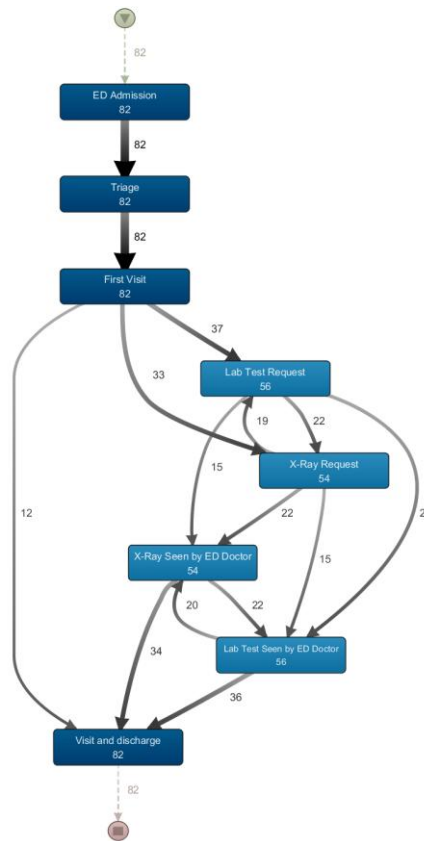

Figure 1. The discovered process blueprint of the hip fracture diagnosis process

Table 1. The activities of the analysed process

Activity	Description
ED Admission	Admission of a patient to the ED;
Triage	First evaluation of the patient severity by the nurse staff for determining the priority of the treatments;
First Visit	First medical visit of the ED patient by the ED staff;
Lab Test Request	Request of blood test(s) by the ED physician to the laboratory to deepen the patient's health condition;
X-Ray Request	Request of X-ray exam(s) by the ED physician to the radiology department to investigate the potential hip fracture;
Lab Test Seen by ED Doctor	Reading of the lab test results by the ED physician;
X-Ray Seen by ED Doctor	Reading of the X-ray results by the ED physician;
Visit and Discharge	Discharge of the ED patient after an additional visit, if needed; the patient can be discharged at home or admitted to the hospital.

Twelve cases skipped both X-ray and lab tests, as the corresponding patients were discharged from the ED after the first visit.

The arrows that link *Lab Test Request*, *X-Ray Request*, *Lab Test Seen by ED doctor*, and *X-Ray Seen by ED Doctor* highlight specific process flows that may appear to be misleading, *e.g.* from *Lab Test Request* to *X-Ray Seen by the ED Doctor*. The reason is that both x-ray and lab test activities are usually requested and executed in parallel. Hence, every sequence among the four above-mentioned activities is legit, as long as the requests precede the reading of the results.

Figure 2 outlines the process flow enriched with the time performances and is divided into two parts. The left side focuses on the lab test activities, while the right one concerns the x-ray activities. These activities were analysed separately for singling out the time impact they may exert on the overall time performance. Near each arch, we indicated both the mean and the median time. Such a time is an idle time between two consecutive activities.

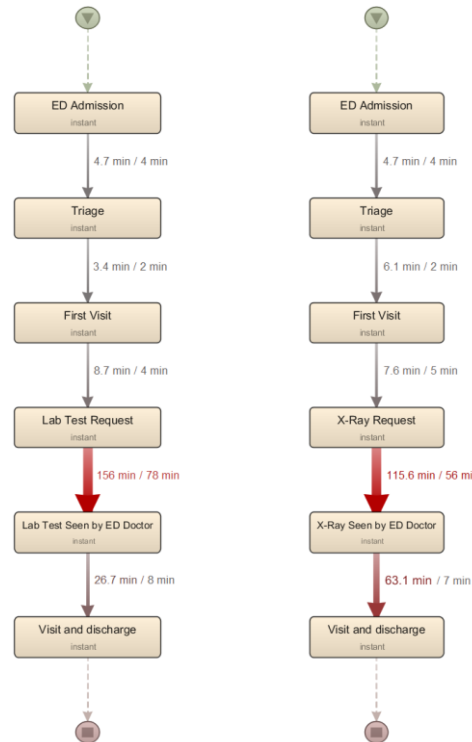

Figure 2. The Lab Test and X-Ray process blueprints enriched with the time performances

According to the evidences, a lab test was needed in 56 cases, while an X-ray analysis was requested in 51 cases. Figures 3 and 4 show the case distribution for the groups of activities: 35 lab test activities overrun the 60 mins threshold, while 31 X-ray activities exceeded the 90 mins threshold. The next section focuses on these cases and on figuring out the causes related to these delays.

Figure 3. Time distribution of the Lab Test activities

Figure 4. Time distribution of the X-Ray activities

4 Discussion

According to the hospital policies, 43% of the 82 cases showed a delay in the lab test activities, while 38% in the x-ray activities. Moreover, over 50% of the cases including lab test or X-ray overrun the time threshold. The discussion with the ED staff allowed to identify two causes for such delays, besides the physiological queue that may occur in the ED:

1. *Lack of integration.* The ED Information System (IS) exchanges information with the Radiology IS (RIS) and with the Laboratory IS (LIS), but this sharing requires a direct human intervention and, thus, it may be characterized by latency. In particular, the ED IS is not able to fetch the medical reports from the RIS and the LIS until their submission by the corresponding staff. Hence, although the medical reports are available, they may not be accessible by the ED physicians. This lack of integration may be due to two reasons: (I) the three ISs were designed and developed separately and in different points in time; and (II) no interventions for coping with this issue were performed because the top

management has privileged other strategic directions, *e.g.* pursuing healthcare-research-related objectives.

2. *Delayed reading of the medical reports.* Even when the RIS and the LIS submit the reports to the ED IS, delays in consulting the attained information may occur because of two reasons: (I) the ED physician may be busy in more urgent tasks, *e.g.* arrival of a critical patient, or (II) s/he may be unaware of the availability of the reports within the ED IS. While the occurrence of the first case may be unavoidable within an ED, the second one relates to inefficient KS.

These two causes for delay may increase the LoS and may be strongly detrimental to the ED decision making. In the following, we report three real-life examples, suggested by the ED staff involved in the case, about how the inefficient KS led to poor decisions.

- The ED physician requested a lab test, which was executed in time (45 min). The lab staff delayed the submission of the medical report to the ED IS because it was busy with concurrent analyses requested from other departments. The ED physician waited almost 260 min, forcing the patient to remain in the ED and constraining another older patient into the waiting room due to lack of gurneys.
- The ED was overcrowded, in particular due to a multiple car accident that involved four people. All of them accessed the ED and two of them had an alleged hip fracture. The ED physician requested two X-ray exams, whose medical report was available to the ED IS after 75 min. Yet, the physician intervened multiple times to calm down the relatives of the patients. These repeated interruptions led him to forget to check for the availability of the medical reports. Involved by the management of the emergency, he checked for them after additional 40 min, deferring the admission to the hospital of the two patients.
- A patient accessed the ED because of an alleged fracture to both left arm and left-side of the hip. The ED physician requests two X-ray exams – one for each limb. The report about the arm fracture was submitted to the ED IS after 50 min, while the one regarding the leg was not available yet. The physician understood that the arm was actually fractured but waited for the second report before intervening. The second report was available in the RIS 60 min after the request, but it was not submitted to the ED IS. The ED physician called the radiology department multiple times for soliciting the procedure, but she received the report only after 50 additional minutes. In the meanwhile, it was needed to hand out painkillers to the patient.

According to the evidences and to the provided examples, we suggest two feasible, potential solutions that may cope with the two above-mentioned criticalities. First, it is necessary to grant integration among the three involved ISs to reduce the information latency. With this aim, two interventions may be planned. On one side, the Information Technology infrastructure of the hospital may be provided with a specific middleware solution (Hsieh et al. 2007; Almadani, Saeed, and Alroubaïy 2016) that may achieve integration via software. On the other side, the IS architecture may be reengineered to develop a single platform with a unified database that may ensure both uniqueness of the

information and the absence of latency in its sharing. Sounder IS integration may foster the data gathering and collection for systematic, analytics-based process analyses, since health event data are typically scattered across different databases.

Second, the ED IS should offer a functionality that alerts the ED staff about the reception of a new medical report. In this way, the ED physician may immediately realise that the outcome from a lab test or an X-ray activity is ready to be evaluated within the diagnosis and treatment processes.

The two proposed preliminary solutions may help in handling the KS latency issue. Also, based on the three real-life examples we reported, they may affect the ED decision making efficiency and, thus, the LoS and the ED resource management.

5 Conclusions

Today, *Business analytics* is a recurring label for defining a wide variety of data-intensive tools which a company can benefit from in terms of advanced decision making. Nonetheless, their practical exploitation within a structured, knowledge-based process has rarely been object of investigation. Through a case study developed in a European private hospital, we applied a PM-based approach to figure out how the business analytics may be leveraged to detect KS issues in the hip fracture diagnosis process and to propose a draft of pertinent solutions. This quali-quantitative approach highlighted the following findings:

- Time and frequency performances of the ED activities regarding the hip fracture diagnosis;
- The main time bottlenecks of the process;
- The cases in which the time thresholds set by the hospital were violated.

By consulting the staff involved in the case study, we found that the evidences are strongly related to inefficient KS between the ED and both the radiology and the analysis laboratory. This inefficiency led to poor decision making, resulting in additional delays (longer LoS), worsening the ED performance and making the hospital missing its ED time targets. In line with the findings, we proposed two preliminary solutions for coping with the detected KS issues.

Thus, this paper answers the call by Pauleen and Wang (2017) about deepening how business analytics, *e.g.* PM, may be exploited for supporting the KM process and for improving knowledge-based decision making. In addition, it enriches the PM literature with evidences from a process enhancement perspective that, in healthcare, is rather low explored when compared to other PM approaches (Rojas *et al.*, 2016).

In so doing, from a health managerial perspective, it proposes a draft of solutions that potentially link a more efficient KS to a more punctual decision making on both a business process and patient care standpoint. Thus, leveraging the analytics-driven improvements in the business processes, it may cope with the current increasing costs affecting healthcare sector (Mans, van der Aalst and Vanwersch, 2015). The latter aspect is quite topical as, in the today's competitive health-care market, hospitals have to focus on ways to streamline their processes to deliver high quality health-care while, at the

same time, reducing costs (Anyanwu et al, 2003). Therefore, the sharing of knowledge among interfaces across different highly specialized organizational units and the implementation of process-oriented management practices becomes a great challenge which can give a valuable contribution to the improvement of the process of care (Lenz and Reichert, 2007).

Yet, this work is not free from limitations. First, our investigation is limited to the ED diagnosis of hip fractures, without involving the main treatment activities. Hence, we were not able to identify and to assess the impact of the KS issues on the whole hip fracture management process. Second, we focused on KS, which is only a portion of the entire KM process (*cf.* Zerbino et al., 2018). Consequently, we did not investigate how the business analytics may be practically used to support all the KM development.

Further developments of this work are strongly rooted into these limitations. In particular, we aim at extending our inquiry to the complete hip fracture diagnosis & treatment process, based on a richer event dataset. Furthermore, we intend to probe the feasibility of the proposed solutions and to practically evaluate their impact on the compliance with the ED time targets.

Abstract

In recent years, the widespread adoption of Hospital Information Systems is enabling hospitals to measure and record an ever-growing volume and variety of patient and process-related data. In such context, analytics are emerging as suitable tools and methods for extracting and analyzing such data and for providing useful insights to assist decision-making. The Emergency Department (ED) is one of the functional areas that could profit from the implementation of such tools and methods. However, the complex and dynamic nature of EDs makes the application of analytics a very challenging task which is attracting increasing attention from both academic researchers and practitioners. This work represents a first attempt to demonstrate the suitability of predictive analytics in ED environment. Specifically, we aim at developing a multi-level classification model to predict patients' length of stay (LOS), by exploiting historical information about ED patients and the advanced machine learning techniques. Given the

high variability affecting patient LOS, we determined a set of candidate predictors from the data, including patients' characteristics, temporal factors and, system-based factors (e.g., the system workload, the abandon rate and the probability of treatments' execution like radiology, laboratory and consultancy). Preliminary results show that the multi-level model achieves promising values of accuracy, outperforming the single-level classification model. It allows the early identification of patients likely to experience a long LOS in ED. Such patients may require a dedicated monitoring by ED service providers who should take appropriate actions to shorten their stays. Accordingly, predicting LOS can help ED management to dynamically monitor the crowding level of the system and make informed decisions about resource allocation.

Keywords – Data Mining, Predictive Analytics, LOS, Emergency Department, Healthcare Management

Paper type – Academic Research Paper

1 Introduction

In the last decades, while EDs were declining in number due to restrictive cost-containment policies, the demand for emergency services increased, because of the ageing of the population (Hoot and Aronsky, 2008; Arkun et al., 2010). The combined effects of these trends have dramatically increased the number of patients inside EDs at any hour of the day, leading to overcrowding situations (ACEP, 2016). Therefore, the ability of EDs to deliver a timely and efficient care is far too often hampered by lack of capacity due to overcrowding and boarding (ACEP, 2016). Consequences of ED overcrowding include increased waiting time, delayed treatment before admission to hospital or discharge, ambulance diversion, etc. (Khalifa and Zabani, 2016). In addition, overcrowding and delays in services may have unpleasant consequences for the ED staff, increasing the risk of human errors and the burnout level.

Thanks to the pervasive adoption of information systems (e.g., Electronic Medical Records (EMR)) within healthcare organizations, it is possible to access to an unprecedented amount of patient and process-related data (Fu et al., 2016). In such context, analytics are emerging as suitable tools and techniques for extracting and analyzing such data and for providing useful insights to assist decision-making (Islam et al., 2018). Accordingly, decision tools based on analytics can provide actionable information without excessive resource expenditure, helping to limit otherwise wasteful spending that may stem from diagnostic and prognostic uncertainty (Janke et al., 2016).

Nevertheless, healthcare sector is lagging other industries in the application of analytics (Bates et al., 2014). This is probably due to the privacy regulations which add a layer of complexity and, the lack of tools and training for healthcare providers to effectively and responsibly use big data for analytics. Furthermore, the quality of the collected data may be the most important rate-limiting factor in big data applications because even the most sophisticated statistical techniques cannot overcome the consequences of error-filled data (Janke et al., 2016).

The ‘always open’ and ‘ready for any eventuality’ nature of EDs makes the application of analytics a very challenging task which is attracting increasing attention from both academic researchers and practitioners. Predictive analytics are very promising tools to improve ED operations even if their potential is not yet completely exploited (Islam et al., 2018). Indeed, literature lacks studies that try to exploit analytics in the ED context. This is mainly due to the inherent complex nature of the ED.

This work represents a first attempt to demonstrate the suitability of predictive analytics in ED environment. Specifically, in this work, we aim at developing a multi-level classification model to predict patients’ length of stay (LOS), by exploiting historical information about ED patients and the advanced machine learning techniques. In so doing, the model allows the early identification of patients likely to experience a long LOS in ED. Such patients may require a dedicated monitoring by ED service providers who should take appropriate actions to shorten their stays. Accordingly, predicting LOS can help ED management to dynamically monitor the crowding level of the system and make informed decisions about resource allocation.

2 Background

Analytics include the use of mathematical and algorithmic methods for data processing, as well as the use of techniques, such as text mining, natural language processing, and visual analytics to analyze and derive insight from data (Simpao et al., 2014). Three main types of analytics exist: descriptive (i.e., exploration and discovery of information in the dataset), predictive (i.e., prediction of upcoming events based on historical data) and prescriptive (i.e., utilization of scenarios to provide decision support). Descriptive analytics are the most widely used in healthcare (48%), but predictive and prescriptive analytics have a great unexploited potential (Islam et al., 2018).

In healthcare literature, there are several analytics applications, whose can be grouped in two main categories: clinical and operational, as shown in Figure 1 (Fu et al., 2016; Islam et al., 2018). The former refers to the exploitation of medical dataset to derive prognostic and diagnostic decision support tools. These tools help physicians and nurses to make more effective decisions about disease’ treatment, improve patients monitoring and prevent medication errors (Wang et al., 2017). The latter relates to the use of analytics to support healthcare service providers’ daily operations, improve the operational flexibility and throughput quality of hospital services, reduce costs and readmission rate (Janke et al., 2016). Specifically, most of applications in the operational category involve the prediction of time - e.g., waiting time (Ang et al., 2015) and length of stay (LOS) (Hachesu et al., 2013) - and of future adverse events – e.g., hospital admissions (Billings et al., 2013), hospital readmissions (Kartoun et al., 2015), ED visits (Zhou et al., 2015), critical events in intensive care unit (Bhattacharya et al., 2014), mortality (Kortoun et al., 2016), etc.-.

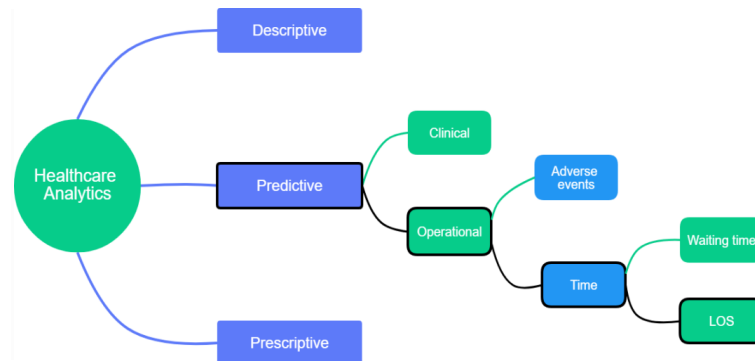

Figure 1: Healthcare Analytics Applications

Given the aim of our work, here following we reviewed the literature related to the prediction of patient LOS. The majority of works exploit predictive analytics techniques to provide an accurate forecast of hospital LOS, by using patient characteristics as main predictors. For example, Hachesu et al. (2013) applied classification algorithms (i.e., neural network, decision tree and support vector machine) to extract useful knowledge and draw an accurate model to predict the LOS of heart disease patients. Li et al. (2013) used a back-propagation neural network to predict hospital LOS. Panchami and Radhika (2014) proposed a novel approach for predicting whether the LOS of hospitalized patients is greater than one week. Their approach identified groups of similar hospital claims from the dataset utilizing a density-based clustering approach called DBSCAN. Livieris et al. (2018) proposed semi-supervised methods to predict the LOS of hospitalized patients, using demographic, clinical, and geographical factors which can be assessed at the time of admission of patients.

Currently, only few papers exist focusing on predicting patient LOS in ED. For example, Wrenn et al. (2005) developed and validated an artificial neural network using clinical and operational parameters that are commonly available during an encounter. Gul and Guneri (2015) presented an ED LOS forecasting model using artificial neural networks. They collected data of 1500 ED patients and identified several predictive variables such as gender, mode of arrival, on-call physician, treatment area and number of tests. The use of predictive analytics in the ED environment seems to be an unexplored field, valuable to investigate.

3 Research Methodology

The research methodology is organized into four main phases: data collection and preparation, data exploration and process discovery, features engineering, model implementation and evaluation.

3.1 Data collection and preparation

We collected data of all patients who presented to the ED of an Italian hospital from February to August 2017. Data was mostly gathered from the ED Information Systems. The initial event log consisted of 36'504 patient cases and more than 453'000 events. Data cleaning and pre-processing involved the removal of repeated records, irregularities, and irrelevancies, and the manipulation of records with missing value and outlier data. The refined dataset included 34'862 patient cases.

3.2 Data exploration and Process Discovery

We analyzed the correlation between the target variable *LOS*, i.e., the time between the arrival of the patient and his discharge, and the patients' characteristics extracted from the dataset (e.g., age, triage code, main complaint), in order to gain useful insights for features extraction. In addition, the dataset was analyzed from a process perspective using the Process Mining approach. Process Mining is able to discover, monitor and analyze real processes by extracting knowledge from event logs (Van der Aalst, 2016). By undertaking Process Mining, we discovered the entire patient-flow and derived information about the current state of the ED (e.g., system workload per hour, number of events occurred from triage to discharge etc.).

3.3 Features Engineering

Starting from the outcome of the previous step, a set of 17 features was developed (see Table 1). The first three features are related to patient's information, including age, arrival mode and main complaint. The temporal features, i.e., *day of the week* and *hour of the day*, consider the moment when the patient arrives to ED. The remaining variables were retrieved from the process discovery. For each triage code, the *Workload per triage code* counts the number of patients between triage and discharge, while the *NYT with priority* the number of patients with higher priority who are waiting for the first treatment. *LWBS* and *Abandon* take into account the number of patients who leave the ED before and after the first visit. *Radiology*, *Laboratory* and *Consultancy* measure the probability of the corresponding exam to be executed by a patient based on his main complaint. Finally, the *Number of events* per patient considers the average number of events from triage to discharge according to the historical data about patients with the same pathology.

Table 1: Features

Category	Attribute	Values
Patient	Age	Min = 0 years, Max = 103 years
	Arrival mode	Autonomous, By ambulance
	Main complaint	25 different pathologies
Time	Day of the week	Mon, Tue, Wed, Thu, Fri, Sat, Sun
	Hour of the day	1-23
ED system	Workload per triage code	5 variables counting the number of patients between triage and exit
	NYT with priority	Count of patients waiting for the first treatment according to priority rules
	LWBS	Count of patients who left without being seen by a physician

Abandon	Count of patients who left after the first visit
Radiology	0-1
Laboratory	0-1
Consultancy	0-1
Number of events	Min = 6, Max = 19

3.4 Model Implementation and Evaluation

In this step, we followed the multi-level classification approach (Tampakas et al., 2014). It consists of a series of hierarchical binary classifications which enable to discriminate at each step the patients with potentially long LOS in ED. This approach allows to obtain a better performance than the single-classifier approach and to solve imbalanced data problems (Srinivas et al., 2015; Tampakas et al., 2014). Specifically, we built two multi-level classification models:

- **M1**, for green codes i.e., urgent patients with serious problems, but apparently stable condition;
- **M2**, for azure codes i.e., standard patients without danger or distress, and white codes i.e., non-urgent patients, whose conditions are not true accidents or emergencies. Azure and white codes were grouped into the same model due to the low number of examples in the dataset.

Yellow codes and red codes were not considered in the analysis because they correspond to very-urgent and life-threatening patients respectively, and thus their stay in ED may mainly depend on their critical health conditions.

The model classes were defined by the quartiles of LOS distribution (see table 2).

Table 2: Triage codes' quartiles

Triage Code	1 st quartile	2 nd quartile	3 rd quartile	Number of cases
Green	75'	130'	210'	19008
Azure+White	45'	90'	160'	5399

The multi-level classification approach is summarized here following (see Fig 2).

Figure 2: Multi-level classification

At first level, we classified patient LOS into two classes c1 and c2, according to the 3rd quartile. Then, at second level, the examples from class c1 were reclassified into two other classes c3 and c4, according to the 2nd quartile. Finally, at third level, we assigned the examples from class c3 to classes c5 or c6 in case of patient LOS above or below the 1st quartile respectively.

An ad-hoc program in Matlab environment was developed to run the two models M1 and M2. We used the k-nearest neighbors (k-NN) classification algorithm (Tan et al., 2006). We performed a stratified 5-fold cross validation to obtain more robust results. For each iteration of the validation process, we optimized the parameters of the k-NN algorithm. Specifically, we found the best value of k (i.e. the number of neighbors to consider) and the best choice of the distance measure (e.g. Euclidean, Jaccard, CityBlock).

To evaluate the performance of the proposed classification model, we considered four performance metrics. The first three are computed at each level of classification, while the last one is the overall accuracy of the model.

$$Accuracy = \frac{\text{number of examples correctly predicted in a single level}}{\text{total number of examples in that level}}$$

$$Precision = \frac{\text{number of examples correctly predicted in a class}}{\text{number of examples predicted in that class}}$$

$$Recall = \frac{\text{number of examples correctly predicted in a class}}{\text{number of examples of that class}}$$

$$Overall Accuracy = \frac{\text{number of examples correctly predicted}}{\text{total number of examples}}$$

4 Experimental Results

In this section we present the results of the proposed multi-level classification approach on the dataset of an Italian ED.

As shown in tables 3 and 4, the accuracy achieves the highest value in the first and third level of classification (77% and 74%). This means that the models seem to discriminate patients with the longest and the shortest LOS with higher accuracy than in the others. Moreover, precision and recall values increase from the first to the third level of the classification (tables 3 and 4). However, at first level, the recall value is quite low (13%). This means that the models may have strong issues capturing examples from the most critical class, i.e., patients with longest LOS. Nevertheless, the multilevel structure reassess these instances – incorrectly classified – in the next level where the recall index significantly increases for both models (up to 64%). In so doing the impact of the bias on the final classification is mitigated. Likewise, precision metric increases from level to level in both models, achieving a value of 75% at the 3rd level in both models.

Table 3: Green Code' Model performances

M1: Green Code Model				
	1st level (LOS>210')	2nd level (LOS >130')	3rd level (LOS>75')	Overall Accuracy
Accuracy	77%	65%	74%	68%
Precision	62.6%	64%	75%	
Recall	22%	68%	97%	

Table 4: Azure and White Codes' Model performances

M2: Azure+White Code Model				
	1st level (LOS>160')	2nd level (LOS >90')	3rd level (LOS>45')	Overall Accuracy
Accuracy	77%	62%	74%	67%
Precision	59%	61%	75%	
Recall	13%	64%	97%	

Finally, table 5 shows the results of the comparison between the performance of the proposed multi-level models and a single-level classification model with four classes. As shown in table 5, the accuracy of the multi-level classification model is almost double compared to the accuracy of the single-level model, in both cases.

Table 5: Performances Comparison between single-level and multi-level classification

	Single-level classification Accuracy	Multi-level classification Accuracy
Green Code	41%	68%
Azure +White Code	39%	67%

5 Discussion and Conclusions

In this work, we present a multi-level classification model for the prediction of patients' LOS in a real ED. The proposed model attempts to identify patients likely to experience a long LOS in ED. Such patients may require a dedicated monitoring by ED service providers who should take appropriate actions to shorten their stays. Thanks to the multi-level approach, at each step examples not correctly classified are reassessed in the next steps. Preliminary results show that the overall accuracy of the models is quite good with a value of 68% and 67% for green code and azure+white code respectively, compared to the case of a single-level classification model. Thus, it can be considered a first promising result given the high degree of variability that affects the ED. Further studies will be necessary to improve the models in order to capture such variability.

From a managerial point of view, an accurate prediction of patient LOS can support healthcare providers' in the monitoring and the early identification of patients likely to experience a long LOS in ED. Through an alert system, ED service providers could be warned of prolonged LOS for certain patients in ED and, thereby, they may take

appropriate actions to reduce their stay in ED. Furthermore, the proposed predictive model could be used as a reference model for offering customized assistance to patients according to the predicted LOS and for decision making in the resource allocation process.

Nevertheless, findings of this research have to be treated as preliminary and further test on different DBs and techniques are desirables.

As future work we aim at applying the proposed method on data from several EDs in order to extract useful information about key factors affecting patients' LOS. Another direction concerns the implementation of different learning algorithms for each level of the classification, such as decision trees and neural network to improve the overall accuracy of the model.

Abstract

Purpose – The tendency of supporting organizational decision-making has moved from traditional industries also to the private healthcare sector, becoming more and more essential, as requirements towards up-to-date and reliable information have increased. Business analytics tools can be considered as one of the solutions to satisfy the growing needs of supporting organizational data-driven decision-making. Also, one of the goals of business analytics is to understand and improve business processes, leading to enhanced performance of the organization. The aim of this paper is to study, how business analytics (BA) can support the future requirements of enhanced decision-making in the private healthcare in Finland. In addition, this paper provides valuable insight into the future of business analytics tools utilization in the private healthcare sector, furthermore discovering the potential for new business practices.

Design/methodology/approach – The research includes private healthcare organizations, BI-vendors and management consultants in Finland. In addition, one of leading Business Analytics tools vendors in Finland and in the world was chosen for the study. The empirical data was collected during 2017-2019. In total thirty nine thematic interviews of key-personnel responsible for BA were conducted, to gain understanding on the future potential of BA in the Finnish private healthcare industry.

Originality/value – Data-driven decision-making, operational excellence and seeking for new business opportunities are currently one of the most discussed topics when considering benefits of business analytics. This study is putting together the future potential of BA utilization in the private healthcare sector, both in decision-making and discovering new business opportunities. The suggested approach has significant novelty value in the context of a Finnish private healthcare. However, it is focusing primarily on the organizational aspect of BA utilization in the private healthcare in Finland, not including clinical data aspects.

Practical implications – There are two practical outcomes of this study. The first outcome will provide understanding on the role of the future BA utilization in the private healthcare sector in Finland. The second outcome of this research provides valuable insight into the data-driven decision-making and potential of new business practices, enabled by utilizing new analytics capabilities.

Keywords – Private healthcare, business analytics tools, decision-making, new business potential

Paper type – Academic Research Paper

1 Introduction

The nature of business has changed during the past years, as globalized business environment together with disruptions in the field of technology have enforced organizations to become more agile and innovative in the ways they respond to their customers demand (Aydiner et al. 2019). During the last decade amounts of data have expanded significantly, and therefore business intelligence (BI) and business analytics (BA) have become increasingly more important in organizations (Vidgren et al. 2017). Likewise the healthcare sector has been moving towards data-driven decision-making, because of growing amounts of operative business data, that is being generated and used to support the organisational or managerial decision-making process (Ratia and Myllärniemi 2017; Stewart et al. 2016; Raghupathi and Raghupathi 2014; Raghupathi 2010; Spruit et al. 2014; Grierson et al. 2015). However, the key challenge for organizations in BI and BA utilization is, how to leverage those capabilities to create business value (Vidgren et al. 2017).

However, private healthcare is not an exception, and the same needs of enhancing the understanding of business practices and related organizational data to enable better decisions and performance are being the same. (Ratia and Myllärniemi 2017; Ratia et al. 2017; Demirkan 2013). Even though, the interest of managers and executives towards BI and BA has grown, in order to be able to explore and utilize organizational data that is traditionally been siloed in various different operational systems, there is still a long way to business analytics ecosystem with a clear data and analytics strategy (Vidgren et al. 2017; Elbashir et al. 2013). Yet, is not completely and unequivocally clear for organizations, how BA improves decision-making process in practice (Cao et al. 2015). However, in addition to enhanced decision-making process, successful utilization of BA capabilities can create potential also for other kind of business value, such as new products and services (Ratia and Myllärniemi 2018).

This paper focuses on the BA and BA utilization in the private healthcare sector in Finland. The purpose of this study is to increase understanding role of BA in decision-making, also providing valuable insight into the potential of BA utilization in creating new products and services in the private healthcare sector. This study is putting together the requirements of enhanced decision-making in the private healthcare organizations. Although it is obvious, that BA benefits organizational decision-making process, it is still unclear what are the mechanisms behind (Seddon et al. 2017). Even though the role of BA in business is becoming more and more significant, the understanding of the business value created by BA is still quite limited (Krishnamoorthi and Mathew 2018). By analysing the future potential of the BA in the private healthcare industry sector decision-making process, the research brings a significant novel value for the private healthcare

sector companies, showing also the future potential of BA utilization. The practical outcome of this research will provide valuable information as well as deep understanding on the future potential enabled by BA and BA tools in the Finnish private healthcare sector companies.

In the second chapter the aim is to show a conceptual basis for BA and business analytics success model framework (Seddon et al. 2017). Chapter 3 presents empirical setting, introducing the methodology and empirical material. Chapter 4 is of showing the results of we present our results by answering to the interview themes, based on the BASM framework, that can also be applied to evaluate competitive advantage brought by BA process. Finally, in chapter 5, the conclusions and discussion conclude the paper.

2 The potential of business analytics in enhancing decision-making

2.1. The concept of business analytics

The concept of business analytics can be seen as a complex combination of several and various definitions and also being interchangeable or alternative also to business intelligence (BI) and as a part of information processing capabilities (e.g. Sun et al. 2016; Cao et al. 2015). The literature is identifying several approaches to BI or BA. It can be described as a unifying phrase or term, combining different tools, applications and methods or as a combination of a technological and process approach (Turban et al. 2008; Nykänen et al. 2016). Another definition of concept of BA is that it enables “the extensive use of data, statistical, and quantitative analysis, explanatory and predictive models, and fact-based management to drive decisions and actions” (e.g. Cao et al. 2015; Davenport and Harris 2007). It can be also noted, that BA and BA tools can be beneficial to organization by enhancing and improving business processes and performance as well as enabling creation of competitive advantages (e.g. Cosic et al. 2015; Davenport and Harris 2007; Kakhki and Palvia 2016). However, it is clear that BA is an emerging and fast-growing field, that can be considered to be disruptive technology and enabler of innovation, that can bring organizational decision-making to the next level (Sun et al. 2016; Cao et al. 2015).

In addition to interchangeable or alternative concepts of BA and BI, there are also several alike concepts, such as competitive intelligence, market intelligence, customer intelligence, competitor intelligence, strategic intelligence and data analytics, and it can be debatable, whether are being similar concepts or under the same umbrella concepts of BA and BI (e.g. Ratia and Myllärniemi 2018; Lönnqvist and Pirttimäki 2006). Furthermore, business analytics can also be identified as a process that is producing information and knowledge for the managers and executives as well as other decision-makers in the organization (e.g. Nykänen et al. 2016). However, BA and BI, being a selection of techniques, technologies, tools, practices and methods, can create deep understanding of business and market for organizations and support appropriate business decisions (e.g. Ratia and Myllärniemi 2018; Côte-Real et al. 2014; Nykänen et al. 2016). An extended concept of BA and BI can also include new methods and technologies, as

well as other related concepts, such as Big Data, machine learning (ML) and artificial intelligence (AI) (Ratia and Myllärniemi 2018; Trieu 2017). However, BA can also be seen as being an art of examining, accumulating and deduce conclusions out of available data (Sun et al. 2016).

Even though the concepts of BA and BI as well as the capabilities have been studied previously, it is still relatively unclear, what are the concrete elements of these concepts, that contribute to business value. However, recent researches show, that there is a connection between business intelligence or business analytics and organizational value creation process (e.g. Krishnamoorthi and Mathew 2018; Fink et al. 2017; Ratia et al. 2018; Ratia 2018). Business value can be generated by timely access to relevant information for decision-making support (Jinpon et al. 2011). Or by connecting different data types from different internal and external sources to be used efficiently in decision making (e.g. Ratia 2018; Wang et al. 2016; Wang et al. 2015).

2.2. Business analytics capabilities creating business value

To be able to follow the benefits of business analytics, executives and management has to have clear understanding of organizational BA capabilities that have influence on performance (Seddon et al. 2017). However, even though research considering BA capabilities is still scarce, it can still be said, that especially advanced analytics can be valuable in creating business value (Krishnamoorthi and Mathew 2018). More precisely, data science, predictive analytics and big data are seen to be increasingly important in business value creation (Vidgren et al. 2017; Waller and Fawcett 2013). However, operationally effective BA design and implementation of solution into practice can be very difficult and thus, true business value is also hard to generate (Nalchigar and Yu 2018). Even though practitioners identify BA and BI practices bringing competitive advantage, the literature does not identify common theoretical explanation or link (Torres et al. 2018).

One of the frameworks is BASM or business analytics success model, that can also be applied to evaluate competitive advantage brought by BA process (Seddon et al. 2017). The model consists of twenty different concepts presented in the below table 2.

Table 2. Concepts of the BASM process model (modified Seddon et al. 2017)

Concept	Explanation
Use analytic capabilities	Utilization of BA capabilities to analyze internal and/or external data to support more evidence-based decision making.
Insights	Gaining of a deeper understanding enabled by use of business BA capabilities.
Decisions	Decision-making followed by insights from BA capabilities utilization.
Purposeful actions that create value that use the organization's existing capabilities	Organizational actions with a goal to create value utilizing existing organizational capabilities or operational use of BA

	capabilities.
Intendedly value-creating actions to change the existing organization's capabilities	Actions taken by the organization with a goal to create business value that leads to changes in its current organizational capabilities.
Organizational benefits from analytics use	An overall measure of perception of the benefits from analytics use.
Enabling technology	BA related hardware, software, data, processing and governance capabilities.
Analytical people	The people within the organizational unit with an analytic mindset who help drive business value from BA.
Analytical resources	The combination of people, technology and data-analysis processes that enable it to make more evidence-based decisions.
Organizational resources	The full set of resource in the organization that enable it to provide goods and services (i.e. value) to its customers and other stakeholders.
Analytic leadership	The level of leadership of initiatives or projects to increase use of BA.
Enterprise-wide analytics orientation	The level of adoption of an enterprise-wide orientation to BA utilization.
Clear targets	The selection of targets for new analytics initiatives are selected carefully based on the combination of their business potential and whether the necessary resources, including data, are available.
Extent to which evidence-based decision making is embedded in the organizational culture	The extent to which a culture of evidence-based decision making is embedded in the core values and processes of the organization.
Current BA improvement projects	Ongoing projects can include both the implementation of new software and initiatives that apply existing functionality to new areas of decision making.
Functional fit of BA tools	Matching of BI tools to the functionalities that the organization needs to access and analyze data effectively and efficiently.
Availability and quality of data	Relevance and accuracy of data that is available for analytics use, from sources both within and external to the organization.
Analytical people	Analytical mindset within people in the organization.
Overcoming organizational inertia	Motivation to learn, use and accept the new system. During initial implementation and subsequent projects, considerable change management effort, training and support are needed to overcome organizational inertia.
Organizational benefits from BA utilization, from the perspective of senior management	An overall measure of senior management's perception of the benefits from BA utilization. For e.g. enabling visibility into organizational data, enhancing evidence-based decision making.

Even though BASM is a result of summarizing insights from numerous researches, it is still strongly a practical framework, that despite of analysis of 100 success-stories, still needs further work (Seddon et al. 2017).

There are also other perspectives to examine business value, for e.g. VRIO framework, that evaluates how valuable, rare, costly to imitate, organizationally embedded organizational BA is (Grover et al. 2018). This framework with its directional questions, enable organization to evaluate business value and potential competitive advantage of BA. However, in this research we use Seddon et al's (2017) BASM framework to show the concepts of BA utilized in the private healthcare sector in Finland.

3 Methods

The aim of this study is to increase understanding role of the future of BA, also providing valuable insight into the potential of BA tool utilization in creating new products and services in the private healthcare sector. This study has been conducted by focusing on the interest group, the private healthcare organizations, consulting companies, to be more specific of both, technology and management consultants as well as international technology vendor organizations' representatives. When examining the potential of BA from several perspectives, we get a wider picture of potential of BA in the Finnish private healthcare organizations.

The research was conducted as a qualitative study. The multiple case research strategy we used, carried out with qualitative methods was suitable for studying this kind of complex and context-dependent research topic (Yin 2003). For the purposes of this research ten different private healthcare companies were chosen. The examined companies were representing multiple different sizes of private healthcare organizations operating in Finland. Also, twenty consultants were interviewed for the study. The interviewees were representing technology and management consulting organizations having operations in Finland. The inductive approach in this research, together with semi-structured, thematic interviews, allowed us to investigate the decision-making and other BA enabled potential. This research method was selected upon others, as it is providing better explanations and deeper understanding on the research questions, also enabling the adjusted questions and gather more information flexibly, than if used quantitative study et al. 2010; Nykänen et al. 2016; Qu and Dumay 2011). The semi-structured thematic interviews were conducted face-to face interviews, skype-interviews and phone interviews. The interview discussions were recorded and transcribed to be able to systematically organize and analyse gathered data (McLellan et al. 2003).

The case organizations from the private healthcare sector, located all over Finland, were having business operations in the dentalcare, social care and healthcare businesses of the healthcare industry. The organizations involved in the research were Finnish and international companies having office representing the foreign corporation in Finland. The interviewees were top managers and executives, mostly representing ICT or financial functions, and they were chosen as of their area of responsibility for BA and BI in their organizations. The list of interviewees as well as their role is described in Table 3.

Table 3. The list of interviewees, their role and responsibility in the company

Interviewee	Position	Responsibility
1	Director, ICT	ICT functions
2	Director, Digital Services	of Digitalization
3	Head of IT	of ICT functions
4	Development Manager	Responsible for BI and development
5		of ICT functions
6	Head of Accounting and Reporting	of Controlling and BI
7	Director, Digitalization	of ICT and Digitalization
8	Manager	of ICT
9	Head of Controlling	of Controlling and BI
10	Head of Controlling	of Controlling and BI

The interviews of private healthcare organizations were conducted during the period between January and May 2017. They were carried out in discursive atmosphere, including discussion on issues e.g. what is business analytics and what is the value potential of BA.

In addition, also twenty technology and management consultants were interviewed for the study. The interviewees were focusing on BA and BI related consulting activities in their organization. In the below table 4 we present a list of interviewees, their position in the organization as well as area of responsibility.

Table 4. The list of interviewees, their position and type of the consulting company

Interviewee	Position	Type of consulting
11	Director	Technology
12	Consultant	Technology
13	Director	Technology
14	Consultant	Technology
15	Director	Technology
16	Consultant	Technology
17	Director	Management consulting
18	Consultant	Technology
19	Manager	Management consulting
20	Manager	Management consulting
21	Manager	Management consulting

22	Manager	Technology
23	Director	Technology
24	Director	Technology
25	Director	Technology
26	Director	Management consulting
27	Consultant	Technology
28	Director	Management consulting
29	Director	Management consulting
30	Director	Technology

The interviews were carried out between April and October 2017. In total twenty thematic semi-structured interviews were conducted. These discursive interviews included discussions on issues e.g. what is business analytics and what is the value potential of BA.

Moreover, one private healthcare company was chosen for deeper case study. The interviewees were business and finance directors as well as representative of controlling function. The list of interviewees among with their position in the organization and main responsibilities is presented in table 5.

Table 5. The list of interviewees of the healthcare case company.

Interviewee		work activities
31	Director	Business
32	Director	Business
33	Director	Finance
34	Controller	Business Control

Finally, one major international BA technology vendor, an international technology company, was also chosen for deeper case study. The list of interviewees among with their position in the organization and main responsibilities is presented in table 6.

Table 6. The list of interviewees of the technology case company.

Interviewee		work activities
35	Consultant	AI, ML and Advanced Analytics

36	Architect	Analytics
37	Consultant	Analytics
38	Architect	Analytics
39	Architect	AI, ML and Advanced Analytics

In the next chapter we present our results by answering to the interview themes, based on the first round of analysis. We also analyse the result with BASM or business analytics success model framework, that can also be applied to evaluate competitive advantage brought by BA process (Seddon et al. 2017).

4 The value creating business analytics capabilities in the private healthcare sector

However, we need more knowledge on about the role of BA in decision-making and other potential in order to point out the business value enabled by BA for organizations. In this chapter we summarize the identified concepts from the empirical study towards the BASM framework. The modifications to Seddon et al.'s (2017) framework have been done based on our earlier research of the private healthcare sector (Ratia and Myllärniemi 2018; Ratia 2018) as well as the recent research, to reflect the current situation in the private healthcare sector in Finland.

The business analytics success model exposes the concepts related, their explanations as well as their presence in the examined organizations. The model has been modified based on our earlier research of the private healthcare sector (Ratia and Myllärniemi 2018; Ratia 2018) as well as the recent research, to reflect the current situation in the private healthcare sector in Finland. The utilization of BA capabilities for analyzing internal and external data to support more evidence-based decision making was clearly present in the research, as many of the organizations were utilizing both internal and external data to enhance organizational decision-making. Also, gaining of a deeper understanding enabled by use of business BA capabilities can be considered to appear in the results. Data driven decision-making followed by insights from BA capabilities utilization was considered to be one of the most important aspects in organizational BA utilization, as organizations found effective and efficient decision-making process as one of the goals of BA and BI. However, organizational actions with a goal to create value utilizing existing organizational capabilities or operational use of BA capabilities was only present partly, as some of the organizations. Actions taken by the organization with a goal to create business value that leads to changes in its current organizational capabilities, such as new innovations and searching for new business opportunities. A very few organizations measure the benefits from analytics utilization, as it is yet unclear how the value can actually be measured.

Whereas in terms of technology, BA related hardware, software, data, processing and governance capabilities were very clearly scheduled for implementation or utilization. It seems, that the technology part is the most under control of the BA concepts. The human resources availability within BA activities were seen to be not so complete, as there overall perception was, that there are not enough capabilities for BA utilization. Overall, the required resources are available only partly. The analytics leadership was neither mentioned to be strongly present. Often targets are not very clear and BA is being practiced even though the goals and targets are not so clear. Organizational culture, or more specifically organizational data-culture is also a difficult issue to implement for many of the organizations. The most of organizations had active BA project activities, just had ones or were planning to implement, as BA was considered to be important in terms of data-driven decision-making. Functionality of BA tools was considered to be important, as BA was seen to be demand-based. Most of the organizations were mentioning data quality to be important, but the quality of external data sources were not mentioned. Overcoming organizational inertia was not mentioned in terms of BA and BA tool implementation. However, it can be also considered to be as part of the organizational culture and its change and development. The perspective of senior management was rather receptive than rejecting. There was a clear interest in enhancing decision-making process, and in some cases also to identify the new business concepts and business possibilities.

So, if summarized, in the conducted research, over half of the presented concepts of business analytics success model framework were present or partly present in organizational processes. Another half of the concepts was not present in the researched organizations. Clearly decision-making and enhancing the process of decision-making were strongly present. But in addition, BA was also seen as an enabler of new business concepts and business opportunities.

5 Conclusions

This paper is introducing a fairly novel approach to discussion of the impact of BA and BA tools to data-driven decision-making and its future potential in other business value deliverables, such as new business concepts, in the private healthcare sector in Finland. The amounts of data have expanded significantly during the last years, and therefore business intelligence (BI) and business analytics (BA) have become increasingly more important in organizations (Vidgren et al. 2017). Also the healthcare sector has been moving their activities towards data-driven decision-making, as of growing amounts of operative business data, that is being generated and used to support the organisational or managerial decision-making process (e.g. Ratia and Myllärniemi 2017; Stewart et al. 2016; Raghupathi and Raghupathi 2014; Raghupathi 2010; Spruit et al. 2014; Grierson et al. 2015). Here, the key challenge is, how to leverage those capabilities to create business value (Vidgren et al. 2017).

The research showed, that there were several concepts of BA utilization that were already in use, such as decision-making and seeking for new data-driven business

concepts, and also several important aspects, that had not yet been considered, such as analytics leadership. However, also the technological part was very strongly managed. Organizational culture and related concepts were though not yet playing a significant role. Also management was interested in BA activities and results. However, the exact goals and targets were not so clear yet. Also measuring BA activities and their success was not very common, and the metrics still remain unclear. As a summary we could say, that over half of the presented concepts of business analytics success model framework were present or partly present in organizational processes. Another half of the concepts was not present in the researched organizations. As a highlight, decision-making and enhancing the process of decision-making were strongly mentioned. Also BA was also seen as an enabler of new business concepts and business opportunities.

The practical outcome of this research will provide valuable information as well as understanding on the BA utilization in decision-making in Finnish private healthcare sector companies. In addition, showing the potential of future business value creation in the private healthcare. Furthermore, advanced BA practices can also open new opportunities for new business concepts. Thus utilizing of BA and BA tools, not only in enhancing decision-making, but also in creating the potential for new business opportunities. However, in order to get more specific view on this issue, we need to gather more empirical data from the private healthcare organizations, from different organizational levels. In addition, we need to study more of capabilities of business analytics, to be able to point out specific requirements and features that are essential for the private healthcare sector to gain deeper understanding of factors having impact on value creation (Ratia et al. 2017; Brandão et al. 2016; Gartner 2017).

Abstract

Purpose – To find tools and methods to research how we can create an entrepreneurial ecosystem in our turbulent and digital time which can be used for further economical growth of the regions and countries.

Design/methodology/approach – We propose an approach to analyse the current situation with creation of entrepreneurial ecosystem.

Originality/value – This methodology puts in evidence several examples of successful profiting from using of entrepreneurship ecosystem in the frame of current digital economics.

The entrepreneurship ecosystem approach has emerged as a response. It recognises that HGFs flourish in distinctive types of supportive environment. Distinguishing features of entrepreneurial ecosystems include the following: a core of large established businesses, including some that have been entrepreneur-led (entrepreneurial blockbusters); entrepreneurial recycling – whereby successful cashed out entrepreneurs reinvest their time, money and expertise in supporting new entrepreneurial activity; and an information-rich environment in which this information is both accessible and shared. A key player in this context is the deal-maker who is involved in a fiduciary capacity in several entrepreneurial ventures. Entrepreneurial ecosystems emerge and evolve in response to specific circumstances, usually operating in combination. In some cases it is triggered by the contraction or closure of an established company

Practical implications – The outcomes of the application can be used in business environment for the new innovative companies working in digital business (IT-technologies, Big Data applications etc)

Keywords – entrepreneurship ecosystem, economical growth, business model design, value creation, intellectual capital

1 Introduction

Over the last sixty years there has been an evolution in the manner in which governments in advanced countries have undertaken industrial and enterprise policies (Warwick, 2013). Over the past twenty years there has been an escalation in both the quantity of policy initiatives and the level of funding committed to these activities in a process termed the ‘developmental’ state (Rodrik, 2004; Block, 2008). These changes can be summarized as a shift from traditional enterprise policies to growth-oriented enterprise policies and has involved significant changes in the unit of focus, how it operates and how it interconnects with other policies.

This has resulted in a gradual change, varying across different countries, towards a much greater focus on support for growth-oriented entrepreneurship. The consequence is that policy makers across the OECD are now strongly focused on promoting high growth firms (HGFs). The rationale for this focus is that HGFs are thought to drive productivity growth, create new employment, increase innovation and promote business internationalization (Brown et al, 2014). The policy interest in HGFs can therefore be explained largely in one word: ‘jobs’ (Coad *et al*, 2014). Moreover, these firms are distributed across all industry sectors, with no bias towards technology-based firms. HGFs do not only create jobs directly; they also have important spill-over effects that are beneficial to the growth of other firms in the same locality (Mason *et al*, 2009) and industrial cluster (Feldman *et al*, 2005; Brown, 2011). There is evidence that HGFs also provide an important Schumpeterian stimulus within economies by increasing competition, promoting innovation and increasing the efficient allocation of resources within economies. Certainly, there is evidence that HGFs have above average levels of productivity growth (Mason *et al*, 2009), high levels of innovation (Coad, 2009; Mason *et al*, 2009), strong levels of export-orientation (Parsley and Halabisky, 2008) and a high level of internationalization (BIS, 2010; Mason and Brown, 2010). Recent research also shows that these firms invest heavily in human capital (Mason et al, 2012) and are more likely than non-HGFs to employ disadvantaged people in the labour market, such as the long-term unemployed and economic migrants (Coad et al, 2014).

Accordingly, policy makers are now beginning to recognize the merit of a more systems-based form of support for high growth entrepreneurship. This represents a shift away from company specific interventions towards more holistic activities which focus on developing networks, aligning priorities, building new institutional capabilities and fostering synergies between different stakeholders (Rodriguez-Pose, 2013; Warwick, 2013). One emerging approach is the focus on ‘*entrepreneurial ecosystems*’ (Zacharakis et al, 2003; Napier and Hansen, 2011; Malecki, 2011; Kantis and Federico, 2012; Feld, 2012; Isenberg, 2010). The term ecosystem was originally coined by James Moore in an influential article in Harvard Business Review published during the 1990s. He claimed

that businesses don't evolve in a 'vacuum' and noted the relationally embedded nature of how firms interact with suppliers, customers and financiers (Moore, 1993).

2 Distinguishing Features of Entrepreneurial Ecosystem

Entrepreneurial ecosystems generally emerge in locations that have place-specific assets.

At the heart of an entrepreneurial ecosystem typically there is at least one, and usually several, 'large established businesses', with significant management functions (e.g. head office or divisional/ subsidiary office) as well as undertaking R&D and production activities. These businesses will also be rich in technology. They play significant roles in developing the ecosystem. First, they are 'talent magnets', recruiting large numbers of skilled workers, many of them recent graduates, from outside the area (Feldman et al, 2005). Second, they provide business training for their employees and enable them to progress up the corporate hierarchy. It is through this process that staff who were initially recruited for their technological know-how acquire management skills to become technology managers. This represents a valuable resource for small firms. Third, they are a source of new businesses as some staff will leave to start their own companies. 'Cluster maps' showing where the founders of businesses were initially employed highlight the key role of certain companies as sources of large numbers of spin-offs. Fourth, large exogenous firms play a major role in developing regional ecosystems, especially in peripheral regions, developing the ecosystem's managerial talent pool (Adams, 2011) and providing commercial opportunities for local businesses.

A second characteristic of entrepreneur ecosystems is that their growth is driven by a process of 'entrepreneurial recycling' (Mason and Harrison, 2006). Entrepreneurs who have built successful (but not necessarily large) companies which they have gone on to sell typically leave the company soon after it is sold (although some remain as employees for a short time to take the opportunity to gain managerial expertise in a global company). But critically, they remain involved in the cluster, reinvesting their wealth and experience to create more entrepreneurial activity. Some will become serial entrepreneurs, starting new businesses. Others will become business angels, providing start-up funding for new businesses and contributing their experience through a position on the board of directors. Some may even set up a venture capital fund.

Entrepreneurial ecosystems are also characterised as being 'information rich'. In such an environment individuals can access information and knowledge on new buyer needs, new and evolving technologies, operating or delivery possibilities, component and machine availability, and service and marketing concepts, and thereby can more easily perceive gaps in products, services or suppliers to fill. Geographic proximity and tacit knowledge sharing often go hand-in-hand (Gertler, 2003). Hence, entrepreneurial ecosystems will also have "bridging assets" that serve to connect people, ideas and resources. The availability of finance is a further critical feature of entrepreneurial ecosystems. Universities also play an important role in entrepreneurial ecosystems, but

not the re-eminent role that is often attributed to them. First, leading research-based universities are not found in every ecosystems.

Finally, it is important not to overlook the presence of service providers – lawyers, accountants, recruitment agencies and business consultants – who understand the needs of entrepreneurial businesses and can assist young firms in avoiding stumbling blocks and perform non-core activities that are outsourced. Such firms are often willing to offer their support to start ups at no charge with the expectation that long term business relationships will emerge in due course.

3 The Dynamic Nature Model of Entrepreneurial Ecosystems

There are limits to the value of identifying generic features of entrepreneurial ecosystems. First, each ecosystem has emerged under a unique set of conditions and circumstances. Second, the time dimension is ignored. However, they are discussed as if they emerged fully formed and do not change. There is little understanding of how successful entrepreneurial ecosystems come into being and evolve (Feldman and Braunerhjelm, 2004).

The first point is that entrepreneurial ecosystems do not emerge just anywhere. As noted in the previous section, entrepreneurial ecosystems have typically emerged in places that already have an established and highly regarded knowledge base which employs significant numbers of scientists and engineers. These knowledge institutions – research universities, public research laboratories and corporate R&D labs – perform several roles in seeding the cluster. First their research generates the scientific discoveries, technological advances, and advancement of knowledge that form the basis for the creation of new businesses. Second they are ‘talent magnets’, attracting talented individuals in the form of eminent scholars, gifted students and ambitious scientists and engineers, further boosting the technological capacity of the region and increasing the pool of individuals who might become future entrepreneurs and employees.

There also needs to be incubator organisations which foster future entrepreneurs. This is where the entrepreneur acquires technical skills and product and market knowledge and develops understanding about appropriate organisational structures, strategies and systems. It is also where, in the course of their work experience they notice market opportunities and identify ways of exploiting them.. Indeed, it is often through this process of job mobility that scientists and engineers derive their management experience. This study also noted that although the last organisation that the entrepreneur worked in before starting their own business was often a small firm, they did have significant prior working experience in large firms. The most effective incubator organisations are rapidly growing firms operating on the cutting edge of new technology, active in the early phases of a new industry and generating too many commercial opportunities to take advantage. Garnsey and Heffernen (2005) have identified the importance of Acorn Computers as a source of spin-offs in Cambridge. Effective incubators also need to provide their employees with exposure to best practice technology and intimate knowledge of markets and customers to uncover business opportunities. Indeed, many of the entrepreneurial

ecosystems in the emerging economies are heavily mediated by foreign direct investment (FDI) which strongly resembles this truncated model. Often in these ecosystems, government intervention undertakes much more proactive forms of intervention to compensate for a lack of local subsidiary autonomy.

Government research laboratories are also ineffective incubators. They lack exposure to markets and their research often does not have an immediate commercial application (Lawton Smith, 1998). For the same reason most universities are also poor incubators. As noted above, while there is evidence of spin-offs such firms typically achieve limited growth (Harrison and Leitch, 2010).

There is an overwhelming tendency for spin-off companies to be located in close proximity to the incubator organisation. This results in clustering. There are three reasons for this. The most important is that entrepreneurs need to utilize their social networks of business associates and former employees to access the knowledge, human capital and other resources needed to start and grow their business. These networks “bind entrepreneurs to the locations in which they reside because only there do they have the access to the resources and social support required to sustain their entrepreneurial ventures (Sorensen, 2003: 24). Second it avoids disrupting family ties, enabling the spouse to continue working and bring income into the household. Third, locational preferences may play a role. As noted earlier, many entrepreneurial ecosystems have emerged in locations of high residential amenity. Moreover, many of the entrepreneurs had moved to the area earlier in their career, in part for quality of life considerations which now operated to anchor them in the locality when they started their business.

Finally, some entrepreneurial ecosystems have emerged for exogenous or even serendipitous reasons.

Once the spin-off process gathers momentum it sets in motion a virtuous, self-reinforcing process which leads to the creation of an ecosystem that nurtures and supports further entrepreneurial activity. One of the consequences is that founding a firm at an early stage in a cluster’s development is very different to founding a firm when the cluster is established (Bresnahan et al, 2001). First, successful businesses provide role models and create legitimacy for further entrepreneurial activity. Spin-offs also have the effect of diffusing high level expertise and competencies within the region when individuals carrying technical and management know how and ‘embodied expertise’ move to new organisations as founders or key employees, taking ideas that they have acquired in other local organisations, creating a process of regional collective learning (Keeble and Wilkinson, 1999). A further effect of spin-offs is that they create the critical mass which stimulates the emergence of an entrepreneurial support network (Kenney and Patton, 2005) that sustains and nourishes the creation and growth of entrepreneurial businesses. This comprises three types of service:

- Specialist business services: notably, law firms with deep expertise in handling IP, marketing firms, executive search firms, accountancy practices that are familiar with the unique needs of technology start-ups, technology marketing and PR firms, management consultants, and technology assessment consultants

- Technical services: precision machining, prototyping, precision moulding, testing, etc.
- Finance providers: venture capital firms, investment banks specialising in IPOs

These support services facilitate the process of business start-up and growth by enabling new firms to focus on their area of expertise while buying-in specialist service and support (Saxenian, 1994).

As the spin-off process gathers momentum so institutions emerge – often through the collective action of the entrepreneurial community - to nurture and encourage the formation of new firms and to solve problems which individual firms cannot solve individually, skilled labour is attracted to the region, and local institutions to develop specialist training courses (Wolfe and Gertler, 2004). These are of two main types (Corona et al, 2006): (i) technology incubation mechanisms, such as incubators, innovation centres and science parks, to provide physical space and intangible support to new technology based firms; these can be public or private sector and often designated as not-for-profit; and (ii) partnership organisations, usually comprising government, universities and the private sector, to promote networking and collaboration between members and which can ‘champion’ the region both internally and externally.

The important point to note is that the supportive conditions for entrepreneurship spontaneously follow the process in which entrepreneurship takes hold in an ecosystem. This is particularly the case with the availability venture capital – which is widely seen as a necessary attribute for technology clusters (Malecki, 1997; Norton, 2001), being required for the sustained growth and development of a cluster (Llobrera et al, 2000). Without venture capital the cluster is likely to stagnate or decline (Feldman et al, 2005). But as several authors have noted, venture capital lags rather than leads the emergence of entrepreneurial activity: it is not part of the initial environmental conditions (Saxenian, 1994; Feldman, 2001; Mason et al, 2002; Garnsey and Heffernan, 2005).

4 Supporting Entrepreneurial Ecosystems: the role of policy

Both framework conditions and general start-up policies have proved to have limited effectiveness in increasing the number of number of HGFs. The objective of ecosystem policy is to achieve this goal by improving the environment that surrounds such firms. But, this poses challenges for public policy since it is not obvious from this discussion how government intervention might promote the emergence of entrepreneurial ecosystems or stimulate the key processes of spin-offs and the emergence of entrepreneurial support in its various forms. Indeed, it is difficult to point to any entrepreneurial ecosystem that has arisen through direct government intervention. There are certainly no simplistic policy solutions or ‘silver bullet’ (Isenberg, 2011a).. This section is in two parts. First, it discusses a number of general principles that underlie the development of policies to promote entrepreneurial ecosystems. It then develops taxonomy of approaches to intervention at the level of the individual ecosystem.

First, policy-makers need to recognize that ‘you cannot create something from nothing’. We noted earlier that entrepreneurial ecosystems are based on pre-existing assets and not just a tool for high-tech industries. Traditional industries like food and drink, energy, logistics, water industry, manufacturing all provide the platform to create dynamic, high-value added entrepreneurial ecosystems. They were generally perceived to be nice places in which to live and already had some significant notably knowledge-based organizations.. However, it is doubtful that policy can systematically ‘create’ entrepreneurial ecosystems.

Second, policy approaches need to evolve over time. Ecosystems are dynamic, complex organisms. Appropriate forms of intervention will therefore be related to the maturity of the ecosystem. For example, at the emergence stage the emphasis may need to be on supporting the start-up processes, but as the ecosystem matures the need to help firms with organizational development, human capital development, internationalization support and access to growth capital will increase..

Third, here is no ‘one size fits all’ approach. Every ecosystem is unique. Many of the components will differ from one ecosystem to another. Local cultural attitudes, the structure of local banking systems and educational policies will all affect the nature of these local ecosystems. An approach which simply seeks to duplicate other ecosystems is therefore inappropriate and likely to fail.. Every ecosystem needs a different approach that is customized to local circumstances. This is underlined by the proliferation of ‘Silicon Somewhere’ (Hospers et al, 2008) which have largely turned out to be policy-driven promotional exercises which paid little attention to the specific nature and capabilities of the specific localities (Martin and Sunley, 2003).

Fourth, initiatives are likely to be ineffective if introduced in isolation. For example, increasing the supply of venture capital is unlikely to be effective if there is no deal flow. Encouraging more people to create start-ups is likely to have little impact if many occur in low growth areas. Introducing entrepreneurship education will be ineffective if graduates move to more conducive entrepreneurial environments. Policy implementation has to be holistic.

Fifth, developing entrepreneurial ecosystems has to be a blend of ‘top down’ and ‘bottom up’ approaches. Appropriate framework conditions are essential. For example, immigration laws should not provide a barrier to the attraction of talented individuals. Property rights need to be enshrined. Both corporate and individual taxation needs to provide appropriate incentives both to reward risk-taking and encourage reinvestment. On the other hand, grants and subsidies should be avoided as they may distort entrepreneurial behaviour. But there also a need for ‘bottom up’ initiatives to improve the environment. Moreover, these bottom up initiatives should not be seen as the exclusive responsibility of government. As noted earlier, Feld strongly argues that the development of entrepreneurial ecosystems requires active input from the entrepreneurial community. Isenberg (2012) sees the possibility of ‘tipping points’ when ecosystems become self-sustaining, thereby enabling government involvement to be significantly reduced.

Sixth, it is important to recognize the distinction between small business policies and entrepreneurship policies. Small business policy is a rather scattergun approach which

focuses on increasing the number of business start-ups. Shane (2009) has memorably described this approach as ‘bad public policy’ on account of their limited growth, short survival and high failure rates and high displacement of the vast majority of start-ups. Nevertheless, this approach is deeply embedded in public policy (Nightingale and Coad, 2014). Entrepreneurship policy, in contrast, is concerned with supporting businesses with high growth potential. Such firms are more likely to require relational rather than transactional assistance. Moreover, they are likely to benefit most from peer-based support (Fischer and Reuber, 2003; Mason and Brown, 2013) on account of the greater opportunities for experiential learning and tacit knowledge sharing. Moreover, in view of the “idiosyncratic and unstable” nature of firm growth (Vinell and Hamilton, 1999) such support needs to be time-sensitive, aimed at supporting firms that have experienced ‘growth triggers’ and therefore experiencing systemic changes to their structure and workings (Brown and Mawson, 2012).

Finally, policies to promote high growth entrepreneurship need to recognise the diverse nature of HGFs rather than basing them on stereotypes (Mason and Brown, 2013; Brown et al, 2014). At least ‘six myths’ can be identified (Brown et al, 2014): HGFs are not all new/young; they are not predominantly in high tech sectors; universities are not a major source of HGFs; few HGFs are venture capital-backed; they do not exhibit linear growth – fast growth is episodic; and they do not only grow organically – acquisition is also significant.

5 Conclusions

The concept of entrepreneurial ecosystems draws upon a long and rich lineage of intellectual inquiry by scholars from economic geography, economics and other disciplines, all seeking to explain why firms cluster together in geographical space and benefits that arise from this clustering for individual businesses. So, what does the entrepreneurship ecosystem perspective offer that is intrinsically ‘new’ or original? First, it has merit as a metaphorical device which offers a holistic understanding how clusters of economic activity come into being and specifically to offer a new perspective on firm growth which emphasizes the firm’s external environment rather than its internal characteristics and operations. Second, it shifts the unit of analysis away from the ‘firm’ to the entirety of the ecosystem where it is situated. This is important because often these externalized and relational aspects strongly mediate firm performance. It is also important to stress the dynamic nature of ecosystems as evolutionary rather than a static phenomenon that can be captured, like a picture, by a snapshot at a given point in time.

From a policy perspective, the implication from the entrepreneurial ecosystem view is that the goal of generating more HGFs requires the cultivation of an ecosystem that is supportive of the needs of ambitious entrepreneurs. Beyond that, its value as a tool to guide policy – and HGF policy in particular – is less obvious. Indeed, it emphasizes the limits of policy. Certain basic economic and social factors need to be present for the emergence of ecosystems, but these on their own are insufficient. Entrepreneurial ecosystems emerge and evolve in response to specific circumstances, usually operating in

combination. In some cases it is triggered by the contraction or closure of an established company. Hence, policy is unable to influence when an entrepreneurial ecosystem develops momentum. On the other hand, the spin-off process, which drives the growth of the ecosystem, is facilitated by particular environmental attributes, notably the presence of talented people, knowledge, networks, the presence of role models and the availability of advice, mentoring and resources to support entrepreneurial activity. Indeed, the more entrepreneurial activity there is, the more that further entrepreneurial activity is stimulated. This provides greater opportunities for policy intervention. However, some of the leading proponents of the entrepreneurial ecosystem approach question whether government has the competence to intervene directly and so urge caution, recommending instead that it should encourage, facilitate and enable both the entrepreneurial community themselves and the large established businesses that anchor the ecosystem to drive it forward.

Abstract

As a growing field of analysis in management studies, several scholars have been looking at the role of human resource management (HRM) practices in boosting a firm's entrepreneurial orientation (Tansky et al., 2009). On the other hand, entrepreneurial orientation has been repeatedly proven to positively impact firm performance both at the organizational level, but also at the level of enterprise clusters. This means that within high-entrepreneurial orientation firm clusters, both the overall cluster and the firms' individual performances are positively affected (Yao et al., 2009). However, existing literature provides little guidance on how HRM practices could help firms improve their performance through fostering entrepreneurial orientation. This paper aims to shed more light on how human resource management could become a major driver of firm performance while leveraging on learning to translate individual and collective abilities into value adding entrepreneurial actions. For this purpose, this paper follows a systematic literature review as a recognized evidence-based tool for theory building (Tranfield et al., 2003). The objective is to develop an integrative theoretical framework that explains how HRM practices provide firms with superior performance, using entrepreneurial orientation as an intermediate construct. A 'grounded theory' approach was used to build higher-order theoretical constructs and the assumptions underpinning their relationships (Glaser and Strauss, 1967). We therefore followed an inductive process based on a comparative analysis to synthesize the gathered information from the

systematic literature review, build on to emphasize the meaning of each concept, and then develop the propositions underpinning the relationships between the studied constructs, which in turn form the foundations of the integrative theoretical framework.

Keywords – Human Resource Management, HRM Practices, Entrepreneurial Orientation, Corporate Entrepreneurship, Firm Performance

Paper type – Academic Research Paper

1 HRM practices

To study the effect of HRM practices on employees' entrepreneurial learning, let us first determine a base definition of HRM practices within a company. There seems to be a general agreement within the field regarding the conceptual scope of HRM practices. An HRM system includes a number of functions, activities, and processes that, put together, are organizing the firms' human capital (Kaya, 2006). The main categories of HRM activities are related to (1) identifying, attracting, and hiring potential talents that can contribute to firm performance, (2) facilitating the development of knowledge, skills, and attitudes that contribute to the company's achievements, (3) compensating employees for their contribution to the firm's success through financial and non-financial rewards, (4) monitoring the performance of the employees to ensure their contribution to the company's achievement of goals, and (5) coordinating the relations and communications between employees and departments to accommodate their needs (Edralin, 2010).

The definitions of HRM practices put employees as the main subject matter that HRM is dealing with. From a different perspective, HRM is viewed as managing the sets of knowledge, skills, and abilities considered relevant to the firm; thus, putting KSAs as the main focus of HRM (Schmelter et al., 2010). In this framework, HR functions, activities, and processes are established by firms to ensure that the employees' abilities and attitudes are continuously developed to allow the firm to attain its goals and objectives (Tang et al., 2015). This is generally based on the widely embraced theory of human capital which argues that under the management of HR practices, the knowledge, skills, and abilities of employees provide a true economic value to the firm (Teo, 2008). Regarding all these practices, Tang et al. (2008) refer to strategic HRM, and how the different functions, activities, and processes are to be viewed as a set that needs to align among its components and to be aligned with the overall strategy of the firm. Firm's HRM practices are indeed seen to be critical to ensure the cohesion between its different organizational departments through maintaining communication channels within the company (Kaya, 2006). By being aligned with the overall company performance goals, installing the appropriate HR practices can provide a strong support system and an organizational framework which ensures that all departments and employees are contributing to the achievement of the short-term but also the strategic performance objectives of the firm.

Different HRM practices have been studied in details to prove their contribution to an organization's performance. Notably, research has proven the role of training and

development. In the rapidly changing business landscape, the ability of adaptation and change is indeed critical to the survival of small and also large firms (Cucculelli and Bettinelli, 2015). Change within an organization requires a change in the behavior of employees, which in turn requires a cognitive change. Through training, the HR department works on assessing the competency gap and developing the skills required to prepare the firm for change (Murray & Donegan, 2003). It is also concluded that an effective HRM system needs to be directed towards the firm's strategic plans to be able to properly evaluate and develop the competencies needed to support its overall strategies (Tang et al., 2015). For learning to be beneficial to the firm, research has proven the necessity for firms to establish a structured process for organizational human resource development (Vasconcelos et al., 2016). First, the organizational learning process starts with information acquisition. Acquiring information can be through the intentional effort of the firm to collect relevant data by conducting customer feedback surveys for example. On the other hand, the company can have existing information about a certain aspect of its business. The second step is to analyze and interpret the information on hand. Analysis and interpretation can be done by different departments, each having a different perspective on the subject matter. When analyzing the firm's performance, for example, the finance department will give a quantitative interpretation of the financial performance, while the marketing department might have a qualitative interpretation of the intangible performance of the firm. The next step is conducting focused experimentation. This step aims at testing the outcomes of the interpretation process of information and to test its conclusions in a more controlled environment. Then, the outcomes of the focused experimentations are disseminated within the firm and communicated within the firm. The last structured step of the process is knowledge restructuring, where the firm as a whole incorporates the new findings, conclusions, and lessons to update its knowledge (Vasconcelos et al., 2016).

Research has also looked at the role of HRM in establishing an organizational structure within the firm. By organizing the hierarchical relationships between departments and employees, the HR department is directly responsible for organizing the workflow and ensuring its effectiveness and efficiency (Theodorakopoulos and Figueira, 2012). Through HR practices such as observing the employee's daily tasks, conducting interviews, analyzing job descriptions, and appraising performance, the HR department can work on analyzing productivity and restructuring the organization's processes (Murray and Donegan, 2003). Practices of company restructuring can be required for instance during times of change implementation, or simply when the company decides to optimize its resources, improve its productivity, or take advantage of a new opportunity (Kuratko et al., 2001). Evidence showed that for service firms to be competitive it is important to restructure their HR to establish an organizational structure that allows for participative decision-making and an inclusive organizational culture (Teo et al., 2008). At a larger scale, company restructuring can be legislated by governments as part of strengthening an industry to overcome an economic crisis. For instance, in 2009 the banking sector in Nigeria had to introduce a series of restructuring practices including HRM interventions to overcome the crisis (Abosed et al., 2018). The mediating role of

HR practices are also playing a critical role in establishing and maintaining the organizational culture. By organizing the relationships within departments and between management and subordinates, HRM policies are on one hand reflecting the management's philosophy and culture, and on the other hand, they are also contributing to the creation and continuous development of the firm's organizational culture (Tang, 2015).

This brings us to develop the following proposition:

Proposition 1: HRM is a set of practices and processes aiming to leverage on employees' knowledge, skills, and abilities to strengthen and further develop organizational capabilities and turn them into performance outcomes. The strategic objective of HRM is to attract, develop, and retain talented employees and to create the necessary conditions for them to use their competences to help the company achieve its strategic goals.

2 Entrepreneurial orientation

Entrepreneurial orientation was defined as the firm's tendency and ability to identify new opportunities (Park et al., 2017). Entrepreneurial orientation is not only about the identification of opportunities, but also the firm's capability to take advantage of these value-generating opportunities (Vasconcelos, 2016). This identification process is facilitated by individual employees, also called intrapreneurs, whose motivations are intrinsic, but who are also expecting the firm to reward their entrepreneurial endeavors (Kaya, 2006). Entrepreneurial orientation is believed to be the driving force behind the adoption of innovative behaviors and is leading firms to be more dynamic and flexible with regards to environmental changes (Kearney, 2013). The entrepreneurial spirit within the firm is the proactive drive to achieve novel capabilities and to update the firm's knowledge to exploit new opportunities (Real, 2014). Entrepreneurial orientation within a firm has been functionally defined as the set of practices, methods, and decision-making strategies that are used by the management to engage in entrepreneurial activities (Real, 2014). Miller's three dimensions have been identified and repeatedly used in existing literature to understand entrepreneurial orientation:

The first dimension is innovativeness, and it refers to searching for novel, original, and creative solutions and challenges (Dess and Lumpkin, 2005). Firms can generally come up with radical and incremental innovative changes, as well as technological and non-technological innovations (Omar et al., 2016). Innovation can be categorized into product, process, and market innovations. Product innovation consists of improvement in the products and services of a firm, for example, by introducing new materials or new designs. Product innovation is believed to increase the variety, value, rarity, inimitability, and differentiation of the firm's offerings, and thus, contributing to its competitiveness in the market and financial performance (Sher and Yang, 2005). Product innovation is generally capital intensive, especially as technology-based innovations and products are becoming obsolete faster (Sher and Yang, 2005). Process innovations are bringing novel ways for the company to conduct some of its operations such as the digitalization of some

administrative tasks. Process innovations aim at improving the efficiency and effectiveness of the company's operations and have been proven to increase productivity and to reduce the overall fixed costs (Kuratko et al., 2001). Finally, market innovation refers to finding new target segments, foreign markets, or niche for a firm's products and services (Gupta et al., 2014). It also includes finding new ways to serve clients in these markets through new distribution processes for instance (Cucculelli & Bettinelli, 2015).

The second aspect of entrepreneurial orientation is proactiveness, and it refers to a firm's aggressiveness in taking action. This factor determines how a firm reacts to current and anticipated market trends (Mohamad et al., 2011). A proactive firm works on predicting changes, opportunities, and threats and strategically acts on them (Serai et al., 2017). It is constantly in search of new solutions and opportunities; and mostly does not engage activities just as a reaction to outside changes (Dyduch, 2008). Urban and Sefalafala (2015) have studied how proactive activities, such as attending foreign trade fairs, particularly help firms in their internationalization strategy. Proactive firms that successfully enter a new market, adopt a new administrative process, or implement a new technology to get the first mover advantage and are likely to benefit from this pioneering position (Dess and Lumpkin, 2005). Proactivity not only allows firms to be industry leaders, but many even seek to change the whole industry and competitive landscape they operate in. Dell is a good example of how a single company's proactive action of selling computers directly to consumers, has changed the way computers are sold in the entire industry (Dess and Lumpkin, 2005).

Finally, entrepreneurial orientation is also related to a firm's tendency and readiness to take risks in investing in new business opportunities whose outcomes are uncertain (Real et al., 2014). Different firms and managers have different aversion levels towards risk. Risks are taken with the assumption that they have a considerable chance of generating high financial returns. This assumption should be backed up by intensive research and risk assessment to minimize the uncertainty and determine the acceptable balance of manageable risk and expected returns (Dess and Lumpkin, 2005). As entrepreneurial endeavors are novel by definition, they do have an inherently high risk. Haar et al. (2009) looked at the owner's passion as a driver of entrepreneurial orientation, finding that passionate owners and managers are more likely to take risks and successfully generate returns from them. However, being too passionate can negatively affect their evaluation of risk and can lead them to keep on pursuing failing business opportunities.

Entrepreneurial orientation has also been linked to organizational learning which represents the firm's attitude towards learning. In practice it is the managerial process that facilitates learning and knowledge seeking within the firm (Real et al., 2014). The nature of entrepreneurial activity involves the continuous update of knowledge, skills, and abilities to be able to identify and take advantage of novel opportunities. Two aspects of learning within an organization can be identified. First, the process of exploration enabling the firm to acquire new information and work on assimilating this new knowledge. The second aspect refers to the exploitation of what has been learned using logical tools and with the aim of applying the new acquired knowledge (Real et al., 2014). Organizational learning can also be viewed from the perspective of information sharing

channels. Feedforward learning refers to the passing of knowledge from individual employees to the group and then the organization; while feedback learning refers to organizations transferring knowledge to groups and individuals (Real et al., 2014). Integrating these channels has proven to boost firms' entrepreneurial ability since establishing a structured process of learning is leading firms to generate a new understanding of market opportunities. New knowledge, paired with the firm's existing resources and capabilities are helping firms to continuously update the knowledge, skills, and abilities necessary to engage in entrepreneurial activities (Real et al., 2014).

From this discussion the following proposition is formulated:

Proposition 2: Entrepreneurial orientation is an organizational capability that translates the firm's ability to generate new product, process, and market innovations. Entrepreneurial orientation encompasses innovativeness, proactiveness, and risk taking attitudes. Individual and organizational learning supports the firm's intrapreneurship capability through generating new knowledge resources and turning such idiosyncratic assets into innovations.

3 HRM practices and entrepreneurial orientation

HRM practices play a fundamental role in boosting a firm's entrepreneurial orientation as illustrated in various studies (Tansky et al., 2009). Kaya (2006) in his study of Turkish firms demonstrated that through activities such as structuring and assisting participative leadership, risk taking, and development of innovative strategies, HRM practices can maximize the effect of value-creating entrepreneurial activities within firms. Notably, practices of training and hiring were mentioned to be particularly important in selecting candidates that exhibit attitudes and behaviors that align with the firm's strategic goals and entrepreneurial orientation, and that continuously engage in developing their skill set. The model proposed used the following HRM practice measures: (1) training on job skills, (2) extensive training, (3) training in multiple functions, (4) written policy, (5) team activities, (6) communication of strategy, (7) interaction facilities, (8) incentives to meet objectives, (9) behavior and attitude, and (10) feedback on performance. It is concluded that firms seeking to enhance corporate entrepreneurship should invest in the development and implementation of the appropriate HRM practices.

Tang et al. (2015) investigated the effectiveness of HRM in promoting corporate entrepreneurship in the Chinese context, while considering the mediation role of devolved management practices between strategic HRM and corporate entrepreneurship. They proved that these two concepts are strongly related. To enhance entrepreneurial orientation, firms need to plan and adjust their HRM practices. The HR practices studied under devolved management include: opening communication channels, decentralizing authority, confiding in employees, delegating tasks, and inspiring subordinates. All of these practices were found to have a positive impact on employee's entrepreneurial orientation. Tang et al. (2015) also highlighted the importance of management style, as a highly contextual factor that considerably differs across cultures, in encouraging entrepreneurial practices. In the same perspective, Zhang and Jia (2010) emphasized the

particularity of the Chinese environments and the social dynamics in the workplace. Their findings suggest that management style and organizational culture play a pivotal role between HR practices and corporate entrepreneurship. Their study also considers the importance of establishing managerial and communication openness as well as a team-oriented environment to encourage employee's entrepreneurial behavior.

Babak (2016) conducted a research in Iran and looked into the hypothesis that HRM practices play a structuring role for entrepreneurial activity through three main aspects in human resource management: (1) empowering employees through improved personal evidences, organizational evidences, professional skills, and management skills; (2) administrative factors in relation to the established organizational structure, control and supervision, performance management, and human resources; (3) motivational factors that include the reward system, management support, personality factors, and job promotions. His research proved that the strongest impact comes from the establishment of empowering and training systems.

To identify the actual HRM strategies that are significant to corporate entrepreneurship, Schmelter (2010) conducted an online survey sampling 214 German companies that operate in a knowledge intensive industry. The team has studied four HRM strategies as independent variables: (1) staff selection, (2) staff development and training (3) staff rewards, and (4) specialist assignment. Also, corporate entrepreneurship was accounted for as a construct of four elements: (1) innovativeness, (2) risk propensity, (3) pro-activeness, (4) new business venturing, and (5) self-renewal. The study proved the positive influence of all the four HRM strategies on corporate entrepreneurship; notably, staff development and training followed by staff rewards had the strongest impacts. Investing in training and development is thus necessary for firms that seek to encourage corporate entrepreneurial engagement. Their study also emphasized the importance of providing insight about the measurements used to evaluate their employees' entrepreneurial engagement, as well as the knowledge, skills, and ability that are aligned with the firm's entrepreneurial orientation.

Another investigation aimed at finding the HRM practices that are the most influencing drivers of corporate entrepreneurship was conducted by Edralin (2010) within large firms in the Philippines. In his hypothesis, he considered innovation as the measure for entrepreneurship and evaluated the effect of the following HRM practices : (1) recruitment and selection, (2) training and development, (3) compensation, (4) performance management, and (5) employee relations. The qualitative analysis showed that recruitment and selection, training and development, and employee relations have a significant positive relationship with entrepreneurship, with the last variable as being the most significant factor. This study concludes with the importance of engaging in employee relations enhancement through for instance group-based introductions, open correspondence and communication channels, fair treatment of all employees, and creating an energetic and constructive atmosphere in the workplace.

Mustafa et al. (2013) studied a framework in which HRM influences corporate entrepreneurship through a specific measurement which is knowledge sharing. The study looked at how some high-performance HRM practices affect manager's behavior in

collecting and donating knowledge within the firm. It investigated the mediating role of managers' knowledge sharing behavior between HRM practices and corporate entrepreneurship. The analysis was based on 292 surveys collected from middle managers working in both private and public firms in Malaysia. The study proved the positive correlation between high performance HR practices, middle managers' knowledge sharing behavior, and corporate entrepreneurship. This research also emphasized the role of middle managers in being the hubs of knowledge, and in being a central drive for learning within the firm.

As a recurrent factor that has been emphasized in numerous studies, HR-enhanced learning plays a fundamental role in boosting corporate entrepreneurship. Learning has been repeatedly considered as a dimension of innovativeness, and thus a considerable aspect of corporate entrepreneurship (Nasution et al., 2011). Employees' knowledge, skills, attitudes, and entrepreneurial competences remain the main trigger of any entrepreneurial activity within the firm (Bin Hashim et al., 2018). In a dynamic environment, such competences require dynamic, consistent, and continuous upgrading and adaptation. Considering the role of HR practices in the assessment of competence gaps and ensuring learning, human resource development becomes a catalyst for entrepreneurial activities within the firm. In addition to considering knowledge and learning as a required input of entrepreneurial activities. Learning also occurs as an outcome of entrepreneurial activities as the identification and implementation of any innovative ideas in the workplace results in experiences that employees and firms can learn from (MacPherson, 2009). Past entrepreneurial experiences can be used as tools to evaluate the effects of such innovations, and to learn from their successes and failures (Park et al., 2017). A firm that enables learning puts in place established processes to evaluate the learning needs of its employees, and provides the strategic training to develop their knowledge, skills, abilities, and creative capabilities (Bratnicka, 2013). Pioneering firms change systematically their HR practices to give more power and autonomy to their employees over their own learning and personal advancement (Vasconcelos et al., 2016). Considering the new knowledge that entrepreneurial endeavors generate, the HR department can also contribute to the promotion of entrepreneurial activity through the establishment of structured learning processes in which new knowledge is both an input and an output of entrepreneurial activities.

This leads us to develop the following proposition:

Proposition 3: HRM practices contribute to enhancing individual entrepreneurial competences and developing organizational entrepreneurship capabilities. The most significant HRM practices include strategic training and development, performance management, and employee relations. Through such activities, HRM promotes both individual and organizational learning that represent the main triggers of any entrepreneurial activity. HRM endeavors also contribute to developing a managerial culture conducive to learning and innovation.

4 Firm performance

Identifying the right measures of business performance is still a concern for both managers and scholars (Marr and Schiuma, 2003). As there are new areas of research and development in the business field, new emerging approaches to evaluating firm performance have been developed. Many frameworks are being currently used for different purposes. However, an integrated framework that has a general approbation in the field is still missing. From the literature, many ways to account for firm performance are identified while emphasizing different indicators.

Performance can be categorized into objective and subjective. Objective performance gives a measurable evaluation of the performance of the company based on tangible figures. Objective performance mostly includes quantitative financial indicators and ratios and can also be distinguished into two types: indicators of profitability and indicators of growth. These indicators aim at projecting in numbers the firm's ability to yield gains, and how these gains improve over time (Bierwerth et al., 2015). Examples of objective performance indicators that researchers have measured include: return on assets (ROA), return on sales (ROS), sales growth (Gupta et al., 2014), IPO and market capitalization (Pastor et al., 2009), total factor profitability (TFP) (Cucculelli and Bettinelli, 2015), among other financial indicators.

On the other hand, subjective performance relies on stakeholder's perception of performance (Bierwerth et al., 2015). Although these indicators are based on intangible and subjective measures, they play an important role in accounting for the complexity of both internal and external forces influencing a company's performance. Taking into consideration that objective indicators fail to account for long-term outcomes and predict future performance, subjective performance is crucial to have a more global evaluation of the firm's real performance (Ali et al., 2016). Data regarding firm's subjective performance is usually collected through surveys and judgmental questions while involving different stakeholders, and generally goes through both quantitative and qualitative analysis. Examples of subjective performance indicators include customer satisfaction, employee satisfaction, perceived profitability, and manager's opinion. These aspects of a company's performance are considered to be strategic assets that although do not necessarily materialize into direct financial gains, they do have a considerable effect on the overall firm's performance.

Non-financial performance directly relates to intangible assets. Such idiosyncratic resources, such as R&D capabilities and licenses, represent a considerable performance driver. They are specifically identified as key resources in gaining competitive advantage in innovation-driven industries as well as for companies operating in international markets (Hsu et al., 2011). The relevance of intangible assets has been repeatedly proven in existing literature. However, an established framework to account for it is still missing. Literature recognizes the importance of performance frameworks taking intangible performance proxy indicators into account while evaluating a firm's performance. For instance, Cucculelli and Bettinelli (2015) used in their study the financial value of R&D and advertising expenses as a performance measure.

Based on the above discussion we suggest the following proposition:

Proposition 4: Firm performance encompasses both objective and subjective measures and indicators. Non-financial measures account for the intangible performance of a company. Such performance relates to the use of idiosyncratic resources that reflect the company's potential to grow and generate value for its stakeholders.

5 Entrepreneurial orientation and firm performance

Entrepreneurial orientation has been repeatedly proven to positively impact firm performance both at the organizational level, but also at the level of enterprise clusters. This means that within high-entrepreneurial orientation firm clusters, both the overall cluster and the firms' individual performances are positively affected (Yao et al., 2009). The existing literature considers different indicators to measure such an impact. Most researchers used different financial (Goosen et al., 2002), and non-financial (Mohammed et al., 2017) indicators to account for firm performance as a consequence to entrepreneurial orientation. Abosed et al. (2018) for instance took manager's perceived international business performance as an indicator. They proved the significant effect of five items of corporate entrepreneurship on international performance. They concluded that Nigerian banks that are expanding internationally are affected by their engagement in corporate entrepreneurship, and thus should adopt innovative, venturing, and proactive strategies. Ambad and Abdul Wahab (2016) also investigated the effect of corporate entrepreneurship on the performance of Malaysian large companies. This research used profitability and growth as dependent variables, while considering the moderating effect of environmental dynamism. Their study confirmed the positive impact of entrepreneurial orientation and precisely the willingness to innovate, risk-taking, and reactivity on both the profitability of the firm and its growth. In uncertain environments, entrepreneurial activity proved to have a stronger impact on the overall performance and consequently on the firm's survival chances. From another perspective, the relationship between corporate entrepreneurship and firm performance was explored through the IQP model (Innovation – Quality – Performance). This model suggests that innovation has a positive effect on product and service quality, which in turn positively affects the firm performance (Cho and Pucik, 2005). The model was proven empirically in earlier studies in the 90s, but a more recent study by Cho and Pucik (2005) also examined this model demonstrating that innovativeness was mediating the positive impact of quality on growth, and that quality mediated the impact of innovativeness on profitability. Results also showed that innovativeness has a direct impact on quality, and also an indirect impact on market value. Technology has also played an important role in improving firm's products and processes. The role of technology and technological updates have been emphasized in both Tech and non-Tech industries. As technology is becoming a central tool in business operations, it was also considered as an inhibitor of entrepreneurial activities. A study conducted in the Netherlands concluded that technological infrastructure is necessary to boost firms' entrepreneurial orientation

through facilitating knowledge acquisition and sharing, as well as integrating different business processes (Rojas, 2014).

A meta-analysis conducted Bierwerth et al. (2015) identified 42 studies whose samples include 13,237 firms. Common indicators across these studies were considered. The indicators of corporate entrepreneurship included: strategic renewal, innovation, and corporate venturing, while the three indicators for firm performance were: subjective performance, objective performance, and overall performance. The analysis tested the suggested hypotheses separately with the moderating effect of firm size, low-tech and high-tech industries, and also across the continents of America, Asia, and Europe. Results show that generally corporate entrepreneurship has a positive relationship with the overall performance, and more precisely a stronger relationship with subjective performance. The effect of strategic renewal and innovation were more significant on the subjective performance, while corporate venturing had a stronger effect on objective performance. Regarding firm size, the study proved its strong moderating effect between strategic renewal and firm performance, indicating that the larger the firm size, the stronger the relationship is. The analysis also found that industry is a significant moderator for the relationship between innovation and firm performance. The relationship is indeed stronger in high-tech industries. Regarding the country of origin, the results show that in Europe and Asia the relationship between corporate entrepreneurship and firm performance is stronger than in North America. This meta-analysis ended up reinforcing the conclusion that most existing literature came up with, demonstrating the positive impact of corporate entrepreneurship on firm performance. However, the analysis pointed out the differences in the magnitude of the impact across different types of entrepreneurial activities. Firms need to take into account such variations while engaging in corporate entrepreneurship practices, which also suggests that firms need to consider the different time frames necessary for these practices to yield any performance effects.

Studying the mediating factors of the relationship underpinning corporate entrepreneurship and firm performance remains crucial to explain the low performance of some firms despite having managers and employees who clearly display a strong entrepreneurial drive. For instance, in their study, Real et al. (2014) used a 140 questionnaire responses to test a model in which organizational learning and the firm's size were used as moderating factors between entrepreneurial orientation and learning orientation on one hand, and the perceived performance of a firm on the other hand. Results confirmed the importance of organizational learning in generating valuable knowledge and competences from entrepreneurial experiences. Corporate entrepreneurship contributes to the firm's performance through the process of learning and competence acquisition. Firms need to actively engage not just in the promotion of entrepreneurial activity but also in entrepreneurial learning. Another study attempted to investigate the relationship between entrepreneurial orientation, organizational learning, and firm performance, while considering a sample of 200 managers from 200 companies located in Brazil (Vasconcelos et al., 2016). The study conducted a descriptive quantitative survey and confirmed the strong positive relationship between entrepreneurial orientation and organizational performance across young, under

development, and mature businesses. Entrepreneurial orientation becomes a critical factor to the survival of small businesses in uncertain environments. The results also proved the considerable effect of organizational learning and suggested that businesses should establish structured learning processes to direct entrepreneurial orientation towards higher performance. Companies should engage in entrepreneurial guidance in order to improve firm's performance, and also for young companies to be competitive and have higher survival chances.

Research about start-up success and failure chances also proven that entrepreneurs who have been involved in prior entrepreneurial ventures have considerably more chances in succeeding in their second and third endeavors (Politis, 2005). This suggests that through the internalization of entrepreneurial experiences, the entrepreneur gains knowledge, skills, and attitudes that are valuable to his/her next endeavour (Minniti and Bygrave, 2001). Entrepreneurial learning is experiential in nature and differs from the conventional organizational learning since it is not transmitted through structured training but through real experiences (Richard & Leitch, 2005). It is critical to gain more insight about the type of entrepreneurial experiences and the learning processes that generate these valuable capabilities (Politis, 2005). It is also important to investigate how entrepreneurs process this newly gained information to update their decisional algorithms (Minniti and Bygrave, 2001). While making daily decisions and judgement, it is argued that entrepreneurs do not rely on exhaustive data collection and analysis but rely instead on heuristics to simplify the complexity of such situations. Although heuristics sometimes lead to errors and inaccuracies, they proved to be an effective cognitive process that generally results in reasonable judgements (Holcomb et al. 2009). Such heuristics not only influence the decision making of entrepreneurs, but also help them give meaning and extract learning outcomes from their entrepreneurial experiences. In rapidly changing industries such as technology, the importance of entrepreneurial learning is paramount to performance and success (Rae, 2006). The need for systematic knowledge updates seems more obvious in the tech field as there are considerable advances occurring at such a fast pace which requires non-structured, continuous, experiential, introspective, and social learning channels (Kelly, 2016).

