- (ii) prudential regulation, so protection of the customers;

2 Methodology

In this paper, we considered the absence of a universally recognized definition of “RegTech”, starting from there to propose a definition of the several definitions elaborated by main authors.

The method shall enable an exploratory approach towards the data with a systematic literature review.

For making the analysis and overlapping of similar concepts we follow the methodological guidelines our work from the following sources: Yin(1984) Zavolokina et al. 2016. We produce a conceptual definition of extracted definitions of RegTech, hence dividing them under three cluster as in the cited paper. We consider papers of academics, practitioners (consultancy firms and one manufacturer, Intel, one Law firm) and authorities as the base of our inquiry bause they present common peculiarity of approach. The applied method needs to acknowledge the not-neutral and not-objective features of some of the considered texts, in particular if provided from a financial institution and consultancy firm. We complete the analysis by developing a systematic literature review and a content analysis. So we distinguish three cohorts: academics, consultants and authorities to better manage the phenomenon.

Clearly all the considered papers are published by academics, consultants and authorities.

For the research of academics’ papers, we used the following services: Scopus, SSRN, Google Scholar, Web of Knowledge, advanced search on authorities and practitioners

involved in “RegTech”. In order to identify relevant articles, we conduct a keyword “RegTech” in a second step in the over-mentioned databases and over the internet.

The research of definitions of “RegTech” proposed by the consultant was conducted in a systematic way by searching the word “RegTech” on research engines conjointly with the internal research engine of the international websites of the main consultancy firms i.e. McKinsey, EY, Deloitte, KPMG, PwC, Accenture, Mc Kinsey. A similar method for search of authorities’ papers, along with looking for the references in the consultant and academics articles. We applied as well the following constraints: (1) dating to 31.12.2018 (without any lower time of beginning), (2) available in English.

Once all the papers with the presented methodology have been collected, they were analysed looking for a definition of “RegTech”.

Considering a paper or document dealing with RegTech, it is considered to provide a definition of RegTech if it uses sentences such as:

- “RegTech is”, “RegTech is defined” or other similar sentences introducing clearly a definition;
- “RegTech exist to”, “is about”, “involves” and similar expressions.
- the explanation of the term is inserted as a parenthetical element;
- The keyword for research is explained in the Appendix’s code matrix.

For each paper, is considered the first sentence that, with one of the previously reported structures, tries to introduce and define “RegTech”.

It is necessary because we need to be clear about the definition and a conditional sentence is not suitable for this aim.

For this motivation we have excluded those parts of definitions of “RegTech” that include terms such as “often”, “sometimes” or other similar adverbs: this because we considered as definitions only those presenting aspects that are considered necessary and universally present in RegTech.

To take this decision of analisys we have made a preliminary literarure review. The paper “Definitions, Dictionaries, and Meanings” by Swartz (Swartz, 1997) gives use of those methodological guidelines.

The main instrument for the creation of a definition applied in this paper is inductive coding.

The first step of the procedure, once collected all the definitions, has been to take one definition per time and extract from it all the concepts included.

This means that the definition of concepts has not been proposed a priori and then each definition analysed through it, but the concepts definition itself have been built starting directly from the definitions.

Concepts obtained were the less comprehensive possible, as long as the single concept had a useful meaning. For instance, the sentence “application of technology to regulatory activities” (Baxter, 2016) can be seen as the union of two concepts, “application of technology” and “in the definition of regulatory activities”, while the single concept of “application” was not considered to have a useful meaning for the definition of “RegTech” if considered alone.

On the other hand, concepts such as “facilitate” or “meet” have been considered as single concepts, because for instance “RegTech” is considered by certain definitions as “technologies designed to facilitate” (Aspen Institute, Modernizing digital financial regulation, 2017), hence the ability to facilitate is considered important.

Concepts have been extracted and collected in order to cover all the possible meanings of a definition: in this way, each definition can be back-built starting from the concepts collected.

This procedure has been iterated for all the definitions, collecting under the same cluster all the word or sentences describing the same concept using simply different words and synonyms. An example is “Use/application/adoption of - technology/technology solutions” in order to describe in different ways the application of technology.

In this way, each concept has a meaning substantially different from the others, providing mutually exclusivity between concepts. The second step of the procedure was to collect in a matrix all the definitions and concepts, in order to conduct different analysis, such as understand the frequency of a certain concept in the literature definition analysed.

Analysis and results will be explained in the next sections.

3. Analysis and Results

A total of 153 papers have been found with the proposed criterion.

The overall number of collected applying the methodology described definitions is 46.

(1) What are the primary actors that proposed a definition of RegTech over time?

The combination of regulatory issues, technological advances, information asymmetries between market participants, economic instabilities and market incompleteness on top created the ground for stimulating innovation on the crossroads of finance and technologies.

This phenomenon attracted the interest of several experts that published preliminary papers on “RegTech”. The primary actors that proposed a definition of RegTech are academics, consultants and authorities classified for their interest.

The first actor of RegTech to propose a definition of “RegTech” were a consultant: in 2015, a paper from EY defined “RegTech” as “proliferation of new applications regulating financial services directly on devices.” (EY, Who will disrupt the disruptors, 2015). Even if academics have not been the first to define “RegTech”, academics are still a fruitful family of actors providing a definition.

The earliest published definitions from an academic, Baxter, with the paper “RegTech, the application of technology to regulatory activities” in Duke law Journal (Baxter, 2016)

The last important cluster of authors is Authorities. The first authority to define RegTech was Financial conduct authority (FCA) in UK, which defined RegTech as “subset of FinTech that focuses on technologies that may facilitate the delivery of regulatory requirements more efficiently and effectively than existing capabilities” (FCA, Call for input on supporting the development and adopters of RegTech, 2016).

EU's EBA definition arrived in 2017 (EBA, Discussion Paper on Fintech, 2017).

Academics interested to define RegTech are mainly Professors of law, economics, and lawyers for consultant and members of Authorities. Management engineers and economists are now fully involved in this topic. Another important category of engineers involved are experts in computer science.

Looking at the whole sample from 2015 to 2018 in Figure 2, the attempts to defining "RegTech" increased in 2016, with a maximum of proposed definitions in 2017.

As previously anticipated, consultants are the most active in defining "RegTech", followed by academics and authorities.

(2) How is RegTech's definition in the literature?

RegTech has not a clear definition, till now but we can establish a definition based on the collected definitions from the most influent authors, namely academics, authorities and consultants. We provide an integrative perception out of the available definitions of "RegTech" presented in the industrial reports and scientific publications.

In this subsection, firstly, we present the list of gathered definitions of "RegTech" (Table 1 in the appendix) and afterwards, taking into account the features and concepts behind them, we propose an inclusive conceptual definition of the RegTech being reflected by the studied sources and extracted with inductive coding. It is interesting to consider, on the overall sample, which is the most frequent concepts in the proposed definitions.

RegTech is presented "as a solution or an application" in 26 (66,7%) of the collected definitions, while is presented "as a company" in 6 definitions (15,4%).

RegTech implies the use of technology and technology solution for 31 definitions (79,5%) and is involved "in the context of / application to regulation, regulatory requirements/ demand/ activity / challenges" for 27 authors (69,2%). Those two concepts appear together in 21 definitions (53,8%).

The application of "RegTech" for "compliance/comply with/ conform to compliance requirements" is considered by 31 definitions (69,2%) and what is still common in all the

categories are that RegTech can facilitate or even solve a certain issue (“facilitate/address /solve/alleviating the burden of/improve/help/ bring solution”) for 23 definitions (60%)

(3) Which topics are discussed in the context of RegTech by actors involved?

In this subsection, we will present how a certain concept is presented more or less frequently depending on the author cluster.

For academics:

The perception and the definition of RegTech provided by the academics are very wide and diversify in its definition. The overall contributes by academic authors are 11.

The most reported concepts by academics are the use of technology in 9 definitions over 11 and the application to regulatory environment appear together in 6 definitions over 11. At the same level are present the using for “compliance” and “RegTech as solution”

Academics are the only cluster of authors proposing the concepts of “Yield better regulation” (Arner et al, 2018), “Real time” (Cave, 2017) and “Support the application of advanced analytics approaches” (Arner et al, 2018).

There are four authors focusing specifically on IT solutions with an augmentation in 2018. Only one of them (Das et al, 2017) considers “innovation” as a necessary aspect of RegTech. Only three academic on 11 authors considers RegTech as something that is applied only by financial institutions (Das et al, 2017)(Yang et al, 2018) (Stepanko et al, 2018), while no other authors specify the sector of application of RegTech. None of the academic authors discusses if RegTech is a sub-segment of FinTech or not.

Along with this, none of them includes the definition of RegTech the concept of “Efficiency”. No function about risk management and KYC (Know you customers) were considered in the definition by academics.

RegTech is not reported by academics definitions as something directly applicable by regulators.

For the consultants:

The overall collected definitions by consultants are 31 and there is a high variety of proposed concepts.

In 9 over 31 definitions (around 30%), innovation plays an important role, both in terms of innovating technologies and innovative applications.

For 6 consultant authors (20% of the total consultant definitions), RegTech is a company, and for 18 of them (58%) is a solution or application. Likewise for the academics, the concepts of “use of technology” and application to “regulatory definition” are among the most present concepts in consultants’ definitions. Those two concepts appear together in 14 definitions (77%) and the regulatory definition for 65% of the definitions. Evaluating the sector of application of RegTech, consultants are not homogenous in their definitions: for 8 of them (30%) RegTech can be used by financial players only, while for 7 of them (22%) can be applied in all sectors. The other authors do not specify the application sector. One of the most important concepts for consultants is “compliance”, that is reported in 22 definitions (70%).

RegTech is supposed to “facilitate” the operations or” help” the companies for 20 consultants (65%). “Supervision” is a key point for only two consultants (Milken, RegTech opportunities, 2018, Only for 4 authors RegTech is a sub-segment of fintech.

For the authorities:

The collected definitions proposed by authorities were only 4, nevertheless showing interesting concepts. The authorities that proposed a definition are FCA and EBA, that proposed 2 definitions each.

Both of them consider “RegTech” as a solution (EBA, Fintech roadmap 2018) (FCA, Call for input on supporting the development and adopters of RegTech, 2016) (FCA, Co-operation Agreement 2017) and not as a company. The concept of “application of technology” is present in all the collected authorities’ definitions, and the concept of “applied to regulatory definition” in three of them. Hence,

compliance is present in three definitions, while “Reporting” is inserted in one definition only (EBA, Fintech roadmap FAQ, 2017).

One important concept reported by both regulators is the “Efficiency” that RegTech is required to bring or even improve in a company.

The last interesting peculiarity is that both authorities consider RegTech useful for regulators themselves (EBA, Fintech roadmap, 2018) (FCA, Co-operation Agreement, 2017).

3.1 RegTech's definition: analysis of matching points and divergence between actors.

It is useful to focus on concepts that are more heterogeneous among authors.

The first important question is whether RegTech can be considered a subset of FinTech.

The answers are very diversified and nowadays not uniform.

According to the FCA RegTech is a part of fintech: 'RegTech is a sub-set of FinTech that focuses on technologies that may facilitate the delivery of regulatory requirements more efficiently and effectively than existing capabilities.' (FCA, Call for input on supporting the development and adopters of RegTech, 2016).

The FCA's definition is taken also from several consultants and Academics as a stand alone definition or as a first step to build a new larger definition.

As well for a consultant firm, EY, that said that there is an "increasing number of FinTechs applying technology to the regulatory process" (EY, UK FinTech-On the cutting edge, 2016). Academics show a wider perspective of RegTech's phenomenon. We can consider some explicative example.

According to authors applied in finance like Colaert, "RegTech is sometimes viewed as a part of FinTech, although this view has – in our view rightly so – been criticized for giving a too narrow account of what RegTech stands for". (Colaert, 2018). On the other hand, Arner said: "Far from being a subset of FinTech, RegTech should be considered a connected but distinct phenomenon" (Dw Arner 2017). If RegTech is a part of FinTech is not already clear but could be propulsion for new studies.

We can argue that legal and the application of IT and specifically Artificial intelligence solution is also applied to other sector involved with compliance and risk. The border in RegTech is for us a bridge between finance, which is one of the first application in the literature, and other fields. For example RegTech application like Compliance and AML are not totally defined into a financial perimeter. In this case monitorTech, ReportTech, DataExchangeTech and the main branch *LegalTech* are strictly connected and this FCA reports about a subset of fintech.

Another important theme, in which there could be an incrementing of research, is the RegTech's sector of application.

We find two different views, all industry or for the financial system only. As explicative examples, we report two definitions, one reported by an academic and one by an authority: According to Das "RegTech as - A blend word of 'regulatory technology' that was created to address regulatory challenges in the financial services sector through innovative technology" (Das et al, 2017), so the specific sector of application of RegTech is the financial sector. On the other hand, according to EBA "[...] regulatory technology ('RegTech') is a commonly recognised term for technologies that can be used by market participants [...]", so the focus is on "market participants". Those are two examples: in our definition we found 12 definitions looking at RegTech as something dedicated to the financial sector, while 5 definitions considering RegTech as something proper of any sector.

But in other fields of research like the law schools RegTech is suitable for meet any regulatory requirement that has an information-gathering element is plausibly a candidate for RegTech innovation.

For example, Allen and Berrn(2018) many resources firms are required to manage existing native vegetation around their projects, and are increasingly using drones to do so.” Autonomous drones— already being used in mines in Western Australia—could be paired with artificial intelligence to identify vegetation loss or invasive species, removing human compliance managers.”

RegTech offers both opportunities and risks. It makes both compliance and enforcement with regulation more efficient. While often requiring a significant upfront investment, RegTech helps not only to meet existing regulations but some applications are designed to dynamically accommodate changes to the regulatory framework. The rapidity of regulatory change is often a big match. Automated compliance through RegTech reduces costs on the firm and regulatory side for auditing and surveillance of the firm.

3.2 Tentative for a common definition and new trends

The differences in definitions revealed by the literature review, underscore that there are definitional problems with RegTech. One of the last and complete contributions on this topic was provided in august 2018 from D. YANG AND M. LI, seems to add other elements about function and the definition of RegTech. “Technology-driven regulation can also help regulators understand innovative products and transactions, market manipulation, and risks closer to real time. “

The key to financial oversight is in data collection and monitoring. Its core concept comprises transparency, equality, and intelligence, so as to create a truly real-time and dynamic regulatory system.” (D. YANG AND M. LI 2018)

If Yang and Li in 2018 seem merge the Technology-driven regulation understand innovative products and transactions, market manipulation, and risks management to real time and regulatory approach based on financial oversight is in data collection and monitoring in this definitions are still lacking very relevant aspects like compliance, an overview of the dialogue between regulatory authorities and the other actors.

Compliance and the use of technology in the context of regulatory requirements, where a certain homogeneity among proposed definitions can be found.

RegTech, while incremental, is still in relatively early stages and follows in parallel as a subset of fintech. (Kaal, 2016).. RegTech takes into regulation richer and innovative technology “ instead RegTech for Anagnostopoulos (2018) refers to a sub-division of the fintech sector that focuses on technologies that may facilitate the delivery of regulatory requirements more efficiently and effectively than existing capabilities. “

A very particular “function” about RegTech is expressed by Bayón, P. S., & Vega, L. G. (2018) that affirm “RegTech is aimed at making financial regulation an efficient instrument to prevent and solve market failures in a technocratic and global economy presided over by the control and analysis of information flows, which have become the main sources of power and social development.” The new legal policy joined with

technology must ensure that the regulation removing not useful legal rules, while avoiding the creation of equally inefficient substitute rules”

This recall to the prevention and the market failures in a technocratic and global economy and considers that rules are more and more decided globally and the Author seems suggesting so the the control and analysis of information flow, are sources of “power and social development”.

The other author, Gomber(2018), proposes a new trend not for defining RegTech but for the technologies involved in RegTech that can help us to create a definition’s definition of regtech. For the author, RegTech can help human intensive jobs in regulatory and compliance process.

RegTech solutions involve technologies that aim to ease regulatory compliance and substitute for manual labor in standard regulatory and compliance processes.

This concept has inspired some start-ups pointed this goal as one of the principal advantages of its legaltech and RegTech solution for banks.

Substituting manual labour with RegTech in that specific case has the effect of lowering compliance cost for the banking.

Another stream of studies is about defining the role of Authorithies in RegTech.

The interesting point comes from a contribution “Regulators and SupTech Solutions Simone di Castri, Matt Grasser, and Arend Kulenkampff”, published by Bfa in August 2018 regulators are able to use RegTech “to process and analyze the data about Financial statements (balance sheet, cash flow, income statement), financial ratios (liquidity ratios, capital adequacy ratios),^{[1][2][3][4][5][6][7][8][9][10][11][12][13][14][15][16][17][18][19][20][21][22][23][24][25][26][27][28][29][30][31][32][33][34][35][36][37][38][39][40][41][42][43][44][45][46][47][48][49][50][51][52][53][54][55][56][57][58][59][60][61][62][63][64][65][66][67][68][69][70][71][72][73][74][75][76][77][78][79][80][81][82][83][84][85][86][87][88][89][90][91][92][93][94][95][96][97][98][99][100]} volume and value of transactions, number of transaction points to number of accounts and total balances”^{[1][2][3][4][5][6][7][8][9][10][11][12][13][14][15][16][17][18][19][20][21][22][23][24][25][26][27][28][29][30][31][32][33][34][35][36][37][38][39][40][41][42][43][44][45][46][47][48][49][50][51][52][53][54][55][56][57][58][59][60][61][62][63][64][65][66][67][68][69][70][71][72][73][74][75][76][77][78][79][80][81][82][83][84][85][86][87][88][89][90][91][92][93][94][95][96][97][98][99][100]}

In a rapidly evolving financial sector that lacks proper tools and infrastructure for supervision and monitoring by providing alternative processes and RegTech permits to central banks to develop appropriate regulations, by “facilitating a better understanding of new market participants and technologies”. Without RegTech central banks may not have the capacity to monitor the new services and additions in the financial system.

The negative aspect is instead that the regulators, with the diffusion of RegTech, are more likely to impose stricter and complicated regulations and this could be a problem for whom has not the infrastructure and scale to implement these solutions so regulation could lower costs with technology but also increasing costs with the multiplication of rules.

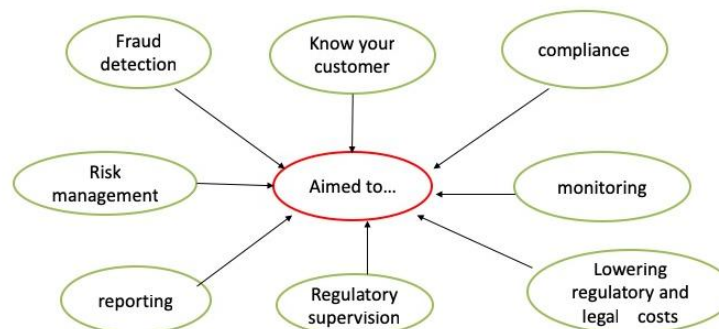

This scenario implies that the authorities should balance with new protection of the client, the technology could help the regulation but write a more complicated but also effective regulation, sources of financial and social development, there is the necessity to follow a new approach of collaboration between financial institutes, RegTech solution technology and Authorities.

We can argue finally that RegTech, in our evidence, is a solution or an application that implies the use of technology that provides technology solution involved “in the context of or in application to regulation, regulatory requirements challenges”.

The application of “RegTech” is suitable for compliance and to comply with regulatory requirements and RegTech can facilitate or even solve these issues given in a new and more complex world regulatory environment. and financial market proposes new needs and new technological solutions with the rapid fintech’s growing. It can be represented as in this graph.

The definition.

RegTech is: use of technology in regulatory field

RegTech is the use of technology in the context of regulatory field in compliance, fraud detection, lowering costs to comply to the regulation, know your customer, monitoring and managing the risk and reporting anomaly more than existing capabilities.

RegTech is the use of technology in the context of regulatory requirements in compliance, fraud detection, lowering costs to comply to the regulation, know your customer, monitoring and managing the risk and reporting anomaly more than existing capabilities. RegTech is born as a part of FinTech is used in the field of financial firms to regulators and for supervision by regulator but now is utilized in all the industries

4 Conclusion and future development

In this paper, we used an explorative and descriptive approach to address the term “RegTech”.

We think that could be a milestone to future RegTech’s study in order to create a perimeter of study for academics, practitioners and Authorities.

Possibilities of development include monitoring corporations, compliance with environmental regulations and real-time, and how technology could be used to improve not only regulation but also regulators and all industry itself.

We wish that our definition of RegTech should be the begin of new studies and elaboration by academics about defining the emerging phenomenon of RegTech.

Appendix

Table 1

DEFINITION INDEX	DEFINITION	SOURCE
1	RegTech is a contraction of the terms regulatory and technology, and it comprises the use of technology, particularly information technology (IT), in the context of regulatory monitoring, reporting, and compliance.	Arner et al., 2017
2	RegTech, the application of technology to regulatory activities [...]	Baxter, 2016
3	(RegTech) which is described as the use of technological solutions to facilitate compliance with and monitoring of regulatory requirements.	Colaert, 2018
4	[...] defines RegTech as - A blended word of 'regulatory technology' that was created to address regulatory challenges in the financial services sector through innovative technology.	Das et al, 2017
5	[...] application of technology to regulation ("RegTech"), it involves digitization of systems which in turn supports the application of advanced analytical approaches to yield better regulation	Arner et al, 2018
6	RegTech, as the use of IT in compliance and supervision/regulation is now labelled [...]	Enrique, 2017
7	[...] RegTech – automated and real-time provision of compliance-related information to regulators.	Cave, 2017

8	Regulatory technologies are a subsystem of financial technologies that ensure more effective implementation of regulatory requirements for participants of financial markets. RegTech reduces the cost of services for participants in the financial market and the costs of state regulatory bodies by reducing time costs and making the whole system more simple	Stepanko A. D. and Surnina K. S. 2018
9	RegTech – or regulatory technology – is emerging as a means to deploy current and emerging technology solutions to reduce the increasing costs of compliance for companies and to improve internal reporting and supervisory capacity for regulators.	Use of RegTech by Central Banks and its Impact on Financial Inclusion Evidence from India, Mexico, Nigeria, Nepal and the Philippines Gurung, N1 and Perlman, L2(2018)
10	RegTech refers to a sub-division of the fintech sector that focuses on technologies that may facilitate the delivery of regulatory requirements more efficiently and effectively than existing capabilities.	Fintech and RegTech: Impact on regulators and banks Ioannis Anagnostopoulos Journal of Economics and Business (2018)
11	However, we argue that RegTech is not a part of fintech; rather, they are related but in different domains. As narrowly defined, RegTech is the adoption and use of technology to help financial services firms to understand and comply with regulatory requirements more efficiently and effectively. Typical examples include regulatory reporting or compliance oversight of conduct through the processing of unstructured-language data. In a broad sense, RegTech refers to regulators taking advantage of technological innovations aimed at synchronizing with the digitized and automated financial sector, which ultimately produces technological solutions that streamline and improve regulatory processes. To realize a desired regulatory goal, regulators need to take certain measures, for instance, create a uniform data format, establish a compatible application programming interface (API), and develop a machine-readable monitoring mechanism. In these definitions, RegTech refers to the use of technology, especially information technology (IT), for regulation, reporting, and compliance. The concepts extracted and presented in Table 2 are better explained now. Consider a certain definition that shows one of the following concepts:

RegTech as a company: According to this definition, a RegTech is a company

RegTech as a solution/application: According to this definition, RegTech is defined as a solution or an application.

Use/application/adoption of technology/ innovative technology/ technology solutions: According to this definition, the concept of RegTech implies the application of technology.

Use of IT: According to this definition, the concept of RegTech implies a central use of IT solutions.

In the context of/ application to regulation, regulatory requirements/demand/activity /challenges: According to this definition, RegTech is implicitly linked to the regulatory environment.

Monitoring / Reporting / Compliance / Supervision: According to this definition, the concept of RegTech is related respectively with Monitoring, Reporting, Compliance or Supervision activity.

Involves digitalization of systems / digital solutions: According to this definition, the concept of RegTech is related to the digitalization of systems or the presence of digital solutions.

Support the application of advanced analytics approaches: According to this definition, RegTech by definition fosters the application of analytics approaches.

Yield better regulation: According to this definition, RegTech by definition has to foster better regulation.

KYC / Fraud detection/protection / Collateral / Risk Management: According to this definition, RegTech helps in KYC practices, counteract frauds and fosters collateral and risk management.

In the financial services sector/organization or banks: According to this definition, RegTech is related specifically to the financial industries and to the banks.

In any sector/organization/industry/ institution /company: According to this definition, RegTech is related to any industry or kind of company.

Manage regulatory risk: According to this definition, RegTech deals with the management of compliance risk.

User authentication / Security Applications: According to this definition, RegTech deals with user authentication practices and applications to improve security.

Directly on devices: According to this definition, RegTech is related to applications developed directly on devices.

Stay ahead of the competition in a digital marketplace/ gain competitive advantage: According to this definition, RegTech is by definition able to provide a competitive advantage.

Sub-segment of the Fintech: According to this definition, RegTech is a sub-segment of Fintech.

Efficiently/ more efficiently and effectively than existing capabilities: According to this definition, RegTech has to solve issues in an efficient way, or in a way more efficient than existent capabilities.

Solutions for increasing automation / automated: According to this definition, RegTech has to increase automation.

New business concepts: According to this definition, RegTech is new business concepts.

Real time: According to this definition, RegTech is/provides real time solutions.

Used by regulators themselves: This concept indicates “RegTech” as something useful for regulators. The concept hence can be seen as “Utility for regulators”

How Much Digital are the Italian Incubators? Level of Diffusion of Digital Technologies in Italian Certified Incubators

Abstract

Digital entrepreneurship represents a relevant socio-economic and technological phenomenon that creates new spaces of opportunities where different kind of organizations can leverage digital technologies to shift the traditional mode of creating, supporting and doing business. Among these organizations, incubators should effectively exploit digital technologies to support the creation and development of innovative startups. Notwithstanding, some studies show that they have still a physical characterization of their operating activities and core initiatives and use digital technologies mainly for communication purposes, through their web sites and social media channels. Moreover, how much incubators and organizations like incubators use carefully digital technologies to support new entrepreneurial and innovation processes has not yet been analysed in literature. Based on these premises, the aim of this paper is

to shed light on how incubators are adopting digital technologies (with a focus on social networking sites) to support the process of creation of new ventures. A web-based document analysis methodology has been used to investigate the level of diffusion and adoption of digital technologies among Italian Startup Incubators using the information available on the websites of the analysed incubators. Results obtained show that, while the contents describing all the phases and issues of the incubation programs (e.g. modules and duration, number of calls, participating requirements, selection process, etc.) benefit of the usage of digital technologies in almost the incubators analysed, the core services for incubating the startups are delivered mainly through a face-to-face and physical approaches, with the unique (few) exception of services provided to submit online ideas and project proposals. Besides, most of the analysed incubators leverage digital technologies to give visibility to their partners and collaborators. Finally, a positive correlation has been found between the number of social media used and the intensity of usage. According to the value of these two variables, four archetypes have been proposed with a brief description and guidelines for the development of the digitalization processes of incubators.

Keywords –Digital Technologies, Social Media, Incubator, Italy

1 Introduction

Today, digital technologies have a significant impact on how new ventures are imagined, designed, launched and managed. Digital technologies permeate every organization, manufacturer and service as well as private and public organizations (Fischer and Reuber, 2011; Fitzgerald et al., 2014; Greenstein et al., 2013), and have the potential to open up fascinating innovation opportunities for entrepreneurs (Cohen et al., 2017; Yoo et al., 2010) to reshape the markets and society globally (Nambisan et al., 2017).

The resulting and relentless convergence among entrepreneurship and information-system related trends can be synthesized into the concept of digital entrepreneurship. It represents a relevant socio-economic and technological phenomenon that creates new spaces of opportunities where existing and potential entrepreneurs can leverage digital technologies to shift the traditional mode of creating and doing business in the digital era (Cohen et al., 2017; Giones and Brem, 2017; Nambisan, 2017; Nambisan et al., 2017).

Actually, digital entrepreneurship refers to the use of digital technologies and Internet to execute most of the processes required to launch a new venture (Giones and Brem, 2017), as well as to manage and implement the business operations with customers, intermediaries, or partners (Shabbir et al., 2016; Ismail et al., 2012).

Digital technologies support the new phenomenon of generativity (the ability of technologies to support the creation of new services and products). This creates opportunities for radically new business models. Entrepreneurs and innovators are adopting digital technologies to develop new forms of entrepreneurial actions that move beyond the traditional industry boundaries to include knowledge ecosystems and communities, thus accelerating the evolution of new ventures. Specifically, digitalization could enable organizations involved in knowledge and startup ecosystems in adopting

business models that are more and more open, allowing ideas and technologies to flow from outside the company and from within to the external environment (Urbinati et al., 2018). Among these organizations, incubators have still a physical characterization of their operating activities and core initiatives. Most of the incubators execute their main activities essentially in a face-to-face modality (Tapscott, 2014).