Park et al. (2017) investigated the effect of entrepreneurial failure experiences on firm performance. The study was based on the human capital and entrepreneurial learning theories implying that entrepreneurs learn from their previous entrepreneurial experiences and contribute to firm's human capital (Harrison and Leitch, 2005). Considering financial and non-financial performance as dependent variables, the study demonstrated a reverse U-shaped relationship between failure in entrepreneurial activity and performance. A certain level of failure in entrepreneurial endeavors adds to the human capital's learning and positively contributes to the firm's financial performance. However, if failure exceeds a certain level, the relationship starts to negatively impact the financial and non-financial performance. This significant correlation was tested for firms that experience failure, but no significant relationship could be proven in the case of companies that had both success and failure experiences.

This leads us to the following proposition:

Proposition 5: Entrepreneurial orientation positively affects both objective and subjective performance. Endogenous factors mediate such an impact, including firm size, innovation, quality, and managerial structure. Experiential learning reinforces the organization's entrepreneurial capabilities but also contributes to nurturing, enriching, and directing the entrepreneurial orientation, at the individual and organizational levels, to attain better performance.

6 Research implications and future research agenda

We believe that by introducing a framework that demonstrates the link between HRM practices, entrepreneurial orientation, and firm performance the paper provides a significant clarification of how human resource development drive value-generation dynamics. This research also provides a step further towards understanding the concept of entrepreneurial orientation as a performance driver.

This paper is also consistent with the knowledge-based view of the firm by emphasizing the dynamic nature of entrepreneurial learning inside the firm, and suggests a conceptualization of some ideas which have recently emerged in HRM and entrepreneurship literatures, offering convergence of ideas and improved definitions of the discussed concepts as well as their relationships. It therefore provides another step towards a 'common language and understanding'.

We believe that the research presented in this paper lays a foundation for further theoretical and empirical inquiry into the nature of HRM processes, entrepreneurial capabilities, and the sources of sustainable competitive advantage. Beyond the fact that this research furthers our theoretical understanding, we hope it provides useful avenues for further empirical inquiry as well as in-depth case studies to find practical evidence of the propositions underpinning the theoretical framework as outlined in this paper. Even with an initial theoretical framework, we still know little about the specifics of how HRM, learning, and intrapreneurship drive sustainable competitive advantage and firm performance.

Abstract

The role of social capital in entrepreneurship has become an increasingly prominent topic in business literature, and the debate about pros and cons has become increasingly complex. This study aims to shed light on the pre-conditions (the so called 'genius loci') that, by leveraging social capital, favour forms of participatory territorial governance aimed at enhancing regional development and wellbeing, also through the spur of high-tech startups.

We focused on a paradigmatic case study: the Marche Region, (Italy). Indeed, in the age of the so-called "Italian economy miracle", the Marche region was an example of flexible specialisation and the development of industrial clusters and districts, investigated by renowned researchers.

The case we have explored focuses on innovative Marche startups and aims to understand if and how the sharing of shared values linked to the history of the territory can still be the source of social capital that allows new businesses to benefit from positive externalities.

From our analysis, focused on the behaviour of three key players of the entrepreneurial ecosystem of the Marche region (the PA, the new crowdfunding platforms and universities), evidence would appear to confirm what has already emerged from other research..

Indeed, social capital is the glue that decrees, at a meso-level, the success of local development thanks to the form of governance and territorial social responsibility promoted by networks of local actors, public and private, who are oriented to sustainable development.

Keywords – entrepreneurial ecosystems, sustainable local development, social capital, Italian Regions

Paper type – Academic Research Paper

1 Introduction

"Entrepreneurial ecosystem" has recently emerged as a popular concept to explain the birth of high-growth entrepreneurship within regions (Stoker 1988 and 2006; Spigel, 2017). In this regard, one aspect that requires particular attention is the link between ecosystems and the endowments distinguishing a territory.

When talking about endowments distinguishing a territory, we are not only referring to the resources made available to entrepreneurs in terms of accessibility and facilities concerning financial capital, skilled human resources (human capital) and new technologies in infrastructure. We are also referring to social capital, which is *the set of personal relationships, trust and cultural, social, institutional and economic bonds that allow entrepreneurs to benefit from positive externalities* (Putnam et al., 1994; Helliwell & Putnam, 1995; Sobel, 2002; Bourdieu, 2011).

Drawing from these perspectives our study aims to shed light on the pre-conditions that, by leveraging social capital, favour forms of participatory territorial governance (Del Baldo & Demartini, 2012, 2014 and 2016) aimed at enhancing regional development and wellbeing, also through the spur of high-tech startups.

We call these preconditions the *genius loci*. In Greek and Roman mythology each location was linked to a particular tutelary deity or *genius loci*. The *genius loci* had a particular relationship with the harmony of the location and presided over the good relationship between the different elements present in the surrounding environment.

The formation of a place's soul was intended as the result of a long process, the accumulation of values, feelings and experiences handed down by generations of the people who had previously lived there. Therefore, the *genius Loci* is the sediment of memories and collective stories that characterise a specific territory that feeds the sense of belonging and commonality of the people who live there.

Social capital, which economists have described as a fundamental factor for the birth and development of industrial districts and the territory, depends, in turn, on what we have mentioned above and labelled *genius loci*.

Thus our paper's two related research questions are as follows:

- a) how does the *genius loci* influence social capital?
- b) how does social capital influence the spur of entrepreneurship?

The paper is structured as follows. In Section 2, a brief review of the relevant literature is presented. Section 3 details the methodology, and Sections 4 summarises the findings of our analysis. Finally, Section 5 provides a research agenda for a more in-depth investigation in the future.

2 Literature Review: Social Capital, Entrepreneurship and Entrepreneurial ecosystems

The role of social capital in entrepreneurship has become an increasingly prominent topic in business literature, and the debate about pros and cons has become increasingly

complex (Casson and Della Giusta, 2007; Light and Dana, 2013; Ramadani and Dana, 2013).

As per the definition of Bourdieu (1986), social capital describes circumstances in which entrepreneurs can use membership in a community and networks to secure economic benefits. This formulation treats social capital as an attribute of an individual that cannot be evaluated without knowledge of the society in which the individual operates (Putnam et al., 1994; Sobel, 2002).

Firms' relationships within regions have been explained through concepts such as industrial districts (Becattini, 1990) and clusters (Porter, 2003). Both streams consider social relations with a community and the actors of the territory, as a fundamental element of the birth and success of enterprises (Minguzzi and Passaro, 2000). In the recent past, the economic geography of clusters has been changing, with new clusters developing in some locations (Bresnahan et al. 2001) and some old clusters, facing intense pressure because of globalisation, which loosens ties with territorial roots.

Recently, the entrepreneurial ecosystem has emerged as a popular concept to explain the birth of high-growth entrepreneurship within regions. Entrepreneurial ecosystems can be defined as “the union of localised cultural outlooks, social networks, investment capital, universities, and active economic policies that create environments supportive of innovation-based ventures” (Spigel, 2017). However, ecosystem literature is still underdeveloped.

One aspect that requires particular attention is the link between ecosystems and the talents and endowments distinguishing a territory, the so-called *genius loci* (Pellegrini et al., 2015). Social capital includes personal relationships, trust and bonds of various kinds (emotional, cultural, social, institutional and economic) that allow entrepreneurs to benefit from positive externalities. Personal relationships can take the form of informal relationships with family and friends. This networking, specifically in the initial phase, is particularly important to bring out intangible resources and competencies of various kinds, such as technological, commercial, administrative and organisational capabilities, that a single entrepreneur hardly possesses (EIU, 2016; Romano et al., 2017). Also, relationships with the community and the territory are equally important because they can facilitate the procurement of financial resources, through mechanisms such as crowdfunding (Giudici et al., 2018).

Furthermore, strong relationships with a local community and business network are even more crucial in shaping small businesses and family firm innovation activities. Historical roots and emotional attachment might also become a source of ideas and knowledge, whose recombination with new technologies or new meanings leads to unique innovations (De Massis et al., 2016).

Finally, another aspect that should be analysed and deepened is whether social capital is the glue that decrees, at a meso-level, the success of local public-private initiatives (Lerro and Schiuma, 2008), thanks to the form of governance and territorial social responsibility promoted by networks of local actors, public and private, who are oriented to sustainable development (Demartini and Del Baldo, 2015).

3 Methodology

In order to answer our RQs:

- 1) how does the *genius loci* influence social capital?;
- 2) how does social capital influence the spur of entrepreneurship?;

a qualitative methodology was adopted: the case study (Yin, 2013; Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Flick, 2009), because it is a research strategy whose goal is to understand in practice, the dynamics characterising a specific phenomenon.

3.1. Case selection

When selecting the case to be analysed the following reasoning was investigated. First, it was necessary to identify a territory that was characterised:

- by the presence of civil society actors, institutional and economic, characterised by a high level of interaction and attention to the issues of social responsibility;
- by an entrepreneurial fabric that has historically made social capital one of its strengths and is still today characterised by a high rate of entrepreneurship and the birth of new businesses.

The presence of these two factors allows us to investigate the "roots" (or *Genius Loci*) of social cohesion among local actors and how this influences social capital at the base of the birth and development of local businesses.

That said, we focused on a paradigmatic case study. We selected the Marche Region, (Italy) as the territory for our analysis for the following reasons:

- The Marche region is an example of regional governance based on multi-actor (i.e., public, private, for-profit and non-profit organizations and civil society) engagement (Del Baldo & Demartini, 2016, 2018).
- After the Second World War, in the age of the so-called "Italian economy miracle" the Marche region was an example of flexible specialisation and the development of industrial clusters and districts, investigated by renowned researchers (Fuà & Zacchia, 1983; Fuà, 1988; Becattini, 1990; Helliwell & Putnam, 1995; Porter 2003).
- Today, after the crisis that hit the companies of traditional manufacturing sectors (Balloni & Iacobucci 2004), the Marche regions is still among the regions of Italy with the highest activation rate of innovative start-ups in proportion to the population, with Ancona and Ascoli Piceno among the top five provinces in Italy (Register of Companies—Italian Chamber of Commerce, 2018).

3.2. Data gathering and analysis

To answer the first question: how does the genius loci influence social capital? We analysed the literature of economists and historians on the economic development of the

Marche region (among other Bagnasco, 1977, 1988; Paci, 1980; Fuà & Zacchia, 1983, Sori, 1999).

To answer the second questions: how does social capital influence the spur of entrepreneurship? We analysed, gathering information from multiple sources (academic articles, websites, interviews released to newspapers), how the main actors of the Marche entrepreneurial ecosystem support the spur of innovative start-ups. Our aim is to assess whether elements such as social cohesion, trust and shared values, can still be considered critical success factors for the creation of innovative start-ups.

In particular, we will analyse the behaviour of actors such as public administration, crowdfunding platforms (as an expression of civil society) and universities, as key players in the entrepreneurial ecosystem aimed at encouraging the creation and development of innovative startups.

The data we collected, focusing our attention on the role that social capital plays today in the birth and development of new businesses, are signs of an emerging phenomenon whose features have not yet been analysed by scholars. For this reason, our research is exploratory, and we adopted the critical analysis approach. In detail, a critical analysis is subjective writing because it expresses the writer's opinion or evaluation of selected texts and data. The objective of this preliminary analysis is to develop a sense of new understanding of the links between *Genius Loci* and social capital in the light of a renewed economic and social context and to develop a research agenda for further investigations.

4 Findings

4.1. The Marche Region *genius loci*: values and roots

In recent years, the perspective with which one looks at the processes of industrialisation that took place in Italy and other advanced countries has changed. In fact, scholars of economic development have given a growing space to the territory and the social environment within which companies are born and develop.

Economic historiography, in particular, has aimed at an analysis on a regional scale with a long-term perspective. This optic has allowed us to identify the "multiple local models of development" (Pollard, 1984, pp. 188-206), offering a plurality of alternatives to the classical model for a long time considered the only possible one, namely that of the << English industrial revolution >>, characterised by a strong and sudden acceleration of the accumulation process that occurred in the eighteenth and nineteenth centuries.

It is precisely from this change of perspective that the reality of the *Terza Italia* (Bagnasco, 1977) or the North-East-Centre (Fuà and Zacchia, 1983) emerged.

Indeed, more precise analyses have shown that many of the Italian districts are rooted in a humus made fertile by previous manufacturing experiences already in the medieval age (from the 13th to the 16th century)¹.

¹ Scholars that deal with the industrialisation of the North-East-Centre cannot forget that Italy does not enter the ranks of the most advanced countries in the twentieth century, but that for several centuries, from the early

In the Marche region, these proto-industrial activities were carried out in the form of craftsmanship in the numerous inhabited centres of medium-small size scattered throughout the territory which, despite their low demographic weight, had the name of the city. Moreover, it is precisely in the Italy of the Municipalities and the "hundred cities" that economic historians have rediscovered the roots of the widespread entrepreneurship that characterised the development of the *Terza Italia* (Moroni, 2001 e 2002; Sabbatucci Severini 1996).

Among the many factors that have contributed to the genesis of entrepreneurial development in the Marche region, the particular production relationships present in the countryside deserve to be mentioned.

Economic historians (For all, see: Paci, 1980) have underlined how important the role of the peasant family, organised as an autonomous productive unit, in transmitting to future generations not only "know-how" and the organization of work but also a set of values that constituted the social amalgamation that allowed the development of local production systems after World War II.

For our purposes, it is especially important to underline the heritage of values that are particularly widespread in the peasant world of the time that constitute the genetic heritage of many entrepreneurs of the second post-war period: the aptitude for cooperation, the ethics of work and sacrifice, orientation towards savings aimed at the purchase of land, the constant desire to improve the social status of family members (Sabbatucci Severini, 1985).

The process of modernisation and the structural transformations that took place in the second post-war period in the Marche region, in fact, occurred combining modernity and tradition, social changes and cultural persistence (Fuà and Zacchia, 1983).

The birth of local production systems (or "industrial districts", Becattini, 1979), which are based on forms of collaboration and trust between companies within a division of labour often organised by a directing company, are also justified, as the work was organised and subdivided among the members of the peasant family (Paci, 1999).

The numerous cases of excellent small and medium-sized enterprises oriented to CSR are also explained, in which entrepreneurs carry out a mission for which the purpose of the company is to create wealth for all those that have decreed its success: employees, suppliers, business partners, customers, as well as in the peasant family of the past. The aim was to improve the social conditions of all members of the group to which they belong (Del Baldo, 2010,2013).

Last but not least, even in a historical key, we explain the attachment to the territory and the sense of belonging to a local community (Crevoisier, 1996; Midtun, 2005) that, even today, characterises public and private actors and, more generally, the Marche civil society.

The influence of local communities on small businesses in the Marche region is expressed, therefore, at various levels, offering the cultural, institutional, political and social milieu that allowed them to reconcile, throughout the years of economic

thirteenth to the early seventeenth century, our country was the centre of the European economy-world (Braudel, 1979).

development, new industrial activities with the identity and traditional values of the local society.

Putnam (1993) underlined the importance of a widespread associative fabric, which has contributed to creating cohesion and promoting efficiency at the political-administrative level. Triglia (1986) investigated the role played by political subcultures (Catholic and social-communist) in promoting less conflicting social relations between capital and labour. Bagnasco (1988) noted that the objective of reconciling competition and cooperation has safeguarded social cohesion and, at the same time, guaranteed the growth of the widespread economy.

It is, therefore, this set of intangible, socio-cultural factors that, in our opinion, constitute the premises that determine collective and individual attitudes favourable to the widespread social responsibility and that characterise social capital on which the Marche entrepreneurs have levered in the era of “the Italian miracle”.

What should now be explored is whether, even today, the various institutional, economic and social actors of the Marche region still have a shared vision on the subject, shifting the perspective from the second world war to the emerging phenomenon of innovative start-ups, whose birth and development cannot ignore the existence of a local entrepreneurial ecosystem.

Based on what has been analyzed, our hypothesis is that the *genius loci*, which we have discussed, is still alive in the Marche civil society, and this can be leveraged as a factor in the development of the territory even today because, as is known, the socio-cultural factors are elements that develop their training and evolution times over the long term.

4.2. Innovative startups and social capital

The economy of the new millennium is driven by new political, social, environmental and technological changes. The development of territorial economies is based on the ability to be competitive and to know how to renew itself thanks to the vitality of its businesses.

The birth of new innovative companies is considered a fundamental element of the vitality of a production system (Romano). Hence, we focused our analysis on the Italian context, where with law 221/2012, the definition of an innovative start-up, which is a new innovative enterprise of high technological value, has been introduced with the purpose to provide a favourable environment for the establishment and development of innovative companies. The legislation in question does not apply to all newly established companies but just to those that present a clear connection to technological innovation, regardless of their sector, be it software, manufacturing or agriculture.

The goals of the Italian Government seem to be multifaceted, as follows: to support innovative entrepreneurship; to contribute to greater social mobility; to strengthen the links between universities and businesses; to make people more inclined to take business risks; and to contribute to making the country more attractive for foreign capital and talents.

In this contest, we can see how fundamental an entrepreneurial ecosystem is in supporting the birth and development of innovative startups. In the literature, an

entrepreneurial ecosystem is defined as “the union of localised cultural outlooks, social networks, investment capital, universities and active economic policies that create environments supportive of innovation-based ventures”.

Based on this definition, in the following section, analyzing the role of three fundamental actors: the Public Administration, the new crowdfunding platforms and the universities, we will highlight whether and how the sharing of shared values linked to the history of the territory can still be a source of social capital that allows new companies to take advantage of positive externalities and gain benefits in terms of obtaining resources (human, capital and infrastructural).

4.2.2. The role of local PA and other institutional actors in supporting innovative startups

In recent years, the role of regions in supporting the Italian startup ecosystem has been strengthened and clearly defined at the institutional level through regional policies, funding, measures and projects in the context of the European and national policy that aims to support the development of young innovative companies with high growth potential and their partners, primarily accelerators and incubators. A clear direction of the local government emerged in support of the startups always with the view of involving the various actors and through synergistic local forms of collaboration, involving research centres (starting with universities), business associations, professional associations, companies and civil society organizations.

With specific reference to the Marche region, a clear direction of the PA emerges in support of innovative startups. “The role of the regions must increasingly be to support the development of an adequate ecosystem to promote the growth of innovative startups, through targeted policies both from the point of view of forms of financing and from the point of view of services and technological and organizational networks, avoiding the fragmentation and overlapping of roles and interventions, thanks to a strategic coordination between the various actors” (Regional Councilor for Economic Development).

This direction is also expressed through concrete, supportive actions. In fact, the Marche Region has dedicated an important part of its policies in recent years to support the start-up and consolidation of new entrepreneurial activities on the market, also through specifically dedicated tenders, issued on the resources of the ROP ERDF 2014-2020 and POR ESF 2014-2020.

The birth and affirmation of new companies in innovative sectors on the market represent a driving force for the development of the regional system, a fundamental and strategic element for renewing and dynamising the local productive fabric for the Marche Region. “An indispensable opportunity to respond to future challenges and create new business models that could serve as technology providers by offering our traditional companies high-value services and technologies to innovate and be competitive nationally and internationally”. (Regional Councilor for Economic Development).

In summary, borrowing from the words of Fuà and Zacchia (1983), the shared objective remains the development of an entrepreneurial system “without fractures”, and of “renewal in continuity”.

4.2.2 Crowdfunding and social capital

Through equity crowdfunding platforms, startups can directly collect capital from private individuals contributing to the improvement of fundraising. Evidence exists that geography matters in crowdfunding, especially if reward-based (Ordanini et al., 2011; Agrawal et al., 2011; 2015). The overarching idea of this research stream, in line with our research focus, is that geographical proximity reduces information asymmetries, which are particularly severe in crowdfunding.

What is even more relevant for our study is that Del Giudice et al. (2017) documented that the *altruism* of people residing in the area increases the likelihood of success of crowdfunding. Additionally, the authors' findings suggest that the strength of this effect depends on the level of *localised social capital* (measured following the approach of Laursen et al. 2012a)

As far as the Marche Region is concerned, we have highlighted the case of the Platform Next Equity, held by Next equity crowdfunding Marche Srl, born thanks to an agreement with the University of Camerino to promote innovative ideas, which was one of the first actors operating in the equity crowdfunding field in 2014. Now there are 32 platforms authorised by the Supervisory authority in Italy (Consob), and three of them are located in the Marche Region.

As it emerges from the last report by the Crowdfunding Observatory of the Milan Polytechnic (2016, 2017, 2018), the Marche Region is quite active, being second only to the Lombardia Region, as individuals and entity investors. In particular, this, in our opinion, seems like an important sign for the purposes of our investigation, aimed at witnessing a level of outreach and engagement expressed by civil society and economic operators in support of new local entrepreneurship.

Another aspect that can be useful to highlight is what the characteristics of the entrepreneurial ideas that have been launched and funded by crowdfunding platforms are, again to assess whether, from the nature of the projects, how the awarded projects are those that present a mission based on common values and shared by the Marche civil society emerges. So far, Next Equity has already financed 4 entrepreneurial projects with success, and 5 others are still running, and from the analysis of the entrepreneurial projects on the platform website, we can see how different businesses develop in the agriculture, bio-technologies, green economy and social field. All this testifies to a correspondence with the values of the *genius loci* of the Marche region: respect for the territory and attention to social issues.

4.2.3. The role of the Universities

In the last decade, Italian universities have developed the institutional purpose of the third mission, which has become an integral part of the policies aimed at developing the themes of social responsibility and orientation towards sustainability.

With specific reference to the Marche, the universities in this region strongly support projects of entrepreneurial contamination and the birth of new enterprises through activities of pre-incubation of ideas with entrepreneurial potential, incubation and

dissemination activities. In particular, we cite, among others:

- the CultLab project (partners: Urbino University, Macerata, Consorzio Meccano), a Creative Business Incubator united in a temporary association of purpose—"CultLab—Spin-off of cultural enterprise" of the inter-territorial cooperation project "Advanced Cultural District of the Marche—Spin-off for the selection of business ideas in the culture sector with features of product and service innovation.

- the ECAPITAL project, business plan competition (partner: Univ. Politecnica, University of Urbino and ISTAO with Adriatic Startup School) Funded by ISTAO and Fondazione Marche

- the BP Lab project (Partner: Urbino University, Marche BP Cube incubator), a competition reserved for students, graduate students and alumni of the University of Urbino in order to select, train and entrepreneurize competent teams and innovative ideas. This project is part of a preliminary phase (pre-incubation), dedicated to focusing on and validating the idea and, finally, verifying the entrepreneurial attitude of the participants.

- collaboration with the local entrepreneurial fabric carried out through research centers, such as the CRIMPI Research Center on Entrepreneurship and Small-medium firms, active at the University of Urbino. The centre aims for the development of collaborative relationships with other universities, companies, bodies and institutions (local, national and international) in the context of the processes and management dynamics of small and medium-sized enterprises and to this end intends to promote agreements and other forms of understanding.

5. Conclusions, limitation and future research

To answer our research questions, we focused the analysis on an Italian territorial case that we consider paradigmatic for our purposes: the Marche region, the territory of the "Terza Italia", which in the past has been the subject of international analysis, as an example excellent of widespread entrepreneurship.

From our analysis of the founding values of the social fabric of the Marche region (the so-called "genius loci"), we have found that social capital has been a fundamental element for the creation of new businesses and the development of the Marche economy from the second post-war period to the present.

Today it emerges how territorial entrepreneurship can no longer be separated from a systemic logic in which different actors play a fundamental role, as is evidenced by the research stream in the entrepreneurial ecosystem. The case we have explored focuses on innovative Marche startups and aims to understand if and how the sharing of shared values linked to the history of the territory can still be the source of social capital that allows new businesses to benefit from positive externalities and obtain benefits in terms of obtaining resources (human, capital and infrastructural). From our analysis, focused on the behaviour of three key players of the entrepreneurial ecosystem of the Marche region (the PA, the new crowdfunding platforms and universities), evidence would appear to confirm what has already emerged from other research on the territory's development. Indeed, social capital is the glue that decrees, at a meso-level, the success of local

development (Lerro and Schiuma, 2008), thanks to the form of governance and territorial social responsibility promoted by networks of local actors, public and private, who are oriented to sustainable development (Demartini and Del Baldo., 2015).

However, it should be emphasized that ours is an explorative analysis subject to limitations.

In our paper, we have adopted a critical analysis approach. In fact, the answer to the questions we asked ourselves is based on the critical reading of literature.

With particular reference to the phenomenon of innovative startups, whose birth and development cannot be separated from the existence of a local entrepreneurial ecosystem, we have also used some partial empirical evidence that can be defined as signalling the importance that still today plays the role of social capital. We deem that it is an emerging phenomenon that has not yet been studied extensively in the literature and that deserves further attention from researchers and policymakers.

A Research Agenda

The research agenda begins with the questions that our analysis brings out and calls for empirical and conceptual articles that could be based on diverse theoretical and methodological approaches for examining the role of social capital in the birth and the development of entrepreneurship and entrepreneurial ecosystems:

- What are the pre-conditions that favour/hinder the development of social capital in different territories?
- How has the concept of belonging to a territorial community for entrepreneurs changed today?
- What is the role that public administration can play in favouring the economic development of a territory by leveraging social capital?

Using Academic Entrepreneurship for Digital Economy Development

Diana Artemova

Saint-Petersburg State University
Universitetskay Emb., 7/9
Saint Petersburg, 199034, Russia

Abstract

The paper is devoted to examining the possibility of developing digital technologies through academic entrepreneurship, which can in its turn boost digital economy implementation. Nowadays, universities are under the process of increasing their part in regional and national socio-economic growth. That objective can be reached with universities' technologies commercialization and Triple Helix collaboration. In Russia, this process is far from the level established by the government. At the same time, Russian authorities put forward ambitious goals for digital economy development. In the government's strategic plans, universities are considered as one of the pillars for that. Universities' administrations have to identify ways to facilitate digital technologies transfer, which forces them to intensify academic entrepreneurship as well. That will require implementing of new forms of management, new official and unofficial organizational rules, and specific support system. Nevertheless, academic entrepreneurship based on digital technologies has a number of advantages. Part of them is attributed to lower consumption of the resources needed to commercialize such technologies. Another advantage comes from young people's and commercial organizations' craving for digitalization. Three forms of academic entrepreneurship (creating spin-offs, joint research and licencing) are reviewed as methods of digital technologies commercialization.

In the last section of the paper, a few hypotheses for the future research are formulated. The goal of the research is to assess differences in perception of business creation and academic entrepreneurship among the respondents from two prominent universities: St. Petersburg State University and ITMO University.

Keywords – academic entrepreneurship, entrepreneurial university, university's innovation infrastructure

Paper type – Academic Research Paper

1 Introduction

In the last decades, the understanding of universities' part in technology transfer has dramatically changed. H. Etzkowitz calls this transformation "second academic revolution", which implies the inclusion of knowledge commercialization in university's main functions (along with traditional functions of research and education) [Etzkowitz,

2001]. This third university's function takes form of so-called academic entrepreneurship – commercial activity for the purpose of technology transfer performed by faculty members, students and graduates of the university. Through this activity, universities become a vital component of Triple Helix collaboration that is the basis for the future economic growth in regions and countries.

Simultaneously, the digital economy concept also requires modern universities to redesign their traditionally established models. Digitalization changes both business practices and education procedures. Since scientists expect digital economy to occur in the nearest future, it is necessary to start modify university practices in the present.

Therefore, the purpose of this paper is to identify advantages of academic entrepreneurship as a tool for digital economy development. In addition, the author frames the research of students' and faculty members with respect to entrepreneurship.

2 Academic entrepreneurship as a vital activity of modern universities

2.1 Forms of academic entrepreneurship

The essence of academic entrepreneurship is commercialization of a university's intellectual capital. That capital involves not only patents and other forms of IPRs, but also university's knowledge and its entrepreneurial ecosystem impact. As far as specific forms of academic entrepreneurship are concerned, they usually include 1) creating of enterprises (spin-offs or joint companies), 2) joint research with the business, 3) selling of technology licenses, 4) scientists' mobility, etc. Some scholars and universities (for example MIT) believe that creating business by alumni is also attributed to the university's impact and, therefore, that is one of the forms of academic entrepreneurship. Summing up, there is a great number of ways how a university can transfer its technologies to a practical application.

Academic entrepreneurship allows universities to receive additional financial resources in the short term, strengthen their status in the medium and long term, as well as to contribute to the socio-economic level of the region in which they are located. Recently, this activity has been also mentioned as a needed essential component for evaluating a university's rank [OECD, 2017].

For a university that actively implements academic entrepreneurship, a special term is used in literature – “entrepreneurial university” [Etzkowitz, 2013]. Among leading entrepreneurial universities in the world, experts name the following: Massachusetts Institute of Technology (USA), Stanford University (USA), Cambridge University (USA), Imperial College London (United Kingdom), Oxford University (United Kingdom), Technion (Israel Institute of Technology) [Brighton et al., 2015]. Obviously, most of leading entrepreneurial universities are located in the United States. That fact can be explained by the peculiarities of higher education system there (in particular, limited government funding of universities), and the established culture of active entrepreneurship. However, in other countries all over the world, a remarkable number of

universities has recognized the need for greater involvement in technology transfer and knowledge commercialization.

2.2 Ways of supporting academic entrepreneurship

One of the key attributes of entrepreneurial university is the specific support system that facilitates academic entrepreneurship in that university – the innovation infrastructure. The development of such infrastructure requires changes in university's structure, management policies and organizational culture. Specifically speaking, it is a set of particular departments (for example, technology transfer office, business incubator, etc.), procedures, formal and informal norms of the university. Obviously, universities vary considerably in their strategic objectives, size, status, financial capabilities, etc. A significant role is also played by the experience of academic entrepreneurship and partnerships with other universities, scientific and commercial organizations. In this regard, establishing and developing of the innovation infrastructure can take various forms.

In the author's opinion, one of the most important components of the support ecosystem is organizational culture and trust with regard to entrepreneurship in or together with a university. In Russia, most faculty members are focused on education and a little less on R&D. It was partly confirmed during the author's study of teaching and research personnel of St Petersburg State University. When conducting research and development, scientists rarely have plans concerning further implementation of its results in business practice. It is the reason why a university's management should identify and properly support "early adopters" of academic entrepreneurship. The first step could be regular surveys containing questions about business aspirations and preferred forms of university support.

A university can improve its support measures through finding and implementing best practices of the universities-leaders (benchmarking). It is especially true for Russian universities since they do not have much experience in academic entrepreneurship so far. For example, St Petersburg State University collaborates closely on this matter with Helsinki University (Finland), Technische Universität Ilmenau (Germany) and other universities.

3 Universities' role in digital economy development

3.1 Digital economy's effect on universities

In recent years, digital economy has become the prospect that cannot be disregarded. Business community pay much attention to digital technologies and the ways of how they can be implemented into business models. Yet, there is no unity in the definition what digital economy's characteristics are. Nevertheless, usually they refer to the active expansion of the ICT technologies and e-commerce [World Bank Group, 2018]. That fact means massive changes in interaction between all actors on markets. The process of

digital technologies implementing transforms processes of designing, manufacturing, delivering, maintaining and providing of services of any kind.

Obviously, universities have no other choice but to follow that trend. Most of all, it affects educational practices. Graduates must meet the requirements of the new digitalized business models. At the same time, it influences the other two main functions of universities – research and academic entrepreneurship. The leading universities all over the world take part in exploring of emerging digital technologies. For instance, The MIT Initiative on the Digital Economy (IDE) is a comprehensive research project that is focused on several areas:

- productivity, employment, and inequality;
- big data and information privacy;
- new digital business models;
- social analytics and digital experimentation [MIT Initiative on the Digital Economy, 2018].

Through this project, the MIT connect scientists and practitioners from different countries and industries in order to understand how digital technologies will change the world in the future. That helps the MIT to be fully engaged in the transition to digital economy and at the same time transform its educational and business practices.

In Russia, the State Program “Digital Economy” was approved in 2017 with allocation of the state budget financing of \$1.8 billons annually until 2025. The main goals of the Program include enhancing of the Russian economy competitiveness and the development of high-tech businesses. With respect to Russian universities, two main tasks are set: 1) proper personnel training; 2) conducting research and development in digital technologies [“Digital Economy of the Russian Federation” Program]. There is no doubt that universities should take part in the human capital development for digital economy and actively introduce innovative educational technologies for that [Richter, Pakhomova, 2018]. At the same time, the World Bank Report notes that there is still weak interaction between business, government, universities and research organizations (i.e. Triple Helix collaboration), which prevents formation of the digital ecosystem in the country [The World Bank Report].

Many Russian universities are considered as leaders in the field of digital technologies research, which can be the crucial in the development of digital economy. Academic entrepreneurship in such universities can make a significant contribution to achieving the goals set forth in “Digital Economy” Program. It also facilitates creating connections between various participants of the digital transformation.

3.2 Forms of digital academic entrepreneurship

As it was stated, universities should be engaged in digital technologies transfer, and not only because the government instructs them to. The first reason is that development of digital technologies has an advantage of relatively less needed resources than, for example, of chemical ones, also it takes less time to design and redesign digital products. The second reason is that young generation should be adequately educated in digital

technologies. Third, young people are especially interested in such technologies and eager to explore them.

Let us discuss some forms of academic entrepreneurship that can be used for digital technologies' commercialization in Russian universities.

1) *Creating spin-offs*. In Russia, the procedure for universities to establish small business enterprises was put into force only in 2009. Since then, 2013 spin-offs were registered [Accounting and monitoring...]. Universities' management rarely pays much attention to this activity, and spin-offs are created under the pressure of authorities and the government's requirements. The most threatening point in this process is uncertainty with regard to assessing spin-offs' performance. In many cases, universities set financial targets for them (such as revenue, profit, cash flow, etc.), which are almost unreachable for new technological businesses in the first years. For digital technologies, on the contrary, it is much easier to meet these requirements.

2) *Joint research with companies*. On the one hand, partnership with business contributes to the rapid transfer of digital technologies from university environment. On the other hand, it provides the reverse process – immediate feedback: information about the required improvements or product customization directions. In addition, business can form an exact request for a university to train the personnel with specific digital technologies' competences. Such cooperation can also result in creation of university spin-offs, though this form is not much widespread in Russia.

3) *Licensing*. Doubtlessly, developing of some digital technologies demands special equipment and competencies which are not available in a university. In such case, the IPRs can be offered for further commercialization in business organizations. Correspondingly, this form enables similar relationship between business and university as the previous one.

Thus, digital technologies development in the form of academic entrepreneurship can be embodied in a variety of forms. A university may choose the form based on its strategy, peculiarities and existing support system. In general, the main obstacle for academic entrepreneurship in Russia is the lack of collaboration experience both of business companies, and universities.

It is worth to emphasize that digital academic entrepreneurship also contributes to modernizing educational programs.

3.3 Proposed research on entrepreneurial component of university's organizational culture

The author has been conducting surveys of students' and faculty members' opinions and business aspirations. Based on the importance of supporting academic entrepreneurship in the sphere of digital economy, the next goal of the research has been set. It is planned to form the pull of respondents from the two major Russian universities that are situated in St Petersburg: St Petersburg State University (SPbU) and National Research University ITMO. SPbU is one of the biggest and oldest universities in Russia. It provides education and research in a wide range of fields – from physics and chemistry

to philology and psychology. Mathematics and Mechanics Faculty's alumni are among the most preferable candidates for companies of software development industry.

The ITMO was founded 100 year ago and used to be the educational institution in the field of mechanics, optics and watchmaking. Since those disciplines require profound knowledge of mathematics, it is no surprise that nowadays it is famous for its alumni's skills in programming and engineering. Additionally, one of the ITMO's goals is to support business initiatives of students and faculty members. It is intended to get answers from students of bachelor and master programs.

The survey is aimed at studying digital business aspirations and preferable ways of support of business creation in the sphere of digital technologies. The minor objectives are assessing dynamics of opinions (comparing to the previous results) and determining the share of early adopters among respondents.

Based on the results of previous research, preliminary hypotheses have been formulated as follows:

- students of major in economics tend to have lower business aspirations;
- students and faculty members are most interested in getting consultancy and entrepreneurial skills training as forms of university support;
- respondents with some business experience value different kinds of support;
- trust matters when creating of business is concerned;
- students and professors of the ITMO are more inclined to start business projects with the participation of their university;
- respondents from the ITMO are aware of entrepreneurship support in greater extent.

The answers obtained will be used to elaborate recommendations for enhancing innovation infrastructure in universities.

4 Conclusions

Universities must take an active part in digital economy development. They traditionally interact with young generation that consists of future producers and consumers of digital products. In turn, universities in Russia possess the widely recognized competence in digital technologies, which can partly provide the strong foundation for developing digital economy.

Summing up, it is necessary to highlight the promise of academic entrepreneurship as one of the tools for digital economy development. The commercialization of university technologies allows to increase the digitalization of business, to provide highly qualified and experienced personnel. However, universities' management is supposed to create the innovation infrastructure in order to support academic entrepreneurship effectively. Implementation of such support system in universities still requires close examination and taking into account opinion of students, research and educational personnel.

Abstract

This study investigates the effect of cross-country differences on online hotel reviews. More in details, it investigates differences in the way Italians, Americans, and Chinese travelers perceive and emphasize hotel attributes. Based on a random sample of 9,000 online reviews, the study used text link analysis to extrapolate the frequencies of predefined hotel attributes on which further multivariate analyses and tests were performed. Answers are provided to two research questions: Do travelers from different countries place different emphasis on hotel attributes? Do travelers from different countries perceive hotel attributes differently? Findings suggest that the differences in perceptions and emphasis are significant. The adopted text-mining method could be useful for hotel business managers to hear the voices of consumers and include them in performance evaluation and service design processes.

Keywords – user-generated contents; cross-country; perception; emphasis; text-mining; hotel attribute.

Nature of the proposed paper: Academic Research Paper

1. Introduction

Customer satisfaction has been defined as a customer's subjective evaluation of a product/service provided on the basis of expectations and actual performance. For example, when judging hotels, customers evaluate their degree of satisfaction based on how they perceive the attributes of hotels that they consider most important. Thus, evaluations of hotels attributes are considered dimensions of satisfaction. Investigating customer satisfaction is of interest as, according to a huge number of studies (e.g., Radojevic et al., 2018; Rajaguru and Hassanli, 2018), it plays a fundamental role in encouraging customers in making a recommendation to their friends, returning, and

giving positive reviews, thus affecting customers' behavioral loyalty and marketing signals.

In the tourism management literature, one significant challenge related to the study of customers' satisfaction and its antecedents is the diversity of consumers, which should be taken into consideration using segmentation (Bodet et al., 2017). Among segmentation variables, consumer culture has received growing interest and was recognized as crucial by several scholars (e.g., Bodet et al., 2017). With the trend of globalization and the emergence of culture-related issues, national and cultural differences have revealed their significance in explaining consumers behavior (Huang and Crofts, 2019).

Despite the recognized importance played in investigating the diversity of consumers, the debate as to 'if' and 'to what degree' national cultural differences should be considered remains unresolved (e.g., Huang and Crofts, 2019). On the one hand, a 'global consumer' perspective has emerged, grounded on the idea that all consumers share a common set of values, preferences, and behaviors (e.g., Nowak and Kochkova, 2011). Scholars belonging to this perspective believe that the cultural differences are collapsing, creating a smaller more homogenous world brought about by a variety of forces including the global media, the internet, economic unifications, and migration and tourism.

On the other hand, others (e.g., de Mooij and Beniflah, 2016) stressed that travelers have different expectations and preferences that are partly rooted in their shared societal or cultural values. This alternative perspective derives from the fields of psychology and anthropological psychology and assert that humans are predisposed, consciously or unconsciously, to break society up into different groups, thus creating an 'us' versus 'them' (Huang and Crofts, 2019).

This study attempts to add to this debate by investigating the effect of cross-country differences on hotels online reviews. More specifically, it is focused on two issues: (i) cross-country differences in terms of emphasis devoted to hotel attributes and (ii) cross-country differences in terms of perception of hotel attributes. This because contrasting findings emerged in the literature with reference to these issues. Therefore, questions such as "Do travelers belonging to different countries emphasize the same hotel attributes?" and "Do travelers belonging to different countries perceive similarly hotel attributes?" remain unanswered. Based on a random sample of 9.000 online reviews, the analysis adopted Text Link Analysis to extrapolate the frequencies of predefined hotel attributes on which multivariate analyses and tests were performed. Answers to the two research questions are provided. The text-mining method adopted could help hotel business managers to hear the voices of consumers and include them in performance evaluation and service design processes.

2. Emphasis and perception of hotel attributes

Schuckert et al. (2015) provided a theoretical summary of previous studies dealing with the effect of cultural differences on customer satisfaction. They classified them into four areas: differences in perceiving hotel attributes (perception difference), different expectations about hotel and service quality (expectation difference), emphasis given to

each hotel attribute or service aspect (emphasis difference), and different behaviors in complaint activities (complaint difference).

In the present study, cross-country differences were investigated with regard to emphasis and perception. For both types of differences, contrasting thoughts were identified in the literature, which made further investigation interesting. In the following, such thoughts will be presented as well as the research questions (RQs) emerging from the debates.

2.1. Emphasis difference

With the term emphasis, Schuckert et al. (2015) referred to the importance placed by travelers on various hotel attributes. In the hospitality management literature, one research stream is focused on understanding whether different cultural backgrounds determine significant differences in the emphasis placed by consumers on various hotel attributes. The large majority of studies compared eastern and western cultures. The results obtained by scholars were often contradictory both in terms of the existence of emphasis differences between users belonging to different cultures and which hotel attributes are emphasized by each cultural group of users.

As for the former (the existence of emphasis differences between users belonging to different cultures), some scholars (e.g., McCleary et al., 1998) found little difference in the importance placed by western and eastern travelers on various hotel issues, thus arguing that no such differences in emphasis exist. Others (e.g., Poon and Low, 2005) argued the opposite, that is, that significant emphasis differences exist between users belonging to different cultures.

As for the latter (which hotel attributes are emphasized by each cultural group of users), several contrasting findings were identified. Poon and Low (2005) argued that Asian travelers place more emphasis on factors such as pricing and staff hospitality, whereas Western travelers place more emphasis on hotel appearance. Regarding staff, Tsang and Ap (2007) proposed that Asians emphasize the staff's competence while Westerners emphasize the staff's attitude. Conversely, Kuo (2007) stressed that American travelers emphasize hotel employees' problem-solving abilities while Taiwanese customers are more affected by politeness.

Based on these contrasting findings, there is a question regarding whether groups of individuals from different countries emphasize hotel attributes differently, which leads to the following:

RQ1: Do travelers from different countries place different emphasis on hotel attributes?

2.2. Perception difference

When evaluating something, people can perceive the same product or service differently. The present study conjectures that an individual's country of origin (and thus his or her culture) could play a significant role in shaping his or her perception of hotel attributes. Weiermair (2000) argued that every country has its peculiar culture and unique perception of hotel attributes, so travelers from different countries may have remarkably different perceptions of the quality of the same service received. More recently, Hsieh and

Tsai (2009) found that cultural differences could create different perceptions of service quality.

Some scholars (e.g., Kuo, 2007; Tsang and Ap, 2007) stressed that Asian tourists, in general, tend to have higher expectations and to evaluate service performance less favorably compared to Western tourists. These authors offered the following reasons for these differences: (i) Asian cultures are collectivistic, and Asian tourists are likely to expect greater courtesy and consideration compared to individuals from less people-oriented and individualistic societies, and (ii) Asian tourists are likely to view themselves as being much more powerful than their service providers due to the fact that the power distance is higher in Asian cultures compared to Western cultures.

Conversely, other scholars (e.g., Zhang et al., 2008) stressed that individuals belonging to more individualistic societies, such as Americans and Europeans, have higher expectations in terms of service quality. Therefore, they should be generally less satisfied compared to Asians and should be stricter in their service evaluation.

Again, based on these contrasting findings, there is a question regarding whether groups of individuals from different countries perceive hotel attributes differently, which leads to the following:

RQ2: Do travelers from different countries perceive hotel attributes differently?

3. Research Settings

The methodological process followed in the study is described in the following Figure 1. In brief, the idea is to analyze UGCs with Text Link Analysis (TLA), using a commercial software able to identify specific parts of speech in the hotel reviews context, classify them according to a predefined number of categories and count the number of comments (frequency) for each category. Based on such extracted frequencies, a series of multivariate analysis and statistical tests were implemented to provide answers to the RQs.

Fig. 1. The methodological process.

Hotels and reviews were randomly collected from one of the leading online booking services Booking.com™. Specifically, 9000 reviews were randomly selected and downloaded.

Table 1 provides additional descriptive statistics:

Table 1. Descriptive statistics

Regions	4
Destinations	4
Hotels (total)	123
1-star	38
2-star	24
3-star	18
4-star	17
5-star	26
Average number of reviews per hotel (approximated)	73
Average length of reviews (words-approximated)	13

Reviews extracted in Italian and Chinese languages were translated in English by two professors, one for each language.

The resulting xls file included, for each review, the user's country (US, China, or Italy), and positive and negative textual comments in English (as Booking.com provides a distinction for positive and negative comments).

Then, hotels' reviews were analyzed through Text Link Analysis. Text link analysis is a pattern-matching technology that enables the definition of pattern rules and compares these to actual extracted concepts and relationships found in a given text. For the purpose of the present research, IBM SPSS Modeler Text Analytics was used. It relies on linguistics-based text analysis, which is based on the field of study known as natural language processing.

The extraction process was based on fine-tuned linguistic resources (libraries, types, synonyms, and more), labeled as Text Analysis Package (TAP). The TAP used is specifically devoted to the analysis of user-generated contents in the hotel reviews environment. This implies that the extraction process was designed to search for hotel-specific part of speech and to classify hotel attributes according to a predefined classification (included in TAP), which includes the following categories:

- Hotel amenities (Booking, Car parking, Check-in and Check-out, Cleanliness, Comfort, Elevator, Internet, Quietness, Restaurant, Sport facilities, Television and newspaper, Transportation, Upgrade);
- Budget - considerations related to the cost of the room and of the other services offered;
- Service (Attitude, Competence, Promptness);
- Location;
- General satisfaction.

The total number of extracted documents is larger than the number of inputs/UGCs, as each online review can include more than one category (for example, a review can express dissatisfaction about cleanliness and large room). At the same time, the extraction was not able to extract information from all reviews (thus a limited number of reviews was not classified).

The last step of the methodology was aimed at answering the RQs through the implementation of multivariate analysis and statistical tests on extracted frequencies. Cross-country differences in terms of emphasis and perception of hotel attributes were

investigated. To detect emphasis differences, correspondence analysis was implemented, while to identify perception differences, several chi-squared tests were conducted.

4. Results

4.1. Cross-country analyses of emphasis and perception of hotel attributes

The first results obtained through TLA consist of frequencies extracted from online reviews (Table 2). Positive (pos) and negative (neg) frequencies for each hotel attributes were extracted for each country, which were then summed to obtain the column total (tot). For example, with reference to the hotel attribute “Check-in and Check-out” (labeled as *h_check_in_out*) the text link analysis for US individuals identified: 21 positive reviews and 40 negative reviews. The sum of these two values results in a total of 61 online reviews discussing this issue. The hotel attributes for which the frequency value was lower than 5 were not reported, as they could not be used for subsequent multivariate analyses.

Table 2. Extracted frequencies

Hotel attribute	US			China			Italy		
	tot	pos	neg	tot	pos	neg	tot	pos	neg
<i>h_check_in_out</i>	61	21	40	102	45	57	98	30	68
<i>h_cleanliness</i>	649	371	278	856	407	449	821	399	422
<i>h_comfort</i>	1912	850	1062	2334	863	1471	1917	447	1470
<i>h_internet</i>	148	25	123	149	37	112	159	61	98
<i>h_quietness</i>	191	89	102	133	31	102	185	66	119
<i>h_restaurant</i>	931	477	454	613	357	256	1499	575	924
<i>h_sport_facilities</i>	261	134	127	141	76	65	95	36	59
<i>h_upgrade</i>	66	28	38	57	26	31	128	81	47
<i>budget</i>	678	220	458	647	287	360	704	57	647
<i>service_attitude</i>	593	409	184	589	318	271	575	401	174
<i>service_competence</i>	829	555	273	725	404	321	186	129	57
<i>location</i>	979	914	66	968	913	55	880	850	30
<i>general_satisf</i>	742	422	320	597	365	232	778	360	418

4.1.1. Cross-country emphasis differences

To investigate cross-country emphasis differences, the columns labeled as “tot” in Table 2 were considered. They indicate how many positive and negative reviews highlight a given hotel attribute for each sample of individuals (Americans, Chinese, and Italians). Discussing a given attribute in an online review is an unconscious revelation of what is important for the user, thus the measure is consistent with the emphasis concept. To test cross-country emphasis differences, correspondence analysis based on chi-squared tests and adopting symmetric normalization (Fig. 2) was implemented. It utilizes the coordinates on the bi-plot, which is the basic outcome of this analysis, showing the correspondence between the items of the two basic categories, countries and hotel attributes, according to their distance to each other. The results of correspondence

analysis are shown in Table 3 and include the number of dimensions, the eigenvalues, and proportions of explained variance from calculated dimensions. To present these results, the same approach adopted by Toral *et al.* (2018) was followed.

Fig. 2. Correspondence analysis - cross-country differences in terms of emphasis placed on hotel attributes

Table 3. Statistical summary of correspondence analysis between countries and hotel attributes

Dimension	Eigenvalue	Variance %	Cumulative variance %
1	0,19	81,1	81,1
2	0,09	18,9	100

Dimensions are formed by identifying those axes for which the distance between the profiles and axes is minimized while simultaneously maximizing the amount of explained inertia¹. Each dimension has an eigenvalue which represents its relative importance and how much of the inertia it explains (Clausen, 1998). Dimension 1 represents the largest deviation from independence; dimension 2, the second largest. The axes of Figure 4 detail the percentage of variance explained by the first two dimensions, which accounted for 81,1% for the horizontal axis and 18,9% for the vertical axis. Dimensions can be only interpreted based on how the variables' response categories separate on either side of the dimensions. Moreover, the further away from the origin a response category is along a particular dimension, the greater its importance on that dimension (Sourial *et al.*, 2010). Consequently, Dimension 1 can be characterized by the attributes "upgrade",

¹ Inertia is defined as the total Pearson Chi-square for a frequency table divided by the total sum of all observations in the table.

“restaurant”, “general satisfaction”, “sport facilities”, and “service competence”, while Dimension 2 by the attributes “check-in and check-out”, “cleanliness”, “comfort”, “quietness”, and “sport facilities”. The significance of the differences observed between countries in terms of hotel attributes is given by the chi-squared test ($F = 1078,37$, $p\text{-value} = 0.000$), which means a highly significant association.

The results displayed in Figure 4 show that there is a clear difference among individuals belonging to the three countries considered, which occupy different quadrants in the bi-plot, thus providing an answer to RQ1. Each country is depicted near the hotel attributes mostly emphasized by its citizens. More in detail, Figure 4 shows that: Chinese emphasized, more than Americans and Italians, attributes like cleanliness, comfort, and check-in/check-out issues; Italians emphasized, more than Americans and Chinese, issues related to restaurant (breakfast-lunch-dinner) and room upgrade; Americans emphasized more than Italians and Chinese sport facilities, quietness, general satisfaction and staff’s competence. Other attributes extracted are not useful in segmenting individuals, thus meaning that no significant differences were identified with reference to the emphasis paid to them by Italians, Americans, and Chinese. These attributes (namely location, service attitude, internet, and budget) are closer to zero when considering both Dimension 1 and Dimension 2, thus demonstrating a low discriminating power.

4.1.2. Perception differences

To investigate cross-country perception differences, the columns labeled as “pos” and “neg” in Table 2 were considered. To measure perception differences, a series of chi-squared tests were implemented, one for each hotel attribute, taking into account the Bonferroni correction for multiple tests. A significant value obtained in the test for a given attribute meant that individuals from different countries perceived that attribute differently. This analysis was possible only because the number of reviews extracted for each country is the same for each hotel considered. Therefore, considering a given hotel attribute and finding a significantly different number of positive vs negative reviews when compared cross-country differences implies a different perception of the same hotel attribute.

For example, as for the first hotel attribute (h_check_in_out), the test was performed on the following Table 4 of extracted frequencies:

Table 4. Contingency table for the Check-in and Check-out attribute.

	pos	neg
US	21	40
CHINA	45	57
ITALY	30	68

in which the result of the Pearson Chi-Square test was 4,110, the degrees of freedom were 2 and the Asymptotic Significance (2-sided) was 0,128, thus indicating non-significant cross-country differences for the perception of the check-in and check-out attribute.

In the following (Table 5), results deriving from chi-squared tests for each hotel attribute are presented.

Table 5. Chi-squared tests –cross-country differences in terms of perception of hotel attributes

Hotel attribute		Value	df	Asymptotic Significance (2-sided)
h_check_in_out	Pearson Chi-Square	4,110	2	,128
	Likelihood Ratio	4,101	2	,129
	N of Valid Cases	261		
h_cleanliness	Pearson Chi-Square	15,697	2	,000
	Likelihood Ratio	15,742	2	,000
	N of Valid Cases	2326		
h_comfort	Pearson Chi-Square	194,024	2	,000
	Likelihood Ratio	199,452	2	,000
	N of Valid Cases	6163		
h_internet	Pearson Chi-Square	18,458	2	,000
	Likelihood Ratio	18,504	2	,000
	N of Valid Cases	456		
h_quietness	Pearson Chi-Square	18,432	2	,000
	Likelihood Ratio	18,897	2	,000
	N of Valid Cases	509		
h_restaurant	Pearson Chi-Square	82,277	2	,000
	Likelihood Ratio	82,639	2	,000
	N of Valid Cases	3043		
h_sport_facilities	Pearson Chi-Square	6,565	2	,038
	Likelihood Ratio	6,621	2	,037
	N of Valid Cases	497		
h_upgrade	Pearson Chi-Square	7,794	2	,020
	Likelihood Ratio	7,806	2	,020
	N of Valid Cases	261		
budget	Pearson Chi-Square	231,865	2	,000
	Likelihood Ratio	259,327	2	,000
	N of Valid Cases	2029		
service_attitude	Pearson Chi-Square	40,265	2	,000
	Likelihood Ratio	39,715	2	,000
	N of Valid Cases	1757		
service_competence	Pearson Chi-Square	25,192	2	,000
	Likelihood Ratio	25,126	2	,000
	N of Valid Cases	1739		
location	Pearson Chi-Square	10,487	2	,005
	Likelihood Ratio	11,117	2	,004
	N of Valid Cases	2828		
general_satisf	Pearson Chi-Square	33,410	2	,000
	Likelihood Ratio	33,458	2	,000
	N of Valid Cases	2117		

From these tests, it emerged that check-in and check-out, sport facilities and upgrade attributes were perceived similarly by individuals belonging to the three different countries, as their relative tests resulted to be not significant. Conversely, Americans, Chinese, and Italians perceived the other hotel attributes differently, thus providing an answer to RQ2. To understand more in-depth which group of individuals perceived more

positively/negatively each hotel attribute, the ‘partitioning chi-squared’ procedure (Agresti, 2007) was implemented. Agresti (2007) stressed that chi-squared statistics having degrees of freedom > 1 can be broken into components with fewer degrees of freedom. The procedure was implemented on each contingency table to understand which group of individuals contributes the most to the significance of the test. This implied the repeated removal of a group of individuals and the recalculation of the chi-squared test for each hotel attribute. As a result, we identified for each attribute which group of individuals perceives it more positively/negatively compared to the others (see Table 6). restaurant, quietness and budget attributes are included in different rows, as the partitioning chi-squared resulted to be significant more than one time.

Table 6. Summary of results for tests on cross-country differences of hotel attributes

	Attributes perceived more positively (compared to individuals belonging to other countries)	Attributes perceived more negatively (compared to individuals belonging to other countries)
US	Cleanliness, Quietness	
CHINA	Restaurant, Budget	Quietness, Service Attitude, Service Competence
ITALY	Internet, Location	Comfort, Restaurant, Budget, General Satisfaction

5. Conclusions

5.1. Discussion

This study investigated cross-country differences in terms of emphasis and perception of hotel attributes, providing answers to the two RQs proposed—*Do travelers from different countries place different emphasis on hotel attributes? Do travelers from different countries perceive hotel attributes differently?*

Results suggest that cross-country emphasis and perception differences are noticeable and could be extrapolated from online reviews. In the following, results obtained for each RQ are discussed in detail.

5.1.1. Travelers belonging to different countries place different emphasis on hotel attributes

The emphasis paid to hotel attributes and the relative countries’ position was graphically displayed in a bi-plot representation (correspondence analysis) where distances are proportional to the dissimilarity of countries and emphasis paid to hotel attributes. Results obtained clearly highlight that each group of travelers (Americans, Chinese, and Italians) emphasized hotel attributes differently. Cleanliness, comfort, and check-in/check-out were considered more important by Chinese, sport facilities, quietness, general satisfaction and staff’s competence were considered more important by Americans, and restaurant and room upgrade were considered more important by Italians. Conversely, for other hotel attributes (i.e., location, service attitude, internet, and budget) no significant cross-country differences were observed. This means that the emphasis devoted to each of

these hotel attributes by Italians, Americans, and Chinese was the same. However, the three groups of individuals were clearly differentiated, as demonstrated by the significance of the correspondence analysis. Therefore, this study suggests that travelers belonging to different countries place different emphasis on hotel attributes.

5.1.2. Travelers belonging to different countries perceive hotel attributes differently

Regarding the second RQ, first strong support for cross-country perception differences was provided, highlighting which hotel attributes were perceived more positively/negatively by each group of individuals. It emerged that, compared to the others: Americans perceived more positively cleanliness and quietness; Chinese perceived more positively restaurant and budget but more negatively quietness, service attitude and service competence; Italians perceived more positively internet and location but more negatively comfort, restaurant, budget, and general satisfaction. The findings also highlighted the presence of three attributes, namely check-in and check-out, sport facilities, and upgrade that were perceived similarly by the three groups of travelers. Despite the presence of these non-differentiating attributes, the large majority of them were perceived differently by Italians, Chinese, and Americans. This suggests that travelers belonging to different countries perceive hotel attributes differently.

5.2. Implications for managers

By identifying the factors of importance for segmented customers and how they are perceived, the findings of this study may also help hotel managers in determining the optimal allocation of scarce financial resources with respect to customer satisfaction criteria.

The effective segmentation of the hotel's customer base and the analysis of emphasis and perception of hotel attributes may reveal subtle performance issues that could be easily remedied but that can hamper the reputation of hotels if left unaddressed. For example, it could be of importance to understand whether guests belonging to specific countries (Americans in our sample) pay specific attention to sports facilities and quietness as managers could establish specific agreements with external structures and reserving silent rooms to them (where possible), thus increasing guests' satisfaction at no cost. Understanding that Italians pay attention to room upgrade could lead to propose such improvement to them, where possible, at no cost. The use of software devoted to analyzing large-volume of text, like online reviews, allows the identification of such issues.

Finally, the identification of detailed cross-country differences in terms of emphasis and perception of hotel attributes may be crucial for hotel managers in designing persuasive marketing campaigns, promotions, and communications based on specific hotel attributes or that emphasize such attributes instead of others.

5.3. Limitations and future research

Two main limitations of the study are recognized. The first refers to the tool used to perform the text link analysis and the categorization of concepts through predefined hotel attributes. The present study represents the first attempt to implement this methodological approach to extract frequencies of hotel attributes from UGCs through a text mining software. Although the tool allows the extraction of concepts from a large set of UGCs, it cannot identify some specific issues deriving from human language, therefore ignoring some potentially useful part-of-speech. This could result in lower frequency values for some specific or for all hotel attributes, thus somehow affecting the analysis. In addition, although categorization based on predetermined hotel attributes has the advantage of extracting issues or topics effectively based on keywords, there are disadvantages. The main refers to the fact that it is not possible to score the degree of positive/negative intensity due to the nature of the algorithm. This degree of intensity, which could be useful in understanding more in-depth cross-country differences in terms of perception and emphasis, cannot be determined through our approach (which is based on frequencies).

The second limitation refers to the number of UGCs considered in the analysis and the generalizability of results. Despite adopting a random sampling method, the number of observations included in the study was limited if compared with the huge number of hotel online reviews. The decision to limit the analysis to 9000 reviews derived from the need to be accurate in manually translating UGCs from Chinese and Italian to English, which was a very time-consuming process. Such limited number led to extract a small number of frequencies for some of the hotel attributes considered, which could not be included in the multivariate analyses. In addition, it prevented the possibility to analyze the effect of geographical location of the hotels on the emphasis and perception constructs, as this would have led to excessive fragmentation of extracted frequencies. Therefore, although the findings suggest that cross-country emphasis and perception differences of hotel attributes are noticeable and could be extrapolated from online reviews, it cannot be claimed that the observed cross-country differences in terms of emphasis and perceptions will be valid when considering UGCs deriving from different settings. Additional analyses considering a larger number of UGCs should be performed to confirm the validity of our findings.

Abstract

Food consumer behavior has changed substantially over the past decades. The contemporary food consumer has become more critical and outspoken, demanding more relevant, accurate and reliable information necessary for his/her food decision making or learning. This new context makes research studies on the relationship between the behaviours of food consumer and food information user quite important. Several studies addressed the role of food information in food consumption activities. However, literature lacks of a holistic overview of the dimensions impacting on consumer's perception of the value of food information when he/she is involved in food a food consumption process. The recent wave of the so-called "Internet-of-Food" (IoF) provide consumer with countless mobile apps and food-related objects and devices which are augmented with sensing, computing and communication capabilities in order to provide advanced information services. Nevertheless, the available research lacks in defining an approach capable to analyze the value of information provided to targeted audiences by Food Information Services (FISs). This paper intends to fill these gaps through a literature review of scientific research that combines knowledge on food consumer's and food information user's behaviours to identify main value dimensions in food information services that constitute a base for a multidimensional framework to identify the value proposition of a FIS.

Keywords – Food Information Services, Information Value, Value Proposition, Internet-of-food

Paper type – Academic Research Paper

1 Introduction

Due to the significant changes in life-styles and values taken place in the last decades, consumer's behaviour in food-related choices has been transformed. Smaller, higher-educated families, single-person have triggered a quiet revolution that is gradually doing away with conventional eating patterns (Costa and Jongen, 2006). The growing importance of values such as quality of life, well-being, as well the renewed interest towards local food-culture and heritage, exerts a high degree of influence on the way consumers perceive and evaluate food. In facts, contemporary food consumer has become more critical and outspoken, demanding and expecting to get more relevant, accurate and reliable information necessary for his/her food decision making.

In this frame, the challenge of food information management is to deliver the information that enables consumers to make appropriate choices according to their own individual objectives as they are involved in food consumption activities. An effective and efficient Food Information Service (FIS) should deliver the right information to the right people, at the right time, and at the right place.

FISs that deliver massive and generic food information have a limited chance of success since they carry high search costs for the consumer and can hamper the ability to detect and correctly identify information that is needed in his/her decision or learning process (Verbeke, 2008; Bialkova, et al., 2013). Employment of conventional channels (e.g., store shelf and package labels) allows neither to retrieve actionable information from sources that are appropriate for the current consumer's situation, nor, more in general, to provide personalized food information.

Recent advances in the convergence of information and communication technologies (e.g. "internet of food") have led to the development of new FISs that let consumers get more relevant food information than they usually obtain through on-product labelling, mass media or other traditional channels. By leveraging on context-awareness, ubiquity, pervasiveness, and mobility features, mobile based FISs are suitable for an effective and efficient food information provision, providing value to the food consumer.

The added value of food information results from the utility that a recipient obtains by appropriating the new data, interpreting them and placing them in context by combining them with existing personal information, while he/she is involved in a food related activity.

Although several studies addressed the role of food information in food consumption activities, literature lacks of a holistic overview of the dimensions impacting on consumer's perception of the value of food information. This paper intends to fill these gaps through a literature review of scientific research that combines knowledge on food consumer's and food information user's behaviour (Browne et al., 2017) to identify main value dimensions in food information services that constitute a base for a multidimensional framework to identify the value proposition of a FIS. This conceptual tool can be used both to map current offerings of these services and to identify added value of mobile and app-based FISs with respect to conventional or traditional information services.

2 Background and motivations

Consumers are daily involved in food-related activities: planning what to eat, purchase, store and cook food, eating, and disposing remnants. The sequence of consumer's food-related activities, triggered by a food related need, is known as food provisioning or food consumption process (Marshall, 1995). Consumers need to get information on food attributes in order to make appropriate choices when they are involved in food consumption activities. Need for information emerges from the recognition of a gap between a person's knowledge current state and his/her desirable state (Belkin et al., 1982). Due to its nature, an information need arises as an output of a more basic need. It is a part of the search for the satisfaction of a physiological, affective or cognitive need, as an individual is engaged on "information seeking towards the satisfaction of needs" (Wilson, 2006).

In that sense, a food information need usually arises from food-related primary needs associated with a consumer's activity in a stage of the food consumption process (e.g. purchasing appropriate food products, choosing where to buy food, planning meals). The identification of a food information need represents the first stage of the information usage process. It starts as soon as the consumer recognizes an aroused food-related primary need or a need to fill a knowledge gap. The food consumer becomes aware that food information should be acquired and collected in order to meet that need. He/she translates a food-related need or the awareness of a food knowledge gap into an information question relevant to a choice in a specific food consumption stage (Lioutas, 2014).

Food information seeking is the second stage of the information usage process. In this stage, the food information user is actively and purposefully involved in a conscious effort to acquire information in response to a food-related need or a need to fill a food knowledge gap (Kuttscheuter et al., 2017). From a decisional point of view, food information users have to choose the appropriate information channel and the information source able to meet his/her food information need. A user may explore several information channels (e.g. labels, social media, mobile apps) and information source (e.g. food producers, distributors or other food supply chain stakeholders) and ends his/her research when he/she evaluates the retrieved information as sufficiently relevant and reliable. The output of food information seeking is an information cue that a consumer could use to support his/her food decision-making or learning process.

Once food information is selected, consumers can use it for some food choices in a food-related activity, i.e. an activity of the food consumption process or an activity of a food learning process. How consumers interpret, give meaning to, evaluate, and use food information depends on their previous experience, expertise, and needs, as well as their current consumption context, i.e. situational and temporal conditions in which the consumer's food choice occurs (Volpentesta et al., 2017). Context awareness has a significant influence on the food information user, as context cues can support user to better interpret food-related information. In fact, context awareness provides the user with sensory and cognitive cues that allow him/her to refer delivered data and information to

food items (Machin, 2014) (Volpentesta et al., 2018). An information content can be properly interpreted by taking into account other elements within the environment surrounding food products the information content is referring to, e.g. other food products, specific physical conditions (e.g. light, humidity, temperature, localization, spatial layout, package integrity) or organizational features (e.g. operation rules, shop opening).

The above food information usage process and its interrelation with the food consumption process is presented in Figure 1.

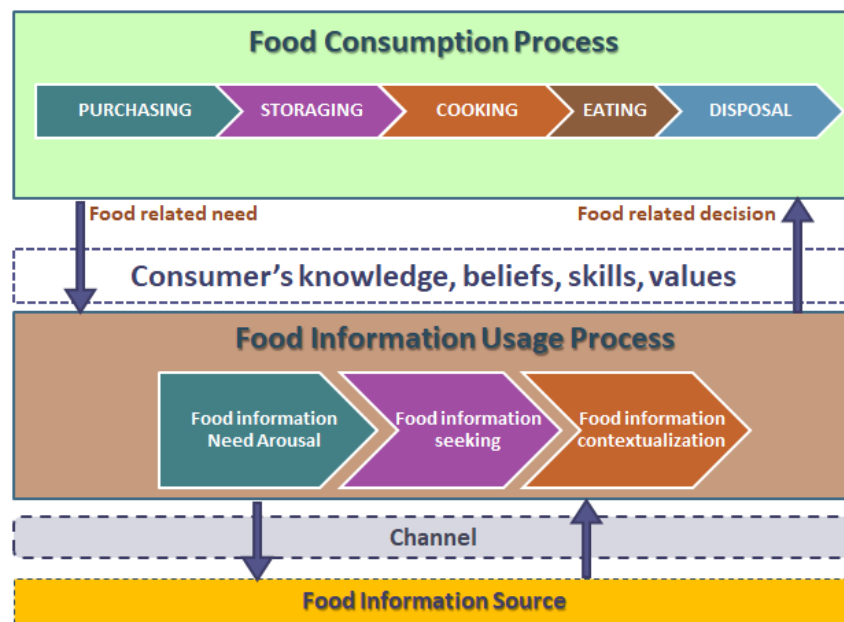

Fig. 8. The food information usage process and the interrelation between the food consumer's behavior and the food information user's behavior.

3 Literature Review

3.1 Methodology

In this paper we carried out a systematic literature review (Kitchenham, 2004), in order to provide a complete, exhaustive summary of relevant literature addressing the consumer's perceived value of food information services when involved in a food information usage process. We selected Scopus as scientific database where to perform our search. We initialized a list L of search keywords with English terms related to the above mentioned scientific domain (e.g. "information seeking", "need for information", "information need arousal", "consumer behaviour", "information behaviour", as well as synonymous, and other broader/wider terms). We performed a search on Scopus database by using keywords in the list L. At the end of this cycle, we obtained the final set P,

consisting of 64 papers to be analysed. For each paper $p \in P$ we identified the components impacting on consumers perceived value of food information services.

3.2 Results and discussion

For sake of clarity, we present our results in three subsections each of which corresponds to one of the main activities of food information usage process. The complete list of papers P we reviewed is available at:

https://drive.google.com/open?id=1NGNDkVRtusIcm_C6w6cBga2DAJQlHT8X

3.2.1 Food information needs identification

Extant literature attempts to explain the link between the rational consumer and necessary inputs, capabilities and willingness to engage in a food decision making process. A food information need arouses as a consequence of consumer's involvement in a food consumption activity, and it is affected by some consumer's attributes (interests, attitudes, experiences, and knowledge) (Nocella et al., 2014). We may summarize the general research questions in literature about the identification of food information needs as follows: "Why do consumers need food information and what information do they need?". These questions have been tackled under either a specific perspective reflecting a psychological perspective related to the antecedents of a consumer's interest. We grouped such perspectives in 6 broad classes, namely healthiness, safety, convenience, hedonism, culture and ethics/sustainability, as reported in table 1:

Table 2. Research directions on food information needs identification.

<i>Perspective</i>	<i>Description</i>	<i>References</i>
Healthiness	impact of health-related consumers' values on food information user's needs. Researches are centred on the identification of consumer's interest towards healthiness/wellness related properties of food. Survey-based research demonstrated that consumers with health related interests, have continuous and more intense information needs about food.	P1,P2,P3,P4, P5,P6
Safety	researches are devoted to investigate the way a consumer's information need arises under a safety-related perspective, They show that this arousal is strictly entwined with the consumer's perception of risks associated to food-related hazards (chemical/microbiological contaminants, preservatives, colorants).	P7,P8,P9, P10,P11,P12, P13
Convenience	Research addressed to study food information need arousal in consumers whose main interest is towards food costs and convenience (e.g. buying food at a lower price, finding the nearest food store, and, in general, gaining benefits during food related activities).	P14
Hedonism	few research works focus explicitly on the relationship between the pleasure of food and information need arousal. Food information needs of consumers are mainly driven by concern for sensory quality of food products, helping to understand how consumers conceptualize and express food information needs into words	P15,P16
Cultural	impact of socio-cultural interests towards the arousal of food information needs. Some researchers have linked up these interests with food consumers (called foodies) who recognize their food information needs in a continuous commitment to self-education (learning about typicity, traditions and values, culinary history)	P17,P18,P19, P20

Ethical	information needs are driven by taking social and environmental concerns of food products into account (ethical consumerism). Research investigate consumer's preferences and needs of information about 'fair trade' aspects (e.g., fair prices to farmers, integration of disabled people, animal welfare) and other food-related sustainable practices (e.g. greenhouse gases reduction, protection of the tropical rainforest, prevention of child labour)	P21,P22
---------	--	---------

3.2.2 Information seeking

When a user is consciously involved in an effort to acquire information about food, he/she has to choose the appropriate information channel and the information source able to meet his/her food information need. Information channel refers to a medium used by the consumer in finding food information (mobile-apps, blogs, newspapers, radio, tv). Information source refers to persons or organizations (public authorities, food firms, third parties' food product certifiers, educational organizations, information practitioners) from which food information comes to consumers (Muth et al., 2014).

Research on food information seeking attempted to understand how users behave when they search for food information, emphasizing factors affecting the selection and the evaluation of information sources and channels. Table 2 reports research directions on food information seeking:

Table 2. Research directions on food information seeking.

<i>Perspective</i>		<i>Description</i>	<i>References</i>
Channel related benefits	Availability	Identification of benefits linked up to information channel availability in terms of time and place. Benefits have been investigated for many internet and mobile-based channels that can overcome some limitations of traditional channels, as making information retrievable whenever and wherever the consumer needs for.	P25,P26,P27
	User's effort	Physical and cognitive efforts required by information searching on a given channel.	P28,P29,P30, P31,P32,P33
Source Credibility	Perceived expertise	the degree to which recipients perceive the information source as having the experience, skills, and capacity to provide accurate information.	P35,P36,P37,P38, P39,P40,P41,P42,
	Trustworthiness	the confidence that the source provides objective and correct information.	P8,P44,P45,P46, P47,P48,P49,P50, P51,P52,P53
	Attractiveness	the degree to which an information source is appealing to consumers by exerting verbal, physical, or technology-mediated communication.	P53

3.2.3 Information contextualization and use

Several studies have been conducted on the influence of food information on consumer choices in food consumption activities, but they rather limited their scope to some aspect of the information use process. Most of them have been focused on consumers' use of nutritional labels for purchasing decisions and dietary change.

Researches from the literature reveal that factors influencing the information use in food consumer's choices pertain to the three main entities involved in food decision-making: consumer (who takes the decision), context (situational and temporal conditions in which the decision should be taken), and information (input of the decision-making process). Table 3 summarizes factors affecting food information use.

Table 3. Research directions on food information use.

<i>Perspective</i>	<i>Description</i>	<i>References</i>
Consumer's characteristics	consumer's attributes that influence consumer's interpretation, evaluation, and use of a food information cue. They may be grouped in demographic characteristics (e.g. age, gender, education), interests (e.g. food involvement), and food knowledge (e.g. ability to understand food information);	P1,P63,P55, P56,P60,P61, P62,P63,P64
Context	the way users give meaning and importance to information depends on temporal and location attributes of items within the context where users make decisions.	P11,P53,P58
Information	Few studies examine how much information use depends on the quality of the information a consumer receives. Aspects pertain information accuracy, currency, completeness, as well consumer preferences about information content format. Unfortunately research limited their scope to investigate nutrition label formats	P54,P59

4 A multidimensional framework for modelling a value proposition space for FIS

Information Service Offering refers to a set of activities performed by an information service to satisfy consumer information needs (Tan et al., 2011). Extending the concept of "fitness for use", related to information value and information quality (Eppler et al., 2004; Borek et al., 2014), the value of an information service offering is usually understood as the overall utility that the user receives when using the information service. In the case of FIS, the user is a food consumer who requires the information necessary for his/her food decision-making or learning process, as he/she is involved in food consumption activities in some situations.

The value proposition is defined as an implicit promise a company makes to its customers to deliver a particular combination of values (Sweeney and Soutar, 2001). Several authors (Fojt, 1996; Walters and Lancaster, 1999) agree that business value proposition of information services leverage on three main components: content (i.e. the product or service to be purchased), context (i.e. the environment in which content is offered) and infrastructure (i.e. the way content is delivered).

A FIS must be useful and add value to the tasks of a food consumer. In other words, the value that consumers perceive as a result of a Food Information Usage Process refers to an assessment of benefits and costs deriving from the interaction between consumers and the process. From the supply side perspective, the value proposition of a FIS refers to the ability of a FIS to facilitate a better performance in accomplishing the food information usage process and it reflects service performances impacting on the consumer's judgement about the utility he/she receives when using the service in a food

consumption process. This assessment varies from a consumer to another and from situation to another as it is affected by consumer's attributes (food related values, attitudes, experiences, and knowledge) and context (food consumption place, time, activity, social relations, etc.) in which the decision should be taken (Grunert, 2002). However, utility dimensions impacting on its dimensions can be objectively identified. In the assessment of the perceived value, the consumer will determine the importance of each dimension and its component levels according to his/her own concerns/attitudes and situational context.

The FIS value is therefore characterized by a set of utility dimensions along which consumers assess the utility they receive from FIS performances during the three phases of the food information usage process. In other words, the value proposition of a FIS is a multidimensional space where consumer values can be mapped. In our view, the FIS value is characterized by a set of utility dimensions emerged from the analysis of literature review on food information consumer behaviour, as presented in section 3

In what follows, we introduce three main FIS performances, namely food information (content), information on context where the content is originated (provenance) and the set of devices where information is made available to consumers (interface). These performances affect, respectively, three basic components of the consumer's value, namely, "content relevance", "content credibility", and "content accessibility".

4.1 Content

It consists of information 'cues' that the service provides to a consumer in order to support his/her food decision-making. An information cue has a twofold nature: declarative (it describes food quality attributes) procedural (it is concerned with food consumption activities). Consequently, any performance factor of the information content has two dimensions:

- **food quality topicality.** This performance factor into account the declarative nature of the content cue that reflects some food quality attribute. From the large quantity of literature concerning food consumption choices, we link food quality attributes to the consumer's food values and interests identified in section 3.2.1, namely *convenience/cost*, *healthiness/ wellness*, *sustainability*, *social culture*, *sensory quality*, *safety*. Despite many classifications are based on when, where and how consumers can evaluate the quality aspects of food products, our categories rather take into account "why" a consumer evaluate food quality aspects, as we are interested in the utility a consumer expects from the information content.
- **consumption stage topicality.** This performance factor dimension takes into account the procedural nature of the content cue that deals with parameters, conditions and steps for food consumption activities. From the literature, we have grouped these activities according to the stages of the food consumption process, namely *purchasing*, *storing*, *cooking*, *eating*, *disposal/tidy-up*.

A consumer usually assesses the relevance of a FIS information content in accordance to his/her own food values and information needs related to a food consumption activity.

Therefore, the relevance of the information content reflects how much (topically) the content corresponds to the information demand of the consumer with a certain food value and involved in a food activity of a certain consumption stage. The higher the value is, the more the content fits specific motivations and information expectations of the consumer, as letting him/her infer, or judge, a food quality attribute, and evaluate actions for better achievement of a stage consumption objective.

4.2 Provenance

The content provenance refers to a set of external information cues on the provenance of the content, affecting the consumer value perception of a FIS, in terms of source credibility. Source credibility is widely recognized as the main determinant affecting consumer's choice of a food information source. It refers to the extent to which a recipient believes that the source has considerable knowledge, skills and experiences to provide objective information without bias. As previously evidenced, source credibility leverage on three main sub-dimensions, namely "perceived expertise", "trustworthiness" and "attractiveness". The higher the information source is credible, the more the content is considered as reliable.

Besides identity characteristics of information source, content freshness is also recognized as important factor in building information reliability. The term "content freshness" refers to the "up-to-dateness" (recency) of an information cue (Lewandowski, 2008). Recency is a structural feature that convey "situational relevance" of the content with regard to current events or new information (Saracevic, 1996). Content freshness-related cues prompt an immediate assessment of information reliability and are found to be often used by information users in determining their information behavior's paths (Sundar et al., 2007). The information freshness can be formally defined as the distance between the time the information was created and the time it reaches the user. The higher the information is "fresh", the more the content is considered as reliable.

4.3 Interface

Interface deals with the set of devices where information are made available to consumers. From an infrastructural point of view, the value proposition of information provision services has changed substantially over the past decades, mainly due to the increasing level of technology readiness in the ICT domain. The role of technologies in improving the efficiency and the effectiveness during the phases of the food information usage process is widely discussed in literature. In particular, research focuses on benefits affecting the selection of information channels.

Some research works have focused on the role of technologies in reducing physical and mental efforts that consumers have to sustain to interact with the process and to carry out food-related decisions (e.g. ability to use food information tools and ability to understand and use food information). Extant research on information systems evidences that the way users give meaning and importance to information depends on temporal and location attributes of items within the context where users make decisions. Unfortunately, contextual factors have not been prioritized in previous research related to food

information use. Few studies deal with the influence of context on food consumer decision making, focusing mainly on environmental factors.

An overview of the framework components and their relationships is given in table 4.

Table 4. Summary of the multidimensional framework for modelling the FIS value space

<i>Performance</i>	<i>Set of performance factors</i>	<i>Utility dimension</i>
Content	food quality topicality	Declarative utility
	consumption stage topicality	Procedural utility
Provenance	identity and quality of information source	Source credibility
	time of information creation	Information Freshness
Interface	spatial availability of information	accessibility in terms of proximity of output device to consumer's place
	time availability of information	accessibility in terms of timeliness with respect to consumer's information need
	Context dependency	environmental closeness: information provision depends on physical and organizational properties of the environment (food in context)

5 Conclusions

Our study examines which attributes of are prioritized in scientific literature as factors affecting the food information usage process. These attributes are used as a basis to identify value components of FIS supporting consumers in their food-related decision making.

Despite the great interest that researchers have shown in food consumer's information behaviour over past decades, the interrelation between the food consumer's behaviour and the food information user's behaviour has been investigated without taking into account current paradigms of FIS. Current context-sensitive technologies make urgent to open up research directions aimed to investigate the role of food information contextualization in the food information usage process.

In this paper, we propose a multidimensional framework for modelling a food information provision space where to position the value proposition of FISs, according their utility in meeting food consumer information expectations. Components fall into three broad classes: content (what information is provided to the consumer), provenance (who is involved in the information provision process, and interface (how/where/when the information is made available to the consumer). Our framework may represent a valuable tool to analyze the value proposition of FISs according to a consumer perspective. Moreover, it could be used to suggest some direction to obtain fruitful insights for the design of a new generation of food information services or to identify potential service delivery improvements within the IoF domain.

Abstract

Recent innovation in digital technologies have triggered public sector organisation in search for improvement of their performance. Social media and participatory web are allowing public sector organisations to implement new form of civil engagements for citizens and to enhance their performance, contributing to the growth of the community.

The paper aims to investigate if and how IT tools (web and social media) affect performance management systems in public-sector cultural organisations, provoking also changes in the relationship with visitors, donors and the local community.

The paper adopts a case-study approach, investigating the Archaeological Park of Paestum (PAE), an autonomous museum of the Italian Ministry of Cultural Heritage and Tourism. Relying on interviews to top-management and consultants as well as on questionnaire to visitors, triangulated with data from official documents, we found that digital technologies have a positive impact of on the performance of PAE, in terms of revenue, donations and sponsorship received, number of visitors, and changes in internal routines.

Findings from the study provide interesting implications for policy-makers regarding the effectiveness of digital technologies, highlighting that public sector entities can improve their global performance investing in innovations and social media.

Keywords – digital technologies, cultural organisations, organisational systems

Paper type – Academic Research Paper

1. Introduction

Reforms implemented in the last decades have stimulated public sector entities to innovate their management in search for efficiency and effectiveness (Pollitt and Bouckaert 2004). Under this wave of change, digital technologies represent a great

challenge in the improvement of organisational performance. In particular, internet and social media are allowing public sector organisations to implement new forms of relationship with citizens (Dahlgren, 2009; Ducci, 2015), at the same time positively affecting their performance. Moreover, management innovations also affect administrative change, including new management systems and processes that make the organisation working more efficiently (Walkers et al., 2011).

Among public entities, cultural organisations have been challenged by a large set of reforms, in part related to the New Public Management philosophy and in part brought by the increasing competition in the world of art and tourism, coupled with the acquisition of a certain autonomy (Bakhshi and Throsby, 2009; Bonini Baraldi, 2014). Managerial innovations, introduced through the performance management system, have become a great opportunity for these organisations to improve their performance, taking advantage of IT innovation and introducing change in administrative processes and practices.

Grounding on the theoretical framework about innovation provided by Walker et al., (2011), this paper aims to investigate - through the case study of the Archaeological Park of Paestum, an heritage assets located in the South of Italy - if and how the use of innovative technologies, such as web and social media, positively affect the performance management systems (PMS) in cultural organisations and the overall performance, also provoking changes in the relationship with visitors, donors and the local community. To this end, after a brief review of the literature on innovation in cultural organisations, section three introduces the methodology adopted, while section four presents and discusses results. Section five concludes and depicts the path for further development of the research.

2. Literature review

Innovation has gained considerable attention in any organisation, not only in relation to technological and product innovation but also in terms of organisational and management style perspectives (Mol and Birkinshaw, 2009). Walker (2007, p. 592), referring to public sector entities, defines innovation as “a process through which new ideas, objects, and practices are created, developed or reinvented.” Moreover, to have innovation, implementation of a new idea has to occur.

In public-sector entities, innovation may be driven by legislation and cannot affect the everyday practices. Furthermore, innovation “is evolutionary rather than radical” (Walker, 2007, p.592), thus it results as a consequence of several incremental changes, progressively bringing modifications in everyday routines (Burns and Scapens, 2000).

Scholars have provided different classifications of innovation, like *service innovation* (Osborne, 1998), *organisational process innovation* (Edquist et al., 2001) and *ancillary innovation* (Damanpour, 1987) which, differently by the first two categories of innovation, depend on factors outside an organisation’s control.

In the context of cultural organisations, Vicente et al. (2012) state that innovations may touch upon management processes (*technological innovation in management*), products and services for visitors (*technological innovations for the audience*),

organisational structure and processes (*organisational innovations*), programming work and exhibitions (*artistic innovations*).

Despite the relevance of the theme, there is scant literature dealing with effects and consequences of innovation in PMS adopted by cultural organisations (Bakhshi and Throsby 2009; Leicester and Sharpe, 2010; Manes Rossi et al., 2015).

Scholars (Rogge et al., 2017) argue that digital technologies are playing an important role in the enhancement of public sector entities' performance, also contributing to the growth of the community. More specifically, among the IT innovation, cultural organisations have been particularly challenged by internet and social media. The former has gained a pivotal role both for communication and for building digital collections (Ke and Hwang, 2000). The need of being digital to meet visitors' expectation and the use of social media to attract visitor have become a question of survival (Bakhshi and Throsby, 2009).

At the same time, implementing IT innovations affect internal processes and involves also the management system in place.

Discussing the different type of innovations, the Walker et al. (2011) framework focuses on management innovations (MIs), interpreted as the generation or implementation of a new management practice, process, structure and technique intended at improving the multifaceted aspect of the performance and involving decisional and operational processes (Walker et al., 2011). This framework is convenient for analysing MIs in public-sector entities and examining their relation with organisational performance, as it takes into account some characteristics such as their multipurpose objective and goal ambiguity, the service production process and the bureaucratic approach, despite all New Public Management reforms promoting managerial logics (Pollitt and Bouckaert, 2004).

Walker et al. (2011) underline that MIs can play a central role in the process of changing organisations, improving the overall performance. Although the framework provided has been developed in regards to local government, the classification of IT and administrative innovations can be applied in public cultural organisations as well, assuming that the public nature of this organisations strongly affects their management.

According to Walker et al. (2011) *IT innovation dimension* includes both new information technology and new management information systems. Similarly, *administrative innovation dimension* encompasses new approaches to service planning and budgeting, new approaches to organisational improvement (e.g., reengineering, quality management) and new management processes (e.g. new job descriptions, establishing new teams of staff) (Walker et al., 2011, p.374). The authors prove that MIs affect organisational performance mainly through performance management systems, thus demonstrating the mediating role of the PMS in allowing innovation to affect the organisational performance.

Applying the framework of Walker et al. (2011) to the case of PAE makes it possible to interpret how and to what extent MIs related to IT tools and the administrative dimension have provoked changes in the PMS with specific regard to decisional and operational processes, definitely affecting the overall performance.

3. Research methodology

The paper adopts a case-study approach, investigating the Archaeological Park of Paestum (PAE), an autonomous museum of the Italian Ministry of Cultural Heritage and Tourism. Preliminary information is provided in the following subsection, to ensure a better understanding of the case under observation.

3.1. *Setting the context*

Several reforms have promoted the adoption of managerial approach to heritage assets in Italy, starting from 1992 with a specific law aimed at “economising” the management of heritage assets (Bonini Baraldi, 2014). Nonetheless, it was necessary to wait for the year 2004 for the first Cultural Heritage Code. The Code represents the first attempt to introduce a certain degree of autonomy in the management of public heritage assets in Italy. Nonetheless, the limited amount of financial resources in the governmental budget devoted to these organisations, coupled with the persisting dependency on the Ministry for human resources, have affected the ability in programming activities.

The turning point arrives in 2014 with the so-called Franceschini Reform, which has definitely determined an increased autonomy through participative management and innovation in the domain of Italian heritage assets. However, despite the claimed autonomy, it should be kept in mind that the directors cannot hire the staff members directly. Their duties include the management of the museum, the organisation of expositions and other performance, the task of conservation, protection and promotion of the heritage assets under their control. To gain a certain ability to operate both current and investment expenses beyond the budget assigned by the Ministry, directors are allowed to collect financial resources through sponsorships and donations, and define the fee for tickets. Furthermore, they can create partnerships with other public or private organisations on the territory (Marzano and Castellini, 2018).

The cultural organisation selected as case study for this research is the archaeological site of Paestum (PAE). PAE is located in Capaccio-Paestum (near Salerno, in the South of Italy) and it is part of a wider national park including a large geographical area of utmost importance from the archaeological viewpoint and the annexed museum. Since 1998, it has been recognised as part of the UNESCO World Heritage Site. As many other archaeological sites located in the same region (Manes Rossi et al., 2018), the park was not well managed neither promoted. The three Doric temples, built almost 2500 years ago, and the annexed Museum narrating the age-old history of the city, today welcome visitors with several innovations, including social media, especially Facebook, to promote events, to engage visitors as well as to attract donors, with the aim of improving both efficiency and effectiveness. These innovations have been prompted by the new Director, Gabriel Zuchtriegel, appointed in 2015. To approach new technologies, the director asks for the collaboration of a web agency, named 3d0, which currently manages both the website and the Facebook page of PAE.

3.2. Research method

The basic criteria for a theoretical sampling approach (Eisenhardt, 1989; Eisenhardt and Graebner, 2007) have been used to select the case-study of the PAE. Firstly, cultural organisations such as PAE are complex entities, having multiple objectives. Secondly, the managerial autonomy of PAE, coupled with the steering at-a-distance role of the MiBACT, has stimulated several innovations (more active use of the web and social media, a pro-active approach of employees towards visitors, and so on), determining an in-depth changing process, based on redefining PAE's strategic objectives. Although these innovations could be considered as a quasi-natural effect of the NPM paradigm, they are not so frequent in this context, characterised by a conservative management culture (Zan, 2000). Only recently, the role and the opportunities related to an active use of web and social media on museums emerge. A holistic approach is required, considering web and social media as components of a broader strategic initiative and investigating the impact on organisational routines (Burns and Scapens, 2000) and on the global performance. Therefore, the case-study selected for this research is expected to give insight on relationships and logic among constructs (Eisenhardt and Graebner, 2007, p. 27).

Following Scapens (1990), our case study can be classified as explanatory, as this research aims to understand and explain the reasons for management change, considering the use of web and social media and evaluating their impact on PAE's decision-making processes and performance.

Consistent with these research objectives, this study adopts both a questionnaire with yes-and-no questions as well as Likert-scale questions, and semi-structured interviews (Qu and Dumay 2011), with open-answer questions.

The survey by questionnaire was carried out in July 2018, involving visitors of the PAE, and it was based on both dichotomous and Likert-scale based questions. It was pilot tested on ten visitors, randomly selected at the entrance of the PAE, to spot any unclear questions or possible misunderstandings. The results of the pilot test were positive.

Semi-structured interviews, conducted between February 2018 and July 2018, involved the Director and key managers of PAE, as well as the CEO of the external web agency (3d0), which is charge of managing the web page also giving assistance to the use of social media (see Table 3).

Table 3: Role of the interviewees and duration

Role of Interviewee	Time (hours)
Director	2
Press office Manager	2
Visitors and surveillance Manager	1
Accounting office Manager	1
Front office Manager	2
Web agency CEO	2
Total	10

Transcripts of interviews were sent to the interviewees for a check, to reduce any bias due to the personal interpretations of the researchers. Moreover, other sources of data

were used, such as statistical data provided by the MiBACT (http://www.statistica.beniculturali.it/Visitatori_e_introiti_musei.htm). This guarantees the triangulation of the data, increasing the probability of credible results (Liguori and Steccolini, 2012; Badia et al., 2018). Furthermore, following Eisenhardt (1989), a multiple-investigators strategy was adopted, allowing the case to be observed from the different perspectives of the research team components; finally, two researchers coded all data independently, and no relevant differences were found.

4. Discussion of results

4.1. Analysis of the questionnaire

The survey respondents were 214. The vast majority (68%) belongs to Italy, while the 23% of them come from Europe and the remainder 9% from outside Europe.

Though respondents mainly ask for information from traditional sources (travel agencies, tourist offices and so on), about 20% of them obtains information from the website, consistently with findings of previous studies (Padilla-Meléndez and del Águila-Obra, 2013) which show the increasing relevance of the webpage of cultural organisations. In this vein, 43% of respondents have visited the PAE's webpage, collecting information regarding the temples, which mainly attract the interest of tourists. Conversely, the vast majority of visitors did not participate in events organised by the PAE. Finally, only the 20% of them knows that the PAE has a Facebook page, and a low level of interaction has emerged from the questionnaire. However, people were asked to express their point of view regarding their future behaviour and their future interaction/use of the Facebook page of the PAE. The vast majority of them is in the "agreement" area.

4.2. Analysis of the interviews

Following the Walker et al. (2011) framework, the interviews were carried out and results were interpreted to capture both the IT and the administrative dimensions of management innovations (MIs), assessing the effects on organisational routines simultaneously. Furthermore, a third line of investigation was followed, to consider the effects of MIs on the global performance, at the same time unveiling future steps to undertake, consistently with the PAE's strategic objectives.

IT dimension of MIs

The IT dimension of MIs focuses on the use of new information systems, aiming to improve the efficiency of operating systems and processes. Therefore, the interviewees were asked to clarify the reasons for implementing a new communication strategy, and several interesting aspects emerged. Firstly, the Director and his staff perceived a broad dissatisfaction among visitors concerning several issues (low quality of several collateral services, lack of clear information regarding how to reach the Park, the time of opening, the events organised, and so on). However, at that time (2015), the PAE did not have a

systematic communication channel: the website was based on a one-way approach, which did not allow establishing a bilateral (or multilateral) relationship with visitors, and it was not so friendly and easy to surfing in; social media were not used. Accordingly, the first implemented measures were improving the webpage and starting using social media (especially Facebook). Therefore, a collaboration with a web agency started.