Digital technologies could leverage the way in which incubators pursues the entrepreneurship process with a pervasive effect on the rationale, processes and forms of entrepreneurship as well as on the stakeholders involved in the achievement of entrepreneurship goals.

In this vein, our interest is to investigate about the how much diffused are digital technologies within business incubators. Indeed, opportunities to create new firms/companies provided by the digital technologies are especially relevant when incubators are considered.

2 Literature background

According to a wider perspective proposed by Nambisan (2017) to highlight the multiple roles of digital technologies into the entrepreneurial process, digital entrepreneurship can be interpreted as the result of three distinct but related elements: digital artifacts, digital infrastructure and digital platforms. A digital artifact represents a digital component, an application, or media content that is part of a new product or service and offers a specific functionality or value to the end-user (Ekbis, 2009; Kallinikos et al., 2013). Digital infrastructure consists in digital tools and systems that offer communication, collaboration, and/or computing capabilities, such as cloud computing, data analytics, online communities, social-media, 3D printing, and digital makerspaces, to provide support to entrepreneurial activities. Digital platforms refer to shared, common sets of services as well as architecture that serves to host complementary offerings, including digital artifacts (Parker et al., 2016; Tiwana et al., 2010), and also software platforms that provide the core functionality shared by the modules, together with extensible codebase and interfaces to guarantee communication and interoperability (Tiwana et al., 2010).

The entrepreneurial process of a new company carried out within incubators can be articulated in three main stages: *desk*, *pre-market* and *market* (Byers et al, 2010; Elia et al., 2016). The activities characterizing each stage can benefit of the potential of digital technologies to share information, connect people, exchange knowledge, execute processes, organize resources, and coordinate tasks. In such digitally-enabled incubators, the access to new knowledge and the speed of transactions increase significantly, thus creating new spaces of opportunities that companies can take to connect with external and complementary partners for innovation purposes (de Reuver et al., 2018).

More specifically, *desk-stage activities* of the entrepreneurial roadmap, which represent the preliminary explorative phase aiming at preparing the venture creation, can leverage the access to specialized databases and reports on market technology and social trends to support the execution of scenarios scanning and the envisioning of new business opportunities. Besides, the usage of virtual collaboration and participative tools may

support the overall idea management process, from the collection of numerous proposals and insights to the selection of the most promising ones, from the enrichment of the business concept to the definition of the value proposition and revenue model. Afterwards, the usage of purposeful software for business planning and interactive simulations complete the support provided to the desk stage activities, in the overall context of the entrepreneurial process, together with the access to MOOC system to guarantee continuous learning process.

As for the *pre-market activities*, entrepreneurs can rely on the access to national and international databases for searching patents, leverage crowdfunding platforms to collect the required money, use crowdsourcing sites to outsource activities or complement competencies and team, or enlarge the network of partners. Also, by accessing and exploiting the intellectual capital services of the incubator, entrepreneurs can reserve and use internal knowledge-based facilities such as administration and legal (human capital), search for interested investors and partners (relational capital), or access to facilities and infrastructural assets for co-working (structural capital). Moreover, by accessing to remote digital infrastructures and platforms (i.e. mobile computing, 3D printing, additive manufacturing, cloud computing, Internet of things, big data, robotics, cybersecurity and blockchain) (European Commission, 2017), the new company can prototype products and services to meet the customers' demand, can experiment new technological features, can test the novelty and market potential of a business idea, and fine-tune the market offering. Besides, also the access to MOOC platforms may support the execution of pre-market activities, thus allowing people to learn and know, thus making their actions more effective.

Finally, *market activities* consisting in the operational aspects that guarantee a real presence of the new company in the market, can benefit of digital technologies to support the day-by-day operations and contribute to the venture growth. In particular, modern ERP systems and CRM platforms can provide the core services to support the execution of primary and supporting activities, web content management tools may ensure an updated presence on the web with e-commerce extensions, social media instruments may provide a valuable support to marketing strategies, artificial intelligence services and big data applications can extract insights to innovate the marketing offering and extend the market scope. Besides, integrated reporting suites and interactive dashboards reveal crucial to organize all data coming from the above mentioned systems and transform them into valuable information through which attracting the interest of potential investors in the final aim to create the right financial, organizational and market conditions for the overall venture expansion, but also to contact experts and professionals to receive a managerial support.

Definitely, digital technologies are defining new ways of collaborating, collecting and organizing resources, thus supporting the design of products and services, the execution of routine activities and tasks, the complex matching between demand and offer, and the development of innovative solutions (Markus and Loebecke, 2013), in the final aim to make innovation possible (Nambisan et al., 2017) and to provide an end-to-end support to the entrepreneurial process.

However, most of the incubators have still a physical characterization of their operating activities and core initiatives. They use digital technologies mainly for communication purposes, through their web sites and social media channels, and provide information about five key components that shape their structure and activities. They refer to (Clarysse et al., 2016): the strategic focus (i.e. the industry verticalization and the geographical scope of the accelerator); the programme package (i.e. the integrated set of contents and services for the startup incubation (i.e. training program, networking events, workshops, customer validation, investor pitch, office spaces); the funding (i.e. both the funds of the accelerator itself and the funds available for startups, including the information about the request of equity); the selection process (i.e. the screening of proposals to identify those ones with the highest market potential to be involved into the program); and the alumni service (i.e. the capacity to keep close and active relations with the companies that graduated from the programs to share their experiences within the new program editions and leverage the alumni network for mentorship and investment sources).

This information essentially refers to three complementary dimensions of the incubator, which are the content delivered, the services offered, and the network of relationships that can be exploited.

Most of the incubators, except for the information delivered through their web sites and social media channels, execute the desk-stage and pre-market activities (i.e. the core of the start-ups' incubation and acceleration process) essentially in a face-to-face modality, without taking advantage of virtuality, immediacy, relational proximity, knowledge exchanges, and spatial-temporal independence offered by the digital technologies (Tapscott, 2014). Some exceptions are: F6S.COM that offers online services to connect directly with accelerators, funds and investors, and search talents to complete the team; ANGEL.CO that provide online support to form the entrepreneurial team and find potential investors; STARTUPCOMPETE.CO that offers virtual spaces where aspiring entrepreneurs, mentors and advisors can connect each other and bring potential business ideas to market through idea competitions, pitch competitions, and business plan competitions; IBRIDGENETWORK.ORG that provide a customized virtual community to support idea discovery, people connection and collaboration, the development of early-stage technological projects, broadcasting of technology needs, discovering of matching technologies and partners, the connection to clients and investors, gaining of market insights.

An insight to social media technologies is necessary. Since social networking sites began allowing organizations to create profiles and become active members, organizations (as incubators) have started incorporating these strategies into their public relations programming. Social networking sites are the locus of relationships (Treddinick, 2006). So far, social networking sites should be used to foster relationship growth (Dugan, 2007). How much incubators and organizations like incubators use carefully social media to foster relationships has not yet been analysed in literature.

In light of these, aim of this paper is to shed light on how incubators are adopting digital technologies (with a focus on social networking sites) to support the process of creation of new ventures.

3 Methodology

This study is based on archival and documentary as secondary data. A web-based document analysis methodology has been used to investigate the level of diffusion and adoption of digital technologies among Italian Startup Incubators.

A dataset of information regarding the adoption and diffusion of digital technologies was carried out using the information available on the websites of the analysed incubators. The websites and the complementary sources were analysed for the presence of information related to the adoption of digital technologies supporting individuals, groups, and startup in the incubation process.

Qualitative research methodology is selected for purpose of the study. Qualitative data is the main priority; however, some quantitative data may be also investigated. Secondary data is collected from robust sources such as reports and websites. We select a list of Italian incubators from the official register of the Italian Minister for the Economic Development, and we study each incubators website to retrieve information about: location, size, governance structure, sector of specialization (if any), average number of incubated startups, services, list of adopted digital technologies, social networking profiles (Facebook, LinkedIn, Instagram, Twitter, Youtube).

After this, according to the goal of this research aimed at evaluating how much digital are the Italian certified incubators, the analysis continued in two steps.

First, we focused the analysis on the level of digitalization of the content delivered and services offered by the incubator, as well as of the network of relationships accessible through joining the incubator. In such a way, three main variables have been defined for this phase, which are the Digital Contents, Digital Services, and Digital Networks.

Digital Contents refers to how much deep and detailed are the information about the acceleration and incubation programs provided by using the digital technologies (e.g. web site, social media channels). This information concerns the programs' modules and duration, the number of calls launched to accept proposals, the participating requirements, the description of phases and criteria for the selection process, the specification of the industrial domains of references, the indication of the geographical focus and profile of the startups targeted, the information on the existence of pitching events or the possibility to use technological and physical infrastructures. Further information includes the typologies of services offered and the delivery modalities, the indications about the limits of investment to request, the possible percentage of equity owned by the accelerator / incubator in case of a successful incubation of the startup.

Digital Services refers to the level of support provided by the digital technologies to the process of incubation / acceleration. This can happen by offering candidates the possibility to submit online their ideas or project proposals, to refine (or enhance) the entrepreneurial idea through external suggestions and online comments, to access to virtual mentoring and use online simulators to develop the business plan and define the

business model, to use online services to recruit people and discovery skill to complete the team, to access to databases for market researches or patent searches. Further services include the online support and guide to choose crowdsourcing platforms and access to resources required for the business startup or outsource non-core activities of the new company. Other examples include the access to online learning modules, online mentoring for preparing the pitch presentation, online booking of co-working spaces, or remote access to technological infrastructure (e.g. Cloud Computing, 3D printing, simulators, IoT platforms, cybersecurity platforms, ERP, CRM, BI suites, digital marketplaces). Finally, digital services refer also to the possibility to access online to professionals for administrative support, legal support, international marketing support, networking support to interact with potential investors and partners, etc.).

Digital Networks refers to level of visibility and attention reserved to the networks of partners, investors, funders, mentors, alumni, teams and startups involved in past incubation / acceleration programs, as well as to the possibility to contact them directly through online links (e.g. web site address, e-mails, etc.).

According to the number of items covered and the level of details provided, the three variables (i.e. Digital Contents, Digital Services, and Digital Networks) are evaluated by using a three-item Likert scale (i.e. low, medium, and high).

Second, we performed a quantitative analysis on the diffusion and adoption of social networking sites visiting the incubators' profiles. We based the analysis by counting the number of social networking sites activated (e.g.: Facebook, LinkedIn, Twitter, Instagram And Youtube as those sites are considered as the top five most adopted social networking sites). We calculated the index of differentiation based on the number of single profiles activated for every of the five sites. The analysis was then detailed by visiting the activities performed in the month of February, counting the number of relationships (e.g.: number of page's likes for Facebook), the number of posts (per each profile activated) and the number of followers per each post. We aggregated those measures in the index of intensity of use, to better understand the extent of adoption of each social networking site.

3.1 Unit of analysis

In the last years, the Italian Government has issued several regulations and laws aimed to support and promote the creation and development of new innovative firms, namely the innovative startups. Recently, such normative about start-ups has been further enriched by a fundamental pillar.

In particular, the Law n.221/2012, which converted the Legislative Decree n. 179/2012, introduce the regulation of the so-called "Certified incubator for innovative startups". The Certified Incubators is a limited company or a cooperative able to offer "even in a non-exclusive way, services to support the creation or the development of innovative start-ups". Put differently, startups incubators are structures that, through the provision of specific business services and infrastructures, assist and support innovative start-ups in the growth and acceleration processes. To be a certified incubator, such organizations have to meet a set of requirements defined by article n. 5 of the Decree of the Ministry of Economic Development of 21 February 2013 (Table 1). The policy framework for

certified incubators has been improved and broadened in the period 2013-17 by further legislative interventions issued. Moreover, it is important to underline that the certification is a necessary condition for registering the incubator in the appropriate section of the business register and obtain some economic, financial and fiscal benefits. According to the regulatory framework, in order to obtain the certification, the incubators should show specific features (Table 1):

Table 1: Incubator Decree's requirements

Requirements	
Structural requirements	<ul style="list-style-type: none"> • The area dedicated to the incubator activities should be at least 400m² • presence of facilities, including real estate, suitable for hosting innovative startups, such as open spaces, labs for testing and/or development of prototypes, research equipments; • existence of equipments and tools suitable for supporting the activity of innovative start-ups, such as ultra-broadband access systems (10mps), meeting rooms, testing machines;
Managerial requirements	<ul style="list-style-type: none"> • portfolio of potential stakeholders, e.g. universities, research centers, supplier, customers, public institutions and financial partners that carry out activities and projects related to innovative start-ups; • presence of adequate and proven competence in supporting innovative start-ups (at least 10 years of experience in such field).

Further requirements were defined in order to prove that incubators, as well as their funders, have the proper competences, capabilities and experience to support innovative startups. For instance, it is required: i) at least 10 applications received in the last year; ii) the presence of 10 startups in the incubator with a total number of 30 employees, iii) a certain number of innovative start-ups that completed the incubation processes and operate in the market, iv) at least 3 registered patents or submitted patent applications in the last year by innovative start-ups currently incubated.

The possession of these requirements is self-certified by the legal representative of the incubator through a declaration signed at the time of application for registration.

Therefore, this research focuses on the certified incubators as the latter are crucial actors of the knowledge ecosystems and digital technologies can play a fundamental role in supporting innovative startups during their development processes. This is also in line with the requirements of the so-called Incubator Decree (DM, 2013/04/18).

4 Results

4.1 Descriptive

The population of Italian Certified Incubators is made up of 34 incubators. It is important to underline that data collection phase was in February 2019. As shown in the Figure 1, the most part of Italian Incubators is localized in the Northern of Italy (65%), while only 9% (3) in the Southern.

Figure 1: Geographical distribution of Italian Certified Incubators

Specifically, it is possible to note the Italian incubators are mainly focused on Lombardy (23,5%), followed by Lazio (14,7%) and Friuli Venezia Giulia 4 (11,8%)(Table 2).

Table 2: Regional distribution of Italian Certified Incubators

Regional distribution	
Lombardy	8 (23,5%)
Lazio	5 (14,7%)
Friuli Venezia Giulia	4 (11,8%)
Marche	3 (8,8%)
Piedmont	3 (8,8%)
Veneto	3 (8,8%)
Campania	2 (5,9%)
Emilia Romagna	2 (5,9%)
Liguria	1 (2,9%)
Sardinia	1 (2,9%)
Tuscany	1 (2,9%)
Trentino Alto-Adige	1 (2,9%)
TOT	34 (100%)

The majority of Italian certified incubators supports digital startups and/or startups that develop new innovative technologies (Figure 2).

Figure 2: Industry focus of Italian certified incubators

In order to better investigate the digital level of Italian certified incubators, their websites were analyzed.

Unfortunately, one Italian incubator does not have an own website; as consequence, we perform this analysis only on 33 incubators.

In particular, we collect data about three different dimensions, namely digital services, digital contents and digital network. Put differently, the aim is to investigate whether and how much Italian certified incubators use digital technologies to support development and innovation processes of startups.

The following digital intensity index was calculated as:

$$\frac{\sum_i X_i(k)}{GTot}$$

$X_i(k)$ is the judgements about the incubators K -ith respect to the dimension i
 $i = 1, 2, 3$ (digital dimension considered)

$GTot$ = the potential maximum score that each incubator can obtained.

Table 3 shows the classification of Italian incubators on the basis of their digital intensity index.

Table 3: Classification of Italian certified incubators

Digital Intensity Index (%)			
A1	100	A18	66.67
A2	100	A19	55.56
A3	88.89	A20	55.56
A4	88.89	A21	55.56
A5	88.89	A22	55.56
A6	88.89	A23	55.56
A7	77.78	A24	55.56

A8	77.78	A25	44.44
A9	77.78	A26	44.44
A10	77.78	A27	44.44
A11	77.78	A28	44.44
A12	66.67	A29	44.44
A13	66.67	A30	44.44
A14	66.67	A31	44.44
A15	66.67	A32	33.33
A16	66.67	A33	33.33
A17	66.67		
Average	64.31		
Stand.dev	18.58		

As shown in Table 3, the digital intensity level ranges from 33.33 to 100, with a mean of 64.3. Focusing on the results shown in Table 3, it is possible to identify three different group, namely:

- the *best performers* that shows a Digital Intensity index that range from 100 to 66,67. This class is composed of the most of part of incubators;
- the *medium performers* that have a Digital Intensity index that range from 66,67 to 33,33;
- the *worst performers* that shows a Digital Intensity index that range less than 33,33.

In general, it is possible to claim that the most part of Italian incubators offer a low level of digital services (54,54%).The Digital network, that is the ability to support the establishment and the development of partnerships and collaborations through the website, appears to be a more considered digital dimension as the 42.42% of the Italian incubators show a high digitalization level (Figure 3).

Figure 3: Digitalization level of Italian certified incubators

Such results are confirmed in the following. Specifically, focusing on the analysis of only two dimensions (Figure 4), namely digital services and contents, it is possible to note that the most part of the Italian incubators (21.21%) shows a very low digitalization level. On the contrary, only 3 incubators are able to offer a high level of digital services and contents (9.9%).

Figure 4: Level of digital services and contents provided by Italian Incubators

On the contrary, only 3 incubators are able to offer a high level of digital services and contents (9.9%). This shows that it is necessary to support the Italian incubators in the digitalization processes.

4.2 Social Media Analysis

Through the analysis of the website, we collect further data about the social media used and the related intensity of use which let to better evaluate the digitalization level of Italian certified incubators. In particular, two different indexes were calculated, namely index of differentiation and intensity of use.

The index of differentiation is defined as the number of social media adopted by the Italian incubators divided by the total number of social media identified, such as Facebook, Twitter, Instagram, LinkedIn, Youtube. It could vary from zero, if no social media is used, to 100 if the incubator uses all the SM investigated. For each incubator, the index of differentiation of SM was calculated (Table 5).

Table 5: Classification of Italian incubators in terms of differentiation level of SM adopted

Index of Differentiation			
A1	100	A18	80
A2	100	A19	60
A3	100	A20	60
A4	100	A21	60
A5	100	A22	60
A6	100	A23	60

A7	80	A24	60
A8	80	A25	60
A9	80	A26	40
A10	80	A27	40
A11	80	A28	40
A12	80	A29	20
A13	80	A30	20
A14	80	A31	20
A15	80	A32	0
A16	80	A33	0
A17	80	-	-
Average	65,45		
Stand.dev	28,84		

Results in Table 5 show that only 18.18% of Italian incubators has all the SM considered, although the most part of them (36.36%) has 4 SM out of 5. The mean value is equal to 65.45, showing that there is a good level of SM adoption among Italian incubators.

While the index of differentiation shows how many SM each incubator adopts, the intensity of use underlines if incubators make of it scarce or intensive use.

In particular, the intensity of use of social media was calculated as described in the following steps:

1) Analysis of the intensity of use on the social media considered by collecting data about the number of published posts, video, photos, comments, sharings, etc; 2) For each social media considered, the mean value of intensity of use was computed;

3) On the basis of the mean values calculated, different ranges of intensity were defined to support the codification by using Likert scale (very poor (1), poor (2), medium (3), significant (4) and very significant (5)).

4) Each incubator was evaluated on the basis of its intensity of use.

As shown in Figure 3, a strong positive relationship exists between Intensity of SM use and number of different SM used ($\rho = 0.794$). This result is confirmed also by the R^2 means that both the considered variables increase simultaneously.

Figure 3: Correlation between index of differentiation and intensity of SM use

To investigate whether the correlation coefficient ($r = 0.794$) between the index of intensity of SM use and differentiation level of SM adopted is statistically significant, a t-test has been performed. The calculated t value is 2.354. As tabulated t value ranges $-1.697 < t < 1.697$, it is possible to reject the null hypothesis (H_0). More specifically, the empirical results show that the intensity of SM use and the differentiation level of SM adopted affect simultaneously each other. The higher the intensity of SM use, the higher the number of different SM adopted by Italian certified incubators and viceversa.

Following Cerchione and Esposito (2017) approach, it is possible to identify 4 areas limited by the average value of the two indices (Figure 4).

Figure 4: Correlation between index of differentiation and intensity of SM use

High-right located Italian certified incubators make intensive use of several different SM. High-left located Italian certified incubators make intensive use of few SM. Low-left located Italian certified incubators do not use the few resources at their disposal intensively. Low-right located Italian certified incubators do not use the many SM at their disposal intensively. These four areas identify different digitalization strategies adopted by Italian certified incubators (Figure 4).

According to these results and following Cerchione and Esposito (2017), it is possible to propose a taxonomy that synthesises the strategies of Italian certified incubators using different SM more or less intensively. Specifically, four strategies were identified: digital leaders, digital addicts, digital explorers, digital laggards.

Table 6: A classification of digital strategies of Italian Incubators

		Differentiation of SM adopted	
		Low	High
Intensity of SM use	High	Digital addicts (A2)	Digital leaders (A1)
	Low	Digital laggards (A3)	Digital Explorers (A4)

The digital leader is an incubator that recognize a strategic value to the SM and adopts several social media, exploiting them intensively (A1). The digital addict is an incubator that intensively uses the few SM adopted (A2). The incubators in this area by investing in the adoption of further SM can quite easily become a digital leader. The digital laggard is an incubator still does not fully understand the value of digital tools as it uses few SM and not intensively (Area 3). In this case, these incubators should invest both in the adoption of further SM and in the development of skills and capability to exploit them more intensively. Finally, the digital explorer is an incubator that, despite use a high number of SM, is still not able to exploit them intensively (Area 4). In order to become digital leaders, these incubators should invest in training and educational activities to improve their ability to effectively use the SM and, in general, the digital technologies.

5 Discussions and conclusions

This article is a first attempt to investigate the level of digitalization of the Italian certified incubators. This issue assumes a particular relevance in today's entrepreneurial economy (Thurik et al., 2013) where digital technologies play a crucial role in the process of ideation, design, launch and management of startups.

Moreover, the topic can be framed into the wider research area of digital entrepreneurship, which represents an impactful socio-economic phenomenon that is creating new opportunities for existing and potential entrepreneurs to leverage digital technologies for changing the way how companies can be founded, managed and developed (Cohen et al., 2017; Giones and Brem, 2017; Nambisan, 2017; Nambisan et al., 2017).

Therefore, this study aims at exploring and understanding how much digital these incubators are, by considering three dimensions of analysis such as the content, the services, and the network.

At this purpose, an analysis of the information publicly available on the web sites of the Italian certified incubators has been conducted in order to determine the level of digitalization of three key dimensions characterizing their core activity, such as the content delivered, the services offered, and the network of relationships accessible through joining the incubator. Moreover, considering the relevance of the social media in

the digital economy scenarios, a further analysis concerned the typology and the intensity of usage characterizing the social identity of the Italian certified incubators.

Preliminary results obtained show that, while the contents describing all the phases and issues of the incubation programs (e.g. modules and duration, number of calls, participating requirements, selection process, etc.) benefit of the usage of digital technologies in almost the incubators analysed, the core services for incubating the startups are delivered mainly through a face-to-face and physical approach, with the unique (few) exception of services provided to submit online ideas and project proposals. Besides, as for the network, most of the analysed incubators leverage digital technologies to give visibility to their partners and collaborators and, in several cases, they provide a rich description and contact information to establish a direct link with them.

Moreover, as for the social identity, a positive correlation has been found between the number of social media used and the intensity of usage. Besides, according to the value of these two variables, four archetypes have been proposed with a brief description and guidelines for the development of the incubator.

This research has implications for both researchers and practitioners. For the former, it represents a preliminary study on the Italian panorama of the certified incubators in the perspective to analyse their level of digitalization and provide possible insights to enhance their performance and increase their impact.

Looking at the practitioners, they can use this research to understand how increasing the virtualization of their activities, thus enlarging their strategic and operational scope, and becoming more aligned with innovative incubators operating at global level such as F6S.COM, ANGEL.CO, STARTUPCOMPETE.CO, and IBRIDGENETWORK.ORG.

This research has some limits that may open the space for further research. A first limit concerns the typology of analysis that has been carried out. Indeed, the desk analysis based on the information available on the web sites can be integrated with the analysis of further documentation available in the web, as well as with interviews with managers and key stakeholders of the incubators.

Another limit concerns the number of incubators considered in the analysis. Indeed, to compare a homogeneous sample of incubators, this research relies on the Italian certified incubators. All the certified incubators listed on the Italian Ministry of Economic Development have been considered, even if it is not possible to extend the results to the more complex phenomenon of digital incubation process. At this purpose, further research can be devoted to analyze other Italian incubators that are not formally certified by the government but can be substantially considered as valuable initiatives for startups creation.

Finally, a more detailed analysis on the relationships between the “digital profile” of the incubator and the performances achieved (e.g. in terms of number of incubated startups, amount of funds attracted by public and private stakeholders and investors, number of new jobs created, number of incubated companies operating successfully in the market) can be performed in the near future.

Abstract

Our paper aims to re-interpret e-health at the intersection between the fields of Social Innovation (SI) and Knowledge Ecosystems (KE). In doing this, a systematic literary review about SI, KE and e-health was carried on, in order to identify common issues between the two selected fields of research. Taking into account the review results, we identified the notion of co-creation as the most effective in the investigation of e-health at the merging between SI and KE theoretical perspectives. The EMSE (Emergency Medical Service Ecosystem) model was, finally, examined within the provided theoretical framework.

Keywords – E-health, Social Innovation, Knowledge Ecosystems; Emergency Medical Service Ecosystem

Nature of the proposed paper: Academic Research Paper

1. Introduction

Nowadays, societies – at both national and regional level – as well as organizations – both for profit and not for profit – face several challenges that need for innovative solutions to the emerging problems. Among these, health and well-being are basic social needs, in both developed and underdeveloped countries (Sliwa et al. 2017). Particularly, within developed countries, current social challenges are associated with the ageing population and growing share of chronically ill people. Solving this problem requires

innovative solutions in health and social care as restructuring of care, housing, and monitoring of disease patients (Howaldt and Schwarz, 2010; Phills et al., 2008). The mentioned resolutions particularly emphasise the relevance of ICT in supporting health and health-related areas. The introduction of innovative approaches to help disabled people; the emergence of on-line self-help health groups; the use of distance learning systems to diffuse knowledge, as well as the adoption of technology to manage health problems, are all examples of the way technical innovations may be applied to overcome the emerging health challenges.

The integration of ICT in health services is referred as "e-health" (Waterson et al., 2012; Eysenbach & Jadad, 2001; Coile, 2000). E-health is interpreted by Eysenbach (2001, p. 1) as: *"an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterises not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology"*.

According to the above definition, e-health may be reasonably interpreted at the intersection between the fields of Social Innovation (SI) and Knowledge Ecosystems (KE).

Particularly SIs refer to *"innovative activities and services that are motivated by the goal of meeting a social need and that are predominantly developed and diffused through organisations whose primary purposes are social"* (Mulgan, et al., 2007, p. 8; Mulgan, 2006). Moulaert et al. (2005) discuss the following dimensions interrelated in SI: satisfaction of human needs, changes in social relations, and increasing socio-political capability and access to resources. Therefore, the nature of SIs is inevitable related to social problem touching group of people, while technological innovations can be supportive.

The context of our analysis – e-health – makes necessary to underline the differentiation between social and technological innovations, as social innovations perceived as institutional innovations, according to Brooks classification (Brooks, 1982), and context dependent (Howaldt & Schwarz, 2010). In the area of health policy, SI may, particularly, include the use of ICT, ICT enabling, on one side, the emergence of new business models, and term-oriented approaches to treatments (Dijkgraaf et al., 2009); and fostering, on the other side, the reduction of social gaps (Moore and Westley, 2011; Biggs et al., 2010; Murray et al., 2010).

By the contrast, KE plays a crucial role in generating new knowledge and technologies (Valkokari 2015), in facilitating collective learning, and in speeding innovation diffusion (Clarysse et al. 2014). The multiplicity of actors involved in innovative and social activities, as well as the dense network of companies geographically clustered/localized and centered on the university for knowledge generation in KE, could explain the creation and the adoption of e-health solutions. As studies show, a knowledge-generating institution is a key player in commercialization and connecting network's actors (Clarysse et al. 2014).

According to the above, our paper aims to re-interpret e-health concept as the result of looking through the joined lenses of SI and KE. In doing this, a systematic literary review about SI, KE and e-health was carried on, in order to identify common issues between the two selected fields of research. Taking into account the review results, we identify the notion of co-creation as the most effective in the examination of e-health at the merging between SI and KE theoretical perspectives. The EMSE (Emergency Medical Service Ecosystem) model was, therefore, examined within the provided theoretical framework.

The remainder of the paper is formatted as follows. Firstly, section 2 describes the methodology employed in the study; section 3 then presents the results of both descriptive and analytical analysis; our theoretical perspective and EMSE model are described in section 4. Conclusions and Limitations of the study are, finally, presented.