“When I was appointed as a Director, initially I tried to improve the quality of the services provided to visitors. I perceived the dissatisfaction of many visitors, but I lacked the information in order to improve them. I felt that the Park needed to improve its relationship not only with visitors but also with the local community.” (Director of PAE).

“When the Director of the Park contacted me, I was delighted to collaborate with him and his staff: supporting the communication strategy of one of the most important cultural site of the south of Italy, made me proud. Indeed, having understood the financial difficulties of the Park, which was in its first time of autonomy, I proposed starting the collaboration without asking a fee.” (CEO of the web agency 3d0).

As a result, the website was completely redesigned, with the primary aim being making it friendlier and more responsive, in order to allow interacting with surfing people and to monitor their activities, receiving valuable feedbacks. Furthermore, it was decided to open a Facebook profile. Actually, some Facebook pages were still active, but they were not managed from the PAE itself (they were labelled as “Friends of the Park” or similar expressions), because the lack of managerial autonomy *de facto* impeded to open an institutional page (several bureaucratic authorisations were required). In this case too, it was asked the collaboration of the web agency regarding how to structure and manage the Facebook page. This implied a complete reorganisation of all the activities concerning communication and relationship with visitors and media.

“In the past, the communication office was not so effective, since the lack of autonomy impeded to have an ad-hoc budget and to implement some basic initiatives to establish a direct relationship with visitors. Therefore, we considered these little innovations (redesigning the website, opening a Facebook page, a Twitter and an Instagram profiles) as the starting point of a new era. My colleague and I were thrilled to be in charge of the new press office.” (Press Office Manager).

The collaboration with the external web agency was reinforced step by step, and many services concerning both the webpage and the Facebook page were outsourced. On a monthly basis, the Park started to promote some events and initiatives on Facebook, with the aim of capturing the attention of (prevalently) the local community. It is worth noting that this focus is coherent with the results of the questionnaire.

Administrative dimension of MIs

The second MIs’ dimension deals with the implementation of new management systems and processes to improve the effectiveness.

The autonomy of the Park changed the role of the Director’s staff and the employees. In the past, employees had a “passive” role, merely keeping under surveillance the archaeological sites to impede people could damage them. However, the Director retained employees as pivotal “assets” of the Park, therefore he contributed to the development

and valorisation of human resources, whose role changed progressively. They understood the importance of being more active and collaborative, especially with visitors. As a result, several initiatives were launched. For example, the project named “Paestum viva” (“Paestum alive”; <http://www.museopaestum.beniculturali.it/paestum-viva-tutti-i-giorni/>) dedicated to families, consists of interactive activities, laboratories, music-therapies, to explain the history of the temples and the whole Park to children in an entertaining and enjoyable way. Moreover, the initiative named “Paestum per tutti” (“Paestum for everyone”), where the collaboration of employees is essential, allows disabled people visiting the areas inside the temples in a comfortable way.

“The strategic reorientation of the Park is possible only if employees and all the staff concretely perceive how essential their role and their collaboration is. Their positive thinking helps make visitors’ experience memorable”. (Director of PAE).

“In the past, employees acted mainly as guards, and their competences were not sufficiently appreciated. The strategic reorientation of the Park has radically changed this. Now, employees play an active role, giving visitors a warm welcome, providing them with all the information they require, assisting disabled people during their visit to the temple of Hera and the temple of Athena, making the innovations possible”. (Visitors and surveillance Manager).

Indeed, when new communication strategies were adopted, and innovative initiatives were launched, a resistance to change was observed. Traditionally, the behaviour of employees was anchored to a bureaucratic set of rules, and organisational routines were based on formal procedures to comply with. Besides, employees were (and still are) paid directly by the MiBACT, which impeded the implementation of a system of punishment and rewards, directly connected with their performance. The autonomy of the PAE has progressively changed - and it is still changing - the organisational behaviour of staff members and employees. Progressively, due to the feedbacks received from the website and the Facebook page and the motivator role played by the Director, they became aware of their mediator role between visitors and the archaeological site and the museum.

“The autonomy of the Park has progressively allowed us to appreciate and develop the skills and competencies of employees, while in the past the human resource management was completely «jammed»”. (Visitors and surveillance Manager).

“Day by day, we have a look at the Facebook page, to collect feedbacks from visitors, to answer their questions and to respond quickly to criticisms. Furthermore, the web agency provides us periodically with a report of feedbacks from the website. Finally, we received 15/20 daily reviews on average on Google. This information helps us in understanding how we [Director’s staff members and employees - ed.] could support this new way of thinking”. (Press Office Manager).

Furthermore, specific fundraising strategies were implemented, to establish a “sense of belonging”, involving visitors, the local community and local firms. The most relevant ones are:

- “Adopting the wall of Paestum” (see <http://www.museopaestum.beniculturali.it/adotta-un-blocco-delle-mura/>): people

can contribute to the maintenance and restoration of the site by giving 50 €, receiving an annual membership card and a periodical newsletter;

- “Circolo di Athena” (“Circle of Athena”), a group principally composed of local firms, which is financing the restoration of the façade of the temple of Athena;
- a local industry has financed three researchers to carry out digs;
- a no-profit organisation, named “Amici del Parco” (“Friends of the Park”) is financing several restorations.

Effects on performance and future initiatives

The interviewees claimed that the managerial innovations described above are boosting internal managerial relations, having a positive effect on the PAE’s performance. To avoid the risk, common to all social research method (Liguori and Steccolini, 2012; Badia et al., 2018), that ex post rationalisations of events could influence such reconstruction of events, the research team triangulated the data, by referring to reports provided by the PAE and data from official sources.

Table 4 illustrates both the number of visitors and gross revenue during the period 2014-2017. A significant increase in both indicators can be easily observed, especially in the last two years. It is worth recalling that all the initiatives described above were implemented from 2015 onwards.

Table 4: Number of visitors and gross revenue (2014-2017)

Year	No. of visitors	Gross revenue
2014	280,503	938,897.32
2015	300,343	1,100,489.93
2016	383,172	1,621,820.59
2017	441,196	1,917,050.23

Source: http://www.statistica.beniculturali.it/Visitatori_e_introiti_musei.htm

These results could be interpreted in the wake of Walker et al. (2011), according to whom performance management systems play a mediating role, allowing innovation to affect organisational performance.

Nevertheless, according to the interviewees, these results should be retained as a starting point, and future goals to furtherly boost high quality and coherent policy are going to be introduced. The keyword of programmed future innovations is “digitalisation”. In fact, future initiatives will concern:

- Improving the webpage in two main directions: participatory web, to interact better with visitors; improving the English version as well as developing it in other European languages;
- Launching an interactive guide, to allow visitors to automatically retrieve information regarding the artefacts they are observing, by using a smartphone or a tablet;
- Publishing a digital magazine regarding the museum and the archaeological site;
- Improving the Street view service, to allow people to go into the museum and the temples;

- Making the touristic tour enjoyable and entertaining both for children, and hearing-deficient people, through ad hoc audio guides (based on cartoons and the sign language, respectively);
- Promoting an interactive and social report, to friendly illustrate both financial results and non-financial outcome.

All in all, these initiatives would consist of both IT and administrative MIs, and a further positive impact on the global performance of the PAE is expected.

5. Conclusions

Public cultural organisations have been challenged in recent years by high competition in the world of art and culture, as well as by normative and institutional changes, including increased autonomy and reduced public resources. In this context, IT tools represent a challenge for these organisation to improve their performance, contributing to the growth of the community.

Grounded on the literature on managerial innovation, the paper has investigated – through the case study of PAE - if and how IT innovations (namely web and social media) and administrative innovations can affect the performance management systems, provoking also changes in the relationship with visitors, donors and the local community.

Results emerged by the case study furtherly proves that when managerial innovations - both IT and administrative one - present a high degree of affinity with existing goals and are able to provide support to cultural organisations in meeting their objectives, they are more likely to succeed and the new practices being implemented. Furthermore, it demonstrates that IT and administrative innovations, mediated through the performance management systems, can increase the overall performance of a cultural organisation, also affecting the relationship between the entity and the main external stakeholders, namely visitors, donors and the local community.

The paper suffers from some limitations, generally related to the case study approach, as results cannot be generalised. Nonetheless, it offers a contribution to the existing knowledge of managerial innovations in cultural organisations, highlighting how these innovations – namely IT and administrative one – can contribute to the enhancement of the overall performance of the organisations. The research may provide interesting implications for policy makers in supporting the wide use of IT tools by public cultural organisations. Future development of the study may consider comparative case studies, in order to better detect the role played by Directors in promoting managerial innovations.

Abstract

The rise of sharing economy, made possible by technological evolution, has changed the way people make use of underutilized goods and has also changed the competition dynamics between incumbents and new players of many sectors. One sector that has been more revolutionized by the sharing economy is the tourism industry, given the rise of many new intermediaries and new players. Among them, Airbnb, an online marketplace that enable people to list, find and book rooms around the world, has very quickly changed the rule of competition of the hospitality industry. Given the strong position in the tourism sector, Airbnb has become a new competitor of hotels, that need to understand how to react and to compete against it.

Previous research has already analysed some perspectives of AirBnB rise phenomenon, but the results vary a lot depending on the context and they are still far to be somehow conclusive regarding the systematic description of sector behaviour.

Thus, given the previous outcomes on the possible disruptive effect of Airbnb on the hotel industry have not reached a final and unique conclusion, and given the importance for hotels to constantly update their strategic choices, the present study has the aim of replying to the following two research questions: “Does Airbnb impact negatively the hotel economic performance?” and “What are the key moderators among hotel’s online and offline positioning strategies, capabilities, and characteristics of the Airbnb’s local supply?”.

Overall, the present study contributes to the emerging literature debate on the economic impacts of sharing economy on the incumbent hotel industry across an even broader variety of consumer markets. From a managerial point of view, this study informs hotels that they are no longer just competing with other hotels in their markets. They are also competing with Airbnb, and other home-sharing services, in their neighbourhood. A way to succeed, as demonstrated by this study, is to develop the appropriate capabilities to defend their economic performance and to look closely at why Airbnb is succeeding, to fight back and protect their investment.

Keywords – Airbnb, hotel industry, performance, online managerial capabilities, sharing economy.

Paper type – Academic Research Paper

1 Introduction

How home-sharing services are changing accommodation sector? That is a pretty interesting question, and given our strategic/managerial background we are going to focus on structure changes looking at performance indicators of involved players. Particularly, looking at the entrance of new players in the sector, we wonder whether they are “stealing” pieces of incumbents’ cake or maybe if the cake is getting much bigger thanks to their intervention.

In 2017 total contribution of travel and tourism industry (included accommodation, transportation, entertainment and attractions of these industries: accommodation services, food & beverage services, retail trade, transportation services and cultural, sports & recreational services) to global economy was 8.27 trillion \$, while direct contribution accounted for 2.57 trillion \$. By comparison in 2017 the whole globe produced goods for a value of 80.05 trillion \$ (IMF, 2018). It means roughly 10 % of economic value produced in the world concerns touristic goods or services, that’s impressive.

In the same year world hotel sector market size was 570 billion \$, 22% of the value of direct contribution to global production by travel and tourism industry (2019, Statista). Even if hotel market size is increasing (+ 8% from 2015 to 2017), direct and total contribution from travel and tourism industry is increasing even more (+ 15 % from 2015 to 2017 for both numbers), roughly twice the rate. It is clear that the weight of hotel in travel and tourism industry is decreasing (from 7.35 % of total contribution in 2015 to

6.89 % in 2017) and that led us to wonder more about possible causes of that phenomenon.

Previous literature explored the impact of new players against hotels value chain from a vertical perspective, where new services suppliers, so called infomediaries, have great bargaining power, (Raguseo, Neirotti, & Paolucci, 2017) while now in this paper we will examine horizontal competition coming from a possible substitute product. In fact, in the last years, we have witnessed an incredible growth of short term private owned homes/rooms rentals offered through websites like HomeAway, VRBO, VayStays and the most important one: AirBnB. Previous research has also already studied the impact of Airbnb on the hotel industry, but contradictory evidences emerged. On the one hand, Zervas et al. (2017) demonstrated that a 1% increase in Airbnb supply decreases hotel revenue by 0.04%. Dogru et al. (2017) demonstrated that an active supply of entire homes impacted hotel RevPAR (Revenue Per Available Room) by 0.02% and both ADR (Average Daily rates) and OCC (Occupancy Rates) by 0.01%. Furthermore, Neeser et al. (2015) shown a negative impact of Airbnb supply on hotel room prices. On the other hand, other empirical evidence did not confirm this negative impact. For example, Choi et al. (2015) did not found any negative impact of Airbnb supply on hotel revenues in Korea. Blal et al. (2018) found that overall hotel RevPAR is not related to total Airbnb supply.

Thus, given these mixed results on the possible disruptive effect of Airbnb on the hotel industry, and given the possible existence of different impacts that Airbnb can have on hotels according to its location in a city, the present study has the aim of replying to the following two research questions: “Does Airbnb impact the hotel economic profitability?” and “Does the hotel location in a city influence this relationship?”.

In order to reply to these research questions, we adopted the theory of disruptive innovation (Christensen, 2015) and we created a large scale database collecting a high volume of information on Airbnb and financial data about hotels in five big Italian touristic cities, that are Turin, Milan, Venice, Florence and Naples. We found that Airbnb supply impacts negatively on the hotel performance. However, our most interesting results consist in identify two different dynamics according to the hotel localization. Specifically, we found that Airbnb supply has a negative effect on hotels’ profitability in case the hotel is not located in the city centre, while it has not any significant effect in case the hotel is located in the city centre.

We chose as research setting Italy since it was in last years the 5th country in the word by international touristic flows (2018, UNWTO), and travel and tourism industry represents one of the biggest sources of value production for the nation, being the 11.5 % of GDP in year 2017, 223 billion \$ over 1935 billion \$ (2018, Statista).

It is clear that travel and tourism industry represents a peculiar and fundamental feature of Italian economic system, and there is evident need of better understanding of what is currently happening under the surface and its consequences.

2 The importance of Airbnb in the accommodation sector

Today Airbnb collects in its website more than 6 million listings from 192 countries (Airbnb, 2019); In august 2017, Airbnb had more listings than the number of rooms built by the top five hotel brands combined (Hotel News Now, 2017), 4 million compared to roughly 3.9 million.

AirBnB business model is simple, given the fact it makes possible the matching between host and guest they both have to pay (Hansen Henten & Maria Windekilde, 2016) a percentage of daily cost: 1) Guests pay a percentage between 6 % and 12 %, this number decreases when more nights are booked, making more convenient booking longer periods; 2) Hosts pay a fixed 3 % fee of the room price.

Just to make a rough estimate of Airbnb alone market size let's consider on average 12 % fee on room price (9 % fee on average from the guest and 3 % from the host), knowing 2017 revenue of 2.6 billion \$ (2018, Zaleski) we can say they come from a number somehow similar to 22 billion \$, which represents the transactions between hosts and guests made possible by the platform.

Looking at those numbers is clearly visible that Airbnb impact cannot be neglected, on the contrary it should be closely measured in order to better understand its consequences on incumbents and society.

Figure 5: Number of Airbnb listing worldwide.

In Figure 5 it is possible to see the elbow of the curve at the end of 2014; at the beginning of the chapter we showed a decrease in the share of hotel market size with respect to direct and total travel and tourism industry from 2015 to 2017; could the two events be somehow related each other?

The impressive growth described by the figure can be explained taking into consideration the following factors. First, easy access to internet – this technological revolution allowed to easily collect, exchange and publish information, dramatically reducing the transaction cost related to making a choice related to travel and tourism;

before this revolution few players (mainly travel agencies) were able to efficiently collect and manage information regarding travel and tourism, while today many users could consider more efficient looking for holiday on the web with respect to going to travel agency. Indeed, the internet allowed some players (Uber, Google, etc...) to organize a lot of information in a way that it is easy to access for everyone, making easier than ever before to compare different solutions. AirBnB is one of those players and it has been able to reduce a lot the cost of comparing possible accommodation solutions for the user (Hansen Henten & Maria Windekilde, 2016).

Second, disruptive innovation effect – as described by Clayton Christensen, competition pushes incumbents to improve their products in order to survive and succeed, and in many cases they end up offering “services that are actually too sophisticated, too expensive, and too complicated for many customers in their market. [...] However, by doing so, companies unwittingly open the door to ‘disruptive innovations’ at the bottom of the market. An innovation that is disruptive allows a whole new population of consumers at the bottom of a market access to a product or service that was historically only accessible to consumers with a lot of money or a lot of skill.” These innovators initially are characterized by a simpler product, lower return and market size, and incumbents often are not interested in competing (Christensen, 2015), but then they “relentlessly move up market, eventually displacing established competitors” (Christensen, 1997). AirBnB has been able to offer a really basic product at low price, and travellers not in need of high level services sustained its growth, until it became so big to make reasonable the following question: Is AirBnB a substitute product with respect to hotels?

In fact, the result is a player able to convince investors about its value, today AirBnB is the undisputed leader of its segment (short term apartment/rooms rental platform) and has a solid position in tourism ecosystem, with an estimated valuation of 31 billion \$ in year 2016, as a comparison the most valuable hotel brand at the time was Marriot International, just 7 billion more valuable (2017, Deanna Ting).

3 Theoretical background

Previous research has already studied the impact of Airbnb on the hotel industry, but contradictory evidences emerged. On the one hand, Zervas et al. (2013) demonstrated that in Texas, a 1% increase in Airbnb supply decreases hotel revenue by 0.04% (Zervas, Proserpio, & Byers, 2013). Dogru et al. studied the phenomenon in 10 main US cities and demonstrated that an active supply of entire homes impacted hotel RevPAR (Revenue Per Available Room) and ADR (Average Daily rates) by 0.02% with significant effect on all hotel segments, while the effect on OCC (Occupancy rate) is not always significant (Dogru, Mody, & Suess, 2019). Furthermore, Neeser et al. (2015) shown a negative impact of Airbnb supply on hotel room prices.

On the other hand, other empirical evidence did not confirm this negative impact. For example, Choi et al. did not found any significant negative impact of Airbnb supply on hotel revenues in Korea (Choi, Jung, Ryu, Kim, & Yoon, 2015).

Other researchers show mixed or complex relationships: Blal et al. (2018) found that overall hotel RevPAR is not related to total Airbnb supply, but that every increase in the review score of Airbnb properties had a negative impact on hotel RevPAR, so hotel negative impact comes from the “quality” of the substitute supply instead of the “quantity” (Blal, Singal, & Templin, 2018). Koh et al. (2017) interviewed a set of hotel representatives in Singapore and the majority of them reported increased competition in the sector with impact on economic performances, but there’s lack of evidences about the source of competition increase (Koh & King, 2017). Xie et al. (2017) observed in Austin that RevPAR of hotels is negatively correlated with total Airbnb listing number, but the relationship is moderated by the pricing strategy of Airbnb listing in the same area (Xie & Kwok, 2017).

Couple of researches even found positive relationship between the AirBnB and hotel economic performance. Aznar et al. measured the number of Airbnb listings in a radius of one km from a set of hotels in Barcelona, then analysed economic results and found positive relationship with Return on Equity. They explained this outcome by linking higher number of Airbnb listing with better areas (Juan Pedro Aznar, Josep M Sayeras, Alba Rocafort, 2017). Ginindza et al. explored the case of an emerging touristic destination, the kingdom of Swaziland: in this developing country the authors noted a positive relationship between the hotel Occupancy rate and Airbnb Occupancy rate, indeed Airbnb platform was found to appeals to a different tourist market profile than does that of hotels (Ginindza & Tichaawa, 2017).

Table 1: Literature review

Research team	Title	Data/Analysis method	Dependent variable	Impact on hotels
Zervas, Proserpio, & Byers, 2013	The Rise of the Sharing Economy: Estimating the Impact of Airbnb on the Hotel Industry	Airbnb’s entry in Texas, US/10; 555 hosts and 13,935 listings from 2008 to August 2014	Room revenue	Negative
Xie & Kwok, 2017	The effects of Airbnb’s price positioning on hotel performance	Airbnb’s entry in Austin, Texas, 86 hotels quarterly financial data from Q3 2008 to Q2 2011	RevPAR	Negative
Blal, Singal, & Templin, 2018	Airbnb’s effect on hotel sales growth	Airbnb’s entry in San Francisco, 11 data points, about 101 hotels between Dec 2013 and Feb 2016	Growth of RevPAR	Negative
Dogru, Mody, & Suess, 2019	Adding evidence to the debate: Quantifying Airbnb’s disruptive impact on T ten key hotel markets	AirBnB entry in Boston, Chicago, Denver, Houston, Los Angeles, Miami, Nashville, New York, San Francisco, and Seattle, between July 2008 and June 2017.	RevPAR, ADR, Occupancy rate	Negative
Ginindza & Tichaawa, 2017	The impact of sharing accommodation on the hotel occupancy rate in the kingdom of Swaziland	46 hotels and 35 Airbnb monthly data from 2012 to 2016 in the towns of Mbabane, Ezulwini, Matsapha and Manzini	Occupancy rate	Positive

Koh & King, 2017	Accommodating the sharing revolution: a qualitative evaluation of the impact of Airbnb on Singapore's budget hotels	6000 Singapore properties average price and interviews to hotels managers	NA	Negative
Juan Pedro Aznar, Josep M Sayeras, Alba Rocafort, 2017	The irruption of Airbnb and its effects on hotel profitability: An analysis of Barcelona's hotel sector	43 hotel in Barcelona data from 2008 to 2013, Airbnb listings 1 km from those hotels	ROE, revenue	Positive
Choi, Jung, Ryu, Kim, & Yoon, 2015	The Relationship between Airbnb and the Hotel Revenue: In the Case of Korea	Hotel revenue in Seoul, Busan & Jeju, from 2010 to 2013	Revenue	No relationship

Literature review in **Error! Reference source not found.** revealed both a lack of researches in our geography (Italy) and a lack of results taking into consideration fundamental profitability ratios like Return On Asset and Return On Sale. Moreover, the outcomes analysed show a great variety of results based on context, environment and variables observed, so we strongly believe our research will add valuable content to the debate ongoing regarding new services impact on incumbents in accommodation sector.

4 Hypotheses

Thus, given these mixed results on the possible disruptive effect of Airbnb on the hotel industry, and given the importance for hotels to choose the right positioning strategies, to develop the adequate online managerial competences for defending their economic performance, and given the influence that the characteristics of the Airbnb's local supply can have in explaining the economic returns of hotels, the present study has the aim of replying to the following two research questions: "Does Airbnb impact negatively the hotel economic performance?" and "What are the key moderators among hotel's positioning strategies, capabilities, and characteristics of the Airbnb's local supply?".

To investigate these two research questions, we refer to the theory of disruptive innovation (Christensen, 1997). According to this author, the process of disruptive innovation occurs in two phases:

- 1) an initial step when the innovation is not adopted by mainstream customers, performs worse than existing products, and is used only in niche markets;
- 2) in a later stage, mainstream customers adopt the innovation rapidly, thus disrupting the leading firms in the market.

Accordingly, we apply this theory because Airbnb passed through these two phases that characterize a disruptive innovation (Blal et al., 2018) and because Airbnb occurs outside the value network of existing firms, and introduces a different package of attributes offered to and valued by travellers that eventually transforms a product or service (Guttentag and Smith, 2017).

Given the impressive growth of Airbnb rooms we are witnessing in the last years and the similarity between the basic needs (a bed in a room) hotels and Airbnb both respond it is reasonable to take into consideration the possibility of substitution effect between the two, with the result that the incumbents lose at least one between market share and profit to remain competitive. Thus, we formulate the following hypothesis:

H1. Airbnb supply in a city lead to a profitability decrease to the hotels in the same city;

The lower fixed cost Airbnb owners face allows them to set lower price with respect to hotels (Einav, Farronato, & Levin, 2015). It is reasonable to suppose that the scarcity of time and money most people have to deal with while choosing accommodation for holidays lead them to make their choice with one of the following criteria, once a general level of quality expectation has been set: 1) the accommodation respecting the budget closest to main touristic attractions; 2) the cheapest accommodation in the area of touristic attraction;

Given the fact that in the cities taken into account in our analysis the centre collects the main touristic attractions it is reasonable to conclude that before the rise of Airbnb people could choose between higher price hotels in the city centre and second choice hotels more distant from it.

Now Airbnb in city centre represents an alternative to hotels in suburbs and our hypothesis comes from the fact that people prefer to stay closer to touristic attraction when facing comparable level of price. Hotels in suburbs consequently saw a decrease in number of bookings or in price requested to customers or both, causing a decrease in profitability indicators. Thus, we formulate the following hypothesis:

H2. In the city centre hotels profitability is not suffering from Airbnb impact, while hotels in suburbs are suffering the most.

Therefore, the research framework investigated in this study is shown in Figure 6.

Figure 6: Research framework

5 Methodology

In order to prove our hypotheses, we created a comprehensive dataset collecting a large volume of information from many different sources about hotels in 5 big Italian touristic cities, that are Turin, Milan, Venice, Florence and Naples. We have chosen those 5 cities because they are among the most representative in Italy regarding touristic flows but we avoided Rome since it is much bigger than the others. We collected the variables from many different sources, that are:

- Tripadvisor website through a scraper;
- Istat through the website and through custom requests;
- AirDNA proprietary database;
- Agenzia delle Entrate real estate quotation database;
- Bureau Van Dijk financial database AIDA;

We merged the data in order to obtain a longitudinal database where each row represents the characteristics of a hotel in a given year.

Variables

The dependent variables of the model are the Return On Sales (*ros*) and Return On Asset (*roa*) of the hotels per each year, the first one represents the ratio between profit and total revenue of the hotel in the year, while the second is the ratio between the profit and the balance sheet value of the assets. They both come from the AIDA financial database.

The independent variable (*log_nearairbn_total*) is the logarithm of total number of active AirBnb listings in the same city of the hotel per each year. The data about monthly performance of AirBnb listings comes from AirDNA proprietary database. We considered as active all listings available for booking, even for a small period of time, during the year.

Here's the list of all control variables used to run the model:

- *count_review_hotel_cum*: it is the total number of reviews the hotels received on Tripadvisor website at the end of previous year, the variable has been collected through a scraper;
- *count_response_hotel_cum*: it is the total number of answers to reviews the hotels wrote on Tripadvisor website at the end of previous year, the variable has been collected through a scraper;
- *average_month_rent_m2*: it is the average between minimum and maximum squared meter monthly rental price for residential real estate in a city in a year, the variable has been collected from Agenzia delle Entrate real estate observatory;
- *log_revenue*: it is the logarithm of the revenue of a hotel in a year, it controls for hotel size, the variable has been acquired from Bureau Van Dijk AIDA database;

- *norm_touristic_flow_presence*: it is the normalized number of overall nights tourists spent in a city in a year, the variable has been acquired from ISTAT website;
- *2015.year, 2016.year, 2017.year*: it is the dummy variable for the year of observation, it has been generated knowing the year of the row;
- *hotel_5l_count*: it counts the number of 5 star or more hotels in a city in a year, it has been acquired from ISTAT;
- *hotel_4_count*: it counts the number of 4 star hotels in a city in a year, it has been acquired from ISTAT;
- *hotel_3_count*: it counts the number of 3 star hotels in a city in a year, it has been acquired from ISTAT;
- *hotel_2_count*: it counts the number of 2 star hotels in a city in a year, it has been acquired from ISTAT;
- *hotel_1_count*: it counts the number of 1 star hotels in a city in a year, it has been acquired from ISTAT;
- *dummy_citycentre*: this variable has been used to explore the effects of Airbnb on two different categories of hotels, the one in city center and the one in the suburbs (see model 3, 4, 5, 6). The authors have arbitrarily set the distance from city center that determines a hotel being in it or in the suburbs given their knowledge of the cities.

The descriptive statistics of the variables are shown in Table 5.

Table 5: Descriptive statistics

Variable	Obs	Mean	Std.Dev.	Min	Max
<i>Roa</i>	2794	3.7	13.019	-145.64	73.12
<i>Ros</i>	2594	4.173	11.355	-49.95	29.95
<i>log_nearairbn_total</i>	1795	9.056	.667	7.783	10.073
<i>count_review_hotel_cum</i>	1468	172.884	235.318	0	2681
<i>count_response_hotel_cum</i>	1468	57.215	145.243	0	1325
<i>average_month_rent_m2</i>	2668	10.667	2.216	5.434	13.338
<i>log_revenue</i>	2782	13.618	2.281	0	17.574
<i>norm_touristic_flow_presence</i>	2020	0	1	-2.262	0.945
<i>hotel_5l_count</i>	2525	15.819	6.191	2	23
<i>hotel_4_count</i>	2525	102.413	31.383	25	141
<i>hotel_3_count</i>	2525	136.931	35.992	63	175
<i>hotel_2_count</i>	2525	56.388	20.798	9	78
<i>hotel_1_count</i>	2525	47.177	15.877	16	70

The number of observation varies across the variables, meaning not all the cells are correctly given a value. That's because some variables cover a longer period than others, we excluded all the rows not 100% complete. Our observed variables, *ros* and *roa*, are positive on average, meaning the set of hotels have a positive return on both sales and assets. We excluded extreme values of those variables in order to have a normal shaped distribution.

Looking at Tripadvisor review count we can note our set received on average 173 reviews and answered to 57 of them. Standard deviation of number of responses is

proportionally higher than standard deviation of number of review, meaning that the value is more spread, that is what we expected, since we observed that most of hotels respond to almost all reviews or do not respond at all.

The log of the revenue of the hotel is an approximation that allows us to control for hotel size, while the average cost of renting and the touristic flows are really important control variables not directly manageable by hotels. The first one gives the model an insight about the perceived value of livable space, while the second allows us to control the effect on profitability coming from a different number of tourists.

Finally, we collected the number of hotels per year per city of any category to control the “competition” from other hotels.

Model

In order to clean the dataset from outliers we plotted leverage vs residual-squared graph to exclude high impact extreme points, then we checked collinearity with variance inflation factor.

Only complete observations have been included in the model, and the two dependent variables have been cleaned from extreme values. **Error! Reference source not found.** shows the correlation matrix of the variables included in the regression model.

Table 3: Correlation matrix

Variables	ros	roa	log_nearairbn_total	count_review_hotel_cum	count_response_hotel_cum	average_month_rent_m2	log_revenue	norm_touristic_flow_presence	hotel_5l_count	hotel_4_count	hotel_3_count	hotel_2_count	hotel_1_count
ros	1												
roa	.66	1											
log_nearairbn_total	.03	0.06	1										
count_review_hotel_cum	.07	.07	.30	1									
count_response_hotel_cum	-.01	.01	.22	.64	1								
average_month_rent_m2	.11	.10	.09	.02	.02	1							
log_revenue	.15	.19	.15	.37	.30	.09	1						
norm_touristic_flow_presence	.12	.11	.48	.13	.10	.88	.12	1					
hotel_5l_count	.12	.12	.52	.12	.10	.84	.12	.99	1				
hotel_4_count	.08	.10	.53	.09	.09	.76	.12	.95	.94	1			
hotel_3_count	.16	.12	.04	.07	.03	.83	.04	.81	.81	.64	1		
hotel_2_count	.09	.07	.53	.01	.05	.56	.05	.79	.81	.73	.71	1	
hotel_1_count	-.01	.02	.62	.01	.07	.50	.12	.74	.71	.80	.27	.68	1

The correlation matrix shows there's no particularly high relationship between dependant variables and independent variables, even if some expected high correlation values appear among control variables.

Fixed effect regression models have been run with robust standard errors in order to verify the hypotheses, controlling for fixed year effects using STATA 14.0 software. In next chapter we present the result of empirical analysis. We expect that models confirm our hypotheses.

6 Results

Overall, the present study contributes to the emerging literature debate on the economic impacts of sharing economy on the incumbent hotel industry across an even broader variety of consumer markets. From a managerial point of view, this study informs hotels that they are no longer just competing with other hotels in their markets. They are also competing with Airbnb, and other home-sharing services, in their neighbourhood. A way to succeed, as demonstrated by this study, is to develop the appropriate capabilities to defend their economic performance and to look closely at why Airbnb is succeeding, to fight back and protect their investment.

Stata outcome (reported hereunder here in **Error! Reference source not found.**) clearly shows negative and significant impact from the logarithm of Airbnb listings per city per year on both dependent variables, ROS (model 1) and ROA (model 2), when considering the whole city, confirming H1 where we stated that Airbnb supply in a city led to a profitability decrease to the hotels in the same city.

Further exploring the models, it is evident that also H2 is confirmed, in fact both ROS (model 5) and ROA (model 6) show negative and significant impacts restricting the model to the hotels in suburbs, and that impact in both cases is stronger than the case concerning the whole city. On the other hand, the impact on the hotels in city centre does not show significant coefficients, so we cannot conclude Airbnb is affecting the profitability of these hotel category and H2, in the city centre hotels profitability is not suffering from Airbnb impact, while hotels in suburbs are suffering the most, is confirmed.

7 Conclusions

This research clearly shows that AirBnB is having a significant impact on hotels' profitability, in fact even if touristic flows are generally increasing (with some exception) hotels are not fully able to benefit from the additional profit and suffer a partial market overlapping from various substitute products, among which the biggest one is surely AirBnb. Generally speaking, the technological paradigm shift we witnessed in last 20 years gave most developed countries citizens access to an amazing quantity of well-organized information and instantaneous communication possibility, allowing the quick development of new services able to threaten incumbents in many sectors, that saw barriers to entry in their space lowered in a short period of time.

In this context some incumbents have been able to benefit from the new range of possible services and they are riding the wave of digital transformation, but in accommodation sector they are mostly large groups, while smaller incumbents struggle to

reinvent themselves. For example, Marriott's group has established a partnership with Netflix to deliver customizable entertainment services, while Hilton, Starwood and Intercontinental Hotels Group partnered with Uber to offer more comprehensive range of services (GrantThornton, 2016). It is not a coincidence two of them, Marriott's and IHG, are listed among the 50 most innovative companies in 2018 ranking by Boston Consulting Group (Boston Consulting Group, 2018).

Having observed that we would like to go more in depth both from the side of the incumbents, analysing strategic choices behind their performances and from the side of the entrants, applying case study methodology to extract new moderators to test with quantitative analysis.

We know the research has some limitation, our main target is in fact to further explore the moderating effects of managerial variables and online reputation variables. Furthermore, we aim at expanding the geographical and temporal scope of current study, including new categories of areas and older/newer data.

Last but not the least, not only hotels are impacted from sharing-economy or technology-enabled services, there are in fact many other incumbents in tourism ecosystem that are facing somehow similar challenges.

Abstract

Knowledge is the most important resources of an organization as depicted in the knowledge-based theory of the firm. Systems to gather knowledge and process it to be useful for decision making are vital. Further, knowledge is time sensitive and hence loses relevance as environment changes. Agriculture and especially seed sector in Africa is one sector which require creation of a seed business knowledge ecosystem to aid in timely exchange of knowledge across, governments, seed companies, supply chain partners and farmers. When knowledge is exchanged between the aforementioned entities, it allows humans to relay thoughts, relay perceptions of environment and adapt hence take advantage of opportunities or minimize potential threats in their operating environments, leading to production and distribution of the required amount of seeds to enhance agricultural productivity and hence reduce hunger and poverty in the African continent. The paper used cross sectional survey design of papers published in the African seed sector as at end of March 2019. The aim of the review was to establish key findings and recommendations advanced with view of providing a workbench to find out whether the recommendations and the findings have been made use of by the time of writing the paper. The authors make the conclusion that its not easy to establish the readers of each report published and value of the information derived from reading the paper and implementing the appropriate recommendations. Due to the shortcomings of housing knowledge in published reports, the authors propose an ICT based seed knowledge ecosystem which will allow aggregation and disaggregation of seed information for ease of decision making. The proposed ecosystem to be dubbed the Africa Seed Sermo will provide an interactive dynamic adaptive system which will enable conversions between actors, online surveys, opinion poling, voting issues, management of awards/pay-outs/registration fees possible. Additionally it will change the landscape of seed related literature to make data gathering, storage, processing and archiving easy creating a solid base for information generation which when integrated with the intellectual capacity of interpretation, comparison, connections and conversations build the intended knowledge for agricultural transformation.

Key words; Knowledge Ecosystem, Aggregation, disaggregation, Africa Seed Sermo, Interactive dynamic adaptive system

Type of Paper - practical paper

1. Introduction

Agriculture is the lifeline of majority of the countries in Sub-Saharan Africa creating 70% employment opportunities, contributing 33% of gross domestic product and 40% of export earnings, (World bank, 2014). Though agriculture is central to economic development in Africa and plays a major role in poverty eradication and reduction of food insecurity, agricultural productivity remains low and indeed has been falling over the years. The foundation of high agricultural productivity is a vibrant seed sector. Overall seed trade done in Africa was US\$ 800 Million being less than 2% of the global total, (AGRA, 2015). This percentage is low because majority of the farmers plant informal seeds which then in return contribute to poor yields.

The seed sector in Africa can greatly benefit through creation of a seed knowledge ecosystem and hence harness the power of knowledge to propel agricultural transformation. Knowledge ecosystem denotes the happenings that occur as collated knowledge is converted into silent knowledge as time progresses mainly through experiential and learning process. To create a knowledge ecosystem, communities of practice interact with bodies of knowledge, tools, technologies and practices which facilitate upgrading of knowledge over time. A seed knowledge business ecosystem consists of knowledge generated by breeders, seed enterprises, agro dealers, farmer organizations, farmers, government regulatory bodies and agriculture funding agencies. These bodies put together under a knowledge management system can be the answer to Africa's food crisis.

The discipline of knowledge management has witnessed three phases of evolution, Snowden, (2002). First stage focused on distributing information to decision makers so as to enable them make decisions timely. The second age replaced the information technology focus with one on tacit/explicit knowledge transformation motivated by Nonaka's SECI model. The third age is the one in which knowledge is viewed paradoxically as a thing and a flow, context, narrative and management of content generated through comparisons and conversations between knowledge generators. The final phase calls for lots of integration among various actors in the knowledge area while at the same leveraging on the power of information communication technology to generate knowledge, synthesize, adapt it and grow it as operating environments change.

2. Rationale for African Seed Knowledge Ecosystem

Countries of Africa have witnessed liberalization of the seed industry for over two decades now. This has led to departure from government monopolized seed trade to perfect competitive seed market where private sector firms play a major role. To better manage seed issues, many countries have country based seed associations and the continent has an umbrella, body dubbed Africa Seed Trade Association (AFSTA) to champion the involvement of private sector enterprises in seed production and distribution. The association (AFSTA) was formed in 2000 with the main objective of promoting the use of improved formal seed in Africa and hence improve agricultural

productivity. Since the formation, membership has grown to include seed associations in respective countries, associations/companies outside Africa, Non-governmental organizations and companies involved in seed trade.

The main mission of AFSTA has been to move farmers in Africa to routinely replace their seed varieties with improved varieties to transform agricultural productivity. Improved seeds are climate smart varieties which adapt to changing climate conditions and are hence key to embrace given the issues of global warming noted. If agricultural productivity is improved, poverty will be reduced, there will be more women engaged in agriculture and nutrition of societies will improve leading to less sick people.

Public and private sector organizations invest in improved varieties for common good. Its however worthy noting that farmers in some areas continue to use obsolete varieties. Knowledge ecosystem should be able to convey information real time to farmers preferably using mobile phone technology about new released varieties. Same channel could also be configured by seed marketing agencies and other entities to promote and distribute the improved varieties more efficiently and cost effectively. Support offered by government agencies should be inline with appropriate policy and if not, the ecosystem should trigger inconsistency to arise before release so as to enable the relevant arms of governments and regulatory agencies to develop the appropriate policy. To create demand for the improved seeds, innovative ways are required to sensitize farmers, this is possible through links with social media platforms like facebook and other highly customized mobile applications like “Viusasa” in Kenya.

3. Methodological Approach

The study utilized an online literature review of existing reports on the Africa seed sector. In total 5 reports were reviewed to uncover key findings which actors in Africa were expected to work on after the reports were presented. From Table below, its clear that even though the findings were useful, its not easy to know how many people have accessed the information and how the information has been of value in creating impact in the seed sector. Sometimes readers of reports may find contradicting information and concerns which were addressed by authors inappropriately and hence a conversion between a reader and an originator of a report would be an excellent opportunity for knowledge sharing.

4. Proposed Africa Seed Sermo

Sermo is a latin word that means “conversation”. It will allow a team of self-described community of crop seed actors and professionals to both communicate and filter knowledge in a knowledge ecosystem. This shall be modelled through an internet-based system which would allow actors in seed business to register in the system so as to be allowed to post seed related literature or retrieve information from such a system. To make sure that information contained in the system is authentic, the system envisaged should be a closed system so as to better manage knowledge quality. A closed system as March (1991), argues can exceed the performance of democratic or open communities in detecting previously unfamiliar elucidations to relevant problems. An indispensable diversity of actors is key if a complex dynamic adaptive system like the one proposed is to respond to unanticipated emergent concerns, as observed by Anderson , (1999).

In order to use the Africa seed knowledge ecosystem, the seed actors will be allowed to voluntarily register in the system. Registration can be set at individual and corporate levels and a registration fee can be agreed on so as to raise funds for running the knowledge system. Alternatively, a registration fee can also be charged for running the system but can additionally be sponsored by philanthropists in the seed industry. It is expected that no confidential Information on seed will be posted into the system and hence interested parties will need to be allowed to register using their official identities. Its however worthy noting that if the community of actors is expected to vote for any of the players concerning an issue for some award, then use of pseudonyms is encouraged. Encouraging anonymous contribution can discourage corruptive influences, extortion and vote buying in a closed knowledge ecosystem and additionally registered participants may feel free to voice their disquiets or opinions which would not be voiced if acknowledgement was a prerequisite, (Wade-benzoni et al. 1996).

The actors in seed business knowledge ecosystem will be in two broad categories, those with expert knowledge on a topical issue of interest and those who would want know and use new and expert knowledge generated from the interaction of the experts. Experts will include breeders, regulators, general research community and marketing officers of seed companies among others. Users of knowledge generated will include farmers, agro dealers and distributors. The ecosystem will allow actors who have the capacity to belong to the two categories to do so and hence categorization will not be mutually exclusive. The knowledge ecosystem designed will be a dynamic adaptive decision support system that fosters knowledge exchange opportunities and enables knowledge generated to evolve as the operating environment changes, Bray (2007). The main challenge of non-decision support based system is that employees may not easily know the knowledge available to be known, its value and the currency of such knowledge. Further disaggregation and aggregation of such knowledge to provide leads to decision making opportunities offers a great challenge.

In many fields of study, Polanyi. (1966) argues that tacit knowledge is better than explicit knowledge which is conventionally housed in forms like published reports in websites, journals or textbooks. It's highly contextualized and experience based knowledge surpassing taught or presented verbatim. The decision support system will allow the seed community to tacitly accumulate the relevant insights in their areas of expertise gathered through regular practice, share the same with others and hence create a more productive force in agricultural productivity increase. The proposed design of the system will be such that it will make actors be able to pose questions and expect to get answers from other ecosystem members a feature which a published report or a textbook hardly provides. The questions will represent unforeseen or unknown problems of decision makers which many writers may not know at the time of writing a book or a report and hence the proposed seed knowledge ecosystem will present a probabilistic rather than a deterministic model in knowledge cultivation, Simon (1991).

Knowledge ecosystems are good frontiers for research. It's envisaged that clients in addition to paying regular subscription fee to hook on to the system will also pay additional fee to post surveys for the entire continent, ecological zones or countries. Additionally, corporations and individuals whose work will be frequently accessed will also be rewarded through pay-outs. This design feature will be a selling point to many support organizations like FAO, AGRA, CYMMYT, Bill and Melinda Gates Foundation, Rockefeller Foundation and others whom in the past have sponsored Africa seed related research.

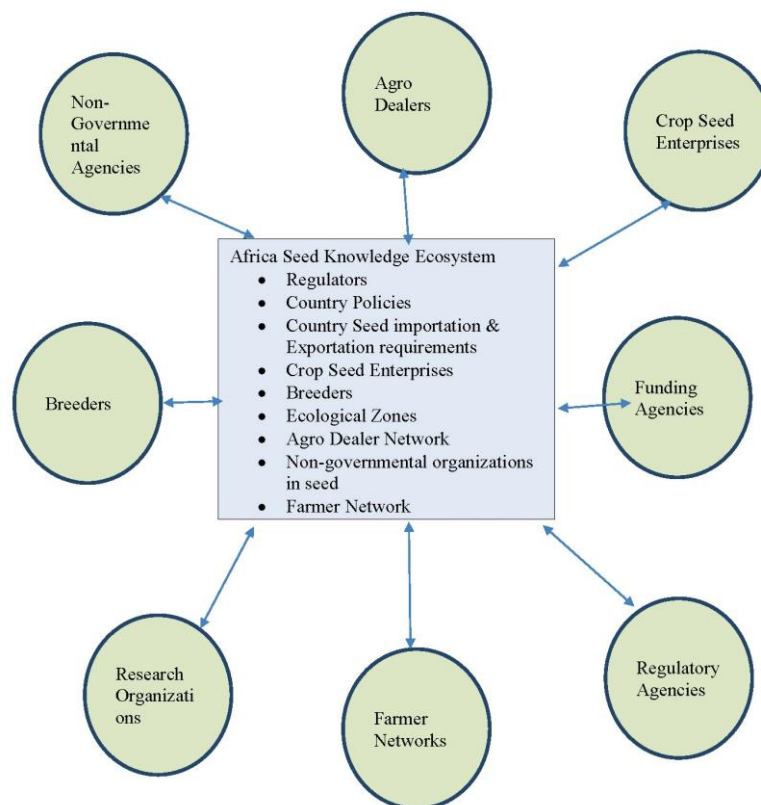

Figure 3.1 African Seed knowledge Ecosystem Components

5. Conclusions

Knowledge management in the seed sector in Africa is centred on published reports many of which are available online. Though this is a great development from the physical documentary archival of yester years, it presents a number of challenges which include;- lot of time required to search for knowledge available, lack of opportunity to converse with originators of the knowledge archived and lack of dynamism in the said knowledge. Moreover, not many farmers can download reports from websites because some don't have computers and others have limited ICT skills.

The mentioned challenges can be overcome greatly through the use of computer software to create an interactive, dynamic and adaptive knowledge management system which will provide timely seed specific knowledge interactively, more efficiently and effectively and hence make seed actors optimize on use of existing knowledge for growth in agricultural productivity. Further, the interactive nature of mobile phone applications has brought ICT power to the palms of farmers and other actors who can now interact

with systems they could not interact with there before at the comfort of their farms. Funding the development of a seed knowledge ecosystem is easy because the money expended in form agricultural aid which approximated at about USD 4 billion annually and also specific country agricultural sector support can be utilized for such endeavour. Resources utilized this way can achieve more value than continuing to fund isolated reports whose impact is difficult to measure and track. After inception, the sustainability of the ecosystem is possible thorough funds collected through registration, gaming, participation in awards, online client surveys and philanthropists who have been companioning agricultural growth.

Abstract

We are living the era of the ecosystem, a concept whose use in management studies has grown exponentially in recent years. On the other hand, the ecosystem is becoming a fuzzy concept. In particular, following Teece (2007), many scholars define the business ecosystem in a rather generic way as an environment that includes the subjects that have some impact on the firm's competitive advantage. Others scholars associate the concept of business ecosystem with the strategy that leads to the creation of a new market space through an (ecosystem) platform. In this paper, we compare this platformation strategy with two other disruptive strategies meant as strategies that create an uncontested market space: exaptation and brokerage. We conclude that the (ecological) niche construction offers a particularly appropriate metaphor (rather than ecosystem) for the three strategies discussed in the paper.

Keywords: business ecosystem, platformation, exaptation, brokerage, niche construction

Paper type – Academic Research Paper

1 Introduction: creating a new market space through an ecosystem platform

We are living the era of the ecosystem, a concept whose use in management studies has grown exponentially in recent years with reference not only to high-tech sectors but also to those more established, from services to manufacturing (Barile, 2016; Jacobides et al., 2018). The ecosystem is also becoming a fuzzy concept. As shown by the recent review by Tsujimoto et al. (2018, p. 49) "the term *ecosystem* seems to be used without clear definition or sound theoretical backing".

The analysis by Tsujimoto et al. (2018) identifies four research perspectives: industrial ecology, business ecosystem, platform management, multi-actor network. Among these, the platform management perspective is distinguished by being anchored to a clear concept (platform), from which derives a specific way of conceiving the business ecosystem, and also a specific disruptive strategy. In this work, we adopt the platform perspective and evaluate its usefulness in understanding disruptive strategies meant as strategies that create an uncontestable market space.

The concept of platform was introduced by Cusumano and Gawer in pioneering works (Cusumano and Gawer, 2002; Gawer and Cusumano, 2002), where the authors analyze cases studies such as Intel and Microsoft, to provide valuable insights for managing innovation by the platform leader. In doing so, they use the term "ecosystem" (industry or innovation ecosystem) quite clearly: "With vision that extends beyond their current business operations or the technical specifications of one product, platform leaders can create an industry ecosystem greater than the sum of its parts. [...] The ecosystem can be greater than the sum of its parts if companies follow a leader and create new futures together." (Cusumano and Gawer, 2002, pp. 51, 58). Subsequently, the same Gawer and Cusumano refined the platform approach, explicitly linking the platform to its own business ecosystem (Gawer, 2014; Gawer and Cusumano, 2014). In particular, the external (industry) platforms are distinguished from the internal (company) platforms, and defined as "products, services, or technologies that act as a foundation upon which external innovators, organized as an innovative business ecosystem, can develop their own complementary products, technologies, or services" (Gawer and Cusumano, 2014, p. 417). Due to the technological characteristics of high modularity that characterize these sectors, empirical studies on ecosystem platforms usually focus on computing, telecommunications, and other information-technology intensive industries (Gawer and Cusumano, 2014; Tsujimoto et al., 2018).

In the ecosystem literature, one of the most cited contributions – appeared when the concept was still in its infancy (Moore 1993; Cusumano and Gawer, 2002; Iansiti and Levien, 2004; Adner, 2006; Dhanaraj and Parkhe 2006) – is that of Teece (2007) where the business ecosystem is defined in a rather generic way as an environment that includes the subjects that have some impact on the competitive advantage of the company. However, recently Teece (2016) proposed a much more limited view of the business ecosystem, defining it as "a group of interdependent organizations collectively providing valuable goods and services to their customers. The collective evolution of the system is typically reliant on the technological and business leadership of one or two firms that

provide common standards and hence a platform around which other system members align their investments and strategies to provide inputs and complementary products. A 'platform' can be said to exist when some common standards and interfaces permit the elements of the ecosystem to innovate independently while advancing collectively" (p. 1). Teece also points out that platform ecosystems develop through the action of an initiator or "captain" that is "an innovator developing and/or establishing standards and choosing which elements of the value chain must be internalized, and what needs to be supported externally, in order to provide it with the best opportunity for capturing value" (p. 2) and that can then become the platform leader. This is clearly a description that perfectly represents what the review by Tsujimoto et al. (2018) defines "platform management perspective".

Moving along the Teece's furrow, Sections 2 and 3 describe two strategies linked to the rise of a new market or a new market segment – exaptation and brokerage; the final section 4 compares these two strategies with that of the creation of a new market space through an ecosystem platform. On the one hand, critical reflections emerge about the evanescent use of the business ecosystem concept prevalent in the extant literature; on the other hand, it emerges the usefulness of the concept if it is appropriately specified, as in the case of platform ecosystems.

2 Exaptation, or creating a new market by means of a functional shift of an artifact

The term "exaptation" was coined by the paleontologists Gould and Vrba (1982) to indicate a distinct evolutionary process following that of Darwinian adaptation. To be more specific, it occurs when a character previously shaped by natural selection for a given function (an adaptation) is coopted for a new use. Unlike the concept of adaptation, in its gradualist sense, the concept of exaptation honors "the unpredictable discontinuity of change in complex systems" (Gould, 1991, p. 64). On the other hand, exaptations give rise to new adaptive cycles. As Gould and Vrba (1982, p. 12) explained, "any coopted structure (an exaptation) will probably not arise perfected for its new effect. The primary exaptations and secondary adaptations can, in principle, be distinguished".

Although evolutionary biologists are still debating the meaning of exaptation, and the ways in which it occurs, what has been generally accepted is the existence of structures associated with one particular function that may later serve another (Casinos, 2017). On these grounds, it comes as no surprise to see the transition from exaptation as an evolutionary mechanism in the history of biological species to exaptation as an evolutionary mechanism in the history of artifacts and their embodied technologies. In this latter sense, exaptation means the emergence of a new function for an existing artifact, a function for which it had not originally been designed (Andriani and Cattani, 2016). Mokyr, the first author to perceive the sustainability and potential of this analogy, ventures that "in the history of technology, exaptation is probably more common than in natural history. Many of the most dramatic inventions of the modern age were originally selected for purposes that were quite different from what eventually turned out to be their

most enduring trait” (Mokyr, 2000, p. 57). Not all exapted artifacts prompt the appearance of new markets, but the cases that have most attracted the attention of scholars of technological evolution are those – such as the often-mentioned microwave oven – in which, in much the same way as a biological exaptation, technological exaptations have generated discontinuities, and been associated with the emergence of new product markets (Bonifati, 2010; Andriani and Cattani, 2016; Mastrogiorgio and Gilsing, 2016). As Bonifati put it (2010, p. 754), “new products and new markets emerge as exaptation phenomena whenever new functionalities activate new uses of a technology, giving rise to transformations in the relations between production, technology, and consumption”. The discontinuity also affects the strictly technological domain: more often, what is exapted is not a fully-developed product, but a product component or module; and its inclusion in an entirely new product involves a fairly effortful development process (Andriani and Cohen, 2013). These are the reasons why, here again like the exaptation studied by biologists, the technological exaptation we are discussing here is a process that includes a primary event (a pre-adaptation) and a number of successive adaptations (Andriani and Cattani, 2016).

Studies that have focused on specific technological exaptation processes also provide information about the agents (firms, inventors, and so on) involved in these processes. They also inform about the relationships between agents, which seem to have had an important role in every case of exaptation studied to date. The role of the agents and their networks remains in the background, however, because the unit of analysis in such studies is usually the artifact or the technology.

In the present contribution, we diverge from the above-reviewed literature on exaptation, shifting: (1) the unit of analysis from the artifact to the enterprise; and (2) the primary focus of analysis from exaptation as a process to exaptation as a strategy. To be more precise, we consider exaptation as a strategy that enables a firm to create a new market by means of a novel product that derives from changing the function of an existing product, or a product component or module. If we divide the process of exaptation into a phase of exploration (moving from the idea of a functional shift to a new artifact) and a phase of exploitation (from the new artifact to a new market), then the crucial agent for the purposes of the strategy of interest to us here is the firm involved in the latter phase. Of course, the same firm might be involved in the exploratory phase too. The firm that succeeds in creating the new market may be in operation already, albeit in another market, or it may be newly established, its birth more or less coinciding with that of its new market. It is worth noting here that studies on exaptation focused strongly on processes of exaptation that involved existing enterprises. Some also tried to pinpoint what makes a firm a likely candidate for the development of a successful exaptation (Dew et al., 2008; Felin et al., 2016; Garud et al., 2016, 2018). Garud et al. (2016, p. 162), for instance, spoke of “some ways for organizations to create *exaptive pools*, maintain them through narratives, and sensitize employees to actively pursue *exaptive events* by cultivating serendipity in forums designed for such purposes, what we have labeled as *exaptive spaces*” such as 3M case (Goldenberg and Mazursky, 2002).

3 Brokerage, or bridging different knowledge domains to create a new market segment

Unlike the concept of exaptation, brokerage stems from original research conducted by the sociologist Ronald Burt (1992, 2004) on the connection between social networks and social capital. His approach is founded on the theory of social capital developed by Coleman (1988), who saw it as a function of social structure producing advantage. Specifically, individuals who do better – i.e. who receive higher returns for their efforts – are better connected. But why are better-connected individuals at an advantage? It is in dealing with this question that Burt adds his contribution. In short, for the purposes of our analysis we can consider two (or more) different networks that are only loosely connected together, and therefore represent non-redundant sources of information and knowledge, sources that are more additive than overlapping. Burt describes such a configuration as being rich in structural holes, adding that it gives a competitive advantage to the player that bridges the holes. Individuals or organizations (through the individuals working for them) that find themselves in this advantageous position may develop innovation by combining knowledge absorbed from non-redundant networks. In Burt's words, "people who stand near the holes in a social structure are at higher risk of having good ideas" (2004, p. 349). Having identified such a perfect position for identifying business opportunities, Burt goes on to delineate the individuals or organizations that occupy it, both as knowledge brokers¹ and as entrepreneurs (entrepreneurial firms).

According to Burt's theory, brokerage is an activity that leads to combine knowledge from networks with a limited degree of overlap, and consequently representing distinct and even distant knowledge domains. As such, brokerage can nurture any innovative process (Hargadon, 2002; Burt, 2004; Fleming et al., 2007a; Tortoriello, 2015). In particular, it can have an important role in supporting the previously-analyzed exaptation strategy, given that the innovation to be developed (a new market) originates from a connection and a combination between different domains (Hargadon, 2002, p. 53). Unlike other innovations deriving from knowledge combination, in the case of exaptation there is a considerable cognitive distance – as Nooteboom would say (2000) – between the domains involved in the combination. On the one hand, we have a technology that, up until the moment of exaptation, had been channeled into certain uses (domain A). On the other, we have a completely novel usage context for this technology, and an entirely new product if the exapted artifact was a product component or module. This new system of relations between production, technology, and consumption (Bonifati, 2010) has yet to take shape when the exaptation comes to light, but there is already a broader system capable of containing it (e.g., cooking at home in the case of the domestic microwave oven), and this is the domain B with which the domain A must be combined. If we consider what Garud et al. (2016) called "planned" exaptation, then the "exaptive spaces" that a firm can create within its own organization (or attend elsewhere) could clearly also be called "brokerage spaces", where the goal of bridging between non-redundant sources

¹ The term "broker" is used very differently here from its common meaning of an agent mediating the transfer of something (e.g., knowledge) between two other parties (Grandinetti, 2018).

of knowledge is to explore potential exaptation pathways. On the other hand, we know that the passage from the exploratory phase of exaptation to the exploitation phase cannot be taken for granted. To achieve this passage, and contain the lead time of the process as a whole, the firm will benefit once again from using brokerage to deal with the numerous problems that crop up after the functional shift.

However, brokerage *à la* Burt can also be a specific innovation strategy, on a par with exaptation. An excellent example of brokerage used for this purpose comes from the Cirque du Soleil, mentioned by Kim and Mauborgne (2005) as a significant example of *Blue Ocean Strategy*. Established in 1984 and still hard to imitate, it was created by a group of street performers in Montreal – a creative city (Cohendet et al., 2010), meaning a setting in which different cognitive domains or small worlds come into contact (Fleming et al., 2007b), creating brokerage opportunities for the emergence of new ideas. For the purposes of our analysis, its most interesting feature lies in the creation of a new market space (or segment) in the vast market of entertainment, and specifically of urban live entertainment, by means of a brokerage between two domains – circus and theater.

While exaptation introduces a discontinuity that leads to the formation of a new market (rather like a new species in the biological world), the new market space opened up by a brokerage strategy is more like a segment in the context of an existing market, even when it is as highly innovative as in the case of Cirque du Soleil. Leaving aside this far from trivial difference (due once again to the different cognitive distance separating the knowledge domains being combined in the two strategies), a successful brokerage strategy also involves an exploratory phase followed by a phase of exploitation. An organization lacking in the necessary capabilities on both of March's frontiers (1991) will not succeed. The broker that develops a new market segment may be a firm already operating in the reference market or a new venture established ad hoc. In the latter case, brokers might be employees of incumbent firms who can exploit their position in their employer's organization to fine adjust the innovative idea, then leave to found a new business (Agarwal et al., 2004; Furlan and Grandinetti, 2016).

Organizations that are large – especially if they are diversified as regards the geographical areas in which they invest and/or the product market in which they engage – have more structural holes, and consequently more opportunities for brokerage (Burt, 2000; Tortoriello, 2015). This situation gives rise to internal networks, which then become connected with specific external sources of knowledge. For such a configuration to be turned to advantage for the organization as a whole, it must contain internal brokers capable of forming bridges between its various domains. A firm that meets these requirements is in a good position to identify new market spaces by acting as an "internal" broker or bricoleur.¹

¹ In a situation like the one described, the concept of brokerage and bricolage tend to overlap. In the wake of Levi-Strauss's idea of "doing things with whatever is at hand" (1966, p. 17), we can see bricolage not as a process or activity, or even as an innovation strategy in its own right, but as a variant of brokerage, with more emphasis on the sources of knowledge inside the enterprise than on those outside.

4 Strategies for creating new market spaces and business ecosystems: a reassessment

In the studies we have considered to analyze exaptation and brokerage as strategies capable of introducing disruptive changes, the concept of ecosystem has almost never been used. Yet in these works, the role played by the innovator relations (with suppliers, customers, coopetitors, institutions, private individuals) in promoting the rise of a new market (new segment) clearly emerges. Basically, it deals with the same elements that have led other scholars to speak of business ecosystem.

Let us return to the definition of business ecosystem contained in Teece (2007). The author aims to enlighten that the dynamic capabilities framework is able to explain the sources of firm-level competitive advantage over time. At this aim, he disarticulated these capabilities "into the capacity (1) to sense and shape opportunities and threats, (2) to seize opportunities, and (3) to maintain competitiveness through enhancing, combining, protecting, and, when necessary, reconfiguring the business enterprise's intangible and tangible assets" (p. 1319). Dynamic capabilities work in a business ecosystem, which Teece defines as "the community of organizations, institutions, and individuals that impact the enterprise and the enterprise's customers and supplies" (p. 1325). Then, in the concept of ecosystem, the interdependencies and the interactions among the subjects that compose it are implicit. The ecosystem affects the firm's dynamic capabilities and thus its ability to build sustainable competitive advantage, but at the same time these capabilities "embrace the enterprise's capacity to shape the ecosystem it occupies" (p. 1320). Teece aims to underline the difference between the business ecosystem and industry, and therefore the difference between its approach to competitive advantage and that of Porter (1980, 1985) based on the Five Competitive Forces. However, it should be noted that Porter was well aware of the difference between the industry (meant as a system of competitive forces) and the wider competitive environment, as well as the fact that the latter includes factors (such as the government) capable of influencing the competitive advantage not being one of the five forces.

Ultimately, in the concept of business ecosystem proposed by Teece (2007) and adopted by many followers, it is difficult to find something that is not already contained in the concept of competitive environment, applied for a long time in studies on strategy, industrial organization, management, or marketing, and also useful for framing the strategies discussed in the previous sections of the paper, such as any strategic action carried out by a company. An interesting shift is to associate the concept of business ecosystem with the strategy that leads to the creation of a new market space through an (ecosystem) platform. As mentioned in the introduction, this strategy – summarized with the term "platformation" (Parker et al., 2016) – was studied in particular by Cusumano and Gawer (Cusumano and Gawer, 2002; Gawer and Cusumano, 2002, 2014 ; Gawer, 2014), and recently attracted the attention of Teece himself (2016, 2018). What distinguishes the platformation from the strategies of exaptation and brokerage is that the platform involves the rise of a system of interdependencies among actors, which in turn is anchored to the platform. Scholars emphasize the bright side of the platform strategy and

leadership: "The industry-wide goal is to facilitate complementary innovations by third-party firms. Platform leaders must also strive to establish a set of business relationships that are mutually beneficial for ecosystem participants and be able to articulate a set of mutually enhancing business models" (Gawer and Cusumano, 2014, p. 423). However, there is also a dark side that has its potential cause in the power imbalance in favor of the platform leader, an aspect that has not yet been sufficiently investigated.¹

Going deeper into the strategy of platformation, we realize that the most appropriate biological metaphor is not the ecosystem but the ecological niche, and only secondarily the ecosystem. It is, in fact, a strategy of construction niche, a relevant concept in the managerial studies, defined by Luksha (2009, p. 273) as "sustained change to the resources and relations in the organizational environment that have long-lasting effects upon the strategy of the focal organization(s) and organizational constituents. The transformation or creation of organizational niche, therefore, results in the sustained change in patterns of strategic activities". Every strategy aiming to create a new market space seeks to foster an ecological niche. It is no coincidence that in the works focused on exaptation scholars frequently use the expression "technological" or "market niche": for example "it took nearly 20 years to elaborate the features that defined the microwave oven market niche" (Andriani and Cattani, 2016, p. 120). Rare, on the other hand, the use of the term in studies on brokerage for market segmentation: for example, Kim and Mauborgne (2005) do not speak in terms of niche in their analysis focused on the Cirque du Soleil, however, the strategy they describe is precisely that of construction of a niche in the performing arts industry, as Ghazzawi et al. (2014) underlined. Curiously, even in the business ecosystems literature the concepts of niche and niche construction are little practiced, with the laudable exception of the theoretical paper by Adamides and Mouzakitis (2009).

It is also interesting to see how niche construction is defined in biology: the capacity of organisms to modify their environments. The concept was developed in the 1980s by Lewontin (1983) and by Odling-Smee (1988). Later, it became an important research ground at the intersection of ecology and evolution studies: "Niche construction refers to the capacity of organisms to construct, modify, and select important components of their local environments, such as nests, burrows, pupal cases, chemicals, and nutrients. [...] Through niche construction organisms not only influence the nature of their world, but also in part determine the selection pressures to which they and their descendants are exposed, and they do so in a non-random manner. [...] A parallel movement has emerged in ecosystem ecology, where researchers stress the utility of regarding organisms as ecosystem engineers, who partly control energy and matter flows" (Day et al., 2003, p. 80). So, the concepts of "niche construction" and "ecosystem engineering" are synonymous. Clearly, the niche construction also involves human beings, who "can and do modify their environments mainly through cultural processes, and it is this reliance on culture that lends human niche construction a special potency" (Laland and O'Brien,

¹ While there is a certain tradition of studies on the dark side of dyadic cooperative relationships, particularly of a buyer-seller type (Grandinetti, 2017), the extension of the concept to an entire network or community is still in its infancy.

2011, p. 194). There seems to be no doubt that the niche construction offers a particularly appropriate metaphor for the strategies discussed in this paper that is exaptation, brokerage and platformation. At the same time, it suggests a more basic use of the concept of (business) ecosystem, remembering that in biology ecosystem is simply "the complex of living organisms, their physical environment, and all their interrelationships in a particular unit of space" (*Encyclopaedia Britannica*).

Abstract

Antecedents of Business Model Innovation (BMI) may be many, different in nature, placed at several levels, and they can be internal or external to the firm. The current debate has barely connected such antecedents to the type of innovation of the Business Model (BM), if modular or architectural. To fill this gap, our study draws on an exploratory case study of an innovative firm operating in the Space Industry that over time developed various BMs capable of creating value by exploiting Earth Observation big data. The Copernicus Programme has in fact opened a vast amount of Earth Observation daily data to the world, giving firms the opportunity to compete in new ways and allowing the development of an ever-increasing number of downstream products and services.

As a result, Big Data from Space has changed considerably the Space Industry and firms are now in need to reconsider their BMs configurations. On the premises that big data in the Space Industry joins the incomplete conversation about the antecedents of BMIs, our study builds on complexity theory and innovation theory as interpretative theoretical lenses, with the aim of developing a research agenda directed towards the development of a theoretical framework for BMI by mean of explorative multiple case study from firms mainly operating in the Space Industry.

Our findings, show the relevance of external antecedents to the BMI. These findings are then organized around a set of propositions, which enforce the up to now scant literature about antecedents and BMI.

Keywords – Architectural Innovation, Modular Innovation, European Space Agency, Copernicus Program

Paper type – Academic Research Paper

1 Introduction

In the last decade the Space Industry has seen the multiplication of initiatives offering open access to Big Data from space and hence the possibility for firms to exploit the huge quantity of data made available at an ever increasing rate. This is for instance the case of downloaded data from Earth Observation satellites that in the past were mainly sold to service providers, which on their turn made a profit by selling them to end-users such as consultant companies, cost guards, fisheries etc.. Indeed, since 2014, the Copernicus Programme, with over twelve Terabytes of Earth Observation (EO) data generated daily (the third largest data provider globally), has established a full, free and open data policy which allows anyone anywhere in the world to access and use the data and geo-spatial information.

Copernicus is coordinated and managed by the European Commission (EC) and implemented in partnership with the Member States, the European Space Agency (ESA), the European Organisation for the Exploitation of Meteorological Satellites (EUMETSAT), the European Centre for Medium-Range Weather Forecasts (ECMWF), EU Agencies and Mercator Océant.

Nowadays, a huge amount of global data from satellites and from ground-based, airborne and seaborne measurement systems are being used to provide information to help service providers, public authorities and other international organisations as well as private commercial partners, improve the quality of life for the citizens of Europe.

Thus allowing many new commercial downstream services to be developed. Hence, ESA, through the Copernicus Programme, has opened a vast amount of Earth Observation daily data to the world, giving firms the opportunity to compete in new ways and allowing the development of an ever-increasing number of downstream services.

As a result, big data from space made available through the Copernicus Programme has changed considerably the Space Industry and firms are now in need to reconsider their Business Models (BM) (Saebi and Foss, 2017). To put it in other words, big data can be interpreted as an antecedent which triggers Business Model Innovation (BMI) in the Space Industry. Building on the fact that a BM whatever is its conceptualisation in the theory (Latronico et al., 2018) - is to be interpreted as a system (Simon, 1962) made up of different components [recurring components in the main BM frameworks proposed in the scientific literature are: the value proposition, the customer segments, the infrastructure resources / activities / partners - required for realizing the value proposition and the financial structure (Chesbrough and Rosenbloom, 2002; Morris et al., 2005; Osterwalder and Pigneur, 2010)], innovation of the BM can be carried out at the architectural or at the modular level (Henderson and Clark, 1990; Demil and Lecocq, 2010; Morris et al., 2005). Innovation is modular if it mainly involves changes in one/more components, without relevant changes in the way components interact with each other. Innovation is architectural if it regards the general structure or the interactions between the above components.

According to Saebi and Foss (2017), up to now the extant scientific literature and empirical research have scarcely investigated the antecedents of BMIs (one exception is

de Reuver et al., 2009). In fact, the current debate has barely connected such antecedents to the type of innovation of the BM, if modular or architectural. To fill this gap, our study draws on an explorative case study operating in the down-stream applications and services commercial domain.

In the following section a general overview of the literature on BMs and BMIs is provided. The third section outlines the methodology. The fourth and fifth sections present the results and their discussion, respectively.

2 Literature Review

Over the last 15 years, BMI has gained an increasing amount of attention in management research and among practitioners. The emerging BMI literature addresses an important phenomenon but lacks theoretical underpinning, and empirical inquiry is not cumulative (Foss & Saebi, 2017). While BM and BMI are no doubt related, research on BMI introduces the additional dimension of innovation. Hereby a number of crucial theoretical and empirical questions are not currently being systematically posed, addressed, and answered, reflecting the emergent nature of BMI research. Notably, in comparison with the huge volume of research on BMs, the number of published papers that address BMI per se is still comparatively low at 349 (peer reviewed and otherwise, see Fig. 1).

Figure 1 Use in the Scholarly Literature of Some Key, Related Macro-constructs

While on the one hand the BMI construct is to a large extent used as mainly a classificatory device, on the other hand, systematic research on the antecedents, moderators, and implications of BMI remains limited, leading to question whether a true theory of BMI exists (Foss and Saebi, 2016). BMI represents a novel and more holistic

form of organisational innovation that warrants theory building, operationalisation, and testing.

Cumulative theorizing and successful empiricism require clear identification of the causal structure in a theory—that is, how the key constructs of interests are causally linked. Postulating certain cause-effect relationships involves unpacking the causal mechanisms at work (Fry & Smith, 1987). As a minimal starting point, BMI theorizing should clearly identify the antecedents and consequences of the focal phenomenon.

As regards consequences, early CEO-level surveys indicated that BMI is a key source of sustained value creation (IBM Global Business Services, 2006), even trumping new products and services as a source of future competitive advantage (Economist Intelligence Unit, 2005). In fact, innovative BMs are found to positively influence the performance of entrepreneurial firms, “even under varying environmental regimes” (Zott & Amit, 2007). Similarly, established firms that innovate their BMs experience positive performance effects (Cucculelli & Bettinelli, 2015).

There are few studies of the drivers or antecedents of BMI. Nevertheless, antecedents of BMI may be many, different in nature, and placed at different levels, and they can be internal or external to the firm. Studies on changing BMs highlight changes in the external environment, such as changing demands of stakeholders (Ferreira, Proença, Spencer, and Cova, 2013), changes in the competitive environment (e.g., de Reuver et al., 2009), and opportunities brought about by new information and communication technologies (Pateli & Giaglis, 2005; Wirtz et al., 2010). Given that BMI differs in terms of scope and novelty, the antecedents for evolutionary or adaptive BMI might be different than for more complex forms of BMI.

2.1 Research problem and questions

On the premises that big data in the Space Industry joins the incomplete conversation about the antecedents of BM innovations, this manuscript builds on complexity theory (Simon, 1962) and innovation theory (e.g., Henderson and Clark, 1990), as interpretative theoretical lenses in order to developing further the topic. Specifically, this manuscript aims at answering the following research questions:

- RQ1 – What are the main drivers of BMI in the space industry?
- RQ2 – Can a specific driver be associated with both a modular and an architectural BMI?
- RQ3 – In the case of modular BMI, in which circumstances a specific antecedent is associated with innovation in a specific BM component (i.e. the value creation, value delivery and value capture)? In other words, while using Osterwalder and Pigneur (2010)’s words, is the same antecedent always associated with the same epicentre from which BMI departs?

3 Methodology

The research methodology adopted in this paper is case study. Two main reasons underpin our choice.

Firstly, case study are recognized as big opportunities (McClintock et al., 1979) in terms of (i) taking into account the richness of the context and hence avoiding instrumentation artefacts of standardized measurement procedures, (ii) allowing detailed examination of organizational process, (iii) and illuminating specific factors which may allow greater understanding of causality.

Secondly, case studies are reckoned to be better than quantitative studies in terms of theory building (theoretical generalisation and falsification) and theory testing. We are aware that it is not likely that a new theory can be developed from a single study, but our study can be useful for generating theoretical implications (Tsang, 2014), according to an exploratory theory building research. Given our aim of throwing light on the mechanisms that relate a specific antecedent with the type of BMI (architectural/modular), we relied on case study methodology because of the possibility it gives to analyse mechanisms and influential drivers.

Specifically we relied on a single, following several steps: definition of the research questions, case selection, identification of the unit of analysis, definition of the reference research framework, data collection, data elaboration, and data analysis (Barczak, 2015).

3.1 Definition of the research questions

As put forward above in the literature analysis, we have three main research questions.

3.2 Case selection

Our case study appeared to be very interesting in that over time it developed BMs capable of exploiting Earth Observation data provided by ESA through which it delivered an appropriate value (i.e. theoretical sampling).

3.3 Identification of the unit of analysis

We address the single firm as unit of analysis. We believe that the firm-level is the most promising unit for this article. Indeed, we are not addressing the process the firm followed to change its BM, but rather the components and/or the architecture of its BM that were object of innovation. And, although the BM could be either explicitly defined or emergent, anyhow it is at the firm-level that the components and the architecture are defined.

3.4 Definition of the reference research framework

In order to answer our research questions we used the BM framework provided by Teece, 2010, composed of value creation, delivery and capture because it is a widely accepted conceptualisation of a BM.

The above research framework served as a starting point to conduct interviews as it allowed the definition of the variables at play (Eisenhardt, 1989). Indeed respondents were asked to describe how the BM was conceived before and after it was innovated. However, according to an exploratory approach, we avoided thinking about specific relationships between the constructs, so striving to maintain a neutral position when asking firms to explain how the BMI took place.

3.5 Data collection

Data were collected in a one-month period, and included several primary and secondary sources (Table 1) according to a multiple data collection method (Eisenhardt, 1989) in order to enhance the validity and relatability of the data provided by the informants.

Table 1: Topics, information sources and supporting tools

Investigated topics	Primary sources	Supporting secondary sources	Supporting Tools
Description of firm; identification of key informants for the case study	CEO of firm A	Firms' website; slides presented at conferences	Interview guide, part I
Detailed description of the BM components and architecture for the analysed firm before the Copernicus Programme			Interview guide, part I
New BMs configuration, in terms of components and architecture, aimed at taking advantage of the drivers			Interview guide, part II
Final verification of the case study validity	CEO of firm A	—	—

As primary sources, the first contact points was the CEO, who allowed us to access two sets of information: i) the detailed description of the initial BM(s) and how it changed across the time ii) the detailed description of the new BM(s) configuration. Semi-open questions were used for direct interviews. Semi-open questions allowed gathering all the necessary data, at the same time leaving interviewed people the opportunity to enrich the context description and to enlarge the set of variables investigated. The interviews lasted one hour and a half.

As secondary internal sources, we analyzed the firms' website. Other secondary sources were provided by the interviewee and used to triangulate information gathered during the interview (slides presented at the 6th international Workshop on On-Based Payload Data Compression).

3.6 Data elaboration

The interviews were recorded and transcribed my means of a software tool (Dragon Professional v.15). All the information gathered by means of interviews and secondary sources were elaborated with data categorization, using the categories/variables suggested by the literature on BMI. For each variable, information collected by the different sources was compared.

For each variable investigated, the triangulation of data was guaranteed: data from the direct interviews were integrated with the secondary sources in order to ensure construct validity and to limit post hoc rationalization.

3.7 Data analysis

Data collected and categorized were used according to the reference models on BMI in order to answer the research questions. Specifically, we analyzed the main drivers of BMI in the space industry (RQ1), and aimed at understanding in which specific circumstances the antecedent we investigated is associated with an architectural or rather a modular innovation (RQ2). In this last case, we analyzed in which circumstances a specific antecedent is associated with innovation in a specific BM component (RQ3).

4 Results

4.1 The firm

Firm A (whose name won't be revealed for anonymity reasons) is an Italian Small and Medium Enterprise (SME), established in 1994, which currently employs 50 employees (in 1994 they were four). Firm A provides solutions to exploit the value of geospatial data through all phases of data life cycle from acquisition, storage, management up to analysis and sharing.

It operates in many application areas ranging from environmental and land monitoring to open-government and smart cities, and including defence and security, as well as scientific missions and planetary exploration. Table 2 reports main characteristics.

Table 2. Main characteristics of firm A

Firm	Founded	Country	Size	Industry	Products / Services	Funding	Type
A	1994	IT	~ 50 employees, SME	Aerospace	-Private Geographical Information Services(GIS) -Earth Observation consultancy - Information land management.	Private and Public	Privately held

4.2 Environmental background

Firm A operates in an environment in which in a few years both the market and the technology evolved, implying both difficulties and opportunities. Indeed, the technology, while evolving, has reduced the technical difficulties in getting higher and higher EO data, characterised by greater levels of quality with lower and lower investments. Many factors contributed in this direction. In a first phase, this is due to better G-resolution; in a second phase, the big data with higher levels of resolution supplied by means of the

Copernicus Programme, the lowering cost of HPC (High Performance Computing) up to the artificial intelligence have allowed the growth of on-board processing capabilities.

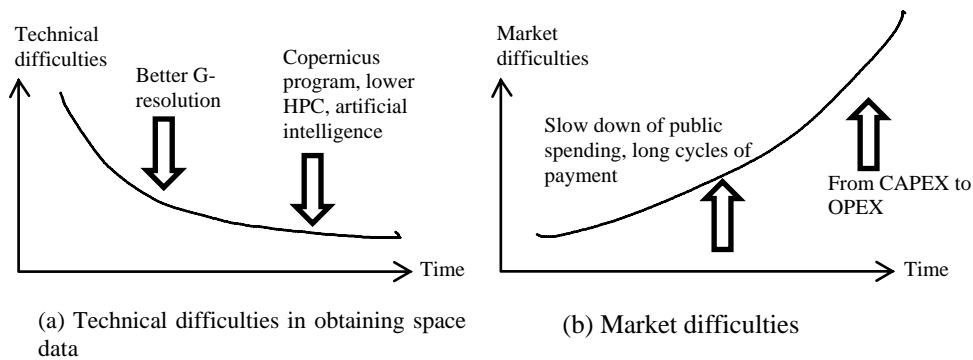

Figure 2 (a and b)

As regards the market, there has been an evolution in the type of actors interested in the value, which can be extracted from EO data, as well as in their needs (Fig. 2b). As regards the type of actors, at the beginning the customers were represented almost exclusively by the public administrations, but over time, the reduction in public spending shifted the attention towards business partners. However, over time the needs in the b2b market changed: in a first phase customers asked for tailor-made software and afterwards the request evolved from bespoke software to software as-a-service (SaaS).

Firm A innovated twice its BM in order to cope with technological and market threats but also to tap into the opportunities both the market and the technological developments entailed. Below we put forward a description of the different BMs firm A adopted and in what the BMI consisted.

4.3 BMI at firm A

Since its very beginning, firm A has been a technology-driven start-up operating in the space industry. In the first architecture of its BM (South-East in Fig. 3), the value creation consisted of offering EO data mainly delivered to the public administration; value appropriation consisted of the revenues from the public administration, accompanied by income cash flows from project funded by the European Space Agency and European Commission. The high technological difficulties – and hence the low level of competition – together with the low attention to the business market made selling EO data to the public administration a viable BM, which indeed allowed delivering value to the only customer who, while being able to find value in firm A's value proposition, was willing to pay for it.

However, soon the BM architecture tuned out to be inadequate because one of the BM component was challenged by the market. Specifically, the slowdown of the public spending, together with the excessive length of the payment cycle (that lasted 2 years), made value capture unable to sustain the whole architecture of the BM.

Therefore, a new way of capturing value was strongly deemed necessary and this, in turn, required the identification of new customers at whom the value could be delivered and who may be willing to pay for it. Private firms, and specifically firms working in the oil&gas and the transport industries, were identified as new customers. In the words of the CEO: *“the main innovations were a modification of our structure that from a more production-oriented became a more market-oriented organisation [...] a new business was created in order to take care of the growth of the interests of commercial services applications for private subjects e.g. oil & gas, transport etc.”*.

A new value proposition was offered them (in the centre of Fig. 3): not only, as before, EO data selling, but also EO data embedded in software applications and software for data elaboration. In a word: geo-information. The creation of a new value was possible because of the technological developments such as better G-resolution.

Firm A is undergoing a new BMI process which, as in the previous innovation, starts from the need of restructuring the value capture. This time, however, the change of the value capture component is not due to an internal need, but rather is a consequence of the necessity of the EO service market to move from CAPEX to OPEX, i.e. to change the nature of the cost: from an investment in a desktop software to an operating cost connected with software subscription: *“abandon selling of the desktop software and provide a software as a service scalable in space and time dimensions”*. Such shift from CAPEX to OPEX determined a new revenue stream: from sales revenues, to revenues from subscription. In addition, this change in the value capture entailed a different value creation: the shift to SaaS entailed *“transform these data in ready-to-use knowledge by user. New available satellite data reshape the design approach from geo-information to geo-analytics Info-as-a-service scalable in space and time dimensions”*. This challenge is particularly felt by firm A in that the threat from new entrants in the market is a really serious concern: *“new players are able to identify downstream services such as tailored analytics [...] and] have great chances of winning funds and advancing in development”*.

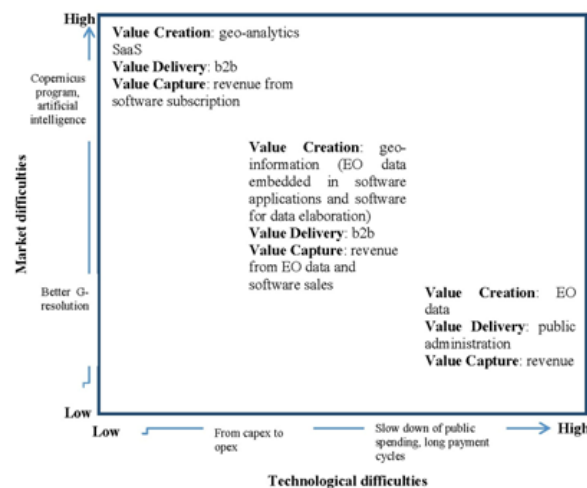

Figure 3 Business Model Innovations over time

5 Conclusions

In this paper we present the case of firm A, an Italian SME, that since its foundation in 1994 went through two BM innovations (the second is still undergoing). These two innovations were initially triggered by threats coming from the market which in both cases challenged the value capture. Also, these two BM innovations were endorsed by the technological opportunities which allowed the access to greater and greater amounts of space data characterised by higher and higher resolution levels, with lower and lower costs. In this sense, the market operated like a challenge to be coped with, while the technology provided the opportunity to improve the value offered to the market (RQ1).

Hence the following proposition can be put forward:

Proposition 1. Start-ups begin as a technology-driven idea but innovate their BM in response to market challenges.

Although both the market threats jeopardise the same BM component - i.e. the value capture - their nature is completely different. The first challenge (slowdown of public spending and length of the payment-cycle) is internal to firm A: in other words, the market does not require firm A to do something different in the way it captures (part of) the value. Rather, the problem is that, at a certain point, the way the value is captured reveals to be unsuitable for the viability of the BM, at the point that the sustainability of the firm is seriously jeopardised. The second challenge (the necessity for EO customers to move from CAPEX to OPEX) is external, in the sense that it is the EO market which requires a change in the value capture. Differently from the previous market challenge, the viability of the BM and the sustainability of the firm would have been maintained, had the market remained the same.

This different origin – internal or external - of the market threats produced different outcomes in terms of BMI. The first challenge to the value capture imposed firm A to looking for new customer segments at whom deliver a value proposition for whom they could be willing to pay. The second challenge to the value capture was required by the EO market that also asked to innovate another component of the BM, i.e. the value creation. This means that in both cases of BMI, a specific driver (in this article we analysed a challenge from the market), even though initially focused on only one component, always implies an architectural innovation (RQ2).

Hence the following propositions can be put forward:

Proposition 2. BMI involves all the value architecture elements: value creation, value delivery and value capture.

Proposition 3. Internal problems regarding value capture determine an increased attention to value delivery in order to find customer segments which can solve the problems connected with value appropriation. After the identification of the customer segments, an effort should be done in order to formulate a value proposition to be addressed to such segments and make those segments willing to pay.

Proposition 4. External problems regarding value capture require a change in the value creation and value capture. Customer segments at whom the value is delivered, do not change. What changes is the value offered to them.

The main aim of this paper is to contribute on the relevance of external antecedent to different kinds of BMI, distinguished according to their modular or architectural level. Therefore, this paper, although retrospective and inductive, is a first step, which enforces the up to now scant literature that has empirically tested the effect of different antecedents on the propensity to innovate the BM.

Acknowledgments

We would like to thank Gianluigi Baldesi, Senior Corporate Development Coordinator at European Space Agency (ESA) for providing expert advices, for helping us out with the selection of the case study and for putting us in contact with some relevant companies operating in the EO Space business.

We would also like to show our gratitude to the “anonymous” company who has shared with us its data and insights.

Abstract

This paper presents the results of an exploratory literature review on Knowledge governance. Looking at the literature this concept was starting be located at firm level and has evolving towards ontological multilevel integration. The challenge is to build a conceptual framework by using the lens defined by article's objectives:

- a) Identify Knowledge Governance definition(s);*
- b) Identify main concepts; and*
- c) Identify the main background theories.*

This article add theoretical contributions to value existing knowledge, as well as understanding and shaping the knowledge base of the Education, Science, Innovation, Ecosystem and Policy ecosystem, which range from different financial to non-financial types of impacts.

Keywords – Knowledge governance, Knowledge processes, Knowledge Management, knowledge dynamics, models

Paper type – Academic Research Paper

1 Introduction

All organizations have a common denominator: they are based on knowledge (Alvesson, 1993). However, some organizations have knowledge as their core output, supply knowledge to the public, or aggregate workers who are mainly experts developing and providing knowledge (Grandori, 1997).

More and more organizations acknowledge that their main activities are related to the management of knowledge, and that knowledge is a strategic resource that must be governed to achieve and sustain competitive advantage (Argote *et al.*, 2003).

To turn clear and avoid some ambiguity, we start by using some working definitions provide by Michael Gallagher (2001):

- *Governance* is the structure of relationships that bring about organisational coherence, authorise policies, plans and decisions, and account for their probity, responsiveness and cost-effectiveness;
- *Leadership* is seeing opportunities and setting strategic directions, and investing in and drawing on people's capabilities to develop organisational purposes and values;
- *Management* is achieving intended outcomes through the allocation of responsibilities and resources, and monitoring their efficiency and effectiveness;
- *Administration* is the implementation of authorised procedures and the application of systems to achieve agreed results.

Knowledge governance is closely related to knowledge management; both seek to capitalize knowledge or creating value from knowledge, but at different scopes. Knowledge management is concerned with knowledge processes at organizational level, Knowledge governance refers to choosing structures and mechanisms that can influence the processes of knowledge looking the interrelation between micro, meso and macro levels, with a strategic focus. From our exploratory review we found some seminal documents (Foss, 2007; Grandori, 1997, 2001; Nonaka, 1994) and some relevants (Antonelli *et al.*, 2014; van Kerkhoff, 2013).

The main goal of our study is the development of a conceptual model showing how knowledge governance can be used to enhance knowledge use in different ontological levels (micro, meso, macro and network). We build a framework that can be used to strategically map the possible alternatives and transversal insights.

In a time of increasing specialization and apparent knowledge silos, it becomes crucial to have a comprehensive picture where the integration of various components and their relationships is clear. In sum, a people-centric knowledge approach is our proposed way to capitalise information systems and knowledge processes.

Why perform a Literature review about Knowledge Governance? The societal and complex problems call for solutions based on knowledge cutting across diverse disciplines, experience and continuous learning which they are embedded in different sectors of human activity. Emerging technologies and new concepts and new drivers such as Big Data, Internet of things, Artificial Intelligence and Open Science create cyber-physical systems that provide new opportunities to value data and information.

Despite this wealth of resources there seems to be a gap in building and valuing existing knowledge. Our focus is on knowledge governance from the perspective of how can we facilitate the use of existing knowledge (intellectual capital) in order to valuing it, through not only by the identification of knowledge needs and its localization but also the integration of specialized and dispersed knowledge. Knowledge integration aims bringing together cognitively unrelated or distant bodies of knowledge (Rafols, 2014). Here we adopt human-centred assets of Bontis' intellectual capital, as the collective intangible assets and their stream of knowledge.(Bontis, 2001, p. 10).

2 Methodology

How the review was conducted? In general the review followed three main stages: planning the review; conducting the review and reporting the outcomes from the review (Tranfield et al., 2003). Arising from initial question (What is Knowledge Governance?) we define specific research question:

- a) What are Knowledge Governance definition(s)?
- b) What are the main concepts that constitute the blocks that structure the topic KGov?
- c) What are their main background theories?

The achievement of our research goal requires searching, filtering and analysing several publications. To deal to this complex work review, we used computer-aided text analysis (CATA) tools to organize and manage data, to code bibliographic categories and to make a content analysis of full text of seminal, relevant and core publications. We choose use *WebQDA* software because it provides an ubiquitous research workspace where researchers can work individually and collaboratively both in data processing and their analysis and validation, by an user-friendly and intuitive way (Fornari *et al.*, 2019a; Fornari *et al.*, 2019b). We choose to use Scopus database to search publications between 1980 and 2018 and next we selected 142 relevant publications.

In order to organize publications into ontological dimension level we classified in four levels (see **Error! Reference source not found.****Error! Reference source not found.**). If we stay at national level (macro), knowledge governance can be about how to facilitate use of scientific knowledge by industry to increase international competitive position. At organizational level (meso) a choice of one strategic focus on how knowledge should be managed to benefit organization, can be considered organizational knowledge governance. Similarly, for individual level (micro) maximize individual knowledge for increasing individual performance can be also part of knowledge governance. This macro-meso-micro perspective can help to separate systems elements and also integrate them when we need a dynamic outlook of the change and coordination of the system. We add another level (network) that cross all the previous levels. Studying social networks not only interest to social researchers (Cross et al., 2006; Cross et al., 2002; Inkpen & Tsang, 2005; Latour, 1996; Watts, 2004) but others ones, like physicists. As Newman (2001b) asked: “why should a physicist be interested in social networks?” He thinks that is because they can apply some familiar techniques of statistical and modelling. This author carried out a study about scientific collaboration networks.

Newman start from social network definition as “a set of people or groups (actors) each of which has connections (ties) of some kind to some or all of the others” (Newman, 2001a, p. 1), but there are a broad types of networks, such as Knowledge Networks (Phelps et al., 2012) or research collaboration networks (Leite & Pinho, 2017).

LEVELS OF ANALYSIS

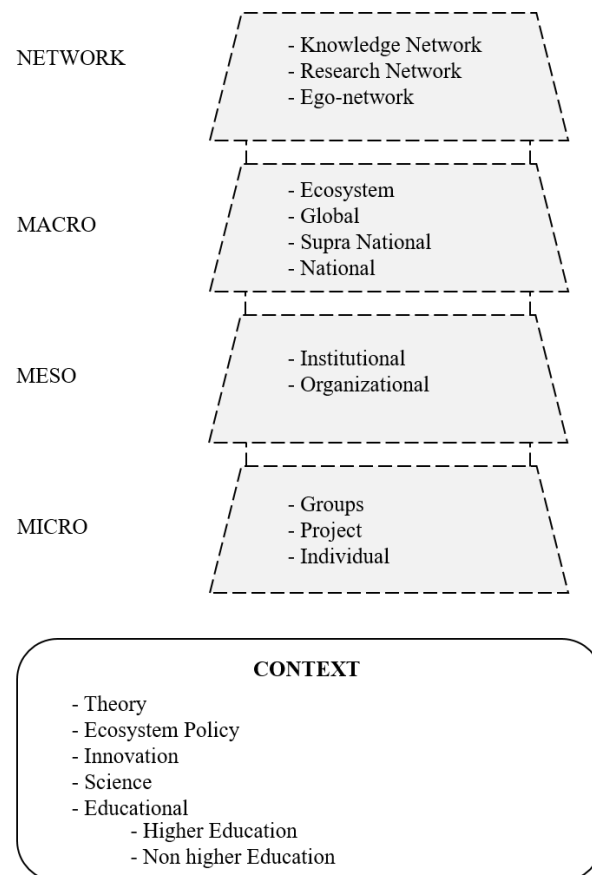

Figure 7 - Levels of analysis and contexts

3 Results

The presentation of main results follows article’s objectives: Identify Knowledge Governance definition, identify main concepts; and identify the main background theories.