2. Material and Method

Material collection was carried out through Business Source Premier (BSP), Web of Science (WoS), Scopus, and PubMed, which are considered, by the scholars, among the most comprehensive and authoritative scientific databases (Merli et al., 2018). After having examined several publications about SI, KE, and e-health, the idea of research approach was developed – as it is represented in Figure 1 – and research criteria were selected.

Source: own elaboration

Figure 1. Graphic representation of research approach

As Gough et al. (2012) pointed out; the first step of a systematic literary review is to define the keywords that better identify the relevant literature. Basing on the shared research approach, we selected criteria to cover the three main topics involved in our investigation: SI, KE and e-health. Since this paper aims to re-interpret e-health concept through the joined lenses of SI and KE, the following search strings were employed in all the databases:

1. (Social Innovation) AND (e-health);
2. (Knowledge Ecosystem) AND (e-health)

The research was conducted basing on each database functionalities.

In BSP, the field selected for search was "Title"; while in WoS Core Collection, it was "Topic" (including Title, Author Keywords, Abstract, Keyword Plus®). In Scopus the chosen field was "Title, Author Keywords, Abstract"; finally in PubMed "All Fields" (embracing: title, author, keywords, abstract).

In BSP, the search bring 4 hits for the first string - (Social Innovation) AND (e-health) - and 0 hits for the second string - (Knowledge Ecosystem) AND (e-health). Query in Scopus was the same. No results were found in both WoS and PubMed.

Therefore, we can claim that the issue of e-health is not analyzed within social innovation and knowledge ecosystem perspectives. This result contrasts with our expectations, as e-health solutions, thanks to information technology, should be targeted to solve social problems by knowledge sharing among involved actors.

Despite this, a descriptive and analytical analysis of the collected data is detailed in the following section.

3. Findings

3.1. Descriptive and Analytical Analysis of the Data

The 4 collected papers were all published between 2015 and 2017, supporting the idea that the proposed field of research is still nascent and unexplored. Table 1 synthesizes the most relevant information about the published articles referring to:

- the area of knowledge within which authors have published their researches;
- the year in which the articles were published;
- the countries of origin of each contribution;
- the journals in which authors have published their research;
- the type (theoretical or empirical paper) and the adopted methodology (qualitative or quantitative) of the papers.

Table 6 – Analytical categories for the selected papers

Ranking	Area of Knowledge	Year	Country	Journal	Type
1	Complex systems; Health system; Home Care Services; Social Innovation	2017	Germany	International Journal of Foresight and Innovation Policy	theoretical/qualitative
2	Design Science, Social innovation, E-health	2016	Netherlands	Conference Proceeding	empirical/qualitative
3	Social Innovation, IT, e-Health, Welfare, Empowerment	2015	Italy	Salute e Società	theoretical/qualitative
4	ICT, Socio-Technical Systems, Social Innovation	2015	Italy	Book chapter	empirical/qualitative

Source: own elaboration

Taking into account the few number of articles published about the topic, no information may be provided about the concentration/fragmentation of the papers, nor about the subjects involved in the examined field of research. It is a matter of fact,

however, that only one paper was published on an international, peer reviewed, and authoritative journal, namely in the *International Journal of Foresight and Innovation Policy*, the last one dealing with knowledge creation, diffusion and utilization in innovation policy.

The first contribution (Sliwa, et al., 2017) explores telecare as one of the practical applications in the field of e-health, able to introduce innovative solutions in supporting patients' wellbeing.

A system-centric framework is proposed to evaluate the interdependencies between telecare, the changing relationships, and the institutional context, thus re-calling the notion of operational and viable ecosystem with clearly defined actors. It is interesting to note that Sliwa et al. (2017) also underline the role of co-creation - together with community - and cooperation as enhancing quality and efficiency vantages. The reconfiguration of roles and relationships takes place through co-creation and knowledge sourcing (Sliwa et al., 2017, p. 176).

In 2016, de Reuver & Keijzer-Broers, analyzed how social innovations affect the Action Design Research (ADR) when chose as starting point, that means how the ADR approach should be adapted for projects driven by social innovation. In doing this, a service platform for health and well-being was launched and used for matching elderly and care providers. The result of this study proves that such artifact, as website, enhances information sharing about aging-in-place and creation of an online community. It also encourages elderly people to switch their role from passive into active. Moreover, the described case demonstrates the capability of properly designed project environment, which took the form of living lab. The designers of this solution involved into living lab: elderly and informal caretakers as end-users, municipality representatives as government, and companies operating healthcare databases as business representatives. In living labs the role of lead users is important, since they do not only provide feedback, but also participate as "co-generators of innovations" (Edwards-Schachter et al., 2012). This reasoning leads to recently popular concept of co-creation.

In the third paper, Clemente (2015) attempts to analyses the role of e-health in the processes of social change, with particular reference to the EU countries. In doing this, the author mainly focus on ICT as a strategic lever to innovate in health service systems, thus missing considerations about knowledge ecosystems and the way different actors may dynamically relate. Similarly, Ocelli (2015) stresses the role of ICT, even in a broad scope, showing collaborative information exchanges using ICT. To sum up the last sources, we observe that the links between social innovation and e-health may be pointed out as aiming to increase the democratization and transparency of healthcare system, as whole.

4. Suggestions for Future Research: Merging SI and KE in E-health

Given the limited number of papers collected, we performed a content analysis of the exiting literature about Knowledge Ecosystems and Social Innovation, identifying the notion of "co-creation" as recurrent word in both of the selected fields of research. The concept of co-creation is, therefore, crucial to understand the merged points of view into

e-health. In 2018, Ramaswamy and Ozcanb proposed a novel conceptualization of co-creation, based on interactions, more than on human actors coming together in activities. According to the authors, *"Co-creation is enactment of interactional creation across interactive system-environments (afforded by interactive platforms), entailing agencing engagements and structuring organizations"* (Ramaswamy and Ozcanb. 2018, p. 200). Focusing on interaction is, therefore, central in any process of co-creation, the last one entailing a multiplicity of interactive system-environments among persons and material entities (e.g., devices), afforded by technological platforms and enhanced by digital technologies.

As Prahalad and Ramaswamy (2004, p. 237) noted, *"It does not matter whether we are dealing with a consumer, an employee, an investor, or a supplier"*. Their main thesis was that *"the value creation process centers on individuals and their co-creation experiences"* (Prahalad and Ramaswamy, 2004, p. 14).

In introducing this new frame of reference, Ramaswamy and Ozcanb (2018) widen the traditional value creation system, by considering all the platform interactions that the increasingly digitalized world make available as set of interactions among the actors.

In accordance with the mentioned perspective, the concept of co-creation entails the notions of relationships and innovation, largely emphasized in the literature about KE and SI, as well.

Within the KEs, the creation of new knowledge bases on joint research work and collaboration (Valkokari, 2015). Similarly, the relevance of networks and collaboration, as effective driver of SI, was emphasized by many socio-economic scholars (Canestrino et al. 2019; Ridley-Duff and Bull 2018; Denning and Dunham 2010; Bakhshi and Throsby, 2010).

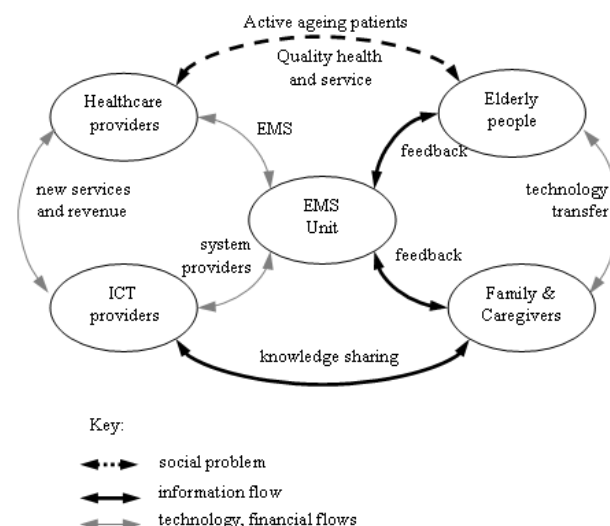

Depending on the above, exploring e-health, within the combined lens of SI and KEs, means to focus on the way all the actors co-create (value and knowledge) through relationship.

In order to support our idea, we assessed the Emergency Medical Service System (EMSS) model, developed by Sukkird and Shirahada (2015), as the most appropriate to explain e-health at the merging between SI and KE perspectives. The EMSS is defined as *"a system that provides for the arrangement of personnel, facilities, and equipment for the effective and coordinated delivery of health care services under emergency conditions (occurring as a result either of the patient's condition or of natural disasters or similar situations) and that is administered by a public or nonprofit entity with the authority and the resources to provide effective administration of the system"* or shortly as *"as a specific arrangement of emergency medical personnel, equipment, and supplies designed to function in a coordinated fashion"* (Moore, 1999, p. 325).

It entails two main groups of different actors creating an ecosystem. The first one is the group of *service receivers*: elderly, family member, and caregivers; the second one constitutes *service providers*, who can be divided in *healthcare service providers* (hospital, insurance company, EMS agent) and *IT service providers* (mobile company, technical support center). Each of them benefits from being the part of the ecosystem, but with different type.

Figure 1 depicts main flows that arise in this ecosystem. Referring to them, we adopted two different perspectives; a knowledge-based perspective, fitting with the conceptualization of KE; and a social-innovation-based perspective. From the KE perspective (knowledge and information flows) a direct knowledge sharing establishes between 'family & caregivers' and ICT providers. It is necessary to feed application (mobile technology) with data transferred to EMS unit. Next two kind of feedback exists among EMS unit and consumes (elderly people) and elderly supporters. Both of them refer to health monitoring and – if needed – emergency request. Apart of information flows, service improvement takes place between ICT providers and healthcare provides. The direct service delivery is triggered by EMS unit, and executed by healthcare providers.

Moreover, in accordance with the SI perspective; relevant connections establishes between healthcare providers and elderly people. It forms active ageing patients that improve quality health and service. The aspect of improving service, and therefore supporting realisation of main aim of the EMSE, also resides in relationship between healthcare providers and ICT providers.

Source: own elaboration based on (Sukkird & Shirahada, 2015)

Figure 1. Emergency Medical Service Ecosystem

Discussed EMMS model from combined two perspectives allows to observe synergy between SI and KE. These aspects supports each other e-health solutions.

5 Conclusions

This paper proposes a new theoretical perspective in the exploitation of e-health, arising from the merging of SI and KE standpoints. Basing on the results of our literature review, we identified the notion of co-creation as common issue in the examined field of

researches, thus enabling researchers to focus on the way new knowledge and social innovation are co-created through actors' relationships.

Our analysis should allow for detailed and meaningful explanation of the specificity of e-health by bringing out issues not fully revealed in existing scholarship, but highlighted separately in SI and KE literature.

Despite the many recent debates about Knowledge and Social Innovation ecosystems, as well as about other co-creation models, a more in-depth understanding of the multi-actor processes of value co-creation remains rather scarce. In the light of the existing gaps, we will concentrate on mechanisms and processes enabling creation (or emergence) of new e-health solutions. Hence, with this article, we provide significant novel insights about knowledge and Social Innovation ecosystems as structures enabling multi-actor value co-creation in e-health.

It is a matter of fact that our paper is at its nascent stage, thus the absence of empirical evidences is one of its main limitations. Another one is the absence of examination of the way co-creation of e-health solutions may be encouraged through the active participation of all the actors belonging to both the examined ecosystem.

Understanding ecosystems dynamics and the way knowledge and resources may be co-created and shared, in a concrete way, represent prominent future research directions.

Abstract

This paper proposes a descriptive review of service ecosystems, as the first step of a systematic literary review aiming to improve the existing understanding of service ecosystems in the management field. For the purpose of this study, 188 articles were selected and examined according to the following analytical categories: 1) Areas of knowledge within which authors have published research on service ecosystems; 2) Years in which the articles were published; 3) Countries where authors have published research on service ecosystems; 4) Journals in which authors have published their researches; and 5) Type of paper and adopted methodology. According to the research's findings, a growing interest toward service ecosystems has been developed for the last ten years, especially referring with the two main areas of Decision Making and Ecosystems Management.

Keywords – Service ecosystems, Literary review, Decision Making, Ecosystems Management

Nature of the proposed paper: Academic Research Paper

1. Introduction

In today's competitive environment, more and more service firms are customer-oriented and focused on experience-based offering (Knutson et al., 2006), thus developing interactions with customers strongly support a joint process of value creation (Canestrino et al., 2018).

Within the field of service research, the Goods Dominant (G-D) logic, the Service Dominant (S-D) logic, and the Customer Dominant (C-D) logic were developed to depict the process of value creation from different perspectives. According to the G-D logic, exchange is mainly responsible for value generation (Vargo and Lusch, 2004). By the opposite, S-D logic emphasizes the role of customers in the process of value creation: far from being simple experiential services recipients, they turn into collaborative partners able to "co-create" value with the firm (Lusch et al., 2007; Vargo and Lusch, 2008a,b; Grönroos, 2011; Yi and Gong, 2013). The C-D logic (Heinonen et al., 2010) finally proposes a truly customer-centric focus according to which the value is formed by customers' life and experiences (Heinonen et al., 2013), as well as by their perception about reality and interactions with the others.

In most recent years, network and system perspectives are gradually adding to the existing paradigms in the understanding the way value is co-created in service domains (Meynhardt et al., 2016). Since services are intrinsically systemic and dynamic, the adoption of system perspectives enables both scholars and practitioners to explore the process by which goods, equipment, and people are harmonically integrated and interact co-creating value (Barile et al., 2016; Barile and Saviano, 2014).

According to the above, the notion of "ecosystems" establishes as a relevant conceptual candidate to capture the essential network dynamics in service domains (Lush et al., 2016). In the biological literature, ecosystems refer to those communities of organisms that interact, over time and space, with other organisms and other elements in the system. The resulting interdependence among the elements is necessary for the joint adaptability of the elements and works as source of dynamism of the system itself. Since markets, economies, and similar human systems are like natural ecosystems (Vargo and Akaka, 2009), scholars (Barile et al., 2016; Vargo and Lusch, 2016, Lusch et al., 2010, Vargo and Lusch, 2011) have identified the concept of a service ecosystem to capture their systemic dynamism. Vargo and Akaka (2012, p. 207) define a "service ecosystem" as "*a relatively self-contained, self-adjusting system of resource-integrating actors connected by shared institutional arrangements and mutual value creation through service exchange*".

The adoption of the new perspective affected the way both services and value are created and delivered. As mentioned, customers embedded in a given ecosystem, are no longer mere passive recipients of service (Vargo and Lusch, 2008; Spohrer et al., 2008; Troisi et al., 2016), but resources integrators (Vargo and Lusch, 2016) for acquiring strategic advantages (Vargo et al., 2008). As Barile et al. (2017, p. 811) detail, service ecosystems are "*interactive networks of actively engaged actors sharing resources through technological tools and common rules toward common purposes*". Actors,

institutions and technology are identified as their main features (Vargo and Akaka, 2012; Vargo and Lusch, 2010) and their interaction as the main source of knowledge sharing and value co-creation (Canestrino et al., 2018).

While scholars agree about what service ecosystem is, the debate is still ongoing with reference to the areas of knowledge within which service ecosystems are investigated. Consequently, this paper aims to identify the research areas that prevail in Management Studies, answering to the following research question: what are the main areas of knowledge, belonging to Management, within which service ecosystems perspectives were mainly developed?

In order to answer to this research question, this paper proposes a systematic literature review. This last one is a type of secondary data analysis that *“that locates existing studies, selects and evaluates contributions, analyses and synthesizes data, and reports the evidence in such a way that allows reasonably clean conclusions to be reached”* (Denyer and Tranfield, 2009, p. 671). Since no systematic literary review was published about service ecosystems until now, our study aims to provide a more comprehensive analysis of the topic, enabling researchers to understand and to deal with the complexities of service ecosystems in different areas of knowledge.

The remainder of the paper is organized as follows. First, Section 2 describes the methodology employed in the study; section 3 presents the descriptive results of the analysis; limitations of the study and proposal for future research directions are presented in the section 4.

2. Method

A systematic literary review methodology includes several steps. First, the research questions were stated and guidelines developed for collecting the literature. Secondly, a plan for classifying, describing, and coding the literature was developed. As a final step, the literature was synthesized (Merli et al., 2018; Deyner et al., 2009; Tranfield et al., 2003).

The first step of this review was to define the keywords that would better identify the relevant literature. In order to collect the higher number of papers as possible, covering the variety of all the issues examined within the selected field of study, we adopted the keyword “service ecosystem” as research criteria.

This study uses the *Business Source Premiere* as database, which features full texts and searchable cited references for top journals covering a variety of business disciplines.

We selected the mentioned database in order to include the most widely used business and economic resources, as including 2.112 active full-text peer reviewed journals, and 3.507 full-text Journals and Magazines¹.

According to the database research functionalities, the keyword “service ecosystem” was searched in title, obtaining 673 documents, including articles, proceedings, reviews,

¹ Source: EBSCO webpage (last update, April 2019).

book reviews, editorial material, book chapters, meeting abstracts, notes, and letters¹. As recommended in the literature, only journal articles were selected, which improves the rigor and quality of a literature review (Vigolo et al., 2018; Orzes et al., 2018; Jia, Jiang, 2018). Subsequently, the application of the filter “type of publication”, namely “only academic papers”, allowed us to obtain 621 articles. Referring to the type of language used in research on service ecosystems, the most common is English (616), followed by Russian (2), French (1), Polish (1), and Spanish (1). This pattern meets our expectations, since the most of academic journals are English based, with English, as the most used language by researchers in the modern global academic community (Snyder et al., 2016). Taking into account the irrelevance of “other languages” of publication, we focused our research on English papers only, obtaining a total amount of 616 articles.

Figure 1 shows the research strategy we followed to identify the articles. After having defined the type and the language of the papers, additional inclusion criteria were adopted in order to screen them for the systematic review. We particularly focused on the area of knowledge within which the authors have published researches on service ecosystems, using Thesaurus to detect the papers in the management field. The final sample was, therefore, of 232 papers. After removal duplication, a final sample of 188 papers lasted.

Figure 1 synthesizes the research strategy adopted to develop our systematic literary review.

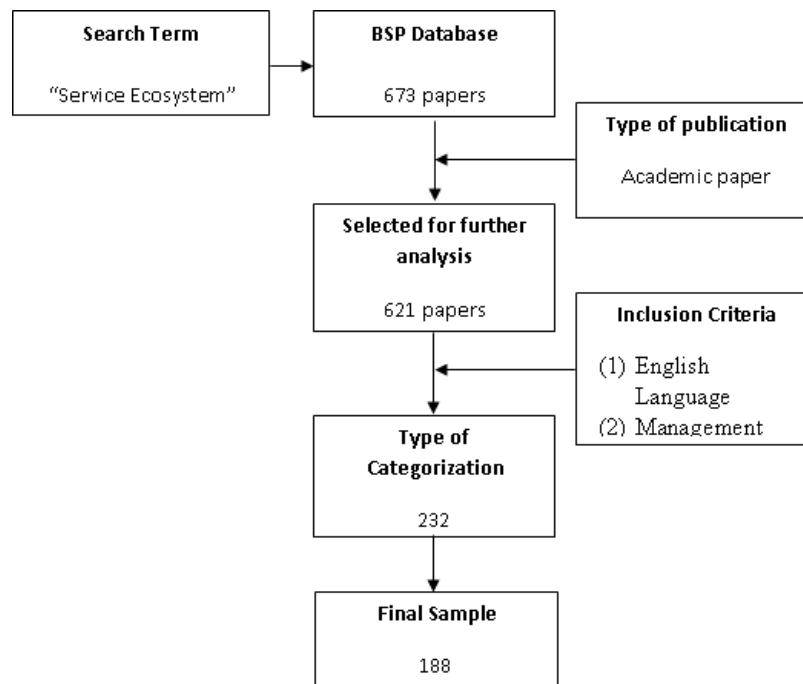

Figure 5 – Search Strategy to identify paper for the systematic literary review

¹ Last access to BSP for research was on March 11, 2019.

According to Rey-Marti et al., (2016), we established the following analytical categories:

- Areas of knowledge within which authors have published research on service ecosystems
- Years in which the articles were published
- Countries where authors have published research on service ecosystems
- Journals in which authors have published research on ecosystems
- Type (Theoretical or empirical paper) and adopted methodology (qualitative or quantitative)

3. Findings

3.1. Areas of knowledge within which authors have published research on service ecosystems

Table 1 shows the number of documents published in different knowledge areas, in Business Source Premiere (BSP). Since some papers belong to different Thesaurus categories, duplicates were removed, according to the linkage between the keywords (provided by the authors) and the selected categories. As mentioned, after the removal duplication, a final sample of 188 papers lasted. Particularly, 48 papers belong to the field of Ecosystem Management, 37 to Decision Making area of research, 19 to Sustainable Development, 12 to Stakeholder, and 12 to Environmental Management. Other researches areas follow the top five ranked with less (or equal) than 12 papers.

Table 7 - Areas of knowledge within which authors have published research on service ecosystems

Ranking	Research Area (Thesaurus)	N. publication
1	Ecosystem Management	48
2	Decision Making	37
3	Sustainable Development	19
4	Stakeholder	12
5	Environmental Management	12
6	Management	12
7	Customer Co-creation	8
8	Business Ecosystem	7
7	Land Management	6
10	Ecotourism	6
11	Resource Management	5
12	Strategic Planning	5
13	Customer Services	4
14	Service Industries	4
15	Value Creation	3
Total		188

3.2. Years in which the articles were published

Articles were also categorized according to the publication year. Our search shows the existence of the first paper mentioning “service ecosystem” in the title in 2001. The

article particularly focus on the changes in service ecosystems due to the urban sprawl of San Antonio, Texas, with the aim to determine whether LANDSAT MSS could be used to quantify the examined changes. Nonetheless, the number of documents published per year before 2009 is very low (max 5 per year).

Table 8 – Number of papers published between 2001 and 2019

Period of time	Year	N. of publications
First Period	2001	1
	2002	5
	2003	0
	2004	1
	2005	1
	2006	4
	2007	5
	2008	2
Second Period	2009	10
	2010	14
	2011	8
	2012	18
	2013	10
Third Period	2014	21
	2015	23
	2016	20
	2017	18
	2018	21
	2019	6
	Total	188

Table 3 shows the number of publications between 2001 and 2019. Last access for research on BSP was on March 11, 2019. It means that publications for the last year are still ongoing. Because of the mentioned, data about the papers published in 2019 were intentionally excluded by our comments.

In order to evaluate and better understand possible trends, we divided the whole period (with the exception of 2019) by three, investigating them through a content analysis.

The first period, defined between 2001 and 2008, consists of only 19 papers.

The interest on service ecosystems has increased time by time with a significant turning point in 2009, thus a second period was identified from 2009 to 2013. This period consists of 60 articles. It starts with the publication by Fisher, Turner and Morling (2009) aiming at offering a definition of ecosystem services likely to be operational for ecosystem service research and several classification schemes. During this period, the concept of service ecosystems begun to attract the attention of the scholars belonging to different fields of research, and turned into an important model for linking the functioning of ecosystems to human welfare. As consequence, great efforts were made by the authors to classify and detail ecosystem services, basing, on one side, on the characteristics of the ecosystems, and, on the other side, on the decision context for which the concept of ecosystem services is being mobilized (Fisher, et al., 2009). *Ecosystem Management*, with 19 articles published is the most important area of knowledge in the period. Management of natural resources, biodiversity, ecology, resources exploitation, pollution, and public

health are the most mentioned words in the articles published during the period, the authors addressing conceptual frameworks to the analysis of given geographical areas or industries. In 2009, for example, Garrik et al., (2009) developed a conceptual framework to examine factors enabling and constraining successful policy reform and implementation in market-based environmental water allocation, analyzing two case studies – namely Columbia (U.S.) and Murray-Darling (Australia) basins – where transactional approaches to environmental water allocation first emerged. Similarly, Green and Isacs (2009) carried out interregional comparisons of development and sustainable use of natural capital for Swedish regions and for two types of ecosystem services - pollution sequestration and recreational services - provided by three types of ecosystems: forests, agricultural landscape and wetlands services. Moreover, an attempt to link economics of ecosystems and biodiversity to the business and social risk arising from the overexploitation of natural resources is made by Sukhdev et al. (2011). The authors particularly underline the importance of a wider recognition of nature's contribution to human livelihoods, health, and security, discussing the annual loss of opportunities due to the overexploitation of global fisheries. *Decision Management*, with 15 articles published, is the second most important area in the period. Some relevant contributions are provided by Fisher et al (2009), as well as by Fontana et al. (2013), this last ones proposing a systematic framework that includes the ecosystem services as criteria into multi-criteria decision analysis (MCDA).

An additional speed up in the number of publications was registered by the 2014. The third period entails 103 papers (excluding 6 papers already published in 2019). Compared to the second period a growth of about 70% was registered in the published documents. The growing number of contributions belonging to the area of *Decision Making* (21 articles published) supports the increasing interest toward ecosystem services concerns in this area of knowledge.

Some relevant contributions are provided by the work of Geneletti (2015), proposing a conceptual approach to integrate ecosystem services (ES) effectively in Strategic Environmental Assessment (SEA), as well as by Ruckelshaus et al. (2015). Starting from the assumption that literature rarely assesses whether biodiversity and ecosystems services (BES) information is used effectively in decisions, the authors offer a framework for considering how information is effectively used decisions, illustrate its use to describe progress in the influence of BES values in several decision contexts, and qualitatively assess the strengths and weaknesses of this framework. One of the few contribution published in the field of management studies attempts to codify knowledge about service ecosystems in order to facilitate communication and decision making in this domain (Dobrica, 2018).

The area of *Ecosystem Management* remains relevant also in the third period with 14 articles published.

3.3. Countries where authors have published research on “service ecosystems”

According to our country analysis, articles from institutions in 37 different countries from five continents – America, Europe, Asia, Africa, and Australia - were identified. The U.S. (170) and China (84) represent the higher number of institutions, collaborating in the 40,31% of all the articles.

Europe is the continent with the higher contribution with 266 articles (42,24%) from 20 different countries, where UK with 57 (9,05% on the whole sample) papers, Italy with 42 (6,67% on the whole sample), and Germany with 35 (5,56% on the whole sample) are leading in the examined field of research. America is the second most important continent with 201 (31,91%) articles from 7 different countries. It is followed by Asia that participate in the debate with a total amount of 100 papers (15,85%) from 5 different countries. Among them China offers the higher contribution. Oceania and Africa are the continents with the lower participation with respectively 46 (7,3%) and 14 (2,38%) articles.

Table 3 shows the countries with the higher contribution in the research field. Ranking is limited to the top 8 countries, since a number of publications under 20 was not considered.

Table 9 – Countries with higher contribution in the field of “service ecosystems”

Ranking	Country	N. of Publications	Contribution to the field (% on the whole sample)
1	USA	170	26,98
2	China	84	13,33
3	UK	57	9,05
4	Italy	42	6,67
5	Germany	35	5,56
6	Australia	27	7,3
7	Finland	26	4,13
8	Sweden	20	3,17

3.4. Journals in which authors have published research on service ecosystems

Knowing about the journals that publish papers on “service ecosystems” is important for two main reasons: the first one is to understand which are the disciplines from which researches draw concepts and theories about service ecosystems; the second one is to become more familiar with scholars’ focus on the issue, thus suggesting the directions for further researches.

The 188 selected papers come from 59 different journals from diversified fields, such as economy (mainly ecological economics), and marketing. Among them, a huge concentration on only one journal prevails, with the 41,48% of the sample (78 papers) belonging to *Ecological Economics*. *Ecological Economics* Journal concerns with ecological science, economics, and the analysis of values, behaviors, cultural practices, institutional structures, and societal dynamics. Issues related to well-being, sustainability, and justice are emphasized to a great extent, as well as those focusing on the interplay between "nature's household" (ecosystems) and "humanity's household" (the economy).

By the contrast, a high fragmentation may be underlined for the residual 110 papers, with 46 journals publishing 2 articles, at least. The mentioned fragmentation may be interpreted as the results of the variety of subjects belonging to the issue of “service ecosystem”.

Table 4 shows the list of the journals that have published articles about “service ecosystems” between 2001 and 2019. Journals with less than 5 papers were not listed, as the number of publication considered irrelevant. Information about Impact Factor (IF), and SCImago rank were collected on the journal official website, as well as on SCImago Institutions ranking systems.

The IF provides scholars with an objective measure of the importance of different journals within a given category (Rey-Martí et al., 2016). In addition, SCImago is a prestige metrics based on the idea that not all the citations are the same. It provides a quantitative and qualitative measure of the Journal’s impact, basing on a similar algorithm as Google page rank.

As noted, 113 papers belong to only 6 different journals, the last ones all cited in SCImago. Analyzing the list, we find that *Ecological Economics*, with 78 articles, characterizes for the higher SJR (1,657), revealing the high quality of the scholars’ contributions in the examined field.

Table 10 – Journals publishing articles on “service ecosystems”

Ranking	Journals	Editor	N. publications	Impact Factor (IF)*	SCImago Journal Rank (SJR):
1	<i>Ecological Economics</i>	Elsevier	78	3,895	1,657
2	Forest Policy and Economic	Elsevier	8	2,496	1,010
3	Journal of Cleaner Production	Elsevier	8	5,651	1,47
4	Journal of Service Management	Emerald	7	3,414	1,49
5	Environmental Science & Technology	ACS Pub	6	6,653	0,18
6	Journal of Environmental Assessment Policy & Management	World Scientific	6	N.A.	0,35

*IF measures the average number of citations received in a particular year by papers published in the Journal during the two preceding years (Clarivate Analytics, 2019)

** SJR is a prestige metrics based on the idea that not all the citations are the same. It provides a quantitative and qualitative measure of the Journal’s impact (Elsevier Analytics, 2019)

Source: our elaboration (last access to data: April, 2019)

The *Journal of Service Management* follows *Ecological Economics* in term of SCImago rank. The journal focuses on service management research, focusing on the following categories: Business, Management and Accounting, Business, Management and Accounting (miscellaneous), Strategy and Management Tourism, Leisure and Hospitality Management¹.

¹ Source: Scimago homepage.

Comparing the two ‘best’ journals (in terms of SCImago ranks), a focus on ecology and economy seems to prevail, with the most articles belonging to *Ecological Economics*. It is a matter of fact that examining service ecosystems within business management studies is a still unexplored field. Despite this, new suggestions for further researches come from the existing gaps, aiming to improve the existing literature/theory and its applications in practice.

3.5. Type (Theoretical or Empirical papers) and adopted methodology (Qualitative, Quantitative or Mixed methods)

In order to provide a full understanding of the selected papers, they were categorized in Theoretical/conceptual and empirical; and between qualitative, quantitative, or mixed methods. Referring to the article types, the 41% of them is theoretical/conceptual (59% of the articles are empirical). With reference to the methodology, 50% of the whole sample is qualitative, followed by quantitative analysis (40%), and mixed-methods (10%). It seems, therefore, that a good balance exists among the selected papers’ type.

4. Conclusions

The aim of this work was to perform a systematic literary review about “service ecosystem” not developed before. For the purpose of this conference, the descriptive reviews was proposed, as the first step for a thematic exploitation of the issue, the last one emerging as a concept of a growing interest for scholars coming from management studies.

We, particularly, selected 188 articles and examined them according to the following analytical categories: 1) Areas of knowledge within which authors have published research on service ecosystems; 2) Years in which the articles were published; 3) Countries where authors have published research on service ecosystems; 4) Journals in which authors have published their researches; and 5) Type of paper and adopted methodology.

According to the research’s findings, a growing interest toward service ecosystems has been developed for the last ten years, especially referring to the two main areas of knowledge of *Decision Making* and *Ecosystems Management*. The U.S. (170) and China (84) represent the higher number of institutions, collaborating in the 40,31% of all the selected articles, the last ones coming from 59 different journals from diversified fields, such as economy (mainly ecological economics), and marketing.

This review contributes to fill the existing literary gap providing the theoretical background for future studies about the value co-creation in service ecosystems. Nevertheless, some limitations should be acknowledged. Firstly, data collection was limited to peer-reviewed articles present in Business Source Premiere, limiting the number of papers considered in our sample. We aim, for the future, to expand data collection including articles collected in Scopus and WoS.

Secondly, analytical frameworks are missing. Although intentionally neglected, the lack of thematic analysis limits the contribution provided by our paper.

Further research will attempt to expand our results, thus improving both the knowledge and the understanding of service ecosystem and their dynamics. Due to the relevance of relationships, sharing experiences and individuals' perception, we expected that the ecosystems perspective can be applied to hypercompetitive sectors such as tourism, whose offering is essentially based on the exploitation of contextual aspects and in which visitors' experiences represent a recent trend (Barile et al., 2017; Prebensen and Foss, 2011; Binkhorst and Den Dekker, 2009). Despite this, very few works are actually available about service ecosystem in tourism and hospitality industry (e.g., Baccarani and Cassia, 2017; Barile et al., 2017), thus representing a literary gap to fill in the future.

Depending on this consideration, our work proposes to evaluate the evolution of the research field offering a conceptualization of the key subjects, suggesting also a path for theoretical advance in some un-explored industries, as tourism and hospitality are.

Abstract

The present research aims at defining the scope of an emerging phenomenon occurring in a peripheral suburb in the East area of the city of Naples (Italy), characterised by the settlement of a knowledge intensive Hub involving innovation, technology and knowledge transfer processes. The main subject of the study is the San Giovanni a Teduccio “Federico II” University Hub, a university campus and research centre named the San Giovanni Hub (“SGH”) or simply the “Hub”. Our work addresses the issue of innovation led by a knowledge-intensive context in a peripheral urban area. Such insight should enrich the specific focus on the competences of a university in terms of technology and knowledge transfer.

The theoretical focus of the study is forged around the “Civic University” (Goddard, 2009) main characteristics, which draw from the transposition of the quadruple helix approach. The rationale underpinning the choice of the university engagement view (Holland, 2001) would help overcoming the vision of the University as “company-like” entity.

The contribution to the theoretical framework resides in assessing the relevance of a knowledge intensive site embedded in a peripheral and less developed urban context in the light of the “Civic University” characterising features. Such insight should enrich the specific focus on the competences of a university in terms of technology and knowledge transfer. The outcomes of the analysis can be used as a valuable tool for both the University governance and managers of local urban institutions to promote or enhance knowledge transfer and entrepreneurial activities in the selected area.

Keywords – Innovation, Knowledge creation, Knowledge transfer, University Engagement

Paper type – Academic Research Paper

1 Introduction

According to the concept of the civic university (Goddard, 2009; Goddard & Vallance 2013; Goddard & Tewdwr-Jones, 2015), universities can be rightfully considered reliable partners with cities, since they acknowledge the linkage to their location as a characterisation of their own identity, notwithstanding the national or international extent of their scope. On their turn, cities are expected to assume further responsibility for the local economy and the social issues implicated in the development process of the communities they are in charge of (Goddard & Tewdwr-Jones, 2015).

Over the past three decades, a relevant bulk of literature has theorised the function and role of universities on urban and regional development (Trippel, Sinozic, & Lawton Smith, 2015; Uyerra, 2010). Within this milieu, “regional innovation systems” (RIS) thinking has emerged as a preeminent conceptual paradigm, by theorising universities as deeply involved in the systemic architecture and practice of innovation. Although subject to debate concerning their very definition and scope (Doloreux & Parto, 2005), RIS approaches emphasise “economic and social interaction between agents, spanning the public and private sectors to engender and diffuse innovation within regions embedded in wider national and global systems” (Asheim, Lawton Smith & Oughton, 2011, p. 878).

Actors representing the demand-side include national governance entities that regulate innovation practice, local and regional governments concerned with territorial economic development, and numerous public and private organisations concerned with high-tech entrepreneurship (Addie, Angrisani & De Falco, 2018).

Conversely, universities and research centres occupy privileged positions as supply-side actors (with varying degrees of efficacy) providing knowledge and research competencies and generating new spin-off firms and tradable outputs (Charles, 2006). The regional functions ascribed to universities in RIS analysis do not depend on their own internal organisation and orientation (as with the “entrepreneurial”, “Mode 2”, or “engaged” university) but rather on contextually-specific relations with other actors and knowledge bases along path dependent growth trajectories (Trippel et al., 2015). Fritsch and Slavtchev (2007) suggest that the efficacy of universities in regional innovation is driven by the quality of research and intensity of interactions with firms, not the size of the institutions involved. This endogenous role is prominently captured in the nonlinear, recursive linkages of “triple helix” university-industry-government relations (Etzkowitz, Ranga, Benner, Guarany, Maculan & Kneller, 2008).

In the light of the theoretical framework presented above, a broad research question will drive the investigation (Braun & Clarke, 2006), in the attempt to answer to the following interrogation:

What are the main patterns and characteristics of the SGH in terms of innovation, knowledge transfer and University engagement?

In order to achieve such purposes, a qualitative analysis has been performed by means of a case study methodology (Yin, 2009) on the San Giovanni Hub where data have been gathered by participant observation, narrative documents and in-depth interviews to the

main stakeholders of the Hub for a total of 25 interviews completed for the empirical investigation.

2 Theoretical framework

Triple helix analyses draw attention to new behavioural trends in which individuals and organizations within helices can assume roles beyond those traditionally ascribed to them. Cross-institutional relationships promote the bundling of resources to support technology transfer, firm formation, and the development of capital-intensive infrastructures. Also, they produce a transformative impact on the university itself; engendering the construction of hybridised structures to integrate teaching, research, and commercialisation activities, with entrepreneurial claims (Audretsch, 2014). Deepening interest in commercialising academic enterprise has fed into a policy paradigm whereby universities are expected to stimulate economic development via knowledge transfer to co-located industries (or catalysing the creation of new-Co). With the implementation of policies pushing investments in innovation by academic and governmental institutions, universities' direct actions (spin-offs, technology parks, etc.) and indirect impacts (increased network thickness, enhanced absorptive capacity, etc.) contribute to the development of localised knowledge spill-over cultures (Lendel, 2010), eventually extending their territorial influence (Benneworth & Hospers, 2007). As RISs reach maturity, it is often the indirect benefits – including mobilising the university as a hub for recruiting, training, and retaining regional human capital – that are of greatest importance for regional development (Berggren & Dahlstrand, 2009).

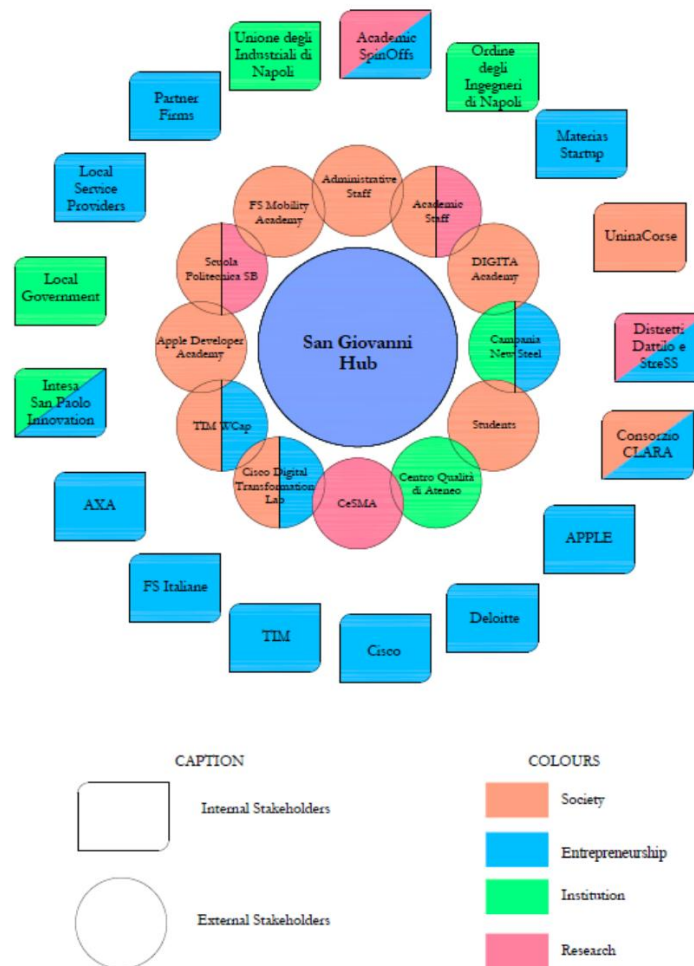

One of the pivotal themes dealt with in the present research concerns the issue of knowledge spillovers (Audretsch & Keilbach, 2007) and proximity (Caragliu & Nijkamp, 2012, 2015), together with the Ba and Co- creation (Nonaka & Konno, 1998; Nonaka, Toyama & Konno, 2000; Huhtelin & Nenonen, 2015) view to explain the way in which space can convey knowledge. The previous matters involve the absorptive and desorptive capacity of actors in technology transfer processes that can affect regional innovation systems (Cohen & Levinthal, 1990; Zahara & George, 2002; Dell'Anno & Del Giudice, 2015). A reference to the main innovation systems (Freeman, 1991, 1995; Edquist, 2005) and the milieu innovateur literature (Maillat, 1991, 1995, 1998; Acs, 2002) will be necessarily provided, also in the light of policy mix approach on strategic policy choices (Borrás & Edquist, 2013). Furthermore, a shared approach concerning the triple helix interaction among university, government and industry and its evolutions will be analysed (Leydesdorff & Etzkowitz, 1998, Etzkowitz & Leydersdorff, 1999; Etzkowitz 2002, Etzkowitz et al. 2008; Carayannis & Campbell, 2014; Leydersdorff, 2012), in order to connect them to the university third mission (Holland, 2001; Molas-Gallart, Castro-Martínez, 2007; Schofield, 2013; Audretsch, 2014) and the service university concept (Goddard, 2009; Goddard & Vallance 2013; Goddard & Tewdwr-Jones, 2015). Finally, a linkage with the service innovation main propositions (Vargo & Akaka, 2012) will be explained to provide a new interpretation of the innovation trends occurring in the selected area.

3 Research design

3.1 The SGH Ecosystem

The preliminary definition of the ecosystem of the SGH has been a challenging task involving a complex analysis on the Stakeholder Map of the subjects interacting with the Hub itself. Being the latter an evolving system, the Stakeholders' list is continuously changing and enriching according to the agreements and connection stimulated by the activities animating the Hub.

Our research shows the actual configuration of the main stakeholders populating the SGH ecosystem, described in figure 3.1 below.

Source: Authors' elaboration

Figure 3.1: Stakeholder Map of the SGH

3.1 The Case study of the SGH

The study has adopted an explorative qualitative inquiry based on a case study methodology to form a new understanding of a previously unstudied phenomenon (Myers, 2013).

The perspective chosen for this study enabled a comprehensive investigation of the SGH as it is perceived and experienced within its context.

For the objective of the investigation, in-depth interviews were undertaken and official documents were analysed to gain exploratory insight into the emergence of the SGH phenomenon and its perceived effects in terms of value creation and knowledge transfer for the area in which the Hub is embedded.

The participants were selected using a purposive sampling technique to provide wide variability and representation of the study context of the Hub (Patton, 1990). Triangulation in the data (Yin, 2009; Patton, 1990) was achieved by examining multiple sources of data (i.e., participant observation, interviews, surveys and documents), and by consulting informants at multiple levels, to either the managerial and academic staff of the Federico II University.

The interview sample included main representatives considered to be the key stakeholders of the Hub, selected according to the more or less formalised partnership with the Federico II University. The information about the stakeholders' assortment has been gathered thanks to the extremely helpful consultation with the SGH key informants. The variety of selection in the stakeholders has sought to ensure capturing perspectives from the academic, entrepreneurial, research and policy-making levels. The sample also included students attending the Apple Developer Academy and the DIGITA academy in partnership with Deloitte Digital to which a questionnaire has been administered with to purpose of gathering the perspective of what the study has considered to be a "selected" category of students.

In total, 25 interviews were conducted, which generated about 24 hours of interview data. Respondent details and their corresponding codes are shown in tables 3.1 and 3.2, below.

Total time allocated to the in-depth interviews			Tot. Minutes	1475'
			Tot. Hours	24,6'

No follow-up interviews were necessary on the contrary, most interviewees spontaneously provided several adjunctive information on the historical, political and institutional background of the Hub. Some of them have been recorded during the interviews, some others are off the record information of which memos and written notes have been taken with the consent of the respondent.

Whilst the in-depth interviews were developed according to a pre-defined scheme to make sure that similar issues are covered to allow analytical comparability (Corbetta,

2003), there was flexibility to explore new issues that emerged during the interviews, data analysis and interpretation process (Creswell, 2003; Patton, 1990, King, 2004).

Since all the interviewees are Italian, the interviews were conducted in Italian, in order to yield rich information and minimise distortion. The interviews were recorded and transcribed verbatim to preserve the precision of the data. Translation of the narratives into English was only completed after interpreting the data to attain precise meanings. In the phase dedicated to the organisation of the gathered data, coded have been attributed to each respondent, following the division in four main categories of stakeholders, or varying combinations of them, namely:

- Research
- Entrepreneurship
- Institution
- Society

The transcripts of the 25 in-depth interviews, performed through a semi-structured set of questions, have been analysed by means of a thematic analysis,” which works particularly well when the aim is to compare the perspectives of different groups of staff within a specific context” (King, 2004, 257).

Table 3.3: Thematic areas for the in-depth interviews

Thematic areas	Definition/Relevance for the study	Open-ended Questions set
1. Knowledge and related mechanisms of transfer and exchange	<p><i>“Facts, information, skills acquired through experience or education; the theoretical or practical understanding of a subject”</i> (The Oxford Dictionary).</p> <p><i>“The knowing, as presence in the intellect of a notion, as already acquired knowledge”</i> (Treccani Encyclopaedia).</p> <p>- The concept of Knowledge dealt with herein is not limited to the learning activity.</p>	<p>- What value would you attribute to the knowledge factor applied to the Polo of S. Giovanni?</p> <p>- Can San Giovanni be labelled a “Knowledge Intensive Hub” (KIH)?</p>
2. Stakeholders	<p><i>Main actors (physical persons, institutions and/or organisations) interacting with the Hub. The definition of internal and external STKH depends on relations with the market or the society</i></p>	<p>- Please observe the STKH Map of S. Giovanni: do you consider the map consistent with the activities and the relations started within the Hub?</p> <p>- Could you explain what is it and in what terms your connection with the Hub unfolds?</p>
3. Technology and Knowledge transfer (TT & KT)	<p><i>Set of activities aimed at bringing new technology or new knowledge from research to the market.</i></p>	<p>- Which TT mechanisms, among those shown in the attached table (table 3.5, below) do you think are or could be applied within the Hub?</p>
4. Third mission	<p><i>Set of activities carried out by the university in addition to those related to teaching.</i></p> <p><i>“Activities concerned with the generation, use, application and exploitation of knowledge and</i></p>	<p>- Do you believe that the SGH is a third mission experience? In what terms and with what characteristics?</p>

	<i>other university capabilities outside academic environments” (Molas- Gallart et al., 2002, ii-iv)</i>	
5. Proximity	<i>Geographical, relational, cultural closeness to the Hub.</i>	- In light of the information provided on the concept of proximity applied in this study, do you think that this concept is relevant for the activities of the <i>Hub</i> ?
6. Space	<i>Value and relevance of the interaction within the Hub spaces.</i>	Express what can be, in your experience, the advantages of being an integral part of the Hub. - Do you think that the physical space in which the Hub is organised is an important element for internal and external dynamics in terms of networking and technology transfer?
7. SWOT Analysis applied to the Hub	<i>Analysis of strengths and weaknesses, threats and opportunities of the Hub.</i>	- What do you think are the main strengths, weaknesses and opportunities of the <i>Hub</i> ?
8. Policy choices	<i>Interventions promoted by the central and local government to define and apply the most effective parameters aimed at encouraging economic growth, in this case in terms of dissemination and marketing of research products.</i>	- What policy choices have guided the establishment and development of the Pole (investment and / or redevelopment)? - Which do you think should be implemented (e.g. if you were a policymaker)?

Regarding the surveys, questionnaires were submitted in English for both sub-samples, i.e. the one attending the Apple Developer Academy and the one attending the Digita (Deloitte Digital Academy in partnership with Federico II University). In fact, as emerged from the personal data collected at the beginning of the surveys, the nationality of all the students belonging to the latter academy is Italian, whilst students attending the former come from different Countries.

Table 3.4: Sample size

Unit of Analysis	Sample Unit
San Giovanni a Teduccio University Hub	Economic/non-economic organisations next to the hub in terms of geographical proximity
	Researchers in the selected research centre
	Economic/non-economic organisations connected to the hub in terms of relational, organisational or cultural proximity (Caragliu & Nijkamp, 2015)
	Supporting/administrative staff
	Apple Developer and DIGITA Academies managing directors
	Local government representatives and further primary Stakeholders
	Apple Developer and DIGITA Academies students

4 Findings

The analysis conducted for our case study identifies themes at the semantic level, depicting what has been said with the purpose of focusing on interpreting and explaining it. The main areas of the interviews have served as categories on which themes have been later detected.

Following a thematic analysis approach (King, 2004; Myers, 2013), data were coded and analysed in a ‘template’, to identify the leading categories, patterns, themes, and relationships (King, 2004). Some initial categories and themes were identified from the literature and have been reviewed and modified in accordance with the collected data (King, 2004). In analysing the transcripts, the aim was to identify elements within the thematic areas object of the interviews able to express the perception of the SGH stakeholders. The coding map for the thematic analysis of the in-depth interviews performed for the empirical investigation of the SGH is illustrated in table 4.1, below.

Table 4.1: Template of the coding map for the thematic analysis of the in-depth interviews performed for the empirical investigation

#	Main categories drawn from the interviews topic headings	Code Level 1	Code Level 2	Code Level 3	Illustrative quotes
1	Value of Knowledge for the Hub				
2	Stakeholders				
3	Technology and Knowledge transfer				
4	Third mission				
5	Proximity				
6	Space				
7	Elements of Strength of the SGH				
8	Elements of Weakness of the SGH				
9	Opportunities for the SGH				
10	Threats/Risks for the SGH				
11	Policy choices				

Recalling the seven dimensions of the “Civic” University, the analysis carried out so far has allowed us to verify the mentioned patterns in the Federico II University SGH. Indeed, the thematic analysis outcomes, together with the results of the surveys performed on the Academy students’ sample have supported the initial assumptions of the study. Thus, the civic university concept applied in the San Giovanni Hub embraces the theoretical aspects described in the literature review on the topic. Table 4.4 below enriches the initial enumerations of the civic university dimensions, by adding the specific linkages with the SGH ecosystem.

Table 4.2: Seven Dimensions of the “Civic University” verified in the Federico II San Giovanni Hub

#	Seven Dimensions of the “Civic University”	Evidences from the “Federico II” University SGH	Themes from which the evidence is drawn	Evidences form the surveys
1	It is actively engaged with the wider world as well as the local community of the place in which it is located.	Local and global dimension of the stakeholders interacting with the Hub.	Knowledge-intensive hub that has bypassed territorial borders.	Both Apple Developer Academy and DIGITA Students define themselves as Stakeholders of the SGH, thus recognising the value of the whole context surrounding their very experience within the Academy.
2	It takes a holistic approach to engagement, seeing it as institution wide activity and not confined to specific individuals or teams.	Engagement approach claimed by the very statute of the Federico II University.	Education and aggregation role; Combination of cultural and relational proximity.	Most of the interviewed students recognise a high value to the social impact of the SGH.
3	It has a strong sense of place – it recognises the extent to which its location helps to form its unique identity as an institution.	Hub open to the local community and embedded with the local social and entrepreneurial context.	Knowledge-intensive hub; Role of knowledge attractor and diffuser; Open and usable space.	Most students agree with the leading propositions of the study, claiming that the SGH is a place where knowledge is created, concentrated and shared beyond its physical borders. Thus, implicitly supporting the knowledge spillover and geographical proximity paradigms described in the theoretical framework.
4	It has a sense of purpose – understanding not just what it is good at, but what it is good for.	Third mission and civic engagement purposes.	Example of Third Mission; Aggregating role.	
5	It is willing to invest in order to have impact beyond the academy.	Partnership with both public (Institutional) and private (Companies) subjects.	Investments in physical space of the surrounding areas.	
6	It is transparent and accountable to its stakeholders and the wider public.	Official annual reviews and three-year University strategic planning.	University and the private sector as the main development drivers for the Hub.	
7	It uses innovative methodologies such as social media and team building in its engagement activities with the world at large.	University – Industry Academies (Apple Developer Academy, DIGITA; FS Mobility Academy, etc.)	Matching professional profiles with companies’ needs; Social impact boosted thanks to dissemination in schools, university and civil society.	Students’ agreement on the capability of both the Apple Academy and DIGITA to improve students’ knowledge.

Source: Authors’ elaboration based on the template reported in Goddard et al. (2016), pp. 10-11

5 Conclusions

The most relevant findings of the study have contributed to add qualitative features and items to the analysis of value creation process occurring in the Hub and addressed to its stakeholders.

The investigation on the role of the “Federico II” University Hub in the peripheral/deprived urban area of San Giovanni a Teduccio has provided a first level understanding of:

- i.* the nature of the Hub in terms of innovation, knowledge and technology transfer, and third mission;
- ii.* the innovation strategy implemented or planned by the university governance and local government institutions according to the “Civic university” purposes; and

The outcomes of the analysis can be used as a valuable tool for both the University governance and managers of local urban institutions to promote or enhance knowledge transfer and entrepreneurial activities in the selected area.

The contribution to the theoretical framework resides in assessing the relevance of a knowledge intensive site embedded in a peripheral and less developed urban context in the light of the “Civic University” characterising features. Such insight should enrich the specific focus on the competences of a university in terms of technology and knowledge transfer.

Abstract

The goal of this paper is to shed light on the connection between national culture, operationalized using Hofstede's dimensions, and individual mindfulness. We obtain data about individual mindfulness levels from published peer reviewed studies to find correlations between values of individual mindfulness and values of Hofstede's dimensions for a variety of cultures. We found that the dimensions of Individualism and Power distance show a relatively strong correlation, with other dimensions showing weak or no correlation at all. In this way we hope to contribute to knowledge concerning the connection between national culture and individual mindfulness, a topic which remains underexplored and which has caught the attention of mindfulness researchers. Additionally, organizational practice may benefit from the contributions that this paper makes regarding the question of individual mindfulness development, i.e. the suggestions that individuals in some cultures may have an easier time developing mindfulness.

Keywords – Individual mindfulness, National culture, MAAS, Hofstede's dimensions

Paper type – Academic Research Paper

1 Introduction

Organizations constantly strive to increase the productivity and performance of their employees, seeking a source of competitive advantage. In this struggle, individual mindfulness has been suggested as a possible path forward as it helps individuals cope with stressful situations (Samuelson et al., 2007), as well as due to its positive effects on mental health (cf. Keng, Smolenski and Robins, 2011; Donald et al., 2016). Though there is little consensus regarding the exact nature of mindfulness, we take the view of Brown and Ryan (2003), who see mindfulness as a state of mind characterized by high levels of awareness and attention toward what is occurring in the present, both outside of the individual as well as within the individual.

Research of individual mindfulness has also gained traction in connection with knowledge management and knowledge creation through its positive effects on innovative thinking and perspective adoption. However, antecedents of individual

mindfulness and its determinants remain an unexplored territory, despite a large volume of research focused on this topic (Sutcliffe, Vogus and Dane, 2016). These authors highlight many potential research directions, including the effect of national culture on individual mindfulness. Thus, the goal of this paper is to find out whether there is a correlation between individual mindfulness, measured using the Mindful Attention Awareness Scale (MAAS), and national culture, operationalized by Hofstede's culture dimensions framework. We ask the following research question: "Is there a correlation between values of Hofstede's cultural dimensions of countries and individual mindfulness measured in these countries?"

In this way, the paper contributes to mindfulness research by providing first preliminary explorations of the connection of individual mindfulness, revealing deeper questions and implications for scholars in this field. Further implications for managerial practice are discussed later in the paper.

2 Theoretical Background

The roots of mindfulness can be found in Buddhist tradition, where the word "sati", referring to the ability of the mind to be aware of a mental object deeply, fully, and accurately (Buddhadāsa, 1998; Gunaratana, 1993). Buddhists have used meditation exercises to increase their mindfulness. As such, they considered mindfulness to be an ability to concentrate on and pay attention to a known, chosen object, such as breath, without getting distracted. In this way they tried to keep a stable, clear, and relaxed mind (Wallace, 2007). In western literature, the term began receiving serious attention after being introduced by Kabat-Zinn (2003, p.145) as "awareness that emerges through paying attention on purpose, in the present moment, and nonjudgmentally to the unfolding of experience moment by moment". However, in this paper, we will approach mindfulness following the definition by Brown and Ryan (2003), who see mindfulness as state of mind characterized by high levels of awareness and attention toward what is occurring in the present, both outside of the individual as well as within the individual.

Multiple methods of mindfulness measurement have been suggested, which differ in the way they operationalize mindfulness, the requirements they put on respondents, and other factors. However, most of these measurement instruments are self-report. This is also true for one of the most used methods of mindfulness measurement, the Mindful Attention Awareness Scale (MAAS), created by Brown and Ryan (2003). The popularity of this method is demonstrated by Medvedev et al. (2016), who state that the number of citations connected with MAAS on Web of Science and Google Scholar was 5028 in 2015, which is almost twice the number of citations connected with the second most cited method, The Five Facet Mindfulness Questionnaire. MAAS consists of 15 questions which are answered on a likert scale. The value of mindfulness is calculated as the mean value of all 15 questions.