From an exploratory questioning to the data some terms and words are more associated to the different ontological levels. At Micro level the most cited keywords are “Project management” (14.8%), “Knowledge governance” (11.1%), “Knowledge sharing”

(8.6%), “Organisational learning” (7.4%) and “Governance mechanisms” (6.2%) are the most cited terms (see Figure 8).

Figure 8 - The 20 most frequent words in keywords for Micro level

At Meso level the most cited keywords are “Knowledge” (12.4%), “Knowledge governance” (8.8%), “Organizational knowledge” (8.0%), “Knowledge management” (7.3%) and “Construction Management” (6.6%), as shows in Figure 9.

Figure 9 - The 20 most frequent words in keywords for Meso level

At Macro level the most cited keywords are “Knowledge governance” (11.3%), “Knowledge” (7.3%), “Organisational innovation (6.9%), “Informal management” (6.5%) and “Project (global)” with 6.2% (see Figure 10).

Figure 10 - The 20 most frequent words in keywords for Macro level

At Network level the most cited keywords are “Information management” (10,7%), “Knowledge network” (10.7%), “Biological” (7.1%), “Climate” (7.1%) and “Health” (7.1%), as shows Figure 11)

Figure 11 - The 20 most frequent words in keywords for Network level

Each ontological level has a particular words landscape that provide a first overlook. Next a ground-theory approach was used to identify key concepts (Charmaz, 2006; El Hussein *et al.*, 2017).

a) *Identify Knowledge Governance definition(s);*

When trying join “knowledge” and “governance” we can find “knowledge governance” and “governance of knowledge” with similar meaning (Pemsel & Müller, 2012; Zyngier, 2012).

Knowledge is an asset for any organization, institution system and country. However, the challenge is to capture and integration of knowledge that exist but are isolated (Davenport, 1997; Grant, 1996). Indeed, knowledge has limited value if knowledge is not shared. The ability to integrate and apply specialized knowledge is fundamental to improve efficiency, resiliency, and added value, to all resources inside and through diverse Context.

In terms of defining the research problem, this is related to the lack of wise use of global knowledge resources at organizational, local, regional and Network levels.

The term “governance” has several meanings. According to the political scientist Roderick Rhodes, the concept of governance is currently used in contemporary social sciences with at least six different uses: the minimal State, corporate governance, new public management, good governance, social-cybernetic systems and self-organised networks. This concept is related to change, or to the need of changing, in our network society. Changing the boundaries of the state meant the boundaries between public, private and voluntary sectors became shifting and opaque and the continuing interactions between network members, caused by the need to exchange resources and negotiate shared purposes leads to game-like interactions, rooted in trust and regulated by rules of the game negotiated and agreed by network participants. Some degree of autonomy from the state is one of the characteristics of networks and they seem to be self-organising (Rhodes, 1996).

From seminal article of Anna Grandori, that coined the “Knowledge Governance” term (Grandori, 1997), others authors developed related definitions in different contexts (Antonelli, 2006; Foss, 2007; Foss et al., 2010; Foss & Michailova, 2009; Gerritsen et al., 2013; Grandori, 2001; Nooteboom, 2000; Pemsel et al., 2014) (see Table 6).

Table 6 – Knowledge Governance definitions

Autor (data)	Definição	Level of Analysis
Grandori (1997, p. 96)	The notion of “knowledge governance” as convergence between organisational economics and the knowledge-based view in strategic management based on coordination mechanisms employed. – Including authority and agency relations, group decision-making, negotiation, and institutionalization of rules and norms – can be found both in inter-firm and in intra-firm governance structures.	Theory
Nooteboom (2000, p. 70)	Thus knowledge exchange is repeatedly identified as a central feature of innovation and of social capital. In that context it is connected with issues of governance: collective action, mutual dependence, relational risk. This article analyses the value of knowledge exchange, how it takes place, and instruments for its governance. For the value and processes of knowledge exchange it employs a constructivist, interactionist theory of knowledge. It attempts to develop this theory into a logic of knowledge and learning.	Organizacional
Grandori (2001, p. 396)	Continuous governance, occurring intra and inter-organization, using mechanisms combine the organization's systems: a) considering both intra-firm and inter-firm relations, and b) explicit and develop the analysis of possible conflict between objectives that were quite limited and ‘buried’ in contingency theory and explicitly ‘suspended’ in recent knowledge-based theorizing.	Meso Organizacional

Antonelli (2006, p. 229)	Business knowledge governance is the set of institutions, corporate strategies, types of transactions and forms of interactions that characterize and shape the organization of knowledge production, exchange and usage in the business sector.	Meso Organizacional
Peltokorpi, C. e Tsuyuki (2006); Peltokorpi and Tsuyuki (2006, p. 36)	Knowledge governance mechanisms – consensus-based hierarchy, shared human resource practices, and performance measures and output control – that promote knowledge processes in project-based organizations	Micro Project
Foss (2007); Foss and Michailova (2009); Foss and Mahoney (2010)	Knowledge Governance, i.e. choosing organizational structures and mechanisms that can influence the processes of using, sharing, integrating, and creating knowledge in preferred directions and towards preferred levels (Foss et al., 2010, p. 456)	Meso Organizacional
Gerritsen <i>et al.</i> (2013, p. 605)	Knowledge governance as the intentional achievement of societal and policy change through the purposeful production and dissemination of knowledge. In other words, knowledge governance aims to deliver new and innovative insights and solutions which enable actors to leave traditional insights and practices behind and move away from inert interaction patterns, stalemate negotiations and conflicts of interest. In the concept of knowledge governance the coordinative power is learning, which is made possible by knowledge production and dissemination of shared ideas in social networks (Van Buuren and Eshuis 2010). In order to achieve its challenging ambitions, knowledge governance may take advantage of knowledge management activities such as: constructing a research agenda, organizing stakeholder platforms, making sense of what is happening in society and producing definitions of problems.	
Pemsel <i>et al.</i> (2014, p. 866)	Knowledge governance practices in project-based organizations. Concern about (1) governance of knowledge creating processes; and (2) knowledge governance in intra- and inter-firm relationships. The unit of analysis is the relationship between knowledge governance practices and mechanisms behind them.	Project

4 Knowledge Governance Conceptual Model

In this section we pretend going from Framework analysis to build the Knowledge Governance Conceptual Model. Here we identify the main building blocks and

4.1 The building blocks

In order to explore how knowledge governance topic is structured we decided organize publications into four levels of analysis: Network, Macro, Meso and Micro (see Figure). Additionally we also classify them into diverse context (Education, Science, Innovation, Ecosystem Policy and Theory).

Educational Context

The new 2030 Agenda for Sustainable Development explicit point Quality Education as a goal (Goal 4-Ensure inclusive and quality education for all and promote lifelong learning). For attainment of inclusive and sustainable growth we must focus on education of all kinds—higher education, postgraduate studies, basic education, technical-vocational education, and life-long and continuing education (Morta et al., 2016). Here we divide Educational Context in two subcategories: Higher Education and Non Higher Education.

Quality Education is also a key enabler for attaining all other goals. This justify our Governance approach by using evaluation tools to implement a monitoring system based on assessment for learning (Wiliam, 2011). The debates about the role of evaluation and the classification evaluation types, between formative and summative evaluation, define a

field of study with a strong link between theory and practice (Leite *et al.*, 2007; Morosini *et al.*, 2016; Pinho & Leite, 2014; Santiago *et al.*, 2003).

Science Context

The importance that both researchers and institutions feel in creating impact is justified (and even legitimized) by the pressure of research agendas; those agendas are now driven not only by the requirements of pursuing scientific excellence, but also by the expectations of multiple (and demanding) stakeholders (Brannback, 2003; Derrick & Samuel, 2016; Gibbons *et al.*, 1994).

Traditionally research evaluation practices seen as part of a system to ensure accountability and manage a resource allocation system, focus on research outputs. From knowledge Governance approach we see evaluation as a tool aligned with a learning function and a constantly improving knowledge valorization, knowledge integration and knowledge application, by knowledge transfer and sharing (Leite & Pinho, 2017a).

Innovation Context

At organizational level, Knowledge Governance is linked with knowledge Management (Pinho & Pinho, 2016). Here we adopt the knowledge Management definition advanced by Carla O'Dell & Jackson Grayson (1998) as “the conscious strategy of getting the right knowledge to the right people at the right time and helping people share and put information into action in ways that strive to improve organizational performance”. With this Knowledge Governance approach we can construct strategies of Knowledge creation that link Education and Research, at University context.

Quality Innovation front, is support by Knowledge Management (KM) inside organizations. Knowledge is a strategic asset necessary for competitive advantage and driver of growth and improved productivity (Argote *et al.*, 2003), but most knowledge management practices lack taken a holistic view (Pinho *et al.*, 2012; Sedighi & Jalalimanesh, 2014). Previous research KM has taken a variety of approaches and has focused on various environments (Pinho *et al.*, 2012). Despite the interest in research on KM, many organizations have a lack of expertise (Zhang *et al.*, 2016) and fail to capitalize its benefits (Szulanski *et al.*, 2016). In this innovation front we will extend our previous research, on barriers and facilitators knowledge processes (knowledge acquisition, knowledge creation, knowledge sharing and knowledge transfer) to identify knowledge Management models in use inside those organizations. Specifically, we need to know who are their users and suppliers and how they are being used. Additionally we want to identify the objectives and results that organizational knowledge management can provide.

The integration of those two previous fronts (Science and Innovation) through the lens of Governance will be the basis for the development of a Research and Innovation knowledge Governance that take into account its potential users and their needs.

Ecosystem Policy Context

The use of knowledge governance concept is increased related to ecosystem-based management paradigm (EBM), where knowledge is an important tool for decision-makers to know, understand and evaluate the socio-ecological systems they intend to govern (Giebels et al., 2016).

Theory Context

Polanyi (1962) divided the human knowledge in two dimensions: explicit (written, codified and easy to transfer) and tacit knowledge (internalised, personal and highly difficult to communicate). This division help to simplify our approach to knowledge, but we must remember that explicit knowledge and tacit knowledge are complementary and its conversion creates chances for the knowledge creation (Nonaka & Takeuchi, 1995)

Another knowledge approach is to associate with knowledge processes (Alavi & Leidner, 2001). Knowledge flows across people, organizations, institutions, places and networks involve creation, sharing, transfer and application of knowledge. In order to improve knowledge-flow processes it is useful to identify the barriers and facilitators (Pinho et al., 2012; Rego et al., 2009). Other approaches from theory of the firm, use the stakeholder concept, with several types of stakeholders (Grandori, 2018).

4.2 Towards Knowledge Governance mode~

Building on prior studies, this article aims to go further by improving our empirical understanding of the interconnection of Education, Science and Innovation systems that added value to knowledge resource. In doing so, we adopt an overarching “Knowledge Governance” model to frame and contextualize our main argument: Knowledge Governance can be implement at each ontological level and additionally this implementation must be aligned across all levels for improving knowledge flows and collaboration to increase economic and societal impacts. Drawing on the gaps in literature this conceptual framework (see Figure 12) aims provides synergies by following objectives need to be reached:

1. Quality Education-Focus on Educational Evaluation
2. Quality Science-Focus on Research Impact
3. Quality Innovation- Focus on Organizational Knowledge Management
4. Quality Ecosystem Policy- Focus on Policy cycle evaluation
5. Quality Theory-Focus on Theoretical development

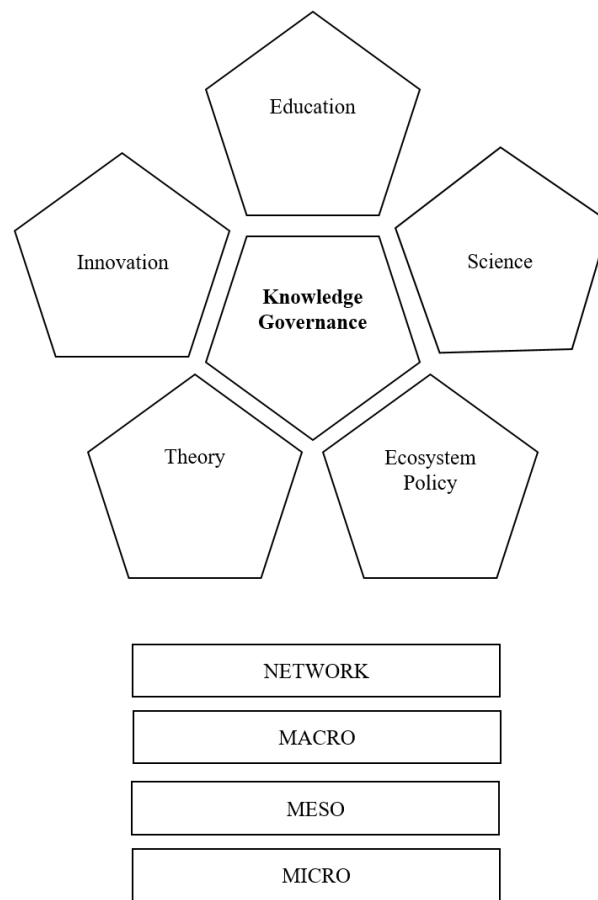

Figure 12 - Knowledge Governance Conceptual model

Taken the perspective of the Italian researcher Anna Grandori, that defend the connection of Knowledge Governance Mechanisms and the Theory of the Firm (Grandori, 2001), it seems there is a lack of understanding of what Knowledge Governance is and how Knowledge Governance implementation can improve knowledge integration from multi-level systems, not only at firm context but also several social spaces where organisations, institutions, networks, cities, regions, countries and global knowledge society interact, by mechanisms competition of collaboration. Although this study have an exploratory nature, its main result - the Knowledge Governance Conceptual Model - contributes to the development of the theory on this topic. We can consider that Conceptual Model is also an important input of integrative review (Torraco 2005).

5 Conclusions

In the last years, the economic and management literature has largely stressed the importance of knowledge assets for firm's competitiveness.

Knowledge governance can be a way from moving the management of hierarchical spaces to self-organizing networks with multi-level governance scales. Connecting knowledge and people is a great challenge and requires the integration of macro, meso and micro social spaces.

This means creating environments that facilitate knowledge sharing, by understanding individuals, groups and the larger systems within which they operate.

Through the interactions of knowledge governance mechanisms and knowledge management processes it is possible to create value and improve organization performance.

Starting by an exploratory review we build a conceptual model that can support the implementation of knowledge governance. This give a new and promising avenue of debate, research and practice, which can be a catalyst for academia, science, industry and government.

This article can be a starting point for further theoretical, empirical and practical research. At political issue we also defend that policy makers must provide a global and local mindset and if they turn knowledge workers they will value this public good: the knowledge. Looking Knowledge Governance as a catalyst, catalyst that can leverage the power of global and local systems across all levels (micro, meso, macro and network), seems to be a useful metaphor to communicate and convey its potentialities and synergies as well as be a facilitator in its transversal implementation.

Abstract

The purpose of this paper is to examine how positive emotions might influence on innovative competencies in the Multi Business Model Innovation (MBMI). Strengthening of the participating individuals' positive emotions such as happiness, gratitude, joy, love, optimism, hope, mindfulness seems to be important to higher the level of creativity during the business model innovation process in the MBMI conceptualization phase. The paper is based on a combination of the MBMI cube process conceptualization (Lindgren, 2018), and the positive psychology's stressing of positive emotions (Garland et al, 2010; Fredrickson, 2001, 2004a, 2004b, 2009, 2013; Fredrickson & Losada, 2005; Flarup & Wivel, 2013, 2018, Flarup et al, 2017, Lyubormirsky, 2007; Sheldon & Lyubormirsky, 2007); and how this wellbeing influences on the will to create and the will to learn (Seligman, the PERMA Model, 2014; Knoop, the Wellbeing Model in Education, 2013, 2017) in the business model (Valter, 2018).

The evidences of the paper is based on a research project on 41 mechanical engineering students at the Aarhus School of Engineering, Aarhus University, which for the first examine whether it is possible to strengthen positive emotions and how. Secondly, whether this strengthening of positive emotions influences on the students' positive experience of teamwork; thirdly, how these results can be transferred on MBMI processes. Findings from this research project illustrate that 1) it is possible to strengthen positive emotions by simple individual exercises. The choice of gratitude and mindfulness techniques points out that in particular gratitude exercises seem to have a stronger impact on positivity in comparison to mindfulness exercises. 2) Positivity leads to several

positive emotions (joy, happiness, creativity, gratitude, mindfulness, love etc.), which finally has an impact on the students' positive experience of a challenging teamwork. 3) There are highly relevant implications for MBMI innovative processes, since they draw on positive emotional competencies such as creativity, hope, optimism, courage and others. Thus, the paper suggests that further research has to be elaborated in the field of positivity and creativity as individual competencies, together with gratitude exercises, and in the framework of MBMI.

Keywords – Multi Business Model Innovation, Positive emotions, Multi Business Model innovation competencies, Multi Business Model Innovation creativity.

1 Introduction

Research indicates that there is a relationship between happiness and innovative competencies, as unhappiness, however, often shows a lower degree of creativity and innovative competencies (Isen, 1987; Valter, 2018). This means that positive thinking and the displaying of creativity is absolutely essential in the MBMI process and for the innovative quality:

If the participants are happy, they have an increased capability to be creative and solve problems that would positive effect the BMI process and the probability for success. However, if the participants are unhappy, they have a decreased capability to be creative and solve problems that would negatively affect the BMI process and the probability for success (Valter, 2018, p. 6).

During MBMI experiments the participants are asked to develop new and very strong innovative solutions to complex MBMI challenges. The MBMI working process is asking for elements that demands a special courageous attitude by the participants – “to think out of the box thinking”. This process can be heavily frightening for human beings in general, but by focusing on how to strengthen the participants’ inner feelings of positive emotions it is possible to encourage them to stay in the process and feel well-being even in very unclear and unconceptualized situations.

2 Concept of MBMI

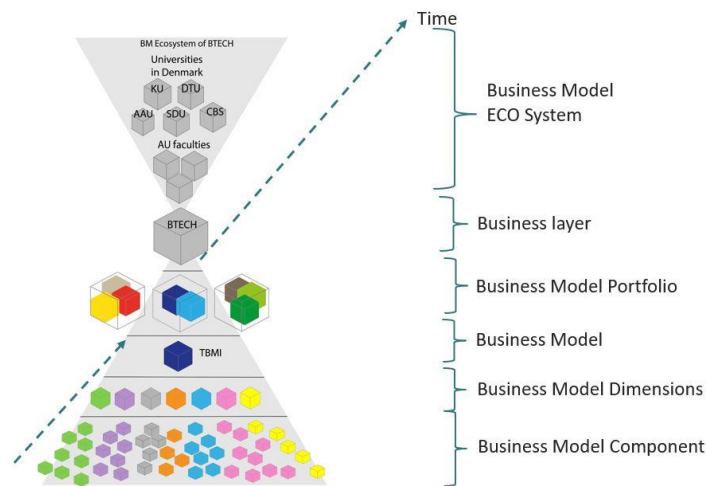

The reason for MBMI curriculum is described in Aarhus University’s course catalogue (University of Aarhus, 2019c):

Modern engineering is continuously faced with issues of and need for rapid MBMI and business model engineering. Knowledge of new support tools and technologies for business models and MBMI is increasingly important. Engineers must know how to develop strategic, tactical and operational approaches to technology-based business model innovation to enhance the business opportunity of achieving a strategic position and strategic advantage.

The curriculum is based on the MBMI concept (Lindgren 2018), which for one thing argues, that a business has more than one business model, most often the business has a multitude of Business Models AS IS and TO BE BMs.

The MBMI concept propose 7 levels of MBMI available to any business as illustrated in the Vertical butterfly model inspired by Horn Rasmussen and Lindgren (2016), see figure 1.

According to the concept we have the *Business* core business (the large grey box) and below, the business's business models grouped into different *Business Model Portfolios*. Each BM portfolio can be unfolded and each BM in the portfolios can be analysed one by one in *Business Model*, *Business Model Dimensions* and *Business Model Components*. Above the Business exists the Business Model Ecosystem (BMES) where the Business propose its BM's and finally, as none of these BM levels are stable, the *MBMI process* (*MBMI Time*) operates.

Own figure 1. The 7 different BM levels in BMI

The Multi Business Model Innovation process concept was inspired by Theory U (Scharmer, 2009) and therefore, the processes when working with MBMI is inspired by his 'U', in the sense, that a business constantly must overview and analyze the existing BMs in the BMES (AS IS). The Business must also continuously do MBMI i.e. change AS IS BM and innovate new bubbles and new BMs (TO BE) to fill in the Gap of existing BM when they begin to leave or have left the BMES. The 'U' inspiration for the MBMI ongoing process cause 7 phases with different activities as illustrated in the MBMI process model beneath:

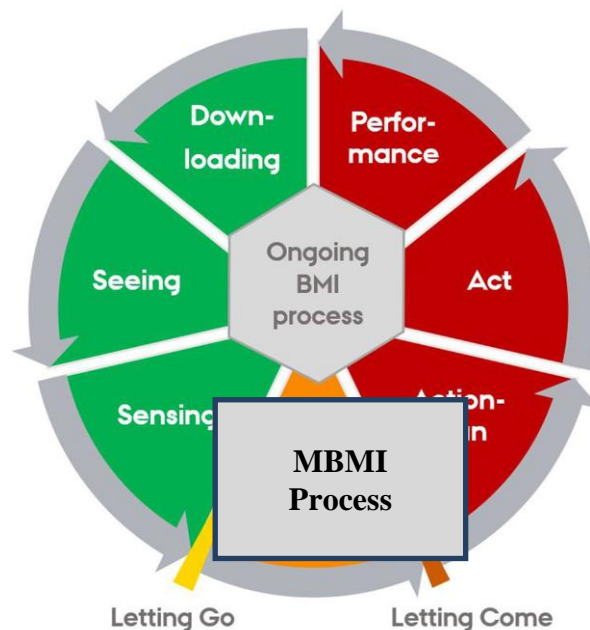

Figure 2. Inspired by Scharmer (2009), Andersen and Lindgren (2019), and Model of Business Model Innovation process, based on Lindgren (2012) and Lindgren and Jørgensen (2012).

The basic for all MBMI and to make this 7 level MBMI process happen is learning, knowledge creation and knowledge capturing. Therefore, it is important to optimize the MBMI participants learning environment and “mood” to learn.

3 How do positive emotions fit into MBMI?

From the theory of positive psychology it is solid described that there are a relationship between creativity and positivity (Knoop, 2013, 2017; Seligman, 2014). As concluded in the quote:

In other words, inducing positive emotions (such as joy, love, or appreciation) enlarges cognitive perspectives and enhances the ability of individuals to attend to more information, make richer interpretations, and experience higher levels of *creativity and productivity* (Isen, 1987; *our italics*).

The theory of positive emotions also suggests that resilience is a healthy side effect of positive thinking; whereas, negativity leads to lack of resilience, and finally to unpleasant emotional and unhealthy states such as depression, stress and survival strategies such as fight, flight, and freeze (Garland et al, 2010; Seligman, 2014).

Instead of letting the negative feelings of fear, fight or freeze flow freely and unconstructively we propose that the participants in the MBMI working process have to be trained to think positive and feel well-being, and by that: to generate an individual

resilience which we want to test in an experiment to see if this lets the creative power flow. Our hypothesis is:

H1 - The creativity in a MBMI process will be affected positively if participants in the MBMI process have received training in positive emotions in beforehand.

H2 - The level of innovative success in a MBMI process is closely linked to strengthening of the participants' resilience and development of positive emotions.

H3 - Positive emotions cause inner positive states in the participants, and this well-being influences on the will to create and the will to learn (Seligman, the PERMA Model, 2014; Knoop, the Wellbeing Model in Education, 2013, 2017) in the MBMI process – particularly the ideation and conceptualization process (Valter, 2018).

Thus, the paper is based on a combination of the MBMI process conceptualization (Lindgren, 2018; Andersen, 2018), and the positive psychology's theory about positive emotions and the concept of broaden-and-build positive emotions (Cameron, 2012; Garland et al, 2010; Fredrickson, 2001, 2004a, 2004b, 2009, 2013; Fredrickson & Losada, 2005; Flarup & Wivel, 2013, 2018; Flarup et al, 2016; Flarup et al, 2017; Flarup, 2018; Lyubomirsky, 2007; Sheldon & Lyubomirsky, 2007; Stephens et al, 2011).

4 Positive and negative emotions

While positive emotions such as joy, happiness, love, hope, creativity, gratitude, optimism extend the subject's palette and imply in "various thought-action tendencies" (Fredrickson, 2004b, p. 147; Fredrickson, 2004a), negative emotions have the opposite effect in the way that the subject experiences a kind of tunnel vision (Young & Hutchinson, 2012, p. 105). The individual's reaction pattern is reduced to a "specific action tendency" (Fredrickson, 2004b, p. 147) as for example the above mentioned intense negative emotions 'fight, flight, freeze' in what the person experiences as dangerous and threatening situations.

Negative emotions is about quick reaction 'by fear' (survival), whereas, positive emotions stimulate to broaden and build the individuals urge to creativity and a joyful living (Garland, 2010). It seems like these competencies to act 'by fear' and 'by joy' are inherited from our ancestors to our days as competencies to live with danger, negativity and even limitations, e.g. learned helplessness (Seligman & Maier, 1967); and the opposite competence to build relations, to find a mate and to reproduce themselves (Fredrickson, 2013). In that perspective positive emotions have an 'undoing' (dissolving) effect on negativity, which creates renewable "effects of positive emotions [that] appear to accumulate and compound over time" so that the subject is given to flourish and prosper (Fredrickson, 2004b, p. 158; Keyes, 2002; Garland et al, 2010; Fredrickson & Joiner, 2002; Seligman, 2014). Negative emotions make the subject languishing (Keyes, 2002; Seligman, 2014).

Thus, positive and negative emotions are diametrically in two different spiral cognitive and behavioral processes: an upward (positive emotions that broaden and build), and a downward (negative restricting emotions). The processes are not each other's

mirror images; however, they are contradictions (i.e. incompatible opposites) and fundamentally incompatible functions (Garland et al, 2010; Fredrickson & Joiner, 2002). The broaden-and-build mechanism of ‘undoing’ extend the subject’s vision and expand the person's action repertoire in situations; whereas restriction reduces to a very few patterns of action (anger calls for battle; fear of flight; Cohen, 2006). Negative emotions such as fear and anger, stress and disease-causing (Garland et al, 2010, p. 850) are:

neural, cardiovascular, endocrine, and muscular changes [and] co-occur with dysfunctional social interactions, which can perpetuate psychophysiological reactivity and trigger destructive behavior against self and others.

Whereas the positive emotions has the opposite effect (Garland et al, 2010, p. 850):

broadened cognition in turn creates behavioural flexibility that over time builds personal resources, such as mindfulness, resilience, social closeness, and even psychical health.

An upward movement of positive emotions strengthens the subjects’ mental and emotional well-being (Fredrickson & Joiner, 2002, p. 172). And not only that: Positive emotions have the ability to remove or blur the negative emotions (Garland et al, 2010, p. 852). The subject may not depressed, stressed or in conflict (Fredrickson, 2004a, 2004b) while feeling a positive emotion such as creativity, gratitude, joy, hope, happiness, love, optimism. The subject cannot feel, for example, gratitude to other people or success in the teamwork or innovation process, and at the same time feel guilt, shame, anger, disgust, dissatisfaction, envy and compare unfavorably with others (McCullough et al, 2002, p. 114). Positive emotions is increasing a sense of well-being and resilience, which is the opposite of a stressful emotional state, and the decisive factors in the individual's will to learn and will to create (Seligman, the PERMA Model, 2014; Knoop, the Wellbeing Model in Education, 2013, 2017) and in the business innovation model.

Below illustrates the process of an upward and downward movement.

Figure 3. The process of broadening and building up resilience and positive emotions (left side), and the process of narrowing and restricting (right side) (Garland et al, 2010, p. 855, 857).

Figure 4. The upward and downward emotional spiral movement. On the top of the positive emotions spiral we find joy, love, freedom, knowledge, empowerment etc. At the bottom of the negative emotions we find fear, grief, depression, powerlessness. Illustration: <https://wiredatheart.com/how-emotion-is-energy-in-motion/>

5 The issue of emotional attachments

In a business context it is important to study the degree of emotional attachment to the change processes that is implied in the MBMI model. The core issue here is that the stronger the feeling of attachment to the organizational values and goals are the stronger is the commitment, loyalty and individual experience of the attachment (Srivastava, 2013; Srivastava & Thakur, 2017). In the perspective of the acronym “VUCA” (Volatile, Uncertainty, Complexity, Ambiguity) change processes have become even more challenging (Hall & Rowland, 2016) together with the rapidly changes in the organizational environment. In a VUCA environment it is necessary for organizations to act agile and to be ready and able to response quickly to change in order to maintain their position. Therefore, it is important to develop a positive mindset so that people are able to work and behave positive in an unclear setting. Developing a good feeling of the values and goals that is part of the process, provides the participants an emotional attachment and commitment to add positive and intense efforts creating a new or strengthen the existing business model of an organization. In short:

Resistance to change can due to the feeling of insecurity of loosing something or a hesitance to in coming out of one’s comfort zone (Srivastava & Thakur, 2017, p. 241).

Thus, the BMI model is a change model which implicit predicts that all participants have a positive attitude to the change which is asked for. However, this is a problem, as not all people feel positive attached to the idea of change. Negative emotions might be the reason why some people are against the whole BMI process. Fear of loosing face,

powerlessness, feelings of uncertainty, lack of insecurity, self-efficacy and self-incompetence (Garland et al, 2010).

In our research of the MBMI processes it is evident that the participants must be strengthened in their positive emotional states. This has led us to the following:

6 Research question

The research project aims to investigate:

How to strengthen the participants' positive emotions in Business Model Innovation Processes?

7 Design/research methodology

The paper is preliminary in the sense that the theoretical foundation is explored in a quantitative and qualitative test design in relation to a cohort of 41 students at the 2nd semester mechanical engineering study at the Aarhus School of Engineering, Aarhus University. The research experiment examined whether it is possible to strengthen positive emotions and how; and secondly, whether this affected the students' positive experience of the project work in teams.

See the research design below:

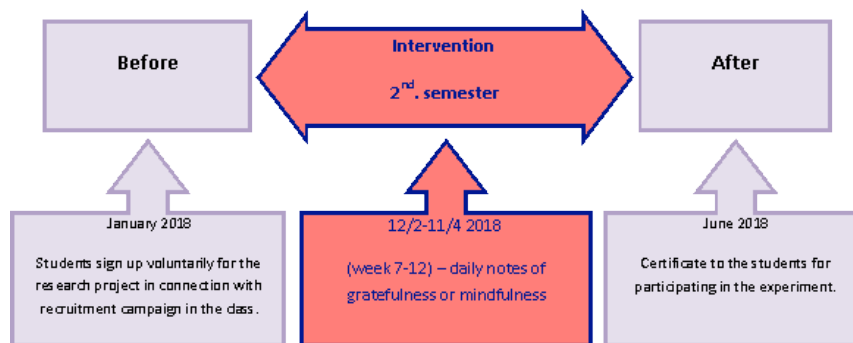

Figure 5: Research design.

The cohort of 41 students consisted of 2 groups – two research groups, and each group consisted of 3 student teams.

To test the impact of emotional intervention the two groups worked with two different types of positive emotions. The one group worked with gratefulness; the other group with mindfulness. Both are positive emotions as shown in figure 3 and 4, and they can be used as 'emotional intervention techniques' in reducing negative emotions like anxiety, stress, sadness and depression. Examples are counting grateful blessings and burdens (Emmons & McCullough, 2003; Emmons & Mishra, 2011; Emmons & Stern, 2013) or mindful meditation techniques (Kabat-Zinn, 2012; O'Leary & Dockray, 2015; Bamber, 2016, 2019). Gratitude and mindfulness might both lead to well-being (Cameron, 2012; Knoop,

2013, 2017; Seligman, 2014). On the contrary, gratitude (and the positive emotion of love, as well; Fredrickson, 2013) is a positive emotion, in contrast to joy, optimism, creativity, hope, mindfulness etc., that includes ‘otherness’ and the strengthening of social relations between benefactors, benefits and beneficiaries (Emmons, 2004; Fredrickson, 2004b; Kini et al, 2015; Flarup, 2018). In this perspective gratitude techniques are highly relevant for the MBMI processes as the basic working methods and strengthening of teamwork affects the quality of the innovative business model (Andersen, 2018; Flarup et al, 2016; Valter, 2018). In contrast, mindfulness is a positive, subjective feeling which also leads to a state of well-being but not (maybe not at all) to the social relations in a team.

During the intervention the participants wrote at least three observations per day as they felt gratitude for (the first group) or which brought them into a state of mindfulness (the second group). Journaling on daily basis seems to be effective and easy for the participants in comparison to, for example gratitude letters, meditation on daily basis or other positive emotional techniques (Kaczmarek et al, 2015). Each participant received a small notebook (pocketsize) for the daily journaling notes.

Figure 6. Diaries for the gratefulness and mindfulness notes on daily basis.

As gratefulness and mindfulness is related to positivity the participants answered a positivity test before and after the intervention.. The test is based on the comprehensive positivity research of Barbara Fredrickson (see www.positivityratio.com) which summarizes the degree of positivity in a ratio (Fredrickson & Losada, 2005). In addition a questionnaire for personal comments was distributed to all students.

8 Findings

On the basis of the positivity test we have calculated the following:

Table 1. Positivity test. The gratitude group before and after the intervention. The average increases.

<i>Positivity Ratio</i>			
<i>Gratitude group</i>	<i>Before (N=20)</i>	<i>After (N=18)</i>	<i>Difference</i>
2.1.	14,24	19,98	
2.3.	12,75	13,15	
2.16.	15,43	12,65	
Average	2,12	2,54	+ 0,42

Table 2. Positivity test. The mindfulness group before and after the intervention. The average falls.

<i>Positivity Ratio</i>			
<i>Mindfulness group</i>	<i>Before (N=21)</i>	<i>After (N=20)</i>	<i>Difference</i>
2.2.	13,38	10,98	
2.10.	14,72	10,38	
2.14	11,60	12,30	
Average	1,89	1,68	÷ 0,21

A degree of positivity ratio between 1 and 3 (before the intervention) in both groups corresponds to 80 per cent of the adult population (American) and is a low positivity (Fredrickson, 2010, p. 153). Over 3 is a high positivity. After the intervention the gratitude group has a direction towards a higher level of positivity in comparison with the mindfulness group which has a downward positivity ratio direction.

According to the comments in the questionnaire the gratitude group experiences a growing well-being whereas the mindfulness group does not seem to reflect the same level of well-being as shown in the examples of quotations in the figure below:

Table 3. Selected comments in the questionnaire for both groups related to keywords from positive psychology.

<i>Keywords</i>	<i>Gratitude group</i>	<i>Mindfulness group</i>
Growth and well-being	"Really good project, which I think everyone should be a part of."	"You learn to be aware of feelings and experiences. It provides plenty of self-insight."
Positivity and reciprocity to other people	"Thank you for the process – it has helped me to meet the challenges more positively and made them more manageable for me. Thank you. "	"I have come in a group who appreciate me and my skills." "It's been nice and sometimes interesting."
Social bonds	"I can feel that it has worked to some extent-it has tied the Group closer together." "Gratitude creates closer ties with your relations."	"It's good to get to know each other." "You will be forced to relate to others in a way that does not contain monosyllables (sweet, nice, stupid, etc. - not saying much). You see yourself from a new angle."

Teamwork	<p>"The project has helped me, both in relation to our group work, where we all have become much more tolerant of each other, and communication in the group is great. The [intervention] exercises have done that we have become closer to each other - and this has strengthened our project work. "</p> <p>"It helps the project work."</p>	<p>"I think it is difficult to see how this has impacted the group work."</p> <p>"Difficult to get started. Disagreements. Not everyone contributes equally."</p>
Positivity exercises help to get out of the negative spiral movement	"I have had a disease process which has been hard for morale and satisfaction, but I get to improve my quality of life and the study/direction."	"I find it hard to concentrate enough about the exercises, as I have been a lot of pressure of my study situation."
Concept of gratitude or mindfulness in general	"Done deeds that make others happy, because it makes me happy."	"It has been a fun and strange topic, 'mindfulness', it is an unpredictable but also a thing you can [learn to] master. It is not something you can measure as such, or collect. It is a feeling you get when you meet or are in a familiar and safe environment."

Findings from this research project illustrate that 1) it is possible to strengthen positive emotions by simple individual positive emotional exercises; 2) the exercises seem to create a stronger connection between positivity and gratitude than between positivity and mindfulness; 3) both gratitude and mindfulness seem to increase the impact on the students' positive experience of teamwork and social relationships. Finally, 4) the gratitude group members comment more positively that they feel better in the team and the project work has been strengthened by the exercises; a similar positive attitude towards teamwork is not evident in the mindfulness-group.

9 Strengths and weaknesses

However, these results should be assessed with caution, as it is difficult to point to a clear statistical significance in the measurement; moreover, the population of students is too small and the research design is not conducted in a MBMI setting but in a student teamwork in general. Differences are highlighted the greater the population concerned. The uncertainties are great for small populations, because it is difficult to know if there is a real difference or chance (Rothman, 2002, s. 11, 19).

Statistically, the result indicates that there is a difference, but that should be subject to uncertainties. These uncertainties may be other causes, which can lead to the result-either issues, which simply amplify the cause, or independent reasons for the result. Despite this, the measurement tend to have had a positive effect on the gratitude group, whereas the mindfulness do not report the same effect.

Another weakness to mention is that there is only two positive emotions involved in the research design. Nevertheless, we believe that there is evidence that the strengthening

of positive emotions, in casu gratitude, can have a decisive influence on participants' experience of well-being in the stressful situation that a MBMI process may cause. And even more when the change process is related to VUCA issues where there is a greater pressure on the organisation and its members to find viable business models.

Finally, it may be a weakness that the research design is not carried out in connection with a MBMI process, but at a population of mechanical engineering students in connection with their innovative project work.

Apart from these weaknesses, however, we believe that we can conclude the following:

10 Conclusion

According to our hypothesis we see in the quantitative and the qualitative part of the research that it is possible to affect the participants' level of positivity by an intervention of either mindfulness or gratitude, even though the compound is most evident between gratitude and positivity than between mindfulness and positivity (H1). This leads us to conclude that gratitude might be an efficient tool when strengthening the positive emotions in order to stimulate other positive emotions like creativity. Further research should examine the impact on creativity by gratitude exercises.

From the comments in the questionnaire we find tendencies that supports hypothesis 2 that both groups express a higher well-being and a more efficient teamwork after the intervention in general, but it appears that the gratitude group is the most positive of the two. Further research should examine the specific innovative success in a MBMI workshop at a deeper level. Finally, hypothesis 3 draws on research in general in positive psychology focusing on well-being as a creator of resilience, learning and innovative processes, and from the comments in the questionnaire it appears that the participants in the gratitude group feel a greater well-being in the project work situation than the mindfulness group. This aspect has to go through a deeper research in accordance to MBMI processes as well.

In general, we find the data in the paper promising as they elicits the relationship between strengthening of positive emotions and the quality of well-being on the one hand, and gratitude exercises as a tool on the other hand. We also find that the above mentioned research is highly relevant for the further research in the MBMI working processes as innovation is linked closely to positive emotional states such as joy, happiness, gratitude, creativity, love. In particular, simple positive emotional tools from the research in gratitude seem to be crucial for the intentions in the innovative MBMI process. Gratefulness is conceptualized as: "a positive, prosocial, and altruistic upward spiraling reciprocity" (Flarup, 2018, p. 21, not yet published), and so it illustrates that the hard and strenuous of any innovation process can draw on the building up of resilience and gratitude to what works in the MBMI team process. Focusing on well-being through positive emotions such as gratitude the result of the MBMI process might be of a higher innovative quality (Valter, 2018).

11 Originality/value – further research

This paper puts in evidence in how to facilitate a strategic perspective collaborating on MBMI for the purpose of “creating, capturing and delivering more ‘TO Be’ Business Models (BM) of high quality, effectiveness and efficiency as the lifetime of the Business BM’s and their related BMI investment continuously diminishes” (Andersen et al., 2018; Gartner, 2018).

As demonstrated in the paper there are fruitful implications for the MBMI process by the link to positivity. We aim to investigate this topic in a larger experiment and in connection with real businesses. This will take place later in 2019.

Another perspective seen in this paper could be how to frame grateful organizations and how to develop and implement gratitude as a part of the communication and organizational strategy (Emmons & McCullough, 2004; Cameron, 2012).

Abstract

This paper is part of a series of papers aimed at creating knowledge about Multi Business Model Innovation (MBMI) Process Management in a special designed Business Lab with the purpose to develop a framework for facilitating university students (and Businesses) in doing Multi Business Model Innovation according to the MBMI concept developed by professor Peter Lindgren (Lindgren & Jørgensen, 2012); (Lindgren & Rasmussen, 2013); (Lindgren, 2016, 2017, 2018).

The research includes Master Engineering students at Aarhus University Herning doing MBMI in three Business Labs during a business case competition. Twenty students worked in three mixed teams with their business cases for three days in the Labs and were observed by 360-degree cameras to explore what kind of interpersonal verbally and non-verbally communication processes appear and could be relevant for a Process Manager.

The Process Managers seem to facilitate the MBMI processes and the students team work in a three-dimensional guidance continuum by communicating through different types of comments, e.g. comments regarding their work processes, provocative comments, and investigating, praising and guiding comments. Yet mostly through open and investigative

questions. Moreover, the Process Managers use body language in an active, smiling and happy way that creates a positive, comfortable atmosphere with positive emotions in the Labs. Finally, the Process Managers use the MBMI B-Lab and tools to show the students how the infrastructure and the tools can help them structure, analyse and create knowledge (new BM's) through the BMI case work.

Keywords: Multi Business Model Innovation, Knowledge creation, Process Management of Business Model Innovation, Business Model Innovation communication.

Paper type – Academic Research Paper

1 Introduction

The Department of Business Development and Technology at Aarhus University in Herning, Denmark, offers students a cross disciplinary Master of Science in Engineering programme. Part of this is the 10 ECTS course: *Technological Business Model Innovation (TBMI)* course bridging Engineering Technology with Multi Business Model Innovation (MBMI) with the purposes to develop the students' competences in doing MBMI.

The research *Centre for TeleInfrastruktur Global Capsule (CGC)* at BTECH, facilitates interdisciplinary research and educational activities among others teaching and research in the TBMI course (University of Aarhus, 2019a). The course catalogue arguments for MBMI as curriculum (University of Aarhus, 2019b) due to the increasing, physical and digital globalization and thereby business competition. Today Businesses must be agile and increase their Business Model Innovation (BMI) capacity faster than previously to survive in the business environment - the Business Model Eco System (BMES) (Lindgren, 2018).

The TBMI curriculum is based on the MBMI concept developed by Professor Peter Lindgren which argues, that a business has more than one business model, most often a multitude of Business Models (Lindgren & Jørgensen, 2012); (Lindgren & Rasmussen, 2013); (Lindgren, 2016, 2017, 2018). Due to the course syllabus the TBMI students work in teams to share existing knowledge and construct new knowledge and skills through activities: reading, listening, writing, drawing and conversation (University of Aarhus, 2019b). They do rapid BM prototyping (artefacts) which is inspired by the IDEO innovation approach (IDEO, 2019) and analyse, investigate and develop MBMI solutions by working with real life business cases in a collaborative way (Bang & Dalsgaard, 2005).

This paper is a part of papers building up knowledge about the MBMI Process Management in the *B-Lab* (section 2.1) with the purpose to develop a framework for facilitation of university students (and Businesses) in doing Business Model Innovation processes according to the developed MBMI concept (Lindgren & Jørgensen, 2012); (Lindgren & Rasmussen, 2013); (Lindgren, 2016, 2017, 2018).

There is much knowledge about BMI (Zott, Amit, & Massa, 2011) (Osterwalder, Pigneur, & Tucci, 2005; Taran, 2011; Teece, 2010) and some knowledge about general

Business Model Coaching (Blackman, Moscardo, & Gray, 2016), but Blackman et al. recommend to do further investigation in communication skills regarding facilitation of BMI. In line with the recommendation right now Aarhus University – CGC has selected few MBMI certified Process Managers to facilitate participants in doing MBMI Processes in the B-Lab. And according to MBMI concept (Gade, 2018; Lindgren, 2018), there seems to be no accepted description of expected competencies and communications skills to fill the position as Process Manager in the B-Lab. As researcher Per Valter noticed when preparing the TBMI 2017 B-Labs in Skive: "As it is now we really don't know very much about the performing inside this innovation cubes, so we are measuring [...] this [digital monitoring] will give more knowledge about what is going on in the cube and how good the tools are working to help the participants overcome their problems" Drobe video interview (Valter, 2017).

In general, the MBMI Process Manager are viewed as coaches even though the MBMI glossary does not define this function. The word 'coach' seems to be marked by numerous connotations (Blackman et al., 2016; Stelter, 2002) and therefore, in this article we use the term 'MBMI Process Manager' as an overall term for the person in charge of facilitating the participants in the B-Lab, inspired by Benedicte Madsen describing 'process' as how the content (tasks and relations) will be organized (Madsen, 2016). And Based on the MBMI concept (Lindgren, 2018) we use the following acronyms:

TBMI = Technological Business Model Innovation

MBMI = Multi Business Model Innovation.

BMI = Business Model Innovation

BMES = Business Model Ecosystem

2 Multi Business Model Innovation as curriculum and didactical framework

The MBMI concepts research is, among others, based on the works by (Chesbrough, 2007, 2010; Gassmann, Frankenberger, & Csik, 2014; Osterwalder et al., 2005; Teece, 2010; Zott et al., 2011). According to the concept a business has more than one BM, often a BM portfolio and therefore, the students must learn the distinction between the 7 BM levels (including the time level) as illustrated in the Vertical butterfly model (figure 1) inspired by (Horn Rasmussen & Lindgren, 2016)

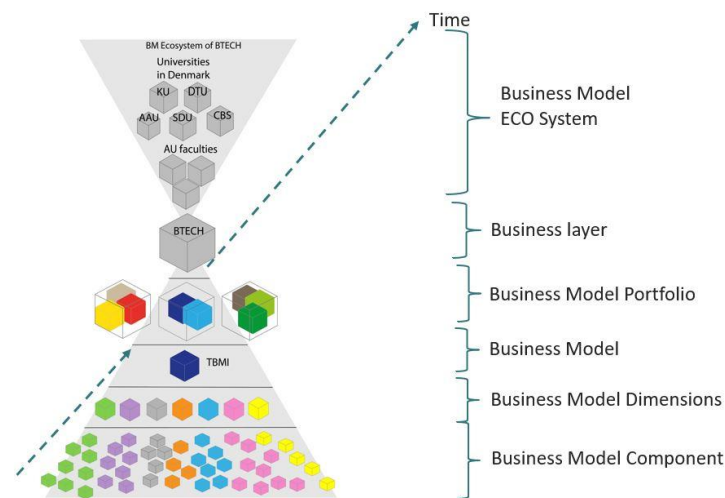

Figure 1. Own figure shows the 7 BM levels in MBMI.

According to the MBMI concept, a Business Model consists of seven BM dimensions (Lindgren and Rasmussen, 2013):

1. *The Value Propositions i.e. products, services processes*
2. *User or Customer in B2B or B2C*
3. *Primary or secondary Value Chain Functions*
4. *Competences as Technology, Staff Resources, Organisation, and Culture*
5. *Network as Physical, Digital or Virtual*
6. *Value Formula as Turnover or Other Values*
7. *Relations as physical or non-physical cords/channels that create contact and carry the values between the dimensions.*

(Lindgren and Rasmussen, 2013).

In the TBMI course, the students participate in a BMI case challenge, where they receive a real business case a business wants to be analysed and ‘innovated’. Therefore, the students visit ‘their’ business and work in here for three days 24/7. Back at the university they continuously work with the cases, participate in a challenge, and finalise their cases to a report and do their oral exam defence.

In this BMI process, the MBMI theoretical approach is a part of the TBMI didactical framework. When doing BMI, the students work in a circular process inspired by Theory U (Scharmer, 2009) where it is important to begin with analysing the existing BM, the case, before thinking in how to change or do a new BMs. This process is illustrated in Figure 2

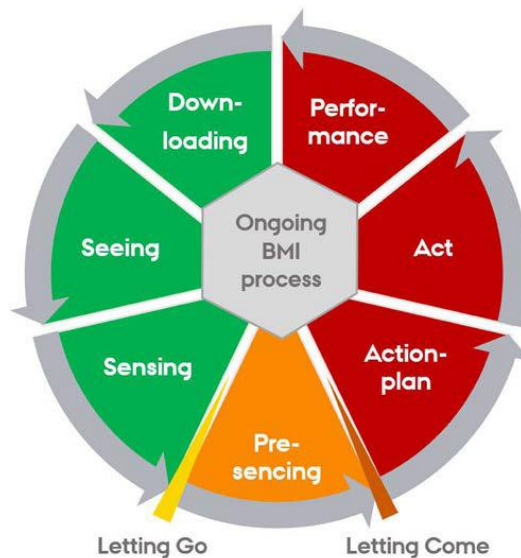

Figure 2. Model of Business Model Innovation process based on Lindgren and Jørgensen (2012); Lindgren, Rasmussen, and Saghaug (2013)

The students begin with the AS IS phase, the *Downloading* process where they must listen, observe and ask questions to understand and map the Business Components on the *B-Star* (Figures 3a and 3b) by writing what they hear regarding the seven BM dimensions. This is followed by the *Seeing* process where the students observe, discuss and reflect all the case's BM components from an outside-in view, by drawing lines (relations in Figure 4) between the components and finally assess the BM, components, and relations.

Now the students are ready to do the *Sensing* process: changed or innovate new BM's by combining the previous 'downloaded' knowledge with knowledge and competences of the students, business employees or the external network. In this process, the students again map and consider how one or more new BM's fit into the existing Business and BM portfolio. The students finally select the BM in *Letting Go*, *Stop and Investigate further*, *No Go* or *Park*. In the TBMI Challenge and further work at the university, the student does not do the last part of the TO BE phase in praxis, because this part must be decided by the business. The students can do the last part of the process theoretically and present the recommendations in their report.

Figure 3a. Small six-pointed B-Star.

Figure 3b. The large B-Star table with hexagons.

Figure 4. Students draw relations between the BM components.

When on or more BM's are found suitable to go through the *Presencing* phase and the business accept the changed or the new business models in the *Letting Come* phase, there is a new connection between the existing BM and the new upcoming TO BE BM. The process now shifts to the Act do phase and in this process the participants adapt a new mindset in the MBMI process inspired by Scharmers theory U. They must close their minds, focus on fulfilling vision, mission, objectives and implementation plan to “make” the BM happen. Energy to do the *Action planning*, implement (*Act*) the BM in the BMES and measure the BM by selecting KPI's to evaluate the BM's *Performance* have to be created and captured, to make the pink TO BE BM - A1 in figure 5 move from ideation phase to implementation phase an into the BMES.

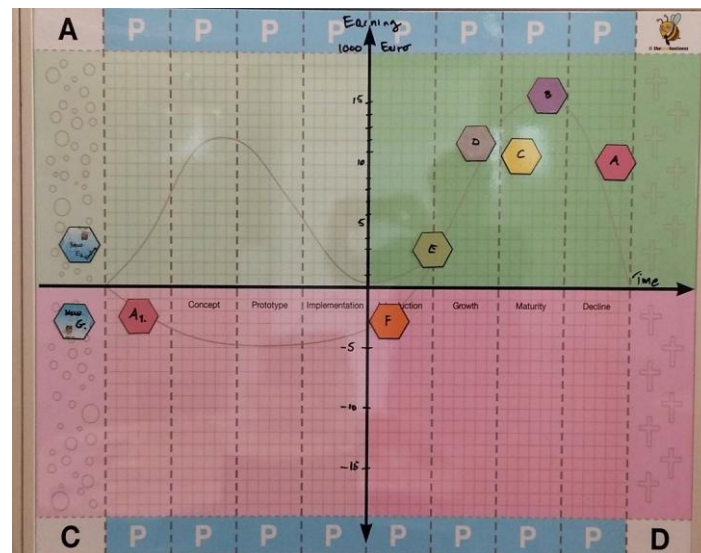

Figure 5. An example. Different BM's KPI 'Earning' measured on the B-Board.

2.1 The B-Lab in the MBMI process

In the TBMI course the student teams are invited to work in a special ‘MBMI room’ named the *B-lab*.

Figure 6a and 6b. Students work in the B-Lab.

The *B-Lab* is a hexagonal team room in the BM seven dimensions. The students sit across each other around the B-Star table and work with their business case, analysing and innovating by the aforementioned BM process and tools. The room is soundproof and has a nice atmosphere which supports the BM work. In order to strengthen the students' human relations and hereby teamwork processes (Tuckman & Jensen, 1977), the student's sit across each other around the B-Star table and communicates while working physical with the BM tools to analyse and share knowledge, create and capture new knowledge through the collaborative work process (Bang & Dalsgaard, 2005).

3. Research purpose and question

When doing MBMI in the B-Lab there are several environmental and tool-related forces that influence the MBMI processes. The forces are: 1) Environment and tools, 2) The Process Manager (Coach), 3) Group force also mentioned Team forces (Tuckman & Jensen, 1977), 4) Individual Forces e.g. culture and personal competencies by the participants, 5) Competition Space force 6) BMI Process Space forces e.g. time affecting the process, 7) and Emotion forces by the participants (Valter, Lindgren, & Prasad, 2018).

As our focus is on developing an MBMI Process Manager Framework for facilitating the participants in doing MBMI processes in the B-Lab, we are examining the Process Manager, force nr. 2.

In a previous paper (Andersen, Flarup, & Lindgren, 2018) we found that MBMI processes seem to take place in a kind of three-dimensional guidance continuum over time - a kind of Multi Business Model Knowledge Ecosystem (Järvi, Almpantopoulou, & Ritala, 2018) where the MBMI Process Manager with advantage to the MBMI process must be flexible and try to manage and facilitate the MBMI work in a non-linear process to heighten the outcome quality of the MBMI processes. Inspired by Løw (2009) we illustrated the continuum in Figure 7.

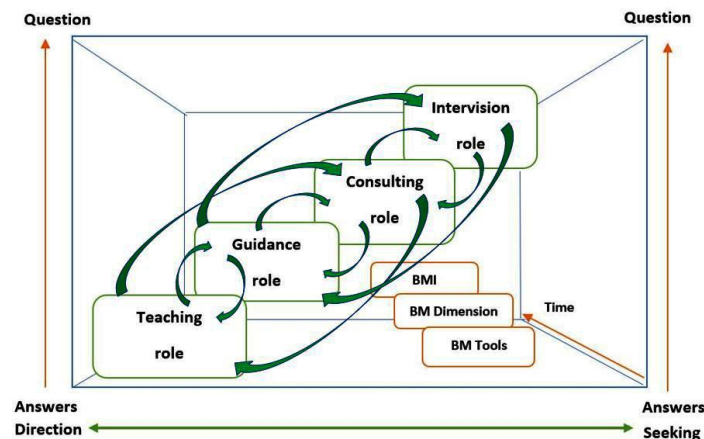

Figure 7. The three-dimensional guidance continuum. Inspired by Løv (2009, p. 97)

The Process Manager must be able to balance his/her perspective among four roles/positions: *teaching*, *guidance*, *consulting* and *inter-vision* between ‘direction’ the answers and ‘seeking’ the answers by questions, appropriated to the participants BMI work processes in the B-Lab. Additionally, the Process Manager must master different kinds of communication when facilitating the participants' knowledge generation and knowledge transfer (Mezirow, 2009) with the BM Tools, BM dimensions and the BMI process in the B-Lab. A vital condition regarding the knowledge transfer is that once the MBMI process is completed the Process Manager (and the participants) can apply the new experience and knowledge in his/her own practices.

In order to develop current understanding, we try to identify the tacit knowledge of being a Process Manager which is more or less conscious for the Process Managers him - or herself (Nonaka & Takeuchi, 1996). We investigated the executive role as an MBMI Process Manager motivating and facilitating collaborative knowledge generation and knowledge sharing in the three-dimensional continuum - what kind of process activities and interpersonal verbally and non-verbally communication processes seems to appear and be necessary by the Process Managers in the four aforementioned positions - more specifically:

1. What type of comments, answers, and questions seems to appear in the BMI process?
2. What are the Process Manager's body language and actions during the process?
3. How seems the BMI tools to support the communication and BMI process?

4 Research frameworks

Our research position is based on Participatory design (Simonsen & Robertson, 2013) and interpersonal communication processes (Jensen, 2004) between: a) participants in the B-Lab, b) between participants and the Process Managers and c) between researcher's in

their interpretation of examination research results. Interpretation is thereby the basis for the knowledge that the processes and experience will produce in a continuous, hermeneutic process based on pre-appreciation and appreciation. Our epistemological position is the philosophical hermeneutic in which each participant come with pre-appreciation and prejudices, which influence the interpretative interaction between the participants among these, researchers and Process Managers (Højberg, 2014). By the interpersonal communication approach (Jensen, 2004) the participants have the possibility to gain insight into the others participants' respective pre-appreciation and prejudices, and thereby the prejudices are revised, and new common knowledge can be developed.

Communication is the cornerstone of the interaction processes in the B-Labs. Without communication no changes, it's that simple - and yet that difficult. In this paper our research is based on the third communication paradigm, the *Co-paradigm* also referred to as the Interaction-paradigm (Due, Asmuf, Nielsen, & Gravengaard, 2016) in which communicating is and acting process between participants with a focus on creating new meaning and knowledge by interaction and interpersonal communication (Jensen, 2004). The communication processes take place in the 3 MBMI B-Lab, where the participants' interpersonal communication is supported by the Process Manager, and by physical analogue and/or digital artefacts. 'MBMI communication' is therefore understood as both verbal and non-verbal activities in order to facilitate participants BMI processes. And to analyse and categorise questions by the Process Managers we use Wichmann-Hansen & Jensen's *Interview model for supervision, inspired by Karl Tomm's four types of questions* (TOMM, 1988; Wichmann-Hansen & Jensen, 2013)

4.1 Research methodology

In 2017 the CGC research centre did a minor TBMI course challenge at the Biogas 2020 conference in Skive, Denmark. CGC invited 20 students from Denmark, Norway, and Sweden to participate in a 3-day-long TBMI business challenge during the conference (Drobe, 2017). The students worked in three mixed teams with their business cases for three days in three B-Labs according to the MBMI concept described in section 2. The students were supported by two Process Managers. During the challenge, the Process Managers and the students were observed in the B-labs by a 360-degree camera on each B-Lab table, and the students were observed by face-monitoring sensors in camera-caps and heart read monitor fixed on the chest as well (Lindgren et al., 2019; Lindgren, Valter, & Andersen, 2018). All students were informed about the research and have given their signed accept to participate in the research Labs. According to signed agreement, the data will be deleted after the IFKAD conference 2019. Face and heart measuring are not a part of this paper but will delete as well.

According to our research question, we have extracted examples of respectively: Answers, Questions, Comments, Body language and BMI Activities in the B-labs, from each ‘content log’ – summarised in Appendix 1.

5 Preliminary Findings

With our current examples of data from 3 B-Labs our preliminary findings seem to show that it is possible to analyse and categorize the Process Managers verbal and non-verbal communication in the B-Labs – being aware that Appendix 1 does not contain all comments and questions from the transcriptions.

Summary: <i>No. of the four different types of Open Questions:</i>	PM Comments: <ul style="list-style-type: none"> ➤ On MBMI process and tools ➤ On Students work process ➤ Provocative ➤ Investigating ➤ Guiding/ Advising ➤ Summarize: ➤ Praising ➤ Interesting ➤ Including language by using the word ‘We’ 	Type of questions by PM: <ul style="list-style-type: none"> ➤ ‘Meta’ questions ➤ Process questions (push the students) ➤ Rhetorical questions ➤ Detailed case questions due to the case ➤ Open questions (see below) Four different types of Open Questions <ol style="list-style-type: none"> 1. Clarify/concrete questions: e.g. What are the needs, expectations and objectives? (5 questions) 2. Investigative questions e.g.: Examine the knowledge, understanding and argumentation (17 questions) 3. Challenging questions e.g.: motivate to reflecting, see new perspectives, new way to solve the problem (9 questions) 4. Evaluating questions e.g.: summarize, highlight knowledge, draw conclusions and look at future goals/perspective. (4 questions) 	Body Language by Process Manager: <ul style="list-style-type: none"> ➤ Reflecting students body language ➤ Listen instead of talking ➤ Nods and signs of listening. ➤ Smiling ➤ Laughing ➤ Ask questions ➤ Says something fun ➤ Intentionally break ➤ Use the body to stress a point ➤ Step forward - step backward 	PM activities with BMI tools: <ul style="list-style-type: none"> ➤ Draw on the walls in B-Lab. ➤ Point dimension in B-Star / B-Table ➤ Points to the different (edges) of the B-Star ➤ Pointing at B-Board & ➤ Place the hand and move BMI on B-board.
--	--	--	---	--

Figure 10. Extract from Appendix 1.

5.1 Answers, comments and questions

The MBMI Process Managers did *Lecturing* the first evening just before the challenge. The students were taught the MBMI concept and associated tools, as well as team theory. The lecturing was followed by a team activity, a collaborative work process building a LEGO figure.

Figures 10a and 10b. Students are taught in MBMI concepts processes and tools.

During the TBMI challenge the Process Managers did a kind of *teaching* in the B-Labs when they repeated or made comment on the MBMI concept processes, dimensions, BMES, and the tools.

The students were *guided* and *consulted* by different type of comments e.g. comments regarding their Work Processes, Provocative comments, Investigating, Praising and Guiding comments as well ; by different types of *Open questions* e.g. *Clarifying* questions: “You have something you wanted to discuss”, and “are you beginning to understand the process of the whey-product?”; *Investigative* questions e.g.:” so...is it right, that I feel, that you don’t have an overview or?” and “so, are you trying to use these tools [BMI] to go around?”; *Challenging* questions e.g.: “but it seems that you are very stocked around product thinking?” and “so why are you not thinking out of the box? you have the opportunity now”; and *Evaluating* questions e.g.:” because, what I hear, I don’t know whether it is right, but I think you are at little bit disappointed as well” and “it is hard to the brain?”. With the current transcriptions is it difficult to place all the comments and questions in the respective phases Downloading and Sensing why there is no line between the two columns in the appendix (Appendix 1).

5.2 Process Manager's body language

One of the Process Managers seem to have a very positive and lively body language. It is characterized by reflecting on the students’ body language, listen and ask questions instead of talking, nods and make signs of listening, smiling and laughing a lot, use conscious breaks, use the body to stress a point, step forward when talking and step backward when the students need to talk, and make a little laughing when asking challenging questions or make provocative comments, as illustrated in the following pictures.

These more or less consciously body gestures by the Process Manager seem to be an active, sympathetic way of communicating, a way to create a positive, comfortable atmosphere with positive emotions (Valter et al., 2018); (Graziotin, Wang, & Abrahamsson, 2014) in order to motivate and help the students developing new BM in the intensive and demanding work processes they undergo. In that sense, the MBMI Process Manager seems to have some influence on several of the seven forces: Emotions, team dynamics and environments and tools (Valter et al., 2018).

5.3 Process Manager and the BMI tools

The Process Managers use the B-Labs and tools when facilitating the students e.g.: Draw on the whiteboard-walls, move BM hexagons on the B-Board, take the B-Star in the hand and points when speaking, point on the B-Star table, i.e. trying to get the students to use BMI tools as guiding and helping process tool in their Downloading and Sensing phases.

Figures 11a. and 11b. Process Manager uses the MBMI tools in the B-lab.

6 Discussion

We are aware that our preliminary findings are biased and do not show the full picture of MBMI Process managers extensive work in B-Labs. Certain respective video and sound recordings from one day are missing due to technical problems with recordings. All the monitoring was technically a brand-new setup with quite new 360-degree recording equipment that sound and video was recorded separately. It has made the analyse process complicated, as the audio and video codes don't match! And in some of the recording, it is very difficult to hear the communication due to background noise from Conference activities. These challenges are described in detail as the *Environment and tools force* in

Valter (2018) and evaluated with proposals for improvements. The results are also biased in the sense that we as researchers assessed and classified the comments and questions based on our interpretation of Guiding, Consulting and the type of questions. In order to accommodate this, similar research in the future must be transcribed and categorized by for example, a psychologist, so that researchers from different professions interpretation underlying the categorisation of the communication.

7 Conclusions

In this paper, we have initiated the second part of our research to develop a Framework for MBMI Process Management of participants in the B-Lab.

An MBMI Process Manager seems to work in a three-dimensional guidance continuum over time - a kind of Multi Business Model Knowledge Ecosystem where the Process Manager must be flexible and try to facilitate the MBMI work in a non-linear process. The Process Manager facilitates the MBMI processes and team work by communicating in very different comments and by most Open, investigative questions rather than giving the answers. The Process Managers seem to use the body language in an active, smiling and happy way that creates a positive, comfortable atmosphere with positive emotions (Graziotin et al., 2014) in the B-Labs. The Process Manager uses conscious the MBMI B-Lab and tools to show the students how tools can help them structure, analyse a create knowledge (new BM's) by the BMI case work.

8 Further Research

We are aware that this preliminary study regarding the Process Manager's communication must be followed by several research initiatives. Now a new course in MBMI processes in 3 B-Labs are planned to be completed in June-July 2019. Each B-Lab will be equipped with the second generation of the video monitoring equipment less intimidating for the participants, partly technically better with audio and included in the same file. And based on this paper it will be possible to encode all communication according to the different types of comments, answers, and questions found in this paper, in order to verify our initial data.

Abstract

The study seeks to investigate the impact of explicit and implicit knowledge sharing on business model innovation of IT Companies in Lahore (Wu et al., 2013), Pakistan through intervention of innovation speed and innovation quality. Based on the tentative deductions derived from Knowledge Based View (KBV) of information technology companies, this paper employs Partial Least Square for Structured Equation Modeling in order to investigate these hypotheses. Sample in the intended cross-sectional study contains empirical analysis performed on primary data collected from knowledge workers employed in IT companies. This envisioned investigation highlights the vivacious role of knowledge sharing within IT based firms that with the sharing of both implicit and explicit knowledge capital entrenched in the form of hidden intangible experiences, perceptions, behaviors, attitudes and as well as coded information in the documents and systems promote the strengthening of innovation capability of their existing business models. Thus, it has been found that business model innovation of IT companies can only be achieved when these firms quickly and more effectively come up with novel and breakthrough ideas, develop and launch new products & services, design and adopt new

business processes and solve business problems as compared to their competitors supported by critical knowledge sharing comprising of explicit and implicit knowledge. This study has significant practical implications for the knowledge workers working in IT based firms committed to increase the innovation capacity of their business model and process through common perspectives of shared experiences and information platforms. Knowledge sharing will thus help them utilize the integrated and collective information capital in order to produce effective, efficient, high speed and superior quality driven innovation in their IT services to reach and equally meet their customers' demands. Thus through resultant innovation in their firms' business model, IT managers can help their organizations gain sustained edge ahead of their competitors. Customer satisfaction and long-standing competitive advantage can be evidently achieved through sharing of innovation building explicit and implicit critical knowledge throughout the organization.

Key Words - Knowledge Based View, Knowledge Sharing, Explicit Knowledge, Implicit Knowledge, Innovation Quality, Innovation Speed, Business Model Innovation, Information Technology

Paper type – Academic Research Paper

1 Introduction

Business Model Innovation signifies an unusual, novel and further holistic idea of organizational innovation that requires for theory testing and analysis. According to the former research studies and data collected from executives of different organizations, Business Model Innovation (BMI) has been considered to be an integral source of continual value creation of the business and long term competitive advantage for the organization (IBM Global Business Services, 2006; Economist Intelligence Unit, 2005). Resultantly Business Model Innovation has considerably positive impact on the performance of the firms under ever changing external business environmental circumstances (Zott & Amit, 2007; Cucculelli & Bettinelli, 2015). Innovation in firms' business models and architectures with their remarkable positive outcomes on their performance warrant for studying the role of knowledge management practices for supporting BMI taking into account both empirical and conceptual research for generating better apprehension.

Various research studies in recent past have defined Business Model Innovation as the replacement in business model of the company to offer entirely novel and innovative products and services to the customers (Mitchell & Coles, 2004); the process of discovering a new business mode in already surviving business of the company (Markides, 2006); reconfiguring existing business model activities toward new product or service market (Santos et al., 2009), challenging current BMs, roles and responsibilities of a company for establishing innovative and unique worth of the business (Aspara, Hietanen & Tikkanen, 2010), involves an organization adopting new approach to making business profits utilizing company's principal assets (Gambardella & McGahan, 2010), discovering and creating new profit sources exploring unique value proposition

arrangements (Yunus et al., 2010), bringing change in existing norms of business model retailing thus changing organizing sense of the retailers for creating business value (Sorescu et al., 2011), re-conceptualizing the material content, authority and structure of the company to revolutionize its existing business model (Amit & Zott, 2012).

Similarly other research have defined BMI as the method or practice of intentionally altering the fundamental elements of the company and its operational logic (Bucherer et al., 2012), the process that involves changing and improving at the minimum of a company's value scopes (Abdelkafi et al., 2013), a transformation in the alleged reasoning of creating value for the business (Aspara et al., 2013), generating business commercial value by introducing a novel business model (Berglund & Sandstrom, 2013), creating and seizing new value proposition for a business' stakeholder by exploring new firm's judgments to institute new ways for profit orientation (Casadesus-Masanell & Zhu, 2013) and activities heading from making gradualist change in singular components of business model, extending existing or announcing new adjacent business models, disrupting previous business model or substituting existing with an entirely new business model through bringing fundamental change in the organization's product and service offerings and processes (Khanagha et al., 2014).

Likewise, a more comprehensive definition of Business Model Innovation has been introduced by Foss and Saebi (2017) that defines BMI as the process of bringing novel, planned and unique changes in the fundamental features of the business model of the firm and its holistic architecture under the commitment and support from top management under the theoretical foundations of Complexity Theory. Former researchers tried to sort out Business Model Innovation (BMI) in diverse terms such as operational, economic and strategic intent of the business innovation (Morris, Schindehutte & Allen, 2005) describe three categories – economic, strategic and operational. Major chunk of the research in Business Model Innovation has been focused on domain of IT and strategic concerns in innovation management and IT Management (Zott et al., 2011). Business model usually echoes key themes such as narratives of resource based view (RBV), transactive configurations, the landscape of the future opportunities, nature of innovation process, organizational design and sense making (George & Bock, 2011). Business Model Innovation has been characterized under three distinct research streams that hold as rudiments of BMI, fundamental elements and procedure of BMI and the outcomes achieved through BMI execution (Schneider & Spieth, 2013; Spieth, Schneckenberg & Ricart, 2014).

Based on a quantitative survey conducted on 138 KM managers from sixty eight technological enterprises in Pakistan, this study capitalizes upon structure equation modelling (SEM) to examine the tentative hypotheses. This research paper differs from earlier research works in three different ways. Primarily, none of studies have related knowledge sharing with business model innovation directly, in this case, current study would be an essential contribution toward closing this gap. Besides, the attempt of this paper is to additionally explore the working of the mechanism of knowledge sharing practices and business model innovation by analyzing the mediating or intervening role of innovation capacities to ensure the affirmance of the theoretical model. Lastly, through

deliberating the effect of categorical and implicit/implied knowledge sharing processes on innovation quality and innovation speed which as a result lead to higher business model innovation, the intended study attempts to offer that when confronted with varied uncertain business requirements and work situations in the future in long term the managers and employees must put emphasis on key processes and behaviors of implicit and explicit knowledge sharing so as to devise consistent strategies in the organization.

2 Literature Review

Exaggerated by the unclear and imprecise understanding of the connotation of business model and mislaid theoretical foundation for this concept itself, the newfangled research field focusing on Business Model Innovation (BMI) bears dearth of foundation for studying its characterization and its antecedents that lack in a structured theoretical base (Morris et al., 2005; O'Connor & Yamin, 2011; Zott et al., 2011). Parallel to this, the interaction based and relational research studies for business model innovation appear to be scarce across wide range in multidisciplinary perspective due to its conceptual isolation and keeping it in silos (Zott et al., 2011). Diverse other literature based studies such as strategic management, innovation management and entrepreneurship provide support to researching the nature and configuration of business model innovation and these researches are still scarce in nature. Resultantly, it can be inferred that the domain of BMI carries insufficiency in terms of large scale systematic and theory driven scientific support of literature, and therefore this is an important need to develop greater apprehension of the given occurrence (Bock, Opsahl, George & Gann, 2010).

Organizations in contemporary business arena consider it vital to actively respond to the changes occurring in the external business environment and use business model innovation as an integral component of creating business value under extreme business turbulence (Pohle & Chapman, 2006). Moreover, this lack of interactions and relational research studies are important need of time in understanding the key enablers of business model innovation, this underpinning of novel BMI idea necessitates the need for develop an advanced understanding of this impression and drives the elevated interest for researching this topic. In concern of this call for research, the requirement for taking a gestalt orientation of the existent literature on BMI and basing upon the prevailing patterns of researches conducted and contributions made, here comes the time to realize the relational edifice guiding the roadmap for prospective research on BMI under the support of knowledge based view.

Massive rise in emerging trends of globalization in business arena, transformations in behaviors of people representing diverse cultural backgrounds and breakthrough advancement in technology are some of the significant triggering elements for organizations to bring innovation in their business models (Lee et al., 2012; Wirtz et al., 2010). Based on the premise of Knowledge Based View (KBV), it is important to conceptualize the existing research agenda based on the role of knowledge management practices in facilitating business model innovation (Malhotra, 2000). The knowledge base and cognitions of knowledge workers are important in stigmatizing the business

transformation and innovation processes (Aspara et al., 2010). According to the strong argument posed by Doz and Kosonen (2010) 'Strategic Agility' has been considered as a vital player for stimulating business model innovation, which claims that inertia and inaction rising as a result of shielding the existing business process constantly in practice, brings elevated challenges while incurring innovation and revolution in existing business models of the firms. Strategic Agility thus denotes the capacity of an organization to proactively anticipate and foresee the external business complexities and turbulence and quickly respond to these unpredictable vicissitudes occurring in the environment (Yusuf et al., 1999; Sambamurthy et al., 2003; Li et al., 2009; Sull, 2009).

Strategic Agility is one of the important prerequisites of business model innovation and must therefore contain three primitive capabilities including unity of leadership, strategic understanding and resource flexibility (Doz & Kosonen, 2008, 2010). Companies thrive for innovating their existing business models rapidly, recurrently, and more comprehensive than their previous practices. Idea generation is also a strong pillar for business model innovation that is driven by the knowledge sharing practices promoted through individual employee inputs and efforts (Björk, 2012). Knowledge sharing supports a collaborative environment supportive of innovation in business model by novel idea generation (Eppler et al., 2011). Business model innovation is an evolutionary continuous learning process that entails innovation made as a result of ongoing external environmental changes (Dunford et al., 2010; Sosna et al., 2010; Chantal & Caron-Fasan, 2010; McGrath, 2010; Demil and Lecocq, 2010). This evolutionary business model innovation is contingent upon double-loop erudition (Moingeon & Lehmann-Ortega, 2010).

Knowledge ecosystems play a contributory role toward support business model innovation (Valkokari, 2015). Knowledge ecosystems are main drivers of novel knowledge creation and innovation under collaboration knowledge sharing, research and development in the organization. More focused toward 'Knowledge Exploration', knowledge ecosystems adhere to the aim of new knowledge generation that is commonly supported by tech-entrepreneurs (Valkokari, 2015).

Businesses can essentially drive their value and effectively realize their potential through adopting a customer-centric approach. This requires them to deliver high customer value and make huge profits by appealing the customer to pay higher for the value they get (Teece, 2010). One other important element for business model innovation and value creation is to manage the knowledge resource of the customers (Rollins & Halinen, 2005). For this, the firms need to interact more with their customer and share their knowledge and ideas. Hence, a two-way interaction between firms and customer promotes enhanced and value-focused sharing of knowledge among the users. (von Hippel, 1994; Franke & Shah 2003; Baldwin et al., 2006). It is therefore important to accomplish the flow and sharing of knowledge within the organization as well as between the firm and its customers and is considered as one of the critical teamsters of business model innovation in IT companies (Novo, 2004; Smith & McKeen, 2005).

Previous research studies reveal a dearth of literature and empirical support toward understanding the link between knowledge dissemination and sharing practices and

business model innovation. Despite of former researches discussing the role of technology oriented support for knowledge administration and business model innovation, the relationship, process and mechanism between implicit and explicit knowledge sharing for result oriented innovation in business models of firms (Amit & Zott, 2001; Rowley, 2002; Zott et al., 2011). Technology platforms provide strong impetus for promoting access and sharing of critical business and customer knowledge and hence, remain supportive for raising the value capture and delivery. As a result, business model innovation supported by value creation, capture and delivery eases the organization in increasing the streams of revenue streams through rigorous reduction in cost (Wu et al., 2013).

Based on the logic of Knowledge Based View (KBV), the knowledge capital and related resources act as levers of an organization's strategic assets to increase organization's long term performance and accomplish sustained competitive advantage in times of high dynamism, competition, complexity and external environmental uncertainty (Grant, 1996; Donate & Guadamillas, 2015; Obeidat et al., 2016; Obeidat et al., 2016). Knowledge Based View in addition also advocates that any organization's ability of value creation and innovation depends upon its capability to generate, share and apply the information (Martelo-Landroguez & Cepeda-Carrión, 2016). Capacity for amplified innovation and performance of knowledge intense firms depends upon effective knowledge management practices (Obeidat et al., 2016).

Knowledge intensive IT based firms have basic involvement in advanced learning, creating, designing, retaining and sharing of knowledge through all the organizational levels. Hence, these play a significant role in financial development and financial growth of a nation through continuous innovation and improvements in their business models (Ahmad et al., 2015; Fullwood & Rowley, 2017). According to various distinguished research studies, knowledge management processes and practices have been referred to as the set of activities relevant to the acquirement, generation, sharing and effective application or utilization of the knowledge resources. These practices ultimately lead toward higher innovation in business model and competitiveness of the organizations (Nonaka & Takeuchi, 1995; Darroch, 2005; Obeidat et al., 2016). IT companies are characterized as knowledge intensive organizations as they help their knowledge workers share their explicit and implicit knowledge capital in in order to achieve exceeded Return on Investment (ROI) in terms of amplified innovation in business model and processes, business performance and value (Rodríguez-Gómez and Gairín, 2015; Fullwood & Rowley, 2017; Yasir et al., 2017; Masa'deh et al., 2017).

Knowledge sharing is describes as one of the key enablers of implementing a successful and effective change in the organization in order to bring breakthrough transformations in business model on continuous basis (Imran et al., 2017). Several researches conducted by preeminent authors such as Gold et al. (2001), Ho (2009), Zack (2009), Ngah et al. (2016), Martelo-Landroguez & Capeda-Carrión (2016) and Valaei et al. (2017) cogently claimed that enabling factors and practices of knowledge management supported by a coherent and an integrated strategy for knowledge management are vital for the sustenance of effective and efficient sharing of implied and codified knowledge,

thus resulting in superior quality and speed of innovation processes which ultimately lead to higher business model innovation.

Majority of former literature studies discussed and stressed upon incremental/radical or competence/structural innovations in products, services and process, yet a very little emphasis has been laid on business model innovation (María Ruiz-Jiménez & del Mar Fuentes-Fuentes, 2013; Chahal & Bakshi, 2015). Nevertheless, a few research studies in addition have been conducted studying the impact of knowledge sharing practices on business model innovation with intervening role of innovation quality and speed (Wang, Sharma & Cao, 2016; Wang et al., 2016). The capability of an organization to accelerate and fast-track the advancement and commercialization of company's products and services for gaining and sustaining long term competitive advantage is known as Innovation Speed (Allocca & Kessler, 2006). Contrary to this, Innovation Quality enabled by knowledge sharing practices refers to process performance responsible for bringing business innovation and long term competitiveness (Haner, 2002).

It has been found that innovation speed and innovation quality, both play key mediating roles in accelerating the mechanism of business innovation when knowledge sharing incurs a positive impact on them (Wang & Wang, 2012; Wang, Wang, Cao & Ye, 2016; Wang, Sharma & Cao, 2016). Therefore, it has been supported that knowledge sharing both innovation quality and speed both can prove to be the crucial mechanisms in boosting the BMI and performance of the company. Still there exists a blur view of the intervening role of innovation quality and speed with respect to the impact that knowledge sharing practices have on business model innovation in IT industry upon reviewing the past literature studies. Alongside much stress have been focused toward developing a strong understanding on the relationship of KM practices and capabilities on driving innovation and performance of the companies. These practices involve attaining, sharing disseminating and applying the knowledge resources of the organization effectively and efficiently for accomplishing breakthrough achievements and boosting organizational performance (Asiaei & Jusoh, 2015; Ramadan et al., 2017).

According to Yang et al. (2005), a mechanism, tool or the process that enables the distribution or dissemination of knowledge base and information capital inside the organization is known as knowledge sharing (Yang et al., 2005). Knowledge sharing provides important source for establishing collaboration among the individual stakeholders of the organization (Tan & Md Noor, 2013). Knowledge sharing comprising of both explicit and tacit knowledge within the organization promotes the inclination of an organization toward unique idea creation and implementing those novel ideas, discoveries and inventions in their business model in order to devise new strategies or managerial procedures and develop & launch new products and services, new ways of doing things and innovative technology (María Ruiz-Jiménez & del Mar Fuentes-Fuentes, 2013; Chahal & Bakshi, 2015). Given the dynamics and complexities of contemporary business era and external business environment, there is a fundamental necessity for realizing the role of innovation quality and speed supported through sharing of critical knowledge within the organization to bring consistent innovations in the business models

(Wang, Sharma & Cao, 2016; Wang, Z., Wang, Cao & Ye, 2016; Iqbal, Latif, Marimon, Sahibzada & Hussain, 2019).

The rate at which the process ranging from generation of novel idea to ultimately commercializing or the capability of an organization to accelerate or fast-track the process of designing new products or processes fast analogous to its rivals in the given sector of industry is known as Innovation Speed (Allocca and Kessler, 2006; Wang et al., 2016; Wang, Sharma and Cao, 2016). It stems from the team based aptitude and competence that assists a firm in responding actively and promptly to the ever-changing needs and demands of the customers (Slater & Mohr, 2006). Innovation speed within the context of information technology based organizations entails the capability or competency of IT firms to lead launch of new IT solutions, tech advancements, software and customer services that are fitting enough to efficiently and effectively meet the requirements and face complex challenges in turbulent technological and economic environment external to their business.

Contrary to this Innovation Quality pertains to the nature of processes and action along with the end outcomes and results of innovation process (Haner, 2002). The value added to the customer, product & service flexibility and aesthetics, dependability, cost and process effectiveness (Haner, 2002; Wang & Wang, 2012). Referring to the context of IT based companies, quality of innovation is characterized by its capability to offer and deliver innovation IT solutions and tech-enabled services more competitive relative to the competitors and appropriately aligned with the global, economic and social needs of society at large.

‘Knowledge’ is referred to as an information that enables decision making and action in an organization (Beccaera-Fernandez, 2004). Cooper (2007) defined “knowledge” as an information that is organized and structured in nature after the detailed validation and cognition process. Knowledge major comprises of two forms i.e. tacit and explicit knowledge (Nonaka, 1994). Tacit or implicit knowledge pertains to the routines or processes in an organization that stem from the practices and experiences retained through action and learning from performing those processes or actions (Choi & Lee 2003). Contrary to this, explicit knowledge is characterized as the information that can be easily created, picked, followed and stored (Keskin, 2005). The strategy of knowledge management involves both the personalization and codification of the knowledge base of critical organizational knowledge based on the type of knowledge been focused (Burn et al., 2012). Codification of knowledge involves ‘people to documents’ plan that entails acquiring and retaining the explicit or written knowledge in form of databank or record for providing an ease of accessibility and usage to other people (Hansen et al., 1999). On the other hand, the other KM strategy is known as ‘Personalization’ strategy that involves ‘person to person’ plan for providing tailored services to the internal and external stakeholders. Majority of focus is emphasized upon the discussion and negotiations among the individual employees rather than storing the knowledge and information in written record forms. (Greiner et al., 2007).

Sharing of explicit and implicit knowledge has two intervening outcomes before it leads toward eventual business model innovation and higher business performance

(Allocca & Kessler, 2006), higher innovation efficiency (swiftness) and effectiveness (excellence). 'Innovation Speed' has been demarcated as the eventual commercialization of some novel services and products in the market. It echoes the capability of a firm to accelerate or fasten the actions, processes or activities and responsibilities for gaining and sustaining long term competitive advantage comparative to company's competitors in the given industry having most squeezed product life cycles (Allocca & Kessler, 2006). Innovation Quality involves higher customer value, higher degree of innovation, process and product complexity, reliability, time effectiveness, and value addition. This comprises of creating sense regarding accumulated innovation performance in each of the domains within the organization. The innovation outcomes are compared with potential and bearing in mind the procedure on how have the results been accomplished (Lanjouw & Schankerman, 2004; Haner, 2002).

Knowledge sharing in organizations helps them capitalize upon new opportunities for providing breakthrough solutions to the customers and efficiently solving business problems in order to realize competitive advantage in industry (Reid, 2003). Earlier research studies by Hogel et al. (2003) defined knowledge sharing as a culture based on social interfaces involving the give-and-take of knowledge, skills, abilities, and experiences of employees throughout the organization. The process of knowledge sharing can occur at multiple organizational tiers such as individual or organizational level. With respect to the context of an organization, the sharing of knowledge comprises of seizing, shaping, reprocessing and transmitting experience based explicit and tacit knowledge existing within the organization and making it readily available to all the concerned individuals in the organization. Concerning the connotation of knowledge sharing at individual level involves interacting and discussing with the organizational employees in order to facilitate them perform more efficiently, effectively and productively. Former research studies have proven that knowledge sharing acts as one of the key enablers of enhanced innovation and performance of the firm through efficient resource utilization in the company (Calantone et al., 2002; Scarbrough, 2003).

Ever since, business model innovation results in redesigning the competitive atmosphere and exploring and shaping new opportunities in the market; several drivers and precursors have been proposed using multiple approaches based on the groundings of Knowledge Based View (KBV) of the organization (Chandy & Tellis, 1998; Smith & Tushman, 2005). The elementary premise of Knowledge Based View (KBV) entails that innovation and new product development are chiefly the function of an organization's capability to manage, retain and generate new knowledge (Grant, 1996). Similarly, research studies conducted by Bierly and Chakrabarti (1996) and DeCarolis and Deeds (1999) greatly emphasized the effect of knowledge based approaches on innovation in the organization. Latest developments in research have advocated that the knowledge base of a firm is considered as its chief unique asset and a distinct resource that stimulates drastic innovation based developments in the company (Hill & Rothaermel, 2003; Subramaniam & Youndt, 2005; Miller, Zhou & Wu, 2010; Fern & Cardinal, 2007).

Nevertheless, existent literature studies propose contradictory views concerning the ways by which speed and quality of the innovation produced in terms of explicit and

implicit knowledge sharing affect business model innovation. It has been advocated that the organizations with more knowledge sharing either explicit or implicit fairly promote innovation in business characterized by integrating new components of knowledge and generating pioneering and radical ideas in the organization (Taylor & Greve, 2006). Existence of broad and rich knowledge base comprising of diverse, gathered observations facilitates the understanding of novel information and need for required changes. This in turn enhances an organization's ability to sense isolated market or technological opportunities in order to execute its thorough innovation (Chesbrough, 2003).

In contemporary business era characterized by knowledge-based and highly dynamic economy, the competencies and resources are considered as integral factors of companies to survive in highly dynamic, competitive and turbulent environment (Teece, Pisano, & Shuen, 1997; Subramaniam & Youndt, 2005). The competitive advantage gained and sustained by companies in their future will depend upon the resources of essential and critical knowledge held by the workers that will actively replace their factors of production, or what is known as knowledge workers. Knowledge therefore must be considered as one of the key intangible assets of an organization managed elaborately. Keeping in view this expansive concern towards the essentiality of the knowledge, researchers and industry experts have put maximum emphasis on organizations to develop and enhance their capability toward knowledge identification, capturing, creation, sharing and accumulation (Nonaka & Takeuchi, 1995; Kogut & Zander, 1996; Jang et al., 2002; Michailova & Husted, 2003).

The effectiveness of highly innovative business models of the organizations chiefly depends on the content and process of knowledge sharing among different levels of an organization (Pentland, 1995; Huseman & Goodman, 1998; Argote & Ingram, 2000; Alavi & Leidner, 2001). Behaviors and processes of knowledge sharing have been identified to be the key contributors toward generating a wide range of firm's capabilities and competencies for instance innovation and consequently enhanced performance of the company (Kogut & Zander, 1996). Nevertheless, being a very difficult process, yet has marvelous positive outcomes in terms of reducing costs of production (Hansen, 2002; Cummings, 2004; Hansen, Mors, & Lovas, 2005; Arthur & Huntley, 2005), fast paced development of new products, improved company's performance with increased growth in sales and revenues, and high innovation outcomes (Lin, 2007; Collins & Smith, 2006; Mesmer-Magnus & DeChurch, 2009).

Speed and quality of knowledge sharing activities always have been identified as the intervening variables between knowledge sharing and performance of the companies, since the practices of sharing knowledge among employees (Davenport & Prusak, 1998) in the organizations never directly result in improving and enhancing any company's performance unless some intermediary outcomes are involved (Choi & Lee, 2003; Hsu, 2008; Law & Ngai, 2008). Based on premise of KBV of firms, the drive of current study is to pose that business model innovation is not directly supported by knowledge sharing practices unless they promote effective speed and quality of innovation (Liebowitz & Chen, 2001). Based on the literature of Knowledge Based View (KBV), the major argument of this paper is that practices of knowledge sharing involving both implicit and

explicit knowledge do not merely have a direct positive relation business model innovation but they also encourage superior quality and speed of innovation processes that resultantly support business innovation (Liebowitz & Chen, 2001). Nonetheless, practitioners and researchers have hardly tried to design and execute an integrative and comprehensive model that with a holistic outlook aims to discover the effectiveness and value of knowledge sharing practices. Moreover, very little pragmatic research with empirical testing has been earlier conducted to examine the antecedents and enablers of business model innovation on the premise of Knowledge Based View (KBV) of the organization (Davenport & Prusak, 1998). Therefore, in order to fill this fissure, this research develops a theoretical model to link knowledge sharing practices, intervening processes, and eventually business innovation. This research study examines the effect of knowledge sharing processes on superior business model innovation with mediating intervention of innovation speed and quality (Liebowitz & Chen, 2001).

According to Wang and Noe (2010), sharing of knowledge must be considered as knowledge centered approach, a chief source of assisting employees in shared exchange of their information and knowledge base. This is consequently instrumental to application or execution of knowledge in an effective and efficient manner, ultimately resulting in business innovation and long standing competitive edge of the firm (Wang & Noe, 2010). Based on the conceptualization of Polanyi (1966), Nonaka and Takeuchi (1995) proposed SECI model of knowledge spiral based on “Socialization, Externalization, Combination, and Internalization” of critical knowledge resources both explicit and implicit during the entire process of knowledge creation within the organization. From one angel, the course of both internalization & socialization involves the active role of knowledge sharing in converting the knowledge based capital into individual employee or group based knowledge. Contrary to this, the other side of the coin shows that, the processes of externalization and combination entail the role of knowledge sharing in translating the individual level and group level knowledge into organizational level knowledge (Nonaka & Takeuchi, 1995).

Innovating the existing business models and initiating fresh and novel work situation within the organization are key results of knowledge sharing rehearses and practices (Law & Ngai, 2008) throughout the organization that importantly help in conserving treasured heritage of the organization, alongside learning innovative techniques, solving unique problems through new approaches, and increasing innovation in the organization by developing core competences (Hsu, 2008;; Hu, Horng, & Sun, 2009). Both tacit or implicit and explicit or codified knowledge play instrumental and significant roles in initiating the socialization process and executing combination process respectively within the organization. Similarly the significant roles of implicit and explicit knowledge in knowledge sharing for internalization and externalization of knowledge capital must be acknowledged (Huang, Chen, & Stewart, 2010).

All the noticeable forms of sharing organizational knowledge that are entrenched with any organization come under explicit form of knowledge sharing. Since, explicit knowledge is acquired, codified and disseminated easily in the organization, therefore such visible and evident knowledge circulation practices are seen commonly around the

workplace (Coakes, 2006;). All the organizational mechanisms involving important operations such as formal business processes and procedures, employee or staff handbooks, official business language and IT systems provide considerable support and assistance in sharing the explicit, written or codified knowledge (Huang, Davison, & Gu, 2010). Contrary to this, sharing of tacit, implied or implicit knowledge base is characterized by one-t-one interactions and shared practices of employees in the organization. For effective tacit knowledge sharing, the capabilities and willingness of individual employees to deliver and use the knowledge are chiefly instrumental (Megan et al., 2007; Lin, 2007; Holste & Fields, 2010). Nonaka and Takeuchi (1995) and Polayni (1966) advocated that the basic foundation of the tacit knowledge rests in individual human experiences, this is due to the fact that an individual human being with the help of already within him built in 'social software' can capitalize upon new knowledge.

A lack of willingness or awareness for sharing and using the tacit knowledge might become one of the other cause of difficulties arising in this process. Moreover, employees may also lead to ineffective and inefficient tacit knowledge allotment due to them finding difficulty in articulating this implied knowledge tangled to mental cognitions and bodily movement, as well as coming across absence of relating and executing context defined implicit knowledge in different settings (Holste & Fields, 2010). The problem may result in hindering the quality and speed of the innovation processes within the organization. Nevertheless, these barricades can be seized by developing credulous relationships among individual employees of organization in the process of knowledge sharing (Spender & Grant, 1996; Spender, 1996; Koskinen et al., 2003; Lucas, 2005).

The quality and speed of the innovation process are intervening consequences of the explicit and implicit knowledge sharing processes. Speed of innovation in any organization is characterized by the time lapse or gap between the preliminary development of innovation or novelty comprising its idea generation and delineation and the ultimate launch and commercialization of an innovative product or service in the market (Allocca & Kessler, 2006). Innovation speed redirects an organization's competence to fast-track the tasks and activities for constructing and sustaining a long term competitive edge comparative to its rivals in related businesses condensed product life phases (Kessler & Chakrabarti, 1996; Kessler & Bierly, 2002).

The foundations of innovation speed supports an exemplar swing from more old fashioned and traditional cradles of advantage toward a preemptive strategic positioning that is well suited with present contemporary briskly changing external business environment (Carbonell & Rodriguez, 2006). Innovation speed is considered as vital component for competing in market for it can lead toward greater performance. Previous studies have exposed an optimistic affiliation amid the speed of innovation and modernization of business products & services (Carbonell & Rodriguez-Escudero, 2009; Carbonell & Escudero, 2010). Innovation speed of an organization entails its dependence on socially imbricated capabilities and team synergies that are highly unique and cannot be simply designed or imitated by the competitors (Slater & Mohr, 2006). Therefore, innovation speed resulting in high business model innovation and successful product launch promotes organizations in keeping in close connection with their customers and

appropriately meeting their demands (Tatikonda & Montoya-Weiss, 2001). Likewise, it has been found that fast paced technological advancements, rising competitive rivalry and smaller product life cycle force innovative firms to innovate at fast pace so as to outperform in the competition (Heirman & Clarysse, 2007; Lynn, 2008).

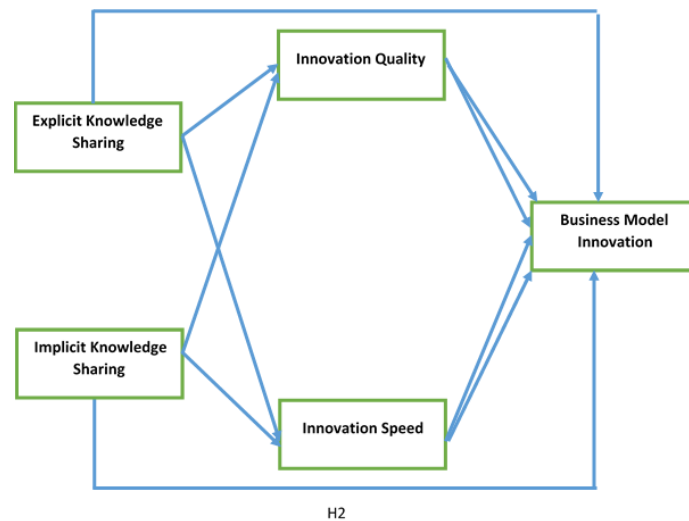

Another important conception in innovation promoted by innovated organizations is the innovation quality (Lin, 2006; Haner, 2002). Innovation quality deals with aggregated performance in product or service innovation through comparative analysis of the consequences on taking account of the process of achieving the results. (Lanjouw & Schankerman, 2004). Since, innovation pertains to a robust link with the creativity or newness of products or services in terms of their quality managed by standardization or customization, adherence to standard operating procedures, and zero tolerance to defects. Therefore, innovation quality with respect to the development of products and services is concerned with effectiveness, aesthetics, features, quantity, reliability, cost, timing, complexity, customer value and extent of innovation (Tseng & Wu, 2007). The quality of innovation is considered as one of the key contributing factors for a company's innovation strategies that assist in achieving competitive advantage. Determining this strategy is very difficult due to augmented process complexity, challenges in determining the catalysts that stimulate innovation, and integrating measurements such as innovation scope, comparative citation ratio, discipline knowledge and citation weighted copyrights and many more (Ng, 2009; Lahiri, 2010).

In context of Knowledge Based View (KBV), there is still an important need for re-conceptualizing the idea of knowledge sharing as facilitator and enabler of business model innovation (Malhotra, 2000). Knowledge sharing is a strategic approach, hence, the business model of the organization defines the rationality of entire system of a business (Al-Debei & Avison 2010). According to Malhotra (2000) and Lin (2006), the extent of organizations' business model innovation is determined by their capability to exploit, create and share knowledge. Organizations when utilize their knowledge sharing capabilities, swift problem solving skills and agile response to external changes may result in business model innovation. Similarly, previous research scholars also have stressed the significance of knowledge sharing in enhancing business model innovation capability (Liebowitz, 2002; Lin, 2006). Effective knowledge management and increased business innovation richly depend on their employees' readiness to share knowledge (Davenport & Prusak, 1998).

The pile stock of knowledge capital is aggregated in through active knowledge sharing that in turn promotes business model innovation when innovation speed and quality play an intervening instrumental role in making knowledge sharing a determining factor for business model innovation. Employees working in groups and at organizational level when share explicit and tacit knowledge, they are more prospective toward innovative idea generation and explore new and innovative business opportunities with high product and service innovation and at fast pace thus resulting in enhanced business model innovation (Darroch & McNaughton, 2002). According to Hansen (1999), knowledge gathering and sharing signify the successful completion of any business innovation project. Business innovation, high absorptive capacity and performance innovation can be

improved by quality and speed ridden innovation promoted through shared knowledge sharing practices (Jantunen, 2005). Unambiguously, any business organization with high aptitude in integrating and sharing organizational knowledge will have more likely chances to encompass rare, unique and inimitable resources, and therefore will have great potential to speedily innovate and produce innovation quality, ultimately endure with maximum business innovation model capability. This study, therefore aims to study the impact of clear and inferred knowledge sharing on sustaining business model innovation of IT companies with an intervening role of innovation quality and innovation speed thus better positioning these firms for longstanding competitive advantage (Lin, 2006).

3 Theoretical Framework

3.1 Methodology

Based on the tentative deductions derived from Knowledge Based View (KBV) of Information Technology Companies, this paper employs Partial Least Square for Structured Equation Modeling for investigating these tentative hypotheses. The sample in current cross-sectional research study comprises of empirical investigation performed on firsthand data gathered from knowledge workers employed in IT based firms using simple random sampling.

3.2 Population of Study and Sampling Technique for Data Collection

The study sample comprises of IT firms in Lahore, Pakistan. According to He and Wong (2004) firms having extensive technology based setup and functioning enjoy the value of knowledge exploring and exploiting activities. Moreover, championing in the innovation entrenched practices through entrepreneurial intentions is also their representative characterization that are vital to gaining and sustaining long standing

competitive advantage by resulting in business model innovation (Grant, 2002; Jansen et al., 2009; Allocca & Kessler, 2006). Technology based organizations take in account a long range of strategies focused on managing knowledge resources including both tacit (routine based) and explicit (codified) knowledge (Yahya & Goh, 2002). Likewise, the influential role of innovation quality and innovation speed should not be undervalued at all as these are fundamental extension to the guidance to steer energy and enthusiasm of employees in pursuit of managing knowledge distinctively in order to support business model innovation (Zott et al., 2011).

The population comprises of Information Technology firms in Lahore, Pakistan, selected as per the specific purposeful bounds having applicability aligned with the aim of this study. An entire list of IT firms 68 in total from Lahore, Pakistan has been chosen according to the practices of Information Technology companies that operate in the domains of business model innovation, information security, customer relationship, knowledge sharing and dissemination to strategically support commercialization of innovative products and services with efficient acceleration and effectiveness through transforming raw information into meaningful one and IT governance and strategy to align IT approaches with the corporate strategy using knowledge management practices for the sustained performance and BMI of these firms (Pakistan Software Export Board).

Primary data will be collected using self-administered survey based questionnaires disseminated in the selected companies recognized as acquiescent with the requirements of this research.

4 Measuring Instruments

The items of the measuring instruments have been adapted from present scales as found in the literature. Some alterations and adjustments have been made in them in order to sync these scales with the Pakistani context. The face validity of all instruments has been obtained from a board of four industry experts currently working at executive and senior management positions in the information technology based companies. Respondents will be requested to label the level of agreement or disagreement across a 5-point Likert Scale denoting 1 = Strongly Disagree and 5 = Strongly Agree. Survey items for each of the constructs are itemized at the end of this study.

The 30 item scale on Business Model Innovation has been adapted from the scale developed by Clauß (2017). The 3 key extents of business model innovation comprise of 'value creation innovation' inquiring about the firms' positioning toward development of new capabilities, technological advancement, partnerships, and processes; 'new proposition innovation' that focuses on asking questions regarding new offerings, markets and customers, networks, and customer dealings and 'value capture/seizure innovation' deals with the organizations' intentions towards introducing new revenue generating models and value cost arrangements.

Likewise, the measuring instrument of Explicit Knowledge Sharing comprises of 6 items pertaining to collection and use of organizational formal documents and reports; information technology systems, and training and development systems. A 7 items scale

for measuring Tacit Knowledge Sharing has been adapted by Wang and Wang (2012) that involves asking respondents on the experiences shared by the employees, their expertise, professional aptitude and learning from the past job experiences.

Innovation Speed has been scaled using 5 items adapted by Liao et al. (2010) and Wang and Wang (2012) that mirror the quickness and speed of IT companies toward generating novel and breakthrough ideas, innovating in launching new products, services, offerings, processes and providing real times competitive solutions to the customer that key rival cannot Liao et al., 2010). The measuring instrument of Innovation Quality comprises of 5 items and has been adapted from Haner (2002), Lahiri (2010) and Wang and Wang (2012) The statements inquire about the inventiveness, novelty and ingenuity of new ideas and concepts, products, services, practices, management and processes currently run with these IT companies.

5 Path Analysis

Cross-Validation Communalities & Redundancy

The authenticity of model strength and fit are determined through cross-validation communalities and redundancy indexes as shown in Table 2.

Correlation Analysis

Table 1 shows the correlation analysis for the model and shows positive correlations among the latent constructs or variables.

Path Analysis or Multiple Regression

The results of first hypothesis (H₁) divulge that explicit knowledge sharing practices hold an insignificant impact on business model innovation in information technology firms. The results of the analysis authorize the presence of an insignificant relationship between explicit knowledge sharing and business model innovation ($\beta = -0.009$, p-value > 0.05). This insignificance vividly declares the non-supporting role of explicit knowledge sharing practices for inculcating effective robustness in innovation of business model of the IT based companies. Besides, path coefficient (β) and the p - value of influence of implicit knowledge sharing on BMI of these companies have been examined. The results grounded on the basis of statistical consideration also do not legalize or support the presence of any considerably impact of implicit knowledge sharing (H₂) ($\beta = 0.023$, p-value > 0.05), on business model innovation of the companies working within the context of technology supported services. Thus, this leads toward the interpretation that that implicit knowledge sharing practices also bear a direct insignificant influence or role in snowballing the innovation in business models of Info-Tech companies.

The results of third hypothesis (H₃) declare that innovation quality does not mediate the impact of explicit knowledge sharing practices on business model innovation in information technology firms. The results of the analysis also do not authorize the presence of any significant mediating role of innovation quality between the relationship of explicit knowledge sharing and business model innovation ($\beta = 0.037$ p-value > 0.01). This insignificant mediating role of innovation quality for making explicit knowledge sharing accelerating BMI obviously states the non-supporting intervening role of quality

of the innovation processes for explicit knowledge sharing practices to inculcate effective robustness in innovation of business model of the IT based companies. Besides, path coefficient (β) and the p - value of mediating influence of innovation speed between explicit knowledge sharing and business model innovation for the IT companies have also been examined. The results grounded on the basis of statistical consideration validate the presence of considerably significantly positive mediating impact of innovation speed in between explicit knowledge sharing (H4) ($\beta = 0.463$, p-value < 0.05), and business model innovation of the companies working within the context of technology supported services. Thus, this leads toward the interpretation that that explicit knowledge sharing practices bear an indirect significant and a positive influence on BMI when with time innovation speed plays an intervening role in cumulating the innovation in business models of Info-Tech companies.

Furthermore, the significant mediating roles innovation quality and innovation speed for assumptions (H₅) and (H₆) respectively have also been supportively confirmed i.e. both innovation quality and innovation speed significantly mediate the relationship between implicit knowledge sharing practices and innovation outcomes of the business models of information technology based businesses ($\beta = 0.687$, p-value < 0.05, $\beta = 0.432$, p-value < 0.05). The estimated results of the path or structured model analysis show the significance of indirect positive effect of implicit knowledge sharing on BMI through the respective intervening connection established by innovation quality and innovation speed.

Table 1: Convergent Validity, Discriminant Validity and Descriptives

Constructs	Mean	S.D.	Series of Loadings	AVE	CR	<i>EKS</i>	<i>IKS</i>	<i>IQ</i>	<i>IS</i>	<i>BMI</i>
Explicit Knowledge Sharing	3.85	1.03	0.60-0.70	0.61	0.68	0.64				
Implicit Knowledge Sharing	4.76	1.86	0.50-0.60	0.50	0.55	0.25	0.56			
Innovation Quality	4.35	1.75	0.81-0.90	0.84	0.82	0.49	0.63	0.85		
Innovation Speed	3.92	1.32	0.65-0.80	0.69	0.71	0.66	0.72	0.23	0.77	
Business Model Innovation	4.59	1.98	0.50-0.80	0.72	0.75	0.11	0.12	0.61	0.54	0.59

All of these item loadings possess p-values significance values < 0.05. Average Variance Explained that is the square root of the variance present among all the variables has been shown as bold highlighted in diagonal.

Table 2: Structured Model Analysis

	Cross-Validation Redundancy	Cross-Validation Communality
Explicit Knowledge Sharing	0.23	0.41
Implicit Knowledge Sharing	0.39	0.28
Innovation Quality	0.48	0.31
Innovation Speed	0.50	0.36
Business Model Innovation	0.49	0.48

Table 3: Path Estimation for Structured Model

Path		t-values (Standardized β Coefficients)		
		<i>Total Effect</i>	<i>Direct Effect</i>	<i>Indirect Effect</i>
Explicit Knowledge Sharing Innovation	→ Business Model	0.39(4.51**)	-0.009(2.10)	
Implicit Knowledge Sharing Innovation	→ Business Model	0.28(3.12**)	0.023(1.98)	
Explicit Knowledge Sharing Innovation	→ Business Model			0.037(1.21)
Explicit Knowledge Sharing Innovation	→ Business Model			0.463(6.41**)
Implicit Knowledge Sharing Innovation	→ Business Model			0.687(5.61*)
Implicit Knowledge Sharing Innovation	→ Business Model			0.432(6.38*)

* p - value < 0.05

** p - value < 0.01

6 Conclusion

This research highlights and puts emphasis on one of the concerning issues being faced by the IT companies today. Current research study is significantly important IT based firms in recognizing the criticality and implications of knowledge sharing practices in boosting their business model innovation. Both explicit and implicit knowledge sharing activities are instrumental to refurbish the innovation capabilities of business models of info-tech companies. Although both explicit and implicit knowledge sharing functions alone do not have a significant impact on business model innovation. However, innovation quality and speed when intervene in between the relationship, implicit knowledge sharing practices are proven to be useful drivers and triggers of business model innovation. Whereas, explicit knowledge sharing plays a key role in assisting IT based firms maximize their speed of innovation in process and hence, lead to have a positive influence on business mode innovation. Implicit knowledge sharing practices are extremely appreciated for technology enabled organizations due to the fact that they provide assistance in maintaining the superior quality of innovation as well as keep it with fast face and up-to-date, thus enhancing the capability of their business models to innovate in highly competitive business market. Business model innovation information technology companies can be assured by using explicit and implicit knowledge sharing in order to capitalize upon the speedy, timely, and competitive and value driven innovation that ultimately drives superb BMI. This research study is in certain an enlightenment for

growing firms in the field of providing technology driven solutions and services to the end users with main focus on business model intensely focused at ensuring quality and timeliness of their innovation through exercising rigorous implicit and explicit knowledge sharing performs.

Model of Knowledge Management for Public Organizations of Science Technology and Innovation in Health

Elaine Lucia da Silva

Department of Human Resources
University of Escola Nacional de Saúde Pública
Av. Brasil 4365, Rio de Janeiro - Brasil

Abstract

The present research aims to propose a Knowledge Management Model for the Oswaldo Cruz Foundation, seeking, from its structure, to characterize its importance to support the innovation process both in the Institution and in Organizations of Science, Technology and Innovation in Health, due to its similar characteristics. In the development of the work, it is sought to understand if there is a relationship between knowledge management (KM) and innovation management (IM), what the difference is among data, information, knowledge and intelligence, if the implementation of a knowledge management model can help achieving the organizational innovation objectives and some existing KM models. At the end, it is proposed to identify the main critical success factors, benefits and challenges for a KM implementation in public institutions of Science, Technology and Innovation and the main steps of a model that meets the requirements of the ISO Norm 30401: 2018 that supports an Innovation Policy.

Keywords – knowledge management. Management. Models of the management. organizational innovation. ISO Norm 30401:2018

Paper type – Academic Research Paper

1 Introduction

The article has the objective to propose guidelines for Knowledge Management Model in Health – considering the context of Oswaldo Cruz Foundation, but characterizing the importance to support the innovation process. In addition, it is intended that the Knowledge Management (KM) is understood as a function even more common and as a mean to help the governmental organization to have a vision on how to incorporate it and transform it in a competitive advantage.

During the 18th century until middle of the 19th century, the society went through evolutionary economic cycles and after the agricultural and industrial eras, we are currently at the Information and Knowledge era. According to CASTELLS (1999), the information and knowledge are the source of productivity and generated product, and in

which the development, the technology innovation incorporation and knowledge will continue changing the world, interfering in the economy and industry in the next years.

Based on this context, the source data, the information and the knowledge have a crucial role in organizational environments because all implemented activities from the planning to the execution of the stages are based on these elements. As knowledge is formed by a constant mixture of contextualized experiences incorporating the elements above mentioned that when gathered with the professional interpretation and creativity it will provide transformations and innovations.

In Brazil, the government has sought to verify with a major focus of expanding the potential of some organizations that operates in the processes of generation, acquisition and sharing developed knowledge. Among them, we can list (I) o Governo Aberto¹, which is an international initiative that intends to spread and motivate globally governmental practices related to the transparency of the government, to the access of governmental information and to the social participation; (II) Law no. 12.527/2011² that regulates the right of accessing governmental information that is active since 2012, and (III) Open Science that has an objective of motivating the promotion of open research data.

Among this context, there are Science, Technology, and Innovation Institutions in Health (S, T, & I), focusing on administrative principles of legality, impersonality, morality, publicity and efficiency as the maximums of public administration according to the (PNCTIS, 2005) and, this knowledge appropriation contributes to the reduction of social inequality in health, and for the development of science and innovation in the organizations.

Thus, an institution such as the Oswaldo Cruz Foundation, under the Ministry of Health, is one of the Institutions responsible for the driving forces of the National Policy on Science, Technology and Innovation in Health (PNCTIS). It encourages the fulfillment of its mission by sharing the knowledge generated in its various areas of activity with the society, in a systemic and organized way and that can produce new approaches and innovations that favor Brazilian science.

It is important to emphasize that the guidelines of the presented model are not limited, but point out dimensions that can be addressed by the Institution and in future research, such as Governance for the implementation of a model based on knowledge, the need for good data and information infrastructure, its own importance of Knowledge Management to support a Policy of Innovation and open science.

2 Methodology

The research method defined for this paper is the field research, under the qualitative approach, because it is concerned with the understanding of the organization studied, i.e., in aspects of reality that cannot always be quantified. Regarding its nature, the research is

¹ <http://governoaberto.cgu.gov.br/>

² http://www.planalto.gov.br/ccivil_03/_ato2011-2014/2011/lei/112527.htm

applied, since it aims to generate knowledge for practical implementation, directed to solving specific problems.

In order to conduct the research, the method of work followed the steps as below.

2.1 Problem Definition

The reason to continue the study done during the MBA on the Diagnosis Model of Knowledge Management in Public Administration implemented at Fiocruz has resulted in a problem definition because despite the fact the Institution had Knowledge and Information Management as fundamental resources for Innovation Management, the institution did not have an integrated model that could be considered as fundamental phases at the Institution.

2.2 Literature Revision

In order to start the research, it was made a literature revision based on Scopus data that is a multidisciplinary basis through kew words (*models of knowledge management*" OR *"models of knowledge management in the public sector"*) and (*model**) AND (*"knowledge management"*) AND (*"public health sector"* OR *"public health"* OR *organizations* OR *"focus on innovation"* OR *"Health Research"* OR *"Management Practice"*).

After, it was done a bibliography research of the main authors in Knowledge Management, the main models of Knowledge Management, Knowledge Management in public organization to fund the study preparation, and probably the application in organizations of S, T, & I in health with focus on innovation.

2.3 Definition of theoretical reference

The referential analysis related to the KM and IM and the relation of these both managements and the ISO Norm 30.401 was essential for the research. It was also important a documentary research of the institution that registered the development of KM at Fiocruz since 2012 as a strategic map of the Institution, the model of governance and the document elaborated by a formal strategic Committee.

2.4 Field Research Planning

During this stage, there was a selection of the analysis units with a view of the data collection in an institutional level.

2.5 Definition of Data Collection Tools

The data collection methods that were used to give basis to the research has included the following techniques: bibliography research, documentation, interviews and questionnaire.

2.6 Questionnaire Application

It was applied a qualitative questionnaire with 10 Managers in which the purpose was to understand the comprehension in relation to the relevance of KM practices for the development of the innovation capacities in the Units.

2.7 Interviews

The study was based on the content through the interviews with 15 managers who have strategic and tactical levels and who work in Innovation and Knowledge Management at Fiocruz.

The method of analysis of this research was based on the study of BARDIN (1997) and had the following steps for its conduction: a) organization of the analysis; b) categorization; c) Inference and interpretation of results. The methodology required a deepening of both the interviews and the theoretical reference, since it served as a basis for interpretations and inferences.

3 Theoretical Context

With the purpose of strengthening the perspective that the Knowledge Management can support the improvement of the efficiency and effectiveness in the public service and support the innovation management in these organizations in favor of the Brazilian society, it was researched in both international and national references that confirm a model of knowledge management in public organizations can interfere in the performance and in their results. (WIIG, 2002), (NONAKA, TAKEUCHI, 1997), (SVEIBY, 1998), (SSYED-IKHSAN, & ROWLAND, 2004), (DAVENPORT E PRUSAK (1998) (BATISTA, 2012).

Among other models, we can highlight the following ones: innovative organization (GALBRAITH, 1997); Organization (NONAKA e TAKEUCHI, 1997); Intellectual Capital (SVEIBY, 1998); Model of Knowledge Chain (HOLSAPPLE AND SINGH, 2002), American Productivity & Quality Center (APQC, 2007), (SOCIEDADE BRASILEIRA DE GESTÃO DO CONHECIMENTO, 2013), Ronald Young and Asia Organization for Productivity (APO, model of Knowledge Management for Brazilian Public Administration – MGCAPB (BATISTA, 2012).

4 Critical Elements for a model of Knowledge Management

Among the models we can highlight Frame Break (MITROFF et al, 1994); Innovative Organization (GALBRAITH, 1997); Organization in hypertext (NONAKA e TAKEUCHI, 1997); Intellectual Capital (SVEIBY, 1998); Individual organization (GOSHAL e BARTLETT, 2000) and Model of Knowledge Chain (HOLSAPPLE AND SINGH, 2001).

The model proposes to fulfill the requirements of ISO Norm 30.401 that was released recently and elaborated by specialists in the implementation of KM in Europe, in Asia and in the USA. The norm established a pattern in relation to the knowledge management.

In order to follow the changes, the knowledge should be treated as an intangible active that needs to be made as any other and consciously produced, used and reutilized for a better flexibility in the processes and speed of answers that are being required even more from the organizations.

The elements of the proposed models are results of the composed conceptual review, of the comparative analysis among existing models and of the thematic context at the institution, the interview analysis, the state of art of the current norm on Knowledge Management.

Composed by critical elements such as: (i) Governance, (ii) KM macroprocesses, (iii) conductors/enablers, (iv) the steps of KM implementation and (v) practices of KM related especially for a better innovation development at the institution.

4.1 Governance

Due the fact the proposed governance in the model is a transversal area, it should go through all managerial levels of the institution in a way that helps the institution to conduct the public institution, its processes, regulations and the relation among many of the players involved and the organizational sustainability development.

In case of Fiocruz, it should be a collaborative management that has the capacity to implement as KM policy in the organization, in the awareness of the topic for all the departments of the institution and in the executions of actions and practices of KM in a way that the institution implements it in a more effective and systemized way.

What is being proposed is a system of governance that brings together: (1) Strategic Level through existing instances in the institution's cronogram, by the deliberative Council of Fiocruz that according to BUSS e GADELHA (2002) has the objective of operationalize the macropolicies defined by the internal Congress that also discusses and approves programs and respective budgeting of the Institution; by the Presidency and by Fiocruz Communication and Information Technical Chamber, all instances already within the Institution; (2) Tactical Level formed by a strategic Committee; (3) Operational Level by the Executive Committee.

4.2 KM Macroprocesses

According to DE SÁ FREIRE et al. (2013), there is not a consense regarding the numbers of phases of KM macroprocesses. Some (MURRAY E MEYERS, 1997) cite three phases: creation, dissemination and use. Other authors (SALMAZO, 2004; SVEIBY, 1997) mention four phases such as creation, sharing and use, or development phases, preservation, use and knowledge sharing. The transfer of knowledge once generated is of paramount importance to organisational knowledge management (MONAVVARIAN & KASAEI, 2007).

This research uses Macroprocesses of KM established in the Knowledge Management Brazilian Society Model that are: (1) Create/Acquire/Develop; (2) Share/Disseminate/Organize; (3) Use/Access/Apply and (4) Retain/Preserve/Guarantee.

4.3 Conductors/Enablers

Usually, most common conductors¹³ in the Knowledge Management Models and also proposed by BATISTA (2012) in KM Model for Public Administration are: Technology, Personnel, Processes and Leadership.

But Public Institutions need to prioritize the data because according to GUANAES et al. (2018) in the near future the Data Opening Policy will be implemented in which the results and data obtained, especially the financed ones or the ones financed by public incentives, are seen as a common interest that should be returned to the society in a secure and organized way. In order to meet this demand, it is important that the proposed model makes a critical reflexion to fulfill the specific norms in an immediate future. It is in this sense the inclusion is better conducted, specific to meet the new demands of open science and the organizations that do not have structured data such as:

1- *Technology*: accelerates the KM processes through effective practices, helping the knowledge management through information systems.

2- *Leadership*: has a key role in the KM implementation, approving the governance structure, resources.

3- *Personnel*: develops a key role in the main KM processes including the tactic knowledge sharing. SVEIBY (1998) and DRUCKER (1993) agree with the need to assign emphasis to the human resources in the organizations and argue in the sense that the power of production in the organizations concentrates in its intellectual ability, i.e., the knowledge generated by the professionals.

4- *Processes*: modeled and sistematic processes in an effective way can contribute to increase efficiency, enhance the quality and social affectiveness in addition to the law, impersonality, publicity and morality in the public administration and for the national development.

According to studied specificities in the context of the Institution and and result of the interviews that were done, it is proposed a conductor as a guideline in this model to enhance the data and information systemization according to what is shown below.

5- *Informational infratructure of data and information*: it refers to all the information and data systematization that are valued by the organization and decisive that need to be administered as other important activities in the organization that allow to promote new research in which there is a possibility of reuse, sharing and, as a consequence, support better decision making.

³ The KM facilitators constitute the mechanisms by which the organization stimulates the creation, sharing and protection of their knowledge (YEH et al., 2006) and defines the necessary infrastructure to improve the efficiency of knowledge management (SARVARY, 1999).

4.4 Phases of the development and implementation

According to the ISO Norm 30.401:2018 there is the need of minimum solid requirements that guide the organization when value the organizational knowledge. So the research proposes the following phases that will be implemented in the operational level according to the orientation of strategic and tactic levels. To SILVA(2019) the first phase consists in identifying and analysing the critical knowledge and existing practices with the purpose of mapping out the most critical knowledge of the institution;

1. After it is necessary to identify whether the critical knowledge is available or not, and the best ways of transference and gaps of knowledge.
2. An this phase, the public organization makes a diagnosis on the practices of Knowledge Management.
3. Consequently, it is necessary to identify the supporting technologies to the management, define the strategy, identify the management system of the organization, in addition to the evaluation strategy.
4. Define the project in which the knowledge management of the institution will be implemented, considering the identification and prioritization of the areas and strategic alignment.
5. During this phase the purpose is to present the benefits of the Knowledge Management implementation and the topic awareness.
6. Plan the trajectory to implement the practices in the processes of the chosen escape, in other words, the project elaboration.
7. Implement the practices that will be aligned to the vision, the objectives and the strategies of the organization, bearing in mind the cost and impact.
8. Define the means to keep the results to be obtained with the KM implementation for enhancements and measurable results.
9. This is a phase in which the organization should create an environment of collaboration to facilitate the exchange and co-creation of knowledge among the involved parts.
10. Evaluate the results.

5 Conclusions

This research analysed the context of applying a management model directed to Knowledge with the purpose to systematize the knowledge that will be appropriate at the Institution and that can support the generation, creation and appropriation of new knowledges.

This way the investigation intends to have contributed with a new proposal of guidelines of a Knowledge Management model that supports the acquisition, creation, preservation and use of knowledge encouraging the Innovation.

Considering that both innovation and KM go through the organizations as a whole and that the public institutions should develop and strength practices that help these institutions with a new way of thinking, with new mindsets, with a management of changing that contributes with the modernization in the implementation of public

institutions business models and, consequently, for the public services enhancement.

Abstract

This study aims to explore the emergence of an innovation ecosystem as a complex network of entities involved in innovation. After reviewing three ecosystem-based perspectives in the literature, we conduct a participatory and longitudinal action research study based on the analysis of a High Technology District for Cultural Heritage. Our analysis reveals three milestones in the establishment of an innovation ecosystem, which we identify as setting the context, establishing interdependence, and giving continuity.

The study contributes to the scholarly debate in that we analyse the dynamics through which an innovation ecosystem emerges as a co-created and co-evolutionary context that shapes actions, interests and rules among a multiplicity of actors and collectively fosters innovation. We further identify different salient tensions between opposing forces that characterize the relationships and interdependencies among actors. The appropriate structures, flexible institutions and negotiation opportunities are necessary for the design and development of the workability and viability of an innovation ecosystem.

Keywords – interactions, innovation ecosystem, ecosystem emergence.

Paper type – Academic Research Paper

1 Introduction

Scholars from different fields of science have dealt with investigations on the intrinsically complex and systemic nature of innovation (Ritter *et al.*, 2004; Chesbrough, 2006). Innovation is seen as a cumulative and broad collaborative activity in which ideas and knowledge are generated, integrated, developed, and applied through continuous interactions emerging at the boundaries of different firms and contexts (Carayannis, and Campbell, 2014; Carvalho and Gomes, 2017); this expanded the previous conceptualizations of inter-organizational or collaborative innovation (Möller and Rajala, 2007).

The complex nature of innovation has been recognised also by European Union in its programmes on innovation and by research companies in studies on the impossibility to understand where a valuable innovation can emerge (e.g., McKinsey, 2015). The focus of EU was addressed towards the R&D efforts, the role of technology, and the advantages in combining multiple actors in setting a suitable context to drive innovation (EU Science Hub, 2017).

Scholars are aligned to this idea as in the concept of innovation ecosystem (Ferretti and Parmentola, 2015; Adner and Kapoor, 2016) to provide much evidence of the importance of the mix of diversity and variety generated by a context of interconnected and wider set of relationships.

Innovation is caught up in a whole network of interdependencies, whereby changes in one part of the network can have far-reaching, and often unexpected, effects in other parts (Adner, 2006; Reynolds and Uygun, 2017). These effects have been demonstrated as mainly depending on the interdependencies among actors based on resource sharing, combination of capabilities and planned goals (Walrave *et al.*, 2018)

However, while the literature broadly discusses the role of multiple actors' interactions and their effects on innovation, less is still known about how an innovation ecosystem emerges and how actions and goals promoted by multiple actors are combined; a recent paper dealt with a literature review on the genesis of an innovation ecosystem (Dedehayir *et al.*, 2018), but the authors called for further empirical investigation on this topic.

The concept of the ecosystem carries many other aspects, like problems in balancing the tensions emerging in organizing interactions, when common actions have to be set to coalesce around unified aims the different interests and perspectives of multiple actors.

A study concentrating on the emergence of an ecosystem has been noted as still a relatively uncommon perspective (Heikkilä and Kuivanuemi, 2012; Russo Spina *et al.*, 2016), so this research deals with the issues of how innovation ecosystems concretely emerge, in particular on how diverse actors relate each other favouring participation in innovation, and how they engage to enable the workability of an ecosystem in a long range perspective.

In order to reach this aim, we firstly address the ecosystem perspective in innovation by discussing three different approaches, namely business, entrepreneurship, and the more recent service and social science literatures, then we adopt an action research approach within an emergent innovation district, namely DATABENC (High Technology District for Cultural Heritage).

2 Perspectives on innovation ecosystem

The literature analysis has showed how the metaphor of ecosystem was first of all used in the business literature (Moore, 1993; Iansiti & Levien, 2004) to better explain how actors interact in a business ecosystem, with a focus on strategy and resources. Within this perspective, an ecosystem has been viewed as having an internal and hierarchical organization orchestrated by a main actor that operates as a platform-sharing

resource (Gawer & Cusumano, 2002), with interacting parts depending on each other for access to resources on which all community members depend (Autio & Thomas, 2013). This business perspective emphasizes market-driven initiatives (Ritala & Almpantopoulou, 2017) where resource provision and adaptation are the fundamental driving forces of the ecosystem and the dynamic evolutionary processes sustain diversity through variation, selection, and retention processes (Iansiti & Levien, 2004).

Other scholars from entrepreneurship and economic thinking address their efforts to the understanding of the complex interplay of business and economic perspectives influencing innovation processes (Basole *et al.*, 2011; Carayannis & Campbell, 2012). In particular, Carayannis and Campbell (2012) debated the competitiveness of an innovation ecosystem determined by its creativity to combine and integrate different knowledge and innovation modes via co-evolution, co-specialization and collaboration and competition. The engine role of ecosystems is the main point of the entrepreneurship ecosystem concept (Isenberg, 2010), defined as environments that nurture and sustain entrepreneurship and innovation (Zahra & Nambisan, 2012); some of these scholars also put forward to entrepreneurs the role of peripheral actors and of high-tech SMEs (Mezzourh & Nakara, 2012) connecting the local and global levels as amplified factors of ecosystem and innovation growth.

The most recent perspective is a community view of the ecosystem with the focus of the service ecosystem conceptualization, as defined by Chandler and Vargo (2011) where the actors are held together by competences, relationships and information, and the actions and interactions sustain and reproduce the system continuously by socially constructing institutional logics or mental models that, in turn, influence activities and goals (Vargo & Lusch, 2011). In this sense innovation concerns how to find a better way to “serve”; that is, to better integrate resources and design systems for value co-creation involving all partners (Lusch *et al.*, 2010). The enduring rules, norms, values and beliefs – and institutional arrangements (Vargo *et al.*, 2015) – of sets of interrelated institutions contribute to the creation and evaluation of value among multiple actors. Thus, institutions become central to innovation, broadly conceptualized as the co-creation or collaborative recombination of practices that provide novel solutions (Vargo & Lusch, 2016; Koskela-Huotari *et al.*, 2016).

3 Methodology

Underpinning the findings presented in this paper is a qualitative and longitudinal action research study (Ramos, 2002) of an emerging innovation ecosystem. The case involves actors setting up a new technological district for cultural heritage named DATABENC (High Technology District for Cultural Heritage), a project launched at the end of 2011 to provide strategic support to the cultural heritage of Campania – a region in southern Italy – through innovation.

The research approach we chose in an action research, namely a process aimed at favouring knowing by bringing together theory and practice (Reason & Bradbury, 2001) through the support of actors involved in specific contexts. Due to interactions researchers

have and the multiple perspectives combined in combining theory and practice, action research is thought as a participatory method.

The research process consists of three phases in a sequence between theory and practice, with an increasing relevance of practical aspects as time goes by.

4 Findings

Findings show three main actions in the emerging of an innovation ecosystem, namely setting the context and connecting actors, establishing of interdependence, and giving continuity to interactions. Actors represent contrasting forces in running these actions and achieving ecosystem viability, thus actors' roles, their interactions, and their perception of a sense of relatedness are key in favouring the evolution of an innovation ecosystem and its viability.

We identified the focus on emergent ecosystems as essential for understanding the process by which a multiplicity of actors establish and enact relationships, and how they perceive each other and act collectively as members of an ecosystem. Negotiating roles and tasks, managing complex interactions, strategizing collaborations in a flexible way, and dealing with continuous tensions due to both internal and external changes are the key elements affecting the emergence and establishment of innovation ecosystems.

5 Discussion

The research opens up the underexplored concept of how an innovation ecosystem emerges; specifically, the existence of relations between actors' relationships and the emergence of an innovation ecosystem has been investigated.

The central contribution is grounded on 1) comparing perspectives on innovation ecosystem and how they address the emergence mechanisms, and 2) the development of an analytical framework to shed light on the processes and practices that are foundational to the formation and viability of ecosystem.

Through an extensive and longitudinal case study of a technology district project, the research links the dynamics of purposeful and emerging relationships and their implications for structuring and developing interdependencies in an innovation ecosystem (Vargo *et al.*, 2015). We identified three milestones in the establishment of an innovation ecosystem: 1) setting the context; 2) establishing interdependence; and 3) giving continuity. In each action, our research identified the different salient tensions between opposing forces that characterize the emergence of actors' relationships and interdependencies. The search for the composition of these differences allows ecosystems to emerge and become established.

6 Implications and Conclusion

This paper extends the discourse on interconnected relationship perspectives on innovation (Adner, 2006) and explicitly links the dynamics of purposeful and strategic

networks and their implications to structuring and developing the interdependencies that allow an innovation ecosystem to emerge.

Instead of assuming that an ecosystem already exists, as a large part of the literature does, the paper analyses the ongoing dynamics tied to innovation ecosystem emergence. Given that this is a substantially unexplored issue, this study offers a complementary framework for a better understanding of how innovation is generated and sustained in a networking context and how it generates incentives for actors to join and align their interests and aims and provides means of working towards shared goals. Explaining how mutual dependence among actors evolves and shapes an effective ecosystem for innovation is one of the hot topics to be addressed on researchers' agendas (Vargo *et al.*, 2015).

Abstract

Although the innovation phenomenon has been receiving increasing attention in the tourism and hospitality domain, it remains a buzzword extremely fragmented and ignored. Tourism research built on traditional forms of innovation emphasizes the key role of information and communication technologies (ICTs) in innovative processes. However, the technology-driven approach in innovation remains limited, neglecting the nature of destination, as a complex system of relationships between diverse public and private actors generating knowledge and innovation. The interpretation of the destination as a continuous process of innovation-based knowledge considers the innovation as a pervasive and holistic result of the interaction between destination public and private actors facilitated by the complementary role of ICT infrastructures and social capital. This paper aims to contribute to the debate on innovation in destination, overcoming the isolated technology-driven innovation and introducing the role of social capital and ICT infrastructures in nurturing diverse pervasive and holistic forms of innovations in destination. An initially exploratory multiple-case study was used to investigate six drivers and two forms of innovations, selecting Italian and international destinations. The discussion and conclusion design some preliminary theoretical implications and outline some managerial recommendations.

Keywords – Knowledge-based destination, pervasive innovations, ICTs tools, social capital, destination actors.

Paper type – Academic Research Paper

1 Introduction

Innovation as a key factor of destination competitiveness and sustainability (Gomezelj, 2016; Hjalager, 2010, 2015; Ozseker, 2018; Pikkemaat, Peters and Chan, 2018; Zach and Hill, 2017).

Although the innovation phenomenon has been receiving increasing attention in the tourism domain, the existing studies are fragmented (Gomezelj, 2016; Hjalager, 2010; Rodriguez, Williams and Hall, 2014) and tourism researches build upon the traditional forms of innovation, mainly based on the manufacturing paradigm and technology-driven innovation. Several papers emphasize on the critical role of information and communication technologies (ICTs) in innovative processes (Ali and Frew, 2014; Buhalis, 1998; Buhalis and Law, 2008; Sigala, 2018). Indeed, destination is a complex system of relationships among diverse actors, public and private, activating the process of knowledge sharing and conversion to nurture innovation in knowledge-based destination (Ozseker, 2018; Racherla, Hu and Hyun, 2008).

Thus, understanding the innovation phenomenon in knowledge-based destination requires a new paradigm including the social connections among the actors, based on the social capital concept. It capitalises as connections producing actors' participation and adoption of the ICT infrastructures, reinforcing the innovation process in destination.

This paper aims to contribute to the debate on innovation in knowledge-based destination. The theoretical framework proposes a new destination interpretation as the result of knowledge-driven innovations, assuming pervasive character, being the result of actors' interaction at multiple levels (DMO, institutions and political actors, local firms and local community).

It interprets ICTs as tools of enhancing innovativeness in conditions in which social capital facilitates technology acceptance, entrepreneurship, networking and co-creation between diverse destination actors.

Building upon the multidisciplinary literature on knowledge-destination, tourism innovation, ICTs and social capital, the paper investigates drivers and pervasive innovations in destination.

An exploratory multiple-case study (Yin, 2014) was used to investigate technology-driven and social-driven innovations, an unexplored phenomenon and thus it provides preliminary insights (Creswell, 2007) for future research. The discussion and the conclusion propose theoretical advances to explore the innovation forms in destination, suggesting future research and challenges for academics, policy makers and destination managers.

2 Theoretical background

2.1 Innovation in knowledge-based destination

The destination is a complex social system of actors, creating and transforming knowledge into rewarding products and forms of innovation (Racherla et al., 2008;

Sheehan, Vargas-Sánchez, Presenza and Abbate, 2016). It can be interpreted as an innovation ecosystem (Carayannis and Campbell, 2014; Ferretti and Parmentola, 2015) in which spatial dimension, tourism industry patterns, and public and private actors (including community and tourists) generate a co-evolutionary process of innovation. Specific local contexts matter in destination innovation assuming a repository role of spatial and cross-sectorial knowledge generation and dissemination (Roper and Love, 2018) and nurturing collective innovativeness and pervasive innovation (Boekema, Morgan, Bakkers and Rutten, 2000).

In knowledge-based destination, the shared and disseminated knowledge plays a critical role in generating continuous innovations and driving process of co-evolution in local context. Although the knowledge in destination – disseminated at spatial, sectorial and network level – is considered as public, many actors cannot access to it easily. Often this implication is relative to the limited capacity of knowledge access and management, but it can be resolved through the positive effects of spatial specificity, concentration, and geographical proximity. These effects encourage the incorporation of single actors into network structure, researching and activating social connections among diverse actors (Baggio and Cooper, 2010; Buffa, Beritelli and Martini, 2019; Roper and Love, 2018).

Networks improve actors' capacity to acquire knowledge, resources or technologies to open new opportunities of cooperation, and to attribute legitimation and power in the innovation management practices (Baggio and Cooper, 2010; Buffa et al., 2019; Roper and Love, 2018). They contribute to consolidate the social connections among actors through the homogenisation of common interests and goals alignment, encouraging new practice of knowledge sharing and dissemination based on personal and trusted relationships (Martínez-Pérez, Elche and García-Villaverde, 2019). Social connections facilitate and integrate the knowledge flows of different actors, transforming the destination in a dynamic system of learning, in which the innovation is the result of the dissemination of incubator and spill-over experiences (Asheim, Coenen and Vang, 2007).

In this perspective, the proposed framework interprets the destination as the result of knowledge-driven innovations, attributing pervasive and holistic character (Fig. 1). Destination drivers are the stakeholders engagement at multiple levels (DMO, institutions and political actors, local firms and local community), social capital, and ICT infrastructures to reinforce the strategies implementation. The two structures facilitate hard and soft connections at inter- and intra-actors' connections level, converting knowledge toward emerging forms of innovation. Finally, structures reinforce the destination vision to be an incubator and spill-over of collective innovations.

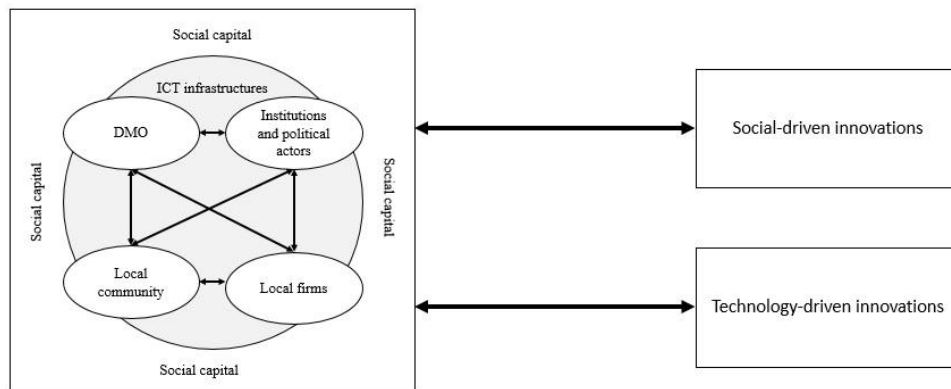

Fig. 1. Technology-driven and social-driven innovations in destination.

2.2 Social capital and innovation

Social capital is considered as a social structure function of different entities such as norms, values, beliefs, trust and alternative forms of interaction (Coleman, 1988; Nahapiet and Ghoshal, 1998; Putnam, 1993). It has received incremental attention, encouraging to analyse a wide range of research at various levels of analysis resulting in an interdisciplinary topic (Adler and Kwon, 2002), though it has not gained much attention in tourism context (Lee, 2015).

Social capital analysis in tourism, including tourism destination, requires application of alternative perspectives that identify actors in social structure – societies, organisations, networks and local contexts (Inkpen and Tsang, 2005; Macbeth, Carson and Northcote, 2018) – in which the resources are embedded in the relations based on the cooperation. It is a driver of the innovation capacity of local context, especially for destinations. It reinforces the traditional assumption of networks role (Macbeth et al., 2018) – based on the effects of geographical proximity, concentration and spatial specificity – to provide actors with access to the processes of sharing, transformation or integration of tacit and codified knowledge to generate new knowledge, implementing collective innovations (Inkpen and Tsang, 2005; Martínez-Pérez et al., 2019).

Encouraging the tie between social capital and innovation, it is possible to readapt the traditional social capital structure – structural, cognitive and relational (Nahapiet and Ghoshal, 1998) – as an analysis tool to define the participation level of destination actors (Go, Trunfio and Della Lucia, 2013; Liu et al., 2014) toward innovation, activating specific knowledge transfer processes.

The structural dimension analyses the network access as a source of knowledge flows and identifies the network role, configuration, and types of ties. The network configuration describes the innovation as the result of social actions subordinated and hierarchical or non-hierarchical. Furthermore, network ties express variety, quantity and nature of connections activated to knowledge sharing to nurture innovation.

The cognitive dimension identifies the elements to stimulate the process of knowledge sharing among the networks. The relational dimension describes the elements impact on

relational behaviour developed by network during connections with other actors. They are expressed in terms of identification, trust, norms and obligations.

2.3 ICTs infrastructure and innovation

ICTs have produced a disruptive change in the traditional paradigm of industry based on the intensive use of knowledge and removing traditional barriers of communication (Buhalis, 1998). The phenomenon includes different sectors, especially in tourism and destination (Buhalis, 1998; Buhalis and Law, 2008). Their continuous application have increased re-engineering process of knowledge-driven innovations in destination, reducing the environmental and market complexity through integration of traditional technologies with new ICTs-based infrastructure. They have opened new opportunities and challenges especially in information management (Sigala, 2018), including: strategic decision support, e-learning tool, alternative access to big data sources, co-gamification or co-creation in experiential platforms and the use of artificial intelligence tools. The main goal will be to transform the traditional destination to a digital and smart innovation ecosystem (Boes, Buhalis and Inversini, 2015; Buhalis and Amaranggana, 2015; Del Chiappa and Baggio, 2015).

The constant growth of ICT infrastructures demand, followed by the need of usability development have contributed to creation of specific ICTs-based tools to satisfy various actors' needs (Ali and Frew, 2014; Holden and Rada, 2011). Thus, ICT infrastructure can be considered as an umbrella, grouping tools with specific missions, such as sustainable tourism management, alternative marketing for destination development or informative systems of big data management (Ali and Frew, 2014).

Although ICTs promote numerous opportunities, they require significant considerations (Lee, 2015) in order to overcome the geographical borders. First, ICTs remove limits of networking derived by the effects of spatial specificity, concentration and geographical proximity. Second, they promote changes in the traditional structures of network in virtual community, amplifying interactions and exchanges of knowledge through the activation of new actors interdependences. Third, social capital plays an important role directing actors towards ICTs-based association forms. Fourth, transition processes often require attitude in the technology adoption, but it is underestimated by many actors, compromising their future possibility to participate to knowledge co-creation for innovation in destination.

3 Forms of pervasive innovations in destination

Our research framework proposes two forms of innovation, social-driven and technology-driven innovations. They are the results of the actors' participation and the use of two platforms (social capital and ICT infrastructures). The framework identifies social-driven innovation based on the social capital dimensions and technology-driven innovation based on the ICT infrastructures – in which social capital influences the technology acceptance and adoption – in the process of knowledge sharing and conversion to nurture innovation in destination.

3.1 Technology-driven innovation in destination

The technology-driven innovation in destination considers the ICTs as fundamental infrastructures to reinforce coordination and integration among diverse actors to innovate (Racherla et al., 2008). Although the research in tourism innovation is limited and fragmented, the concepts of technology and innovation have received increasing attention, emphasising the tourism a perfect place of ICTs application to drive the innovation (Buhalis, 1998; Buhalis and O'Connor, 2005).

The interconnection use of the ICT infrastructures in different processes of destination management opens new opportunities of intelligent knowledge sharing and conversion (Racherla et al., 2008; Sheehan et al., 2016), transforming the traditional social connections in a dynamic and technological system. Various destinations have embraced the power of ICT infrastructures, combining human capital, social capital, technology and innovation. In this perspective, they identify new forms of innovations to resolve and anticipate emerging urban and social problems: introducing new business models through the application of smartness concept (Buhalis and Amaranggana, 2015; Del Chiappa and Baggio, 2015; Gretzel et al., 2015); re-inventing the personalisation processes with forms of experience co-creation driven (Neuhofer, Buhalis and Ladkin, 2012; Stamboulis and Skayannis, 2003); engaging stakeholders in digital model of destination management (Cabiddu, Lui and Piccoli, 2013; Sigala and Marinidis, 2012; Trunfio and Della Lucia, 2019).

3.2 Social-driven innovation in destination

The phenomenon of social-driven innovation considers the social capital as a critical element to nurture innovation. It analyses the social structure of local context which are the local actors' motivations to create opportunity of social change.

In innovation literature, it has been often overlooked, presenting a strong focus at the innovation based on the technological approaches (van der Have and Rubalcaba, 2016). Some studies have attempted to provide explanations of the phenomenon analysing its effects with multi-disciplinary perspectives. Although they have identified its effects with the social innovation concept, they do not know exactly its causes and consequences, remaining an ambiguous concept.

Social innovation effects can be summarised as new social practices to revitalise the social structure of a local context, generating multi-level social changes (Swedberg, 2009), activating stakeholders engagement of unusual actors (Neumeier, 2017) and exploring new creative solutions (Caulier-Grice et al., 2012).

The effects are the result of a co-evolutionary process, in which the local actors externalise their social problems, expressing new interests, defining actions delineation and co-ordination. These moments are the expressions of the social capital dimensions. First, the problematisation reveals the structural dimension identifying the actors' integration capacity into a network or other forms of collaboration to represent their interests. Second, the shared of common interests concerns the cognitive dimension, networks define common interests to orient its vision, codes and languages. Third, the co-

ordination reflects the relational dimension, in which the elements of trust, identification, norms and obligations amplify the possibility of success or failure of social change. Indeed, the effects of social innovation do not always turn into co-created social value – expressed in terms of new product, service, process or business model, including also forms of social technology – but they can generate positive spill-over or incubator actions within the local context.

The analysis of social innovation effects identifies forms of bottom-up actors' participation, reshaping the social structure of the destination, and promoting new business models, typically of the destinations of community type or cities with a strong creative identity (Go and Trunfio, 2011).

4 Case study

4.1 Dolomiti Paganella in Trentino: a top-down approach in social-driven innovation

Dolomiti Paganella is a small Italian destination, situated in the province of Trento (TN) in Trentino. It includes the Paganella highland with its five locations – Andalo, Molveno, Fai della Paganella, Cavedago and Spormaggiore – the Pradel highland, the Alpine area of the Brenta Dolomites (UNESCO site), the Molveno lake and the Andamello-Brenta park. In 2015, Dolomiti Paganella was chosen as the first Italian destination for the application of St. Gallen Destination Management Model (Beritelli et al., 2015). In critical terms, it reshaped the architectural destination toward a management structure based on the experience co-creation between the system heads (offer) and market mavens (demand), attributing new indirect role of intermediation to the DMO with the use of ICTs-based tools. The new governance model revitalised the social structure of the destination including local firms and local community in projects co-creation, removing its maturity state (Reinhold, Laesser and Beritelli, 2018).

The co-evolution process was composed of different phases including diverse actors' roles and functions in different steps (institutions and political actors, DMO, local firms and local community).

Diverse social problems were: internal competition among local actors; absence of a common vision and strategy of destination development; fragmentation of the tourist supply; and finally, the requires of redefinition of the destination leadership.

Successively, the emergence and consolidation of social problems have encouraged the DMO to activate a coordination action on the interests of the local community and local firms. Local actors have participated tracing their personal strategic business area about the tourists movements in destination. In this mode, the DMO stimulated high levels of co-participation by the local community and local entrepreneurship, following management perspective of top-down approach (Go and Trunfio, 2011).

The process finished with the validation of common strategic business areas, defining new roles and responsibilities for divers actors, and re-organising the financial resources in three experiential projects of biking, family and trekking (Buffa et al., 2019). In particular, the DMO role was changed in an intermediation position in destination

management between local, institutional and political actors. It assumed the tasks of data collection and knowledge creation and sharing through the use of ICTs-tool (Ali and Frew, 2014; Sheehan et al., 2016). Its new intelligent role in knowledge management in destination helped to enrich the experiential products promoted by the local actors (Buffa et al., 2019).

4.2 Helsinki European Capital of Smart Tourism in 2019: a convergent approach in technology-driven innovation

Helsinki is the Finland capital (pop. c. 620.982), including over 300 beautiful green islands – in particular the fortress of Suomenlinna is a UNESCO World Heritage Site – bathed by a sea. The capital presents diversity of design, architectures and cultures, with a laid back city's rhythm. Its vivacity and creativity reflects more the entrepreneurial activity, in terms of both number and quality of restaurants and nightclubs. In general, it is a compact city easily explored on foot through all its angles and large park areas, forests, lakes, and the blue coastline. Originally it was an area occupied by Tavastian population during the Iron Age in the 14th century. Successively, the Swedes colonized the Helsinki region in the late 13th century with the defeat of the Tavastians.

In recent years, the institutional and political actors drove Helsinki toward an important tourism development with a smarter perspective. They were the key actors in this process contributing to the implementation of continuous investments in ICT infrastructures, creating digital services, opening big sets and building accessible experiences. This development action considered a new destination management model based on the accessibility approach. The success of the model is certified with the achievement of the leader position of European Capital of Smart Tourism in 2019. The title is an important opportunity for the future of the city, especially in term of reputation as an accessible city.

The DMO consolidated the smart integration process with MyHelsinki project. It is based on the use of ICTs to improve the functionalities and fruition of the city – in term of accessibility – for the local community and visitors. It is a digital and intelligent personal guide of the city, constituted by an APP-mobile. The ICTs recourse is the function of the capacity to satisfy the diverse actors' needs (local community, local firms and tourists).

Through the APP, the local firms could insert and integrate their information in three principal databases, about the activities, locations and events present in the city. The information were managed with systems of data integration (Ali and Frew, 2014).

Finally, local community and tourists could enjoy the APP through a structure with re-creative style and each resident could share and collect the tourism information, customizing and saving the contents and services, developing mini-programs to provide recommendation, mobility planning and purchase options for other actors.

In this mode, the continuous investments of institutional and political actors in the social and technological capital, co-ordinated with the help of DMO, have contributed to involve local community and local firms toward strategy forms of active co-participation of the city – following a convergent approach (Go and Trunfio, 2011) – and promoting a

continuous process of technology acceptance and adoption with processes of social re-organisation.

5 Discussion and conclusion

The paper attempts to explain the complexity of interpreting destination innovation phenomenon considering the continuous process of actors' connections among political and institutional actors, DMO, local community and local firms, to promote knowledge sharing and conversion. It presents some preliminary contributions to the theoretical debate of destination innovation.

First, the paper argues that the tourism destination is representative of specific innovation ecosystems, characterised by processes of knowledge sharing and conversion among diverse actors at multi-level (Ozseker, 2018; Racherla et al., 2008; Roper and Love, 2018). It proposes two perspectives, social-driven innovation and technology-driven innovation. Both innovation forms are the results of complex spiral of knowledge sharing and conversion activated by four actors and supported by two structures.

Local actors can promote networking, generating dynamical spiral of knowledge sharing and disseminating positive effects of spill-over experience in destination (Asheim et al., 2007; Baggio and Cooper, 2010; Roper and Love, 2018). Second, the framework reveals that diverse actors implement innovation in destination through continuous investments to re-shape and re-organise their two structures of support, social capital and ICT infrastructures. Both the structures reinforce the actors connections, in terms of knowledge sharing and conversion, contributing to innovate through forms of stakeholder engagement at multi-level, following a bottom-up or top-down approach (Go and Trunfio, 2011). They contribute to the destination innovation in different modes, e.g. stimulating goal alignment, common vision and strategies, relationships based on mutual elements, etc., contributing generally to the knowledge management.

Furthermore, the framework proposed represents an alternative model of thinking, identifying a different levels of support between social capital and ICT infrastructures (Lee, 2015). ICTs acceptance and adoption are the results of the process of knowledge sharing among actors involved, considering at the base of the interdependence relationships that shape the common social structure. In this perspective, ICTs infrastructures and social capital have both common actions of support but their role is not complementary.

Third, the ICT infrastructures offer new business models – in terms of accessibility, digitalisation, cultural heritage and creativity, and sustainability – of destination management. The ICTs application promotes high levels of stakeholder engagement, but it is required to prior widespread the feeling of technology acceptance and adoption driven by the social capital. Finally, it will be necessary to analyse the impact effects of the technology-driven innovations on the social capital, in terms of destruction or re-vitalise the culture, values and other elements of the destination identity.

The paper is not without limitations. First, the framework does not consider external pressure, especially that produced by tourists. Future research will include the tourists'

role in the destination innovation to provide a holistic framework. Second, the case studies are analysed with a desk analysis. Future research will consider more rigorous qualitative methods and tools to collect primary and secondary data from multiple sources of case evidence, collecting semi-structured interviews with destination managers.

Abstract

Recent advances in Information and Communication Technologies (ICT) have exploded the potential for value creation in a variety of innovation ecosystems (Vilhelmson, 2006). The vast increase in potential can be attributed to two distinct underlying factors. First, ICT has extended the reach of more possible actors to the point where nearly any actor can be connected to any other and, as a result, geographic proximity is becoming less and less relevant (Boschma, 2005). Second, the responsiveness of one party in a relationship (to the needs of existing parties or the opportunities from a nearly limitless number of other possible parties) has become almost instantaneous to the point where time has become compressed and essentially (a less differentiating factor (Nachira 2002, Boschma 2007). However, despite the vast size of the potential value that, ICT enables, we argue that it is likely that only a tiny fraction of this potential may be realized, unless and until relevant risks are anticipated and effectively managed (Fransman 2010).

In this paper, we consider risk at two levels of a prototypical digital ecosystem: First is the level of possible interacting actors. Second is the level of those actors who contribute to the design, organization and maintenance of the ecosystem (Doloreux 2002, Asheim 2002). In each case, extended reach and quicker responsiveness enhances opportunities for greater utilization and better experience of any asset among the parties it also exposes various parties to greater risk. (Adner 2006, Graca P. and Camarinha-Matos 2017).

Accordingly, we apply a value creation-appropriation theoretical framework to consider the managerial challenges that risks pose. We develop a number of scenarios to illustrate how various risk mitigation strategies can influence not only who wins and who loses but also the amount of value that is likely to be created by the digitalized ecosystem (Basole

2015). Some prominent features of the relative dynamics, that our theoretical framework highlights will be illustrated by an agent-based simulation model. This model will comprise multiple agents that can interact according to their level of reach and responsiveness (Leavy and Adner 2012). By manipulating the extent of reach and the degree of responsiveness afforded to agents (a proxy of the level of digitalization) The study seeks to contribute to innovation ecosystems by focusing on the risks that the digitalization of ecosystems (Baldassar 2016) gives rise to (as a direct result of the value potential that it enables) and the inherent managerial challenges that may require a rethinking of the role of eco-system actors and even of non-actors that could be positively or negatively impacted.

Keywords – Innovation ecosystem, reach, responsiveness, risk, digitalization

Paper type – Academic Research Paper

1 Introduction

Digitalization enables a vast increase in potential value (by dramatically enhancing reach and responsiveness) but also gives rise to significantly greater risk. ICT has extended the reach of more possible actors to the point where nearly any actor can be connected to any other and, as a result, distances are essentially shrinking and geographic proximity has become less and less relevant. The responsiveness of one party in a relationship (to the needs of existing parties or the opportunities from a nearly limitless number of other possible parties) has become almost instantaneous to the point where time has essentially become compressed and is a less differentiating factor.

The consequence of greater reach and responsiveness is an expansion of the value creating potential of the resource. When advances in technology have extended reach or enhanced responsiveness, they have greatly expanded the potential for value creation. Reach has been extended dramatically many times throughout history, to clarify the phenomenon we can compare the advent of IT tools to the development of technologies in the transport industry, for example, transcontinental shipping that allowed far greater distances to be spanned; canals, railways, highways and airplanes that have shortened travel times and/or lowered its cost; and refrigerated trailers that expanded the types and volumes of goods that can be transported. Greater reach brings more and different buyers and suppliers together. It has the effect of reducing the distance between service provider and user, thereby providing greater access to more potential users of a given service, from any resource, and of particular resources to more users. More recently, advances in information technology have contributed to extended reach. Specifically, digitalization has enabled and extended reach through the internet and virtual networks (like social media), which make it easier for more actors to connect.

While reach indicates the numbers and variety of potential exchange partners, responsiveness reflects how quickly, richly and efficiently they can understand each other and react/respond to changes in the situations of either (for example changes in supply,

demand, quality, quantity, timing of production/delivery, etc.). Such changes may present several opportunities. Quicker responsiveness has the effect of reducing the time required for the resource owner to interact with a user and communicate the value proposition or adapt it to the user's needs. Responsiveness increases with the speed, volume and immediateness of information transfer and with declining costs of data gathering, storing, access and transfer. In each case, extended reach and quicker responsiveness enhances opportunities for greater utilization and better experience of any asset among the parties it also exposes various parties to greater risk that other parties will appropriate value from them (a risk that may not even have existed for that party before) (Fransman 2010, Graca P. and Camarinha-Matos 2017). In this study we use a simulation model that allows us to create a predictive model, that analyzes the risk associated to reach and responsiveness increment within the ecosystem. The research question is: How does technology expose the actors of the innovation ecosystem to risks?

2 Theoretical background

2.1 The role of technology in innovation context: Digitalized Innovation Ecosystem

The process of creating value via leveraging the power of innovation ecosystems has become increasingly important in academic studies and in management practice. Recent advances in Information and Communication Technologies (ICT) have exploded the potential for value creation via a variety of innovation ecosystems. Technological advances have revolutionized the concept of the traditional value chain. Networked systems have replaced traditional linear production schemes. The concept of the digital innovation ecosystem, is an evolution of the typical business ecosystem. Nachira (2002) was among the first to introduce the idea of digital business ecosystems, focusing on the importance of technology and digital platforms as a tool for the exchange and aggregation of resources and information.

Digital technology has a crucial role on the relationships between actors within the network. A digital ecosystem is a network in which the evolution of relationships is moderate through the innovative development of software and hardware (Nachira et al. 2007). Digital technology endows the ecosystem with IT infrastructure, that dramatically expand the range of action of individual actors of a traditional network. The geographical ecosystem perimeter is radically re-conceptualized.

In our study, the Briscoe framework (2009; 2010) was used to further clarify the concept of the digital innovation ecosystem. The authors have identified eight key factors of a prototype ecosystem: multi-agent system, economy, business, ecology, population, community, innovation, technology. This framework is very clear and highlights the fundamental pillars of a digital innovation ecosystem. In our study we analyse how technology incrementation (in terms of "the multi-agent" feature) generates more risks with the other aspects of the framework (in terms of "innovation", "business" etc). According to Camarinha-Matos and Afsarmanesh, we can define a digitalized innovation ecosystem as "*a network consisting of a variety of entities (e. g. organizations and*

people) that are largely autonomous, geographically distributed, and heterogeneous in terms of their operating environment, culture, social capital and goals, but that collaborate to better achieve common or compatible goals, and whose interactions are supported by computer networks”(2008a).

2.2 Reach and responsiveness as a factor of interoperability within digitalized innovation ecosystem.

According to the Institute of Electrical and Electronics Engineers (1993), interoperability is defined as "*the ability of two or more systems or components to exchange information and to use the information exchanged*". Major definitions in the literature state that interoperability is the ability of a network to exchange information (Figay et al.2012) Previous studies have identified two main lines of research on interoperability: process interoperability, which concerns the technological study of interfaces and software (Jardim-Goncalves et al., 2006); and information/knowledge interoperability, which concerns the study of relationships between subjects within the ecosystem (Peltoniemi and Vuori, 2004). The knowledge interoperability strand analyses the processes of information exchange within systems, the absorption capacity of actors, the interconnection between developers and users of knowledge and the re-modulation of relationships throughout the life cycle of the system. The significant IT technology growth within ecosystems, has fostered the phenomenon of symbiosis. In agreement with Adner (2006) the use of digital technologies within ecosystems improves relations by raising the degree of interdependence, to the point where each individual entity cannot create higher value than the entire ecosystem outcome. Digital infrastructures impact on the degree of interoperability within ecosystems. The vast increase in connectivity can be attributed to two distinct underlying factors: reach and responsiveness. In our conceptual framework reach is measured by numbers and diversity of buyers and suppliers that have access to one another for exchange. Reach has been extended dramatically many times throughout history, largely by advances in transportation First, ICT has extended the reach of more possible actors to the point where nearly any actor can be connected to any other and, as a result, distances are essentially shrinking and geographic proximity has become less and less relevant.

The second factor is the responsiveness, that corresponds to the agility of one party in a relationship (to the needs of existing parties or the opportunities from a nearly limitless number of other possible parties) has become almost instantaneous to the point where time has essentially become compressed and is a less differentiating factor. IT technologies increase the degree of interoperability within the innovation ecosystem (Aulkemeier et al 2018). This happens thanks to the more agile relationships between the components of the network. The degree of agility is measured by the responsiveness of the actors. According to Koppius(2009), the speed of connection between the parties in a network reduces the costs of interacting inside and outside the network (van Hillegersberg et al. 2012)

2.3 The risk evaluation within digitalized innovation ecosystem

The risk management in a complex systems, is a heavy activity. Risk management traditionally focused on internal operational process, underestimates the importance of the risk related to the partners within the innovation ecosystem.(Calandro 2015). Possible threats to business profitability may come from the dynamics within the innovation ecosystems. In this study we operate a risk classification: by nature of the involved actor, and by risk typology. In terms of involved actor we consider risk at two levels of a digital prototypical ecosystem:

- First, is the level of possible interacting actors;
- Second, is the level of those actors who contribute to the design, organization and maintenance of the ecosystem.

In the first case, we analyse the risks faced by the actors present within the system, during the value creation process within the ecosystem. The major risk is that one of the component of the network could expose other parties to a greater risk that external entity will appropriate value from them (a risk, and level of exposure, that may not even have existed for that party before). The second level concerns an analysis of all those actors that contribute to structuring, organizing and reshaping the ecosystem(Letaifa,S. Rabeau, Y. 2013). At this level the risk could affect the relationship among actors.(Adner 2006) In fact, a problem that affects one of the components of the network could spread to other actors (Adner, 2006). In this study we analyze the types of risk from three different perspectives: performance risk coinnovation risk, relational risk. The performance risk in the innovation ecosystem is assessed in literature at individual and collective level. In the first case, the balanced scorecard(Kaplan and Norton 1996) method is widely used. This method uses four evaluation categories: financial, internal business processes, customer satisfaction, and learning and growth. In recent years, this method has been applied by some scholars to the analysis of digital innovation ecosystems. Welter et al.(2011) proposed an analysis tool called the IT Network Balanced Scorecard (ITNBSC), which changed the four perspectives of analysis by introducing four levels of investigation refocused on the network and the impact of technology: information technology financial, stakeholder orientation, future orientation, and network contribution (Graca P. and Camarinha-Matos 2017).According to Leavy and Adner (2012) innovation is the outcome of a process within an ecosystem. therefore the success of an actor depends not only on its management but on the success of the other components of the network. The most common risk is the snowball effect, typical of systems with a high degree of interdependence. Coinnovation risk and relational risk are linked to the possibility that part of the value created in the innovation ecosystem, is faded away along the process of interaction between the actors. Technology has a dramatic impact on the nature of relationships, so it is necessary to analyse the process of sharing information and knowledge between the digitised actors.

3 Methodology

We developed a number of scenarios to illustrate how various risks can influence not only who wins and who loses but also the amount of value that is likely to be created by a digitalized ecosystem. Some prominent features of the relative dynamics that our theoretical framework highlight will be illustrated by an agent-based simulation model. This model will comprise multiple agents that can interact according to their level of reach and responsiveness. By varying the extent of reach and the degree of responsiveness afforded to agents (a proxy of the level of digitalization) we expect the simulation to show the impact on the amount of value created and on the associated level of risk exposure.

The agent-based simulation model has been designed assuming that:

1. each interacting actor can control a fixed number of resources that can be modified in order to develop an innovation;
2. interactions are (for sake of simplicity) dyadic. This means that each actor can interact only with one other actor at a time;
3. each set of resources belonging to an actor creates a certain value. The combination of the resources of two actors creates an overall value that stems from the innovation that is realized through that specific combination;
4. a moderated complexity characterizes the interactions, in that the contribution of each set of resources to the overall value created by an interaction among two agents is not linear and additive. Through a Nkc model, the non-linear effect of the resource combinations on the total value has been simulated. Similarly, it has been simulated the effect of the changes in the resources under control of one agent on the value of that resources and on the value of those belonging to the other interacting agents.

In order to simulate different levels of reach, the number of agents reachable by the focal agent was increased from a minimum of 1 to the maximum of all existing agents. For each possible interaction, the total value created by the combination of the resources under the control of the interacting agents (without introducing any changes) was calculated, thereby estimating the value of the resulting innovation.

In this simulation setting, the total value created by each interaction was recorded. The risk was captured by the range from the maximum to the minimum value obtainable at different levels of reach and by the difference between the average value on an innovation and the minimum value. That is, the maximum loss to which an agent is exposed was calculated in order to have a proxy of the Value at Risk.

In order to simulate different level of responsiveness the focal agent was allowed to introduce a growing number of changes in the set of controlled resources in order to develop an innovation with increasing levels of value obtained by the interaction with another agent. The responsiveness was progressively increased from the minimum of 1 to the maximum of all possible changes available in the set of resources controlled by the focal agent. The risk here was evaluated measuring the total value and the value created by the two actors involved in an interaction at different level responsiveness. The balance

of the value between the actors was used as a proxy for the risk for the non-responsive actor to be expropriated of the value of an innovation.

Table 1 reports the key parameters of the simulation.

Variable	Parameter
<i>Number of resources available for all agents</i>	N=20
<i>Number of interdependencies among resources</i>	k=c=4
<i>Number of resources under the control of each agent</i>	Ncont=4
<i>Total number of agents</i>	Agents=1,820 one for each combination in groups of 4 of the 16 resources remaining by excluding the 4 under the control of the focal agent
<i>Number of runs</i>	Runs=100
<i>Rules for increasing reach</i>	Reach varying from 1 to 1,820 Value from each interaction is accepted by the focal actor (assuming that the focal actor cannot respond in any way) Minimum, Average and Maximum value obtained by the interactions available are recorded and then averaged over the 100 runs
<i>Rules for increasing responsiveness</i>	Responsiveness varying from 1 to 16 (assuming the possibilities to switch from 0 to 1 or vice versa for each resource under the control of the focal actor) Value from a change in one or more resources is accepted if the value created by the innovation through the interaction is higher than the value created before the change. Among the changes satisfying the previous condition the option creating the highest value for the focal agent is retained (assuming that responsiveness is employed to increase value creation and maximize value appropriation). Value from the interaction and for each actor is recorded and then averaged over 100 runs.

4 Results

The results of the simulation about the risks associated to increasing levels of reach, obtained by the digitalization of an innovation eco-system, are reported in Figure 1 and Figure 2.

Figure 1 highlights the minimum value created by an innovation through a dyadic relationship among the focal agent and the other agents reachable in the eco-system.

Figure 1: minimum value of innovation at different levels of reach

Figure 2 reports the maximum possible loss in terms of difference between the average value from an innovation and minimum value at different levels of reach.

Figure 2: maximum loss of an innovation at different levels of reach

As can be observed in the Figures, the minimum value obtainable by an innovation realized through a dyadic relationship decreases sharply with increasing levels of reach (Figure 1). This implies that the risk of encountering very negative but rare events (a so-called black swan), that can be interpreted as disastrous innovations, grows with larger possibilities of reaching a bigger number of agents via digitalization. Accordingly, the average maximum loss (i.e., the loss calculated as difference between an average value of innovation and the lowest) increases rapidly (Figure 2). This means that an actor of an ecosystem that expands reach through digitalization is exposed to losses that largely exceeds those that can be encountered at lower levels of reach.

The results of the simulation about the risks associated to increasing levels of responsiveness are reported in Figure 3 and Figure 4.

Figure 3 shows the value created by an innovation realized through a dyadic relationship, at different levels of responsiveness of one of the two actors involved.

Figure 3: value created by innovation at different levels of responsiveness

Figure 4 illustrates the divergent trend of value for the parties involved in the dyadic relationship at different levels of responsiveness.

As can be noted increasing levels of responsiveness, allowed by digitalization, produce higher value obtainable by innovations realized through dyadic relationships (Figure 3). This means that the ability to immediately respond to other parties and accordingly adapt most of the controlled resources improves the possibilities of combining resources of different parties in valuable ways.

However, when one party has higher possibilities to respond than the other, increasing levels of responsiveness can produce higher inequalities in the distribution of the created value (Figure 4). This implies that the innovation's value, although higher, is mostly appropriated by the more responsive agent at the expenses of the other. This value disequilibrium creates two different risks: (a) for the less responsive agent, the risk of not benefiting from the innovation created through the relationship; (b) for the more responsive agent, the risk of being abandoned by unsatisfied partners and thus of losing all the value created. This second risk is even higher when an expanded reach, obtained by digitalization, make it easier to find new partners.

5 Discussion

To illustrate how digitalization affects both reach and responsiveness, consider the emergence of the sharing economy – a phenomenon made possible largely by digitalization. Unused services, like spare bedrooms in a house or empty seats in a car, have existed ever since there have been homes and automobiles. However, most of these services had remained unused for decades or longer, until digitalization effectively collapsed the time and distance that separated resource owners from prospective users. Digitalization makes it possible for the owners of these resources (i.e., houses and cars) to reach many more potential users in near real time. Airbnb allows hosts with available accommodation to reach and subsequently transact with prospective guests who can be

coming from any part of the world. Similarly, Uber extends the reach of passengers in need of a ride to far more available drivers than are usually available via conventional taxi services. Even more dramatically, Uber and similar ride sharing services have vastly enhanced responsiveness so that both driver and passenger know far more about the other. This knowledge includes: precise location, estimated time of pick-up and even their reliability. Because of ride hailing apps like Uber, Lyft Didi, and Grab, safer and more reliable rides are more widely available and rarely more than minutes away (The promise of 5G technology (to provide reliable data exchange with zero latency and huge bandwidth), will further enable reach to extend to and among inanimate objects (e.g., the promise of the ‘internet of things’) and responsiveness to be so quick that little or no human intervention will be needed (e.g., autonomous vehicles promise the service of ubiquitous, safe navigation without drivers). This extended reach and quicker/richer responsiveness enabled by digitalization vastly increases the potential for value creation by greatly enhancing the availability of a service to nearly all potential users who might be interested in the service and enhancing the resource owners’ ability to tailor a service to a prospective user with no or very little time delay. However, despite the vast size of the potential value that a digitalized ecosystem makes possible, the extent to which any of this potential is likely to be realized and who will benefit hinges on the concomitant proliferation of risks that always accompany any change (both in potential value and in the number and composition of possible players) and how those risks are managed. We argue that, regardless of the enormous increase in potential value that ICT enables, it is likely that only a tiny fraction of this potential may be realized, unless and until relevant risks are anticipated and effectively managed. To illustrate the need to consider risk, recall the early days of AirBnb. When it was first launched, the lion’s share of properties offered for sharing were relatively meager and many were made available only for guests willing to stay while the host also used the facilities. There were significant risks to the guest – that the accommodation wasn’t the same as advertised – and to the host – that the property could be misused. Indeed, in a well-publicized case, a host returned to her home to find it had been trashed by the guest and those he invited to a party he had held there. Initially AirBnb argued that they were merely matchmakers and not responsible for the behavior or reliability of the parties who used their platform. Over time, Airbnb, saw that by mitigating the risk for both parties many more prospective property-owners would be willing to offer to list and share their accommodation. Today, AirBnb lists moored yachts, castles and whole islands on their platform. This is only possible because AirBnb has found ways to reduce the risks to hosts and to convince prospective hosts that their property would not be misused. AirBnb did the same for the concerns of guests.

6 Implications and limitation

We consider some implications of this study for theory, practice and policy. The study seeks to contribute to a greater understanding of innovation ecosystems by focusing on the risks that the digitalization of ecosystems gives rise to (as a direct result of the value

potential that it enables) and the inherent managerial challenges that may require a rethinking of the role of eco-system actors and even of non-actors that could be positively or negatively impacted.

This study aims to provide a tool for scenario analysis. The phenomenon of digital innovation ecosystem is characterized by a high degree of complexity, due to the multitude of actors and factors present. In this predictive model we have isolated the aspect of technology, and simulated how it can impact on two crucial aspects such as reach and responsiveness. It was already clear in the literature that digital technology is positively related to the number and responsiveness of actors, but this study provides a conceptual tool to analyze the degree of risk associated with the increase of these two factors. This study could be increased by analyzing the degree of risk associated with the entry into the ecosystem of non-existing actors. following this line of research we could develop a new tool to predict the risk connected with new possible competitors or cooperators.

Abstract

In the healthcare setting, real-world data (RWD) could be a useful support to measure the impact of disease-management interventions, in order to create a knowledge base, for the design of effective, efficient and satisfactory healthcare pathways.

The present paper aims at investigating the factors affecting patient rehabilitative pathway. Such factors make up the knowledge assets that might influence the design of a patient rehabilitative pathway (in terms of clinical outcomes, patients' satisfaction and economic resources' absorption), after the Anterior Cruciate Ligament (ACL) rupture, assuming the hospital wards perspective.

For the achievement of the above mentioned objective, a review on the topic is performed for revealing the principal rehabilitative pathway factors, impacting on clinical outcomes, patients' satisfaction and economic resources' absorption. An observational study was developed, in two private rehabilitative hospitals in Italy, in order to retrieve RWD with regard to the rehabilitative pathway, thus collecting information from 59 patients, on the factors determined by literature analysis.

Patients' data were analysed considering three methodological approaches. i) Relationships between variables, were investigated to test the existence of correlations among them. ii) A hierarchical sequential linear regression model was implemented to define the predictors of the three dependent variables (clinical outcomes, patients' satisfaction and economic resources' absorption). iii) A Qualitative Comparative Analysis – QCA, was implemented, in order to complement previous statistical approaches with a comparative-configurational one.

Results reported that rehabilitation effectiveness is well explained by patients' satisfaction ($\beta=0.368$, $p\text{-value}=0.007$) and compliance ($\beta=0.224$; $p=0.009$), reaching an Adjusted R2 equal to 0.211. Both the rehabilitation process effectiveness ($\beta=0.333$, $p\text{-value}=0.008$), and compliance ($\beta=0.269$, $p\text{-value}=0.035$) are required to achieve

patients' satisfaction (Adjusted $R^2=0.287$). Older age ($\beta=0.145$, $p=0.049$), higher sportiveness level ($\beta=0.169$, $p=0.022$), as well as the length of the rehabilitation clinical pathway ($\beta=0.550$, $p\text{-value}=0.000$) and the performance of threshold tests ($\beta=0.389$, $p\text{-value}=0.000$) are antecedents of higher management costs (Adjusted $R^2=0.703$ and $F=24.482$). Furthermore, summarizing QCA results, we can observe that the age and the level of sportiveness of patients, in combination with the compliance, play an important role in the emergence of the selected and analyzed outcomes.

Results of the study would be useful for the optimization of economic resources, as well as for the achievement of an adequate rehabilitative effectiveness, guaranteeing a personalisation of the process, thus becoming more efficient and effective, consistent with cost-containment strategies.

Keywords –Real-world data, healthcare sector, rehabilitative pathway, regression analysis, Qualitative Comparative Analysis

Paper type – Academic Research Paper

1 Introduction

The main scientific approach for generating knowledge in healthcare field is represented by randomized controlled trials (RCTs) and meta-analysis of RCTs. It is uncertain whether these methods are likely to lead to discovery of new treatments, identification of effective ones, or comparison and determination of the best of several approaches, for specific types of patients (Berguer et al., 2004).

In this view, the use of real-world data (RWD) in the healthcare setting, is currently achieving a greater strategic relevance. RWD could generate the opportunity to create new knowledge assets, recombining hospitals and patients' perspectives, with outcome and efficiency data (Celin et al., 2014; Garrison et al., 2007), contributing to improve the delivery of health products and optimizing outcomes (Holtorf et al., 2008).

RWD would be a useful support to measure the impact of disease-management interventions (Nguyen et al., 2016), in order to create a knowledge-based pathway, for the design of effective, efficient and satisfactory healthcare services. The use of RWD could support personalised decisions, based on treatment options, and healthcare delivery strategies, built on equity and coverage principles, quality and costs analyses.

Moving on from the above, the present paper aims at investigating the knowledge assets that might influence the design of a patient rehabilitative pathway, after the Anterior Cruciate Ligament (ACL) rupture, assuming the hospital wards perspective. Rehabilitation programs are designed to rebuild muscle strength, re-establish joint mobility and neuromuscular control, and to enable patients to return to pre-injury activity levels. Thus, the relevant assets for the design of the pathway are clinical outcomes, patients' satisfaction and economic resources' absorption (Justo et al., 2018). These assets are affecting by factors that make up the knowledge base for improvement of rehabilitative pathway.

Coherently to these premises, the study addressed the following two research questions.

1. Which are the main factors influencing the effectiveness (in terms of clinical outcomes), the patient satisfaction, or the efficiency of the rehabilitation process?
2. What configurations of such factors are sufficient to generate the emergence of a certain level of clinical outcome, or patient satisfaction, or efficiency, in the absorption of resources?

2 Research design and theoretical background

For the achievement of the above objectives, theoretical frameworks with independent variables, and their relationship with rehabilitation effectiveness, patients' satisfaction and rehabilitative pathway management costs, were accordingly developed.

2.1 Hypotheses development

A literature review revealed the principal rehabilitative pathway factors, impacting on clinical outcomes, patients' satisfaction and economic resources' absorption.

Age, compliance, length of the rehabilitation pathway, level of sportiness, number of physiotherapy sessions performed, number of muscle strength and threshold tests performed (De Valk et al., 2013; Wierike et al., 2013; Thomee et al., 2011; Czuppon et al., 2014; Christino et al., 2016), were considered as independent variables in the present analysis.

Age

De Valk *et al.*, (2013) declared that age is a fundamental factor for the achievement of a successful outcome of the rehabilitation pathway. In particular, younger patients present a higher probability to achieve a better clinical outcome, thus positively impacting on the satisfaction.

Since, in other settings, younger patients absorbed fewer economic resources (Duarte et al., 2018;), age could decrease the overall rehabilitation clinical pathway costs.

Based on the above considerations, the following hypothesis were displayed.

- HP 1.1: Younger age has a positive impact on effectiveness.
- HP 1.2: Younger age has a positive impact on satisfaction.
- HP 1.3: Younger age has a positive impact on rehabilitative pathway management cost.

Level of sportiness

De Valk et al. (2013) reported that healthy conditions and a higher level of sportiness (i.e. being professional athletes), would be antecedent factors of a successful rehabilitation program, improving the patient's clinical outcome. In particular, a patient with an athletic background presents a higher probability to reach the level of functionality of knee, antecedent the injury (Darain et al., 2015). Furthermore, such

patients are facilitated to complete a physiotherapy session, with more probability to accomplish the sessions (Darain et al., 2015). The level of sportiness impacts on rehabilitative pathway, thus having a role in the resources absorption and in the efficiency of the patients' rehabilitation. A higher level of sportiness, facilitating the functionalities recovery, could optimize the rehabilitative pathway, reducing the patients' management costs.

Different attitudes and level to play sport, could lead to different rehabilitation performance, in terms of outcomes, satisfaction and related costs.

According to these factors, the following hypotheses were formulated.

- HP 2.1: High level of sportiness, positively impacts on effectiveness.
- HP 2.2: High level of sportiness, positively impacts on satisfaction.
- HP 2.3: High level of sportiness, positively impacts on rehabilitative pathway management costs.

Compliance

Rehabilitation compliance and adherence are frequently challenges for the healthcare professionals. Despite clinicians schedule patients for rehabilitation sessions, not all patients keep their appointments and fully participate in the rehabilitation activities (Byerly et al., 1984).

Scientific evidence confirmed that adherence to a rehabilitative pathway is important for the achievement of the expected final clinical outcome (Wierike et al., 2013), thus positively impacting on patients' satisfaction (Rotter et al., 2010). Furthermore, if a patient completely adheres to the rehabilitative pathway, a fewer frequency on sessions could be suggested, with important economic advantages. Non-adherence to rehabilitation, leads to poor outcomes, could increase healthcare services utilization, and the overall healthcare costs (Iuga & McGuire et al., 2014).

Thus, the following hypotheses were proposed.

- HP 3.1: compliance has a positive impact on effectiveness.
- HP 3.2: compliance has a positive impact on patients' satisfaction.
- HP 3.3: compliance has a positive impact on rehabilitative pathway management costs.

Length of the rehabilitation clinical pathway

The length of the rehabilitation clinical pathway is strictly related to the above mentioned compliance. In this view, clinical outcomes could be positively influenced by the length of the program (Thomee et al., 2011). Conversely, in the hospital setting a shorter hospitalization as well as a shorter follow-up, would impact on patients' satisfaction and healthcare costs (Stuck et al., 2017; Lingsma et al., 2018), with a positive general impact. The same trend could be expected, in the rehabilitative setting. A simpler rehabilitative clinical pathway could encourage patients, with important advantages for both the patients, and the related caregiver satisfaction. In contrast, a longer rehabilitation program would increase the overall economic resources absorption.

The following hypotheses were defined.

- HP 4.1: the length of rehabilitation positively impacts on effectiveness.
- HP 4.2: the length of rehabilitation negatively impacts on satisfaction.
- HP 4.3: the length of rehabilitation negatively impacts on rehabilitative pathway management costs.

Number of physiotherapy sessions performed and number of muscle strength

The number of physiotherapy sessions, and the number of muscle strength tests performed, are related to the overall length of the rehabilitation program, scheduled for the patients, with specific healthcare needs. Risberg et al. (2004), highlighted the relationship between the prolonged rehabilitation and the improvement of the patient's physical conditions, and his/her earlier return to work, with a consequent increase in costs to support the intensive rehabilitative program.

According to this, the following hypotheses were displayed.

- HP 5.1: The number of physiotherapy sessions improves effectiveness.
- HP 5.2: The number of physiotherapy sessions negatively impacts on satisfaction.
- HP 5.3: The number of physiotherapy sessions negatively impact on rehabilitative pathway management costs.
- HP 6.1: The number of muscle strength tests improves effectiveness.
- HP 6.2: The number of muscle strength tests negatively impacts on satisfaction
- HP 6.3: The number of muscle strength tests negatively impact on rehabilitative pathway management costs.

With regard the potential relationship between the dependent and the independent variables, various possible interactions emerged.

In particular, a different level of clinical outcomes could influence the patients' psychological and functional factors (Winters et al., 2013). The achievement of better clinical outcomes, and higher levels of perceived satisfaction are strictly related (Kane et al., 1997; Hiraoka et al., 2009).

In this view, the following hypotheses were formulated.

- HP 7.1 The level of satisfaction positively impacts on effectiveness.
- HP 7.2 A better effectiveness positively impacts on satisfaction.

Furthermore, literature evidence (Fucai et al., 2005) declared that a long rehabilitation program could generate higher costs, thus decreasing the perceived satisfaction of the patients.

Moving on from this consideration, the following hypothesis was displayed.

- HP 8.1 The rehabilitative pathway management costs negatively impact on satisfaction.

2.2 Frameworks

A synthesis of the research frameworks developed is proposed in Figure 1, 2 and 3.

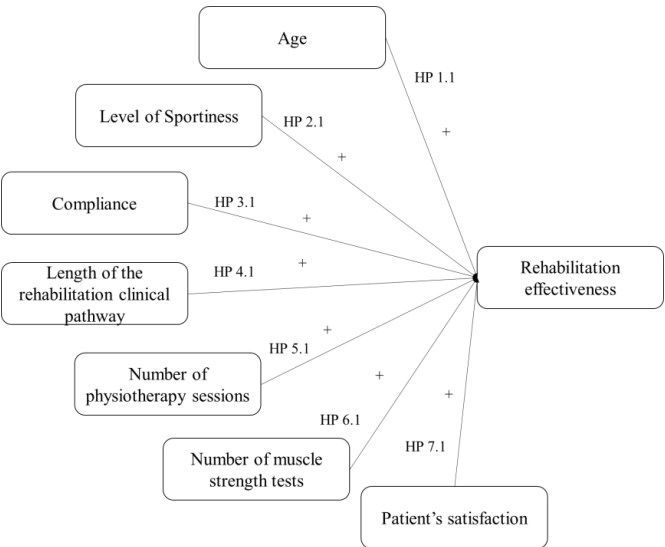

Figure 1: Conceptual framework for rehabilitation effectiveness

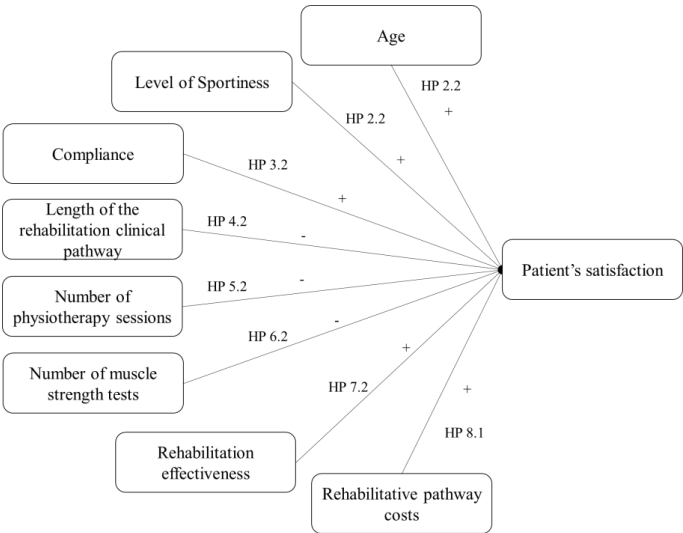

Figure 2: Conceptual framework for patient's satisfaction

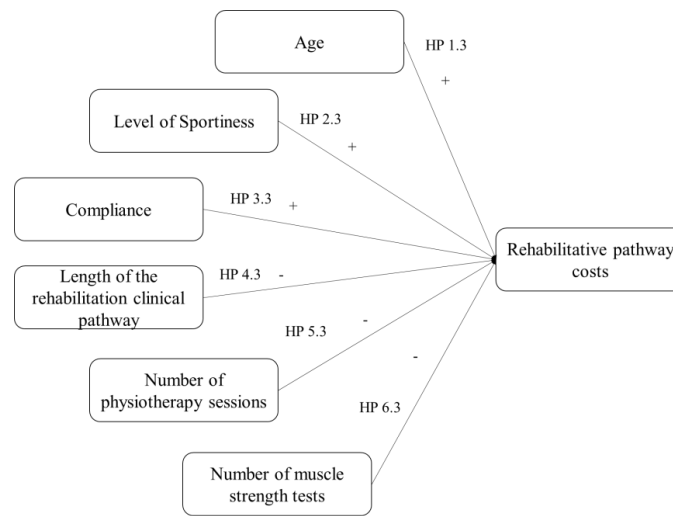

Figure 3: Conceptual framework for rehabilitative pathway costs

3 Methods

An observational study was developed in two private rehabilitative hospitals in Italy, in order to retrieve RWD with regard to the rehabilitative pathway, thus collecting information from 59 patients.

3.1 Definitions of the measures

According to the above mentioned hypotheses, the CRF was composed of the following variables, derived from RWD.

Dependent Variables

- Clinical outcome (effectiveness). The clinical outcome represents the effectiveness of the rehabilitation program, thus defining its overall quality. At the end of rehabilitation program, the patient undergoes a test that allows the calculation of the strength deficit, of the injured limb, compared with the healthy one, with the consequent estimate of a percentage difference, between the initial and final expected strength, from rehabilitative program. The result ranged from a minimum of -1 (higher strength deficit), to a value equal to 0 (perfect healing).
- Patient's satisfaction. The variables measured the patient-reported experiences during the rehabilitation program. *i)* Complete achievement of the therapeutic objectives shared with the clinician of reference, at the beginning of the rehabilitation program; *ii)* level of trust and confidence created with the clinicians; *iii)* attention received by the clinicians, the physiotherapist and the nurses; *iv)* evaluation of the organisational services (administrative support, website); and *v)* evaluation of the facilities. The

above items were evaluated, considering a scale ranging from 0 (complete dissatisfaction), to 1 (complete satisfaction).