Individual mindfulness has been shown to have multiple positive effects, including improved attention, awareness of the body, emotional peace and a view of oneself (Hölzel et al., 2011). Its positive effects on mental health have also been observed by e.g. Keng,

Smonski and Robins (2011) or Donald et al. (2016). Additionally, individual mindfulness helps with taking a non-linear approach to problem-solving, through which it supports creativity and flexibility (Ie et al., 2012), it aids in improving attention (Hales and Chakravorty, 2016), task performance (Dane, 2011) and productivity (Altizer, 2017). Due to its effects on knowledge creation, individual mindfulness also found a place in knowledge management. It was found that individuals who process information mindfully are more likely to apply the collected information in innovative ways and in original contexts (Langer, 1989), and take into account different perspectives (Langer, Janis and Wolfer, 1975). As such, individual mindfulness supports innovation and knowledge creation.

Individual mindfulness, knowledge and behavioural ability stand as inputs into the Cultural Intelligence model (Thomas, 2006). Cultural intelligence provides an organization with the ability to facilitate communication and management between people from various cultural backgrounds (Earley, 2002; Earley and Ang, 2003), which may lead to better knowledge transfer and innovation. Since mindfulness plays a central role in the model (Thomas, 2006), it also seems central to management of knowledge within an organization. As such, it is beneficial to know how individual mindfulness comes about and influences it. Despite a large amount of research focused on the topic of antecedents of individual mindfulness (see Sutcliffe, Vogus and Dane (2016) for a review), questions still remain unanswered. It is still unclear how, or whether, national culture influences individual mindfulness. Additionally, multinational corporations which strive to increase the individual mindfulness of their members may benefit from this paper when making decisions regarding the locations of new bases in culturally diverse countries. As such, this paper strives to contribute to filling this research gap.

3 Method

Using a traditional literature review, we obtain data about individual mindfulness in 18 different countries around the globe. The literature search began by searching the Web of Science database using the following algorithm:

((TS=((Mindful) AND ((MAAS) OR (Mindful* NEAR attention NEAR awareness NEAR scale)) AND (Assess* OR measure* OR Test* OR survey*)))) AND LANGUAGE: (English) AND DOCUMENT TYPES: (Article).*

The search took place in 2018. We decided on the relevance of literature found based on several criteria. First, we included empirical studies of individual mindfulness which measured mindfulness using MAAS. This criterion was introduced in order to avoid the problem values of mindfulness diverging due to different measurement methods. MAAS was specifically chosen due to its popularity, which maximized the chances of finding sufficient literature. Second, the study had to state which country the measurement took place in and disclose the actual values of mindfulness measured using MAAS. We included only published peer reviewed articles in the English language. Using this method

of search, we identified 18 research papers that were used as the source of our data. This means that for each country, we only obtained one value of individual mindfulness, as we use the results of a single paper for each country to determine the value of individual mindfulness. The study is further limited by the nature of the papers found, specifically by the composition of the researched sample, which were in some cases quite small or unrepresentative, consisting disproportionately of mental patients or students. As such, the results of this paper are hardly representative themselves, and should be taken as preliminary explorations rather than hard conclusive evidence. The process of literature search, filtering and selection can be found in Figure 1.

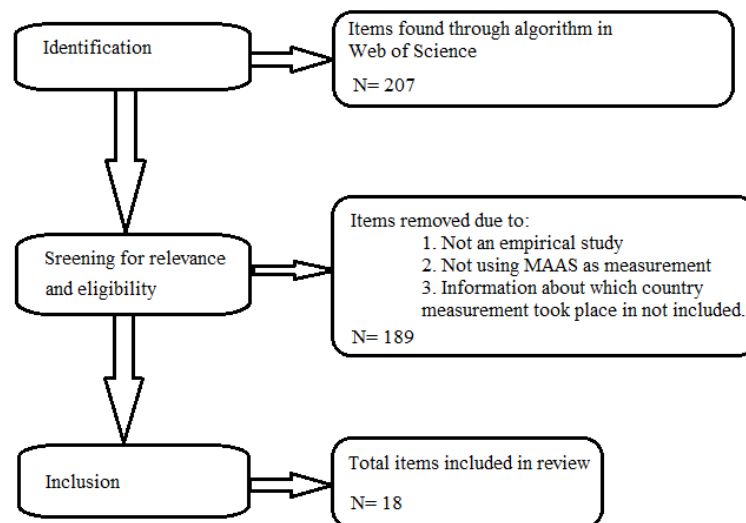

Figure 6: Literature search and selection process

We obtained values of Hofstede's cultural dimensions for individual countries on the Hofstede Insights website. Hofstede's cultural framework consists of 7 dimensions, Power Distance, Individualism, Masculinity, Uncertainty Avoidance, Long-term Orientation and Indulgence. All of these dimensions are bipolar, measured by indices, the value of which can range from 0 to 100 (Hofstede, Hofstede and Minkov, 2010). Although the framework has received criticism regarding its validity, it is still used to classify and operationalize national cultures (cf. Kąkol et al., 2018; Benaida, 2018; Laitinen and Suvas, 2016; Kedmenec and Strašek, 2017, Huang and Crotts, 2019). Hofstede's framework is primarily criticized due to it using nations as a unit, despite nations not being necessarily homogenous. Minkov and Hofstede (2014) addressed this criticism by demonstrating that culture is shared at the group level.

After we obtained values of individual mindfulness and Hofstede's cultural dimensions for individual countries, we used the Pearson Correlation Coefficient to calculate the correlation between individual mindfulness and indices of cultural dimensions.

4 Findings

Values of mindfulness of individual countries can be seen in Table 1, with cultural dimension indices being shown in Table 2. Data were obtained for countries in Europe, North America, South America and Asia, which are culturally quite different. Indeed, values of cultural dimension indices diverge between the countries. However, the means of all dimensions are limited to a rather thin interval between 49.89 and 59.94. The correlation coefficients calculated from values in Table 1 and Table 2 can be seen in Table 3.

Norway	31	69	8	50	35	55
Slovenia	71	27	19	88	49	48
Bangladesh	80	20	55	60	47	20
Brazil	69	38	49	76	44	59

Table 13: Correlation Coefficients between Individual Mindfulness and Cultural dimension indices

	Correlation
Mindfulness/Power Distance	-0.6551
Mindfulness/Individualism	0.5078
Mindfulness/Masculinity	0.1526
Mindfulness/Uncertainty Avoidance	0.0657
Mindfulness/Long-term Orientation	0.0704
Mindfulness/Indulgence	0.2646

The correlation between mindfulness and Power Distance can be considered strong (Evans, 1995), as it reaches the value of $r = -0.655$, suggesting an inverse relationship. In other words, high Power Distance in a culture is correlated with low average individual mindfulness. This can also be seen in Figure 2.

Figure 7: Correlation between Individual Mindfulness and Power distance index

Despite the low number of observations, the graph in Figure 2 does display an inverse relationship.

The correlation between Individual mindfulness and Individualism is $r = 0.508$, moderate. The value is positive, suggesting that an increase in Individualism is correlated

with an increase in Individual Mindfulness. The correlation between Individual Mindfulness and Individualism is displayed in Figure 3.

Figure 8: Correlation between Individual Mindfulness and Individualism index

The graph in Figure 3 displays a shape of observations that can be expected from a moderate correlation. The other indices of cultural dimensions are only weakly correlated with individual mindfulness, or not at all, suggesting that there is no relationship between these dimensions and individual mindfulness.

Although dimensions of Individualism and Uncertainty avoidance are of almost the same mean value, the correlations between Individual Mindfulness and Individualism and between Individual Mindfulness and Uncertainty avoidance are very different. This may be caused by differences in variance of the values of the two cultural dimension indices.

5 Discussion

We looked for correlation between national culture and values of individual mindfulness. Our findings reveal a strong negative correlation between the Power distance dimension of culture and individual mindfulness. This suggests that individuals in countries of high Power Distance are on average more mindful. The cause of this correlation is debatable. In cultures with high power distance, individuals have less power to make decisions, potentially reducing the need to be mindful.

Our findings further show a moderate positive correlation between Individualism and Individual mindfulness. This is consistent with the concept of mindfulness itself, being a greater awareness of the self. Individuals who devote more attention and energy to their own goals and themselves than to the goals of a group seem to achieve greater mindfulness.

However, correlation between two phenomena does not necessarily imply a causal link between them. It is possible that the correlation found in this research is a result of the rather small sample of literature used. However, this points to a different problem, that

being a lack of mindfulness research that even considers national culture as a potential factor worth taking into account. We found a lack of studies which would talk about the national culture of participants. With the current unclear link between national culture and individual mindfulness, this may lead to potential loss of information in resulting data. If national culture and individual mindfulness are indeed connected, as the results of this research suggest, then mindfulness researchers should begin observing national culture of participants in their research.

Because this research reports no correlation, not only can it not be interpreted as suggesting a causal relationship, but also does not speak in any way about the direction of the relationship between national culture and mindfulness. In other words, it does not suggest that a decrease in Individual Mindfulness is caused by an increase in Power Distance, or vice-versa. This research is further limited by the data obtained from the papers included in our sample, which was not always based on a representative sample of respondents.

On the other hand, this research found only weak or no correlation between individual mindfulness and five Hofstede's dimensions of culture, Masculinity ($r = 0.1526$), Uncertainty avoidance ($r = 0.0657$), Long-term orientation (0.0704), or Indulgence ($r = 0.2646$). This suggests that there is indeed no causal or any other relationship between these dimensions of national culture and individual mindfulness. In other words, our research suggests that mindfulness scholars do not need to take these dimensions of culture into account when designing their research.

The finding that there is no correlation between Individual Mindfulness and Uncertainty avoidance is somewhat surprising. Mindfulness is an integral part of some organizational theories that seek to deal with uncertainty in organizational practice, such as High-Reliability Theory (Weick and Sutcliffe, 2001). This theory suggests that by incorporating several processes in which individual mindfulness plays a pivotal role, organizations may achieve greater success when faced with an uncertain, ambiguous and high-risk environment. Seeing as uncertainty avoidance describes the tendency to avoid unpredictable and unorthodox behaviour and ideas, some correlation between individual mindfulness and Uncertainty avoidance may be expected. However, no such correlation was found. This may be again caused by the limitations of this research.

Our findings suggest that organizations which seek to improve knowledge transfer through improved communication should consider including members from cultures low in power distance and high in individualism, as these dimensions are correlated with individual mindfulness. This is in connection with the Cultural Intelligence model (Thomas, 2006), which suggests that individual mindfulness is integral to successful communication, and thus knowledge flows, in organizations. Improving individual mindfulness within an organization may not only improve knowledge transfer, creativity (Ie et al., 2012) and innovative behaviour (Langer, 1989), but also mental health (Byron et al., 2015) and task performance (Dane, 2011).

6 Conclusions

The goal of this paper was to find out whether there is a correlation between Individual Mindfulness, measured using MAAS, and Hofstede's dimensions of culture. We found strong negative correlation between Individual Mindfulness and Power Distance, moderate correlation between Individual Mindfulness and Individualism, and weak or no correlation between individual mindfulness and the other dimensions of culture. The results suggest that national culture may be a relevant factor to take into account when doing mindfulness research. This paper further reveals how little attention is put on national culture of mindfulness research subjects. In organizational practice, the research contributes by suggesting a possible link between national culture and knowledge creation and transfer, offering a perspective in which individuals from cultures low on power distance and high on individualism may be more mindful and thus more likely to share and create knowledge. Future research may follow up on this paper with empirical research which would measure the mindfulness of a representative sample of respondents in various cultures and look for causal relationships between national culture and Individual Mindfulness as opposed to merely correlations. This would further contribute to answering the question whether national culture has any impact on individual mindfulness, which despite this research remains open.

Abstract

In light of fiscal austerity and mounting pressure to meet new and emerging social needs, governments across Europe are finding the need to experiment with new methods and approaches to serving citizens. An intermediary, supporting infrastructure is growing around the need to increase the innovation capacity of public sector organizations. This can be seen in the rise of public innovation labs, internal innovation teams/labs and consulting services directed specifically at public innovation. These intermediaries often employ approaches, methods and tools coming from the design field, most often grouped under 'design thinking'. Considering the complex nature of the social problems and the complexity of the socio-technical systems in which they are embedded, design processes must include a wide range of actors in order to gather the necessary knowledge to properly frame and solve the problem. Design processes in these settings often take on a participatory nature, providing a collaborative, and more democratic, approach to problem resolution.

In order to understand better how design is helping governments increase their innovation capacity, a 4-month experimentation, under the SIC H2020 project, was conducted with the Municipality of Turin. The objective was to help them design a new service and in the process overcome organizational barriers to innovation, of which include a highly, siloed organizational structure. While the process confirmed some of the initial hypotheses regarding the potential of co-design in contributing to organizational transformation through the translation of new knowledge, three critical points emerged from the experimentation which provide useful insight for future research and experimentation.

Keywords – codesign, experiential learning, organizational change, public innovation, service design.

Paper type –Practical Paper

1 Introduction

Governments across Europe are facing new challenges, emerging from the changing socio-technical paradigm characterizing the welfare needs of society today, but that is also prompting rapid changes in other sectors. The shift is seen in social needs of a different nature that embody the weaknesses of current social structures and the fragility and vulnerability of certain social groups. These *wicked* (Buchanan, 1992; Eggers & Muoio, 2015; Kolko, 2012) problems can be seen in issues like migration, the long-term unemployed, rising numbers of youth not in education, employment or training (NEET), urban decay in cities and demographic changes including an increasing ageing population accompanied by diminishing fertility rates. The social problems are also accompanied with problems regarding access and awareness, as well as appropriateness of the existing services. These issues owe in part to technological advances which have heightened expectations around service structures and delivery, while also opening up new avenues to address these problems.

In response to the turbulent and fast changing environment in which governments, and not only, operate today, new patterns of production and consumption are arising, characterized by a collaborative nature. This was highlighted by the 2016 World Economic Forum in Davos, that placed the phenomenon under the realm of the fourth industrial revolution, which is distinguished not only by technological innovations but also by their capacity to enhance communication between actors and thereby fuel more collaborative socio-economic models. These new models have heralded a “co-“ paradigm that recognizes strength in collaboration between actors, acknowledging the value held in each as resources and knowledgeable agents in the resolution of challenges and in the production of value. This acknowledgement of the value of external actors as knowledge agents and partners in the production of value is not unique to the public sector but has rather established itself in the private sector which has seen, in parallel development with the technological advances in the 1980s and 90s, the rise of new organizational forms, of which include the network organization and the learning organization (Daft & Lewin, 1993; Senge, 1990). These new forms, in contrast to vertically integrated organizations, work on horizontal relationships of collaboration between different organizations who work to fulfill a shared objective. The value of harnessing the collective knowledge and resources of the entire ecosystem of actors around a specific purpose – social or economic in nature – has empowered new approaches that are re-formulating: (1) how knowledge is created and shared; and (2) the relationship between actors who together work towards transforming the organization through the translation of ideas.

The co-paradigm is changing how governments and citizens interact, leading to the co-responsibility of each actor for the welfare needs of communities (Rizzo et al., 2017). Many governments have started to experiment with new approaches and methods through innovation labs that are either housed inside the organization, span across agencies or are external to the organization and left outside government. Many of these approaches and methods are rooted in design, and specifically service design, as most innovation demands of public sector organizations are service-based. An intermediary, support

system of professionals and service structures is thus growing around public sector innovation, acting as mediating devices between the “on the ground” realities of the social service delivery system and the policies guiding its implementation. This system has exacerbated a gap between the ideation of services and their implementation that is rooted in a long-standing policy of the public sector to commission services to other actors, thereby effectively cutting the learning loop and knowledge feedback systems. In other words, while horizontal subsidiarity is a social value for welfare systems, it requires real collaboration and active participation between actors and by *all* actors.

By gathering and involving actors from the service ecosystem, including citizens and users, in the service design, we posit that co-design processes are valuable towards the management and translation of new knowledge that contribute to the transformation of organizations. The experimentation done with the Municipality of Turin, which we will discuss below, confirmed two interconnected organisational challenges: 1) how to achieve a holistic approach to service delivery; and 2) how to overcome internal resistance and barriers connected with the current organisational culture and structure.

2 Theoretical Framework

2.1 Knowledge Management

The production of knowledge and its management has been deeply covered by literature, especially as the value of knowledge has become more and more a lever of competitive advantage with the emergence of the knowledge economy. Nonaka (1991, 1994) was one of the leaders, asserting the importance of externalizing and combining tacit and explicit knowledge, popularized in his spiral of organizational knowledge creation. From this model, the concept of ‘knowledge as an object’ took form based on the idea that knowledge management systems could externalize tacit knowledge for organizational learning and benefit (Cohendet et al., 1999; Crossan et al., 1999). Walsham (2005), however, notes that these interpretations contradict Polanyi’s (1966) definition of tacit and explicit knowledge which are at the base of Nonaka’s model. The problem, he states, rests on the fact that “the meaning of any objective ‘knowledge’ will always remain the subjective product of the person in whose mind this is constituted, always relationally defined, and therefore [not easily transferrable] to others in a form which may be operationalized to the benefit of the organization” (Thompson & Walsham, 2004, p. 726).

Thompson and Walsham (2004) highlight the importance of context in knowledge processes: “the relationally situated ingredients through which knowing occurs” (p. 735.). Theories regarding the practices of knowing and learning (Blackler, 1995; Blackler et al., 2000) have fueled the emergence of concepts like ‘communities of practice’ (Lave and Wenger 1991; Wenger 1998) or knowledge communities (Barrett et al 2004), which have been found (Anand et al., 2002) to be effective in bringing people together – whether from different organizations, different departments within the same or even across

boundaries – to learn and share knowledge. Markus et al. (2000) similarly demonstrated their efficacy in collaborating in artifact development.

Communities of practice are built around the idea that knowing and doing come hand in hand and occur in situated contexts of practice (Lave & Wenger, 1991). In other words, in contexts in which there is room for repeated interaction. Thus while learning is individual, it happens in relation to others. Tsoukas (2003), in fact, states that: “Tacit knowing cannot be ‘captured’, ‘translated’, or ‘converted’, but only displayed and manifested in what we do. New knowledge comes about not when the tacit becomes explicit, but when our skilled performance is punctuated in new ways through social interaction.” (p.410). This focus on the importance of communication and interaction in learning and the generation of new knowledge is also supported by Kaneko and Imai (1987) who note the special quality of networks to interpret new information which in turn fuel new linkages. Compared to hierarchical organizational forms, information flowing through a network is freer and more open to interpretation, allowing for new meaning and thereby providing a context for learning by doing (Powell, 1990, p. 325).

2.2 Design Thinking and Experiential Learning

Design thinking has gained a lot of attention from practitioners and scholars alike in the last decade for its attributed ability to tackle complex, ‘wicked’ problems. Despite its recent fame, the concept can be traced back to the late 1970s in Bruce Archer’s statement: “there exists a designerly way of thinking and communicating that is both different from scientific and scholarly ways of thinking and communicating, and as powerful as scientific and scholarly methods of enquiry when applied to its own kinds of problems” (Archer, 1979). The systematized process of design thinking has only recently emerged as an innovation formula to help businesses (Brown, 2009) adopt a designerly way of thinking (Cross, 1982) and doing and to push knowledge forward through stages leading to breakthrough innovations and competitive advantage (Martin, 2009). Beyond the business context, it has also taken hold of innovation spaces that span across the sectors with varying objectives, including social ones, as seen in its uptake in social innovation development (Brown & Wyatt, 2010). Design thinking is also heavily used by intermediaries – innovation labs, consultancies and internal innovation teams – to introduce design skills into public sector organizations and help guide innovation processes that also seek to enable cross-agency collaboration (Tönurist et al. 2017). These processes however often encounter difficulties in achieving their goal of embedding an experimental culture in public sector organizations or in co-designing better services from a user-centered perspective, as these practices conflict with the long established organizational practices and cognitive patterns that shape the organizational culture of the public sector, which runs in stark contrast with those found in the assembled design teams (Bason 2010; Tönurist et al. 2017; Elsbach & Stigliani 2018). This speaks to the low absorptive capacity (Cohen and Levinthal, 1990) of these organizations and their need for transformation, which in short, calls for knowledge creation and learning.

Most innovation projects with and within the public sector can be considered small-scale experiments. As such, they can be interpreted not only as a means of providing

better services but also as vehicles for deeper transformation through the iterative cycles of analysis and synthesis of the design process (Owen, 1998). These innovation experiments can thus be considered as learning processes (Owen, 2007; Beckman & Barry, 2007), that can lead to organizational transformation (Rizzo et al., 2017). Overlapping the design process with Kolb's (1984) experiential learning model, based on its four iterative steps: experiencing, reflecting, thinking and acting, creates an interesting design-based learning framework (Beckman & Barry, 2007; Rizzo et al., 2017) for reflective learning.

2.3 Co-Design

In a recent paper, Rizzo et al. (2017), point out that when design thinking is applied to societal challenges it takes on complex, participatory processes, engaging a vast number of actors and stakeholders, which extend the nature of participation to include: "1) the [relationship] between the context of the problem to be addressed and the design of the network that will co-produce the solution; and 2) the [experimentation] of different configurations of that network until [...] a robust partnership is individualised and established [into an] institutional form" (p. 130). These configurations, if designed well, have the knowledge resources needed to frame the problem, not only from the perspective of the user but also of other actors involved in the production of the service (and also consumption, even in secondary forms – e.g. caregivers, family members, etc.). Regarding the second point and as will be evidenced in the findings from the case study, finding the right configuration and institutionalizing the interaction is essential towards successfully implementing the new service in the long run and is one of the larger challenges of the translation of these experiments from "nice insights" to applicable knowledge.

Co-design, defined as "the creativity of designers and people not trained in design working together in the design development process" (Sanders & Stappers, 2008), thus represents a powerful method for creating change in government. By including all actors in the design and development of products and services, it threatens existing power structures (ibidem, p. 9) by dismissing and going beyond the 'expert' mindset. In fact, while user-centered design was widespread in the 1990s in consumer product development, it fails to address the complexity of 21st century problems which requires a shift towards a more egalitarian view on idea sharing and knowledge holding, viewing future users as experts and active co-designers rather than passive participants.

Building on the theoretical framework discussed above, we will explore the building of a new service for the Municipality of Turin, to understand how co-design is able to translate new knowledge and contribute to organizational change through: (1) the engagement of a network of actors; and (2) the translation of knowledge through the design process.

3 Methodology

3.1 Method

This research used a descriptive case study approach, supported by a review of literature, to analyze the co-design process of a new service which integrated services, traditionally coming from different departments. The case study method was chosen as a research frame particularly appropriate for examining a contemporary phenomenon within its real-life context during its evolution, when boundaries are blurred and not so clearly defined (Yin, 2014, p. 13). The authors adopted a qualitative approach with the aim of exploring a real-life, contemporary bounded system (a case) over time, through a detailed and in-depth data collection involving several sources of information (Creswell, 2013, p. 97).

This qualitative approach is useful for answering “how” and “why” questions (Yin, 2009). In this research, the question examined was: “how can design increase the innovation capacity of public sector organizations?”. It is important to acknowledge the limited capacity of a single-entity case study to provide generalizable lessons. The results instead are qualitative and allow for detailed insight and lessons useful for inferring or explaining other similar and parallel happenings (King et al., 1994). Therefore, in order to protect the reliability and validity of the study, it is essential for diverse perspectives to be represented and grounding the research findings in theory and other relevant comparative data (Yin, 2009).

3.2 Data Collection

The primary sources of data for this work were first-hand observations made through action research conducted by the authors, as well as other project reports made available by consortium partners through deliverables and tasks completed under the framework of the SIC H2020 project (GA No. 693883).

4 Case Description

Turin is the third largest Italian city, well known in the world as the hometown of FIAT automobiles. The crisis of the automotive sector that started, in 2007, however, led to the delocalisation of production and to a relevant increase in the level of unemployment. Under these premises, the Municipality prioritized the development of internal capacities to design and deliver innovative services that respond to the needs of citizens affected by the crisis. Most of these services, however, call for an integrated approach, requiring the Municipality to first promote a smoother cooperation among departments, with the aim of overcoming organisational silos. Similar to most Italian Public Administrations, the Municipality of Turin is divided into administrative and institutional structures. The administrative side is further divided into eight offices to service the eight districts, each with its own social service office. These offices are in turn further divided into service specific divisions, creating hierarchical layers of nested silos.

These departments then operate according to an organizational logic that benefits their own division, putting organizational needs first rather than those of the user (who is often in contact with several departments to wholly satisfy their needs). The organizational structure and logic with which it operates thus impedes holistic reasoning and planning of problem resolution and social service provision at the macro-level (e.g. understanding and addressing citywide social needs and allocating resources accordingly) and at the micro-level (e.g. the specific needs of citizens).

Even though, Turin is receiving widespread attention for its experimentation with collaborative models of innovation, as seen in its social innovation program – Torino Social Innovation – the high level of bureaucracy and the strong organizational culture characterizing its infrastructure, disincentivizes civil servants to take part in experimentation and organisational innovation, which is seen as an ‘extra’ activity. Understanding how to foster communication between departments and enable reflective processes around the user of their services was pivotal towards the improvement not only of the quality of social services but also their efficacy.

The design of the new services was conducted with the support of design researchers from the Politecnico di Milano within the SIC H2020 project, who saw this as an opportunity to introduce new knowledge and foster cross-agency and cross-sector cooperation, through a service co-design process to develop innovative solutions. The challenge was to combine departments dedicated to employment, social housing, education, and support to disadvantaged families, to design an integrated service, which supports citizens and families at risk of losing their home, by making them economically active. The experimentation allowed 20 employees from different divisions of the Municipality of Turin to take part for 4 months (December 2016 - March 2017) in a service co-design loop, structured in four phases that overlap an experiential learning loop (Owen, 2007; Beckman & Barry, 2007): i) analysis of the problem; ii) problem reframing and envisioning of new solutions; iii) service co-design; and iv) prototyping/experimenting.

The main outcome of the experimentation was a new, integrated service called “TO-HOME”, in which employees from the housing, employment and social care departments could collaborate and work together on social service delivery with increased awareness of the needs and perspectives of their users. The aim of the service is to create a “one-stop-shop” for vulnerable groups at risk of eviction by integrating the knowledge and experience of different departments tackling different facets of the same problem, often starting with the loss of employment. The new service allows for new relationships and collaborations to emerge within the Municipality (between employees from different departments) and with external actors coming from the third sector, civil society or the private sector, who are also involved in the same space. This allows for a new network of actors from across agencies and sectors to form and build experience and knowledge around the problem.

5 Critical Issues and Reflections

The analysis of the experimentation, conducted through the case study methodology, shed light on a few critical issues connected with the embedding of service design knowledge and processes in the culture of a public organisation. The first issue of which is the difficulty of the employees to assume the point of view of the end users as an alternative perspective from which to analyse the current services and design new ones. In our perspective, the deep knowledge of the existing procedures and constraints acted as a barrier, which made the participants very adept at identifying organisational or systemic constraints (e.g. budget and other required resources, service governance, legal framework, etc.), but at the same time quite unable to find ways of spotting alternative solutions by adopting a more user-centric attitude.

A second issue that clearly emerged, whose solution was indeed one of the objectives of the experimentation, is the employees' difficulty in overcoming internal resistance to change and barriers bound to the current organisational structure, based on a divisional model that harks back to the idea of creating efficiency through specialisation. This model is actually quite typical not only in public administrations, but also in all those situations where efficiency and the exploitation of existing resources tend to prevail over exploration and the creation of new knowledge within the organisation (March, 1991). In this respect, introducing service co-design processes has been a way to foster organisational transformation (Sangiorgi, 2011), combining the exploitation of internal knowledge and vertical competences with cross-sectoral cooperation. In our view, this strongly confirms the idea that the co-design approach is not only a matter of introducing a user-centred perspective, but also a wider human-centred one, which recognises the importance of employees as resources to be valorised in service design (Deserti & Rizzo, 2011).

A third issue faced during the experimentation is the difficulty of the employees to reconnect the design of the new service with its real implementation. In particular, during the design of the service blueprint we observed that the participants were unable to come up with effective solutions to four main problems, which could ultimately affect the delivery of the new service:

- how to individualise the competences of the operators that should deliver the new service;
- how to make the service visible and how to communicate it to the end users;
- how to obtain the availability of enough houses to accommodate fragile families; and
- how to engage the users of the services in co-production mechanisms.

A coherent explanation of the difficulty to bridge ideation and implementation of new services could be linked with the policy of outsourcing service implementation and delivery to intermediaries. Extensive externalisation of the delivery of services may actually prevent an organisation from learning from the interaction with users, and better designing new services.

6 Conclusions

Despite the issues mentioned above, the co-design process did see positive developments beyond the creation of the new integrated service. The process allowed for new relationships to be formed and an awareness to be created around the responsibilities and tasks of other departments. The frequent interaction over the four-month period of time also allowed for repetitive interactions, fostering a collaborative spirit around the project. However, if these innovative projects want to go beyond experimentation and create organizational change, the issues explored above must be addressed. These problems are in fact symptoms of a wider cultural problem that hinders innovation in the public sector and is a product of current patterns of operation.