- Costs. In order to estimate the rehabilitation program costs, the following health expenditure items were investigated: number of physiotherapy sessions and number of procedures/tests performed during the program. In particular, economic data were evaluated, in accordance with outpatient visits and tests Regional Reimbursement Tariffs.

Independent Variables

- Age. The age of the patient at the beginning of the rehabilitation program.
- Level of sportiness. The level of sportiness declared by the patient, at the beginning of the rehabilitation program, classified as follows: *i)* none; *ii)* practitioner; *iii)* amateur; and *iv)* athlete.
- Compliance. Adherence/compliance to the program was measured by attendance at and participation in scheduled rehabilitation session. In particular, patients were divided in compliant patients and not-compliant patients, on the basis of two characteristics. *i)* Patients who have completed the rehabilitative pathway prescribed by the clinicians, and *ii)* patients who have abandoned the rehabilitative pathway earlier.
- Length of the rehabilitation clinical pathway. The duration of the pathway referred to the number of days occurring between the beginning of the rehabilitation program (with the first physiotherapeutic session carried out), and the final medical examination, with the consequent discharge of the patient.
- Number of physiotherapy sessions performed and number of muscle strength. These variables referred to the number of sessions and tests performed by each patients, during the entire rehabilitation clinical pathway.

3.2 Statistical analyses

Data derived from the CRFs were analysed considering descriptive statistics, frequencies and distributions. Preliminary analyses were performed, in order to ensure no violation of the assumptions of normality, linearity and homoscedasticity.

Furthermore, three methodological approaches were used to answer the above research questions.

i) Relationships between variables, were investigated, to test the existence of correlations among them. In particular, the “person product-moment” correlation coefficient was assessed, to test the existence of small (from 0.10 to 0.29), medium (from 0.3 to 0.49), or large (from 0.5 to 1) correlations among variables (Cohen, 1988). The exact value equal to -1 or $+1$ indicated a perfect correlation among variables.

ii) A hierarchical sequential linear regression model (with enter methodology) was implemented to test the hypotheses proposed, defining the predictors of the above three dependent variables (clinical outcomes, patients’ satisfaction and economic resources’ absorption), useful in order to establish the independent variables impacts. In particular

the Adjusted R2 was examined, in order to control the explanatory power of each model (Tabachnick & Fidell, 2007). This approach allows to test the hypotheses, through incremental models, in order to establish the specific impact of each single input variable, on the dependent variables. The option “exclude case pairwise” was implemented, because was the preferable methodology, in particular for a small sample (as described in this research activity) and avoiding any kind of data exclusion.

All the statistical analyses, referring to the coefficients test, and the development of the hierarchical sequential regression model were performed using the Statistical Package for Social Science (IBM SPSS Statistics Viewer - Version 22).

iii) In order to complement previous statistical approaches with a comparative-configurational one, a Qualitative Comparative Analysis - QCA (Ragin, 1987, Ragin 2000) was implemented.

The QCA is a comparative case-oriented methodology (Marx et al., 2013), useful to find, through an in depth comparison of real-world cases, consistent configurations of causal conditions (the independent variables in our study), sufficient to determine the emergence of a specific outcome. In the QCA, a symmetric relationship is disarticulated into two asymmetric analyses formalized by set and sub-set relationships (Ragin 2008): one on the necessity of the conditions with respect to the outcome and the other on the sufficiency. This fact allows researchers to deal with the complexity of real phenomena. The QCA, in fact, assumes the non-linearity of phenomena under investigation and is based on the principle of causal complexity. This means that, in most cases, it does not make sense to isolate the effect (positive or negative), of a single independent variable on the outcome, but configurations of variables are identified, being related to the outcome. Moreover, several different configurations can be recognized as "causal recipes" of the same outcome (Ragin, 1987).

According to Vis (2009), that discusses the advantages of using QCA technique to complement regression analyses, for moderately large-n samples (between 50 and 100), we studied the 59 empirical cases collected in this research, through QCA, in order to better understand the relationships between the combinations of the independent variables (the complex interactions effects among the causal conditions) and the three outcomes (dependent variables) presented above.

In QCA approach, the variables can be considered crisp or fuzzy. The crisp set variant (csQCA) is the version in which the variables of the study are dichotomous and the empirical analysed cases are classified as alternatively “fully in” or “fully out” in the sets representing causal conditions and the outcomes. The fuzzy-set variant (fsQCA) is characterized by the fact that the empirical cases are classified in terms of membership degrees in the fuzzy sets of causal conditions, and of the outcome. In this preliminary analysis, we adopted the crisp set QCA.

Coherently with the research frameworks, three different QCA analyses are carried out, considering respectively as outcome rehabilitation effectiveness, patient’s satisfaction, and rehabilitative pathway costs, and as casual conditions, the independent variables taken in account in each research framework.

4 Results

4.1 The sample under assessment

The sample was composed of 59 patients, requiring a specific rehabilitative pathway after ACL rupture. Most part of the sample was composed of males (66%), with an average age of 34 years.

With regard to the level of sportiness, it emerged that only 3% of patients performed high-level professional sport, whereas 64% belong to the “practicing” category.

In general terms, the sample presented an economic resources absorptions equal to € 3,334.07±269.28 for the rehabilitative pathway, with an overall effectiveness of 0.84 ± 0.03 , and an overall satisfaction of 0.81 ± 0.02 . In particular, compliant patients require more economic resources’ absorption than non-compliant patients (€ 3,634.47 vs € 2,157.50 p-value=0.026), leading also to the achievement of a better clinical outcome (0.88 vs 0.67 , p-value = 0.026) and a higher patients’ satisfaction (0.85 vs 0.69 , p-value=0.000).

4.2 Hypotheses testing

Table 1 depicts that patients’ satisfaction (p-value = 0.021), age (p-value = 0.047), compliance (p-value = 0.026), the length of the rehabilitative pathway (p-value = 0.000) as well as the number of threshold tests (p-value = 0.000), significantly influenced the rehabilitative pathway costs. The significant relationship between the rehabilitative pathway costs, and the number of physiotherapy sessions ($\beta = 0.995$, p-value = 0.000) depict that the two variables present the collinearity phenomena, thus being two aspects explaining the same concept. For this reason, the variable number of physiotherapy sessions was not included in the regression model.

Satisfaction was positively related to the patients’ clinical outcome (p-value = 0.000), compliance (p-value = 0.000), and number of threshold tests (p-value = 0.000). The same trend emerged, considering the patient clinical outcome.

With regard to the independent variables, age, compliance and the length of the rehabilitative pathway, showing a significant p-value < 0.05. The same relationships emerged among the length of the rehabilitative pathway, the number of threshold tests and the number of physiotherapy sessions (p-value = 0.000).

Table 1 – Relationships between variables

	1	2	3	4	5	6	7	8	9
Rehabilitative pathway management costs (1)	1								
Satisfaction (2)	,299*	1							

Effectiveness (3)	,155	,461**	1						
Age (4)	,260*	,212	,107	1					
Compliance (5)	,290*	,444**	,381**	,565**	1				
Level of sportiness (6)	,244	,084	-,108	-,195	,015	1			
Length of the rehabilitative pathway (7)	,735**	,108	,058	-,265*	,252	,082	1		
Number of threshold tests (8)	,637**	,601**	,381**	,043	,373**	,062	,403**	1	
Number of physiotherapy sessions (9)	,995**	,245	,124	,477**	,270*	,259*	,738**	,559**	1

After having tested the correlation among variables, a regression analysis was conducted to test hypotheses, with regard to rehabilitation effectiveness (Table 2), patient satisfaction (Table 3) and rehabilitative pathway management costs (Table 4).

Rehabilitation effectiveness is well explained by patients' satisfaction ($\beta=0.368$, $p\text{-value}=0.007$), and compliance ($\beta=0.224$; $p=0.009$), reaching an Adjusted R^2 equal to 0.211 ($F=6,169$).

Table 2 – Regression model for rehabilitation effectiveness

	<i>Rehabilitation effectiveness</i>		
	Mod 1	Mod 2	Mod 3
Satisfaction	.461**	.364^	.368^
Compliance		.219^	.224^
Number of physiotherapy sessions			.026
R^2	.213	.251	.252
Adj. R^2	.199	.224	.211
F value	15.402**	9.390**	6.169*
ΔR^2	.213	.038	.001
F (ΔR^2)	15.402**	2.873^	.047

Both the rehabilitation process effectiveness ($\beta=0.333$, $p\text{-value}=0.008$), and compliance ($\beta=0.269$, $p\text{-value}=0.035$) are required to achieve patients' satisfaction (Adjusted $R^2=0.287$).

Table 3 – Regression model for patients' satisfaction

	<i>Patients' satisfaction</i>		
	Mod 1	Mod 2	Mod 3
Rehabilitation effectiveness	.461**	.425**	.333*
Rehabilitative pathway management cost		.233*	.170
Compliance			.269*
R^2	.213	.266	.323

ΔR^2	.068	.073	.053	.421	.114
F (ΔR^2)	4.134*	4.766*	3.632^	59.089**	22.208**

4.3 Configuration of factors through QCA

The QCA analysis requires a preliminary step for calibration of variables transforming them in crisp one (table 5).

Table 5: Calibration of the variables

Variable	Value in regression model	Calibration
Age	a) 50-60 years b) 30-49 years c) 20-29 years d) < 20 years	0: <30 years 1: 49-60 years
Level of sportiness	a) none b) practitioner c) amateur d) athlete	0: none and practitioner 1: amateur and athlete
Compliance	a) compliant b) not compliant	0: compliant 1: not compliant
Rehabilitation Effectiveness	a) effectiveness b) no effectiveness	0: no effectiveness 1: effectiveness
Patient Satisfaction	a) satisfaction b) no satisfaction	0: no satisfaction 1: satisfaction
Length of the rehabilitation clinical pathway	Number of Rehabilitation days	0: < 100 days 1: >= 100 days
Muscle strength test and threshold tests	Number of test	0: < 2 1: >= 2
Pathway Management Cost	Value of the pathway	0: < 3,360€ 1: >= 3,360€

After the calibration step, we assess the consistency and coverages of a configuration set of variables.

Consistency is the extent to which the results are in line with the statements of necessity or sufficiency. Coverage gives information, on the empirical importance of necessary and sufficient conditions.

Each configuration has a raw coverage value that “measures the relative importance of several combinations of causally relevant conditions” (Ragin 2006: p. 305): the proportion that a configuration covers the outcome. It is assessed by the sum of consistent scores of the configuration divided by the sum of outcome scores (Poveda and Martínez, 2013). In the QCA analysis, the crisp value 1 is reported in uppercase whereas the crisp value in reported in lowercase.

According to regression analysis, compliance is a variable present in all configurations, therefore it has a high impact on effectiveness. Concerning the configuration recipe, the effectiveness is greater if the whole treatment is performed (compliance) and the patients are young with a high level of sportiness.

Table 6: QCA analysis for rehabilitation effectiveness

OUTCOME: EFFECTIVENESS			
		Raw Coverage	Consistency
1	COMPLIANCE*age*SPORTINESS*length rehabilitation * STRENGTH TEST*SATISFACTION	0.097	1.00
2	COMPLIANCE*age * SPORTINESS * THRESHOLD TEST* STRENGTH TEST * SATISFACTION	0.161	1.00
3	COMPLIANCE*age* length rehabilitation * THRESHOLD TEST* STRENGTH TEST * SATISFACTION	0.097	1.00
4	COMPLIANCE* AGE*sportiveness * LENGTH REHABILITATION * THRESHOLD TEST* STRENGTH TEST	0.097	1.00
5	COMPLIANCE* SPORTINESS * length rehabilitation * THRESHOLD TEST* STRENGTH TEST * SATISFACTION	0.194	1.00
6	AGE* SPORTIVENESS * length rehabilitation * threshold test* strength test * satisfaction	0.032	1.00
7	COMPLIANCE*age* sportiveness ** LENGTH REHABILITATION * threshold test*strength test * satisfaction	0.032	1.00
Solution Coverage 0.613			
Solution Consistency 1			

Concerning the satisfaction outcome, we obtain only one optimal configuration. Also for this outcome, the compliance, young age and level of sportiness represent the main factors associated with a greater satisfaction.

Table 7: QCA analysis for patients' satisfaction

OUTCOME: SATISFACTION			
		Raw Coverage	Consistency
1	COMPLIANCE*age* SPORTINESS *effectiveness*rehabilitative cost	0.115	1.00

The compliance and length of rehabilitation are the variables that most affect management costs.

The most representative recipes show that level of sportiness associated with young age affects the management, as well as the length of rehabilitation, also for the patients with a lower level of sportiness.

Table 8: QCA analysis for rehabilitative pathway management cost

Modello_1_OUTCOME COST			
		Raw Coverage	Consistency
1	COMPLIANCE*age*SPORTINESS* REHABILITATION * strength test	0.154	1.00
2	COMPLIANCE*age *LENGTH REHABILITATION *SOGLIA*TEST DI FORZA	0.077	1.00

	Solution Coverage 0.615		
	Solution Consistency 1		

5 Discussion and Conclusions

Regression analysis results, demonstrated that a high level of sportiness and a strong compliance could be considered antecedent of a higher total rehabilitative pathway management cost, for an ACL patient. A sport professional, since his urgent priority, is the recovery of normal daily and sportive activities, is expected to undergo to a more intense and onerous rehabilitative pathway (De Valk et al., 2003). The same trend emerged with regard to patients' compliance and satisfaction. This is consistent with literature evidence available on the topic, revealing: *i*) the importance of compliance in the achievement of a positive clinical outcome (Wierike et al., 2013), and *ii*) the relevance of a higher rehabilitative sessions and threshold test frequency, as a determinant of rehabilitation effectiveness (Czuppon et al., 2014).

The QCA complements these results identifying combinations of factors that are able to determine the emergence of a given outcome. For example, more consistent solutions of QCA analysis show that the compliance has a major impact on the absorption of economic resources by patients, but also higher levels of sportiness associated with the young age of patients determine in combination higher costs of the rehabilitation pathway.

When considering the effectiveness of the rehabilitative pathway, the compliance together with the young age, and the high level of sportiness is conducive to the best clinical outcomes. Another consistent and empirical relevant solution shows that a potential “recipe” to obtain a high effectiveness of the rehabilitation, also exists for younger patients: they need to be compliant and to exhibit high levels of sportiness. Finally, the patients' satisfaction in this sample is determined by the compliance in combination with the high level of sportiness.

The findings could contribute to enlarge the existing research, with regard to the use of real-world data in the healthcare sector, within the specific setting of the rehabilitation process. Despite this is particularly relevant because the concept of value is receiving

greater attention in rehabilitation and the broader healthcare environment, healthcare stakeholders, often lack sufficient information on outcomes to make well-informed decisions. In this view, the knowledge of some aspects that could positively or negatively impact on the patient's pathway, would be useful for the optimization of economic resources, as well as for the achievement of an adequate rehabilitative effectiveness, guaranteeing a personalisation of the process, thus becoming more efficient and effective, consistent with cost-containment strategies (Justo et al., 2018). This become even more important, given the recent Italian law "Legge di Stabilità" requirements (2016), where the optimization and the evaluation of the patient's clinical pathway, based on RWD, is becoming mandatory.

Abstract

In the present paper we show the potentiality of the Stochastic Multicriteria Acceptability Analysis (SMAA-2) in evaluating 31 general hospital structures across the Kingdom of Saudi Arabia (KSA) in 2017.

The method allows for a global evaluation of each hospital beginning with a set of 41 key performance indicators (KPIs) that are computed monthly by the Saudi Ministry of Health (MoH).

The paper clearly shows the importance of this multi-criteria technique in supporting decision makers (DM).

Keywords: Key Performance Indicators (KPI), Stochastic Multicriteria Acceptability Analysis (SMAA), Healthcare, Decision Making, Kingdom of Saudi Arabia (KSA)

Proposed Paper: Academic Research Paper

1. Introduction

In line with the goals and strategic objectives outlined in Saudi Arabia's 2030 Vision, the Ministry of Health (MoH) has introduced Aadaa', a national improvement transformation program encapsulating the whole healthcare sector. This unprecedented program aims to improve the efficient utilization of available resources, enhance the efficiency and effectiveness of the healthcare sector leveraging the power of digital transformation and information technology, strengthen training and development, improve healthcare provisions before and during hospitalization, attain acceptable waiting times across all stages of service delivery, and improve governance in the health system in order to enhance the accountability with regards to quality issues and patient safety.

The Aadaa' program aims to build and initialize performance measurement processes in the public healthcare sector by providing the necessary support through the utilization of unified tools and models that assist MoH public hospitals in their ability and efficiency to deliver better performance. This program continuously monitors the delivery progress of strategic goals, initiatives and KPIs of MoH hospitals, tracking their development in achieving the Saudi MoH's mission 2020 in addition to measuring beneficiary satisfaction on public services.

Since its official launch in 2017, Aadaa' has monitored and tracked healthcare facilities on a monthly basis through a set of 41 KPIs and has had a positive impact on the quality of therapeutic care delivered to patients as well as the efficient utilization of available resources. The program also aims to enhance the skillset of health professionals so that they are better equipped to understand and interpret the indicators, and thus able to identify performance improvement opportunities.

The MoH is the regulator for all healthcare-related activities and services within the Kingdom and has played a dominant role in the provision of healthcare services in KSA. It is the largest provider of healthcare services in the Kingdom, providing over 60% of inpatient care. MoH facilities are established to provide free healthcare to the Kingdom's population of over 32 million nationals. Although the MoH is responsible for healthcare of all citizens, other public and private facilities play an important role in healthcare delivery, providing over 20% and 17% of the inpatient facilities health services, respectively. Accordingly, the main challenge faced by decision makers was in identifying the best performing hospitals as a function of the set of KPIs. Moreover, decision-makers faced difficulties conceptualizing selection models. The number of actors participating in the decision-making process is typically large and accordingly, it is often unclear whether the final DMs or those responsible for preparation should be considered the source of preferential information. In this framework simulating all the

possible preferences, that is all the possible weights assigned to the KPIs through the SMAA-2, should represent a valid aid in supporting DMs decisions. To the best of our knowledge, this is the first time that SMAA-2 is applied to rank hospitals with respect to a set of KPIs.

This paper is organised as follows: section 2 briefly describes the variables employed and existing data, and section 3 discusses the methodological approach. Section 4 outlines the main results. Section 5 provides conclusions.

2. Data and variables

From January 2017 to January 2018, we collected data for 31 general hospitals across the Kingdom around 7 key therapeutic aspects or domains, including: (emergency, clinics, surgeries, hospitalization, critical care units, radiology and labs). These 31 general hospitals are acute care hospitals that provide medical and surgical care, including diagnostic and treatment services. They are scattered across the Kingdom in which 7 are in central region, 5 are in eastern region, 8 are in the southern region, 11 hospitals in the western region and 7 are in the northern region. The average bed capacity is 323 bed units with a maximum of 575 bed units and a minimum of 150 bed units.

The presence of non-negligible variability in the monthly data has led us to consider the median value of each KPI. The complete list of KPIs is reported in Table 1.

Table 1. Hospital Aada set of KPIs

	KPI Abbreviation	KPI	Domains
1	ED 1	Door to Doctor	Emergency Department
2	ED 2	Doctor to Decision	
3	ED 3	Decision to Disposition (Admit or Transfer only)	
4	ED 4	% of Non-Urgent Patients	
5	RAD 1	Order to Scan (By X-Ray, CT and MRI)	Radiology Department
6	RAD 2	Scan to Release (By X-Ray, CT and MRI)	
7	LAB 1	Lab TAT (Turnaround Time)	Laboratory
8	OR 1	OR Utilization	Operating Rooms
9	OR 2	% First Daily Cases Start on Time	
10	OR 3	OR Cancellation Rate	
11	OR 4	Surgery Volume	
12	OR 5	% of Elective Surgeries	
13	OR 6	Day of Admission to Day of Surgery	
14	OR 7	% Day Surgery Compliance to Ministry of Health List	
15	OR 8	% Day Surgery Conversions to Admission	
16	OR 9	Nursing Staff with Certifications (BLS, ATLS, PALS)	
17	OR 10	Physicians with Certifications (BLS, ATLS, PALS)	
18	IP 1	% of Patients Seen by Consultant in First 24 Hours	Inpatient Department
19	IP 2	% EDD (Expected Days to Discharge) Compliance on Admission	
20	IP 3	Admission LOS (Length of Stay)	
21	IP 4	EDD to Actual LOS Comparison	
22	IP 5	Time from Clinical to Physical Discharge	
23	IP 6	% Weekend Discharges	
24	IP 7	Number of Long-Stay Patients	
25	IP 8	Mortality Rate (Inpatient & Critical Care)	
26	OPD 1	Waiting Time for Appointment (in Days)	
27	OPD 2	Surgical Conversion Rate	

28	OPD 3	% of New Patients	Outpatient Department
29	OPD 4	Patient Volume	
30	OPD 5	Patient's No-Show Rate	
31	OPD 6	Clinic Waiting Time	
32	OPD 7	Patient On-Time Arrival	
33	CC 1	ICU Length of Stay	Critical Care Department
34	CC 2	Nurse to Bed Ratio	
35	CC 3	Presence of Admission & Discharge Criteria	
36	CC 4	Adherence to Admission & Discharge Criteria	
37	CC 5	% Nursing Staff with ICU Certifications (ACLS, ATLS, PALS, NRP, FCCS)	
38	CC 6	% of Physicians with ICU Certification (ACLS, ATLS, PALS, NRP, FCCS)	
39	CC 7	Number of Long-Stay Patients	
40	Patsat	Patient NPS (Net Promotion Score)	Patient & Staff Satisfaction
41	Staffsat	Staff NPS (Net Promotion Score)	

The KPIs in bold are not included in the analysis since these variables may be affected by selection bias: severely ill patients may choose high quality hospitals (Gowrisankaran and Town, 1999); if the unobserved component of severity of illness affects a patient's choice of hospital, then the selection problem remains, and the evaluation of hospital will be incorrect. A possible solution is to employ the Case Mix Index (cmi) which measures the average complexity of a Diagnosis-Related Group (DRG) treated in the hospital compared with the average complexity of data from a set of reference hospitals. However, nowadays this kind of data is not consistent or readily available in the Saudi health system. Table 2 reports the descriptive statistics for the sample of 31 general hospitals considered in the analysis.

Table 2. Descriptive statistics

	KPI	Min.	1st Qu.	Median	Mean	3rd Qu.	Max.

29	staffsat	-0.708333	-0.008333	0.241852	0.159553	0.348333	0.543333

What can be noticed in Table 2 is that the variables differ in the unit of measure as well as in their impact on the measurement of hospital performance. For example, low level in the LAB1 KPI -turnaround time- has a positive impact. On the contrary an increase of the KPI CC4 -adherence to admission & discharge criteria – indicates a rise of performance. Thus, to make the variables comparable we normalise them in [0,1], where 0 always indicate minimum and 1 the maximum, by employing the following formulas:

$$\xi_i^o = \frac{\xi_i - \xi_{max}}{\xi_{max} - \xi_{min}}; \text{for a KPI that indicates improvement when it increases}$$

$$\xi_i^o = \frac{\xi_{max} - \xi_i}{\xi_{max} - \xi_{min}}; \text{for a KPI that indicates improvement when it decreases} \quad (1)$$

3. Methodological approach

Stochastic Multicriteria Acceptability Analysis (SMAA-2) belong to the family of the so-called Multiple Criteria Decision Aiding (MCDA) methods which allow to choose, rank and sort a set of alternatives in terms of a set of criteria (Roy, 1966; Figueira et al., 2005). The SMAA-2 overcomes one of the main problems in the various MCDA methods (Lahdelma et al., 1998) which is related to the assignment by the Decision Makers (DM) of weights, even if in a nondeterministic, to the alternative criteria. For example, the Multi-Attribute Utility Theory (MAUT) employ a priori probability distribution, while the Elimination and Choice Expressing Reality (ELECTRE) method utilize thresholds. In the SMAA-2, the choice among alternatives is obtained by employing Montecarlo simulation in which the weights are randomly extracted from a convex polytope identified through a set of linear weight constraints. In the SMAA-2 the introduction of uncertainty to the weights space implies that the result is represented by a probability distribution of rankings rather than a single “representative” one (Tervonen and Ladhema, 2007; Tervonen and Figueira, 2008; Greco et al., 2018). Consequently, this characteristic of the method is suitable whenever:

- DMs are not able to assign any weights due to the complexity of the problem;
- DMs do not want to restrict themselves to some weights;
- DMs would like to obtain a preliminary system of weights.

Currently the MoH faces the above challenges in pursuing the broader objective of improving the quality of the healthcare outcomes through the analysis of the set of KPIs defined in section 2. In what follows we describe the employed methodology where, in accordance to the MCDA framework, the alternatives are the hospitals and the criteria are the KPIs. In a typical MCDA setting a set of m alternatives $A = \{a_1, a_2, \dots, a_i, \dots, a_m\}$ is evaluated on a set of n evaluation criteria $G = \{g_1, g_2, \dots, g_j, \dots, g_n\}$. In order to compare an alternative a_i respect to the m criteria an utility function u , which assigns a non-negative weight $w_j \in W$ - $W = \{(w_1, w_2, \dots, w_j, \dots, w_n) \in R^N: w_j \geq 0, j = 1, 2, \dots, n, \text{ and } \sum_{j=1}^n w_j = 1\}$ - to each criterion $g_j \in G$, is employed:

$$u(a_i, w) = \sum_{j=1}^n w_j g_j(a_i) \quad (2)$$

In a fortunate case in which the alternative criteria has been clearly defined, and they present equal importance for DM, equation (2) can take the form of a simple arithmetic mean. But in most of cases neither values of criteria nor the set of weights are clearly defined. In order to take into account such an uncertainty in the evaluation of the alternatives, the SMAA introduces two probability function on the weight space and on the evaluation space, χ , which is the space of the value that can be taken by criteria $g_i \in G$:

$$\begin{aligned} f_W: W &\rightarrow \mathcal{R}^+. \quad \sum_{i=1}^n f_W(w_i) = 1 \\ f_\chi: \chi &\rightarrow \mathcal{R}^+. \quad \sum_{i=1}^n f_\chi(\xi_i) = 1 \end{aligned} \quad (3)$$

Then the following ranking function, r_i , is introduced for each alternative a_i :

$$r_i(\xi_i, w) = 1 + \sum_{h \neq i} [\rho(u(\xi_h, w)) > u(\xi_i, w)] \quad i=1, 2, \dots, m \quad (4)$$

Where, ρ is an indicator function: $\rho(\text{false})=0$ and $\rho(\text{true})=1$. For each ranking r_i , each alternative a_i , for each evaluation of alternatives ξ SMAA-2 individuates the set of favourable rank weights:

$$W_i^r = \{w \in W: r_i(\xi_i, w) = r\} \quad (5)$$

which are employed in a set of indexes that describe the set of rankings obtained through the Montecarlo simulation. In particular, in what it follows we employ the rank acceptability index, b_i^r , to explore the alternative rankings of hospitals which measure the frequency that the alternative a_i gets rank r respect to the set of weights and evaluations of alternatives:

$$b_i^r = \sum_{\xi \in \chi} f_\chi(\xi) \int_{w \in W_i^r(\xi)} f_W(w) dw d\xi \quad i=1, 2, \dots, m \quad (6)$$

In other terms b_i^r allows to compare how different varieties of weights support each rank for each alternative (Lahdelma and Salminen, 2001).

4. Application to the general hospitals in Saudi MoH ranking

We apply the aforementioned SMAA-2 to rank the 31 general hospitals in KSA regions according to the set of the remaining 29 KPIs described in section 2, after the exclusion of the 11 KPIs in bold from the total of 41 KPIs as mentioned in section 2. The index has been obtained by mean of the R libraries *smaa* (Valkenhoef, 2018) and *hit and run* (Tervonen and Valkenhoef, 2019). Our explorative analysis begins by computing three naïve rankings which can easily obtained from the KPIs:

- Patient ranking (Patient Satisfaction KPI), r_{pat} ;
- Staff ranking (Staff satisfaction KPI), r_{staff} ;
- Average ranking (Simple arithmetic mean of the 27 KPIs), r_{avg} , excluding r_{pat} and r_{staff} ;
- In this first phase of the empirical analysis the objective is to simply assess the existence of differences in the perception of the hospitals among patients, employees (doctors and nurses) and a set of neutral indicators, e.g. the 27 KPIs. The results are shown in Tables 3, 4 and 5.

Table 3. Patient ranking (r_{pat}) vs Avg ranking (r_{avg}).

H30	Hail General Hospital	12	3	9	+
H31	Buraydah Central Hospital	30	30	0	-

The three rankings clearly differ. Nonetheless, before applying a statistical test we can highlight the following empirical evidence emerging from the above tables:

1. The differences between patient ranking and average ranking is greater than the one between staff ranking and average ranking. In Table 3 there are only 2 changes in the ranking that are at least of 1 position against 6 in Table 4;
2. There is accordance between patient ranking and staff ranking for the hospitals that are ranked in the last position.

We employ the Cohen's kappa statistic to assess the statistical significance of differences in the above naïve rankings. Cohen's kappa statistic measures inter-rater reliability (sometimes called inter-observer agreement). Inter-rater reliability, or precision, happens when the data raters give the same score to the same data item. Like most correlation statistics, the kappa can range from -1 to $+1$. In Table 6 the test results are shown:

Table 6. Cohen's Kappa and associated p-value in parenthesis.

	r_{avg}	r_{pat}	r_{staff}
r_{avg}		-0.0333 (0.309)	0 (1)
r_{pat}			0.0333 (0.309)
r_{staff}			

The results in table 6 indicate the absence of agreement, or concordance, among the three rankings: values of Choen's Kappa close to 0. However, the associated probability to the Choen's Kappa coefficient suggest that the absence of agreement is due to chance instead of a "true" difference between rankings.

Therefore, it seems reasonable to apply SMAA-2 as a method offering a broader perspective to tackle the measurement of the general hospital's performance in KSA. Thus, according to the SMAA-2 approach, we introduce a uniform sampling of 10^6 of weights vector on the 27 KPIs, - the KPIs measuring staff and patient satisfactions has been excluded- which generate through, the rank acceptability index, b_i^r , the set of all possible rankings related to the 31-general hospitals. The index has been multiplied for 10^6 , obtaining absolute rank frequency, to facilitate the Table 7 readability.

Table 7. Rank Frequency: table shows the number of cases out of the 10^6 cases generated by different weights sets in which each hospital achieves a given rank from 1 to 31

Starting from the data in Table 7 we derive Table 8 which reports the SMAA-2 ranking, r_{SMAA-2} , obtained taking the highest absolute frequency, the green values in Table 6, reached by each hospital in the 10^6 cases generated by Montecarlo simulation.

Table 8. SMAA-2 ranking, r_{SMAA}

Hospital	r_{SMAA}
H1 King Salman Riyadh	1
H2 King Saud Oneiza	1
H7 King Khalid Hafar Al Batin	1
H28 Rafha Hospital	1
H4 Jubail General	2
H25 Prince Muteb Al Jouf	2
H16 Heraa Hospital Makkah	5
H21 King Faisal Medical Complex Taif	6
H10 Prince Mushari Bin Saud Beljurashi	9
H31 Buraydah Central Hospital	9
H27 Arar Central Hospital	10
H26 Al Qurayyat General	11
H12 King Abdullah Central Bisha	14
H22 Al Qunfudhah South Hospital	14
H20 Yanbu General	15
H5 Qatif Central Hospital	16
H29 King Khaled Hail	16
H8 Asir Central	17
H11 King Fahad Baha	18
H9 Khamis Mushyt General	19
H15 Prince Mohammed Bin Nasser Jizan	19
H6 King Fahad Hofuf	20

H17	King Abdulaziz Makkah	20
H18	Ohod Medina	23
H14	Sabia General Jizan	25
H13	King Fahad Central Jizan	26
H23	King Khalid Tabuk	26
H30	Hail General Hospital	26
H24	King Khalid Al Kharj	28
H3	Dammam Medical Complex	29
H19	King Fahad Medina	30

It is immediately observable that with respect to the previous ranking, the SMAA-2 ranking identifies a group of hospitals that are ranked with respect to the optimal value of the KPIs in the first position: H1 -King Salman Riyadh-, H2 -King Saud Oneiza-, H7 -King Khalid Hafar Al Batin-, H28 -Rafha Hospital-, H4 -Jubail General- and H25 -Prince Muteb Al Jouf-. To appreciate the difference between the naïve rankings we compare the r_{SMAA} with the previous ones: r_{avg} , r_{staff} and r_{pat} . The results are reported in Tables 9, 10, 11 and 12.

Table 9 Average ranking (r_{avg}) vs SMAA-2 ranking (r_{SMAA})

Hospital		r_{avg}	r_{SMAA}	$r_{avg} - r_{SMAA}$	sign ($r_{avg} - r_{SMAA}$)

Table 12. Cohen's Kappa and associated p-value in parenthesis.

	r_{avg}	r_{staff}	r_{pat}
r_{SMAA}	0.133 (3.58e-05)	0.0333 (0.301)	0 (1)

Looking at Table 9 it can be noticed that the differences between the r_{SMAA} and the r_{avg} rankings are moderate except for H8 - Asir Central - and of H9 -Khamis Mushyt General-: they moved 14 and 8 positions respectively. However, the Cohen's Kappa coefficient, Table 12, shows only a slight level of concordance between rankings which is not due to chance. For the two remaining comparisons between r_{SMAA} , r_{staff} and r_{pat} rankings, Tables 10 and 11 respectively, we obtain quite a different ranking even if "SMAA ranking" seems to be aligned with the extreme positions in the ranking. However, the Cohen's Kappa, Table 12, shows absence of any form of concordance; even this result can be due to chance.

5. Concluding remarks

In the present paper we apply the SMAA-2 techniques to generate a possible ranking of 31 general hospitals with respect to a set of 29 KPIs collected and calculated monthly by the KSA Ministry of Health, as part of the Adaa' national improvement transformation program.

The SMAA-2 through the Montecarlo simulation mimic different class of individuals with different preferences and consequently with different weights for the alternatives.

The paper clearly shows the potentiality of this multi-criteria technique to support the MoH in comparing the general hospital facilities without recurring to a system of a-priori weights.

Abstract

This work reports preliminary outcomes from the project LINFA, whose aim is to develop a technological, information and organizational system to support the procurement process of medicines and medical devices within healthcare organizations. Such system integrates simulation and optimization algorithms and forecasting models along with advanced logistic practices and traceability technologies by exploiting the increasing availability of historical information about drugs and patients. Accordingly, the paper presents a real case study within an Italian Hospital where the project team has gone through-out the phases of process discovery, use-cases identification and analysis to devise an integrated tool for supporting logistic operation. Results provide a complete identification and formalization of the drug management process, primary process users and functional requirements of such tool for supporting pharmaceutical last-mile logistic including simulation utilities within a hospital or hospital network setting. Final expected benefits from the project include the minimization of stocks and the effective and efficient management of medicines, with a consequent reduction in healthcare expenditure.

Keywords – Healthcare; Pharmaceutical Logistics; Hospital Information System; Simulation; LINFA project.

Paper type – Academic Research Paper

1 Introduction

Logistics function has gained a strategic role in the management of hospitals. As a matter of fact, hospital material management has been identified as one key cost driver to cope with steadily increasing healthcare costs in industrialized countries (Volland et al., 2017). This is particularly true for pharmaceutical logistics where supply chain management has become more and more complex in the last decades since it has to meet life-saving interests at sustainable costs. Solving this trade-off requires to enable the collaboration of different stakeholders such as pharmaceutical manufacturers, wholesalers, distributors, customers, information service providers and regulatory agencies.

‘Last-mile’ of logistics in this context refers to the challenge of the final movements of goods and services to the delivery or consumption point. The ‘last-mile’ of pharmaceutical goods tends to be less efficient and most problem-prone. On one side this is due to the variability and unpredictability of the patient’s needs and the rising demand for care (Wieser, 2011; Bourlakis et al., 2011), on the other to the high process fragmentation and the increasing touch-points that are often related to additional costs and complications. Nevertheless, emerging IT tools (such as Radio Frequency Identification, Enterprise Resource Planning, etc.), vertical organizations as well as the new disruptive technologies for last-mile logistics solutions (e.g., automatic guided vehicles) have risen consistent expectations of reducing the costs of distribution while guaranteeing adequate service levels.

In such an evolving context, scholars and practitioners widely agree that information systems and ICTs used to manage hospitals’ daily operations represent an important knowledge source (Kritchanchai et al., 2017) and possibly a prominent opportunity of improvement for the hospital practices (Mazzocato et al., 2010). Definitely, exploiting evidence from real-world data can enable effective support to demand planning with related purchasing decision-making process, internal/external communication and process coordination (e.g. supporting the information sharing between medical departments, hospital pharmacy, administrative office, external logistic partners, suppliers, etc.).

This work reports the experience gained during the project LINFA, whose aim is the development of a technological, information and organizational system to support the procurement process of medicines and medical devices within healthcare organizations. Such system integrates simulation and optimization algorithms and forecasting models along with advanced logistic practices and traceability technologies by exploiting the increasing availability of historical information about drugs and patients. Accordingly, the paper presents a real case study within an Italian Hospital where the project team has gone through-out the phases of process discovery, use-cases identification and analysis to

devise an integrated tool for supporting logistic operation. Results provide a complete identification and formalization of the drug management process, primary process users and functional requirements of such a tool for supporting pharmaceutical last-mile logistic including simulation utilities within a hospital or hospital network setting.

2 Background

Literature evidence shows that logistics is an interesting and much-debated field in healthcare. Nowadays, several strategic decisions related to logistics are constantly evaluated and implemented by hospital organizations, such as the centralization, decentralization and outsourcing of purchasing and supply management, sterilization, stock management or intra and inter-site transport, etc. Significant results in reducing errors, improving process quality and reducing wait times (Mazzocato et al., 2010), e.g. by implementing various tools for information management and methods of lean management allowing a continuous improvement approach, are available in the literature.

Past studies have analysed the circulation of physical flows by focusing on the management of pharmaceutical flows (Narayana, Pati, and Vrat 2014). Kim and Schniederjans (1993) identified three types of materials management systems traditionally used in healthcare: conventional, just in time, and stockless. The conventional approach coincides with the inventory-based structure and reorder-point logics and results in high costs of operations since the high involvement of hospital staff, the obsolescence costs, and the considerable space to devote to stocks. The widely spread pull-based JIT policy uses Kanban containers while the stockless system, also called "hybrid stockless", combines the "no-stock" logic with the conventional approach. In line with this approach, the distributor must supply high-volume items directly to departments while low-volume ones are delivered through the pharmacy or the central storage point. In so doing, the central warehouse is responsible for distributing these items to the final requiring departments in the due time and quantity (Rivard-Royer et al., 2002). Such a method has been implemented in a pilot project in Canada with contrasting results: it has led to a reduction in costs, improving inventory management and the efficiency of nursing activities, but it has also increased the workload of distributors (Rivard-Royer et al., 2002). Despite this evidence, authors worldwide seem to broadly agree that the introduction of JIT logics in hospitals can lead to significant reductions in general costs and costs related to the provision of services (Lai and Cheng, 2016; Law, 2016; Heinbuch, 1995; Aptel and Pourjalali, 2001; Bruno et al., 2018).

Aptel and Pourjalali (2001) compared French and American hospitals based on selected logistical parameters. Their study found differences in stock management and type of alliances between hospitals and between hospital and vendor. They observed that although hospitals provide critical services and require unexpected stock levels, JIT deliveries can be adopted to minimize inventory costs. Hospital wards, with tangible and high-volume products, represent the ideal terrain for the adoption of JIT systems in materials management, but problems may emerge in case of rural environments characterized by long distance distributor-hospital. It is easy to understand that stock-outs

of critical supplies could have catastrophic consequences in the hospital context (Lapierre and Ruiz, 2007; Pasquet et al., 2010).

One of the main problems of health logistics remains the information deficiency and scarce information exchange between subjects of the supply chain. This evidence has accelerated the need to make the healthcare SC more demand-driven, improving the standardization of processes and collaboration between all the involved parties (Krichanchai and MacCarthy, 2017). Indeed, the collaboration between different subjects was the starting point for the many optimization initiatives implemented in the inventory management area (Krichanchai and MacCarthy, 2017).

Miroslava et al. (2017) propose an empirical SCM classification in healthcare based on different characteristics of Hospital Supply Chain Management (HSCM). Evidence shows that establishing strategic alliances similar to the CPFR - Collaborative Procurement Forecasting Replenishment - and the VMI - Vendor Managed Inventory - is a relevant and investigated topic in healthcare literature. As a matter of fact, given the potential benefits of VMI, the approach has rapidly risen the attention of pharmaceutical companies, medical distributors and health providers including hospitals, which have started to implement it (Haavik, 2000; Bertolini et al., 2015; Turhan and Vayvay, 2009; Sari, 2008). While shifting the responsibility for the decision-making process to the supplier or another deputy, adequate information sharing on the demand and consumption is required to hospitals in order to support the central decision maker in defining the inventory management policy (Govindan, 2013; Mustaffa and Potter, 2009). Differently from VMI, CPFR extends the partnerships to several supply chain parties called to jointly manage the sales forecasting process. This multiplicity in responsibilities has so far tended to subordinate it to the VMI in the healthcare sector since the central decision-making process avoids the duplication of functions and allows the increase in organizational productivity of hospital staff allowing them to focus specifically on the core management of patient care. However, VMI is not a standard model in supply chain operations and its adoption is not obvious (Niranjan et al., 2012). Implementing this technique does not guarantee that the organization will attain the recognized benefits and the main challenges in the VMI adoption tend to differ significantly depending on the application context (Waller et al., 1999; Sari, 2008; Niranjan et al., 2012).

Although the difficulty in its implementation, the successful application of VMI in hospitals are relatively numerous in the literature (Sari, 2008). Haavik (2000) considered the implementation of VMI in US hospitals suggesting that its optimal use requires improvements in data collection and joint work with suppliers to establish an electronic communication system. Mustaffa and Potter (2009), on the other hand, analysing the Malesya health SC where this technique was adopted, have stated that, due to transport restrictions, the VMI can be an appropriate solution for the pharmaceutical industry and preferable in respect to other collaborative approaches, such as JIT and stockless approach.

3 The LINFA project and related objectives

LINFA is a research project funded by the Region Tuscany and carried out jointly by companies and research organizations with a focus on the regional drug logistics at the hospital level. The idea originating the project is to provide decision support tools to facilitate the activities of operators, who deal with the replenishment orders and inventory management in hospital departments while developing methodologies, practices and cooperation tools oriented to their extension and scale up.

Exploiting the availability of historical information about drugs and patients, the development of forecasting methods, together with optimization algorithms integrated into a shared technological platform, the project aims to deliver a technological, information and organizational system for improving the procurement process of medicines and medical devices within healthcare organizations. In so doing, it will make possible to move towards the minimization of stocks and the effective and efficient management of medicines, with a consequent reduction in healthcare expenditure.

Specifically, the LINFA system aims to integrate demand forecasting models and process optimization systems with advanced logistics practices and increased traceability with the use of RFID technologies by exploiting health and administrative data flows. To this purpose, LINFA would make available and shares information about departmental stocks, hospital stocks and the actual availability of drugs at regional central warehouses. LINFA also proposes an innovative approach for managing safety stocks by enabling a unitary virtual warehouse based on the real stocks stored in the several hospital departments and permitting the transfer of drugs between them.

Summarizing, LINFA aims to provide a tool:

- To monitor the current drugs stock and the expiring date of drugs;
- To support more efficient reorders thanks to the demand forecasting and optimization algorithms;
- To share stock information among the different hospital departments to deal with emergency orders;
- To record drugs withdrawals and exchanges between different departments.

4 Method

To discover and formalize functional requirements for the LINFA system and to fully understand the hospital staff needs, we accomplished a case study within an Italian Hospital. It goes through the following four phases:

1. **Analysis of the drug management process:** This phase aimed at understanding the current procedures of drugs procurement and inventory management and identifying potential criticalities and bottlenecks within the process. The analysis was carried out within an Italian Hospital by means of field observations and interviews with hospital staff. The resulting process model was represented through the BPMN language - see Chinosi & Trombetta (2012) for methodological details about this notation - and validated with hospital staff.

2. **Primary users' and functional requirements identification:** The aim of this phase was to identify LINFA system primary users within the hospital and to collect key information from their field experience. Identifying who will be involved in the information gathering process is important due to the input these individuals can provide regarding technological needs. The collection of functional requirements was conducted through interviews and focus groups with hospital staff. In so doing, we focused on two main questions: (i) How can the LINFA system contribute to the operational goal of each user? (ii) What features are desirable for achieving such result? The main outcome of this step was a list of functional requirements written in natural language.

3. **Formalization of functional requirements for the LINFA system:** In this step, we formalized the functional requirements previously identified, by using the UML (Unified Modelling language) language (Rumbaugh et al., 2017). In so doing, it was possible to automatize the traceability of requirements in the subsequent phases of LINFA system development. Specifically, we translated functional requirements into UML use case diagrams representing the relationships between primary users and system functionalities. Each use case was accompanied by text explaining its main purpose as well as what functionality is accomplished when it is executed. The use cases can capture the intended behaviour of the system being developed without specifying how the behaviour is implemented.

4. **Creation of a simulation environment to support decision making:** One of the most important features of the LINFA system is that it will embed forecasting and optimization models. The former, based on the actual drugs consumption, will allow forecasting the drugs needed for the incoming days. The latter, instead, will support the drug replenishment process, suggesting the type and quantity of drugs that should be ordered, in order to minimize inventory cost while at the same time achieving a satisfying service level. The optimization models will support periodic and continuous (s, S) inventory review policies, both in settings where wards do not exchange drugs each other's and in settings where the lateral transshipment of drugs across wards is allowed. The development of forecasting and optimization models is a complex and time-consuming process that usually involves several trials and error iterations. Given the criticality of the setting under study - hospital wards - it is clearly not advisable to implement inventory models without an accurate ex-ante assessment of the effects of their implementation. Such an assessment is most needed especially when the optimization inventory models used are deterministic (i.e. mixed integer programming models, as it this case). Replacing stochastic parameters with deterministic ones allows simplifying the model formulation but can create problems in terms of robustness of the solutions. In fact, when the actual value of the parameters (e.g. the amount of drug being consumed) significantly differ from the expected one, the optimization model's solution turns out to be sub-optimal. To overcome these problems and create a testing environment where the inventory models could be tested prior to implementation we developed a simulation environment. The simulation environment was developed in Rockwell Arena. The optimization and forecasting models were coded in Python and embedded in Arena via VBA.

5 Results

5.1 Analysis of the drug management process

The drug management process includes the following sub-phases: inventory management, drug procurement, drug receipt and storage, and control and reporting (reported in fig 1). Each sub-phase is detailed below.

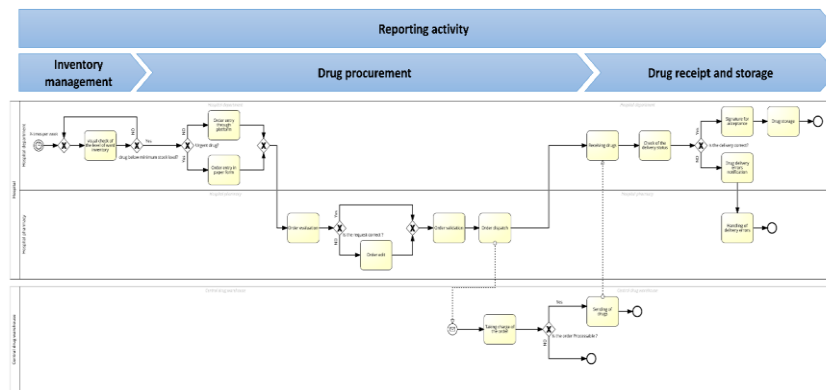

Figure 5: Drug management process: a BPMN diagram

- **Inventory Management:** At fixed intervals and independently by prescription, the head nurse or the nurses check the ward inventory level, manage drug's expiration dates, and quantify the drug needs. Such monitoring is usually carried out by a visual check. In addition, the evaluation of the number of drugs to be reordered is based on nurse personal experience and knowledge;
- **Drug procurement:** Regular requests for drugs are executed by the head nurse through a specific IS platform. On the other hand, urgent drug requests are drawn up in paper form. Each type of request is validated by the hospital pharmacy and sent to a central drug warehouse;
- **Drug receipt and storage:** Once drugs arrive in the ward, the head nurse checks the delivery status and signs for acceptance on the bill of delivery. Specifically, each incoming delivery is checked against the relevant purchase order and each container physically verified, e.g. by the label description, batch number, type of material or pharmaceutical product and quantity. The storage of drug packages on the appropriate shelves is handled by nurses and nursing assistants. The drug packs order criteria may vary from department to department. In the case of incomplete or incorrect delivery, the hospital pharmacy has to define a new replenishment request;
- **Control and Reporting:** The hospital pharmacy periodically monitors and measures the performance of hospital departments as concerning drugs management.

Interview and focus groups with process owner and participants have shown that the drug management process suffers from several criticalities. The lack of control over actual consumptions, together with the unpredictability of the demand for healthcare

services, causes high levels of ward inventory and, then, considerable holding costs, obsolescence risk, and a negative effect on the hospital service level. In addition, drug replenishment requests are usually independent from real needs and quantities are determined based on nurse personal experience. This often results in oversized and too frequent orders. Drugs are often stocked without a standard codification and may be placed in different positions, thus determining an inefficient space utilization and code retrieval. Consequently, applying a First-In-First-Out (FIFO) picking rule is also difficult. Accordingly, nurses and nursing assistants tend to be overly involved in logistics duties, reducing the time available for medical activities.

5.2 Primary users' and functional requirements identification

Primary users within the hospital who will be using the LINFA system include:

- *Hospital pharmacy*, which validates, sends to, and reminds the central warehouse the drug requests (regular requests, urgent requests, and requests for drugs not included in the hospital therapeutic handbook) elaborated by each hospital department. In addition, the pharmacy evaluates and monitors the performance of the drug procurement process of all hospital departments. It periodically analyses purchased drugs;
- *Doctor*, which takes care of the prescription of the patient therapy in the medication record. In addition, he sends to the pharmacy requests for drugs not included in the hospital therapeutic handbook;
- *Head nurse*, which is responsible for the procurement, storage, and preservation of pharmaceutical products at the departmental level;
- *Nurse*, which is deputy to check the availability of the prescribed drugs on the medication cart and notify the missing ones from the ward inventory. Nurse usually manage the drug delivery and administration to patients. Also, they periodically check the level of ward inventory and manage expiration dates of drugs. If delegated by the head nurse, they can take care of the storage and preservation of pharmaceutical products.

We defined a set of 17 functional requirements according to the primary users. For the sake of brevity, table 1 shows just an excerpt of such list.

Table 3: An excerpt of the functional requirements list

Functional requirement	Description
<i>Drug stocks visualization</i>	The system must provide real-time information about the quantity and type of drugs in stock, keeping track of the batch number and the expiration date.
<i>Drug stocks update</i>	The system must allow the updating of the drugs in stock, as a result of drug loading (storage of drugs) and unloading (administration to patients).
<i>Notification of a drug new availability</i>	The system must notify the unavailability of the requested drug and the failure to process the order, indicating a potential date for drug availability.
<i>Order status display</i>	The system must allow the tracking of the order, providing information about its status (e.g., the complete or partial execution of the order)

5.3 Formalization of functional requirements for the LINFA system

The overall use case diagram including all functional requirements identified in the previous step is shown in figure 2. Some use cases, such as *drug stocks update* and *order status display*, incorporate the behaviour of other use cases as fragments of their own behavior. Others (e.g., *order edit*) are an incremental extension to a base use case (e.g., *order validation and dispatch*).

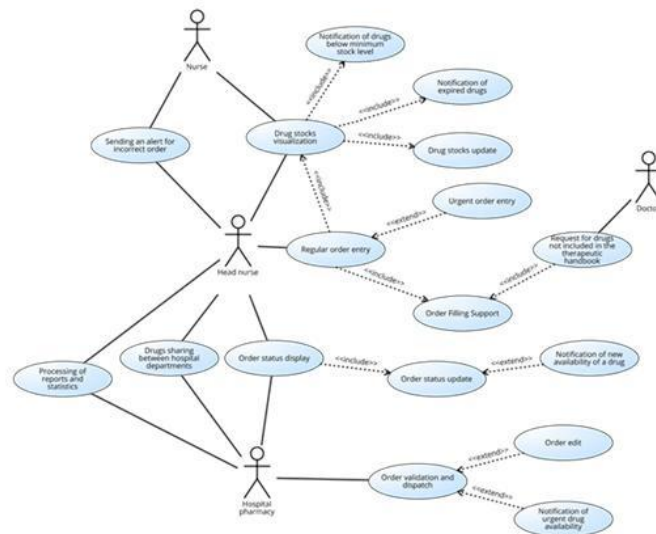

Figure 6: Overall use case diagram

Each use case was also translated into structured textual specification format to identify the temporal sequence of behaviors and the state of the system and of the actors before and after the execution of that use case. As an example, the textual specification of the use case "*Notification of urgent drug availability*" (Table 2) is given below.

Table 4: Textual specification of the use case "Notification of urgent drug availability"

Use case name	Notification of urgent drug availability
Actor	Hospital Pharmacy
Pre-conditions	The operator must be logged into the system. The system must have notified an urgent order
Basic flow of events	<ol style="list-style-type: none"> 1. The operator displays order items; 2. The operator selects the drug code and enters it in the search field; 3. The system shows the list of departments where the drug is available with the related quantity;
Extensions	<ol style="list-style-type: none"> 2.a The system is not able to find any correspondence with the parameters entered <ol style="list-style-type: none"> 2.a.1. The operator checks the text correctness in the search field. 3.a The system shows a null result for the search <ol style="list-style-type: none"> 3.a.1 The system shows the appropriate message and terminates the operation.
Post-conditions	The system shows the list of hospital departments with drug availability

5.4 Creation of a simulation environment to support decision making

The simulation model reproduces the operations of one of more hospital wards and it is subdivided into three sub-models.

The first one replicates the patients' arrival process. For each simulated day, it creates a certain number of patients and assigns to each patient several attributes, including their therapy. The therapy defines the patient's length of stay and the type and quantity of drugs she needs for each day of her stay. Upon arrival, patients are accommodated in a ward and seize a bed, which is released at the end of the patient's stay.

The second sub-model replicates the administration process. In this sub-model, a nurse entity carries out a "patient tour" and administers each patient the drugs she needs. Upon administration, the stock level of the administered drug automatically decreases. If a drug is not available, the nurse issues a rush order, which will be fulfilled with a short lead time. If later transshipment is allowed, before issuing a rush order, the nurse will try to borrow the drug from another ward, and in case of success she will issue a regular order and give back the borrowed drug as soon as it becomes available. In case of continuous (s, S) inventory review policies, following the tour, the nurse issues (regular) orders to restore a stock level of S for each drug whose stock level went below s. The levels (s, S) are determined at the beginning of the simulation run by means of an optimization model and can be updated during the run based on the actual drugs consumption.

The third sub-model allows simulating the implementation of periodic review policies. In this sub-model, an auxiliary entity, every d days, instantiates an optimization model that, based on the current stock levels and on a forecast of the drugs that will be needed in the short term, determines for each drug the number of boxes to order and the day when the order should be placed. The simulator allows to keep track of the number of stockouts, the number of orders issued, the stock level, the number of transshipment and so on. Hence, it will be used to select the more promising optimization models and to refine them prior to implementation.

6 Conclusions

This work reports some preliminary outcomes from the LINFA project. Specifically, we discovered and formalized a set of functional requirements for the LINFA system that fully meet the needs of the hospital staff. In so doing, we conducted field observations and interviews with the hospital staff of an Italian hospital to collect key information from their field experience. In addition, given the criticality of the setting under study - hospital wards – we developed a simulation environment to allow an ex-ante assessment of the effects of the implementation of optimization and forecasting models supporting the drug replenishment process. Final expected benefits from the LINFA system include:

- Reduction of errors and times for drugs reorders;
- Reduction of delivery time;
- Reduction of expiring drugs in hospital departments;

- Improvement of the overall procurement and cost awareness at every level of the supply chain;
- Support to monitoring and quick identification of anomalous situations;
- Optimization of transit points from the central warehouse to the hospital departments;
- Reduction of drugs stock costs and needed space in hospital departments.

Future project steps will concern the design and test of demand forecasting models and optimization algorithms, the conceptual architecture design, the design of the interfaces, the development of a test version, and the field testing.

Abstract

In Italy, the healthcare sector is the one that absorbs the largest economic resources, immediately after Social Security, and, hence, it has been coping with an enduring reforming process. The latest health reform, namely DM 70/2015, suggested the adoption of the Hub & Spoke model for the redesign of regional hospital networks. The aim of this intervention was to have a capillary presence of less specialized disciplines, concentrated at the Spokes, in order to improve users' accessibility conditions. In this paper, we deal with a particular case study concerning the STEMI (ST-Elevation Myocardial Infarction) network of the province of Naples, in Southern Italy. In particular, we perform a spatial analysis in order to assess the impact on users' accessibility determined by the occurred reconfiguration. Moreover, we also propose a mathematical programming model aiming at producing alternative reorganization scenarios to improve spatial accessibility. Our results confirm that users effectively benefit from the reorganization process but also that further, and significant improvements, are possible. In particular, our computational experiments reveal that a strategic intervention oriented at redistributing capacities, i.e. the supply of hospital beds, among the existing facilities could lead to averagely better and even more equitable accessibility conditions.

Paper type – Academic Research Paper

1 Introduction

Health care access is concerned with the timely and safe entry process of persons to the health-care delivery system and with the factors influencing it. Penchansky and Thomas (1981) defined health care access as a multi-faceted concept expressing the "degree of fit" between the clients and the health care system according to five dimensions: availability, accessibility, accommodation, affordability and acceptability. In particular, accessibility refers to the relationship between the location of health suppliers and the location of clients, involving both spatial (e.g. travel times, distances) and non-spatial factors (e.g. demographic and socioeconomic variables). In this paper, we are interested in spatial accessibility, which, according to Wang (2012), can be defined as the relative easiness of a client to reach health care facilities from a given location.

Research on this topic has been flourishing along the years. In the extant literature, a significant number of scientific papers have been devoted to propose methodological approaches to measure spatial accessibility to health services with applications to real case studies. Yin et al. (2018) employed a geographically weighted regression model involving social, economic and natural factors, to assess inequalities in the spatial accessibility to health care facilities in China. Shin and Lee (2018) analysed the spatial accessibility to the case of the Korean emergency system proposing an improvement of the floating catchment area method by including patients' inherent resistance to travel. Mayaud et al. (2019) deployed a hybrid competition-based approach to assess future pressures in accessibility to essential services in the case of Surrey, a growing city in Canada. Higgs et al. (2019), instead, used a GIS-based approach to integrate temporal availability of services in assessing spatial accessibility to primary health care in Wales. For an extensive review on the topic, interested readers may refer to Neutens (2015).

As Wang (2012) highlights, measurement is not the only issue at hand when dealing with spatial accessibility. In fact, as the same author argue, decision-makers can benefit of optimization models for the strategic siting of health care facilities. Spatial accessibility is typically embedded in optimization models by means of median or covering objectives. The former seeks to minimize the average users-to-facility distances. The latter aims at maximizing the total demand captured within predefined distances from the located facilities. Examples can be found in the studies by Burkey et al. (2012) and Smith et al. (2013). Alternatively, when the focus is on the total management costs, accessibility conditions can be translated in to specific constraints to be satisfied. This is, for instance, the case of the reorganization of existing networks, as in the works by Guerriero et al. (2016) and Bruno et al. (2018).

In this paper, we perform an analysis of the effects produced on users' spatial accessibility due the reorganization of an existing hospital network in the province of Naples, in Southern Italy. Moreover, we also propose a mathematical model aiming at optimally redistributing the capacities, i.e. the supply of hospital beds, among the hospitals of the network to show which interventions could be planned to further improve users' accessibility conditions.

Notably, Ahmadi-Javid et al. (2017) argue that only few papers considered these type of decisions. These studies, however, either show numerical examples to validate their model (Chu and Chu, 2000) or solve the problem at the level of municipalities (Oliveira and Bevan, 2006; Mestre et al. 2012) thus making use of aggregated data. Hence, there is no evidence of studies focused on municipalities' census tracts, where the effects in terms of accessibility can be better highlighted and even measured, and that are at the core of the developments we present in this work.

The remainder of the paper is organized as follows. In Section 2 we describe our problem. In Section 3, we present our case study and the results of the performed spatial analysis. In Section 4 we present the mathematical model we propose for the reorganization of the network while, in Section 5, we discuss the main findings of the realized computational experiments. Conclusions and directions for further research follow in Section 6.

2 Description of the problem

In Italy, the healthcare sector is the one that absorbs the largest economic resources, immediately after Social Security (OECD, 2017). Hence, in recent years, it has been coping with an enduring reforming process. Interventions adopted by the Central Government, mainly oriented to reshape or introduce new ceilings to the overall spending in health services, positively affected the regional deficits, being reduced by 80% in the time span 2007--2016 (Italian Ministry of Economy and Finance, 2018). As a consequence, the latest health reform, namely DM 70/2015 (Italian Ministry of Health, 2015), marked a significant shift towards a rationalization paradigm. In particular, it required Regions to gradually reduce two main parameters: the hospitalization rates and the hospital beds-to-population ratio. Moreover, it suggested the adoption of the Hub & Spoke model for the redesign of the time-dependent (emergency) hospital networks. This model shapes the network according to a two level hierarchical structure: the Hub concentrates all the major technologies and specialized teams to deal with high and medium complexity cases referring to all medical specialties; the Spoke, instead, offers medium and low complexity treatments for the main medical and surgical disciplines.

In this paper, we analyse a specific problem concerning the case of the STEMI (ST-Elevation Myocardial Infarction) network in the province of Naples, in Southern Italy, where a significant reconfiguration process began due to the introduction of the regional decree DCA n.33/2016 (Official Bulletin of the Campania Region, 2016). that implemented DM 70/2015. According to the above regulations, hospitals belonging to the STEMI network are differentiated on the basis of the offered disciplines: i) *Spokes*, offering only Coronary Intensive Care Unit (CICU); ii) *First-level Hubs* (HUB-I), offering CICU and Hemodynamic; iii) *Second-Level Hubs* (HUB-II), which, in addition to the previous mentioned services, include cardiac surgery specialization (CS).

The adoption of the Hub & Spoke model is supposed to contribute in twofold manner: on the one hand, this model envisages the centralization of the most complex health services into fewer facilities, thus fostering the achievement of economies of scale and a

greater appropriateness of care; on the other, it allows a more capillary diffusion of lower complexity services to improve users' accessibility conditions.

In this paper we try to investigate whether this latter objective was accomplished. Therefore, our scope is to perform an accessibility analysis of users to the Spokes of the network that is, in practice, evaluating the spatial accessibility to the lowest level discipline of the network (CICU). To this end, some notation is required. With reference to a given study area, we consider a set I of nodes where potential users are located and a set J of hospitals. Each hospital j has a limited number of available beds, which we denote by Q_j . We also indicate by a_i the demand at node i and by c_{ij} the distances between pairs of nodes i and j . Finally, in order to describe the allocation mechanism of users to hospitals we introduce the binary coefficient α_{ij} , equal to 1 if demand coming from node i is served by facility j (0 otherwise). In particular, considering that we are dealing with an emergency service and relying upon the existing literature (Neutens, 2015), it is reasonable to assume that demand coming from node i , namely a_i , is served by the closest facility. Mathematically, we have:

$$\alpha_{ij} = \begin{cases} 1 & \text{if } c_{ij} = \min_{k \in J} \{c_{ik}\} \\ 0 & \text{otherwise} \end{cases}$$

The application to the selected case study is discussed in the next section.

3 Case study

In this section, we report on the spatial analysis performed on the selected case study. First, we describe the data test used. Afterwards, we discuss the main results obtained.

3.1 Test data

In Italy, at the regional level, the organization of the STEMI network is delegated to local bodies, named Aziende Sanitarie Locali (ASL), whose competence areas coincide with the single provinces. Hence, we select the province of Naples, the chief-town of the Region, as an appropriate case study to our problem. To this end, we discretized the location space, comprising 92 municipalities, into 10,711 territorial units, corresponding to the provincial census tracts (ISTAT, 2011) and we assumed that all users located in a census tract are concentrated in its centroid (Figure 1).

Figure 1 – Province of Naples: Census tracts' centroids

Since our goal is to assess the impact on users' accessibility conditions determined by the occurred changes in the network, hereinafter we present a comparison between the configurations of the STEMI network before and after the introduction of DCA n. 33/2016, which we denote, respectively, by Scenario 1 and Scenario 2. The characteristics of the two scenarios are summarized in Table 1. For each facility, labelled with a unique ID code, we report the number of beds per discipline. Since Hemodynamic (H) does not require any bed, we just highlight its presence (✓) at the considered hospitals. In order to enhance an easier comparison with the current configuration, the last column reports the "Type" of each hospital (S, HUB-I, HUB-II) according to the guidelines set by DCA n. 33/2016. As it is shown in the Table the reorganization process involved an increase in the number of hospital beds for both CICU (from 117 to 146) and CS (from 56 to 79) and in the number of hospitals offering Hemodynamic (from 7 to 10), as well as an increase in the total number of activated hospitals (from 16 to 19). In both the scenarios, demands a_i are assumed to be proportional to the population p_i living in each census tract by means of a standard demand rate δ , whose value is indicated in DCA n. 33/2016. The latter is expressed in terms of the need of hospital beds per 1,000 inhabitants. In particular, $\delta = 0.0392$.

Finally, distances c_{ij} between the centroids and the hospitals are determined as the shortest paths on the road network.

3.2 Analysis of the results

In order to assess the impact of the described reconfiguration on users' accessibility, we calculate the cumulative distributions of users' distances from their closest hospital in the two scenarios. In practice, we define an accessibility function $\gamma = f(c) \rightarrow [0,1]$, representing the percentage of users γ having a distance from their closest facility not exceeding c . Conversely, $c = f^{-1}(\gamma)$ represents the accessibility condition of a given percentage γ of users, i.e. the distance c at which these users have at least one facility. Figure 2 depicts the distributions obtained in the considered scenarios. By setting, for instance, $\gamma = 0.80$ we observe that, in Scenario 1, 80% of users have the closest hospital within 5.66 km, while in Scenario 2 this value is reduced to 4.54 km. In general, we observe that the distribution yielded by Scenario 2 "dominates" the one yielded by Scenario 1. This, in fact, reveals an average improvement in accessibility (see also Table 2). However, despite the increased number of hospitals in the network, the maximum accessibility distance, i.e. $c(\gamma = 1)$, remains equal to 17.67 km. Therefore, we can deduce that the transition towards Scenario 2 did not really affect the accessibility conditions of the least well served users, i.e. those already having the worse accessibility conditions in Scenario 1.

Figure 2 – Comparison of accessibility function between the two scenarios.

Table 2 – Accessibility distances by the percentile of users

γ		0,00	0,10	0,20	0,30	0,40	0,50	0,60	0,70	0,80	0,90	1,00
c [km]	Scenario 1	0,02	0,91	1,40	1,99	2,69	3,39	4,07	4,79	5,66	6,90	17,67
	Scenario 2	0,02	0,80	1,26	1,68	2,17	2,72	3,23	3,80	4,54	6,14	17,67

Moreover, it is worth noting that the above improvement is just potential rather than actual. In fact, our allocation mechanism does not consider the capacity of the hospitals. In Table 3, we calculate the differences between the estimated demand A_j ($\sum_{i \in I} \alpha_{ij} a_i$, $j \in J$) and the capacity Q_j per hospital in the considered scenarios, where A_j expresses the total number of beds needed by hospital j to satisfy its nearest users. Hence, if positive, the above difference indicates the number of hospital beds (Δ_j) to be activated at each hospital in order to guarantee all the users the best accessibility conditions. The penultimate row of the Table reports on the total estimated demand, the total number of available beds, i.e. the actual capacity of the network, and the difference between these two indicators. If positive, the latter indicates the number of hospital beds (Δ_{tot}) needed to serve the overall demand. These values are reported at the bottom of the Table.

Table 3 – Supply (capacity) vs. demand of hospital beds in the analysed scenarios

ID	Scenario 1				Scenario 2			
	A_j	Q_j	$A_j - Q_j$	Δ_j	A_j	Q_j	$A_j - Q_j$	Δ_j
1	4	8	-4	0	4	8	-4	0

18	-	-	-	-	13	10	3	3
19	-	-	-	-	5	6	-1	0
20	-	-	-	-	11	6	5	5
21	-	-	-	-	9	6	3	3
TOTAL	121	117	4	45	121	146	-25	28
Δ_{tot}	-	-	4	-	-	-	0	-

Our findings show that, in Scenario 2 the activation of new hospitals and the increase in the total available capacity rendered the network able to satisfy all the potential users. In fact, differently from Scenario 1, it now results $\Delta_{tot} = 0$. However, 9 out of 19 hospitals (hospitals 6, 7, 9, 11, 12, 14, 18, 20, 21) would require the activation of new hospital beds to serve their closest users. Although this value turns out to be globally reduced from 45 to 28, thus denoting a positive impact of the undertaken reorganization actions, it should be noted that the oversupply of hospital beds exhibited by the remaining facilities could have called for an adequate capacity redistribution. In this regard, it is particularly explanatory the case of hospital 2, where both the increase of the capacity and the redistribution of the demand determined an excessive oversupply of hospital beds (from 11 to 21) that might be adequately spread among the other hospitals according to the estimated demands. Similar considerations can be drawn for Scenario 1.

In conclusion, our analysis reveals that obtaining better accessibility conditions underpins the adoption of strategic decisions aiming at reconfiguring the existing capacities of the network. To this end, we propose solving a mathematical programming model that we present in the next section.

4 A mathematical model for the reorganization of the hospital network

To formulate the model, in addition to the already introduced parameters, the following notation is required:

- Q_{min} minimum capacity, in terms of hospital beds, to be offered at any hospital;
- Q_{max} maximum capacity, in terms of hospital beds, to be offered at any hospital;

Q_{tot}	current total capacity of the network;
f_{ij}	ost for allocating a unit of demand in i to hospital j ;
g_j	cost for reconfiguring, i.e. expanding or shrinking, a unit of capacity at hospital j .

The decision variables are as follows:

x_{ij}	binary variable equal to 1 if demand in i is allocated to hospital j , 0 otherwise;
z_j^+	binary variable equal to 1 capacity at hospital j is expanded, 0 otherwise;
z_j^-	binary variable equal to 1 capacity at hospital j is shrunk, 0 otherwise;
Δ_j^+	non-negative integer variable indicating the increase in the capacity at hospital j ;
Δ_j^-	non-negative integer variable indicating the shrinkage of the capacity at hospital j .

The model is then formulated as follows:

$$\begin{aligned}
\text{minimize} \quad & \sum_{i \in I} \sum_{j \in J} f_{ij} a_i c_{ij} x_{ij} + g_j (\Delta_j^+ + \Delta_j^-) & (1) \\
\text{subject to} \quad & \sum_{j \in J} x_{ij} = 1 & \forall i \in I & (2) \\
& z_j^+ + z_j^- \leq 1 & \forall j \in J & (3) \\
& \sum_{i \in I} a_i x_{ij} \leq Q_j + \Delta_j^+ - \Delta_j^- & \forall j \in J & (4) \\
& Q_j + \Delta_j^+ - \Delta_j^- \geq Q_{min} & \forall j \in J & (5) \\
& Q_j + \Delta_j^+ - \Delta_j^- \leq Q_{max} & \forall j \in J & (6) \\
& \Delta_j^+ \geq z_j^+ & \forall j \in J & (7) \\
& \Delta_j^+ \leq (Q_{max} - Q_j) z_j^+ & \forall j \in J & (8) \\
& \Delta_j^- \geq z_j^- & \forall j \in J & (9) \\
& \Delta_j^- \leq (Q_j - Q_{min}) z_j^- & \forall j \in J & (10) \\
& \sum_{j \in J} Q_j + \Delta_j^+ - \Delta_j^- = Q_{tot} & & (11) \\
& x_{ij}, z_j^+, z_j^- \in \{0,1\} & \forall i \in I, j \in J & (12) \\
& \Delta_j^+, \Delta_j^- \in \mathbb{N} & \forall j \in J & (13)
\end{aligned}$$

The objective function (1) minimizes the sum of the allocation costs, weighted by the demands a_i and of the costs occurring for the reorganization of hospital beds. Constraints (2) guarantee every demand to be served by exactly one hospital. Constraints (3) assure that capacity at each hospital j can be either expanded or shrunk. Constraints (4) ensure that the total demand served by each hospital j does not have to exceed the available capacity of the hospital itself, given by initial capacity therein installed, net of the occurred expansion or shrinkage. Constraints (5)-(6) set, respectively, a lower and an upper bound to the available capacity at each hospital. Constraints (7)-(8) impose that, if an expansion decision is taken at hospital j , the number of hospital beds to be added can be, at most, equal to $Q_{max} - Q_j$, i.e. the residual capacity to reach the upper bound Q_{max} . Similar considerations apply to shrinking decisions, as it is ensured by Constraints (9)-(10). Constraint (11) guarantees the invariance of the total available capacity of the

network. Finally, Constraints (12) – (13) define the domain of the introduced decision variables.

5 Experimental results

Model (1)-(13) is, in fact, a bi-objective model as it requires the combined minimization of two inherent but, at the same time, conflicting goals: allocation costs and capacity reconfiguration costs. Therefore, the adequate setting of parameters f_{ij} and g_j is a critical issue as it implies a priority system between the considered objectives.

We first solve the model by imposing $f_{ij} = 1, g_j = 0, \forall i \in I, j \in J$. With this setting, we are implicitly assuming the attitude of a decision maker interested in optimizing only one objective, i.e. the allocation costs and, hence, the average users' accessibility. Accordingly, our model returns in output the maximum number of hospital beds Δ^* to be reconfigured in order to optimize the latter objective. In our case, we obtain $\Delta^* = 52$.

Of course, a decision maker who is careful about the occurring reconfiguration costs might be interested in alternative reorganization scenarios representing trade-off solutions between the two objectives. Hence, our goal is to produce a range of feasible reorganization scenarios that may allow the decision maker to evaluate the obtainable improvement in accessibility conditions against a fixed proxy cost for capacities redistribution. To this end, we add the following Constraint:

$$\sum_{j \in J} \Delta_j^+ + \Delta_j^- \leq \Delta \quad (14)$$

and solve model (1)-(14) for different values of Δ , with $\Delta < \Delta^*$. In particular we progressively reduce Δ from 52 to zero with a pace equal to two. Clearly, we keep considering the already introduced setting for cost parameters. As an example, we report in Table 4 information on the distributions of the accessibility distances yielded by a sample of values of Δ .

Table 4 – Accessibility distances by the percentile of users for different values of Δ

γ	0,00	0,10	0,20	0,30	0,40	0,50	0,60	0,70	0,80	0,90	1,00	\bar{c} [km]
$\Delta = 52$	0,98	2,20	2,59	3,33	4,08	4,87	5,44	6,67	7,68	9,46	16,01	6,23
$\Delta = 40$	0,98	2,20	2,59	3,33	4,28	4,87	5,99	6,73	8,17	9,46	16,01	6,34
$\Delta = 30$	0,98	2,23	2,59	3,33	4,34	5,06	6,07	6,79	8,45	10,55	16,01	6,64
$\Delta = 20$	0,98	2,23	2,59	3,33	4,34	5,13	6,48	7,43	8,74	11,11	21,82	6,95
$\Delta = 10$	0,98	2,20	2,59	3,33	4,87	5,80	6,79	8,43	9,46	12,06	24,52	7,50
$\Delta = 0$	0,98	2,20	3,03	4,06	5,13	6,31	6,82	8,45	9,45	12,65	23,14	7,65

Solution obtained with $\Delta = 0$ represents the status quo. Hence, one can notice how the current accessibility conditions could be improved by means of capacities redistribution. The average accessibility distance (\bar{c}) results to be reduced by almost 1.40

km for $\Delta = \Delta^* = 52$. However, significant reduction in the average accessibility distance could be obtained also for lower values of Δ . For instance, we can find an improvement of about one km, i.e. 13.07 % less than the status quo, by setting $\Delta = 30$. Interestingly, relevant results are obtained in the improvement of the accessibility conditions of the least well served users. Indeed, the maximum accessibility distance, i.e. $c(\gamma = 1,00)$ presents a strong decreasing trend with the increase of Δ , being potentially reducible by 30.81% (from 23.14 km to 16.01 km). Similar trends are found for other values of γ , although they tend to be less intense as γ decreases. This result is consistent with the fact that the performed reconfiguration of the network did not really affect the accessibility conditions of the least well served users, as we showed in Section 3. In Figure 3 we summarize the overall computational experience by showing, for each value of Δ , the quartiles of the distributions of the accessibility distances. In the context of the analysed case study, our consolidated recommendation to the decision maker would be to adopt the solution obtained by setting $\Delta = 30$. Indeed, looking for a trade-off solution between the considered objectives and beyond the average improvement already discussed, this solution corresponds to the lowest value of Δ which minimizes the maximum accessibility distance.

Figure 4 – Quartiles of the distributions of the accessibility distances by Δ

6 Conclusions

In this paper we analysed the case study of the STEMI network of the province of Naples, in Southern Italy, where a significant reorganization process occurred after the introduction of DM 70/2015. The main aim of this reform, which led to an increase of the number of hospitals in the network as well as of the total supply of hospital beds, was to improve users' accessibility conditions. Hence, we performed a spatial analysis to investigate whether this objective was accomplished. Our results show that, although the average accessibility conditions were actually improved, these effects were rather limited for the least well served users, i.e. those that were already far from the closest hospital

before the occurred changes. Moreover, we also find out that further improvements could have been obtained by adequately redistributing capacities among the hospitals of the network. Therefore, we proposed solving a mathematical programming model aiming at finding a trade-off solution between two opposing needs: improving accessibility and containing reconfiguration costs. Based on the realized computational experiments, we can conclude that, with equal resources (i.e. with the same number of facilities and with the same number of newly activated hospital beds), it would be possible to modify the current configuration of the network obtaining a considerable improvement of the users' accessibility conditions.

Further developments of the work suggest the adoption of different spatial interaction models to reproduce users' behaviour and to assess spatial accessibility. Furthermore, the hierarchical structure of the considered network may also call for a more comprehensive analysis extended to all its disciplines. Finally, comparative studies with other provinces could also represent promising research directions.

Abstract

“Healthcare is a knowledge driven process” (Shahmoradi et al 2017) and “the effective exploitation of knowledge in building decision-making tools” (Patel et al, 2009) is gaining attention. To this respect, both artificial intelligence and the use of specific algorithms may play a key-role. The present paper aims at discussing the potential use of fuzzy logic algorithm, to be a supportive tool in the clinical decision-making process, in particular with regard to patients with renal impairment.

After a literature review, which enable to make allowance for the principal factors involved in a clinical decision-making process led by artificial intelligence, and by fuzzy logic approach specifically, two questionnaires were administered to clinicians, working in an Italian Hospital. Two algorithms were built. Algorithm 1 (ALG 1) was implemented to perform “conservative” decision-making whilst the Algorithm 2 (ALG 2) was thought to simulate a less cautious decision-making process. Inferential analyses were performed: i) the existence of correlations among variables were investigated; ii) a regression model was implemented in order to test the hypotheses and reveal the predictors of the dependent variable (i.e. degree of diagnostic accuracy). Both algorithms showed that only information quality (algorithm 1: $\beta=0.389$; $p<0.001$; algorithm 2: $\beta=0.370$; $p<0.001$) was required to approximate the diagnostic accuracy of a decision-making process supported by artificial intelligence tools (Algorithm 1: Adjusted $R^2 = 0.346$; Algorithm 2: Adjusted $R^2 = 0.407$).

Keywords – Fuzzy logic, contrast medium, reduced renal functioning, heuristic models, decision-making process

Paper type – Academic Research Paper

1 Introduction

Taking rational and adequate decisions, according to the literature suggestions (Von Neumann, 2007), thus maximizing the expected utility of such decision, represents the major challenge of the real-life decision-making processes. Risk and decision analyses are central tools of contemporary healthcare governance, in contexts ranging from the appraisal of novel healthcare technologies, to climate change adaptation and mitigation planning (MacGillivray, 2017).

On the one hand, when individuals make decisions, their rationality is limited by the tractability of the decision problem, the cognitive limitations of their minds, and the time available to make the decision (Simon, 1955), seeking a satisfactory solution rather than an optimal one. On the other hand, Kahneman and Tversky (2013) demonstrated that individuals would take decisions on the basis of heuristic models, that are simple and efficient rules which people often use to form judgments and make decisions. In particular, they are mental shortcuts that usually involve focusing on one aspect of a complex problem and ignoring other. Both artificial intelligence and the use of specific algorithms, play a key-role in the decision-making process.

Artificial intelligence “aims to mimic human cognitive function” (Jiang et al, 2017), such as “the ability to reason, discover meaning, generalize, or learn from past experience” (Bali et al 2018). In this view, medicine in general, is one of the most promising application area (Yu et al, 2008; Dilsizian & Siegel, 2013).

“Healthcare is a knowledge driven process. Thus, knowledge management, and the tools to manage knowledge in healthcare sector, are gaining attention” (Shahmoradi et al 2017). Knowledge management refers to the “exploitation and development of knowledge assets of an organization” (Metaxiosis et al, 2003), and the so-called “real world data” could be new sources of information. To this respect, in their position paper Patel et al (2009) recognize that “the effective exploitation of knowledge in building decision-making tools and in extracting information from the data” is an important point, in the field.

According to Wahl et al (2018), a classification of subfields of artificial intelligence regarding health’s domain lacks. Nevertheless, the authors put forward five main areas of interest, such as expert systems, machine learning, natural language processing, automated planning and scheduling, image and signal processing. The areas acknowledged as most frequent or powerful in the checked literature area fuzzy expert systems, image and signal processing and machine learning (Yu et al, 2018; Jiang et al, 2017; Pannu, 2015; Gürsel, 2016; Ramesh et al, 2004; Chan et al, 2018).

In the present paper, the attention will be place on the fuzzy expert system. The rationale behind this approach is that fuzzy expert system are knowledge-based system, and knowledge management field may gain advantages to use their techniques to “support the codification of the knowledge in the knowledge management systems” (Metaxiosis et al, 2003). Moreover, the “fuzzy nature of the medical decision-making process” (Grüsel, 2016) requires a methodology able to include the “vagueness required to describe complex systems” (Vitez et al, 1996).

In this view, the present paper aims at discussing the potential use of fuzzy logic algorithm, to be a supportive tool in the clinical decision-making process, in particular with regard to patients with reduced renal functionality. As iodinated contrast medium used to perform CT, angiographic, and coronary angiography is nephrotoxic, patients with renal impairment are likely to develop acute renal failure, with all the related adverse events and complications, such as the dialysis. Therefore, the paper aims at proposing the results achieved by the implementation of a fuzzy logic algorithm (a sort of many-valued logic, in which, the truth values of variables, may be any real number between 0 and 1 inclusive), to be used for the definition of the proper dose of contrast agent to be administered to such a patients. Accordingly, this research seeks to demonstrate whether the fuzzy logic algorithm may assist clinicians in improving clinical decisions toward patients with renal impairment.

2 Literature review

Studies in the field of cognitive psychology claim that “the reasoning skill of clinicians is imperfect (and) radiologists are prone to cognitive errors” (Jager et al, 2014). Cognitive errors in the radiology practice stand at 20-40% of total radiologic errors (Brady, 2017). By focusing on diagnostic errors in internal medicine, Graber et al (2005) concluded that cognitive errors lead to diagnostic errors in 74% of cases compared with the system-related ones that are less frequent (65%). Therefore, “cognitive error is pervasive in clinical practice” (O’Sullivan & Schofield, 2018), and the importance of those factors needs to be taking into account for understanding the clinical decision-making as a whole.

Lee et al (2013) outlined cognitive errors as a set including faulty perception, failed heuristic and biases. “A significant part of physician’s cognitive effort is properly selecting and utilizing pertinent heuristic approaches” (Patel et al, 2009). Heuristics are often referred to, as mental short cuts (Thompson & Dowding, 2004), relying on “a subconscious integration of somewhat haphazardly gathered patient data, with prior experience rather than on a conscious generation of a rigorous differential diagnosis that is formally evaluated, using specific data from the literature”(McGee, 2018). Likewise, cognitive biases cause a faulty medical reasoning, as they are “the results of psychologic distortions in the human mind, which persistently lead to the same pattern of poor judgment, often triggered by a particular situation” (Lee et al, 2013).

Dilsizian & Siegel (2013) listed five cognitive biases likely to feature in faulty clinical reasoning, and state that “(...) artificial intelligence systems have the potential to be less susceptible to these biases and, despite their limitations, can serve in a complementary role to human decision makers”. For instance, Saifi et al (2013) described the adoption of artificial intelligence to reduce improper use of diagnostic imaging in cardiology field, and the related decrease rate obtained from 10% to 5%. Liao et al (2015) investigated the use of artificial intelligence as supportive information system in enhancing nursing diagnosis, showing consistency with nursing staff’s diagnosis by 87%. Stamey et al (1996), as quoted by other scholars, implemented a

model, based on artificial neural networks to detect prostate cancer, with a diagnostic accuracy of 90%. Artificial neural networks is an artificial intelligence technique, mimicking the function of human brain (Ishak & Siraj, 2004) in processing multiple data and shaping patterns for decision making process (Mintz & Brodie, 2019), used in “image analysis in radiology, data interpretation in intensive care setting and waveform analysis” (Ramesh et al, 2004). In this respect, Esteva et al (2017) implemented a specific subset of artificial neural intelligence, called convolutional neural networks, for classify skin cancers, stating a performance level achieved comparable to the experts tested.

Fuzzy expert systems make use of expert level competence and inference procedures based on fuzzy logic for “complex problems with high degree of uncertainty” (Wahl et al, 2018), whose solutions “can be satisfactorily approximated heuristically relying on human expertise in form of If-Then rules” (Aly & Vrana, 2006).

The work by Djam & Kimbi (2011) focused on the use of such an approach for the management of hypertension risk. Managing hypertension is a complex task due to the multiple variables involved in the diagnostic process. Information obtained from patients are often not exhaustive and imprecise to perform a consistent diagnostic and medical decision. Moreover, conflicting information sometimes arise due to both inaccurate laboratory tests (Vitez et al, 1996) and to unexperienced medical personnel. As a result, the choice about the clinical treatment to be adopted get fuzzy and the increasing level of uncertainty and vagueness lead physicians to make decision based on intuition. To this respect, the study performed a test on a cohort of patients affected with hypertension, showing that the system’s reasoning engine, built upon the experts’ knowledge, alert about the moderate hypertension risk of the sample, assisting clinicians in being aware of monitoring need of patients among possible treatment options.

Bates & Young (2003) described the use of fuzzy logic in determining the amount of intravenous fluid to be administrated to the patient in an intensive care unit. In such a setting, the cognitive load experienced by the physician grow. Physicians have to handle complex trade-offs and making rapid decisions, by relying much more on a subjective assessment. To this respect, the methodological review paper by Patel et al (2008) precised that decision-making in critical care environment, such as intensive care unit or emergency department, bases on the “flow of information between clinical members”. Therefore, detecting the underlying cognitive mechanism that rule the information process is the early stage “for design change that emphasize clarity of communication and the implementation of technology that support specific user tasks”.

Bates & Young (2003) reported a simplified theoretical model, based on two input variables (mean arterial blood pressure and hourly urine output), and compare it to six variables model adopted by Nemoto et al (1999) and Bates et al (2001) for controlling the level of pressure support ventilation in patients in the ICU with chronic obstructive pulmonary disease (Bates & Young, 2003). In the last case, the algorithm displayed recommendations consistent with the clinical choices made actually for the patients, less than narrow variations in the range of 2 cm H₂O in pressure ventilation levels, as reported by Bates & Young (2003).

Based on the literature, a *degree of diagnosis accuracy* comparable to the one of experts is the main expected benefit of any artificial intelligence algorithm in healthcare management. Therefore, the performance of the algorithm, in terms of precision of control achieved, may be assumed as a driver of diagnostic accuracy.

In particular, as discussed above, “fuzzy logic has the ability to capture the experience-based of a particular individual and code it as an algorithm” (Bates & Young, 2003). This suggests that a strong medical expertise, both professional knowledge and clinical experience, affects positively the performance of a fuzzy algorithm. As a result, the following hypothesis is accordingly developed.

H₁: *Medical expertise has a positive impact on the degree of diagnostic accuracy.*

As suggested by Liao et al (2015), by improving the quality of the information available in the decision-making process, the diagnostic choices tend to converge with those indicated by the system of artificial intelligence. Therefore, the following hypothesis is displayed.

H₂: *The quality of information has a positive impact on the degree of diagnostic accuracy*

Moreover, based on Patel et al (2008), critical care environment may mitigate the potential of the algorithm to generate accurate diagnostic predictions based on quality information. This may influence the underlying cognitive mechanism that rule the information process. To this respect, medical setting may be considered as a moderator, in particular with regard to i) the relationship between the medical expertise and the degree of diagnostic accuracy; and ii) the relationship between the information quality and the degree of diagnostic accuracy. The following hypotheses are accordingly developed:

H_{3.1}: *The medical setting has a negative moderator effect on the relationship between quality information and the degree of diagnostic accuracy.*

H_{3.2}: *The medical setting has a negative moderator effect on the relationship between medical expertise and the degree of diagnostic accuracy.*

A synthesis of the research framework developed is proposed in Figure 1.

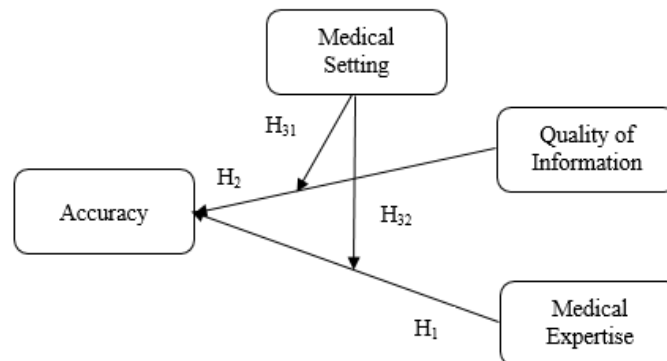

Fig. 1. Model

4 Materials and Methods

Based on the above-mentioned hypotheses derived from literature, variables to be tested were identified.

Firstly, the degree of diagnostic accuracy may be assumed as dependent variable of the framework. Concerning the literature (Liao et al., 2015), the diagnostic accuracy may be explained as a convergence between experts' diagnostic choices and those indicated by artificial intelligence algorithm, thus in the following the variable will be defined as the offset between experts' decisions and algorithm recommendations, namely the doses of contrast medium to be administered to patients.

Secondarily, the medical expertise and the quality of information may be assumed as independent or predictor variables, according to the literature, whilst the medical setting acts as a moderator. In fact, medical setting is described as a variable affecting the strength of the relationship between medical expertise and the output variable, and the potential of the algorithm to generate accurate diagnostic predictions based on information quality.

To complete the model, some control variables were included (i.e. clinician's age, addiction to computer, GFR and weight), to account for the effects of factors which are not a decision-making leverage, but they may affect the algorithm's performance.

Accordingly, to collect data, two questionnaires were developed. The first questionnaire was designed to shed lights on the constructs stemmed from the literature review. In particular, besides personal information (e.g. age, gender, professional role), the questionnaire was composed of mainly quantitative responses, with a 5-items Likert scale ranging from a minimum value of 1 to a maximum value of 5. The domains covered were: i) medical setting, in terms of environmental and personal factors perceived as crucial for the cognitive burden (i.e. uncertainty of clinical profile to be treated, workload and time-dependent decision context) ; ii) medical expertise, depending on seniority; iii) quality of information, in term of knowledge, as basically inferred from literature (Liao et al., 2015).

To assess the decision making model two algorithm were developed. Both algorithms start from two input variables (patient weight and the related Glomerular Filtration Rate – GFR), able to evaluate the dose of contrast agent to administer to the patient with mild or moderate impairment of renal function. Both the algorithms are designed as follow: 1) The input fuzzy variables (patient weight, GFR,) and the output one (contrast medium) are clustered and inserted in specific charts, following the fuzzy logic; 2) the input variables (patient weight and GFR) are transformed from numerical values to non-numeric values used to facilitate the expression of rules and facts. In the present case, the non-numeric values are “low”, “medium” and “high”. After their transformation (fuzzification into fuzzy membership functions), the above variables are inserted in the rulebase to compute fuzzy output function; 3) the decisions defined by the algorithm is de-fuzzified, thus being transformed from non-numeric value to numerical values, leading to the development of output values, thus identifying the level of contrast medium.

In particular, algorithm 1 (ALG 1) was implemented to perform “conservative” decision-making. The reasoning engine was set for working out below risk threshold (i.e. $\text{gIodine/GFR} < 1$) (Andreucci M., 2014). Algorithm 2 (ALG 2) simulates a less cautious decision-making process, by running on the edge of the risk threshold.

To collect the experts’ clinical choices a second questionnaire was employed. Based on the case history of patients observed over time, three tests were included in the questionnaire. i) *Pulmonary embolism*: the test was design to force the radiologists to administer the lowest possible contrast dose for patients with impairment of renal function, seeking to get a sufficient diagnostic iconography. ii) *Hepatic metastasis from colorectal cancer*: unlike the previous test, abdominal triphasic study necessitates a significant dose of contrast medium. Therefore, the test was executed to press radiologists to opt for the highest possible contrast dose consistent with risk of acute renal insufficiency. iii) *Pulmonary nodule*: the test was carried out to observe medical decisions in an intermediate case study.

Each test included 10 case studies. The radiologists accomplished each test and the related case studies as to collect the diagnostic choices without supportive systems to decision-making. The data collected are measured in ml/contrast medium. Only 8 out of 10 radiologists performed the tests. Therefore, a set of 80 results were compared to algorithms’ recommendations.

Subsequently, a correlation analysis was performed to assess both the multicollinearity among variables, and the strength of their relationships. Furthermore, a regression analysis was conducted both for algorithm 1 and algorithm 2, useful to test the above-mentioned hypotheses and define the predictors of the level of diagnostic accuracy. In this view, for each dependent variable (algorithm 1 and algorithm 2), three different models were developed.