While co-design offers potential opportunities for breaking down these barriers by introducing civil servants to new tools and methods, more work needs to be done to connect the different actors of the service network, particularly the users. Joint collaboration of citizens in service design in both the planning and production could lead to more citizen-centered services. This confirms what is found in literature regarding designing ‘with’ rather than ‘for’ citizens (Junginger, 2014) and is what was missing in the Turin experimentation. Lastly, moving beyond design thinking as an independent process and focusing also on the system of knowledge, competences and skills needed to develop services, embedding a culture of design (Deserti & Rizzo, 2014) in the network of actors could offer more promise in transforming public sector organizations and instilling a culture of experimentation. Further research and experimentation should be done in this direction.

Abstract

Technology transfer is one of the three dimensions of the university's third mission, described as a process that allows an effective exchange of knowledge from the producer to the user. Indeed, while at the beginning of their existence universities were not concerned with social and economic issues, today they are completely involved in the development of society.

In this sense, Italian higher education institutions are now exploiting several instruments, in order to better connect themselves to their internal and external stakeholders, as well as to contribute to the common good.

The aim of this paper is to assess if and how this trend is part of the strategic planning process of each institution and of the national university system as a whole. To do so, this paper will analyze the mission statements disclosed by the 97 Italian universities, in order to individuate what values they communicate, as well as to evaluate their interest in transferring research results for social development.

The findings suggest that in about one-third of the institutions analyzed, this "new" role seems to be their primary task and it's regarded as a means to better address the traditional missions of teaching and research. This is especially true for state universities, while non-state universities appears to be more focused only on teaching activities.

Future research will aim at identifying whether there is a correspondence between what is officially declared and the actual engagement of the institutions to the development and enhancement of the common good.

Keywords – University, Knowledge, Technology Transfer, Social Development.

Paper type – Academic Research Paper

1 Introduction

In a time when higher education institutions, previously perceived as “ivory towers” (Etzkowitz, 1998), are called to share the results of their research with the society, knowledge transfer can represent one of the activities or instruments through which universities can contribute to social and economic development. Indeed, even if universities are commonly accepted as generators of knowledge, they have changed their role over the past years and now they appear more engaged and connected with the society.

In this sense, knowledge transfer is one of the three dimensions of the universities’ third mission, seen as an exchange of knowledge between academia and other actors, both public and private, in order to provide solutions to societal issues. It also represents an opportunity for universities, that start to open themselves to community and to perceive the results of their research as “marketable products” (Power and McDougall, 2005). According to Clark (1998), higher education institutions start to act in an “entrepreneurial” way and to appear more business-like, by adopting a strategic behavior and by building connections with the external environment (society, institutions, the economy). Thus, the third mission underlines universities’ ability to connect themselves with their external environment, to understand social needs and expectations, and to offer appropriate answers, in a continuous interchange. A third mission that, along with teaching and research, seems to summarize this new and wider role for universities.

In this context, where higher education institutions struggle for competitiveness and international visibility, strategic planning becomes crucial. Mission statements represent the starting point in this process, by summarizing the universities’ identity and the objectives that they want to achieve. In this sense, Drucker (1973) sees a mission statement as a vital document for every kind of organization (included universities), that can be used by every institution in order to distinguish itself from competitors. Commonly, a university’s mission statement is based on the three basic university’s functions, but there are several factors that can influence the content of these official declarations, represented by the influence and the expectations of governments and markets, or the historical and cultural background of the specific institution.

Based on these premises, this paper answers the following research questions: do Italian higher education institutions disclose their mission statements? Does their content reflect the new role of universities in knowledge transfer and sharing?

This work is structured as follows. In Section 2, an extended literature review on knowledge transfer and strategic planning in higher education institutions is provided. In Section 3, the methodology adopted in examining results is described. Findings are reported in Section 4. Finally, Section 5 is dedicated to Conclusions.

2 A wider role for universities: a literature review

In a context where education is perceived as one of the solution to many of today's problems, universities, with the results of their activities, are able to influence the economic wellbeing and the innovative potential of society.

In this sense, knowledge transfer is seen as the activity that allows an effective exchange of knowledge from the producer to the user (Wellsandt and Thoben, 2016). In the academic literature, this topic has been studied from different points of view. Gibson and Rogers (1994) focus on the process of "technology transfer", explained as the application of information (in the form of a technological innovation) into use, without considering its relationship dimension. On the other side, according to Feller *et al.* (1987), research and technology transfer represents a set of interactive relationships, able to connect basic or disciplinary research, applied research, development, diffusion, adaptation, and dissemination, by converging into an overall technology delivery system. Levin (1993) considers technology transfer as a socio-technical learning and development process, by adding a social dimension to the definition. Power and McDougall (2005) show the marketable aspects of technology transfer, seen as that process through which the new technologies introduced by universities start to be commercialized. Finally, Gibbons *et al.* (1994) explain an innovative way to intend the knowledge exchange, represented by a transition from "Mode 1" to "Mode 2": from a traditional science with no immediate outcomes for society (Mode 1), knowledge production would be represented by a system open to those who use such science (Mode 2). So, while teaching and research allow to preserve, create, apply, and disseminate knowledge, knowledge transfer belongs to the new role of university and refers to its transfer and application to the community (UNESCO Workshop, 2007).

In a knowledge-based society, universities are called to become more "entrepreneurial", to act as a natural incubator in order to transform ideas into social and economic entrepreneurial initiatives (Kirby *et al.*, 2011). They have re-conceptualized their role and now appear as important institutional actors in order to generate new value in a regional or national context (Mowery and Sampat, 2005). This is in line with the Triple Helix Model, introduced by Etzkowitz and Leydesdorff (1995), that recognizes a primary and innovative role of universities in a knowledge-based society.

Thus, the role of universities has evolved over time and Uyarra (2010) identifies five different models to explain this evolution. At the beginning, universities were seen as playing a "knowledge factory" role (Youtihe and Shapire, 2008), able to transform research inputs into social and economic outputs. Then, around the 1980s, universities were called to look for new opportunities in order to face reductions in public funds and support their research; in this sense, linkages with corporations became very important for both, the academic and the economic system (Géiger and Sà, 2008). The model of "entrepreneurial university" (Etzkowitz, 2000; Clark, 2001; Siegel *et al.*, 2007), instead, underlines the institutionalization of technology transfer in universities. Then, other and more recent approaches emphasize the role of universities in networks with firms and other kinds of organizations (Braczyk *et al.*, 1998; Koschatzky and Sternberg, 2000;

Asheim and Coenen, 2005). The impact generated by universities in a specific context would depend on their abilities to mobilize stakeholders for innovation; in this sense, they would play a wider role, that goes beyond the simple capitalization and dissemination of knowledge (Gunasekara, 2006).

Finally, in order to describe the new and more adaptive role for universities, Chatterton and Goddard (2000) use the term “engaged university”, by analyzing their official declarations. According to them, an engaged university declares, in its mission, a specific interest in the regional context, with the aim of building coalitions with state and non-state actors. The adaptation would refer to the university’s ability of considering regional needs and providing a response; thus, higher education institutions would contribute to the social, cultural and environmental development. There are several barriers to the effectiveness of this university engagement, that could be represented by inadequate funding and incentives to research, or the limited capacity of other actors to get involved with higher education (Gunasekara, 2006). In several cases, limitations could regard also the characteristics of universities, such as their age (modern universities are more focused on the social and economic development), their location (newer institutions are more geographically dispersed), and the type and the degree of collaboration (Boucher *et al.*, 2003; Kitagawa, 2004; May and Perry, 2006). In this sense, by considering their mission statements and discourses, universities show different approaches to knowledge transfer, linked to their different levels of interest in contributing to the social and economic development. Indeed, several universities seem fully committed to this new role, others look at this as a complementary part of their mission and others as a small additional activity, separated from their core mission.

When education started to be considered as a public good (Nedbalova *et al.*, 2014), higher education institutions start to develop a strategy, in order to enhance the entrepreneurial mindset and to expand interactions with key stakeholders. In a globalized society, knowledge, research, and innovation are considered the most important resources and universities have to adopt several business practices (Gibbs and Murphy, 2009) and to define the guidelines to follow. In this sense, a mission statement represents an organization’s key document, in which the organization identifies its business objectives, its values, its long term objectives, the essential business activities, and the features in order to be distinguished from its competitors (Drucker, 1963).

The definition of a mission statement represents a widespread practice also for universities, especially in the United States, while its introduction in European higher education institutions has produced less systematic results.

Historically, universities were expected to serve three different missions: teaching, scientific research and a sort of “public service”, the transmission of culture, in order to foster the development of society (Perkins, 1972; Scott, 2006; Montesinos *et al.*, 2008).

Different authors have explored the content of universities’ mission statements, by identifying declarations about their status and market position, their intention or their leadership style (Mackay *et al.*, 1995; Davies and Glaister, 1996). Connell and Galasinski (1998), instead, aim to understand how universities’ statements could represent a paradigm change in their intentions, by adopting a more “business-like” perspective.

The impact exercised by the government and the market could influence the content of mission statements (James and Huisman, 2009), but also the history (Davies and Glaister, 1996; Kuenssberg 2011; Ozdem, 2011; Kosmutzky and Krucken, 2015; Oertel and Soll, 2017; Seeber *et al.*, 2017) and its cultural background (Efe and Ozer, 2015) could influence the essence of universities' activities.

In Germany there are several and notable studies focused on the content of universities official declarations (Hladchenko, 2013; Kosmutzky and Krucken, 2015; Jungblut and Jungblut, 2017). Less studies on this topic have been done about the Irish context (Lillisa and Lynch, 2014), the Ukrainian one (Hladchenko, 2016), and the Spanish one (Palomeras Montero *et al.*, 2012). In Italy the only studies about the university's mission content are from Giusepponi and Tavoletti (2015).

3 Methodology

As previously mentioned, the aim of this work is, first of all, to analyze the extent to which Italian higher education institutions declare in their official documents their mission statements; then, to examine their content; finally, to investigate whether mission statements include considerations on the "new" role of universities with regards to knowledge transfer and sharing.

To do so, the research was focused on the Italian university system, which comprises 97 higher education institutions. Among these, 67 are state universities and 30 are non-state universities. The term "non-state" does not mean "private": indeed, among the 30 non-state universities, 8 do not belong to the State but to other public entities, while the other 22 are effectively "private". Among the non-state institutions, 3 are characterized by a religious orientation, while 11 are online universities.

Data collection on universities' mission statements was realized between January and March 2019, mainly from the institution's strategic plan or statute, but also from the official website. For most institutions, the mission is included in a specific section of the strategic plan, while in a few cases the mission statement is not disclosed in any document.

Mission statements are used to show the reason for the university's existence, by answering to questions such as "Who are we?"; "What we do?"; and "Why are we here?". Several authors have studied the content of these statements by following different qualitative approaches. The first were Mackay, Scott and Smitt (1995), who combined a discourse analysis approach (Faucault, 1982) with a document-based case studies method (Yin, 2003), in order to examine the 101 official declarations of the German universities. Lillisa and Lynch (2014) adopted a documentary analysis approach, based on the strategic plans and the institutional review reports, combined with interviews with senior managers in charge with strategic planning, in order to define the current situation about strategic planning in the Irish education system. With regards to the Italian context, Giusepponi and Tavoletti (2015) studied the strategic orientation of higher education institutions by conducting interviews.

It was decided to adopt the same approach used by Arias-Coello *et al.* (2018), who performed a documentary analysis with specific reference to the Spanish context, based on the following steps. Firstly, the research aims to individuate the major purposes included in mission statements (teaching, research and third mission) and focus on the specific messages related to the knowledge transfer dimension. At the end, findings will be interpreted through a qualitative method.

4 Preliminary Findings

In the sample, composed of 97 institutions, 21 do not disclose a specific and official mission statement. Their intentions and objectives emerge from what they are used to sharing through their strategic plans, their websites or other means of communication, such as the statute, interviews or the declaration of a vision statement. In particular, we can note that 8 Italian universities share their intentions through their strategic plans, without mentioning the word “mission”; they are all state universities, except one. Then, another 5 universities use their statutes in order to communicate what we consider as their mission (all of them are state universities); only 4 universities identify their activities by exploiting their websites and they are all non-state universities. Only one university (non-state) discloses its mission through a declaration of its Dean, reported in the website; in only one university we cannot find, neither directly nor indirectly, any reference to its strategic orientation in terms of mission. Another university does not declare anything, but every department shows its specific mission in its website; another non-state university discloses its objectives in the performance plan; finally, only another university reports its mission in the vision statement.

All the mission statements can be compared on the basis of their different length and the scope declared. The shortest declaration counts only five words, while the longest one is about 423 words.

As previously mentioned, the main scope pursued by the Italian institutions are represented by teaching, research and third mission, with some universities declaring their engagement in all the three “tasks”, while others appearing more focused on only one or two of them. Out of all the 97, 25 universities declare to pursue all the three missions. The most of them are state universities, only 4 are non-state universities.

For 33 institutions, instead, the third mission is considered as the priority role that any university has to play in the society. Almost all of the institutions in this category are characterized by being state universities, with only 2 non-state universities. The engagement in third mission, for 17 of them, is declined in conducting technology/knowledge transfer activities; their aim is to contribute to the social and economic development by sharing the results of their research and this is also written in their mission statements. The other ones are focused on the third mission, without directly referring to the knowledge transfer, but in a wider manner: they want to offer help to society by “fostering the social wellbeing”, or the “civil and economic development”, by “playing as a social operator”, by “building linkages with the external environment”, by

considering teaching and research as “means in order to achieve a knowledge-based society”.

10 universities, according to the tradition, continue to consider teaching as their first and principal mission; 6 of them are non-state universities and this leads to the consideration that there could be a correlation between the public nature of university and its interest in social and economic progress. Some of them underline their effort in order to ensure lifelong learning and distance learning experiences for their students, by exploiting new technology devices. One of them is focused on a specific target, by offering lifelong learning experiences only to teachers.

Then, there is one institutions that bases its mission on teaching, but, at the same time, shows its interest in technology transfer activities (patents, start-ups, and spin-offs). Another 3 universities, instead, present themselves as online universities, they are all non-state universities, with the aim of facilitating the access to education for their students.

14 are the institutions that declare their engagement in the two missions of teaching and research, without including third mission references in their official statements. Out of them, 7 are non-state universities and 1 is engaged in providing postgraduate education.

3 institutions exploit their missions in order to identify and present themselves, by introducing their nature and their history or the values through which they intend to operate.

Only 2 universities declare a pursuit of an international vocation in carrying out their activities of teaching, research, and integration with community.

The Catholic University inserts “religious messages” in its mission: Christianity is shown as a means to solve societal issues. There is another one university that distinguishes itself from the competitors by focusing its efforts on teaching and research activities, even if only in the sports field. Finally, there are other two universities with a peculiar mission: one of them, characterized as a state university, declares its engagement in teaching, research and building linkages with external actors, with a specific interest in wellbeing, for citizens and for the ecosystem; the last one, instead, is a higher education school and declares, through its mission, an attention to the international PhD students and to the social and economic development.

5 Conclusions

In a context where higher education institutions are commonly accepted as playing a teaching role, they have been called to take into account of other two missions, represented by the research activity and a sort of engagement in society, known as the third mission (Uyarra, 2010).

According to this new third mission perspective, universities, traditionally concerned with addressing the results of their research only to an élite of people, started to perceive their activities as being useful for the society, capable of providing solutions to common issues and fostering economic and social growth. In this sense, knowledge creation is not enough, but universities have to transfer and share this new knowledge. In several cases

they also started to commercialize their “outputs”, by operating in an “entrepreneurial” way (Etzkowitz, 2000; Clark, 2001; Siegel *et al.*, 2007). In order to cope with these new challenges, higher education institutions need a strategic orientation, by defining and communicating their mission statements.

After an extended literature review on knowledge transfer and the adoption of strategy in higher education, the aim of this study was to conduct a documentary analysis on the content of the Italian universities’ official mission declarations, in relation to understand the role they played in the society, by individuating their actual interest in knowledge transfer.

The analysis was not easy, as the aim was to retrace all the Italian universities’ declarations in terms of mission, but also to exploit several sources: some of them communicate their intentions and objectives in their strategic plans (not necessary in a specific section identified as “mission”), others in their statutes or performance plans, while others prefer to exploit their official websites. Two of them, instead, had decided not to communicate anything about their activities.

On the basis of available information, the research findings suggest that about the 33% of the Italian universities considers third mission as the primary task to assume: it seems more important than teaching and research, considered as a means to realize it. In particular, in the sample of 97 institutions, results showed that 17 universities were engaged in knowledge transfer activities, by directly sharing this interest in their mission declarations.

The Italian higher education system is characterized by the presence of state and non-state universities: the research can conclude that the public nature of the institution suggests a deeper interest in third mission (in all its manifestations), while non-state universities result more focused only on teaching activities. The practical implication of this work concerns the importance of stimulating a new conception of knowledge, seen as a powerful good, a commons, for social development.

Limitations concern the preliminary work, based on what is disclosed by Italian higher education institutions. It requires further research, aimed at verifying a correspondence between what universities are used to communicate and how they actually operate in the society. In this sense, the engagement in third mission could be exploited by higher education institutions only to improve their visibility and their position in international rankings. In terms of future perspectives, the aim will be to identify best practices in order to ensure first a significant correlation between universities declarations and their activities, then an effective contribution (in terms of knowledge transfer) for social, cultural and economic development.

Abstract

Commons is a general term that refers to a resource shared by a group of people. Over the years scholars have identified two generations of commons. The first generation of commons was about sharing of physical things; the second one is about intangible commons pool resources such as science and culture. These generally can be recognized as "rights" (Hess 2008). Among the various New Commons sectors there is medical and health. In the perspective of guaranteeing the right of Health, the "Access to Healthcare" could be considered as a New Commons provided by worldwide National Healthcare Systems (NHS).

However, healthcare sector is characterised by plenty of stakeholders with myriad, often, conflicting goals. The value-based approach (Porte, 2010) attempts to introduce a new universal language in healthcare management around the value for the patient that reconcile all stakeholders' interest. The goal of this approach is to improve the outcome and increase the number of treatments. This aim is very difficult to be enriched for rural residents; when patients live in remote areas, providing them with valuable medical care can be considered a hard challenge for the NHS, which has to be addressed also by the employment of new healthcare strategies and technologies.

Defined as "a new healthcare delivery process provided when patient and professional are not physically in the same place" (Italian Ministry of Health, 2014), telemedicine could be seen as an answer to this challenge.

Accordingly, this study aims at discovering if telemedicine employment can be effectively considered as a successful strategy to improve healthcare in location far from specialized hospital, enhancing the New Commons "Access to care".

A statistical-based narrative review of the literature was conducted in the field of telemedicine, with the aim to understand which experiences of telemedicine applications have got successful results as support of healthcare delivering in rural locations.

With regards to rural and remote areas, several Authors recognized telemedicine-based strategies as a method to facilitate the access to healthcare in different medical disciplines. In particular, many studies highlight that telemedicine improves patient care by increasing the capacity of the rural clinician to manage patient locally, minimising time away to support networks and reducing unnecessary transfers. Telemedicine could also be considered a cost-effective method whose outcomes remain similar (if not better) in quality to "staffed" services, whose infrastructural costs could be easily paid-back.

Keywords – Commons, Access to Healthcare, Telemedicine, Value-based Healthcare, Rural Areas.

Paper type – Academic Research Paper

1 Introduction

Commons are recognized as the cultural and natural resources accessible to all members of society. From physical and social dimensions, categories of commons have expanded to immaterial objects such as knowledge, intellectual property and software, namely New Commons (NC) (Hess 2008), which generally can be recognized as "rights".

In this perspective, guaranteeing the right of "Access to Healthcare to the population could be considered as a NC provided by worldwide National Healthcare Systems (NHS), "In any field, improving performance and accountability depends on having a shared goal that unites the interest and activities of all stakeholders" (Porter 2010, p. 2477); coherently, the rise of New Public Governance emphasizes the relevance of service processes toward the achievement of ever better outcomes, based on the improvement of inter-organisational relationships and the governance of processes (Osborne, 2006). Therefore, public sector has been affected by a higher necessity to identify innovative managerial and operational models aimed at public Value Creation.

In Healthcare, value is defined as the health outcome achieved per dollar spent. The measure of value encompasses all services and activities that contribute to determine the capability to meet patients' needs; however, this is still often unmeasured and misunderstood. Thus, there is an ever-higher need for healthcare strategies that could support not only the provision of the service but also the assessment of its value around the patient.

The value created for patients is usually measured for group of people with similar needs (medical condition, epidemiology, comorbidity). Therefore, what happens when patients share the geographical condition of living in a rural area? Delivering valuable healthcare in rural areas (du Toit, 2017, Moffat and Eley, 2010) is one of the higher challenges of NHS, and to get this goal, a possible strategy is the employment of

telemedicine infrastructure. Telemedicine is defined as "a new healthcare delivery process provided when patient and professional are not physically in the same place" (Italian Ministry of Health 2014). Based on ICT infrastructure, "it brings a safe biomedical data & information transmission in the form of texts, sounds, images, or other forms necessary for prevention, diagnosis, treatment and follow-up of patients" (Italian Ministry of Health 2014).

Starting from these preconditions, the challenge of this paper is to understand how telemedicine approaches enhance the New Commons of "Access to Healthcare" in rural areas, in coherence with the creation of Value in Health principals.

To achieve its purpose, this paper follows this outline: after this brief introduction, the second section reports a background addressed to the issues of commons, new commons, and their relationship with telemedicine in the lens of value-based healthcare principles; the third section explains the methodology used in this study. The fourth presents findings of the inquiry. The last section discusses results obtained and provides some consideration about the employment of telemedicine as an effective strategy for enhancing access to healthcare in remote locations.

2 Background

Commons is a general term that refers to a resource shared by a group of people. In a common, the resource could be both small and serve a tiny group and it can be community-level or it can extend to international and global level (Hess, Ostrom 2007).

Accordingly, commons are recognized as the cultural and natural resources accessible to all members of society. Held in common and not owned privately, these resources could be managed for individual and collective benefit from groups of people (communities, user groups) (Ostrom 1999, Basu et al. 2017). Commons analysts have found it suitable to distinguish between a common as a resource or resource system and a commons as a property-rights regime (Hess Ostrom 2007) In particular, over the years scholars have identified two generations of commons. The first generation of commons was about sharing of physical things as natural resources (e.g. forester, fisheries, grazing pastures etc.). The second generation is about intangible commons pool resources such as science and culture. Particularly due to a second generation of commons studies the categories of commons have extended to immaterial object such as knowledge, intellectual property and software, namely New Commons (NC) (Hess 2008). These generally can be recognized as "rights". For these reasons, analysing the new commons it is more difficult because it means analysing commons based on intangible 'ideas' rather than commons of tangible 'things' (first generation of commons) (Allen et al 2016). However, the "new commons" alternative is interesting both because of its distributional implications and because of its potential for raising the rate of innovation and value creation. Moreover, the new commons pay specific attention to the right to "distribute" than the right to "exclude". However, the previous commons shared property rights and they do not create a problem of overuse (Evans 2005). There are many different ways that new commons evolve or come into being. Some of them evolve from new technologies that have enabled the capture of previously uncapturable public goods, such as the

Internet, genetic data, outer space, deep seas, and the electromagnetic spectrum (Hesse 2008). Hesse (2008) identified the various new commons sectors, sub-sectors, and representative collective-action communities involved in new commons. One of these sectors is medical and health. In this field, referring to commons and to the right to distribution means referring to the access to healthcare that is the right to access to all medical services and sanitation. Access to health care should be universal, guaranteed for all on an equitable basis.

Healthcare should be affordable and comprehensive for everyone, and physically accessible where and when needed. Accordingly, if the new commons are related to the right of distribution and not to the right of exclusion, improve access to healthcare means improve a new common. Therefore, in the perspective of guaranteeing the right of Health to the population by worldwide National Healthcare Systems (NHS), the “Access to Healthcare” could be considered as a New Commons.

In order to manage complexity of healthcare field, a deep analysis of stakeholder involvement within the different processes performed is requested. This sector, indeed, is characterised by plenty of stakeholders with countless and often conflicting goals. In particular, as underlined by Porter in 2010, the lack of clarity about shared goals was the main reason of slowing down the performance improvement process in healthcare; moreover, the constant growth of the population's health needs has requested a more “patient-oriented” healthcare management. Hence, both for public and private healthcare providers, the traditional approach focused on staff needs over users’ needs becomes no longer acceptable (Fulop et al. 2003).

Value based healthcare represents an advancement of the Total Quality Management (TQM). This is aimed to enhance performance by increasing the quality of services (Deming, 1994). In order to face limitations for patients about choice and access to care (Porter and Teisberg, 2004) caused by financial restrictions, value-based healthcare principles were introduced by Porter and Teisberg in 2006 in United States. Authors’ goal was to introduce an “universal language” for healthcare management, designed around the value for the patient.

Starting from previous theories (Porter, 1991; Porter, 1997), value-based logic has involved an intellectual change: shifting from a healthcare based on volume and intensity of services, to a “patient-centric” healthcare based on value created for the consumer of services. This logic has a two fold aim: improving the outcome and increasing the number of treatments. However, to be practically feasible, this approach implicates a radical modification of the traditional paradigm of healthcare: moving from a vertical “organizational-centric” approach in treating diseases, to a horizontal one tailored on the patient expectations. Thus, this implicates that management should move the attention on process of cares rather than on operational structure.

Therefore, distinguished by similar primary care needs (Kaplan and Porter, 2011), the patient population becomes the unit of analysis of healthcare policy. For the managerial assignments, this implicates the necessity to analyse the omni-comprehensive cycle of cares (Porter, 2010), rather than an individual phase, clinical episode, or single technology for treating diseases.

Accordingly, in the lens of this logic, the concept of Value in Health encompasses all the following variables:

- access to services,
- profitability,
- quality,
- cost,
- safety,
- patient-centeredness,
- patient-satisfaction.

Thus, the achievement of a high value for patients should be the purpose that drives the delivery of healthcare services. Patients, payers, providers, and suppliers can all benefit if the value improve while the economic sustainability of the healthcare system increases (Porter, 2010). Consequently, the achievement of this goal could be considered as the most effective way to gather the interests of all stakeholders involved.

In particular, the Value in Health equation can be expressed as the ratio between outcomes and costs: *outcomes* are multidimensional and related to specific-condition; *cost* refers to the total amount of resource employed for the full cycle of care for the patient's medical condition (and not for the mere individual service). Very often, cost reduction regardless of the outcomes obtained is dangerous and self-defeating; it could lead to false "savings" by limiting effective care for patients (Porter 2010). Accordingly, to reduce cost, the best approach is often to "spend on more service to reduce the need for others" (Porter 2010).

Healthcare delivery in rural and remote areas implicates a choice among two alternative strategies:

- 1) "moving" patients to hospital;
- 2) "moving" hospital to patients.

It is clear that this kind of choice is valid only for those "soft" healthcare services (e.g: diagnosis, monitoring, follow-up, specialized medical consultation, etc), but often the second strategy (patient-centric) is the most effective, also thanks to the availability of new technologies which foster new operational approaches.

Telemedicine is "the use of information and communication technology to provide health care services to individuals who are some distance from the health care provider" (Roine et al, 2001). Many experiences of telemedicine employment have shown improvement of outcomes for patients together with cost containment (Burri et al. 2011; Calò et al. 2013; Hasan and Paul, 2011). One of the major advantages of telemedicine over conventional care is the potential for increased access to medical care for population that experience at level of isolation (eg. prisoner, person working at sea or in war zone) (Norton et al, 1997). Accordingly, many Authors have demonstrated the positive impact of telemedicine strategies in healthcare delivery in remote areas, both for early diagnosis and follow-up. Moffat and Eley, in 2010, have provided literature background with evidences about four areas of benefit of telehealth service for Australian population who live in remote location: i) patients and family, ii) medical provider, iii) participating hospital, iv) society. In particular, this study emphasized that telemedicine strategy could

have a positive impact on two on-going issues: the poorer health status of rural areas, and crisis in the rural health force. In accordance with these endpoints, Du Tuit et al (2017) have showed that a HUB-SPOKES model to delivery healthcare in remote areas is cost-effective. Authors underlined, by a literature review, that the design of healthcare policy based on a clear separation of tasks between high specialized healthcare centre (HUB) and rural clinics (SPOKE), interconnected by telemedicine infrastructures, has excellent impact on the management of rural and remote emergency departments.

Therefore, on the basis of these examples, this study aims at discover if telemedicine employment can be effectively considered as a successful strategy to improve healthcare in location far from specialized hospital, enhancing the New Commons “Access to care”.

3 Methodology

A literature review was conducted in the field of telemedicine in order to understand how this approach improve access to healthcare in rural areas creating value for the patients. Scopus was the database used for conducting the research. The keywords used for the whole inquire are contained in the following table 1.

Table 1 Table 1. Keywords used for the enquiry.

1st Keyword		2nd Keyword
<i>“e-health”</i> or <i>“ehealth”</i> or <i>“telecare”</i> or <i>“telemedicine”</i> or <i>“telehealth”</i> or <i>“telemonitoring”</i> or <i>“telepractice”</i> or <i>“telenursing”</i>	AND	<i>“rural areas”</i> or <i>“rural communities”</i> or <i>“rural population”</i>

Source: Authors’ illustration

Keywords contained in the same column are alternative within them. Papers that containing at least one keyword belonging to each column within title and/or abstract and/or keywords was considered relevant for this study. Other search criteria used to define the selection of papers are the following:

- Language: were selected only studies published in English;
- Document type: were considered only peer-reviewed articles. The other categories of study from Scopus as Conference papers, editorials, book chapters, articles in press, conference proceedings and letters were excluded.

All articles published from 1976 to March 2019 were considered. After the selection of data set a descriptive analysis of final sample was conducted. In particular, there have

been analysed the following dimensions: i) papers/years; ii) journals; iii) countries; iv) research areas.

Moreover, another dataset was defined composed by the twenty most cited papers of the previous sample; then from the application of the snowballing technique, four articles were added. On all these studies, was conducted a conceptual analyses of the papers.

4 Results

At the beginning of the process, 2263 papers were identified; then, by following the search criteria the final sample is composed of 1624 studies. In particular, 1402 are article and 222 literature reviews. The following figure (figure 1) shows the number of Paper per Year, there is a growing interest in the last ten years.

Figure 3: Documents by country

Several subject areas are involved. The following figure (figure 4) represents the documents divided by subject area involved.

Source: Authors' elaboration from Scopus

Figure 4: Documents by subject area

After reading of the twenty most cited papers four papers were excluded as they were not considered consistent with the research question of this work. In table 2 all documents considered relevant have been reported. Number of citations lists them. The timeline of papers selected for conceptual analysis is very huge; they are published from 1992 (Preston et al.) to 2017 (du Toit et al.).

4 Discussion and conclusion

The analysis of the sample by the publication year discloses an even-higher interest about the topic from 2009 until now. The increasing number of studies might be caused by the scientific advancement and the subsequent increasing of new technologies availability. The three most relevant journals are in the field of telemedicine. Probably this is due to the complexity and the extent of the topic or for the specific target of audience. The most productive Country is the USA, followed by Australia and Canada.

The interest of these countries might be due to their land morphology. Regarding the extent of subject areas involved it is very heterogeneous due to different fields of studies that telemedicine embraces for his delivery (e.g. medical, social science, engineering etc.).

However, economic aspects of telemedicine in rural areas are still understudied. The analysis of subjects covered by the sample highlighted a prevalence of neurological and emergency disciplines: telemedicine allows a fast exchange of information that can be critical in emergencies and neurological emergencies like a stroke.

Regarding the condition of rural residences, distance to healthcare provider was recognized as a significant barrier to healthcare access in the U.S. in the 19th century (Guiagliardo 2004). Accordingly, the people who live in remote areas are more disadvantaged to get the healthcare they need. Rural residents often experience what Hess (2005) calls "rural penalty". Indeed, in his study, about a rural telestroke network, he stressed the condition of urban and suburban hospitals that are lacking for acute stroke care (Hess 2005). As solution to this problem of access to healthcare for rural residents, Ricketts identified telemedicine. This has been described as the single most important tool aimed at flattening the difference in available resources between rural and urban areas (Ricketts 2000). Several Authors, in different medical disciplines, recognized telemedicine strategies as a tool to facilitate the access to healthcare, especially in rural and remote areas. For example, Griffiths (2007) observed their function in delivery of

mental health assistance; in this case, telehealth represented an efficient alternative for the delivery of help for depression in rural regions and for exceeding of a strong culture of self-reliance of rural residents. Burdea (2003) identified teleconsultation as a provider of expertise from specialist centre such as university hospital in rehabilitation program. In this case, telemedicine allows the access to a better care and improve the outcome. This also happens in neurology field; all Authors underlined how telehealth improves stroke care in rural areas and bring stroke expertise to rural community hospitals (Wiborg 2003; Wang 2003; Kleindorfer 2009). In accordance, the same results came from the literature reviews analysed (Moffatt 2010; Wade 2010). In particular, the Authors stated that telemedicine is utilised in order to improve accessibility or timeliness of service delivery and it may contribute to decreasing the urban–rural health disparities.

Moreover, based on "hub and spokes" model (Mueller 2014), telemedicine improves patient care by increasing the capacity of the rural clinician to manage patient locally, minimising time away to support networks and reducing unnecessary retrievals (Matheus 2008, Kyle 2012).

Fore sure this contribution has some limitations related with the methodology, which restrict generalization of its findings. First of all, the review of the literature is not systematic, but narrative on statistical basis. Second, results on which we based our discussions come from a limited sample made by the 16 most cited papers on Scopus Database, together with 4 paper arisen by the "snowballing" technique. To make reliable our findings probably we should enlarge the sample of papers included in the literature review, also by considering others Database, such as Ebsco – Business Source Complete and Web of Science.

Notwithstanding these limitations, the study shows that telemedicine can significantly improve healthcare provision of both emergency and non-emergency department in rural and remote areas. In this sense, the contribution fosters the debate about the role of information technology and new organisation models in healthcare service providing in remote locations.

In particular, we can surely affirm that telemedicine allows for simplified access to specialist consultation via one port of call (or transmission): this provides remote diagnosis and, when required, it might assist in managing patients locally, by also reducing unnecessary transfers. It can be considered a cost-effective method whose outcomes remain similar (if not better) in quality to "staffed" services, whose infrastructural costs could be easily paid-back. These endpoints completely coherent with the value-based healthcare principles. In fact, "telemedicine-based" healthcare takes into consideration "real-life" patients' needs and not only those clinical.

This contributes to create higher value for patient on the whole process of cares, from patient first engagement with the Healthcare System to patient follow-up after cares (Porter, 2010).

Finally, answering to the research question, we can surely conclude that telemedicine approaches enhance the New Commons of "Access to Healthcare" in rural and remote areas, guaranteeing also more affordable, fair and reliable levels of cares.

Abstract

Based on the definition of knowledge as commons, the aim of the paper is to investigate the impact of nudges and considerations stemming from behavioural economics on the promotion and enhancement of commons. Commons are described as goods (material and immaterial) belonging to specific community or to humanity as a whole, and we believe that an approach based on nudging individuals toward desired behaviours may be more effective than top-down policy actions that may be perceived as excessive. In order to answer our research question, we will analyse a case study regarding the network of public libraries in Rome, called Biblioteche di Roma (BdR). BdR launched its online platform in 2009, but it was never able to create a strong connection with offline activities, and contributions by readers (such as comments and ratings) remained very low. In 2018, BdR introduced a gamification section in its website, with the goal of increasing users' interactions and book circulation. We will present and analyse data resulting from the use of gamification, both at city level and within different neighbourhoods. Finally, we will provide suggestions for introducing additional nudges in BdR's gamification strategy, and will make considerations regarding policy implications and paths for future research.

Keywords – Knowledge; Commons; Gamification; Public Sector

Paper type – Academic Research Paper

1 Introduction

The purpose of this paper is to analyse the possibilities for enhanced knowledge sharing in public spaces, and especially public libraries, by using gamification. The field of commons has evolved from the consideration of common pool resources, which were mostly natural ones, to new commons, that are immaterial objects such as knowledge, the Internet and music, to name a few, whose borders are unclear and which raise interesting issues regarding their governance and the identification of those entitled to participate to it. Building on the perspective of knowledge as commons (Hess, 2008), the paper presents a case study regarding a broad network of public libraries in a major Italian city, where a gamification strategy was implemented. The objective of the strategy is to encourage readers, users and citizens to increase their interaction with the library network, especially by borrowing books and by leaving comments on the network's website to encourage others to read and watch films, as well as to provide feedback regarding their appreciation of borrowed books. At the same time, participating in gamification operations is completely free of charge for users, which makes it clear that the strategy is aimed at enhancing knowledge circulation within the network, with the expectation to broaden it to a greater number of citizens/users. The paper will analyse the situation in terms of borrowed books and movies, as well as participation to library activities, before the introduction of gamification, and will then present the impact of strategy implementation by providing data on the increase of activities that it caused. Such evidence will be analysed on the basis of the theoretical framework of behavioural economics and nudging. One relevant aspect of the paper is the direct participation in the project by one of the authors, who collaborates with the team in charge of the gamification strategy and thus has access to first-hand data and information.

In order to answer our research question, the paper is organised as follows. First, we build the theoretical framework of the paper by reviewing the literature on commons, starting from common pool resources toward the new commons. The second pillar of our theoretical framework is built on behavioural economics, more precisely on the concept of nudging. Thirdly, we present the methodology, which is qualitative, and explain data collection and analysis strategies. Fourth, the case study is described and analysed on the basis of the theoretical framework on commons. The final section includes concluding observations and remarks, as well as research limitations and possible paths for future studies. This methodology highlights the relevance of adopting a commons-based perspective in the public sector, and of implementing creative strategies to enhance participation and commons (in this case, knowledge) circulation. The paper is original as it presents a new, ongoing case study, whose preliminary results are described, and which can benefit from feedback and discussion by the academic community. Moreover, one of the authors directly participated in data monitoring with the gamification team in public libraries, thus providing access to first-hand data. The outcome of the application of this work is represented by the possibility to design innovative strategies which enhance citizens' participation and engagement with commons, especially in the cultural and

creative sector; we believe this paper provides interesting insight on how public policy-making could be adjusted to promote culture-based commons.

2 Theoretical framework

As we mentioned in Section 1, the theoretical framework of the paper is built on two pillars, the first being the concept of commons and new commons, and the second being the theory of behavioural economics and nudging.

2.1 The commons

We believe it is possible to define knowledge as a commons, and the objective of this section is to trace the path behind our statement.

The field of commons is quite complex and varied, with numerous authors providing contributions from different disciplinary backgrounds. One relevant aspect is the absence of a single, shared definition of what “the commons” are. The first contributions by Ostrom and Ostrom (1977) focused on common-pool resources, i.e. local commons for which usage rights are regulated, such as lakes, fisheries and woods. The main issues regarding common-pool resources concern their management: it is important to identify those who have the right to make decisions on how to use the resource (usually, it is the community that owns them, as in Ostrom, 1990), and establish clear rules to avoid excessive appropriation (Patnaik *et al.*, 2017; Dietz *et al.*, 2003). Several authors have studied institutional arrangements for managing common-pool resources (Agarwal, 2001; Gibson *et al.*, 2000; Berkes, 2006), the most relevant being Ostrom *et al.*’s Institutional Analysis and Development Framework (1994). In 2007, Hess and Ostrom defined eight principles for self-managing communal resources, mainly based on the necessity of setting clear rules, boundaries and sanctions, and on the idea that community members should have a say in defining such aspects. Since the 1990s, studies on commons have started to look further than common-pool resources, resulting in the identification of a new category, the “new commons” (Hess, 2008), such as the Internet, knowledge and digital libraries, just to mention a few examples. They are defined as “various types of shared resources that have recently been recognised as commons” (Hess, 2008), and they take into account a large number of interests and issues, such as concerns regarding globalisation and the increasing privatisation of public goods. This shift influences management systems: today multilevel governance defined as “institutional arrangements that facilitate the co-production, mediation, translation and negotiation of information and knowledge within and across levels” has become a key concept in managing the commons (Ruiz-Ballesteros and Gual, 2012; Brondizio *et al.*, 2009).

Based on the evolution of the field from material, communal resources to immaterial and global ones, we believe it is possible to define knowledge as a (new) commons, whose protection and enhancement requires the cooperation of a large network of stakeholders.

2.2 From behavioural economics to nudges and gamification

This section builds the theoretical framework of behavioural economics, a topic that has been receiving increasing attention in the last years, and then moves to analyse in detail the practice of nudging and the instrument of gamification, which are the basis of the paper.

The field of behavioural economics is complex, so we will present a selection of concepts that will be useful for framing the research conducted for the paper. First of all, the idea of bounded rationality (Simon, 1955) indicates that when an individual makes decisions his/her rationality is limited by a number of factors, such as the amount of information, the available time and mental structures. Consequently, the decision-maker will aim at achieving a satisfying outcome, rather than the best possible one. Kahneman (2011) tried to explain bounded rationality by building the dual-system theory, according to which the human mind is formed by two cognitive systems, the first being automatic and intuitive, and the second being more reflexive and analytic. The first system is subject to cognitive biases, especially when decisions require that we process large amounts of information that has to be simplified. The author suggests paying attention to mental schemes underlying decisions and not being too quick in following one's impressions.

Another relevant element in behavioural economics is time, especially for what concerns changes in individual preferences: according to theory, individuals tend to prefer present events than future ones (e.g. receiving 100€ today or 110€ in a month).

Finally, behavioural economics does not see the individual decision-maker as rational and isolated: on the other hand, he/she is included in a social context which influences the outcome of individual decisions, for example by the tacit enforcement of social norms. Moreover, others' opinions are strongly linked to emotional aspects that, too, have an influence when making decisions. Thus, behavioural economics paints a complex, multi-faceted picture of individuals and their decision-making processes, where many factors have to be taken into account.

A key concept within the field of behavioural economics is that of nudge, i.e. "any aspect of the choice architecture that alters people's behaviour in a predictable way without forbidding any options or significantly changing their economic incentives. To count as a mere nudge, the intervention must be cheap and easy to avoid." (Thaler and Sunstein, 2008). According to Hausman and Welch (2010), nudges can be used when errors occur in the decision-making process, and their role is to exploit such errors.

Nudges can aim at reducing cognitive biases (a process known as "debiasing") by allowing individuals to acknowledge the mental schemes they employ in decision-making that can lead them to unsatisfying outcomes. Nudges can also be used to modify the choice architecture, i.e. how the choice is presented to the decision-maker, in order to encourage individuals toward the "better" choice.

Sunstein (2014) identifies the ten most important nudges:

- Default rules, such as the automatic enrolment in programs such as wellness or education, where it is always possible to opt out but the default option presented is to opt in;

- Simplification, i.e. the idea of providing clear and intuitive information in order to reduce complexity in decision-making;
- Social norms, i.e. stressing what others would do in the decision-making situation;
- Increases in ease and convenience, i.e. making the “best” decision outcome easier to choose;
- Disclosure, which brings all elements of the decision-making process out in the open;
- Warnings, such as graphic images on cigarettes packaging, which can contribute to increase awareness regarding a specific issue;
- Pre-commitment strategies, that help people to keep up with particularly complex commitments (such as giving up smoking);
- Reminders, for example notifications that remind people of their appointments in case they are too busy;
- “Eliciting implementation intentions”, i.e. asking questions about future intentions can sometimes be enough to trigger the desired behaviour;
- “Informing people of the nature and consequences of their past choices”, i.e. reminding individuals of the results of decisions they made in the past, so that they can avoid making similar mistakes in present and future decisions.

The specific object of this paper is gamification, defined as “the use of game design elements in non-game contexts” (Deterding *et al.*, 2011) and it is built to apply the features of games, in terms of individual stimulation, to non-ludic situations. Gamification is used to solve actual problems, not virtual ones (as they would be in a computer game), which are not connected to the game itself. It builds on the idea that in real life people can experience frustration and stress, while they do not when playing games: according to Chou (2016), gamification is the employment of fun and rewarding aspects of games to real-life situations, such as productive or organisational activities.

Gamification can help to “nudge behaviour to be healthier, work better together and achieve goals, all the while having more fun” (Oberprieler, 2017). Thus, it can be considered as an element of nudging, a way to achieve the nudging effect toward the desired result by working on the choice structure.

According to Wu (2011), both gamification and nudges can influence human behaviour, but each works at a different level: the former focuses on motivation, the latter on abilities and triggers. Nudges make context analysis and choices easier, while gamification has an impact on motivation and stimulates the individual’s skills: without a combination of these three elements, long-term behavioural changes cannot occur.

3 Methodology

The research methodology employed in the paper is based on a case study analysis, which allows us to make considerations regarding possible ways to enhance knowledge sharing and to govern the new commons. The case study describes the experience of the network of public libraries in Rome (Italy), called Biblioteche di Roma (from now on,

BdR), with gamification, and the impact that this had on knowledge circulation. Data were collected first-hand by one of the authors, who cooperated with the ICT department of BdR that was in charge of promoting and monitoring the gamification strategy. Data analysis allowed us to evaluate the impact of gamification on the system of BdR, and we were able to suggest additional steps (presented in the concluding section) on the basis of the theoretical framework on behavioural economics and nudges.

We selected BdR to be the object of our case study as it is the largest network of public libraries in the country, and it presents interesting conditions such as a very large pool of possible users (all those who live in Rome and its surroundings) combined with a relatively limited amount of financial resources (which decreased by 10% in the last five years) and of materials available for lending. Moreover, one of the authors cooperated directly with the ICT department of BdR and was thus able to have first-hand access to data regarding the gamification project.

4 Gamification and knowledge sharing in public libraries: a case study

The objective of this case study is to assess whether the introduction of elements from the field of behavioural economics, such as nudges, can represent an innovative way of enhancing knowledge circulation in the public sector.

BdR is a network of 44 public libraries and research centres in Rome, with a very large pool of possible users (more than 3 million citizens) and around 1 million books, DVDs and e-books for lending. In 2017, BdR had 34.000 registered users and lent more than 800.000 books and other materials. The network is financed by the public administration, and its funds decreased by 10% from 2012 to 2017: this forced BdR to adapt parts of its strategies and come up with innovative technologies in order to provide a high-quality service with limited resources. This is the context where the gamification strategy was launched as a low-cost tool to promote borrowing operations and, consequently, knowledge circulation and sharing.

First we will explain how the gamification strategy is organised, and then we will analyse and discuss data by using the D.R.I.V.E. framework and the nudge classification matrix, which were introduced in Section 2.2.

4.1 The gamification strategy

In early 2018 the ICT department of BdR launched its gamification strategy, to be included in the website and in the mobile app. The objective of the project is to promote knowledge circulation by encouraging library users to behave positively, e.g. by returning borrowed books on time and by interacting on the online platforms (website and applications) by providing feedbacks, writing comments and rating books.

The gamification is based on increasing levels of achievement, that can be reached by accumulating points. The points system is linked to actions carried out by users, such as subscribing to the library network, borrowing books and bringing them back within the required timeframe, downloading the mobile app, posting comments and ratings for books and movies. It is also possible to lose points when returning a book late, or when

comments are disrespectful or “useless” to the website: this mechanism aims at ensuring that users’ actions are thought out and meaningful, rather than just ways to collect points. Points can be accumulated throughout each calendar year, and if the highest level is reached it is possible to obtain a free library card (whose cost is usually 10€).

It is possible to speak of gamification as game aspects are used in a non-ludic context with the objective of influencing behaviours by working on how choices are made.

4.2 Data analysis and discussion

We will now apply frameworks and tools from the behavioural economics field to the BdR gamification strategy in order to interpret and analyse it. In this section we will analyse the project using two frameworks, first the D.R.I.V.E. method and secondly the nudge classification matrix. Thirdly, we will present and discuss quantitative data resulting from the project.

The D.R.I.V.E. approach can be used in order to frame BdR’s strategy in behavioural terms by splitting it into the following steps:

- Define: this is the step where behavioural goals are defined. In the case of BdR, behavioural objectives included the decrease of delays in returning borrowed books and materials, the increase of user engagement inside and outside libraries, and the increase of online interactions and activities.
- Review: the aforementioned goals were defined on the basis of unsatisfactory data for the time period from 2009 to 2017. One example is the amount of comments submitted to the website and application: in the 2009-2017 period, they were 1.693, quite low considering that at least 3.000 users had registered to the website by 2017.
- Identify: in this stage it is important to indicate the target behaviour and how it differs from the present one. According to Hansen (2016), behavioural interventions should be contextual, intuitive and measurable and they should leave target individuals enough freedom of choice. Thus, BdR identified gamification as the most adequate intervention tool to promote users’ desired behaviour.
- Validate: when the intervention is being carried out, it is necessary to evaluate its outcome and to implement corrective measures when needed. In the case of BdR, three months after the launch of the project, in March 2018, the amount of comment since the beginning of the year was higher than the total number of comments from 2009 to 2017. This was a positive indication that the strategy was correct. On the other hand, many users were asking questions regarding the existence of rewards for their participation in the game, which led BdR to introduce the possibility of winning a yearly library pass when reaching the final level.
- Execute: this is the final step, after the implementation of the strategy and corrective measures. In the BdR case, results were successfully attained.

It is also possible to use the nudge classification matrix to analyse the case of BdR. Its gamification strategy mainly aims at stimulating the automatic system and cold affects,

thus influencing users' routine. BdR's gamification employs emotions linked to fun, achievement and rewards in order to encourage users to play and eventually to change their routines, for example by acquiring the habit of returning books on time and posting comments online.

For what concerns data analysis, BdR provided yearly data from 2009 to 2018 regarding comments and ratings uploaded to the website, new subscriptions and return times for borrowed books.

The gamification initiative was very successful in terms of comments, as indicated in Table 1: in 2018, 3.239 comments were posted, more than double the amount during the 8 years before. However, this result over a 9-year period may be influenced by the widespread diffusion of mobile phones and digital technology. The difference between 2017 and 2018, on the other hand, is striking, with an increase in comments close to 1000%, which clearly shows the effectiveness of the gamification strategy in reaching this goal.

Table 1: Comments per year

Year	Submitted comments	Refused comments	% refused
2009	51	0	0%
2010	60	0	0%
2011	107	0	0%
2012	130	2	1,54%
2013	177	6	3,39%
2014	217	2	0,92%
2015	375	3	0,80%
2016	242	2	0,83%
2017	334	2	0,60%
2018	3.239	177	5,46%

Source: Own elaboration

The information regarding comments that are refused because of being inappropriate is particularly interesting: the risk of using a gamification approach is to attract users whose passion is playing more than reading, which would have determined high amounts of comments posted in the hope of obtaining points without paying attention to their content. The introduction of a significant penalty for posting inappropriate comments has allowed to reduce the risk of such behaviour occurring.

The mobile application of BdR was launched in 2012, and so far was downloaded 15.000 times, 4.500 of which in 2018 alone, which represents a relevant increase with respect to previous years.

For what concerns rating submitted by users, 7.488 were submitted throughout 2018, and the final amount is 10% higher than forecast in May 2018.

In 2018, 544.925 books, DVDs and e-books were borrowed, 73,8% of which were returned on time: this is an area where additional work could be done to obtain further improvement; in the concluding section, we will indicate possible solutions that could be adopted to increase timely book returns.

Data are available for the first 4 months of 2018 regarding the age of new subscribers to BdR, and they show a decrease of almost 5 years on average (30 years old vs 25 years

old, and less). This could be linked to the positive impact of gamification on younger users, who are attracted by the possibility to play and earn points to win a free library card. On the other hand, data regarding borrowings indicate that users taking books are around 38-43 years old with no significant change from 2017 to 2018: it is possible that younger new subscribers limit their engagement with BdR to commenting and rating books, but are not really interested in borrowing them.

It was also possible to analyse the geographical location of comments submitted in 2018, and many of them were posted from areas close to universities. This finding confirms the relationship between public libraries and students, who may also be more interested than adults in the chance of obtaining a free library pass, and creates new opportunities for collaboration between BdR and public universities in Rome with the objective of increasing knowledge circulation.

5 Conclusions

The gamification strategy implemented by BdR can be considered successful, given the results of the previous section. In its first year, the adoption of gamification allowed to obtain a massive increase in submitted comments (close to 1.000%) and contributed to the engagement of younger users.

We believe that the implementation of a gamification strategy contributed to enhancing knowledge circulation and sharing in public libraries in Rome, thus providing a positive answer to our research question. At the same time, based on the theoretical framework of behavioural economics and nudges, it is possible to make a series of considerations regarding possible improvements to the strategy. First of all, the assignment of points is not clearly specified anywhere: this would be an easy improvement that could add greater clarity to the whole strategy. Secondly, by exploiting planning fallacies, it is possible to reduce return times for borrowed books by including a nudge in the online lending procedure. When the user selects the book he/she wants to borrow, a pop-up window could appear, asking the estimated time that will be necessary to read and return it and providing several pre-determined choices ranging from 10 days to 30 days (maximum borrowing duration). The user should be nudged to choose middle options such as 15 and 20 days (based on the middle option bias), and if he/she manages to return the book within the selected timeframe he/she could gain a small amount of bonus points. Since this is a nudge, users would not be forced to select any option, and there would be no penalties if they take longer than expected to return the book.

For what concerns research limitation, although results are encouraging they refer to a specific case study. On the other hand, the case of BdR can serve as a best practice in the field of public libraries, since it refers to a very large urban area, with many potential users and high complexity. Public libraries in smaller municipalities may find it easier to engage their users and increase their interactions by using a gamification strategy, thanks the possibility of creating stronger online-offline connections by organising cultural events. Thus, we believe that interesting insight can be gained from the analysis of the BdR case, namely in terms of public policy implications. For certain services public

administrations could consider adding gamification elements to their strategies, especially when users are required to be involved and to interact with the service provider. By employing game-like tools in a non-game environment it is possible to obtain changes in users' routines, which could benefit the administration in terms of a smoother service provision.

Finally, future research should focus on following further development and results of gamification in BdR, and keep track of similar strategies adopted in other contexts in order to define guidelines and strategies that can be easily replicated.

Abstract

Social innovation, as an element of modification of a pre-existing status quo, does not necessarily find an easy life in the production of new services, products and solutions able to solve questions and problems of a community.

The experience of the long iter for the redevelopment of the formerly psychiatric hospital “Santa Maria della Pietà”, in Rome, is a clear example.

Since 2004 the self-management popular experimentation of Pavilion 31 (the “Ex Lavanderia - former Laundry of the mental hospital”) has started, in a place that since the mid-70s had already been converted from the administration of the asylum into an open space for cultural and social production and use.

The economic and cultural relevance of the asset, the length of the dispute, the repeated and contradictory positions taken by the different institutions involved (municipality, region, province, LHU - local health unit), the various attempts made by the involved community and the experimentation initiated by the Ass. Ex Lavanderia in Pavilion 31 make this conflict a paradigmatic case, even if not unique of its kind.

The research aims to evaluate to what extent the uncertainty due to a conflictual context may have influenced the social innovation impact.

Keywords – social innovation, commons, goods of civic use.

Paper type – Practical Paper

1 Social innovation and common goods

Towards the end of the 1980s, Anthony Giddens introduces the concept of “social innovation” into his text “The third way”, envisaging a model according to which it is necessary to reduce the centralized action of the government and to promote the development of the free citizens' initiative joining together to find alternative solutions to social needs. Every social innovation action can be read as the ability of citizens to organize and produce solutions for recognized problems, with the consequence that a change in social relations is a condition and effect of social innovation itself (Maiolini 2015).

The paragraph four of the Article n.118 of the Italian Constitution, by stating that “State, Regions, Metropolitan Cities, Provinces and Municipalities encourage the autonomous initiative of the citizens, individual and associated, for carrying out activities of general interest, based on the principle of subsidiarity”, introduces a new perspective in the relations between citizens and the Public Administration, sanctioning the principle of subsidiarity in a horizontal sense: a privileged power of action is granted to citizens, individual or association, for carrying out activities of general interest. It is the legitimization of the citizen's disinterested right to take care of public affairs (Arena 2006), building new forms of relationship between the various actors involved. On this basis, the debate on *shared administration* was triggered, and in particular on the horizontal relationship between administration and citizens “in such a way that they leave the passive role of administrated to become co-administrators” (Arena 1997, p. 29). The need for new forms of relationship between public authorities has been defined as “corporate citizenship” (Donati 2000), which cannot be traced back only to the formal form of participatory or procedural citizenship, but must aim, according to the opinion of the Council of State, “to be understood in its immediately relational dimension” (Opinion Council n.1440/2003).

A characteristic feature of the *shared administration model* is certainly that inherent to the management of “common goods”, in particular those goods that have become common in urban areas and in relation to certain fundamental rights and needs (Rodotà 2015). Maurizio Zanardi, speaking about the “Ex Asilo Filangieri”, as a common good, affirms that “the good is not a ‘thing’ but a practice. It is not something that already exists, something to regain possession of, but above all a collective action to be invented. An act that does not pre-exist its appearance. Around the *good as a thing*, inevitably, appropriately dynamics are unleashed: everyone try to tear off a part, a fragment, of the good. The good-thing is ‘torn apart’ to be divided between groups, particular interests, existing powers. The *good as a practice* is, on the contrary, inappropriate and indivisible, because, as long as the practice is at work, it coincides with the autonomy and the set of gestures of those who exercise it. To be clear, if there is a common good, is not the Ex Asilo Filangieri building, which can be badly used, but the practice that invents it as a place for good encounters”.