- Model 1: Model composed only of control variables.
- Model 2: Model composed of Model 1, with the inclusion of the independent variables.
- Model 3: Model composed of Model 1, Model 2 with the inclusion of the moderator nature of the clinical setting.

5 Results

Both questionnaires were administered to a sample of 10 radiologists, working in an Italian hospital ward, in the month of March 2019. 8 out of 10 radiologists answer to the questionnaire. The final sample was composed predominately of males (60%). In both cases the response rate was of 80%.

The extremes values given back from the algorithms for each run were set as a reference range. This allows to grasp preliminary indications in terms of cognitive burden experienced by the radiologists.

Surprisingly, 15% of radiologists chose doses of contrast medium above the risk threshold in test 1, which refers to case studies with lower scope for taking decisions. Moreover, the risk to induced impairment renal function led radiologists to administer

doses lower than what was proposed by the more cautious algorithm 1 (28,8%). By measuring the standard deviations within the decisions' group belonging to each expert, only 4 out of 8 showed a limited decision making variability. This may make supposing that they did not relied on an initial reference point in making decisions (anchoring bias).

Likewise, radiologists in the test 2 tend to exaggerate the quantities of contrast medium, by exceeding the risk threshold (33,8%), and the intra-expert anchoring in decision making continue to be wide (7 out of 8 experts). It is noteworthy that radiologists tend to overestimate the doses relative to those recommended by the algorithm working out on the edge of critical threshold (45%), in test 3.

Focusing on algorithm 1, Table 2 depicts the correlations among variables. In particular, a significant relationship was found between the degree of diagnostic accuracy and clinician's age ($p < 0.01$); patient's weight ($p < 0.01$); medical expertise ($p < 0.01$). Even a positive correlation was found between clinician's age and medical expertise ($p < 0.01$); information quality ($p < 0.01$). Moreover, medical expertise showed a good positive relationship with clinician's age ($p < 0.05$).

Table 2. Correlation among variables for the algorithm 1

	1	2	3	4	5	6	7	8	9

(8) Information quality x medical setting	.078	.267*	.347**	.000	.000	-.154*	.151*	1	
(9) Medical expertise x Medical setting	.274**	.914*	-.349**	.000	-.000	.971**	-.203**	-.002	1

*Significance levels: * $p < 0.05$; ** $p < 0.01$*

Table 3 and Table 4 displayed the regression analyses for algorithm 1 and 2, respectively. Both tests showed that only information quality (algorithm 1: $\beta=0.389$; $p<0.001$); algorithm 2: $\beta=0.370$; $p<0.001$, thus focusing on Model 2) was required to approximate the diagnostic accuracy of a decision-making process supported by artificial intelligence tools (Algorithm 1: Adjusted $R^2 = 0.346$; Algorithm 2: Adjusted $R^2 = 0.407$). The exhaustiveness and the systematization of information was confirmed as necessary to steer an accurate diagnostic choice. A negative relationship emerged between medical expertise and the level of diagnostic accuracy in both the algorithms (algorithm 1: $\beta=-0.032$; $p>0.05$); algorithm 2: $\beta=-0.030$; $p>0.05$), even if no statistical significance emerged. Moreover, noteworthy was the statistical relevance of control variables, which are able to explain 27.8% and 34.6% of dependent variable's variance (Model 1).

Focusing on the medical setting as moderator, no significant effects was reported in both the algorithms. In this view, Model 3 is able to explain the 34.2% and 40.4% of the variance of algorithm 1 and algorithm 2, respectively.

6 Conclusions

The model demonstrated that only information quality was required to achieve a comparable diagnostic accuracy to a decision-making process supported by artificial intelligence tools. Despite literature (Bates & Young, 2003) suggested that medical expertise affects positively the performance of a fuzzy algorithm, in this paper, it is not confirmed, as well as the moderator role of medical setting (Patel et al, 2008).

The results may be interpreted as the need to pursue an in-depth analysis on the proxies adopted in literature to better explain the constructs, especially with regard to the specific context, such as the healthcare sector. Further investigations should focus on this important aspect.

Despite the limitations, the present paper provided insights on the potential key role of artificial intelligence in managing clinical decision-making in three different cases of renal impairment. As acknowledged by the model, the wholeness and systematization of knowledge required to implement a clinical decision-making process might enable to ease the cognitive burden sustained by clinicians, by boosting potentially the diagnostic accuracy's convergence. Nevertheless, the cognitive burden experienced by radiologists induced them to desert the tests (2 out of 10) and to rely on heuristic reasoning. In fact, the study revealed a potential anchoring bias, (40% in test 1 and 87% in the last ones), which guided radiologists to assign doses of contrast medium by means of a reference value used to relate intuitively the quantity chosen in each choice. Therefore, future investigations should further stress the analysis, by unbundling the information quality's construct in distinct items.

Limits and Merits of Transition to Circular Economy in (post-) Transitive Economies of CEE

Gabriela Vaceková

Department of Public Economics
Faculty of Economics and Administration
Masaryk University, Lipová 41a, 60300 Brno, Czech Republic

Abstract

The transition to a more circular society has been adopted as a guiding principle in several countries' policies. The present paper reviews the international definitional and theoretical approaches to the circular economy originating in the Anglo-Saxon environment with a view to assessing their applicability in the (post-) transitional context of CEE and identifying the elements of their integrative conceptual core. The main finding is that scientific research of circular economy and circular business thinking takes two relatively independent directions (normative/positive), as it is grounded in two different methodological approaches. The paper shows that it is possible to use a starting point for further research on circularity that would not be based on dichotomous approaches but on integrity (holistic approach).

Keywords – Circular Economy, Circular Business Thinking, Transformation Process, CEE

Paper type – Academic Research Paper

1 Introduction

Having gone through a transformation to a market economy, the concept of circularity in the (post-) transitive European countries has tremendous potential. The achievement of this potential, however, depends on the post-communist countries' ability to deal with the socio-economic and political challenges that are no less tremendous. Much of the work that needs to be done toward achieving the potential the circularity offers involves the scientific analysis and reconstruction of basic conceptual foundations. The paper aims to review the international definitional and theoretical approaches to circular economy originating in the Anglo-Saxon environment with a view to assessing their applicability in the (post-) transitional context and identifying the elements of their integrative conceptual core.

The theoretical relevance and practical importance of the development of circular economy (cf. Ellen MacArthur Foundation, 2013; Ghisellini et al., 2016; Lieder and Rashid, 2016) around the world has been experienced, among others, by the post-

communist economies. The trend towards emerging circularity in the transitional economies of Central and Eastern Europe (CEE) has grown in recent years. It can be evidenced also on recent research projects the academics from the Czech Republic are currently working on, e.g. H2020 “Resource-efficient Circular Product-Service Systems”, and TACR “Analysis of Potential of South Moravia regarding the Circular Economy”, as well as their newly published papers, e.g. Škapa and Klapalová (2019), Klapalová (2019), Škapa (2018a, 2018b).

Transition to a circular economy requires a radical change of existing business models and new ways of thinking and doing business (Bocken et al., 2016). The knowledge base of circular economy and circular business models needs a substantial work on expanding, deepening and interconnecting existing pieces of knowledge from multidisciplinary perspectives, which holds true even more for the (post-) transitive context of CEE.

The concept of the transitional economy came into existence at the end of the 1980s when all the countries concerned were gradually abandoning the path towards socialism they had followed under the leadership of the Communist Party. Those were the years when the western countries had already started to cope with the circular economy. While it can be argued that some elements of the market economy also existed in a centrally-commanded economy (just as the state might have intervened in the market), the key feature of the communist regime was the way in which the economy was controlled or planned by the state and not driven by market forces (Shleifer and Treisman, 2014).

The economic transition was not conducted in the vacuum. At the macro level, the transformation of economy has included changes to its structure: in terms of different sectors, industries, branch specializations, and products; in terms of the size of corporations; and in the nature of foreign trade (Vaceková et al., 2019). The accession of several post-communist economies to the EU has involved the complete transformation of the former command economy to one based on the market. And the transformation of the economy was the precondition for a radical change in the political system to create a capitalist social system, a process that was much broader than changes to the economy (ibid). It opened a space for circular business thinking. Has this space been sufficiently used by (post-)transitive economies? If so, how? And if not, why?

Two types of research methods were used to meet the paper goal. Analysis was selected as the general scientific research method; it was used specifically in searching through theoretical resources. The synthesis method and the generalization method were applied in particular in connection with formulating theoretical conclusions. The paper is organized around three major themes. The first one presents the circularity conceptualization in the Anglo-Saxon environment. The next part is an inquiry that provides an analysis of the economic determinants of circular business thinking in the (post-)transitive area. This opens the third one which is devoted to the discussion of limits and merits of transition to circular economy from methodological and conceptual point of view. The paper ends by drawing conclusions, and making suggestions for further research.

2 The transition to a circular economy

In recent years there has been a proliferation of scholars' publications on circular economy (Merli et al., 2017). There are several concepts defining it, nevertheless, no commonly agreed definition yet (Kirchherr et al, 2017). According to Geissdoerfer et al. (2018, p. 712) circular economy „*is based on the idea of putting private business into the service of the transition to a more sustainable system.*“ System view is stressed also by Merli et al (2017, p. 703) arguing that circular economy „*proposes a circular system in which the value of products, materials and resources is maintained in the economy as long as possible.*“ Camacho-Otero et al (2018, p.1) state that a circular economy „*aims at decoupling value creation from waste generation and resource use by radically transforming production and consumption systems.*“

Despite the lack of conceptualisation, circularity has been attracting the attention of scholars, as the shifting to circular economy demands the understanding of how companies can introduce circularity into their business models (Lewandowski, 2016). Until now, most studies use a case study approach. This captures several possibilities and context-based features in specific firms or sectors, but it also limits their generalization (Lewandowski, 2016). Merli et al. (2017) highlight circular economy as an evolving concept that still requires development to consolidate its definition, boundaries, principles and associated practices.

Nevertheless, most of the concepts defining circularity point out the transformation process and the transition to the new phenomenon. This can be seen as a parallel to the transformation process from central-planned to market economies of the post-communist countries. The ‘transitional economies’ constitute a varied mixture of 27 countries, predominantly from the CEE but complemented by the republics of the former Soviet Union situated to the south of the Caucasus and in Central Asia. The concept of the transitional economy came into existence at the end of the 1980s when all these countries were gradually abandoning the path towards socialism they had followed under the leadership of the Communist Party. Instead they were setting out on a phase of transition from a state-controlled economy to one that was driven by the market, a change that was seen as the general goal of economic transformation. While it can be argued that some elements of the market economy also existed in a centrally-commanded economy (just as the state might have intervened in the market), the key feature of the communist regime was the way in which the economy was controlled or planned by the state and not driven by market forces (cf. Vaceková et al., 2019).

In 1989 and 1990, citizen movements were decisive in overturning the political order and, with it, the economic configuration in CEE countries (Strachwitz, 2015). There are big differences in the extent to which individual countries have implemented the development of market economies and the growth of democratic institutions that are seen as complementary to them. Today the transition to the market economy of the post-communist countries is seen to be far from complete but generally typical of states at similar stages of economic development.

When it comes to the issue of business thinking innovation the focus is also on emphasis on the transformation of existing business models. Business model innovation is considered an important source of firm's competitive advantage (Spieth et al. 2014). Recently, it is also pointed as a fundamental aspect in a transition to a more sustainable economy (Klapalová et al., 2018). The transformation is considered as a major driver and obstacle to the implementation of a circular economy (Lewandowski 2016).

At the macro level, the transformation of economy has included changes to its structure: in terms of different sectors, industries, branch specializations, and products; in terms of the size of corporations; and in the nature of foreign trade. The transformation of the economy was the precondition for a radical change in the political system to create a capitalist social system, a process that was much broader than changes to the economy. This holds true even for the circular business thinking.

3 Discussion

While the concept of a transitional economy has always been a kind of simplification or abstraction, all of the economies concerned, even after more than quarter century of transformation, share certain characteristics essentially because the institutions of their democracies and their market economies are not fully developed (Vaceková et al., 2019). This lack of development also holds true for circular economy.

An analysis of the literature shows that scientific research of circular economy and circular business thinking takes two relatively independent directions, as it is grounded in two different methodological approaches. The first approach is descriptive and based on non-normative methodology and the corresponding explanation tools that clarify the role of the circularity and circular business models in the economy. The second approach turns in the normative direction. It is based on normative methodology and on the explication or interpretation of a researched topic. The contrast between these two different methodological approaches to circular economy is a specific example of the current state of scientific discussion in the areas of economics and social sciences. The contrast takes the form of "two cultures" (Snow, 2002) or, in terms of scientific methodology, a form of commensurability or incommensurability between normative and non-normative statements about, or explanations of, a researched topic (Ochrana, 2015).

The general contradictions between economics and social sciences are reflected in the scientific discussion about the circular economy and influence the circular business thinking. The paper is based on a critical evaluation of this discussion and offers a different solution. The solution is an attempt to depart from the existing traditional approaches and reach some synthesis. The paper works on the assumption that it is possible to use a starting point that would not be based on dichotomous approaches but on integrity (cf. Vaceková, 2016; Valentinov 2009; *ibid* 2011; *ibid* 2012; Valentinov & Iliopoulos, 2013; Valentinov et al., 2015)

The methodological basis for this integrity is the holistic approach (Fay, 2002; Ochrana, 2015), enabling a shift in direction toward the integrative approach. The paper seeks answers on how the circular business thinking participates and contributes to this

process which indeed integrates normative and positive aspects: there is a normative imperative to solve problems, and there is positive interest in discovering how circular economy can actually do it.

The need for integrative research of circularity is determined by two groups of factors. The first group is the new economic and social reality within which businesses operate. This new reality includes transformations of the positions, roles, and functions. Therefore, this represents an objective side of the issue: the ontological layer of circular economy. The recent and ongoing changes in the position and functioning of business require a corresponding scientific approach and tools that would enable proper research of these changes. Traditional existing approaches offer dichotomous solutions: either explanations or interpretations (Vaceková, 2016). The integrative theory (see Vaceková, 2016) bridges this dichotomy, offering a comprehensive view of the current issues related to the operations of circular economy. The ambition of the paper was to contribute to the theoretical elaboration of the issue.

4 Concluding remarks

Circularity has received increasing attention in the scientific literature worldwide. This literature is, however, largely Anglo-Saxon and it is not perfectly suited to a context of the transitional economies. The lack of relevant research on circularity in the post-communist countries of CEE shows a considerable gap that strongly indicates the need for deeper insight. The proposed paper contributed to the conversation by rethinking the existing literature in the context of transitional economies, focusing on the merits and limits of transition to circular economy in (post-) transition economies. Furthermore, it aimed to create a space for discussing critical implications and making suggestions for further research.

Consumer Knowledge and Young Consumer Purchase Behaviour towards Remanufactured products

The Faculty of Economics and Administration
Masaryk University
Žerotínovo nám. 617/9, 601 77 Brno, Czech Republic

Abstract

Remanufacturing plays an important role in the transition towards the circular economy. Since many companies have already begun to implement remanufacturing strategies, consumer's adoption of already used products (e.g., remanufactured products) are highly essential. Hence, the consumer's acceptance of the remanufactured product is now receiving more researcher's attention. The findings of recent studies, however, indicate that consumers have a poor opinion on remanufactured products and thus remain reluctant to buy them. Moreover, these studies focus only on the adult generation and overlook the young generation which will become a new purchase power in the near future. Therefore, the main objective of the presented study is to deeply investigate how product-related knowledge influences the young generation's purchase intention towards remanufactured white goods. The author uses the theory of planned behaviour as a theoretical framework and for data collection questionnaire survey. Furthermore, the proposed model is empirically tested, using Ordinary least squares (OLS) regression, based on the responses from 234 university students. The results indicate that consumer's intention to purchase remanufactured products is positively and significantly influenced by consumer attitude, social norm and perceived behavioural control. Moreover, the presented study also demonstrates that consumer's product-related knowledge is positively associated with both consumer's attitude and consumers' intention to purchase remanufactured products. Thus, based on the presented findings, the study not only brings new insight into the purchase behaviour of the young generation towards remanufactured products but also several theoretical and practical implications.

Keywords: consumer knowledge, remanufactured products, purchase behaviour, theory of planned behaviour

Paper type – Academic Research Paper

1 Introduction

Since the 1990s, fast economic growth has escalated worldwide consumption, which subsequently led to the unprecedented levels of the produced waste and unsustainable exploitation of natural resources (Taufique et al., 2017). Thanks to it we have witnessed the rapid environmental deterioration results in increasing global warming (Satterthwaite, 2008). In response to worldwide concern about environmental especially in the recent decade (Vafadarnikjoo et al., 2018) the environmental issues in the context of business activities have become a major topic of academic research interest (Jiménez-Parra et al., 2014). Companies have been starting to implement end-of-use strategies in remanufacturing, recycling and reuse, to contribute to the transition to more sustainable production and consumption.

In the case of remanufacturing, the implementation of these practices (e.g., reused, repaired, replacing degraded, worn out and obsolete components) has been mainly driven by its environmental friendliness and thanks to it has begun play important role in reducing energy consumption and use of virgin material (Wang et al., 2018). Although many studies have already been conducted on this subject, most authors have focused primarily on the supply side of remanufactured products and dismissed the demand side i.e., the consumers' perception. Despite this little attention, the consumers' acceptance of remanufactured products is regarded as one of the most important requirements for transition to the circular economy. And thus, it becomes inevitable to understand the consumers' behaviour, especially they purchase intention towards the remanufactured product.

This paper contributes to the existing literature by the examination of consumers' purchase intention towards the remanufactured product. Specifically, it focuses on remanufactured white goods (major household electrical appliances such as fridges and washing machines), because there is a new effort from its manufacturers (e.g., in Gorenje). Moreover, since responsible consumption is at least partially depending on consumers' knowledge about the product, the author also empirically investigates how product-related knowledge influences consumers' purchase behaviours. Therefore, the key question is set up as: *"How product-related knowledge influence consumers' purchase intention towards the remanufactured product?"*. To answer this question and better understand the consumers' behaviour the author approaches the topic from two perspectives - first, the author investigates which factors play a significant role in determining the purchase intention; second, the author focus on how product-related knowledge influence the attitude-behaviour relationship. Combining both steps the author contribute the research of remanufacturing from consumer's perspective by assessing the purchase intention of Czech young consumers towards remanufactured products.

2 Theoretical framework

2.1 Remanufactured products

Remanufacturing is a production strategy, where the goal is to bring used products to at least their original quality and performance just like newly manufactured ones (Atasu et al., 2010). Therefore, remanufactured products are defined as "*one which has undertaken the process of disassembling, cleaning, inspecting, repairing, replacing and reassembling the components of a part or product to like-new condition*" (Thorn and Rogerson, 2002:35 "in" Hazen et al., 2012). Thanks to it remanufactured products are considered as the engine of closed-loop supply chain and one of the keystones of circular economy (Hazen et al., 2017). Moreover, these products bring several benefits mainly related to the environment, because its production is more sustainable - i.e., up to 70 % less raw material is required, up to 80 % less emission is produced and up to 60 % less energy is consumed (Wang et al., 2013:871).

The remanufactured products also taught the attention of media and prior business leaders in a variety range of industries. Therefore, remanufactured products can be found in the range from automobile parts to office furniture and electronics - e.g., laptops, mobile phones, cameras, mp3 players (Michaud and Llerena, 2011; Wu, 2012). Moreover, the development of remanufactured products has grown rapidly in recent years. In 2015 the remanufacturing industry even generated €30 billion in turnover and by 2030 it is expected that annual value will reach €70-100 billion (Parker et al., 2015 "in" Vafadarnikjoo et al., 2018).

Remanufactured products also bring several benefits to customers such as lower price, availability or purchase flexibility. According to Giutini and Gaudette (2003) price of remanufactured products is usually 30-40 % lower than the price of new products and their lead time is in many cases shorter than by new products. Moreover, in the context of access-based business model, which shifts the emphasis from selling product ownership to selling product use or its functions (Mont, 2008 "in" Edbring et al., 2016) the remanufacturers may offer customers additional services such as leasing, take-back, upgrading, etc. (Vafadarnikjoo et al., 2018).

2.2 Theory of Planned Behaviour

The theory of planned behaviour is (TPB) proposed by Ajzen (1991) is an extension of the theory of reasoned action and assumes that the behaviour is determined by behaviour intention (Wang et al., 2013). The Theory of Planned Behaviour (TPB) is an important social a cognitive model, which stems from extensive empirical confirmations in variety contexts (e.g., environmental, social and cultural context). While TPB is one of the most influential theories in health psychology, it finds its usefulness also in the context of green purchase behaviour (e.g., organic food, Zagat, 2012; visitation of the green hotel, Chen and Tung, 2014 - Wang). Moreover, its validity was also confirmed in predicting consumers' purchase behaviour towards remanufactured products (Jiménez-Parra et al., 2014; Khor and Hazen, 2017; Wang et al., 2018).

The TPB built on the assumption that the consumers make their decisions based on rational and reasoned choice, which stems from all available information (Wang et al., 2018). Thus, behavioural intention is determined by individuals' attitude, subjective norm, and perceived behavioural controls (Ajzen, 1991).

Attitude refers to an individuals' favourable or unfavourable evaluation of self-performance of behaviour (Ajzen, 1991). The attitudes are represented by an individual's beliefs, which clarify why people hold given attitudes. Additionally, the attitudes influence the intention, and so the more positive the attitude, the stronger the intention to perform the behaviour will be (Smith, A. Paladino, 2010).

Subjective norms can be conceptualized as the social pressure exerted from people that are important in the individuals' life (family, friends, teachers, etc.) to behave in a certain way (Ajzen, 1991; Singhal et al., 2019). In other words, the greater the influence of others is, the more likely is that he/she will perform the behaviour (Jiménez-Parra et al., 2014; Wang et al., 2018).

Perceived behaviour control is described as an individual's perception of the degree of easiness or difficulty performing the behaviour (Ajzen, 1991; Singhal et al., 2019). It deals with situations where people face external factors - i.e., ability, time and money. Therefore, the fuller control over these circumstances the individuals have, the more likely they will act like that (Wang et al., 2018; Smith, A. Paladino, 2010).

Based on the aforementioned constructs of the TPB, the following hypotheses are proposed.

H1: Attitude positively influences the behavioral intention to buy remanufactured white goods.

H2: Subjective norm positively influences the behavioral intention to buy remanufactured white goods.

H3: Perceived behavioral control positively influences behavioral intention to buy remanufactured white goods.

2.3 Remanufactured knowledge

Product knowledge can be defined as consumers' awareness of specific information (i.e., the features, warranty, price, quality, etc.) related to a particular product (Brucks, 1985). Wood et al. (1995: 283) explain that all this information comes to consumers' mind when encountering a particular product and considering its purchase. Moreover, since knowledge is considered an integral part of the consumers' attitude, the product related information also influences the consumers' purchase intention. The same assumption can be applied in the case of remanufactured products. Therefore, the deeper product knowledge related to remanufactured products, the better consumers' attitudes which results in significant influence on consumers' purchasing decision (Lin and Chen, 2006; Fabrigar et al., 2006).

On the other hand, there exist evidence (e.g., Wang et al., 2018; Hazen et al., 2012; Wang and Hazen et al., 2016) that the majority of consumers are not familiar with the remanufactured product and thus prefer new product before the remanufactured ones. According to Xu et al. (2017) consumers feel uncertain about remanufactured products'

characteristics (Wang et al., 2018) and even have incorrect information, because they think that remanufactured products are unusable or second-hand (Wang et al., 2018). This shows that consumers have a lack of understanding of remanufactured products and do not perceive the equivalences with new products (Thorn and Rogerson, 2002 "in" Hazen et al., 2012); although, from the definition, the remanufactured products are brought back to a new-conditions (Jiménez-Parra et al., 2014).

Hence, the level of understanding of the remanufactured product – i.e., the product knowledge – reduce uncertainty and provide a better understanding of all benefits of the remanufactured product (Wahjudi et al., 2018). Since it consequently increases consumers' acceptance and improves their purchasing decision, the author hypothesis that:

H4: Product knowledge about remanufactured white goods positively influence the consumers' attitude towards remanufactured white goods.

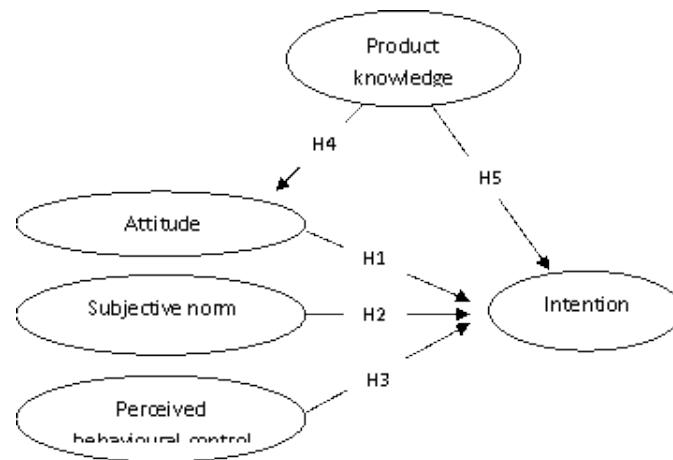

H5: Product knowledge about remanufactured white goods positively influence the consumers' purchase intention towards remanufactured white goods via attitude.

3 Methodology

3.1 The conceptual model

To investigate the reasons why consumer's purchase remanufactured white goods, the study is based on the TPB. The TPB provides more social psychology view by incorporating both social and personal factors thanks to it has very strong explanatory power in behavioural intention (Wang et al., 2013). The validity and reliability of its instruments were already confirmed by studies focusing on remanufactured products (e.g., Wang et al., 2013; Khor & Hazen, 2016; Singhal et al., 2019). Moreover, as stem from a literature review, the consumers have a lack of product knowledge about remanufactured products, and thus their perception is misleading. Therefore, the study also controls for product knowledge and integrate this factor into the conceptual model. On the other hand, since knowledge is an integral part of the consumers' attitude, it is expected that knowledge effect on purchase intention is not direct but mediated via the attitude. This two-step approach will enable us to deeper understand the customers' behavior, and the reluctance of consumer towards the purchase remanufactured white goods.

Based on the aforementioned arguments, the author proposed the following theoretical framework (Figure 1).

Source: Author

Figure 7: Proposed theoretical framework

3.2 Questionnaire development

The data for the proposed survey was collected by using a structured questionnaire, which was developed after an in-depth literature review. Moreover, the wording of single questions was taken over from previous research (see Appendix A). Thereafter, the draft of the questionnaire was sent to experts in the area of academia, psychology and remanufacturing industry to overview the framing and reading of the questions. After incorporating minor correction, the author conducted a pilot survey. As the research focus on the young generation, it was necessary to verify, if the questions are also understandable for this segment. A few questions were slightly corrected, and the final version was drafted.

A final questionnaire comprises of three parts. The first part contains questions prepared in accordance with the TPB. The second part captured the respondents' knowledge about the remanufactured products, especially as regards cost, quality, and environmental impact. The last part describes the respondents' characteristics such as age, gender, education, income, etc. Based on Ajzen's (1985) recommendations, each construct was measured by multiple items on a seven-point Likert scale – ranging from 1 = strongly disagree to 5 = strongly agree.

3.3 Sample and data collection

The study was designed as a cross-sectional survey and thus the data was obtained by surveying undergraduate, graduated and postgraduate students from the second biggest university in the Czech Republic - Masaryk University. The young adults (20-30 years) were chosen primarily because they represent new purchase power and hold new unexamined buying habits. Moreover, they have a higher ability to reflect their attitudes in purchase decision making (Yadav and Pathak, 2016). Data were gathering during February and March 2019, when the questionnaire was spread by snowball methods

through Facebook - most widely used social network by the young generation Eger (2015).

The responsive rate was 46 %, and the survey yielded 234 completed questionnaires. Since some responses were unusable (i.e., contained incomplete responses or was filled by older generation or were outliers), the final sample size was reduced to 197 surveys. Based on Kline's (2011) recommendation (i.e., the number of responses should be at least 10 cases per parameter), the final size is enough to satisfy.

Subsequently, to measure the strength of product-related knowledge, the final sample had to be reduced a second time. This was because some respondents did not know what the refurbished products were (i.e., they had no knowledge of remanufactured products and the definition had to be provided to them). Thus, the second final sample included 109 surveys.

4 Data analysis and results

Testing for the data was carried out with confirmatory and regression approach. First of all, Cronbach's alpha values and consequently confirmatory factor analyses were chosen to measure the reliability and inner consistency was chosen. Although the validity of used questions was confirmed by previous studies, in case of perceived behavioural control, the Cronbach's alpha value did not meet the proposed benchmark - i.e., the value should be greater than 0,70. Therefore one question had to be omitted. Thereafter the ordinary least squares (OLS) regression was run for the model fit and hypothesis testing. Moreover, the author also estimates the effect of control variables – i.e., gender, age, education background, nationality, income, and product-related knowledge¹.

The final regression model has following equation:

$$\text{Purchase Intention} = \beta_0 + \beta_1 \text{Attitude} + \beta_2 \text{Subjective norm} + \beta_3 \text{Perceived behavioural control} + \beta_4 \text{Age} + \beta_5 \text{Education} + \beta_6 \text{Nationality} + \beta_7 \text{Income} + \beta_7 \text{Knowledge}$$

Moreover, as the literature indicates, the effect of product-related knowledge on purchase intention is mediated via attention. Therefore, the author follows Baron and Kenny's (1986) approach and set up the following regression analyses:

$$\text{Purchase Intention} = \beta_0 + \beta_1 \text{Product related knowledge} + \beta_4 \text{Age} + \beta_5 \text{Education} + \beta_6 \text{Nationality} + \beta_7 \text{Income}$$

$$\text{Purchase Attitude} = \beta_0 + \beta_1 \text{Product related knowledge} + \beta_4 \text{Age} + \beta_5 \text{Education} + \beta_6 \text{Nationality} + \beta_7 \text{Income}$$

$$\text{Purchase Intention} = \beta_0 + \beta_1 \text{Attitude} + \beta_4 \text{Age} + \beta_5 \text{Education} + \beta_6 \text{Nationality} + \beta_7 \text{Income}$$

¹ Product-related knowledge means, whether respondents know remanufactured product or not.

$$\text{Purchase Intention} = \beta_0 + \beta_1 \text{Product related knowledge} + \beta_2 \text{Attitude} + \beta_4 \text{Age} + \beta_5 \text{Education} + \beta_6 \text{Nationality} + \beta_7 \text{Income}$$

4.1 Measurement model: confirmatory factor analysis

First, follow Fornell and Larcker's (1981) recommendation, the inner reliability of each construct was measured by Cronbach's alfa score. All constructs excepted perceived behavioural control meet the recommended value of 0,7 (Hair et al., 2010). Therefore, one question from the construct of perceived behavioural control had to be excluded. Afterward, the benchmark for this construct was also met. The value of factor loading for each construct exceeds 60 %. Hence measures have good internal consistency and lay within the recommended boundary, the new factors representing the overall value of constructs were created. Consequently, the author uses confirmatory factor analyses (CFA) to measure the validity of the model.

4.2 Ordinary least squares (OLS) regression

Based on the characteristics of the data the author uses ordinary least squares regression model to test the proposed hypotheses. To deal with heteroscedasticity in the presented sample the author uses robust (HAC) standard errors. Moreover, the values of variance inflation factors (VIFs) are well below 10 (range from 1.050 to 1.894), which signal no problems with multicollinearity.

Firstly, the effect of all three factors determining the purchase intention is tested. The findings show that the proposed model accounts for 56 % of the variance in purchase intention towards the remanufactured product. As Figure 2 shows, attitude ($\beta=0.385$, $p < 0.001$), subjective norm ($\beta=0.379$, $p < 0.001$) and perceived behavioural control ($\beta=0.121$, $p < 0.025$) positively influence the purchase intention. Moreover, since the effect of all TPB constructs is significant, the results support H1, H2, and H3.

Figure 8: Analysis of hypothesis (n= 197)

Determinants			coefficient	p-value	
Attitude	→	Intention	0.385	0.000***	Supported H1
Subjective norm	→	Intention	0.379	0.000***	Supported H2
Perceived behavior control	→	Intention	0.121	0.025**	Supported H3

Note: p-values in parentheses: ** $p < 0.05$; *** $p < 0.01$

Secondly, it was investigated, how product-related knowledge influence purchase intention towards remanufactured products. As the mediation effect is expected, the author follows Baron and Kenny's (1986) approach. In Figure 3, the author reports the results of each regression analysis: Model 1 shows the relationship between product-related knowledge and purchase intention; Model 2 reports the effect of product-related knowledge on attitude; Model 3 shows the association between purchase intention and attitude. Since all models indicate significant relationships, the author proceeds to another

step and run Model 4 including both product-related knowledge as well as attitude. The results confirm partial mediation, i.e., supporting H4 and H5.

Figure 9: Analysis of the mediation hypothesis (n=109)

Independent		Dependent	coefficient	p-value	
Product knowledge	→	Intention	0.347	0.000***	Supported in Model 1
Product knowledge	→	Attitude	0.318	0.001***	Supported in Model 2
Attitude	→	Intention	0.650	0.000***	Supported in Model 3
Product knowledge	→	Intention	0.153	0.059*	Supported in Model 4
Attitude			0.611	0.000***	

Note: p-values in parentheses: * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$

5 Discussion

This paper uses the well-established social-psychological model (TPB) to examine the purchase intention of the young generation towards remanufactured white goods. Consistent with TPB, the results shown that all key predictor (i.e., attitude, subjective norm and perceived behavioural control) are positively and significantly associated with the young consumer's purchase intention. Moreover, the author highlights the importance of product-related knowledge, which influences consumer's attitude and consequently also determinates the purchase intention.

In this respect, the consumer's attitude has shown as a key element (with the strongest effect) in the process of purchasing remanufactured white goods (also confirm by Jiménez-para et al., 2014; Khor and Hazen, 2017). Moreover, since the attitude is also positively influenced by product-related knowledge (support by e.g., Singhal et al., 2019), the more educated consumers are about the remanufactured products, the more favourable the attitude towards these products they hold. Based on these findings, the author states that if the consumer has a higher level of knowledge related to remanufactured white goods, especially as regards their benefits, his/her purchase intention will also increase.

Additionally, the young consumer's purchase intention is also significantly influenced by subjective norm (i.e., social pressure exerted from people that are important in the individuals' life such as family, friends, teachers, etc.). This finding supports the results of Jiménez-para et al. (2014) and Khor and Hazen (2017). Moreover, the strength of the effect indicates, that this factor also significantly influences young consumer's purchase intention. For this reason, young consumers are intensively influenced by social media, where they stay in contact with close people to them (Seemiller & Grace, 2016). Thus, it is not surprising, that the opinion of these people is important for them.

The findings also reveal that purchase behavioural control has a positive impact on young customer's purchase intention. This result is in contradiction with the findings of Khor and Hazen (2017) and Singhal et al. (2019). This can be partly explained by the fact that young customers use the internet on the daily base, so there is no problem for them to find needed information, such as a place, where to buy remanufactured products.

Moreover, we are living in a world where consumers can buy goods online in seconds, which saving time.

6 Conclusion

In response to new the effort of white goods producers to sell remanufactured version of these products, the main purpose of this study was to investigate how product-related knowledge influences the young generation's purchase intention towards remanufactured white goods. The presented survey is conducted on a sample of 234 students attending the seconds biggest university in the Czech Republic – Masaryk University. Based on the presented results, the study leads to two major findings. First, the author concludes that the purchase intention of the young generation is positively influenced by the consumer's attitude, subjective norm and perceived behavioural control. Secondly, the author states that purchase intention is also influenced by product-related knowledge, however, via the consumer's attitude.

Moreover, this paper contributes to the current research in many areas of the circular economy. First, it provides a deeper understanding of the young generation, which becomes a new purchase power and its habits considerably differ from the habit of the older generation. Secondly, the study brings several practical and theoretical implications. Since the knowledge positively influences the attitude, which is decisive for consumer's acceptance of remanufactured products, the remanufactures and marketing managers should put more attention to promoting information about benefits, specifications and warranty of remanufactured products. Moreover, they may provide educational materials to help consumers to eliminate their negative perception of these products. Thirdly, the study also contributes to the existing literature by confirming the applicability of TPB in the context of remanufactured products.

The presented study also has several limitations. First, the generalizability of the chosen sample is limited. Although the university students are potential consumers of the remanufactured product, in 2017 only 20 % of the Czech population were university graduates (Báčová, 2018). This leads to non-random convenience sampling errors. Therefore, future studies may focus on the young population which finishes its education at high school. Secondly, the study focusses only on the purchase intention towards remanufactured white goods (i.e., fridges, washing machines and household electrical appliances). Since the remanufactured products exist in a wide range, the future research can investigate the consumer's purchase intention towards remanufactured automobile parts, office furniture or electronics (e.g., laptops, mobile phones, cameras, mp3 players). Thirdly, the author uses only the basic TPB model, although Ajzen (1991) recommends incorporating additional variables. Since the remanufactured products bring environmentally benefits the inclusion of new constructs (e.g., environmental concern) in the TPB would be more than desirable.

Czech Republic

and

Univ Portucalense, Research on Economics, Management and
Information Technologies – REMIT, Portugal

Abstract

The shifting to a circular economy (CE) demands the understanding of how companies can introduce circularity into their business models, that is, how companies develop and implement circular business models. In this process networks assume a critical role.

This paper contributes to the theoretical grounding of the role of network forms of organization for Circular Economy, by providing an analysis on how networks have been integrated into the CE literature. For that, it draws on bibliometrics to map and analyze the evolution of the literature on Circular Economy that mentions networks. Moreover, it conducts a systematic literature review (SLR) considering five analytical dimensions: 1) research method used; 2) level of analysis of the study; 3) type of actors in the analysis/network; 4) purpose of the network; 5) network building strategies and challenges.

The results show that the integration of networks in the CE is being accomplished using a diverse set of methodologies, with an underrepresentation of social network analysis and covering several levels of analysis (micro, meso and macro). Studies tend to stress relations inside the value-chain established to manage physical and energy flows. The CE literature also tackles the main challenges in network management, namely coordination, trust and alignment.

Keywords – Network, Circular Economy, Circular Business Model, Bibliometrics, Systematic Literature Review

Paper type – Academic Research Paper

1 Introduction

The main idea behind a Circular Economy (CE) is to develop an economic model in which the production of waste is minimal and resources are used several times to create value (EC, 2014). The shifting to a circular economy demands the understanding of how companies can introduce circularity into their business models, that is, how companies develop and implement Circular Business Models (CBMs)(Lewandowski, 2016).

A CBM can be defined as “a business model in which the conceptual logic for value creation is based on utilizing economic value retained in products after use in the production of new offerings. Thus, a circular business model implies a return flow to the producer from users, though there can be intermediaries between the two parties” (Linder & Williander, 2015: 2).

The literature on CE has already concluded that CBMs have some specific traits since the implementation of CE principles should affect all the BM building blocks, due to the above-mentioned change in the logic behind value creation, delivery, and capture. Some examples found in extant literature are:

- New value propositions, namely based on longer product life cycles, designing for more durable products (Hawken et al. 2000), supporting the end of life strategies and on higher customer service levels (Barquet et al. 2013; Bocken et al. 2016);
- New customer relationships, namely those that promote the shared use of products among users (collaborative consumption) and reward customers that embrace CE behaviors (Bocken et al. 2016);
- New revenue models, namely those based in selling services (instead of selling products), leasing or accessing the products under the pay per use mechanisms (Barquet et al. 2013);
- New key activities, related to closing supply chain loops, like reverse logistics and maintenance (Bocken et al. 2016), enabling components and materials to enter again the production process (Wells & Seitz 2005).

However, scholars have been given less attention to the key partnerships and networks that need to be built in order to implement CBMs. These networks should underlie the relations with all stakeholders and support the new aspects of BM mentioned above, with emphasis on developing new revenue models and closing the supply chain loops.

The paper addresses this gap by contributing to the theoretical grounding of the role of network forms of organization for CE. For that, it draws on bibliometrics to map and analyze the evolution of the literature on Circular Economy that mentions networks. Moreover, it conducts a systematic literature review (SLR) in the two most relevant bibliographic academic databases: SCOPUS and Web of Science.

The paper is structured as follows: section 2 presents the potential of network theory and analysis for the CE literature; section 3 presents the methodology used for the SLR and the results from the bibliometrics analysis; section 4 presents the results from the SLR; and section 5 concludes.

2 Networks as an important form of organization in the Circular Economy

In this section, we resort to some of the main lessons from the literature on network forms of organization from strategy, innovation, and organizational studies. This literature may provide useful insights into the role and configuration of networks for the transition to a CE.

Collaboration with other organizations and actors has long been acknowledged as vital for innovation and value creation (Ahuja, 2000; Lechner & Dowling 2003; Powel et al 1996; Romero & Molina 2011). Through networks companies access a wide variety of resources; perform collaborative R&D, product co-creation, production, and commercial activities; share risks and investments; and get legitimization and counseling.

Network forms of organization are particularly relevant when ambitious, radical and disruptive transformations are at stake, involving risk and experimentation, and where inertia and resistance can hinder the change (Hill & Rothaermel, 2003; Lahti et al, 2018), as is the case of the transition to a CE. It is acknowledged that one single enterprise does not own the entire set of skills and resources required to deliver its value proposition

According to the literature, collaborations can assume diverse formulas. They often materialize in formalized, inter-organizational partnerships/alliances, contractual agreements and joint ventures along the value chain (Ahuja, 2000; Gulati, 1998), or with stakeholders outside the value chain (Geissdoerfer et al, 2018). Collaborations can also be kept in an informal, more personal-based form (Salavisa et al, 2012). These diverse configurations, namely formal and informal relations should also be relevant for the transition to a CE, as suggested by Velenturf & Jensen (2016).

Among the relevant partners, previous research has highlighted the role of other companies, namely competitors, suppliers and clients, universities and research centers and public entities (Baum et al, 2000). It has shown that the diversity of actors in the network impacts on its performance (Nieto & Santamaría, 2007). Partners bring specialized and complementary resources and capabilities (Dyer & Singh, 1998). In the case of the transition to a CE, it is important to cooperate with a broad range of stakeholders (Geissdoerfer et al, 2018), and therefore multi-actor networks should be present. CE scholars suggest that collaborating with actors inside the supply chain is important in order to close material loops (Bocken et al. 2016; Rizos et al. 2016), collaborations with specialized service providers (e.g logistics and after-service) in order to ensure reverse logistics and customer satisfaction (Lahti et al, 2018; Lewandowski 2016), and collaboration with users and clients in order to redesign products for the CE (Bocken et al. 2016; Tukker 2004). These collaborations involve both large companies and SMEs, namely start-ups exploiting new business opportunities and using CBM from the start (Lahti et al, 2018).

Networks also serve as conduits for accessing resources, with emphasis on intangible ones like technological knowledge, know-how, expertise, information and legitimization (Salavisa et al, 2012). Therefore, networks can be built or mobilized to access several tangible and intangible resources for the transition to a CE. As mention in the introduction, when firms are embracing the CE principles they must perform new activities and use a new set of resources and capabilities. The creation of formal partnerships or informal networking enables to access them without huge in-house investments.

Finally, the literature also stresses that building of networks is a complex process, relying on governance mechanisms based on reciprocity, reputation, and trust that demand long-term and recurrent interactions (Gulati, 1995; Powell, 1990). They involve

complex interdependencies among partners and have a reflex on actors' behaviors and strategies (Kim et al, 2006; Powel, 1990). Coordination and alignment between partners are vital to meet benefits, not only at the economic level but also at social and environmental levels that are of utmost importance in CE. The transition to CBMs may demand the reconstruction of the firm's network, since traditional partners may be not aligned with the principles of CE. Therefore, partner selection is also an important topic for the development of CBM.

3 Method

3.1 Systematic Literature Review: Advantages and Procedures

In order to detect the knowledge stemming from network literature and how it is being adapted within circular economy studies a Systematic Literature Review (SLR) was conducted. A SLR is a way to summarize existing evidence, identify gaps and suggest some directions for future research and enables to "comprehensively identify, appraise and synthesize all relevant studies on a given topic" (Petticrew & Roberts 2006: 19). This approach requires scholars to provide explicit and rigorous criteria for searching, including, evaluating and synthesizing the literature. Decisions are noted down, leaving an audit trail, in order to assure its replicability and transparency (Tranfield, et al, 2003).

The search of the literature was made on the two most relevant bibliographic databases: SCOPUS and Web of Science. The steps used for the search and selection of documents are presented in table 1.

Table 1. Systematic literature review procedures

Step	Decision	Comment / Result
Selection of the database	SCOPUS Web of Science	databases containing journals that are generally highly regarded by the academic community; large number of sources, providing broad coverage of the academic literature
Keyword search SCOPUS	Search query: TITLE-ABS-KEY(network* AND "circular economy")	N = 256
Keyword search Web of Science (all databases)	TOPIC: (network* AND "circular economy")	N = 246
Inclusion criteria	Document type = Article OR Article in Press Language = English	SCOPUS: N = 127 Web of Science: N = 132
Database integration	Exclusion of duplicates (documents that are in both databases)	N = 183
First scanning through title, abstract and keyword reading	Exclude 41 papers because did not meet the research criteria, as did not contain the words "network" or "circular economy" within the title, abstract and keywords Exclude 37 papers because they were out of scope (e.g papers dealing with the optimization of materials or energy Flows, namely in	N = 105

	industrial parks, industrial symbiosis or waste collection networks; bibliometric studies using social network analysis)	
Access check	4 articles were excluded because full text was not available	N = 101

Source: Author's own elaboration

Therefore, the database used for the SLR has 101 papers. The SLR was organized in five structural dimensions: 1) research method used; 2) level of analysis of the study; 3) type of actors in the analysis/network; 4) purpose of the network; 5) network building strategies and challenges. For each dimension, several analytical categories were considered. Initially, a deductive approach was used, based on the literature review on networks presented in section 2. After the analysis of the documents, new analytical categories were introduced in an inductive procedure, namely the separation between single and multiple case studies in the research method, and build business models in the network purpose.

Table 2 summarizes the structural dimensions and the analytical categories used in the analysis of each document.

Table 2. Dimensions and categories used in the systematic literature review

Dimension	Categories
Research method	Theoretical, conceptual and literature review Single case study Multiple case studies Social network analysis (SNA) Models and methods for decision making Other quantitative approaches Other qualitative approaches
Level of analysis	Micro - Firm-level network Industrial symbiosis or industrial parks Supply chain Macro
Actors	Companies in the value chain Other companies Universities and research centres Governments Other stakeholders
Purpose	Close material loops Flow management (e.g. materials, energy) Access to complementary services Product/solution design/development Access to knowledge and information Build business models Access to other resources/capabilities
Network building strategies and challenges	Selection/identification of partners Trust Alignment Coordination Other aspects

Source: Author's own elaboration

3.2 Bibliometrics analysis

The bibliometrics consists in a quantitative analysis of the bibliographic references of a body of literature (Hawkins, 1977), enabling to detect patterns of authorship and publication strategies (Lancaster, 1977), as well as the development of scientific fields (Calero-Medina & Noyons, 2008). In the context of this research, bibliometrics enables the characterization of the database extracted before access check (N=105).

The evolution of the number of papers reveals that networks only recently have become a research topic in the CE literature. Prior to 2010, few studies were published as indicated by the low number of annual publications. Moreover, over three-quarters of the documents were published in the last 2 years (2017 – March 2019).

Source: Author's own elaboration

Figure 1. Evolution of the number of publications (annual and cumulative), until March 2019

Most of these articles were published in journals that have environmental topics (Figure 2), with emphasis to Journal of Cleaner Production (with almost ¼ of the papers) and Resource Conservation and Recycling (with 10% of the papers), which are prominent journals in the area of circular economy (Merli et al, 2018). The 4 most productive journals account for 37.1% of the published articles.

Source: Author's own elaboration

Figure 2. Number of articles per journal (journals with at least 2 articles)

The papers involve a total of 352 authors, most of which (91.8%) have only one paper on this topic. The authors with more than 2 articles are listed in table 3, where one can observe a predominance of Chinese and Japanese authors.

Table 3. Authors with more than 2 articles

Author	Number of papers	Country of affiliation
Bocken, N.	4	Sweden
Dong, L.	4	Japan
Fujii, M.	3	Japan
Geng, Y.	3	China
Liu, Y.	3	China
Wang, Y.	3	China

Source: Author's own elaboration

Table 4 lists the six articles with more than 50 citations. From these, three articles have more than 100 citations in both databases, all originally published between 2010 and 2012, being among the first papers in the topic covered in this analysis.

Table 4. Most cited articles (more than 50 citations)

Paper	Scopus	Web of Science
Shi, H., Chertow, M., & Song, Y. (2010)	177	171
Chertow, M., & Ehrenfeld, J. (2012)	155	145
Boons, F., Spekkink, W., & Mouzakitis, Y. (2011)	127	113
Gregson, N., Crang, M., Fuller, S., & Holmes, H. (2015).	91	75
Dong, L., Zhang, H., Fujita, T., Ohnishi, S., Li, H., Fujii, M., & Dong, H. (2013)	77	67
Winkler, H. (2011)	69	-

Source: Author's own elaboration

4 Results

This section presents the results of the SLR, using the dimensions and categories presented in the Table 2. In this analysis, each document can be simultaneously assigned to more than one analytical category, and therefore, the total count of documents in each dimension may differ.

4.1 Research method

Around 1/5 of the studies have a theoretical, conceptual or review nature. Authors are proposing new frameworks or reviewing the state-of-the-art. This is the case of half of the most cited documents mentioned in the previous section (Boons et al, 2011; Chertow & Ehrenfeld, 2012; Winkler, 2011)

Most empirical studies use a case study methodology, either focusing on a single case or using multiple cases for comparison and generalisation. Some cases studies are combined with models for decision-making (e.g. Accorsi et al, 2015; Dong et al, 2016; Promentilla et al, 2016).

Quantitative methodologies are frequently employed to solve problem of optimization of material flows (waste, energy, by-products) and to help decision-making, either by

firms or network planners, namely in terms network design and location of facilities. Scholars use a diverse set of approaches, including mix integer linear programming (Accorsi et al, 2015; Bangera et al, 2018; Rentizelas et al, 2018), agent-based models (Fraccascia & Yazan, 2018; Lieder et al, 2017), and Life Cycle Assessment (Krystofik et al, 2018; Piezer et al, 2019). Other quantitative approaches, like regressions and cluster analysis, are also used, but less often (e.g. Bag et al, 2019; Barrie et al, 2019; Dubey et al, 2018).

Surprisingly, social network analysis (SNA) is not often employed in this literature. Only six studies use this methodological approach. This is unexpected because SNA is a tool that enables to understand and mapping networks and to analyse the actors/stakeholders in terms of their position in the network, reflecting their power and roles (namely in terms of coordination and brokerage) (Scott, 2000).

Source: Author's own elaboration

Figure 3. Research method employed in the studies

4.2 Level of analysis

Most studies have a meso perspective, focusing either on networks related to industrial symbiosis and industrial parks (e.g. Boons et al, 2011; Chertow & Ehrenfeld, 2012; Dong et al, 2013; Shi et al, 2010), or on networks related to specific supply-chains (e.g. Accorsi et al, 2015; Lin et al, 2018; Winkler, 2011).

The macro level includes networks developed at a city, region or national level (e.g. Gregson et al, 2015; Nuss et al, 2019; Tong et al, 2018) and networks related to the promotion of the circular economy principles (e.g. Barrie et al, 2019; Ogondo et al, 2013; Pialot et al, 2017; Spring & Araujo, 2017). Finally, in the micro level, authors are focusing on the networks at the firm level (Dubey et al, 2019; Hsieh et al, 2017; Niero et al, 2017).

Source: Author's own elaboration

Figure 4. Level of analysis adopted in the studies

4.3 Actors/Stakeholders

Regarding the network actors/stakeholders considered in the analysis, the majority of studies is concerned with the role of companies in the value chain, namely in terms of material flows. Governments (either central or local) are also included in a large number of studies, stressing its role in policy-making (e.g. Gumley, 2014; Lokesh, 2018), partnership creation (Baldassarre et al, 2019) or public procurement (Abreu et al, 2018). Fewer studies include other actors: universities (e.g. Mengal et al, 2018; Perey et al, 2018), companies outside the value chain (e.g. Shi et al, 2010; Winkler, 2011), NGOs (e.g. Herczeg et al, 2018; Kristensen et al, 2016; Mathews et al, 2018) or stakeholders like citizens (Hsieh et al, 2017; Petrescu et al, 2016), consumers (Korhonen et al, 2018; Pialot et al, 2017) and regulatory bodies (Mulrow et al, 2017). Some scholars stress the need to develop networks with a diverse/heterogeneous set of actors (e.g. Bellantuono et al, 2017; Domenech et al, 2019; Giezen, 2018; Wang et al, 2017), or the need to develop tripartite networks including companies, public organisations and the academia (e.g. Barrie et al, 2019; Dong et al, 2016).

Source: Author's own elaboration

Figure 5. Network actors/stakeholders included in the analysis

4.4 Purpose of the network

The documents reflect two main reasons for networking behaviour: the management of physical (by-products, materials, waste), energy and monetary flows and the access to knowledge and information.

The management of flows is vital for replacing the linear take-make-disposal/waste model and attaining circularity (Ghisellini et al, 2016), as stressed by the definition of CBE previously presented. Therefore, this is not an unexpected result. The number of studies explicitly addressing the closing of loops is considerably lower, when compared to the number of studies that tackle the issue of flow management.

The relevance of networking to access knowledge and information, strongly acknowledged in innovation studies, is also recognised in these documents. Scholars not only stress the relevance of partnerships to access and sharing knowledge and information, but also to generate new knowledge (e.g. Barrie et al, 2017; Mathews et al, 2018). Some authors distinguish between types of knowledge (for instance explicit vs tacit) (e.g. Aid et al, 2017; Barrie et al, 2019). Several studies (15) stress the role of digital technologies in facilitating information sharing between the network members (e.g. Dino et al, 2017; Dounavis et al, 2019; Fraccascia & Yazan, 2018). This information sharing is related to the path of material flows and to the quality of materials and partners and enables to reduce transaction costs along the value chain.

Access to complementary services through partnerships with third-party service providers for logistics, waste management, IT and remanufacturing is also highlighted in some studies (e.g. Bernon et al, 2018; Perey et al, 2018).

The authors also address the use of networks for co-creation and development of products/solutions (e.g. Brown et al, 2019; Leising et al, 2018; Niero et al, 2017) and business models (e.g. Mengal et al, 2018; Perey et al, 2018). Other purposes include credibility (Gavertsson et al, 2018) and vision (Mengal et al, 2018; Parida & Wincent, 2019) building.

Source: Author's own elaboration

Figure 6. Network purpose

4.5 Network building strategies and challenges

The last dimension of the SLR is related to the network building strategies and challenges in network management. All categories traditionally acknowledge in the network literature are present in this set of studies, chiefly those related to the governance of the network: coordination, trust and alignment.

The coordination challenge is usually raised in the debate between decentralised, bottom-up networks versus planned top-down initiatives (e.g. Giezen, 2018; Guo et al, 2016; Mengal et al, 2018) and to some specific roles that some actors may perform in structuring the network (e.g. Prosman et al, 2017; Zucchella & Previtali, 2019). Some scholars also stress the need to deal with conflict management (Baldassarre et al, 2019; Gupta et al, 2018; Petrescu et al, 2016).

Alignment issues cover a wide range of challenges, namely interest and vision alignment (e.g. Sellitto & Murakami, 2018; Strebel & Posch, 2004), collective goal setting (Aid et al, 2017), expectation management (Baldassare et al, 2019; Barrie et al, 2019) and culture (Walls & Paquin, 2015).

5 Conclusions

This paper provides an analysis on how networks have been integrated into the CE literature. For that, it draws on bibliometrics to map the evolution of the literature on Circular Economy that mentions networks, showing that only very recently the CE scholars started to pay attention to the role of networks, since the majority of the studies has 2 years or less.

Moreover, the paper conducts a SLR considering five analytical dimensions: 1) research method 2) level of analysis; 3) type of actors; 4) purpose of the network; 5) network building strategies and challenges.

The results show that the integration of networks in the CE is being accomplished using a diverse set of methodologies, with an underrepresentation of social network analysis and an emphasis on case studies and decision making models (optimization of material flows and facility location). Studies cover all levels of analysis (micro, meso and macro) and tend to stress relations inside the value-chain established to manage physical and energy flows. Despite this fact, there is also the acknowledgement of the role of other stakeholders (e.g. government and universities) and network purposes, like access to information and knowledge. Moreover, the CE literature tackles the main challenges in network management, namely coordination, trust and alignment.

Further research is needed in order to perform a more fine-grain analysis of the contributions of the network theory to the design and implementation of circular business models.

Knowledge Sharing among Supply Chain Members: the Benefits for Circularity

Radoslav Škapa

Department of Corporate Economics
Masaryk University
Lipová 41 a, 602 00 Brno, Czech Republic

Abstract

In the article, the circular economy is elaborated from the reverse flows perspective, as these flows are the essence of the circular economy. The link between these two areas is straightforward as both focus on transition from linear to circular business environment. To make reverse logistics effective, companies need more than (just) the refinement of reuse/repair/recycle activities, but a more thorough redesign of the production system including product design and the whole business model redefinition is often necessary. In particular, the analysis uncovers managerial characteristics typical for companies that include their first-tier supply chain members in their knowledge ecosystem.

The paper utilises the data collected in structured interviews among representatives of companies operating of the Czech market. The interviews covered multiple topics ranging from general management issues to circularity-specific areas such as general business views and motivation, and diverse aspects of management system. For this exploratory research aim, the inferential statistics were employed: besides frequencies, the Mann-Whitney tests and bivariate correlations were calculated for scales and dichotomies variables.

The analysis revealed managerial attitudes and practices, which are related to the intensity of knowledge sharing with the business partners; with the first-tier supply chain members. In other words, based on the perceived level of knowledge diffusion across a company, its customers, and suppliers, we identified typical features of management systems in companies that put effort into boosting their knowledge ecosystem.

First, these companies are more integrated (internally and externally). The multiple indicators suggest that companies boosting the knowledge diffusion in the supply chain also take slightly different actions in tactical and operational level as expressed by planning activities. The ambitions for circularity (as expressed by the motivation for reverse logistics) are not so much solely focussed on marketing motives such as customers loyalty, satisfaction, or image, but their aim is more shifted towards value creation (out of reverse flows) and (environmental) legislation compliance. These companies often believe that reverse flows are useful/necessary to deal with, which is not always the case in companies in general.

Finally, the statistic calculations identified that knowledge sharing has no apparent link to company size, manufacturing/service affiliation, but it is more intensive in companies that are closer to end customers, i.e. in downstream supply chain members.

The findings of exploratory nature provide insight into relationships and mechanisms in companies that share their circular economy related knowledge with their suppliers and

direct customers. Based on perceived company performance, it provides support for the economic rationality of knowledge sharing in the area of reverse flows.

Keywords – circular economy, reverse flows, knowledge sharing in the supply chain, empirical research, secondary data

Paper type – Academic Research Paper

1 Introduction

The transition from linear to circular economy is a complex task requiring a redefinition of business models as well as theoretical concepts and frameworks. The area of logistics belongs to the core of domains that are affected by the transition; however, the theoretical interconnection between the circular economy and (much more elaborated concept of) SCM has not been well developed (Homrich et al., 2017).

The paper put stress on one particular area in circularity - on reverse flows and their logistics and management. As the concept of reverse logistics is older than the circular economy initiative, it is natural that the circular economy is not among factors identified as a driver for reverse logistics in the published research papers. Nevertheless, reverse logistics is accepted as an essential tool, as an environmental initiative, that may close the material loop in supply chains (Govindan and Bouzon, 2018) and in this way it is essential for the circular economy.

In other words, the paper approaches the circular economy by focusing on reverse flows specifically. Obviously, this is a less complex view; still, the coverage of related issues is wide: besides product design issues aiming to maximize value creation over the product's lifecycle and its after use (Genovese et al., 2017), the problem of multiple parties involvement and governance in establishing closed loop supply chain (Tseng et al., 2017), are just examples. The papers aim is to identify such company's attributes that are related to external knowledge sharing to answer the question of what is typical in companies sharing knowledge with suppliers and customers.

2 Data and methods

The paper utilizes the data, which was collected by the department the author is affiliated and which was aimed at the understanding of managerial approaches of Czech companies to improvement initiatives and processes. In this way, the presented analysis belongs to the secondary data research, as it interprets a subset of variables relating to areas specified below.

The original data were collected through personal, structured interviews with the companies' representatives (top and middle management; operations specialists). As the questions asked for the data that companies usually do not measure, collect, and reprocess, the answers are the statements of informants. That was the only source of

information – no financial or any other quantitative data were used. The quick overview of sample structure containing 166 companies is in Tab 1.

Tab 1. Sample structure

Company size:	small	69%
	middle	25%
	large	6%
Industry: services / manufacturing		32 / 67%
ISO 9001/9004 certification		38 %
ISO 14001/ EMAS certification		18%

The questions in the original survey were adopted from papers of de Brito and Dekker, (2003), Jack, Powers, and Skinner (2010), Mollenkopf and Closs (2005), Rogers and Tibben-Lembke (1998).

Methodologically, the paper explores diverse aspects of the company's management system using statistical tools: the most variables are measured on ordinal level (seven-point scales). Therefore the analytical part relays on Spearman rank correlations and Chi-square tests in a lesser extent. The calculations were done in SPSS v24 and MS Excel 2016.

The main variable, which measured the cooperation of companies with its business partners, was then related to variables reflecting the motivation, barriers, and internal processes. Its distribution is apparent from Fig 1. This variable has no relationship to companies size or companies industry affiliation (measure on manufacturing/service level only).

Figure 1: Distribution of Knowledge management 1st-tier integration

3 Findings

The general view on the strategic role of reverse flows is apparent from Tab 2. The mean values (calculated on positively designed scale 1 - 7) give evidence about a slightly above-average role of reverse flows in terms of usefulness, if we accept 3.5 as cut point. The data about innovativeness in the sphere of reverse flows is more impressive: the mean value of 5.03 and 4.4 suggest that companies are intensively trying to optimize/innovate the reverse flow management.

For companies sharing the knowledge with business partners, the above approaches are even more intensive as suggested by significant correlation with the Role of reverse logistics (first line in Tab 2) and Changes in approach to reverse logistics in the last 5 years (the effectiveness of reverse logistics would fit here too if we accept the 1-sided significance).

Tab 2. The general perception of reverse flows

Variables related to knowledge sharing	Spearman rho	mean
Role of reverse logistics (useless vs. very necessary)	0.227**	3.982
The effectiveness of reverse logistics (causing high losses vs important competitive advantage)	0.131	3.920
Management approach to reverse logistics (conservative vs. innovative)	0.106	5.036
Change in approach to reverse logistics in the last five years (no vs substantial change)	0.237**	4.406

Note: ** Correlation is significant at the 0.01 level (2-tailed); * Correlation is significant at the 0.05 level (2-tailed).

Building on the previous research, we proposed ten business drivers/motives, which might be relevant for companies then thinking about reverse flows. The list of them in Tab 3 is sorted in decreasing way indicating that in general, the main motivation is related to marketing issues and societal aspects such as fulfilling the legislation requirements and conduction of CSR are weaker factors. Speaking about companies sharing the knowledge with the partners, we see some specific relations: in terms of correlation coefficient (and significance), the knowledge sharing is the most closely related to different drivers; it is value retrieval, legislation, and CSR (with some distance). Value retrieval (and CSR to a certain extent, depending on the interpretation of CSR and its real practice), can be interpreted as more circular thinking.

Tab 3. Overview of motivation for reverse flows

Drivers for reverse flows management	Rho	Mean
Customers' satisfaction	0.245**	5.94
Customers' loyalty	0.244**	5.765
Image	0.211**	5.337
Differentiation from competitors	0.186*	4.789
Cost reduction	0.285**	4.735
Productivity increase	0.193*	4.582
Differentiation from competitors	0.276**	4.277
Value retrieval	0.386**	4.021
Legislation	0.365**	3.909
Corporate social responsibility	0.292**	3.581

Note: ** Correlation is significant at the 0.01 level (2-tailed); * Correlation is significant at the 0.05 level (2-tailed).

Further analysis focused on sources of innovation for companies – both product and process innovations. The internal companies' resources (R and D departments, marketing,

quality departments etc.) are the main innovation sources as expressed using several scale questions. One interpretation of the specifics in companies sharing the knowledge is that slightly more attention is also given for fewer importance sources like unaccepted warranty returns, unsold product quantities, unsystematic complaint collection. In this way the approach of these companies is more diversified – they probably try to learn from any available data, not just relying on internal professionals.

Finally, the internal management system was tested for a relationship to external knowledge sharing. In the case of dichotomous variables, the Mann-Whitney test was applied.

Tab 4. Sources of innovation for companies

Innovations sources	Rho	mean
internal corporate resources	0.062	4.64
customers	0.152	4.22
competitors	0.167*	3.52
suppliers	0.181*	2.87
returned warranty product - accepted	0.147	3.40
returned warranty product - unaccepted/refused	0.202**	2.29
customers complaint collected systematically	0.151	3.69
customer complaints collected by employees unsystematically	0.205**	3.51
other unsystematic resources, (e.g.) customer online reviews	0.098	2.76
quantities of unsold products	0.272**	2.96
waste	0.188*	2.32

Note: ** Correlation is significant at the 0.01 level (2-tailed); * Correlation is significant at the 0.05 level (2-tailed).

One block of question on reverse flow planning is summarized in Tab 5 – each line shows the presence of the topic (reverse flows) in a particular planning level (the column “yes”). The most typical level dealing with reverse flows is the operational, followed by strategic plans. The relationship to knowledge sharing was found in tactical and operational plans.

Tab 5. Reverse flows planning

Level of planning	Mann-Whitney U	P-value	“yes” in %
Corporate strategy plan	2923.5	0.265	54.9
Functional/departmental strategy plans	2667	0.102	41.7
Tactical plans	2388	0.003	50.9
Operational plans	1928	0.001	68.3
No plan – presence of ad hoc decisions	2517	0.063	41.9

There is no relationship to ICT support for reverse flow, ISO 9001/14001 certification and the existence of a specialized department for reverse flows (Tab 6).

Tab 6. Diverse management system aspects

Other management system aspects	Mann-Whitney U	P-value	“yes” in %
ICT support for reverse flow	2753	0.075	47.6
ISO 9001 certification	3018	0,574	62.0
ISO 1004 certification	2045	0,945	81.3
Specialized department for reverse flows	2201	0,841	78.7

The cross-functional integration (relating to the process management approach) was divided into five aspects – internal one, the integration for reverse flows processes, integration for customers/suppliers and end-customers, which is relevant if the company is not final product produced, or/and if there are some intermediaries in the distribution.

As it might be expected, all the above integration areas have significant relationships to knowledge sharing, out of which the internal integration is the strongest (both corporate-wide and reverse flows specific). The last line in table 6 suggests that knowledge sharing is more intensive in companies that are closer to its final customers.

Tab 6. Measures of integration

Management system features	Rho	mean
Corporate-wide integration across functions	0.340**	4.2
Cross-functional integration of reverse flows activities	0.291**	3.93
Integration with customers in the area of reverse flows	0.162*	3.91
Integration with suppliers in the area of reverse flows	0.227**	3.54
Direct (directness) relation to end-customers	0.169*	5.51

Note: ** Correlation is significant at the 0.01 level (2-tailed); * Correlation is significant at the 0.05 level (2-tailed).

4 Conclusions

The intensity in knowledge sharing with business partners belongs to those attributes that distinguish the companies in terms of their general strategic orientation (their view on reverse flows in particular) and operational settings. As it was documented by many relationships (identified statistically), the knowledge sharing is linked with circularity – the different view on and the approach to reverse flows is documented by specific motivation and more intense tactical and operational planning. The difference was also found in the innovation sources – compared to whole research sample, the companies with intensive knowledge sharing learn more from diverse sources – in relation to circularity, the reverse flow (refused warranty products) as a source for innovation process is of relevance. The link to integration was confirmed too, even though, this finding was expected. To the contrary, no links were documented in the data in terms of ISO certification.

The study faces several limitations that need to be considered when assessing the validity of the findings. First, the research sample is rather small. There is also a risk of data distortion as a single informant approach was chosen (for a practical reason). As

explained in the beginning, the most questions related to the *non-monitored* facts, so the data were personal perceptions only; the interpersonal view, in this case, would be more relevant here.

How Knowledge Management is Approached in Circular Economy Academic Research?

Alena Klapalová

Department of Corporate Economy
Faculty of Economics and Administration
Masaryk University
Lipová 41a, 60200 Brno, Czechia

Abstract

The main objective of the paper is to gain understanding and overview of how knowledge management practices are understood and approached in the current academic research of circular economy with the focus on business life. A systematic literature review was conducted to identify knowledge management concepts, implemented knowledge management methods, tools or models as well as the areas of knowledge management theory applications and the contexts of applications in the existing academic papers. The aim of the paper behind the main objective is not only to summarize existing evidence but also to draw attention of business practice to the role of knowledge management and complex knowledge ecosystems for meeting the circular economy challenges and overcoming the circular economy barriers.

For this paper peer-reviewed journals articles included in the Web of Science and SCOPUS databases were analysed within the systematic literature review. The main findings show that most of the current body of knowledge management theory is ignored in circular economy and circular business literature and the interest is focused mainly on knowledge sharing, knowledge acquisition and lack of knowledge while other important themes are not elaborated at all or only marginally.

Keywords – Knowledge management, Knowledge ecosystems, Circular economy, Systematic literature review

Paper type – Academic Research Paper

1 Introduction

Circular economy (also CE) is rapidly developing phenomenon which is strongly promoted by many governments worldwide and also in the European Union through different policies, legislation and regulations (Kalmykova et al, 2018) but also by supporting and supportive programmes and actions. CE is an umbrella term encompassing heterogeneous initiatives, multiple schools of thoughts and their principles belonging to the sustainability and sustainable development and sustainable growth movement (Blomsma and Brennan, 2017; Pauliuk, 2018). The “wide-angle view” of the

coverage and complexity of CE concept is reflected also in the understanding of CE given by Murray et al (2017, p. 5) who define it as a “*general term covering all activities...*” that indirectly in the form of policies, strategies and programs or directly in a real life practice aims to “*...reduce, reuse, and recycle materials in production, distribution, and consumption processes*”. The core idea behind CE movement lies in still more urgent problematic global situation when the pursuit of the economic growth leads to serious eco-environmental degradation, to the reduction of the biosphere reproductive capacity (Merli et al, 2018) and to destruction of whole ecosystems (Winn and Pogutz, 2013) which in turn - with some delay - negatively influences also business environment (Dean and McMullen, 2007).

In the business practices the ideas and principles of CE are rather difficult to implement as the transition from the linear way of doing the business into the circular one needs specific innovative capabilities and knowledge of a network of stakeholders within and around the firms (Ritzén and Sandström, 2017; Govindan and Hasanagic, 2018). Closer collaboration with stakeholders (and with more and new stakeholders) especially from the external environment and more intensive utilization of the information technology is inevitable for provision of circular flows of products, packaging, information, finance and knowledge and to make business to become circular (Lahti et al, 2018) as the needed – and sometimes specific – skills, capabilities, knowledge and other resources often “*reside outside of the organizational boundaries*” (Levering and Boss, 2018, p. 44).). Circular value creation and value delivery may also have different impact on the environmental ecosystems (that also can be different) (Zucchella and Previtali, 2018, in press). All these differences are connected also with the changes in knowledge ecosystems and knowledge management (also KM) – of the focal firm and of its stakeholders.

Not only new knowledge will be created with new actors and new processes, but also new patterns and new processes will emerge of how to acquire, capture, analyse, utilize, store and share the knowledge. KM plays the essential role in sustainable and competitive value creation reflected in the organisational performance in general (Schiuma et al, 2012) as well as it plays the crucial role for designing adequate and not only the circular economy promoting knowledge ecosystem (Valkokari, 2015). However, until now there is no study identifying state of the art in the literature and highlighting research gaps and areas of concern for the practice and future research in case of KM in CE.

The main objective of the paper is to gain understanding and overview of how knowledge management practices are understood and approached in the current academic research of circular economy with the focus on business life through the systematic review of literature. As the novelty accompanies circular economy concept, the research questions which guide the review are as following:

How is knowledge management conceived in circular economy theory?

What novel, specific and innovative characteristics and features of knowledge management explored, studied and published are related to circular economy and what specific knowledge, skills, competencies, capabilities are needed in CE?

The first section of the paper presents research approach, in the second results of systematic review are summarized and discussed. Finally, conclusions are drawn, and future research streams are outlined.

2 Methodology

To reach the objective, a systematic literature review was conducted. The main purpose of a systematic review is to identify the key theory-based understanding of the phenomenon of interest (Becheikh et al, 2006), to map “what” and “how” issues in the theory and also to identify gaps in current knowledge and delineate the avenues for future research (Aquilani et al, 2017). Based on Correia et al (2017) the process of the review employed for this paper consists of three broad and general phases: *1) problem formulation and question identification* (see Introduction); *(2) literature search and conducting the review*; and *(3) reporting results*“ (next chapter). For the review of final selected articles, the content analysis was performed.

Only peer-reviewed articles written in English were included in the search. They were obtained by querying the Web of Science and Scopus databases. These databases are commonly used for the purpose of a systematic literature review and are considered as the most comprehensive scientific databases (Aghaei Chadegani et al, 2013). No other exclusion criteria were applied e.g. for publication years and research areas. First, only the basic combination of the general terms “knowledge management” AND “circular economy” was used, but only 3 (Web of Science) and 4 (Scopus) articles were found with one overlap. Therefore, in the second search broader term of “knowledge” (instead of “knowledge management”) was applied. This resulted in 152 articles in Web of Science and 159 articles in Scopus, with 132 overlapping cases.

After the inspection of titles, abstracts and keywords 47 articles entered the step of the whole text screening. The excluded articles did not correspond to the research aims as in the title, abstract or key words they mentioned either one or both keywords in other context than was needed for the review. For the inclusion/exclusion business context of the article must be presented. Full text screening of 47 articles involved evaluation of the relevancy of articles in term of the typical representative concepts and terms of KM that are relevant and connected to KM practices. Similar to the approach to understand the scope of CE also in this case the screening was realized using list of the concepts and terms based on the brief review of 20 most cited articles on “knowledge management” in Web of Science supplemented by the search results of 30 most cited articles within the period 2016 – 2019. Again, in this step – despite promising wording of the titles and abstracts – exclusion of several articles was done if KM was only touched upon, but KM was not the main area or at least one of the areas examined in the articles. The list is not exhaustive and both list and references – due to the limited extent of paper - are available on request from the author.

Thorough reading of the body of the texts lead to the further elimination, so the final list consists of 23 articles relevant to the point of interest. From the 47 articles which entered the steps before the final analysis one was not available.

3 Results

CE needs KM which would help to process, store, visualize, share, exchange amount of data and information from, to and about stakeholders, processes and products and materials involved in circular business in the efficient and effective manner. Online platforms seem to be an appropriate tool for this issue. This is confirmed for instance in the article exploring the role of institutional capacity-building through industrial symbiosis in the development of a circular economy. (de Abreu and Ceglia, 2018). Online platforms help to reduce uncertainties and implement a trustful business, they are an important source of information that firms could use to find business opportunities and they also promote synergies. Collaboration and data sharing tools as very helpful for harnessing knowledge-bases outside traditional knowledge areas needed for the innovative activities are mentioned in the research among waste management sector managers in Sweden (Aid et al, 2017).

Information availability and visibility is crucial for a product lifecycle management (PLM) system and product and material passports are considered to be very helpful to provide right information aiming to increase efficiency in resource management. Research done by Portillo-Barco and Charnley (2015) shows how challenging is to develop the content of a product passport (identification of data requirements and applications of sensing technologies) which would meet all requirements for data and information of the relevant stakeholders and reflect also specific condition of the environment through which product flows in cycles.

For designers and engineers in case of remanufacturing and recycling the knowledge of disassembly time is essential information for designers and engineers to make changes or adaptation into the process (and product design), however this knowledge is gained at the dismantling and de-manufacturing centres. Mandolini et al (2018) suggest and test method which enable to assess the disassembly time, estimated by using an exact disassembly sequence planning approach and a structured repository for the classification of knowledge about elementary disassembly tasks.

Tolio et al ((2017) present a broader and deeper view on different information and knowledge flow for CE in material engineering. They reviewed methods and tools as well as strategies for different CE processes in manufacturing – both theoretical and from practise and gather also information and knowledge processing-related examples.

Jiang et al (2019) proposed and tested a new hybrid method combining rough set (RS) and cased-based reasoning (CBR) for remanufacturing process planning of cores with an interactive interface. This method based on mathematical modelling helps to reuse knowledge generated from existing used parts intended for remanufacturing to facilitate process planning for the new arrival of used parts. The interface allows a user to input important information for decision making related to remanufacturing regarding part as well as failure(s) characteristics. Evaluation of the input information offers user recommendation for remanufacturing.

Network of actors (or stakeholders) represents one of the most important themes in CE. All empirical, all reviews, most of the mixed and some of the conceptual

methodology-based articles deal with issue. Barrie et al (2019) explored the position and role of the triple helix-based system intermediary as an approach to governance for tacit and explicit knowledge transfer, exchange and coordination and facilitation of shared learning in national industrial biotechnology niche network. They also developed concept of “Total knowledge transfer” which “is a multiplex relational attribute formed through the combination of values from tacit and explicit knowledge transfer relational attributes facilitating shared learning” (p. 2013). De Abreu and Ceglia (2018) explored the role of institutional capacity-building through industrial symbiosis. Three dimensions of the institutional capacity must but managed – knowledge and relational resources and capacity for mobilization. Formal structure of industrial symbiosis is beneficial for the development of the CE. Wang et al (2017) confirm the role of a network in industrial symbiosis by promoting relational links across organisations and governance levels. Network, purposely managed helps to increase various types of knowledge.

For a network to work effectively and efficiently collaboration is indispensable. Xiang and Yuan (2018) proposed and tested a “Collaboration-driven mode” based on information sharing which incorporated all relevant information sharing paths and their contents among stakeholders, role and description of role of promoters in the mode and the incentive strategies for information sharing.

Facilitation of networking can be realized via ICT online tools (or the aforementioned platforms). Alvarez and Ruiz-Puente (2017) present “SymbioSyS”, a tool which helps to promote the sustainable use of resources through building of a large database that stores both more or less tacit knowledge of experiences and practices and explicit information about activities.

Leadership, role of champion and enthusiasm and collaborative experimentation within innovative activities, the role of a change agent and an industrial symbiosis promoter for knowledge generation and sharing within CE networks of actors are also stressed as the KM approaches to support transition towards CE (Brown et al, 2019; de Abreu and Ceglia, 2018).

Salvia and Quaranta (2018) present findings from their research studying the attitudes and perceptions of groups of cereal farmers regarding two projects in Basilicata (Italy) region with the aim to return the old traditional knowledge to the nowadays practice of land use and so to reduce production costs and promote soil conservation. They found that full understanding of the advantages/ disadvantages of approaches, transparency of recommendations, more confidence in trusting recommendations for practical applications from other farmers than from researchers and high involvement in the process of learning is critical for the success of transition to this CE practice. Based on the findings from the interviews and survey the authors propose the adaptation of SECI model of KM: 1. receive knowledge (the best source are those who share the same problem), 2. identify knowledge as useful, 3. understand implications of knowledge, 4. choose options to work on knowledge, 5. action the option(s), 6. evaluate results of action(s) and 7. share evaluation with others.

Bueren et al (2018) analysed four existing plant breeding orientations and based on the positive and negative feature suggested the novel approach – „a systems-based

breeding”. Plant breeding is an extremely complex process with long-term impact on whole ecosystem(s). This is why transdisciplinarity of knowledge is needed to create a synergy of social and natural sciences and integration of knowledge at and from various levels – socio-economic, agro-ecological among all. The importance of transdisciplinarity for CE, especially for the transition from linear to circular economy is accentuated also by Marra et al (2018). The authors reviewed 1244 research publications on circular economy and revealed that existing body of knowledge for macro or policy making level, which creates necessary conditions for CE – is extremely deficient and what is missing (also for micro and meso levels) is knowledge coming from social sciences, economics and behavioural sciences and their integration. To this stream of research findings from Antonnen et al (2018) review of key industrial texts, policy reports and abstracts of the academic articles devoted to CE utilizing topic modelling methodology can be added. The aim of the review was to discover how big is “the consensus space” of three institutional spheres of Triple-Helix (industry, government and university) which constitutes an important system to accomplish systemic innovations typical for CE success. Their findings show that the consensus space is rather small, and many crucial aspects of CE functioning are missing not only in this space but also in the individual domains. They point especially to consumer behaviour (in larger social dimension view) and paradoxically also environmental dimension of sustainability (as the current interest is concentrated only on a few areas).

Mutual learning and sharing of the individual knowledge of designers designing CE products and processes is incorporated into the serious game for professionals called „In the Loop: The Critical Raw Materials Game“, developed and tested by Whalen and Peck (2014). Their article is one of the several examples dealing with the changing role and capabilities of designer in CE environment. Mutual learning and increase of understanding as well as overcoming biases for human-machine interfaces is evaluated by Arnold (2018) through the application of a “structural systemic constellations” as an innovative tool which might help to integrate unconscious knowledge in a research context and should be suitable especially in complex systems that are typical in CE. Workshops are another way how to stimulate common understanding and support sharing of knowledge and generation of new knowledge (*De Abreu and Ceglia, 2018*).

With regard to consumers 3 articles pay closer attention to this stakeholder and his role in CE in case of KM. Lofthouse and Prendeville (2018) discuss the role of designers in CE who should integrate knowledge from the social sciences (especially consumption, consumer psychology, cultural studies). Also research on design needs to develop knowledge on how to design products and services for different circular business models “*by considering norms, behaviours, attitudes and the contexts of people’s social live*” (p. 466).

Seminal article written by Tukker (2015) on Product Service Systems (PSS) points to challenges and problems with convincing consumers to shift from the ownership to relatively more circular business models. This may be ranked to the “know-why” and “know-what” issue from KM. In context of PSS Hobson et al (2018) discusses empirical research exploring consumers' reactions to a novel, hypothetical mobile phone. Research

examines consumers' knowledge about current mobile phone life cycles, and responses to the proposed product service system. Action-based research demonstrates also the function of a “systems of practice” framework to discuss the potential for significant changes in phone purchase and use stemming from the increase of understanding and awareness of the complexity of phone production, distribution and recovery options.

*Some articles stress role of designers and innovators for CE and also changes of their role, especially in the broadening of the scope of their work. This is reflected in new knowledge, skills and capabilities requirements. De los Rios and Charnley (2017) focus directly on designers and allege that for designer a variety of new capabilities will be needed, from deeper knowledge of material composition to rich understanding of social behaviour“ (p. 109). Brown et al (2019) point to both **hard capabilities and soft skills** needed for collaborative circular innovation-oriented activities of companies. Specific hard capabilities include specific CE design strategies and product criteria that are linked to different recovery operations across whole product life cycle considering multiple life cycles as well together with the incorporation of knowledge and requirements of stakeholders in circular value network. Knowledge might be rather interdisciplinary and includes also assessment of impacts across multiple product life-cycles and not only at the individual but at the system network level. Skills to build and support collaboration with stakeholders vital for successful circular business models and to translate and communicate CE complexity into a clear future vision to be fully comprehended by stakeholders who operationalize business models belong to the most important soft skills. Barrie et al mention also an urgent need of “transition thinking” for CE.*

Specific manual and technological skills for core CE activities and more complex cognitive skills for the CE enabling activities that should be part of the educational curricula and trainings programs for the future were investigated by Burger et al (2019) in the U.S.A. environment, nevertheless with the general applicability anywhere. They stress particularly skills to collaborate to create joint value, to design for the future, to incorporate digital technology, to be able to prioritise regenerative resources, to use waste as a resource. To rethink the business models, complex problem-solving skills and resource management skills.

Tukker (2015) demonstrates that particularly result-oriented PSS requires different and specific skills (product knowledge and more dedicated and unique customer knowledge and customer and relation management skills) and also the organization. Knowledge is generated not only from relationships but also from remote monitoring and maintenance systems incorporated into the product and tracking the performance. Bottom-up knowledge sharing techniques are supportive to PSS design.

Van Schalkwyk et al (2018) reviewed literature on the metallurgical knowledge, the behaviour of technology elements and existing simulation and modelling techniques in lead metallurgy, which is considered to be a key to the CE. The authors also think about challenges of digitalization for tracking the metallurgical knowledge. The conclusions show that there are big gaps in current knowledge which make barriers for process optimisation and more efficient use of metals in CE.

Aid et al (2017) looked into the Swedish waste management sector and analysed challenges for inter organizational resource network to create circular value offer. Core competencies or in-house technical knowledge of waste management companies are identifying, developing, and implementing solutions (specifically sorting and valuation technology knowledge) for complex wastes and by-products. Advanced market and technology intelligence are perceived to be of increasing importance for companies

Barrie et al (2019) highlight specific transition thinking for the successful move from linear to circular business model.

4 Conclusions

Review manifest enormous inattention to knowledge management in CE theory in comparison to many other fields of study and this conclusion only support idea of Jabbour et al (2017, in press) that CE as a body of knowledge is in its infancy but also the statement that it “*is an exercise in knowledge creation and application....*” (de Abreu and Ceglia, 2018, p. 106).

Paper has several limitations. For instance, conference papers should be included into the review or other databases as well.

Abstract

The aim of this paper is to investigate the role of boundaries management when firms should implement open innovation. The paper is based on: the review of relevant literature on strategic management, firm's boundaries and open innovation fields; a survey of a sample of Italian listed firms. Findings show, from a side, that open innovation and many modern paths growth are connected to the firm's boundaries and, on the other side, that boundaries management play a key role for the implementation of open innovation. Indeed, we provide implications for practitioners by shedding light on the advantages and the risks that can jeopardize the successful outcome of opening up the innovation processes without the effective management of boundaries.

Keywords – open innovation, boundaries management, corporate growth strategies

Paper type – Academic Research Paper

1 Introduction

Corporate growth strategies should be properly developed to create innovative paths and competitive advantage (Liu and Liang, 2015; Zhang, 2011). Scholars investigating the innovation paths have recently juxtaposed the “open innovation” to the traditional “closed innovation” perspective (Chesbrough, 2003a; Chesbrough, 2003b; Chesbrough, 2003c; Von Hippel and von Krogh, 2006). Studies on open innovation have at first paid attention to the potential benefits of opening up the innovation processes (Gambardella, Panico, 2014). Following literature highlighted that the implementation of open innovation involves organizational, cultural, managerial and technological challenges (Lombardi et al., 2016; Von Hippel, 1986; Von Hippel, 1988; West and Bogers, 2013) by suggesting issues to face within the firm boundaries and beyond them (Giannopoulou et al., 2010; West et al., 2014). However, despite the relevance of organization boundaries in innovation literature stream (Lakhani et al., 2013), there is a lack of studies analysing the relationships between corporate growth strategies, the implementation of open innovation and firm boundaries (Fiorentino, 2016; Garzella, 2000; Trequattrini et al., 2012). Conversely, studies need to investigate the role of boundaries management – how managers coordinate resources, activities and business processes on the boundaries of the firm - in the implementation of open innovation in order to lead firms in searching the right balance between open and closed approaches. By shedding light on the relationships between corporate growth strategies, open innovation and boundaries management, Scholars should provide implications for seizing open opportunities by effectively managing risks related to the protection of firm internal assets.

Accordingly, approaching the call for what challenges have to face firms embracing open innovation approaches (Chesbrough, 2006; Hossain et al., 2016; Huizingh, 2011; Van de Vrande et al., 2009), the aim of this paper is to investigate the role of boundaries management when firms should implement open innovation.

In order to achieve paper’s purpose, we have developed: a review of relevant literature on strategic management, firm’s boundaries and open innovation fields; an empirical analysis based on a questionnaire survey of a sample of Italian listed firms. An interpretive methodology is used to analyse empirical data. By critically integrating literature review and empirical analysis, a framework is provided with the objective of supporting the open innovation implementation.

The next section provides the theoretical background. Section 3 discusses methodological issues, providing a detailed description of the research methods used to address the research questions. Section 4 presents and discusses the findings. Finally, section 5 presents conclusions, implications and limitations.

2 Theoretical background

Current markets are witnessing a rapid increase of activities, traditionally within companies, realized by outsourcing processes (McIvor, 2009). The search for success pushes frequently towards partnerships and strategic alliances (Boddy et al., 2000). The

traditional “internal” and “external” growth strategies are becoming less useful to analyse corporate growth strategies. Traditional theories, such as “transaction cost economics” and “resource-based views”, generally investigate growth strategies by a “make or buy” lens (Barney, 1991; Coase, 1937; Williamson, 1975). These theories have been recently developed based on the evolutions in competitive and technological landscape pushing towards collaborative decisions in resource, knowledge and business processes management (Foss, 1996; Milgrom and Roberts, 1990; Parmigiani and Mitchell, 2009; Santos and Heisenhardt, 2005; Tortoriello and Krackhardt, 2010).

The rise of new growth strategies characterizes managerial issues and makes the management of firm boundaries a key variable (Foss et al., 2013; Swink et al., 2007). Studies increasingly focus on firm’s boundaries as a third alternative, over integration and market, and the joint use of skills and knowledge has highlighted the role of boundary management (Alexander, 1997). The topic of boundaries was analysed by studies from economics, management and organizational behaviour (Villalonga and McGahan, 2005). These studies have referred to the boundary concept to analyse resources, activities and processes that can be jointly controlled and influenced by many organizations (Yang et al., 2010). Scholars have found that the “control” should be the most useful criterion to define where firm boundaries should be placed: “the organization ends where its discretion ends and another begins” (Pfeffer and Salancik, 1978, p. 32). More in depth, boundaries should be viewed as a continuum area that represents an intermediate form of hybrid governance (Normann and Ramirez, 1993). Since this continuum constitutes a “border area” in which it is not easy to distinguish the firms from the external environment, it is increasingly necessary to use the concept of boundaries and the “boundary zone” (Caputo et al., 2018).

Boundary management should be the way to integrate benefits of internal and external growth strategies (Hargadon, 2002; McEvily and Zaheer, 1999; Park et al. 2004; Lavie, 2006; Steensma and Corley, 2001; Takeishi, 2001) and it is becoming a new paradigm to obtain and sustain competitive advantage (Dyer and Singh, 1998; Garzella, 2000; Wagner, 2003). Scholars suggest advantages from boundaries management (Cao and Zhang, 2011; Cassiman and Veugelers, 2006; Parmigiani and Mitchell, 2009). These findings lead managers to overcome the traditional trade-offs among internal and external growth strategies (Cao and Zhang, 2011; Cassiman and Veugelers, 2006; Fiorentino, 2016; Parmigiani and Mitchell, 2009). These trends suggest to jointly analyse the literature streams on open innovation and boundaries management.

Over the last decades, the relevance of open innovation in management research is showed by an exponential number of studies on the topic (Hossain et al., 2016; Huizingh, 2011). Through the introduction of new paradigm (Chesbrough, 2003a; Chesbrough, 2003b; Chesbrough, 2003c; Von Hippel and von Krogh, 2006), open innovation has been investigated under several perspectives and specific issues referring both to large firms and to small and medium enterprises (SMEs) (Hossain and Kauranen, 2016). In this direction, the pioneering study by Chesbrough (2003a) defines open innovation as “a paradigm that assumes that firms can and should use external ideas as well as internal

ideas, and internal and external paths to market, as the firms look to advance their technology”.

Open innovation is based on outside-in, inside-in and coupled processes or modes (Aloini et al., 2017; Enkel et al., 2009; Gassmann and Enkel, 2004; Trequattrini et al., 2012; West and Bogers, 2013). Thus, open innovation is guided by external versus internal modes of ideas and knowledge (inbond), internal versus external modes of ideas and knowledge (outbond) and a combination of previous modes. Chesbrough et al. (2006) state that open innovation is a “purposive inflows and outflows of knowledge to accelerate internal innovation and to expand the markets for external use of innovation”. Van de Vandre et al. (2009) recognize purposive outflows and inflows of knowledge in the technology exploitation versus technology exploration, including a combination of them: “Purposive outflows of knowledge, or technology exploitation, implies innovation activities to leverage existing technological capabilities outside the boundaries of the organization. Purposive inflows, which we will refer to as technology exploration, relates to innovation activities to capture and benefit from external sources of knowledge to enhance current technological developments.”

Although several open innovation modes exist in terms of openness (Gambardella and Panico, 2014). Abulrub and Lee (2012) study shows as firms use only few types of thirteen identified modes of open innovation among which joint research development, contract R&D, customer involvement, and external networking. Implementing open innovation modes, firms change activities process transforming innovation management model, business model (Lombardi et al., 2016) and sharing knowledge with producers, providers, users, research centers, universities and other network actors (Von Hippel, 1986). The involvement of several external resources becomes a focal issue in recognizing firm boundaries resources and in governing firm through strategic boundaries management (Giannopoulou et al., 2010; West et al., 2014). Although the influence of openness in innovation modes on business performance should be defined (Von Hippel, 1988; West and Bogers, 2013), Toma et al. (2018) underline “OI has been defined as a distributed innovation process based on purposively managed knowledge flows across organizational boundaries (Chesbrough and Bogers, 2014)”. Boundaries management gains a key role (Adamides, 2015; Foss et al., 2013; Garzella 2000; Ritter et al., 2004; Swink et al., 2007; Villalonga and McGahan, 2005). The boundaries management should favour the design and management of innovation in a wider perspective to identify new integration and coordination opportunities among the value chains of the firm and the value chains of external “partners” (Boddy et al., 2000; Pil and Holweg, 2006) by “linking” and “bearing” strategies (Caputo et al., 2018; Scott, 2003). The “linking strategies” seek to internalize the resources and skills of the partners. Firms, pursuing the information sharing and the alignment of internal and external innovation processes, should allow redesigning the entire business model innovatively. At the same time, however, firms need to supervise innovation processes by developing “bearing” strategies that allow protecting from the risk that external actors should acquire key information by the relationship with the firm. Boundary strategies add specific potential to the strengths that characterize open innovation paths.

However, in this scenario, there is a lack of studies analysing the relationships between organizations boundaries, open innovation and corporate growth strategies. Thus, a relevant issue is to discover what challenges have to face firms embracing open innovation models and approaches (Chesbrough, 2006) in the light of boundaries management. In the light of previous considerations, the research questions are the following:

RQ1. What is the link connecting open innovation, new paths of corporate growth and firm boundaries?

RQ2. What are the boundaries resources and activities to foster management and implementation of open innovation?

RQ3. How firms can face the typical risks in implementing open innovation by boundaries management?

3 Methods

An interpretive-qualitative methodology (Yanow et al., 2014; Schwartz-Shea et al., 2012) has been applied to answer the research questions. Particularly, the chosen technique has been the survey questionnaire (Cooper et al., 2006; Hoque, 2018). Although this method is influenced by some bias, such as non-response bias (de Villiers and Dumay, 2014), it is relevant in collecting empirical data and information on the firm through the utilization of one or more questionnaires allowing researchers to propose relevant reflection on results by respondents. The following subsections describe the sample selection, data collection, measures and, data analysis

The sample selection occurred through the utilisation of the data source AIDA provided by Bureau van Dijk. In this way, all Italian listed companies at 31st march 2018 were selected. Thus, the sample of this research is composed of 334 national listed companies belonging to several economic fields. In order to investigate the role of boundaries management when firms adopt and implement open innovation approaches, data were collected using a survey questionnaire created through Google docs and directed to CEO, GM and R&D Responsible of each selected company composing the sample. In this perspective, it is relevant to underling that CEO, GM and CEO-R&D are deputy to assume significant decision-making processes in the organizations, among which decision making on corporate strategy and open innovation implementation. Thus, at the beginning of May 2018, an invitation - via email - to participate to an online questionnaire was sent to Investor Relators of firms sample. To increase the response rate, such invitation included a cover letter. Although the total of questionnaires filled were expected, the data collection process resulted in 18 responses by alternatively CEO, GM and CEO-R&D. Thus, the response rate was about 5%.

Questionnaire used for the online survey reflected what is open innovation and what is implementation of open innovation in the firms. Thus, it was directed to obtain evidence supporting the purpose of this research. Thus, the questionnaire was divided into three main parts in addition to an introduction to this study composed of the general context and aims of research: the first was directed to collect general data about key internal

actors; the second aimed to discover the role of open innovation in the corporate development strategy; the third was directed to obtain information on success factors and risks deriving from open innovation implementation in the firm.

Additionally, the questionnaire included 21 questions of which 2 open-ended questions, 8 open-closed questions (“yes”, “no” and “other”), 11 closed-ended questions. The closed-ended questions were structured in a five-point scale model ranging from “not essential” to “highly essential”. In this perspective, a deep investigation of questionnaire results was conducted according to the responses received at 8th June 2018.

The reliability of proposed questionnaire derives from pre-testing activities conducted by authors. However, the integrity of the proposed investigation is guaranteed by a joint work strategy among the authors as well as by the long-time experience and knowledge of authors in the field. Particularly, the results of the online questionnaire were analysed and discussed among the authors to achieve significant research and practical considerations and implications on the topic analysed. In this direction, findings and discussion are presented in the following section.

4 Findings

Our explorative research aimed to provide a comprehensive view on the role of boundaries management when firms should implement open innovation. We have asked for the links connecting open innovation, new paths of corporate growth and firm boundaries, for boundaries resources and activities to foster management and implementation of open innovation and for the role of boundaries management in facing the typical risks in implementing open innovation. Thus, the experts’ answers provide interesting insights to advance theories in the field of firm boundaries (Cao and Zhang, 2011; Garzella, 2000; Villalonga and McGahan, 2005), open innovation (Chesbrough 2003a; Enkel et al., 2009; Trequattrini et al., 2012) and corporate growth strategies (Fiorentino, 2016; Foss et al., 2013; Garzella, 2000) discovering relevant issues about boundaries management when firms embracing open innovation (Chesbrough, 2006).

Testing in the questionnaire the presence of actions directed to implement open innovation strategy, almost all respondents of our questionnaire declare the existence of several corporate actions directed to develop strategies fostering open innovation contributing to existing theories (Fiorentino, 2016; Foss et al., 2013; Garzella, 2000). Many respondents’ answers consider the activation of collaboration with some partners on innovation projects in next three years more than essential for the firms.

Additionally, we have asked which is the firm willingness to collaborate with some key individuals. In this direction, providers of goods and services and territorial organizations seem the most relevant key individuals in approximately half of expert’s answers. Highly essential key individuals are confirmed in providers of goods, clients, research centres and university and territorial organizations. However, substitute providers and new entrant on the market seem to be the less relevant than other key individuals.

RQ1. The findings suggest that open innovation is equally important for product, process and business model innovation (Fiorentino, 2016; Garzella, 2000; Trequattrini et al, 2012). In the new competitive contexts, the open innovation is an obligatory choice more than a chance. The open innovation represents a real alternative to traditional strategies for achieving positions of competitive advantage.

Most important, respondents suggest that open innovation can be framed mainly as a rethinking of the traditional distinction between internal and external growth strategies. Firms move to open innovation in order to increase creativity, to reduce time to market, and to improve product and process quality more than to reduce risks and costs.

The questionnaires underline that open innovation makes it possible to enhance the knowledge produced outside the company by transferring it within. However, relations with partners emerge as one of the main risks of external growth strategies, and open innovation. Accordingly, in the respondent's opinion boundaries management can play a key role to improve corporate strategies and open innovation first by reducing the timing of innovation processes (so increasing the value of innovation) and avoiding inter-organizational conflicts. Furthermore, boundaries resources and activities can help firms in questioning consolidated thinking models.

RQ2. The findings suggest that the effectiveness of the open innovation process depends mainly on the relational skills of top management (Chesbrough, 2003a; Enkel et al., 2009). In open innovation implementation, relations with customers are, surprisingly, more important than relations with suppliers. The success in implementing open innovation is also related to: the creation of organizational units devoted to boundaries management by new ad-hoc organizational unit for each open innovation process; the creation of culture and organization favourable to open innovation.

Our results underline that in order to foster open innovation, the boundaries managers should be engaged in relevant boundaries activities such as, in order of importance in respondent's perception: the formation of people with boundaries management skills; the selection of subjects to be involved in open innovation implementation; the capability to adequately assess risks and goals of open innovation with other involved subjects; the adoption of linking strategies with partners; the adoption of bearing strategies.

RQ3. The survey confirms that the boundaries management can play a key role (Cao and Zhang, 2011; Cassiman and Veugelers, 2006; Garzella, 2000; Parmigiani and Mitchell, 2009; Wagner, 2003) in: increasing cohesion and collaboration of open innovation working team; reducing the coordination costs; improving the commitment on the project; facing resistances due to corporate culture and leading change management processes; enhance the willingness to share know how in fair mode; protecting internal know-how. Moreover, one generally overlooked factor that was discussed as relevant in our survey is the relations among internal functions, which are more important than relations with external partners. In this regard, the role of boundaries managers is strengthened.

The respondents felt boundaries management to be relevant because it impacts on the management of typical firm risks in implementing open innovation. The boundaries management can improve the selection of partners by effective negotiation processes.

Indeed, the focus on boundaries resources and activities can foster continuous process of manager formation in order to bridge the gap about the lack of skills in the management of collaborative relations. Finally, boundaries management should be useful in the management of internal resistances.

5 Conclusions

Results show that open innovation and many modern firm paths growth are connected to the boundary of which the main significant element is represented by the management.

It is possible both to identify boundary strategies and to understand distinctive resources from which derive their successful implementation. Among these resources, high relational skills, the control of information technology, a strong corporate image within the innovation network, and the managerial skills to dynamically harmonize the power/dependence relations (with partners, customers and suppliers) stand out. Alongside strengths of boundary management and their ability to reading the weak signals from environment, risks of strategic approach and modality for their implementation have also emerged.

This study sheds light on the advantages and the risks that can jeopardize the successful outcome of opening up the innovation processes without the effective management of boundaries studies. Recognizing the boundary as the core of open innovation implementation issues, the boundary management should be based on elements both internal and external and they outline paths difficult to place in the typical and traditional dichotomies and taxonomies of strategic management studies. Consistently, the current theoretical and managerial solutions on open innovation, such those from strategy studies, result insufficient to provide useful contribution to the implementation of paths that are, instead, increasingly based on boundaries resources. Future studies should provide in-depth research on the role of boundaries in open innovation implementation to learn more and to limit the risks of centrifugal thrusts.

Our findings push to overcome the traditional contrast between closed and open innovation models to move the focus on the boundaries of the company. The managerial implications of our research push to shift the focus of open innovation implementation towards the management of the boundaries, where boundaries capabilities and activities play a key role. Thus, we identify and advance insights maximizing potentiality and reducing risks in implementing open innovation.

The implementation of open innovation implies that essential decisions about innovation have been made to shift the attention of corporate leaders neither inside nor outside but in the firm periphery. Our results highlight the importance of overlooked aspects in open innovation implementation such as firm internal relations besides external relations. Accordingly, firms should create ad-hoc organizational units with boundaries management specific skills.

Until today, open innovation scholars have looked, in a two-dimensional perspective, inside or outside the funnel. Our study suggests that it might also be useful to analyze its edges by switching to a three-dimensional perspective.

Abstract

The Italian banking system has profoundly changed during the last 20 years both due to the privatization of the major State banks and out of the greater use of market financing taken place on the stock exchange. Thanks to the M&A process, nowadays, banks are larger and more complex than in the past but, M&A is a dangerous process if it is not appropriately dealt. The major risks are related to the numerous different items that must be well managed during the transition period such as, e.g., employees and information systems. Concurrently, banks’ managers are being asked to incorporate the new features and changes deriving from the recent years’ digitization. These important changes, unavoidably, lead to the need to close branches reducing the number of employees which has repercussions on the relations that the bank has with the territory and this could compromise the economic local grow.

The present work revolves around the idea of understanding which actions the managers could undertake to ensure that the relationship with the territory is not lost while facing exponential growth in size, caused by the M&A process, and the challenges brought about by digitalisation.

The methodology used in the present paper is an ethnographic exploratory single case study where the information will be collected using semi-structured interviews.

In this first part of a wider project, in addition to a literature review, the process required to elaborate the schemes of the semi-structured interviews is explained.

The value of the work is interesting for scholars as well as for practitioners; in fact, from the analysis of the answers provided by managers it will be possible to learn a lesson regarding the actions that were carried out, but also about the activities that have not led

to the desired results and therefore should be avoided. At the same time, this study could contribute to the academic debate as it allows us to add literature on management while selecting which prior author's position to endorse, regarding the influence of managers' behaviours on obtaining profitability in banking institutions.

Keywords: local banks; M&A; banks dimension; managers' actions; digitalization

Paper type: Academic Research Paper

1 Introduction

In the last years, also due to the merger and acquisition (M&A) processes, banks have had greater gains than in the past and they have become more complex while their organizational structure has evolved (Paoloni, 2018).

The fast step towards M&A in the banking industry was taken many years ago and, with time, many more have been taken (Benston et al, 1995).

According to Altunbas and Ibáñez (2004) between 1992 and 2001 bank mergers in the EU banking industry generally lead to improved accounting profitability. From 1991 to 2005 a process of integration has taken place at the European level, when instead the US banking industry was already integrated. A dismantlement of trade barriers occurred in the European financial services, as shown by the deregulation through the Second Banking Directive (1989), the creation of the single market in financial products and the introduction of the Euro (Molyneux and Wilson, 2007, Beccalli and Frantz, 2009). Moreover, the European bank system has traditionally been different than the US system, because of the prevalence of mutual banks like cooperative and saving banks (Altunbas *et al.* 2001). Precedent studies provide mixed evidence and many fail to show a clear relationship between M&A and performance. Some of the previous literature has examined the impact of M&A operation on different indicators. Although an improvement in performance is found for more recent deals, neither earlier studies nor more recent analysis find evidence of clear positive effects of M&A operations on the performance of US banks (Knapp *et al.* 2006; DeLong and DeYoung 2007). In addition, studies on the M&A activities in the EU banking industry conclude that performance improvements are seldom realized (Altunbas and Ibáñez, 2004).

During the global financial crisis, started in 2007, the landscape of the procedures of M&A changed, because different causes at the basis of this strategy arose, sometimes to gain major access to new geographies (Grave *et al.*, 2012) and sometimes to profit from a greater dimension, necessary to counter increased competition and maintaining (or sometimes regaining) positive levels of profitability. Regarding this there are two different strands, where scholars have different points of view. In fact:

- i) Some researchers believe that an increase in bank size may increase both the standalone and the systemic risk (Laeven *et al.*, 2016; Boyd and De Nicoló, 2005; Altunbas *et al.*, 2016), and

- ii) Others connect the increase in bank size with implicit subsidies related to “too big to fail” (Acharya *et al.*, 2017; Bertay *et al.*, 2013).

The past studies show that M&A failure is not unusual, indeed one operation out of two fails (Demeure, 2000; Habeck *et al.*, 2001) or, within the first two years of merger operations, over half of all mergers fail to meet shareholders’ expectations for value or earnings potential. This is particularly possible in cross border operations caused by contextual and cultural differences among the participants. The success of cross-border M&A depends on the choice of participants and their objectives. Companies’ management must face this challenge (Vander Vennet, 2002; Powell, 2001).

At the beginning of the M&A process it is important to aim to create a large dimensional banking companies because it allows, on the one hand, to better manage the necessary diversification of the businesses and on the other hand, it allows for a reduction of different types of risks and some costs, as well as providing greater access to capital.

But, if in one hand, M&A process became necessary, in the other hand this process is so risky. In fact, is not easy to have an M&A process succeed, as the factors to be managed at the same time are many and different and sometimes controversial. In one M&A transaction there are two primary parties, represented by the buyer and the seller of the company, but other many stakeholders’ interests are involved as advisors, creditors, suppliers, customers, employees, communities, governments, and so on (Bruner, 2002).

To all this, it must be added that a further challenge the banking sector companies are facing is represented by the digitization occurring on the same factors the merger process has already affected.

In the present work, the major problems arising from a M&A process are analysed, regarding both the employees and information system integration, as well as the operations and proceedings integration, without neglect the advent of the technology.

Furthermore, it cannot be forgotten that a larger banking institution and digitalisation could lead to a more distant relationship with the territory, putting the growth of the local economy at risk (Caporale *et al.*, 2016).

If on one hand, it is, also, important to create a large size bank, on the other it is important to maintain the characteristic of territoriality, despite the differences in the *modus operandi* of small and large banks (Berger and Udell, 2002; Felici and Pagnini, 2008). Therefore, analysing the current context in which the banks operate, the research question this work addresses is:

RQ: What are the most effective managerial actions to simultaneously confront the M&A process as well as the advent of digitization, without deteriorating the relationship with the territory?

In an attempt to answer this question, the work is organized as follows. The next section reviews academic literature on the major problems related to the M&A process, as well as the digitalisation and the difficulties in maintaining the “local” dimension. Followed by describing the research method used to elaborate the schemes of the structured-interview that will be done in the next weeks. The last section presents the discussion regarding the findings expected within the interviews and elaborated in consideration of the contents of the literature.

2 Literature review

Following the recommendations provided by the European Central Bank (European Central Bank, 2018) it is important to reduce the number of banks and one of the suggestions is to merge banks in a strategic way and to create sustainable banks. This is the reason why, the M&A processes has undergone a substantial acceleration (Vander Vennet, 1996).

Aware that banking M&As process is composed by two temporal phases (firstly domestic consolidation and secondary international expansion), by analysing the European banking system current situation it is possible to assert that it is in the second phase, namely, international expansion. This phase is characterized primarily by European operations supported by the actions and policies taken by the European Central Bank and the European commission in order to integrate the European financial systems for a better allocation of capital through Europe while supporting banking competition. One of the main catalysts of this process of consolidation is represented by the regulatory harmonization, as, e.g., Basle II, Basel III and IAS/IFRS (Ben Slama *et al.*, 2012), which improves transparency and reduces bank risks.

An acquisition has the effect of bringing together the management groups of two organizations, with styles which might be similar, or alternatively, very different. Significant differences can contribute to, what Buono *et al.*, (1985) call, “cultural ambiguity”, a situation characterized by uncertainties concerning whose style or culture will dominate. The need for post-acquisition integration of operations in an acquisition is primarily bounded by its objectives. An acquisition might form a part of a strategy of related diversification and, therefore, be expected to provide synergistic benefits. Such benefits could be in the form of operating efficiencies and economies of scale requiring high levels of integration as might be feasible in related acquisitions (Porter, 1985; Salter and Weinhold, 1979). The primary objective in post-acquisition integration of operations is to make more effective use of existing capabilities. Merging firms can reduce unit costs in production, inventory holding, marketing, advertising, and distribution integrating similar departments and functions (Howell, 1970; Rappaport, 1987).

Summarizing the problems linked to merger and acquisition processes found in literature, it is possible to assert that the main difficulties regard:

1. Employees integration;
2. Information system and business-processes integration;
3. Banks' over-sized structure.

Regarding the first problem, past literature on M&A consider employees as victims of unintended negative effects of integration, resulting in poor motivation and productivity (e.g. Shrivastava, 1986). Although integration is indispensable for taking advantage of potential synergies, it simultaneously may have negative effects on employees. The organizational and psychological turbulence which often follows can cause stress, anxiety, internal power struggles and politicking (Meyer and Altenborg, 2007). In response, managers are seen as responsible for conducting integration while at the same time considering the well-being of employees and are able to find the best motivation

from the merger. A good integration is difficult if managers, too, suffer during integration, since they are the ones who should be able to lead integration or, at least, limit its negative effects on other employees (Schriber, 2012).

The second critical challenge companies' face during a merger is integrating their information systems. A large number of merging companies run into problems causing delays lost opportunities, and all of these could be the effect to decrease revenues. A primary purpose of integrating diverse information system is to realize ideal synergies among departments. Information system professionals must be an integral part of the M&A team from the early stages of merger planning if the information system merger is to be successful. Otherwise, involving professionals after time could compromise the result of the process (Harrell and Higgins, 2002). According to Harrell and Higgins, (2002) there are different common strategies available when merging IS systems:

- Maintain Status Quo, without integration problems and interruption of business processes but not data sharing between systems;
- Use one company's system or best of breed; or acquire a new system;
- Outsource.

One more challenge for companies and specifically for banks after merger or acquisition is represented by the integration of both the operations and proceedings.

The organization's M&A integration process and capabilities must be in place before the deal gets done (Galpin and Herndon, 2003).

The past studies of Mylonakis (2006) showed that bank employees feel personally threatened by mergers and acquisitions, which are not considered to be justified and necessary entrepreneurial activities conducive to enhanced, quality banking services.

Human resources management within M&A environment is problematic due to changes in the general procedures and in the practices followed by the acquired companies to carry out various tasks, and also due to the growing competition between the employees of the merged parties (Gunu and Olabisi, 2011). Most employees regard Merger and Acquisition as a threat to their jobs, since shareholders often demand limitations in the number of employed staff. Today's facts verify these fears as, during mergers, the number of employees working in the engaged companies is actually less than before (Gunu and Olabisi, 2011).

The restructuring process of European and global banking has brought substantial changes in the nature and quality of employment. This restructuring process is a result of not only the Merger and Acquisition wave observed in the last 15 years, but also of the massive introduction of new technologies into banking. The introduction of new technologies in banking preceded the Merger and Acquisition wave, whereas the latter has accelerated the restructuring process. This is because a bigger M&A wave may exploit new technologies in a more efficient manner and, most of all, it may also undertake to a great extent the cost for the application of these technologies (Koutroukis and Terzidis, 2010), so, at the end, the scenario has become complicated as a result of the change in consumer behaviour and the impetuous digitalization process that requires the identification of new channels and products, as well as to adapt the technological infrastructure, to change the organisation directly, especially if the purpose is to obtain a

strategic positioning in the digital environment (Cuesta *et al.*, 2015). In such cases, the digitalisation is regarded as a driver for ‘disintermediation’ in an established ecosystem (Milkau and Bott, 2015).

Following the idea provided by Cuesta *et al.*, 2015, the major changes resulting from this process impact on the relationship between customer and their experience; on the new idea of branches’ format, revised considering that mobile banking offers benefits such as true freedom from time and place and efficiency for banking transactions (Laukkanen, 2017; Yakhlef, 2001), as well as on the role of employees that, according to some authors, will be revised and certain professional figures will be deleted (Haake, 2017; Gastaldi *et al.*, 2014). At the same time several writers share the view that internet based connections can be used as a means of building relationships with customers and add that they can allow banks to customize and personalize their offerings much more appropriately (Hotchkiss, 1997).

The logics that should be undertaken in this context have to tend to retain the most talented resources and those that are most prone to change within the organization; in fact the employees who remain will be called to make a huge effort to ensure that their training and personal skills adapt to the changes that have occurred and to future ones, as well as to align their skills to the new strategic objectives the bank will define (Lodesani *et al.*, 2018).

Therefore, the need to adopt new technologies to provide additional banking channels for customers has become much more of a strategic necessity for the services industries and, above all, for banks (Ibbotson and Moran, 2003) and involved the existing relationship between the bank and territorial economic organizations, as e.g. SME (small and medium enterprises).

The role played by small regional banks on local economic growth is another important aspect that must be addressed (Modina and Polese, 2008; Hakenes *et al.*, 2009), above all considering that it has emerged that, during the financial crisis, local banks have had a key role. Indeed, some scholars (e.g. Barboni and Rossi, 2013) showed that companies at the local and regional level, during the recession period, have been less affected compared with others.

The idyllic dimension of banks became one of the main topics for discussion in a context in which, on the one hand, there are pressures to create large banks but on the other it is considered important to maintain a relationship with the territory, both to ensure levels of profitability and to avoid endangering local economic growth.

Currently, the banking market is dominated by big-players in some country.

The scenario has changed also in Italy when compared with the past. In this situation it is difficult for the bank to link the “internal” exigencies with customer territorial relationship.

In this paper, the aim is to understand how after a merger among two Italian banks their manager attempted to combine the digitisation process to maintain the customer territorialism.

3 Research methodology

3.1 Background

The aim of the present work is to understand the actions undertaken by banks' management following the dimensional growth due to the M&A process, while taking into account the effects of the digitalization, to maintain the traditional "local" link with the clients.

The present research was developed using a case study methodology that is an empirical method aimed at investigating contemporary phenomena in their context (Runeson and Höst, 2009; Robson and McCartan, 2016). This approach is considered one of the scientific methods that include both quantitative and qualitative data and it is useful to support and explain both the process and outcome of a phenomenon through complete observation, reconstruction and analysis of the cases under investigation (Tellis, 1997).

In detail, following the classification provided by Yin (1984), in which he determines three different categories: exploratory, descriptive and explanatory case studies, the present work is placed in the exploratory case study category, defined as an approach used to explore any phenomenon in the data which serves as a point of interest to the researcher. General questions, such as, "Does a student use any strategies when he reads a text?" and "if so, how often?" are usually for research conducting by exploratory case study. According to Neale and Liebert (1980) that identified two different types of designs when using case studies for explanatory purposes in this work, a single-case design is used.

Considering the goal of the work, for which a community of people must be studied to understand how the members of that community make sense of their social interactions (Robinson *et al.* 2007) the research method could also be defined as an ethnographic study, that is a particular and specialized type of case study focused on cultural practices through field observation (Easterbrook *et al.* 2008).

As different scholars suggest (i.e. Runeson and Höst, 2009), for the present ethnographic exploratory single case study the information was collected using the semi-structured interview, in which the questions are formulated considering the research aim and although planned, they are not necessarily asked in the same order as they are listed. Semi-structured interviews were chosen to permit the interviewees to feel free (Corbetta, 2003) to explain thoughts and to highlight areas of particular interest and expertise that they felt they have (Horton *et al.*, 2004), as well as allow both the interviewers and interviewees to improvise (Runeson and Höst, 2009).

Since our study aims at offering starting points to suggest to other managers how to better deal with the controversial situation they face, it is unnecessary to identify in content theory (Diefenbach, 2009; Rudestam and Newton, 1992).

3.2 The conceptual drawing of the research process

3.2.1 Sample

This study will involve the top management of one of the most important Italian banks who operated an M&A process and that must face the digitalisation issue.

The idea is to interview the managers at the highest levels of the areas that play a key role in the two processes mentioned above, such as administration, communication, organisation, planning and control, human resources, and others. Managers that were already within the entity investigated at the time of the M&A.

3.2.2 Questions

In line with the suggestions to conduct the semi-structured interviews, provided by the main methodology scholars, the questions that will be asked to managers, after requesting some introductory information, are subdivided into consideration of the different domains identified in the literature: i) challenges and opportunities in mergers and acquisitions; ii) digitalization process; iii) oversize structure of banks; iv) territoriality dimension of banks to ensure that all issues of the present study will be covered during the interviews .

The domain “challenges and opportunities in mergers and acquisitions” is investigated considering the main problems that could arise from this process, such as the difficulty to integrate previously employed workers in two different realities, the problems emerging from the integration of the information system, and the challenges in the integration processes of management concerning issues like credit granting. Another problem could sometimes arise from the M&A transaction as well as from the digitalisation process. A problem that the managers are must solve: the oversized entity, in other words the large number of employees and branches. Regarding this specific issue, a new group of questions was created (4th).

The questions were developed based on contributions provide by scholars (Patton, 1990; Salama *et al.*, 2003; Lewis *et al.*, 2004) and revised considering the peculiarities of the present work. The structure of interviews, formulated to stimulate interviewees, is shown in table n.1.

Table n.1: Semi-structure interviews scheme

<u>1st group: Introductory questions</u>	
▪	Describe your work experience prior to the present one.
▪	Describe your last work experience prior to the present one *(Patton, 1982).
▪	How long did you work in the last company?
▪	Describe your current role *(Patton, 1982).
▪	How did you join this company? *(Patton, 1982)
▪	For how many years have you been with this company?
▪	Describe your level of satisfaction with your involvement with this company* (Patton, 1982).
▪	How does your role on this company differ from your previous work experience? * (Patton, 1982)
<u>2nd group: Focus on challenges and opportunities of M&A processes</u>	
<u>Problems in employee integration processes</u>	
▪	What practical steps can be taken to minimize the feelings of uncertainty normally expected

by employees, and also to facilitate the learning process between two groups of people in their cultural and behavioural integration, as an M&A process? *(Salama et al., 2003)

- What perceptions and obstacles did most employees bring forward regarding the M&A process?* (Galpin and Herndon, 2003)
- Were any social activities undertaken to create a better environment during the M&A process? *(Galpin and Herndon, 2003)
- Were Employees benefits defined during the M&A process? *(Galpin and Herndon, 2003)

Problems in information system and business-processes integration

- Were different management systems applied in the merged organizations or were the existing company's systems used? Was a new system chosen or was the IS system outsourced to a third party to process all information requirements?**(Harrell et al., 2002)
- Did one company's strategies predominate over another's? *(Harrell et al., 2002)
- How was the IS department structured? *(Harrell et al., 2002)
- Were Business processes and systems created or was a pre-existing one used during the process? *(Galpin and Herndon, 2003)

3rd group: Focus on the digitalisation process

- What are the primary factors emerging from the digital economy? *(Patton, 1992)
- What are the challenges associated with working within the digital economy? *(Patton, 1992)
- How does working within the digital economy change the communication of teams? *(Lewis et al., 2004)
- In your opinion, which channels are more effective, least effective? Why? *(Lewis et al., 2004)
- What are the communication challenges? *(Lewis et al., 2004)
- What are the communication success? *(Lewis et al., 2004)
- Have you found the lack of adequate skills in the staff, with reference to the IT systems?**(Khalfan and Alshawaf, 2004)

4th group: Focus on the link with clients (territoriality dimension)

- What are the primary channels used to communicate with clients?*(Lewis et al., 2004)
- How does working within the digital economy change the communication with clients?*(Lewis et al., 2004)
- Have sponsorship activities been carried out in the territory in recent years?
- Have any actions been taken to maintain contact with the territory recently?

5th group: Focus on oversize structure of banks

- Have employees been fired after M&A or have other measures been taken to increase the number of employees to actual needs?
- Were the remaining employees trained in consideration of the new skills needed to face a different competitive environment as well as to align their skills with the new strategic objectives defined by the bank?**(Draghi, 2008)
- Have there been ad hoc interviews with employees to understand the abilities and attitudes of each person?
- Have branches been closed in recent years?
- Are there some employees that were assigned to a different role after the M&A process, because the previous task does not exist in the new entity?

*These questions are based on quoted works but are revised considering the specificities of the present study.

** These questions are elaborated considering the literature found in the quoted papers.

4 Discussion and conclusion

The present discussions are elaborated considering both the information and the pieces of evidence raised from the literature analysis.

M&A transaction must be preceded by the definition of a broader medium or longer-term strategy that must in turn, consider different variables that could compromise the success of the process. In the current European banking context, M&A transaction, defined by the ownership and carried out by managers, are direct in respect of the European legislation, issued by European Central Bank (ECB), in a perspective view of patrimonial consolidation and not greatly related to short-term profitability. Furthermore, the additional challenge that managers are called to take on is represented by the impact of digitalization on numbers of employees and branches.

As mentioned in previous paragraphs, the major challenges related to the M&A process refers to employees' management as well as the integration of both information system and business processes.

In fact, an oversized structure usually emerges from the merger, where employees and branches are numerically more than the needed, and consequently increase the operative costs that can in turn, compromise the profitability. A solution for this potential risk could be to manage "digitalization" breaking down structural costs. Both M&A and digitalization bring about a transformation of the traditional bank/customer relationship (Barnes and Howlett, 1998).

The necessary rationalization operations are one of the levers that banks can adopt to increase their profitability. On the other hand, however, it is important to highlight that the processes of rationalization will retain within the organization the most talented resources and those that are most prone to change. In fact, the employees who remain will be called to make a strong effort to ensure that their training and personal skills adapt to the changes that have occurred and to those that will occur, as well as to align their skills to the new strategic objectives defined by the ownership of the bank (Lodesani *et al.*, 2018). It becomes important to identify the key people (Galpin, 2014) and their ability and skills as well as to elaborate a strategy that considers these strengths; furthermore incentives to employees could play a key role in the success of these processes (Gates and Very, 2003)

While regarding the branches, it seems appropriate to underline how the logic related to these has changed over the years, due to the change in the market context. In the past, in fact, it was believed that opening new branches would correspond to growth in funding/lending volumes, while in this context agencies are currently mostly operating costs.

All this, as already stated by some authors, does not mean that employees and branches will disappear but that it will be necessary to change and modify their strategic and operational activities so that they adjust to a new way of relating to customers that, in the latter years, profoundly changed their behaviors. In some cases, the customers do not require face-to-face contact with the employees in a specific branch, which is one of the reason why some scholars assert that it not necessary to maintain the offices throughout the territory. However, on the other hand, most authors showed that the presence of the intermediaries on the territory have a positive effect on local economic growth, as in the case of Italy (Cetorelli and Gambera, 2001; Dalla Pellegrina, 2005; Cosci and Mattesini, 1997).

5 Limitations and value of the paper

The major limitation of the present study is the lack of interviews. In fact, in the work only the literature and the methodology was used to structure the interviews that are taking place currently. A further limit is represented by the use of a single case study, but this limit can be overcome in the future, interviewing managers who are employed by different banks.

The value of the analysis is represented by the implications that will emerge from the interviews and can be used both by insiders as suggestions and by academics to further the debate concerning the management of large banks and their role in the territorial economic context.

Abstract

If the “early modernity” contemplated the antagonism between high and low complexity, the transition to the new paradigm of so called global and digitized capitalism modifies this relationship in the direction of complementarity. Complexity, far from representing an entity to be compressed and simplified, becomes a source of value for the variety of products and processes and for the management of network interconnections.

The notion of enterprise as a cognitive system, which uses knowledge as a source of sustainable competitive advantage and which continuously creates new knowledge from existing capacities provides researchers with a significant reading key to redirect itself into complexity and to give representation to the new organizations: from the model of the castle to the model of the network, of the widespread enterprise, in whose knots represent subsystems connected in a continuous dynamic of relationships, of knowledge and economic exchanges. In the context outlined, organizations face complex challenges in terms of changing business models and reconfiguring the value chain. In particular, new alternative paradigms emerge with respect to the concept of innovation in the traditional sense, such as that of open innovation. Unlike traditional innovation, based on the vertical integration of the innovative process and on defence, open innovation is based on the idea that the company can create value through a strategic path to open up to the competitive environment.

The level of analysis is twofold. First, an exploratory comparative analysis was conducted with reference to companies that have embraced the “open” approach in their innovation processes, shedding light on the interconnections existing between the various organizational systems, whose complexity determines the spread of the network. A framework that we called SKIN was applied. Second, through the analysis of Enel Open

Power case, attention will be paid to the role of the strategy in the management of the process of transition to a "network" type of business model with a special emphasis to the ecosystem concept where actors, technologies, and institutions co-evolve through their interactions and shared purpose.

Keywords – Measuring, Interconnections, Knowledge-oriented, open business ecosystems, case study.

Paper type – Academic Research

1 Introduction¹

How easily it emerges from the critical literature on the knowledge economy studies, a conceptual and terminological turbulence invests the identification and the very naming of transit between systems which is what commonly goes under the antinomic formulations of *Fordism VS post-Fordism*, of *industrial VS post-industrial*, of *modern VS post-modern* and that signal three different transitions, in competition with each other. In the first terms the characters of the strong paradigm of the rigidity - mechanistic, deterministic, systemic, structuralist - have been attributed; in the second, different characters that over time interact overlapping and that have in common the departure from the codified, Fordist, industrial and modern paradigm: these are from time to time assimilated to the fluidity - organicist, evolutionary, post-structuralist, deconstructionist (Rullani et al., 1999). The dialectic of transition, combined with the impossibility of reducing the multiplicity of complex systems within linear analytical grids, is among the elements that indicate the high degree of complexity, which, as is known, has become a constitutive and qualitative element of the so called "global and digital capitalism". Current research has, in this regard, tried to outline coherent investigation paths aimed at highlighting the persistence - in the transition between paradigms first stated - of complexity, in its various manifestations, while registering differences in the ways in which it is managed (Morin., 1993; Burnes, 2005).

Neither the fluidity of 'postfordism', nor the immateriality of the 'postindustrial' proved to be definitive concepts which can manage the complexity of the transition.

The paradigm that instead is proposed as truly alternative to Fordism, due to its intrinsic strength and its ability to convey all the problems that emerged in the attempts to name the present and to manage complexity, is that of a different perspective on *knowledge* as a reproducible resource, a concept that has represented the source from which - from the industrial revolution onwards - all modernity has drawn, but the novelty lies in the different production and use of knowledge regime, linked to the digital paradigm (Rullani, 2004). This Knowledge is a very creative knowledge that explores, that "imagines" and that cannot try to constrict complexity but it tries to explore it, and it

¹ This paper is the result of a joint reflection of the three authors, however paragraphs 1, 2 3 and 7 are to be attributed to Stella Lippolis, paragraph 4 is to be attributed to Francesco Grimaldi, paragraphs 5 and 6 are to be attributed to Angelo Ruggieri.

is inscribed within a circular, "reflective" process which is nourished by experience but also by other knowledge which exceeds that which can be used immediately. Precisely this auxiliary knowledge, the so-called "cognitive surpluses", represent the space of freedom, creativity and experimentation of the "new knowledge" circuit, within which complexity is inserted (Micelli, 2000).

If the so-called early modernity contemplated the antagonism between high and low complexity and between codified and generative knowledge, the transition to the paradigm of global and digitized capitalism modifies this relationship in the direction of complementarity. Complexity, far from representing an entity to be compressed and simplified, becomes a *source of value* for the variety of products and processes, for the management of network interconnections, for the freedom of choice that characterizes open innovation situations in a digital world (Chesbrough, 2003; Rullani, 2018). Opportunities are identified for the search for new ways of learning and managing knowledge flows within which new value can be generated precisely by the complexity of products, processes and meanings. The cognitive surpluses created by innovation and multiplied by digitalisation are "distributed" among the various actors involved in the supply chain - that can be defined digital and global - according to network logic, and no longer by the single company as in Fordism, or by the typical territorial ecosystem of capitalist district.

In this context it is appropriate to reconsider the business models of companies according to two dimensions: *the one* that allows to realize a sort of "division of labor" in the use of knowledge, participating in the construction of an open innovation system in which each one brings its own knowledge and at the same time uses those of others; *the other*, which allows to initiate flows of communication and cooperation between bearers of needs and possessors of skills, according to the perspective which - thanks to digitization - is transforming all companies into companies that put their skills at the service of potential customers found in global and digital networks (Rullani, 2018).

In these business models organized around the digital network, there is a complex interaction between the participants in the innovation ecosystem (Dat   et al., 2017; Clarysse et al., 2014), whose actions and ideas co-evolve: the creative relationships that the collective intelligence of a community directs towards the realization of a change that has value give shape to the result. The study of open innovation system becomes the study of the forms with which the imagination paths of new ideas are organized, and the enabling contexts are created which make it possible to apply those ideas.

And it is precisely in this perspective that we intend to investigate the quality and the directions of inter-organizational knowledge flows in innovation ecosystems. The level of analysis is twofold. First, an exploratory comparative analysis was conducted with reference to ten companies that have embraced the "open" approach in their innovation processes, shedding light on the interconnections existing between the various organizational systems, whose complexity determines the spread of the network. A framework that we called SKIN was applied by identifying knowledge flows "inbound" and "outbound" (Chesbrough, 2006), shaping the appearance of the ecosystem and highlighting the way of exchanging knowledge.

Second, through the analysis of Enel Open Power case, attention will be paid to the role of the strategy in the management of the process of transition to a "network" type of business model with a special emphasis to the ecosystem concept where actors, technologies, and institutions co-evolve through their interactions and shared purpose (Moore, 2013).

2. Company as a living system (*Impresa vivente*) and the concept of ecosystem: two perspectives to investigate the knowledge-oriented organizations.

The search for the defining coordinates of what is considered a new season for modernity has led researchers to resort to systems and principles learned from other disciplines, based on experimentation and able to propose, from differentiated perspectives, innovative methods to manage complexity. Interdisciplinarity is one of the distinctive features of the recent survey in which, for example the notions of company as a living system (Vicari, 1991) and ecosystem (Ceccherelli, 1923; Moore 1993, 2013, Aarikka, Stenroosa, 2017) draw on heterogeneous approaches and languages.

In fact, the use of organicist, biological and philosophical analogies represent the tool used by economic language to investigate the company and to represent it in respect of the variety, variability and entanglement of connections and relations that the new cognitive dimension of complexity entails.

One of the modes of representation that appears particularly suitable for interpreting the company in internal and external interaction dynamics is the metaphor of the company as a living system. In this system, individuals and institutions are considered knowledge processing and transmission nodes, but the knowledge of the company does not derive from the simple summation of the individual decisions of the single nodes: it results from the constant interaction of them, from the procedures, from the functioning organization, resulting in a complex cognitive process. The communication mechanisms represent the cohesive force that holds the system together allowing the components to interrelate and the individual cognitive patterns to dynamically connect.

Precisely the notion of enterprise as a cognitive system (Rea, 1999), - which uses knowledge as a source of sustainable competitive advantage and which continuously creates new knowledge from existing capacities - provides researchers with a significant reading key to redirect itself into disorder into instability inherited from the deconstruction of 'Fordist firm' and to give representation to the new organizational solutions that arose from the need to overcome the limits highlighted by the Fordist hierarchical organization: from the model of the castle to the model of the network, of the widespread enterprise, in whose knots represent subsystems connected in a continuous dynamic of relationships, of knowledge and economic exchanges (Butera, 1990). If in the Fordist firm the glue, the element of cohesion was represented by the hierarchy, in the reticular organizations the tool of sharing of knowledge is the set of interactions that are established with the aim of achieving a common project and digital technologies represent

the connective tissue that allows nodes to produce and share knowledge in a truly alternative way, the relational infrastructure "that allows the current network to become a virtual network, a 'place' for sharing knowledge (Lippolis, 2010).

The concept of ecosystem has also been borrowed from studies in the biological field, as an analogy to explain the interdependence and co-evolution in economic activity. In this perspective a company belongs to a business ecosystem, that develops itself around an innovation that brings together companies that co-evolve and compete to produce products and meet customer needs and, above all, to develop the next innovation phase. The interaction within the ecosystem allows an evolution of the capacities and roles of the different actors (Moore, 2003; Mancini 2018). This approach allows the investigation "of a new form of organization...that shows promise in achieving shared purposes, sharing value among many contributors, and in bringing the benefits of technology to a range of people, cultures and problems far beyond what earlier systems have achieved" (Moore, 2013). An ecosystem can be also defined as "a co-evolutionary business system of actors, technologies, and institutions" (Aarikka-Stenroos L. et al., 2017, p. 25), in which economic actors are consumers, research centers, competitors.; institutions are legislators, politicians, interest groups.; the technology is understood as the different types of platforms used in the ecosystem for the interaction between the various actors (Aarikka-Stenroos L. et al., 2017).

The concept of ecosystem has been evolved over time, enriching itself with the aspects linked to the use of technology and those connected with other aspects of sharing. Thus, we speak of the digital business ecosystem, when we intend to emphasize the use of information and communication technologies as tools within the ecosystem that allow us to increase collaboration capacity, representing a platform within which the various actors interact and share values and goals (Mancini, 2018). Instead, we speak of collaborative business ecosystem, when the emphasis is on collaboration, which develops between different partners within the ecosystem based on long-term alliances, (Moore, 2013).

Different are the perspectives of analysis of the new form of organizations (company as a living system, ecosystems) that have made instruments and concepts borrowed from time to time by the Industrial Economy, from the Resource-based Theory, from social network analysis. The aspect that, for the purposes of the present discussion, is useful to emphasize, is, as already mentioned, the cognitive and relational dimension associated with the new organizational solutions within which the meeting and the 'contamination' between knowledge and specialized competences are realized, i.e. *learning by interacting*.

This is the concept used by the literature to indicate a way to generate knowledge determined by the nature of the relationships established between the nodes of the network. Dynamic and continuously evolving relationships in which potentially feasible interactions exceed at all times those actually implemented and in which, thanks to the synergies between the competences of the different actors, the tension between specialization needs and contemporary need for flexibility is solved, which characterizes the actions of companies in the complexity of the transition.

"The relational infrastructure" that allows the current network to become a virtual network, a 'place' for sharing knowledge, is represented by the digital technologies that

with their potential for connection and the ability to manage a growing wealth of information, have made it possible to run an increasingly complex environment.

3. The innovation process in Knowledge-oriented organizations.

In the context outlined above, organizations face complex challenges in terms of changing business models and reconfiguring the value chain. In particular, new alternative paradigms emerge with respect to the concept of innovation in the traditional sense, such as that of *open innovation* (Chesbrough, 2003). This concept was formalized by Chesbrough for the first time, but already before companies have practiced forms of open innovation in an unconscious and informal manner within the geographies and supply chains of the districts thus anticipating the phenomenon then synthesized in literature.

Unlike traditional innovation, based on the vertical integration of the innovative process and on defense, open innovation is based on the idea that the company can create value through a strategic path to open up to the competitive environment (Teece, 2006). According to this approach, the innovative process does not have a defined origin in the context of business activities but is fed by flows and processes external to the organization.

This leads companies to reshape their business model in an open way and operate also with regard to the development of innovation with a view to belonging and co-evolution within an ecosystem. The transition from a closed innovation system to an open innovation system came from Chesbrough symbolically represented through the figure of the *funnel* that represented the traditional system of research and innovation. Through a path of "*inbound*" open innovation in the broad part of this funnel to an internal technology base of the company, an external technology base is associated, intercepting the assets needed to innovate. (Chesbrough, 2015; DiMinin, Crupi, 2018). Instead, through an opposite path of "*outbound*" open innovation the funnel itself is designed as a permeable membrane that allows the company to enhance the internal development of technologies by placing assets in different contexts and markets.

The inbound process focuses on finding assets to be acquired from outside to accelerate the innovation process. An example of this is the so-called crowdsourcing, a process that uses digital mediation to acquire knowledge, know-how in the organization. This mode configures the so-called exploration processes. Outbounding, on the other hand, pushes companies to focus on exploitation, that is, by marketing not only the final outputs, but also intermediate inputs and outputs, expanding the strategic options available.

The drivers of the phenomenon of the open innovation are known: an ever-increasing convergence between technological fields, an increasingly widespread diffusion of centers of excellence. There are, indeed, more numerous presence of tools such as venture capital and corporate venture capital, as well as a more careful protection of intellectual property assets.

As widely highlighted in the literature, it is possible to find more often cases of organization in a hybrid position that alternate moments of closed innovation with moments of open innovation (Huizing, 2010; Binci, 2016).

It is in this perspective that our study intends to analyse, first of all, through an exploratory survey, the innovative ecosystems of which companies are part, which, along with classic innovation strategies, have combined open innovation strategies. In particular, attention is focused on the type and direction of knowledge flows, ideas and know-how, which in turn determine the configuration of the ecosystem itself (Chiang, Y et alii., 2010). In the analysis we took into account the literature on the subject of Inter-Organizational Knowledge Transfer and the problems connected to the factors that can affect the effectiveness and the result of the transfer of knowledge (Easterby-Smith M. et alii, 2008).

A second level of investigation concerned, instead, the role of the strategy, in a knowledge-oriented organization where actors, technologies, and institutions co-evolve through their interactions.

4. Methodology and Research Design

This research aims to highlight, using the case study method (e.g, Chiucchi, 2012; Fattore, 2005; Grandori, 1996; Yin, 2003), how individual businesses and closed organization may evolve in open ecosystems focused on knowledge and innovation and how this process requires companies to adopt a business model that allows ideas and technologies flowing from outside the company and, the other way around, from the internal to the external environment.

The choice of the study of a single case is consequent to a well defined motivation: that is, the examined company represents a critical case (Yin, 2003) functional to the verification of what previously formulated. Specifically, it contains numerous conditions that allow the verification of what is shown in the previous paragraphs.

The analysis units selected by the sampling theory, by an empirical investigation referred to a population and through which generalizations are made are denominated cases (Fattore, 2005). Throughout this research, though, the term will be utilized to indicate a complex context whose multiple variables and characterizing size make the object of a monopolistic, deep analysis: hence, we will talk of a “case study” (Chiucchi, 2012).

According to Grandori (1996), a case study is a thorough study of a context not too far in time, which, therefore, can be reconstructed not only through documentary sources, but also through the witnessing of contemporaries (questionnaires, interviews, etc.) and which founds the (inner) validity of knowledge on the system analyzed mainly through the very multiplicity of information sources.

When defining a case study, therefore, some characterizing elements are underlined (relation with the context and contemporaneity of the phenomenon under analysis; multiplicity of data collection and analysis techniques), which are peculiar to that

particular method and make it stand out among other research strategies, influencing both its development process, range and aim. (Chiucchi, 2012).

The object of research is a phenomenon, that is to say a specific empirical context, more or less complex, "close" in time to the investigator, therefore contemporary or related to a recent past. This entails that the researcher has the possibility to observe directly the phenomenon under investigation, or to get into direct contact with those who took part to – or witnessed – it. Another important aspect of the case study-based research is the context: a phenomenon is analyzed within its context of reference. A further characterizing element of this method is the multiplicity of data collection and data analysis techniques, both qualitative and quantitative, available to the researcher. Among the many data sources, the following stand out in importance: the analysis of documents and archives, direct observation and interviews.

All in all, this research employs the case study method according to the perspective indicated by Yin (2003), that is to say, research through study case is meant as an empirical enquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between phenomenon and context are not clearly evident. The case study enquiry copes with the technically distinctive situation in which there will be many more variables of interest than data points, and as one result relies on multiple sources of evidence, with data needing to converge in a triangulating fashion, and as another result benefits from the prior development of theoretical proposition to guide data collection and analysis.

5. Abilities and knowledge as enrichment for ecosystems: the SKIN representation

In this research, in order to achieve a better understanding of the effects eventually explained by the implementation of open innovation systems, the analysis is developed, first of all, by taking as reference the initiatives undertaken in the SKIN representation.

Starting from skills, critical success factors and distinctive traits, companies can implement open innovation strategies, by increasing their value and developing forms of networking and ecosystems with other companies and organizations to build relationships, exchange of ideas and knowledge flows both "inbound" and "outbound" (Chesbrough, 2006) with them. In fact, companies need to assume a position of interchange with their partners and, more generally, with the stakeholders of the ecosystem that comes to be created. The *tab. 1* collects ten cases of companies that have broadened their horizons in a strategic perspective of open innovation, by creating ecosystems that are the result of an exchange between the elements of the first column, *Skills* (overall considered as a set of tools and attributes determining the know-how already present in the company) and those of the second column, *Knowledge*, that is the set of the "hard" and "soft" knowledges (technologies, organizational models, managerial approaches, informative logics ...) that the company draws, as enrichment, from the ecosystem itself. The last column of Networks reports the details relating to the forms and the ways in which the various ecosystems have been conceived and created.

Tab. 1 – Ten cases of ecosystems and networks - SKIN representation. (Source: our elaboration)

	Skills (know-how, tools and attributes)	Knowledge (enrichment)	Network features
AGOS	<ul style="list-style-type: none"> – Brainstorming – Value proposition canvas – Blue ocean strategy – Prototyping – Interdependence e transversality of the community (collective intelligence) 	<ul style="list-style-type: none"> – Lean innovation – Customer centricity – Design thinking – Agile approach – Artificial intelligence 	<ul style="list-style-type: none"> – Innovation lab (AGOS 2020) – AGOS Incubation Program – Collaboration platforms (Skype e Hangouts) – Innovation community – Innovation café – Start-up ecosystems
DOMPÈ AND ENOVIA	<ul style="list-style-type: none"> – Technology transfer (digital e biotech) – Open innovation approach 	<ul style="list-style-type: none"> – Scouting of technologies and patents (assembly) – Internet of things (IoT) and wearable device – E-drug (“inside” technology) 	<ul style="list-style-type: none"> – Department of open innovation (within R&D, with 200 research centers worldwide) – Relations with specialized universities – Venture capital and start-up
FASTWEB AND ONE TRAY	<ul style="list-style-type: none"> – Supply chain – Sponsorship 	<ul style="list-style-type: none"> – New forms of communication (branding of the baskets used in airport security systems) – Blue ocean marketing 	<ul style="list-style-type: none"> – Partnership strategies – Alliances for agreements with airports
ENEL	<ul style="list-style-type: none"> – Divisional structure – Innovation and sustainability as a new business model 	<ul style="list-style-type: none"> – Agile approach – Distance from logics related to purely economic-financial parameters – Zero-waste investment logics – Disruptive production – Crowdsourcing ideas 	<ul style="list-style-type: none"> – Enel innovation hub – Start-up ecosystems – “Open innovability” strategy – Call 4 ideas hub
INTESA SAN PAOLO AND CISCO	<ul style="list-style-type: none"> – Coaching skills 	<ul style="list-style-type: none"> – Digital Factory – IoT – Cybersecurity – Augmented reality – Integrated supply chain – Connected machine – Asset tracking 	<ul style="list-style-type: none"> – Start-up initiative
AUTOGRILL	<ul style="list-style-type: none"> – Valorization of the territory – Craftmanship – New eating styles (sustainable interpretation) 	<ul style="list-style-type: none"> – New restaurant model – “Bistrot” as a flexible concept – Creating shared value (CSV) 	<ul style="list-style-type: none"> – Collaboration with virtuous universities (UNISG)

NESTLÉ	<ul style="list-style-type: none"> – Leadership in the food sector – Strength of the brand 	<ul style="list-style-type: none"> – Meal-delivery knowledge – Production of meal-kit – Packaging sustainability 	<ul style="list-style-type: none"> – Investments in “Freshly”, a meal-delivery start-up
ENGIE	<ul style="list-style-type: none"> – Supply of energy efficiency tools – Distribution network 	<ul style="list-style-type: none"> – Organizational innovation – Elimination of reporting charges – Deconstruction 	<ul style="list-style-type: none"> – Corporate venture capital – Call 4 ideas – Incubators and projects (in agreement with Accenture) – Research centers
LEONARDO	<ul style="list-style-type: none"> – Defense of the territory/aerospace – Safety 	<ul style="list-style-type: none"> – Cybersecurity – Communication – Incremental innovations in air transport 	<ul style="list-style-type: none"> – Corporate entrepreneurship and startup
UNILEVER	<ul style="list-style-type: none"> – Leadership in the mass market and large consumption 	<ul style="list-style-type: none"> – Enhancement of internal skills – Acceptance of external skills 	<ul style="list-style-type: none"> – Crowdsourcing platforms – Talent swap

The cases shown in the *tab. 1* are based on the information identified and collected directly from the institutional websites of the companies considered and from video interviews released online by their main managers. This representation can be defined with the acronym SKIN (Skills and Knowledge improving Networks) and has two implications: first, the interchange between the elements "Skills" (internal factor) and "Knowledge" (external factor) determines the appearance and conformation ecosystem; in the second place the ecosystem, in the forms in which it operates and is conceived, restores indeed new knowledge to all the involved actors, both in terms of "Skills" and "Knowledge".

6 Abilities and knowledge as enrichment for ecosystems: the ENEL case

The analysis is developed through the study of a single case, among the projects implemented in SKIN representation. The choice of the ENEL case derives to the best possible exploitation of the elements characterizing the case study technique, such as a better contextualization of the phenomenon, the contemporaneity of both the phenomenon and the multiplicity of collection and data analysis techniques.

Among these ten cases, it is important to highlight the case of the ecosystem developed by ENEL which, in 2016, met 1550 start-ups and started 80 collaborative projects in many of the 30 countries where the company is present, with a vision originated by the *Open Power* strategy (now *Open Innovability*). Eight projects are part of the open innovation strategy of the first European operator in the energy sector:

1. *Nuvve* is part of a consortium, with Enel and Nissan, which provides Vehicle-To-Grid (V2G) services to customers; these are services that allow vehicle owners to supply the energy stored in the network, thus contributing to its balancing.

2. *Bidgely* is a software developer that remotely identifies the consumption of individual appliances, providing, information for the adoption of efficient behaviours in terms of energy consumption, by using the app, with a view to involving the customer.
3. *Ultrasolar* produces quantum power optimizers that increase the power extracted from photovoltaic modules through new technologies. The partnership between Ultrasolar and Enel concerns the testing of the solution on residential-scale modules first, and then industrial-scale ones.
4. *Archon* realizes hardware and software solutions for simultaneous management of drones, thus made able to independently reach the charging station when the battery is running down and then return to their operations as soon as the recharge is completed.
5. *Nozomi* conceives computer security software for industrial plants, which automatically creates an internal industrial network model even concerning physical processes, by using behavioral analysis and continuous, real-time monitoring.
6. *Demand Energy* has developed a solution that maximizes the economic performance of the behind-the-meter storage systems, alone or in combination with distributed generation which combines the modeling, design and simulation with installation, operational monitoring, control and financial optimization, for implement storage systems quickly and on a large scale.
7. *TeleSense* develops and provides real-time environmental monitoring solutions for industrial applications designed to help managing the risks associated with climate change, by collecting data and processing them with cloud and IoT technologies (Internet of Things) to monitor a series of critical parameters and adopt adequate and real-time measures. This removes human error, improves operational efficiency and reduces risks, costs, damages for liability and regulatory burdens. The collaboration with Enel aims to develop a portable sensor able to collect safety related data.
8. *Sparkcognition* develops really predictive functionalities able to allow important

Figure 10. Source: our elaboration

cost savings and to improve the operating efficiency of the operators, by identifying, on the basis of the data collected, by the sensor imminent failures before they occur and warns the operators of any malfunctions before they can cause damage. The collaboration with Enel aims to reduce the instability of combustion in gas turbines, as well as to reduce maintenance costs.

As can be seen in *Figure 1*, the open innovation ecosystem that Enel has built

(thanks to commercial agreements and partnerships) has mainly reported flows of both “hard” and “soft” technological innovations (*continuous flows*). Although to a lesser extent, there is no lack of purely informative flows (*dashed flows*) and only one experimentation flow (*dotted flow*). It is important to highlight that even these last two types are, however, attributable to the development of new technologies: the difference lies in the effective contribution that these flows make to the company, as the technology is, in these cases, only a propaedeutic tool for information and experimentations.

The predominant presence of flows deriving from technology transfer is an evidence that explains what are the motivations that, nowadays, push companies and organizations to move further away from the traditional (and certainly more rigid) “castle” business model and to move towards “network” models (Butera, 1990), with a view to “open organization” and “open innovation” (Whitehurst, 2016; Chesbrough, 2003).

As the most valuable sources of innovative ideas are *start-ups*, Enel has decided to open a series of *Innovation Hub*, a physical space where start-ups can meet each other and exhibit their projects to Enel; at the selected start-ups, Enel provides all the necessary tools for take-off: technological advice of experts (both internal and external to the Group, following the strategic logic of Open Power, combining innovative and sustainable approaches), access to the network of partners (including investors) and the possibility of testing the innovations in its laboratories and plants. Each hub is a nerve center for the start-ups of its geographical and economic area and the network organization is an added value for them: hubs have the opportunity to connect and collaborate with each other and enrich themselves with other experiences. Thanks to this strategic model, Enel manages to be present into the most important innovation ecosystems in the world and collaborates with venture capital funds, accelerators, incubators, universities, large industrial players and government institutions in the constant search for startups and SMEs to open its product experimentation in collaboration with different realities, in order to make traditional businesses more efficient and/or provide industrial growth through new business models. Enel Innovation Hubs network communicates to ecosystems of innovation what are the main problems that the Group is trying to solve and provides an indication of its innovation needs.

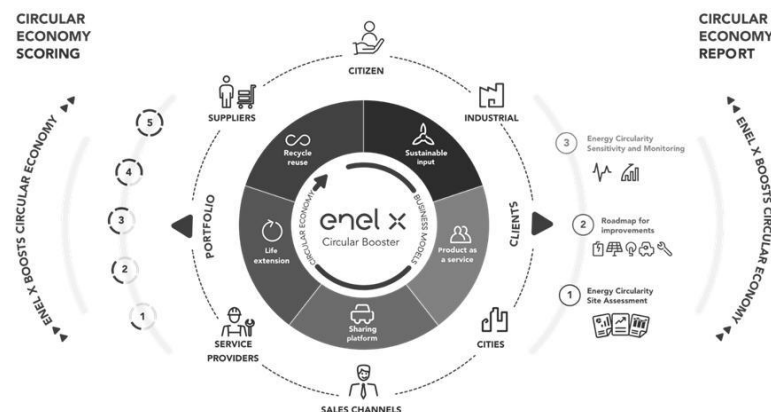

Figure 2. Source www.enelx.com

In 2018, on the wave of its *Open Power strategy*, Enel launched a new brand division, *Enel X*, proposing a new identity that includes four areas of action: *city, industries, home and mobility*. Drawing inspiration from the Circular Economy business models, Enel X positions itself as a *Booster*, or rather an accelerator of circularity, within its ecosystem of suppliers, partners, installers and customers. The aim is to accelerate the level of circularity through the *Circular Economy Boosting Program* (fig. 2), a particularly useful programmatic tool that creates a scoring verified, exported even beyond the internal portfolio of solutions, offering to industrial customers and to Public Administrations the possibility of obtaining an *Energy Circularity Report* that measures energy circularity and identifies a structured roadmap to increase its level through a series of innovative solutions. Enel X cooperates locally with startups and small and medium enterprises in the development of alternative businesses supported by a strong tech support, in a hyperconnected system of horizontal sharing of ideas, needs and solutions.

The case of Enel “Open Power” strategy helps to understand how the knowledge measurement does not always pass through merely numerical or regressive data, but it is necessary to take into consideration also the qualitative analyzes that emerge by observing the great extent of investments in open innovation policies and interconnections where knowledge is a fundamental asset: the growth of companies like Enel is bound, in fact, by the enriching contribution that the ecosystems they create provide in terms of knowledge transfer, know-how flows and skills enhancement.

7 Conclusions

As we have been able to highlight the great attention paid by recent research is due to the transition from what we have defined a 'traditional knowledge', based exclusively on replicative exploitation, to a 'new knowledge' that goes beyond the simple propagation of this which is already known, recombining it and enriching it to produce new knowledge. The transition between these two "epistemic" modes accompanies the difficult transition between systems and is catalyzed by the development of digital technologies and their potential for integration and interaction. The new organizational forms become reticular, in whose nodes represent subsystems connected in a continuous dynamic flows of relationships, knowledge and economic exchanges.

In this redefinition of organizations and inter-organizational flows there are no codified rules, but tendencies (De Biase, 2018). The first is the tendency to consider companies within an ecosystem in which, just like in natural ecosystems, the evolutionary direction is not linear, collaboration is as possible as competition.

The organizations in the ecosystem can be designed so as to favor collaboration and knowledge flows and know-how or, on the contrary, to closure. The same platforms on which open innovation can be developed are therefore not given: they should in turn be imagined, experimented, improved. From this it is possible to point out the role of qualitative investigations that, in this domain, work alongside quantitative surveys.

Open Innovation and Green management: a Framework to Support Environmental Strategies Implementation

Rosita Capurro

Department of Accounting, Management and Economics
University of Naples "Parthenope"
Via Generale Parisi, Naples (NA), 80132

Abstract

This paper proposes a theoretical framework that aims to support firms to adopt the processes of open innovation for implementing successful environmental strategies. The aim of this paper is to investigate the open innovation processes when firms should implement environmental strategies. Through a theoretical analysis, the study highlights the links between environmental strategy and open innovation practices focusing on specific theme of open sustainability innovation model. Drawing on and extending prior studies and practice oriented approaches to environmental strategies, this study identifies some relevant open innovation tools which may provide insights for more effective models of green management. Specifically, the theoretical framework suggests implications for practitioners by shedding light on the sources and methods to translate the transferred/shared knowledge into effective environmental ideas and therefore in goals and actions, to support the strategic decision-making.

Keywords – sustainable innovation; open innovation; environmental strategies; green management.

Nature of the proposed paper: Academic Research Paper

1 Introduction

The increased attention towards social, economic and environmental issues for sustainable development pattern creation requires firms an evolution in their corporate objectives and new management approaches to better meet the needs of its customers, business partner and several stakeholders. Environmental strategies should be properly developed to ensure growth and competitive advantage.

In the past decade, research on green management has expanded rapidly to increase understanding of the ways in which new social and environmental practices enable firms to become more sustainable.

Indeed, the literature shows ample interest in whether and how firms select tools and practices of green management to integrate the environmental dimension in their competitive, financial and organizational strategies (Florida and Davison, 2001;

Dahlmann *et al.*, 2008; Lee, 2009; Garzella and Fiorentino, 2014). At the same time, recent studies argue that open innovation paradigm can be considered a promising approach to develop sustainability ideas, actions and practices. (Hall *et al.*, 2003; Montalvo, 2008; Hansen *et al.*, 2009). In this vein, open innovation practices have started to merge with the sustainability concept, giving rise to open sustainability innovation models (Boons and Lüdeke-Freund, 2013; Peattie and Belz, 2010; Dangelico *et al.*, 2017).

However, despite of the growing attention on these issues in innovation literature stream, the relationship between green management processes and open innovation paths has been the object of limited research. In fact, very little attention has so far been given to open innovation processes to understand their role for shaping, building and controlling the environmental strategies. Indeed, the literature does not provide the needed support to knowledge transfer process and business collaboration from an environmental welfare viewpoint.

In order to bridge this gap, the aim of this paper is to investigate the role and the support of open innovation when firms decide to implement environmental strategies. Specifically, this study sets the following research questions: what is the link between open innovation paths and green management processes? how can open innovation background drive firms to achieve and implement environmental strategies? and how is it possible to identify the benefits of collaboration and to reduce the typical risks of opening up the innovation processes, with regard to green management?

In an attempt to answer these research questions, the paper follows a qualitative approach based on the review of relevant literature on open innovation fields and green management processes. By a literature review and the integration of the compatible elements of previous research on green management, a theoretical comprehensive framework is provided with the objective of supporting the open innovation paths for implementing successful environmental strategies.

This paper is structured as follows. The next section provides the theoretical background. Section 3 analyses the role of the green management as a key capability for the successful environmental strategies. Section 4 advances a theoretical framework based on paths and tools of open innovation for supporting environmental strategies implementation. Finally, Section 5 summarizes the main contribution of the paper and provides implications and ideas for future research.

2 Theoretical background

In order to explain the evolution in the environmental management approaches to support firms to effectively “do well by doing good” (Devinney, 2009; Lee, 2009), the theoretical background is developed with reference to the environmental strategies and open innovation paradigm.

2.1 Environmental strategies

Environmental sustainability is increasingly relevant theme in the current economic context. According to stakeholder and corporate social responsibility approaches, more

and more firms decide to recognize the relevance of the environmental dimension related to the impact and the protection of the biophysical environment in addition to financial and social dimensions (Freeman, 1984). In this seam of research, scholars developed the Environmental Social Responsibility as an autonomous research topic (Hart, 1995; McWilliams and Siegel, 2001). By this way, the environmental strategies have growing importance and relevance of academics and practitioners (Porter and van der Linde, 1995).

In broad terms, “environmental strategies” can be defined as “the organization-wide recognition of the legitimacy and importance of the biophysical environment in the formulation of organization strategy and the integration of environmental issues into the strategic process” (Banerjee, 2001). In this sense, environmental strategies reflect the degree of acceptance and adoption of environmental values and principles in the strategic management (Garzella and Fiorentino, 2014).

However, despite the relevance of environmental issues, the studies on the environmental strategies are characterized by several approaches not always harmonically related (Bowen, 2007).

Some scholars argued that developing environmental actions imply cost higher than benefits and usually the environmental strategies are developed only for moral and social reason or to mitigate reputational and legal risks - for example possible accidents or sanctions for failure to compliance of environmental regulation. (Freedman and Jaggi, 1998; Marcus and Fremeth, 2009).

Differently, other studies agree that correct implementation of environmental strategies can be considered a critical success factor for firms able to trigger new competitive dynamics (Bowen, 2007; Clarkson *et al.*, 2011); in particular, environmental strategies may constitute a support for developing corporate resource and capabilities and for increase competitive advantage. (Porter e Kramer, 2006; Russo e Fouts, 1997).

The link between environmental strategies and competitive advantage should push firms to engage the environmental strategies in response to legitimate demands from stakeholders (Sprengel e Busch, 2011). This voluntary proactive approach to environmental strategies has been proposed as urgent, profitable and sustainable ways for firms to face the variability and the volatility characterizing current competitive context (Darnall, *et al.*, 2010); implementing environmental strategies firms could be pay off in terms of social reputation, corporate image, compliance, sustainability reporting and customer preferences (Lamboglia *at al.*, 2018; Hart and Milstein, 2003).

As a consequence, firms need to understand how to implement proactive environmental strategies. In this vein, the “green management” can be considered a successful factor for competitive and organizational strategies that help a business develop advanced environmental practices while simultaneously lowering costs and creating differentiation benefits (Siegel, 2009).

2.2 Open innovation paradigm

Open innovation is defined as “the intentional use of inflows and outflows of knowledge to accelerate internal innovation, and expand innovative external markets”

(Chesbrough, 2006, p.1). Open innovation approach has been juxtaposed to the traditional paradigm of innovation management, known as the closed innovation model, based on the full control of the R&D process coupled with the full ownership of innovative assets and intellectual property (Chesbrough, 2003a; Chesbrough, 2003b; Berkhout *et al.*, 2006; von Hippel and von Krogh, 2006).

Differently, open innovation approach claims that successful innovation implies that the knowledge sources to feed innovation efforts are widely diffused outside the firms; indeed, the open firms are primarily concerned with leveraging this external knowledge to unlock own potential innovative efforts and improve economic performance.

The increasing diffusion and adoption of open innovation processes has determined an exponential number of studies on the topic (Hossain *et al.*, 2016; Huizingh, 2011). In the literature, open innovation has been investigated under several perspectives and specific issues in terms of number and type of phases in the innovation process, level of integration, organizational and managerial implications related and forms of governance (Emdem *et al.*, 2006; Gassmann and Enkel, 2004).

The studies evolution toward the open innovation approach brought to recognize the increasing permeability of firm's boundaries, stimulating transfer knowledge in-and-outflows between firms and other firms and between firms and creative consumers (Pil and Holweg, 2006; Caputo *et al.*, 2018); this trend provides enabling environments for business collaboration fostering dissemination of knowledge through the network effect. (Chesbrough and Bogers, 2014; Rohrbeck *et al.*, 2009; Traitler *et al.*, 2011).

Many authors have studied the specific advantages firms may gain by opening their innovation process (Reed *et al.*, 2012; Chesbrough and Appleyard, 2007; Enkel *et al.*, 2009).

In particular, embracing the open innovation model, firms can potentially access external sources of ideas, technology and know-how and integrating them with internal resources and skills (outside-in process) or externalize their knowledge and innovative ideas to the outside environment in order to achieve the market faster than they could through internal development (inside-out process). Moreover, firms can combine the outside-in process with the inside-out process to gain external knowledge and, at the same time, to bring ideas to market (coupled process).

Recent studies argue that open innovation can be considered a promising approach to develop sustainability innovations, giving rise to open sustainability innovation models (Varadarajan, 2017; Dangelico and Pujari, 2010; Leach *et al.*, 2012).

Open sustainability innovation model uses the open innovation paradigm in order to development sustainable products, services, processes and initiatives focused on the social needs of people and on the environmental preservation (Peattie and Belz, 2010; Hansen *et al.*, 2009). Thus, this model recognizes the importance of sharing firms' knowledge to elicit direct or indirect ecological improvements and/or to solve particular social-environmental problems (Rauter *et al.*, 2017).

An open sustainability innovation approach could be play a crucial role in the process of developing successful environmental strategies to achieve sustainability goals and increase competitive and financial performances (Arcese *et al.*, 2015; Cappa *et al.*,

2016). Through the correct implementation of environmental strategies based on the open sustainability innovation approach, the firms can benefit from cost savings and environmental benefits.

In particular, the adoption of open sustainability innovation approaches could represent an effective way to gaining competitive advantages and differentiation to environmentally sensitive customers. This approach could lead to reduce production cost and time to market due to development of more environmental efficient technologies reducing at the same time the environmental impact and also increasing firms' process security.

The open sustainability innovation model uses, as stated, the open innovation principles and practices to increase the socio-environmental performance of firms. In truth, the link between environmental strategies and open innovation paths is generally underestimated by firms.

In order to identify the variety of tools and processes of open innovation to support environmental strategies implementation, it is important to analyze, firstly, the strategic process of environmental dimension and the role of green management.

3 Green management process

The adoption of environmental strategies implies multi-lens perspective to green management decision making that concern the overall strategic process in both the formulation and the subsequent implementation steps (Garzella and Fiorentino, 2013).

In attempt to identify the factors that facilitate, or inhibit, the development and implementation of environmental strategies it is important to analyze the strategic process along which these are articulated.

In particular, environmental strategic process may be analyzed with regard to three main steps.

The first step is related to the “formulation of the environmental strategy”, with reference to the integration of environmental, ethical and social issues in firms’ mission and vision (Campbell, 2006; 2007). The second step is related to the “implementation process” with reference to transform environmental decisions into strategic actions aimed to achieving concrete and tangible results (Ilinitich *et al.*, 1998). The last step is based on “analysis of results” generated by implementing environmental strategy. These results must be evaluated with reference to impact of strategic actions on the biophysical environment on one side and environmental performance on firms’ financial dimension and competitive advantage on the other (Clarkson *et al.*, 2011; Epstein, 2008).

The strategic process of environmental dimension is summarized in *Table 1*; for each steps, the table shows different actions, decisions and practices that firms can develop to improve environmental strategies.

The adoption of environmental strategies implies some essential decisions for firms with regard to the environmental aims to selected and their transformation into strategic action in order to improve own environmental performance. The firms' ability to strategically green management has led, firstly, to understand the opportunities of this

development model and then to impose considerations regarding its effective, efficient and correct implementation.

In fact, both the formulation and implementation of environmental strategies do not necessarily guarantee positive outcomes (Wood, 1991). In this vein, the green management play key role to translate strategy into profitable action. Thus, green management adds specific potential to the strengths that characterize the several perspectives of environmental strategies (Capurro *et al.*, 2018). The predisposition and effective application of green management processes facilitates the attainment of strategic aims, driving results along overall strategy process by facilitating internal and external communication goals.

However, firms have erroneously narrow view of environmental strategies; in this way they do not pay adequate attention to environmental growth opportunity and leaves them vulnerable to competitors with broader perspectives (Epstein and Roy, 2001). In new competitive and dynamics contexts where new sharing knowledge tools and new ways of governing relationships are established, the choice of bringing the environmental dimension into the overall strategy promotes the research of business practices that can be the source of great creative stimulus and strong pushes to innovation.

Table 5 - Strategic process of environmental dimension

Strategic steps	Actions
FORMULATION	<ul style="list-style-type: none"> ➤ Integrating “green” in mission/vision and in strategic goals ➤ Eco-R&D investments ➤ Green business entry ➤ Pollutant business exit ➤ Programs to educate employees/consumers on environmental issues ➤ Green innovations ➤ “Green unit” projects
IMPLEMENTATION	<ul style="list-style-type: none"> ➤ Waste reduction actions ➤ Initiatives for pollution abatement ➤ Decreasing emissions and discharges ➤ Consumptions reduction ➤ Environmental certification ➤ Environmental standard adoption ➤ Using renewable energy and replaceable resources and components
ANALYSIS OF RESULTS	
ENVIRONMENTAL RESULTS	<ul style="list-style-type: none"> ➤ Waste reduction ➤ Consumptions and emissions reduction ➤ Scarce resources protection ➤ Decreasing of environmental incidents, crimes and lawsuits ➤ Environmental certification ➤ Green awards
FINANCIAL AND COMPETITIVE RESULTS	<ul style="list-style-type: none"> ➤ Decreasing production costs ➤ Increasing revenues ➤ Product quality ➤ Quality perception ➤ New competences ➤ Improving corporate image and reputation.

4 Theoretical framework

The environmental strategies call for new perspectives in business process management. In current context, sustainability performance of products and services has experienced continuous improvements; fuel efficiency improvements in cars, implementation of hybrid cars, encouragement of car sharing, increased use of recycled materials in packaging, growth in fairly traded products and organic foods and passively heated houses are just some examples of sustainability innovations carried out in cooperation with target consumers group, non-government organizations, policy makers, suppliers, complementary firms and even competitors.

The management of environmental issues needs, from one side, the definition of green management process and, from the other side, a contribution to select the right strategic moves in order to identify new technologies and social practices enable firms to become more sustainable (De Medeiros *et al.*, 2014).

Thus, in an attempt to bridge the gap in literature, to investigate the role and the support of open innovation when firms decide to implement environmental strategies, the study provide a theoretical comprehensive framework that allows to capture the variety of open innovation practices and tools that can be connected in different stages of green management process (*Table 2*).

The theoretical framework covers the formulation and implementation steps of environmental strategies by identifying for each environmental actions open innovation's tools in order to facilitate the achievement of the environmental goals.

Openness in collaboration as joint ventures, in/out/cross-licensing, contract R&D, customer involvement or external networking, can change firms' innovation management model. Indeed, through the correct open innovation process implementation, firms can be gaining access to new areas of knowledge, managing capacity problem with more flexibility, focusing on core competencies, reducing time to market and sharing of risks and costs (Parmigiani and Mitchell, 2009; Tortoriello and Krackhardt, 2010). These advantages can also be exploited to implement environmental strategies.

However, in this context, characterized by high complexity of open business models, a high degree of interdependence among actors and consequently high coordination and control costs, the appropriability issues are crucial aspects that can be checked (Bogers, 2011). Therefore, firms need to develop a careful management of open innovation and environmental process which allows for the maximization of the knowledge creation and use, from a side, and the minimization of the risk of illicit appropriation by external actors, on the other (Van de Vrande *et al.*, 2006).

Table 6 - Open innovation tools in environmental strategies

Strategic steps	Actions	OI tools
FORMULATION	➤ Eco-R&D investments	➤ Crowdfunding
	➤ Green business entry	➤ Strategic alliances
	➤ Pollutant business exit	➤ Joint ventures

IMPLEMENTATION	<ul style="list-style-type: none"> ➤ Programs to educate employees/consumers on environmental issues ➤ “Green unit” projects 	<ul style="list-style-type: none"> ➤ Technological cluster
	<ul style="list-style-type: none"> ➤ “Green innovation” 	<ul style="list-style-type: none"> ➤ Strategic alliances/ Crowdsourcing/ Cross-licensing
	<ul style="list-style-type: none"> ➤ Waste reduction actions ➤ Initiatives for pollution abatement ➤ Decreasing emissions and discharges ➤ Consumptions reduction 	<ul style="list-style-type: none"> ➤ Crowdsourcing/Crowdfunding
	<ul style="list-style-type: none"> ➤ Environmental certification 	<ul style="list-style-type: none"> ➤ Open collaborative networks
	<ul style="list-style-type: none"> ➤ Environmental standard adoption 	<ul style="list-style-type: none"> ➤ Collaboration with Research centers/Universities
	<ul style="list-style-type: none"> ➤ Using renewable energy and replaceable resources and components 	<ul style="list-style-type: none"> ➤ Strategic alliances/Cross-licensing

Indeed, green management and open innovation are complex processes that have the potential to engage a wide range of management decision, mostly if they shall be start together. Firms should choose the environmental actions, strategic paths and open innovation tools that better reflect the corporate objectives, skills and capabilities by identifying the most suitable ways of integration.

In this way, the proposed framework aimed to offering possible applications and methods of open innovation dedicated to better face the environmental challenges in order to maximize the environmental, financial and competitive performance of firms.

5 Conclusions

This study develops a theoretical framework aimed at supporting the process of green management adoption and the success of environmental strategies by application of open innovation paths. Indeed, to link all the relevant success factors of environmental strategies, open innovation may provide insights for more effective models and tools of green management.

The analysis suggests that many modern practices of open innovation – such as crowdsourcing open network, crowdfunding, collaborative networks, strategic alliances and technological clusters – can be connected to the implementation of environmental strategies.

In particular, by a structured literature review on environmental strategies and open innovation paradigm, and the integration of the compatible elements of previous research on green management, a theoretical comprehensive framework is provided with the

objective of supporting the open innovation paths for the firms that want to develop successful environmental strategies.

The proposed framework provides suggests sources and methods to translate the transferred/shared knowledge into effective environmental ideas and therefore in goals and actions, to support the strategic decision-making.

The list of items is not intended to be a comprehensive one but rather that address the main areas of environmental practices.

Based on early theoretical results of this study and the absence of an empirical test, future research could test the effectiveness of this framework and to analyse and to measure the relation between environmental strategies, supported by open innovation, and firm's environmental, financial and competitive performance.

Although, the proposed framework, highlighting the multiple dimensions of green management and its link with the open innovation processes, confirms the need for an operational approach that is able to develop and to integrate monitoring tools for the strategic assessment of performance and results achieved in order to provide a concrete response to corporate issues in terms of sustainability and environmental responsibility.

Abstract

This paper aims to provide an explanatory representation of the concept of ecosystem by mean of a systemic review of a selected sample of research papers hinged on the study of ecosystems in the field of management and business.

Reviewed papers were selected according to a multistep process and the following criteria: 1) coverage of a comprehensive range of business and management-related peer-reviewed journals chosen from Scopus database; 2) timeframe of the investigated topic restricted to the period 1993-2019; 3) papers mainly focused on providing a general framework on ecosystems drawn from research.

This paper represents an attempt to give a systemic representation of the existing research on the definition of ecosystem.

This study has implications not only for researchers, but also for business practitioners. By means of this literature review it is possible to properly interpret, according to the criteria selected, the concept of ecosystem as depicted in the field of management and business.

Keywords – ecosystem, literature review, business, innovation.

Paper type – Academic Research Paper

1 Introduction

Managerial and business literature have long studied the firm within its environment trying to examine the nature of its relationship with external actors and the system (societal, technological and institutional). However, over the last three decades technological transformation and liberalization of trade policies have strongly contributed to blur and eventually dissolve the traditional multiple boundaries between and within firms and industries and spurred increasing collaboration across different knowledge and technological domains.

At the dawn of the Internet era, an emerging academic literature has started observing business and industries as complex, evolving and adaptive ecosystems and questioning how firms survive in a fast-changing and competitive environment continuously disrupted by technological innovation. The business lexicon has then been enriched with the term “ecosystem” which encompasses a wide range of meaning and categories. Since the seminal paper of Moore (1993) the analogy with biological and natural ecosystems has been employed by numerous scholars to depict business communities consisting of firms and other actors that coexist, co-evolve and collaborate in order to innovate and survive in an “open” environment highly competitive. According to Moore (1997), who pioneered and for long mastered the topic, business managers should think of themselves as part of organisms participating in an ecosystem instead of focusing on the focal organization and its external counterparts, either competitors, partners or consumers which all together form a linear and peer-to peer representation of the business environment (otherwise defined as the “extended enterprise”).

Managerial literature on ecosystems is not recent but has scattered over time and so far, has not yet accomplished a definite and comprehensive systematization of the topic. Any attempt to explain the concept of ecosystem is still considered a challenging task and as in any emerging research field there is still substantial uncertainty about the definition of ecosystem and its boundaries within a business context.

The literature on ecosystems is highly fragmented and other authors have noted that a relevant number of studies come from practitioners rather than academics (Erkko and Llewellyn, 2014) and the word itself is sometimes a convenient catchphrase used by management consultants to impress without substance. Yet it is also a fact that the word ecosystem has widely been used in academic journals in the field of management in the attempt of finding a coherent theoretical framework and a holistic view of the concept of ecosystems are still lacking in literature. As noted by Tsujimoto et al. (2018) the concept of ecosystem in the field of management of technology and information was used in an increasingly number of papers published on scientific journals from 1995 to 2014.

Scholars has long attempted to define the concept of ecosystem. The mainstream literature has identified different types of ecosystems arising from the analysis of their inherent characteristics (Scaringella and Radziwon, 2018): business ecosystems (Moore, 1993; Iansiti and Levien, 2004); innovation ecosystems (Adner, 2006); entrepreneurial ecosystems (Prahalad, 2005; Roundy et al., 2017); knowledge ecosystems (Jarvi et al., 2018).

The goal of this paper is to present a literature review of the concept of ecosystem within the research field of management and business. We argue that a thorough review of existing literature on ecosystems may eventually: 1) give a proper valuation on the extent of studies already undertaken on this specific topic; 2) give support to a better understanding of the concept of ecosystem in the field of management and business in the view of developing a coherent theoretical framework which would highlight specific issues, methodologies and theories in prior investigations.

In order to reach the previously mentioned goals we address the following research questions. RQ1: what have been investigated in prior ecosystem research? RQ2: what kind of analysis have been used in prior ecosystem research? RQ3: what is the existing gap in current ecosystem research that future studies may further investigate?

In the attempt to give an answer to the aforesaid research questions this paper employed a multistep process of reviewing existing literature selectivity chosen from the Scopus database. The selected papers were then classified according to the criteria suggested by Jarvi and Kortelainen (2017) who identified three units of analysis in ecosystem research: individual actors, the relationship between the actors, and the ecosystem as a whole.

2 Research method

In order to properly collect existing studies on ecosystems in the business and management literature, starting from January to March 2019 we conducted a multistep focused search on the Scopus database. Research papers dealing with the concept of ecosystem in a business setting were gathered based on the following criteria.

First, the search was limited to papers published between 1993 and 2019 containing the term 'ecosystem' in the title, abstract or keywords; books and book chapters were excluded from the search. Second, the search was then limited to articles published in journals belonging to the subject category "business and management". Third, we decided to focus on peer-reviewed journals and consequently conference proceedings were dismissed coherently with Tranfield et al. (2003). As a result of this multistep selection process, a subset of articles were identified and chosen for subsequent analysis.

The initial search based on the term ecosystem returned results with a lot of 'noise', meaning that not all the articles dealt with ecosystems in the business context. For example, some of the articles considered as 'noise' focused on the natural and biological ecosystems. Consequently, those articles deemed out of scope were eliminated. The final sample consisted of 43 articles.

We have then examined existing literature review such as the one proposed by Pilinkienė and Maciulis (2014) who identified five different types of ecosystems: business ecosystems, entrepreneurship ecosystems, innovation ecosystems, digital ecosystems and industrial ecosystems. We also built our analysis on literature reviews proposed by Gawer (2014), Gawer and Cusumano (2013), Jardi and Kortelainen (2017) and Scaringella and Radziwon (2017). Finally, the systematization of the selected papers was conducted according to the methodological approach employed by Jardi and Kortelainen (2017) who

identified three units of analysis in ecosystems research: the individual actors; the relationship between the actors and the ecosystem as a whole.

3 Analysis of the findings

Ecosystems have been analysed from different theoretical perspectives and at different level of analysis. Ecosystems have been analysed through the lens of institutional theory (Di Maggio and Powell, 1983) or resource-dependency theory (Pfeffer and Salancik, 1988). Scholars have also associated the concept of ecosystem with open innovation (Chesbrough, 2003) and dynamic capabilities (Teece, 2018). Furthermore, scholars in the field of business and management have been approached the study of ecosystems using different units of analysis. As already mentioned, we have drawn from Jarvi and Kortelainen (2017) the methodological approach of systematizing the reviewed papers according to whether they focus on individual actors in the ecosystem, on the relationship between actors or the ecosystem as a whole.

Early researchers in the field such as Moore (1993) and Iansiti and Levien (2004) have focused on individual actors. The individual actors involved in ecosystems can play different roles (e.g. customers, seller of complementary products and services, supplier, policy maker) and occupy distinct positions performing for instance the role of hub or focal firms (Iansiti and Levien, 2004; Moore, 1993). Autio and Thomas (2013) define hubs as connecting production and use-side participants, giving rise to the first type of observed relationship between different actors in the ecosystems. This relation has been addressed in a study by Henierth et al. (2014) and in studies examining how users adopt technological platforms in ecosystems (e.g. Makinen et al., 2014). Other studies of technology or platform owners (Iyer and Davenport, 2008; Isckia, 2009; Li, 2009; Tee and Gawe, 2009; West and Wood, 2013; Gawer and Cusumano, 2014; Wareham et al., 2014) have also placed particular emphasis on focal firms in ecosystems (Cohen, 2006; Nambisan and Baron, 2013; Li and Garnsey, 2014). Much research attention has also been devoted to strategic interactions with independent complementors (Pierce, 2009; Adner and Kapoor, 2010; Ethiraj and Posen, 2013; Kapoor, 2013; Kapoor and Lee, 2013; Kapoor and Furr, 2014).

Ecosystems have been discussed under different labels, including business ecosystems, digital ecosystems, innovation ecosystems technology ecosystems and platform ecosystems.

Referring to the above units of analysis (the individual actor, the relationship and the ecosystems), we analysed in more detail the different theoretical perspectives applied to these different units of analysis, based on our sample selected articles.

Table 7 Existing studies on ecosystems by unit of analysis

<i>Unit of Analysis</i>	<i>References</i>
The individual actor	Moore (1993), Iansiti and Levien (2004) Autio and Thomas (2013), Xu et al. (2010), Kang and Downing (2015) and Mäkinen et al. (2014) Gawer and Cusumano (2013), Teece (2018), Helfat and Raubitschek (2018), Cohen (2006), Hagel et al. (2008), Arker and Van Alstyne (2017)
The relationship	Moore (1996), Adner (2006), Pereira et al. (2017), Pierce (2009), Adner and Kapoor (2010), Gyrd-Jones and Kornum (2013), Wareham et al. (2014), Ethiraj and Posen (2013), Kapoor and Lee (2013) and Kapoor and Furr (2015), Acs et al. (2018), Immomen et al. (2016), Hein et al. (2019), Aulkemeirer et al. (2019)
The Ecosystem	Adner (2017), Anzari et al. (2017), Clarysse et al. (2014), Dattée et al. (2017), Gawer and Cusumano (2013), Battistella et al. (2013), Ritala et al. (2013), Adner (2006), Tencati and Zsolnai (2009), van der Borg et. (2012), Calcei and M'achiurgi (2012), Cennamo and Santalo (2013), Jackson (2011), Gomez et al. (2016), Russel and Smorodinskaja (2017), Xu et al. (2017), Luo (2017), Oh et al. (2016)

Research that takes the individual actor as the unit of analysis focused on firms and consumers. In particular, research on firms in ecosystems examined both focal and peripheral firms, on different positions within the ecosystems (Cohen, 2006; Hagel et al., 2008). The individual actors were examined in the context of platform ecosystems and some authors suggested two types of platforms: internal or company-specific platforms, and external or industry-wide platforms, (Gawer and Cusumano, 2013). They defined internal platforms as a set of assets organized in a common structure from which a company can efficiently develop and produce a stream of derivative products; while they defined external platforms as products, services, or technologies that act as a foundation upon which external innovators organized as an innovative business ecosystem, can develop their own complementary products, technologies or services.

Expanding the literature on adoption and diffusion, consumer-related decisions to adopt have been examined in the context of platform ecosystems (Xu et al., 2010; Kang and Dowling, 2015; Makinen et al., 2014).

Other studies addressed the issue of the optimal levels of openness and of intellectual property duration in a platform ecosystem (Parker and Van Alstyne, 2017).

Another part of the literature examined the distinctive capabilities of firms in ecosystems. Teece (2018) placed firms at the center of platform-based ecosystems and argued that dynamic capabilities can enable firms to create and capture value by building ecosystems and designing appropriate business models. Similarly, Helfat and Raubitschek (2018) proposed three types of dynamic capabilities which are critical for platform leaders: innovation capabilities, environmental scanning and sensing capabilities and integrative capabilities.

Studies focusing on the relationship between the individual actors of the ecosystems, moved from the notion that ecosystems changed the view from traditional inter-firm

competition to a joint approach of coopetition – simultaneous competition and cooperation – between actors (Moore, 1996; Adner, 2006; Pereira et al., 2017). In fact, many recent studies have gone beyond value creation in individual companies, because firms have integrated customers, partners, and stakeholders in a mutual value co-creation process.

A group of such studies examined the relationship between the focal firms and the complementor (Pierce, 2009; Adner and Kapoor, 2010; Gyrd-Jones and Kornum, 2013; Ethiraj and Posen, 2013; Kapoor and Lee, 2013; Kapoor and Furr, 2015). Other recent studies described the role of entrepreneurial ecosystems in economic growth (Acs et al., 2018). Research has, above all, highlighted how ecosystems' members can strengthen their forces by co-operating, though remaining independently, that happening especially in the digital service ecosystem (Immomen et al., 2016) and in the context of emerging Internet of things (IoT) platforms (Hein et al., 2019). With regard to inter-organizational collaboration in digital ecosystems, Aulkemeier et al. (2019) underlined that current systems tend to rely on static collaboration patterns between individual partners and are engineered without interoperability in mind, limiting the opportunities for firms to engage in dynamic collaboration relationships. They argue that a platform with a federated architecture can improve the agility of the collaboration between members of a business network and propose a corresponding platform architecture and a prototype for the online retail sector.

The third unit of analysis – the ecosystem as a whole – has also been examined from different perspectives.

The ecosystem approach has recently gained a great deal of interest in disciplines such as strategic management (Adner 2017; Ansari et al., 2017; Dattée et al., 2017) and innovation and technology management (Clarysse et al., 2014; Ritala et al., 2013).

Based on ecosystem level outcomes, interest has focused on collective and collaborative value creation within the ecosystem (Adner, 2006; Tencati and Zsolnai, 2009; Adner and Kapoor, 2010; Van der Borg et al., 2012) and competition between different ecosystems (Calcei and M'Chiurgi, 2012; Cennamo and Santalo, 2013; Kang and Downing, 2015).

In this context, previous research remarked a turning point in the literature, that is the transition from business ecosystems to innovative ecosystems (Jackson, 2011). Business ecosystem relates mainly to value capture, while innovation ecosystem relates mainly to value creation (Gomes et al., 2016).

In this direction, some scholars attempted to develop a specific framework about innovation ecosystems (Russell and Smorodinskaya, 2017), considering the integrated value chain and the interactive network (e.g. Xu et al., 2017). Other studies focused on the architecture of innovation ecosystem (Luo, 2017), on its risks and critical aspects (Oh et al., 2016).

4 Conclusions

Studies on ecosystems have shown there is a methodological issue related to different concepts and definitions of ecosystems that have been originated by diverging streams of research dealing with ecosystems. It is worth noting that scholars have been placing some efforts in order to identify a common ground across different research streams (Scaringella and Radziwon, 2017) and to strengthen the theoretical foundations of this research field. Specifically, we suggest to associate the recently published ecosystem literature with the well-established literature strands adopting the territorial approach such as for instance the literature on industrial districts, Marshallian districts and regional innovation clusters.

In this study we systematized the reviewed papers using three unit of analysis suggested by other researchers in the field (Jarvi and Kortelainen, 2017). From the analysis of the existing literature it emerged that academic research has been focusing on the analysis of specific case-studies particularly in the context of innovation ecosystems. Furthermore, it emerged that empirical studies that take the whole ecosystem as their unit of analysis are relatively limited and only recently have begun to emerge. Indeed, the ecosystem as unit of analysis is very challenging for empirical researchers mainly due to the difficulty to draw precise boundaries for the concept of ecosystem. Likewise, the interconnectedness between actors in ecosystems and their evolution (and co-evolution) can hardly be captured by conventional research methodologies such as qualitative case studies or network analysis. From this viewpoint, Jarvi and Kortelainen (2017) urged for the use of alternative research methodologies such as simulation and agent-based modelling which are especially well-suited for theory development.

Abstract

The present study explores organizing knowledge co-creation for radical innovation within knowledge ecosystem. Building on research on knowledge creation, innovation, and organizing, the study at hand understands knowledge co-creation as central basis for organizing and source of interdependence. Study sheds light on temporary and emergent organizing of knowledge co-creation within knowledge ecosystem. The findings of the study reveal that process of knowledge co-creation is cyclic in which each cycle builds on previous one. In addition, knowledge co-creation considers multidimensional orientation between technology, business and regulation throughout the process. Hence, beyond formal project organization, organizing knowledge co-creation is temporary, dynamic, informal, and follows cyclic and generative process. Specifically, organizing comprises activities of shared problem identification, shared goal setting, making experiments (testing), open demonstrations, and seeking internal and feedback and knowledge synthesis. Such an organizing enables contextual, situational, and flexible involvement of critical knowledge for the development of innovation, building novel business, and changing regulation. The paper discusses the findings and implications more detailed.

Keywords – knowledge co-creation, organizing, temporary, radical innovation, knowledge ecosystem

Paper type – Academic Research Paper

1 Introduction