2 Social innovation, mental hospitals and Law 180/1978

The social innovation, that characterizes the struggles for the management of public goods, has one fundamental characteristic: attention to practice. A practice that we can track back in the social dynamics put in place by the movement for the closure of mental asylums in Italy in the 1970s. The possibility of an inclusive and at the same time democratic management, where nothing is sanctioned before the relationship between people, it was at the base of the first assemblies of the movement, that after a long culture battle lead to the closure of asylums (Basaglia 1998).

3 The transformation of the former places into common goods: the case of the Santa Maria della Pietà and the Ex Lavanderia

In the experiences of reusing abandoned places, public or private buildings, the notions and the practices of *common goods* and *participatory democracy* are now in the process of merging up, giving life to the “immense non-city, anonymous and disordered” (Berdini 2014, page 138). Abandoned spaces have become real incubators of civic activism, in defence from degradation and privatization, have become places for a new generation of social mobilization. The case study presented here concerns the pavilion used as laundry in the former mental hospital Santa Maria della Pietà in Rome, called since the mid-1970s “Ex Lavanderia”.

The Santa Maria della Pietà, built between 1909 and 1913, was the largest psychiatric hospital in Europe: over 30 pavilions on 27 hectares of land, in an agricultural area of 130 hectares. Its closure was completed at the end of 1998, already preceded, however, by a series of cultural and social initiatives open to citizenship since the mid-1970s.

In 1995, while the local institutions started a process of re-valorisation, also favoured by the Law n.833 of 1978, 40 associations (national and local level, psychiatric, environmental, urban and cultural associations) gave birth to the network “La Città Ideale” and in 1997 promoted the project “La Città Ideale”. In 2003, the network collected the signatures for a resolution of popular initiative aimed at the acquisition the complex by the Municipality and, in 2004, against the project of transformation of the Ex Lavanderia into a health service (nursing school), it occupied the pavilion to maintain its socio-cultural function.

From 2004 until 2016, the successive administrations neither have completed any urban planning relating to the complex nor activated forms of participation for its development. In 2016, the Region, with a Regional Executive’s Resolution, sanctioned its return to health functions, entrusting the entire estate to the LHU of competence. What initially appeared to be a temporary occupation has turned into a permanent action, demonstrating the demand for places of sociality from the territory and the city.

The Ex Lavanderia therefore proposes itself as an open and inclusive space, where the activities carried out “are not selected on the basis of the contents, as happens for example in the artistic direction, but on the sustainability of the projects based on criteria of self-

organization and exchange of time” (Micciarelli 2017, pag.148). In fact, the association provides spaces for artistic, recreational, cultural and educational proposals.

The research in progress, whose first results are illustrated here, starts from the reconstruction of the history of this experience. The intent is to explore the dimension of action and social innovation in the suspension/conflict, which the activists of the Ex Lavanderia have been living for years, and how this condition has influenced, and is influencing, their participatory, creative, social experience. For this reason it was decided to use a non-directive approach in the interviews conducted with the activists, so that they filled our cognitive questions with their own experience. Two interview tracks were articulated, one for the representatives of the laboratories and projects and one for the members of the Association's board. The first explored the personal history of activism, the relationship with the territorial framework, the relationships with other referents of projects and with the Association, the positive and negative peculiarities identified in carrying out a project in a context like this. The second explored the personal history in the Association, the relationship between association and the environment, exploring how much one's commitment could be considered an instance of the territory, the internal organization, the relationship with the institutions, the voluntary status, the collaboration with similar realities. In both cases it was then asked if operate in a former asylum provoke any emotional feeling. The interviews were conducted in tandem, with a leading and a shadow researcher (Tusini, 2006), the material obtained does not coincide with the results of the research, that is not a self-evidence to show (cfr. Martire, 2012) and this is why the text contains only excerpts, faithful to the language used, to support advanced reasoning.

The activities currently present in the Ex Lavanderia are divided between laboratories and projects. The workshops include: papier-mâché, Yoga course, Peruvian and popular dance course, meditation, integrated movement, Brazilian percussion. Among the projects: Tatawelo cafeteria (as a reception area, presentation of the activities of the Ex Lavanderia and promotion of fair trade projects), popular bicycle workshop, public theater and the recovery of the old Park for Children of the Municipality with “Le Belle Lavanderine” (beautiful sinks). It also houses the venue of the “Banca del Tempo” of the XIVth Municipality. Almost every week a cultural initiative is proposed (exhibition, concert, event) and a children's party is hosted - organized by the same families. All the activities are free.

4 Planning and conflict

From the reconstruction provided by the White Book on the Santa Maria della Pietà, it emerges that over the years the institutions involved in the process of reusing and enhancing the complex have succeeded in carrying out, in succession, mutually contradictory actions, often incomplete or inadequate, leaving, to every step, a more tangled and difficult situation.

A representative of the Association Executive Board:

The only functions that have increased in the Santa Maria della Pietà are health services. The ASL with the approval of the Region, occupies pavilions in an area like this one, that is surrounded by hospitals and clinics. This is the district of Rome with more "health services". Politics does not imagine the city in 20 years, this is the problem. I imagine that for this neighborhood the Santa Maria could be a resource that goes far beyond its sanitization, but politics does not understand it and wants to continue with the process of sanitization, it is what happening, one pavilion at a time, just read the story of the ASL in here since 2004.

It is different what it happens on the front of "civic" planning. The associative form has undergone changes over the years, the participants have changed or have changed themselves, there was the difficulty of having always adequate tools to intervene in the processes, but the clarity of the objectives does not seem to have disappeared within the Ex Lavanderia. The various successive local administrations have tried to bring this experience back into the category of "occupations of social centers", but its different and specific nature clearly emerges: the association inherits the lead of the *La Citta Ideale* Coordination, which promotes in 2013 a second popular initiative resolution (given the failure to discuss the first, then Del. Comune n.40/2015) and a proposal for a regional law for the planning and inter-institutional and participatory management of the complex (2014); in addition, it participates in the activities of the Urban Center of the Municipality. In the meantime continuing to act, with the support of a wide network, even if disarticulated, to demonstrate the possibility of using the Ex Lavanderia for what had been considered its function since 2000, a place of sociality and culture.

Represented Theatre laboratory:

It is easier to capture the cultural ferment of a city like Rome from the Ex Lavanderia than from the Theatre of Rome. The problem is what can be the prejudices, what may be the institutional closure, but really it moves me everything that happens here at the Ex Lavanderia from the milonga, to the theatre, to the activities for children, everything brings back to the role that should have the culture in a society. Surely the biggest disadvantage is the one with institutions, they don't have a vision. The institution does not understand that a place like the Ex Lavanderia should be a wealth to be exploited.

This would probably not have been possible without two conditions: *i*) a broad acceptance of Basaglia's approach to mental and social distress (Basaglia 1998) and of the processes and methodologies for its overcoming in the context of civil society *ii*) and an urbanistic vision centred on the development of places that could reconstruct the social fabric swept away by too large processes of economization.

Representative of the Cafeteria:

It makes me think that we are in the former asylum in Rome... in the sense that from this space comes a different response from what it was. Producing a different thought from what this place has been it's positive. The institutions think that they are a bit like providence, that they are able to govern disorder, they think they will arrive and fix things. Here at the Ex Lavanderia happens the opposite, here we are

doing politics in a horizontal way, there is initiative and freedom to be able to do. It is the idea of a small community that can be governed without a leader, we are all equal.

5 Participatory planning and conflict resolution

Theoretically the city of Rome has adopted a specific Regulation since 2006 for citizen participation in urban planning choices and also determined instruments such as the Popular Initiative Decisions. In reality there is no guarantee to protect the citizens' efforts: as for the Resolution for the acquisition of Santa Maria della Pietà in 2003 the Capitolina assembly can simply decide never to arrive at an evaluation of the proposals. Even in the presence of rules and instruments of participation the administration decides to take into account the bottom up process only when an analysis of the pros and cons suggests an utility. Still talking about participatory planning and about the popular initiative bill presented to the Region, on the participatory planning of reuse and ignored, a representative of the board states:

Since we made our law proposal, three years have passed and no one has ever taken up this. We have collected 12,000 signatures in 6 months... In my opinion there is no conflict with the institutions, there is a "no listening", there is indifference, I repeat we have made a law proposal and nothing. At least tell me "no" and reject it but they didn't even take this responsibility. The truth is that politics not only does not want dissent but not even proposals, or consultation. I believe that there is no way in Rome to have a relationship with institutions because on the other side there is no form of reception, nothing. There is really an inability to understand, I think that doing an health district is more "economical".

What emerges is not so much a clear conflict with the institutions as an absolute indifference to realities, like the Ex Lavanderia, which are bearers of possible alternative solutions.

Representative of the bicycle workshop:

Over the years there have been several administrations and not that much has changed between them. We have always found resistance.

Representative of the Cafeteria:

The institutions do not speak to you and this don't talk to you is a form to govern you. We do not have a relationship with institutions. There is a lot of indifference.. I believe there is a lot of ignorance. They have no idea of the concept of the common good that the Ex Lavanderia represents.

Participatory planning should be a circular process in the relationship between the needs of citizens and the system of interventions and services at the territorial level, a space for participation and shared responsibility for the various actors involved (Giachi, 2015). Consequently, the decision-making process should take place in terms of the

inclusiveness of all stakeholders, taking into account the non-reducible domain and pluralism of interests, objectives and points of view (Fetterman and Wandersman, 2007), of the exchange between procedural and tacit knowledge, and non-shared that become explicit, conscious, circulating (Castelfranchi, 1985; McAllister and Walsh, 2004). This process promotes and does not hide phenomena of conflict between the subjects, overcoming the logic of the Nimby syndrome (Bobbio 2004). Giving vent to the conflict through the inclusiveness of a participatory planning demonstrates that: “the conflict is not a pathology, but a sign of health: if not feared and suffered as a complication, but recognized as a source of problems that politics can face, it becomes an opportunity for knowledge and a necessary opportunity for government, for dialectical confrontation” (Bassetti, 2004, p. 17). In the absence of a clear process, the conflict here is expressed in two different ways. The first way is the “veiled” conflict, where the episodes, such as the cutting of light by the LSC to the Ex Lavanderia, symbolize a threat that inevitably influences who operates within the structure. No coincidence that this important episode was reported by all the interviewees, without a specific question being asked about this event.

Representative of the Association Executive:

The idea of conflict is well represented by the fact that the LSC has taken away the light, and now we use a generator. Not directly, but more or less veiled attempts to send us away have been made on several occasions. Veiled not even so much, they gave us three causes and we lost one. They don't attack us on the merits of what we do, because on that they would lose, how can they attack you because you do “theater”? They attack us on the fact that they consider us illegitimate, that we don't pay you the light, they don't attack us on what we are giving to the neighborhood.

Representative of the bicycle workshop:

When they turned off the light, we thought they would send us away, but it didn't happen. When it happened there were acts of solidarity on the part of the territory, we received economic offers to buy the generator.

The other way in which the conflict manifests itself is represented by the difficulty of planning in the medium-long term. The undeclared weight, but somehow present, of the possibility of an eviction ends up influencing the activities that are carried out.

Represented in the theatre laboratory:

Specifically for the Lavanderia, the closure of the institutions makes it difficult to plan.

To the specific question about *the future of the Ex Lavanderia in three years* the answers were the following:

Representative of the bicycle workshop:

I am optimistic by nature but at the moment we are struggling. They can evict us at any moment, they don't do it because they know that we do useful things for the territory, we do beautiful things. Let's say that now

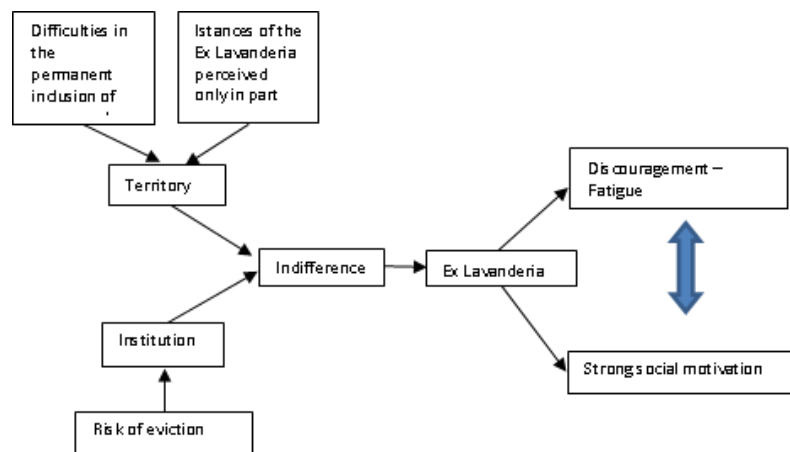

in particular we need something that gives us a new boost, a new energy because two years ago they turned the light off (...) a series of things that happened sucked our energy out.

Represented in the theatre laboratory:

I do not know. We need to understand the institutions, after 14 years I believe it is difficult to put a point also at institutional level. There are no people who take responsibility at the institutional level (...) I can't make a forecast, of course if there were intelligent minds betting on the Ex Lavanderia, this place could become an international model of relationship with the territory, of cultural growth, however, to find these people.

6 Partial conclusions

The following graph tries to summarize a first conclusion to which the research came. From what emerged, the conflict manifests itself in terms of indifference on the part of the institutions. However, this phenomenon also seems to invest a theme on which the activists of the Ex Lavanderia have often returned: the relationship with the local territorial community. In particular, the difficulty of activating the citizenship of the neighbourhood towards the Ex Lavanderia as a common good.

Representative of the Board:

The difficulty of relating to the territory also arises because we are all volunteers. We are here at the Ex Lavanderia, we carry on this battle, when we do not work, mainly in the evening and on Saturdays and Sundays. The difficulties we encounter in the territory, are not only of the territory that does not listen to us, but it is also our responsibility.

Representative of the Cafeteria:

We have difficulty communicating with the territory. Over the years I had thought it was our inability, then as time went on I began to think that it is not

entirely our fault. I also believe that there is the influence of being in the former asylum of Rome. The Santa Maria remains as a great fief, a closed space.

Representative of the bicycle workshop:

It is difficult to involve people in the initiatives we do (...) we would like people to be more active. Here are young families and perhaps we should build our activities starting from this user. For example, when there is theater for children there are often many families (...) in general, initiatives involving children work. We usually distribute flyers to let people know about our activities, but this is the time when we are most active. Otherwise, people discover the Ex Lavanderia accidentally when they visit the park.

Even if there is no permanent response from the neighborhood, at least in the terms that the Ex Lavanderia activists would like, it should be remembered that the initiatives and laboratories are proposals coming from the local territory and the city, which however require internal management. This "temporary" participation generates processes that result mainly in the lack of a replacement in the organizational nucleus of the Ex Lavanderia and in the inevitable tiredness, which is amplified by being all volunteers without income, or almost, within the structure.

Representative of the Board:

We could not make a breach. Perhaps because we don't offer "fashionable" activities for a 20-year-old boy. (...) Then there is the theme of volunteering, as there is no income at the base of the activities you do, you end up doing them when you can.

Representative of the bicycle workshop:

Finding new volunteers... we've been the same for a very long time. Some volunteers come occasionally, but after a period of time, they go away. Everyone recognizes that this place is potentially fantastic, but they remain for a short time or remain only in words. As a Ex Lavanderia we have often asked ourselves why there is no replay. Now we are looking for new partners, associations that give us a hand both in terms of organization of events, and of ideas to make the participation of the territory more active.

Represented in the theatre laboratory:

Another difficulty is the age group which is difficult to get involved. I mean young people. Although this place is open to new ideas, the only age range that offers us activity is always quite old, never young. My explanation comes from my experience in schools: in young people the ability to associate is lacking. Politics is missing now, a young man now has no awareness that he can count for anything.

It should however be emphasized that the relationship with the environment is effectively contradictory: although it is difficult the one with the closest citizenship, it is not lacking with the city of Rome, which uses the Ex Lavanderia both as a user of its proposals and using the structure itself as a common good.

Represented in the theatre laboratory:

The incredible thing is that often here at the Ex Lavanderia, for the theater, there are people who are not from the area. Where institutions do not provide space to try, a place like the Ex Lavanderia becomes ideal to try. In Rome there are no big opportunities for theatre companies at this time.

Representative of folk dances:

In my laboratory only four people are from this district, the majority come from other areas. I think they knew the lab via the internet. I once had a person who came from Acilia.

In this delicate and precarious balance in which the Ex Lavanderia moves, we can say that the main reason that still holds the activists together, and the very survival of the structure, is a very strong awareness of the importance and value of their activism for the community, as well as the dispute over the area of the District, which is clearly the main reason why problems are faced.

Representative of the Board:

If there were not a strong sense of belonging, ending up arguing with the volunteers who run the Ex Lavanderia each time would be a snap. A sense of belonging that can be translated into the idea of “doing something here, in this territory”.

Representative of the bicycle workshop:

I stayed because I like what I do and I like to make a contribution to this territory because it's like a second home for me. And this is a dead neighborhood. And the fact of doing laboratories, activity, I feel I revive this territory. To make myself useful so that this territory is alive, for this reason I do not give up despite the thousand difficulties.

Representative of the Cafeteria:

The idea of living in another way. Living in the idea of a common good. With the Ex Lavanderia I can think of another way of life. We are here to defend a space that wants to be common.

The intention of research in the near future will be to investigate the reasons why in certain circumstances virtuous circuits have been created between local administrations and citizens in the management of common goods. In the next future, More, we are going to study in deep the local territory, involving all the stakeholders of this process (like also the municipality and the LHU), and comparing this case study with other experiences of management of “common goods”. In fact there are positive examples in this regard, just think of the regulations drawn up by 189 administrations scattered in Italy (es. Naples or Potenza). The intent of all similar realities, is to make public administrations change their sign, which can no longer decide in a exclusive way for goods that belong to the entire community (Ferrajoli 2013).

Abstract

Observing the contribution that an approach using the Innovation Networks Analysis involving the Triple Helix spectrum, its contributions to the diffusion of a knowledge-based economy, potentializing regional socioeconomic development, the present study carried out a literature systematic review with the purpose to verify the contributions that Innovation Network Analysis, as a strategic analysis tool, can bring to establish strategic Regional Knowledge-Based Development. At the conclusion of this study, it was verified that Network Analysis and Knowledge-Based Development are emerging themes, with emphasis on scientific production in the last five years, and converge towards a strategic approach to policies and practices at local, regional, national and multinational levels, contributing to the diffusion of a knowledge-based economy, enhancing regional socioeconomic development.

Keywords – Knowledge-based Development, Regional Development, Network Analysis, Innovation Networks, Knowledge Management.

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Much has been said about the opportunities and challenges range facing countries, regions, sectors, institutions and individuals, associated with emergence and diffusion of an 'era', 'society' or 'economy' of knowledge. A new technical-economic pattern emerges based on increasing intensity and complexity of knowledge developed, accompanied by an accelerated incorporation of this knowledge into goods and services produced and marketed. Knowledge-based development is the knowledge resources transformation into local development, providing basis for sustainable development, and as society becomes more and more knowledge-based, development nature changes as activities in knowledge sector are becoming more important.

Studies that synthesize the literature are extensively developed with the purpose of aggregating research evidence to guide new studies that seek to advance scientific knowledge. Evidence-based practice is a rather widespread methodology and consists of scientific evidence use produced by studies developed with methodological rigor to make decisions about conduct in face of problems that professional / scientist is facing. Scientific evidence formation starts from formulation of a question, seeks evidence, which is found, undergoes a critical evaluation and decision making is carried out based on this evidence (PEDROLO, 2009).

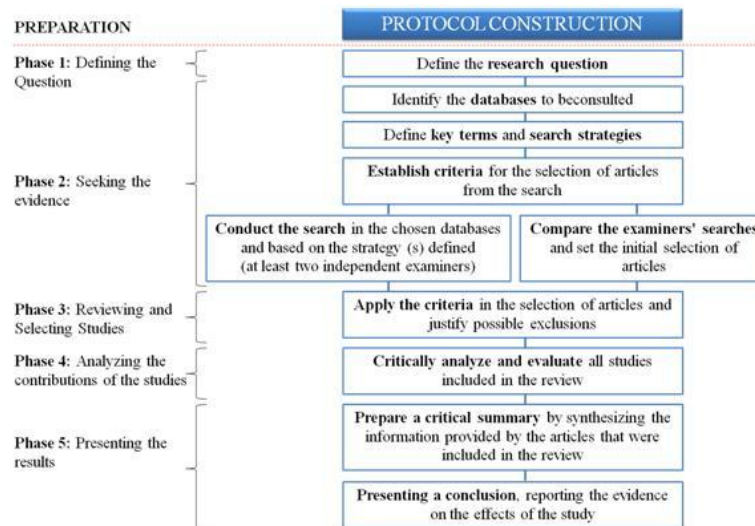

According to Amaral and Silva (2011), "the systematic review results allow us to identify gaps in the theory that can be explored by other researchers but which have not been identified in similar studies due to superficiality and lack of rigor in review bibliographic".

In this way, systematic reviews are designed with the explicitly explaining intention their design in a methodical, explicit and reproducible way. Sampaio and Mancini (2007) point out that this study type is used to guide projects development, indicating new directions for future research and identifying which research methods were used in a given area.

In this sense, this literature systematic review aims to research evidences around the theme: Regional Development based on Knowledge in an approach using Innovation Networks Analysis. Specific objectives are to demonstrate study relevance and its contribution to new studies and to identify knowledge gap already produced about subject, demonstrating study contributions to the science advancement.

2 Systematic Literature Review

A literature systematic review requires a clear question, a search strategy definition, criteria establishment for articles inclusion and exclusion and, above all, a careful analysis of selected literature quality. Sampaio and Mancini (2007) suggest that conducting a systematic review involves work of at least two researchers, who will independently evaluate the methodological quality of each selected article. The scheme used to elaborate the present research follows steps suggested by Sampaio and Mancini (2007), as shown in the steps of Figure 1, with the appropriate adaptations.

Source: Adapted from Sampaio and Mancini (2007).

Figure 1 - Scheme of the Systematic Literature Review process

Before describing the five phases of this systematic review, authors emphasize the importance of elaborating a research protocol, which was elaborated in research preparation phase, since it will guide work during the systematic review entire process.

2.1 Defining the Question

Based on research origin, presented in research contextualization, it was identified as a guiding theme the Regional Development based on Knowledge in an approach using Innovation Networks Analysis. In this sense, the research question was established as follows: How the social interconnections between a local network agents can contribute to the Regional Development based on Knowledge?

2.2 Seeking the evidence

For development this systematic review two databases with significant relevance to search were identified:

- Elsevier BV's Scopus Platform: selected due to its wide breadth and indexed data relevance, considered the largest abstracts and citations database of peer-reviewed international scientific literature, has intelligent tools to monitor, analyze and support the search. With access to 70 million records in the areas of Science, Technology, Medicine, Social Sciences, Arts and Humanities, bringing together 22,800 titles from over 5,000 international publishers, including 2,600 open access journals, 370 trade publications and 420 book series.

- Clarivate Analytics Web of Science platform: a multidisciplinary reference framework integrated with the ISI Web of Knowledge database, which has approximately 12,000 journals and offers tools for citation, reference and index analysis, allowing bibliometric analysis and is also considered one of the larger databases.

Using the protocol built in research and selection phase as databases for research sources search, we define the key terms based on the research question: Knowledge (K), Regional Development (RD), Analysis of Networks (NA) and Innovation (I). In independent searches, the term Economic Development (ED) was also used, which was considered relevant for inclusion.

From this, search strategies were established, when Galvão, Sawada and Trevizan (2004) suggest that, for this stage, the strategy used should be broad, so there was no restriction regarding document type, area geography, language or knowledge area, the search fields were Article Title, Abstract, Keywords in Scopus and using the Topic selector in Web of Science. The chosen time period covers every year, from the first records to current publications. Using search capabilities of both databases, the quotation marks were used to avoid lematizations and to restrict search in determined term, it was necessary, also, use of the boolean operators "AND" to combine terms.

Table 1 shows the total production recorded in selected databases using each key term selected individually and in combination between them.

Table 1: Scientific production resulting from search strategies

Key Terms	Scopus		WoS		TOTAL	
K	1.775.007	76,88%	1.185.416	79,06%	2.960.423	77,74%
RD	15.159	0,66%	9.802	0,65%	24.961	0,66%
ED	82.921	3,59%	53.657	3,58%	136.578	3,59%
NA	85.794	3,72%	28.427	1,90%	114.221	3,00%
I	349.915	15,16%	222.040	14,81%	571.955	15,02%
TOTAL	2.313.640	100%	1.499.432	100%	3.808.138	100%
RD + ED	2.401	10,38%	1.461	8,51%	3.862	9,58%
RD + NA	62	0,27%	43	0,25%	105	0,26%
ED + NA	208	0,90%	138	0,80%	346	0,86%
RD + K	1.269	5,49%	1.186	6,91%	2.455	6,09%
ED + K	5.089	22,01%	3.662	21,33%	8.751	21,72%
RD + I	1.643	7,10%	1.529	8,90%	3.172	7,87%
ED + I	5.234	22,63%	4.352	25,35%	9.586	23,79%
NA + K	5.603	24,23%	3.439	20,03%	9.042	22,44%
NA + I	1.525	6,59%	1.271	7,40%	2.796	6,94%
RD + NA + K	12	0,05%	13	0,08%	25	0,06%
ED + NA + K	31	0,13%	30	0,17%	61	0,15%
RD + NA + I	16	0,07%	15	0,09%	31	0,08%
ED + NA + I	31	0,13%	29	0,17%	60	0,15%
RD+ED+NA + K + I	2	0,01%	3	0,02%	5	0,01%
TOTAL	23.126	100%	17.171	100%	40.297	100%

Source: Prepared by the author from the Scopus and Web of Science databases (2018).

The Table 1 data allow a scientific production analysis, initially showing that the key term Knowledge (K) has a significant emphasis on scientific production, representing 77.74% of registrations, followed by the production in Innovation (I), 15.02 %.

2.3 Reviewing and Selecting Studies

During the initial survey, with extensive search strategies use in databases, it was possible to observe that in combination of terms Regional Development and Network Analysis (RD + NA), as well as Economic Development and Network Analysis (ED + NA), there is a significant reduction in records found, being this determinant to review a search strategy with objective of selecting studies for critical analysis.

It is also worth noting that, by combining the five key terms selected for systematic review (RD, ED, NA, K and I), it was observed that there are few studies, representing that there is a possible gap in scientific knowledge published on these bases, thus, the search strategies in these combinations are determined in order to select all studies relevant to this systematic review.

Table 2 shows the combination of key terms and respective strategies used in studies search.

Table 2: Scientific production resulting from search strategies for review and selection of studies

Key Terms	Search strategy	Scopus	WoS	TOTAL
RD + NA + K	TITLE-ABS-KEY ("Regional Development" AND "Network Analysis" AND Knowledge)	12	13	25
ED + NA + K	TITLE-ABS-KEY ("Economic Development" AND "Network Analysis" AND Knowledge)	31	30	61
RD + NA + I	TITLE-ABS-KEY ("Regional Development" AND "Network Analysis" AND Innovation)	16	15	31
ED + NA + I	TITLE-ABS-KEY ("Economic Development" AND "Network Analysis" AND Innovation)	31	29	60
RD+ED+NA+K+I	TITLE-ABS-KEY ("Regional Development" AND "Economic Development" AND "Network Analysis" AND Innovation AND Knowledge)	2	3	5
TOTAL		92	90	182

Source: Prepared by the author from the Scopus and Web of Science databases (2018).

Once the 182 studies were selected, was made a critical evaluation of the titles and abstracts, obeying the inclusion and exclusion criteria defined in research protocol. When title was not enlightening and the abstract was not retrieved by database, the article was searched in its entirety, so as not to risk leaving important studies out of systematic review. Table 3 shows the studies selected number after a critical evaluation of studies.

Table 3: Scientific production resulting from search strategies for review and selection of studies

Key Terms	Scopus	WoS	TOTAL	Deleted	Repeated	Selected
RD + NA + K	12	13	25	3	2	20
ED + NA + K	31	30	61	21	8	32
RD + NA + I	16	15	31	2	7	22
ED + NA + I	31	29	60	19	8	33
RD+ED+NA+K+ I	2	3	5	0	2	3
TOTAL	92	90	182	45	27	110
DUPLICATIONS						45
RESULT						65

Source: Prepared by the author from the Scopus and Web of Science databases (2018).

About the 182 studies selected for critical analysis, 45 were eliminated, because they did not show adherence to research, 27 replications were identified in both databases and 45 studies were duplicated, that is, they were registered in more than one search using two or more terms resulting in 65 selected studies.

3 Results

3.1 Analyzing the contributions of the studies

According to Galvão, Sawada and Trevizan (2004), the any systematic review usefulness depends largely on quality of the studies included in it. The authors also point out that critical evaluation consists on phase where all selected studies are evaluated with methodological rigor, in order to determine if research results are sufficiently valid to be considered. Table 4 presents synthesized contributions of 65 selected articles.

Table 4 - Contributions from selected studies

Theme	Author(s) / year	Contributions
Management in network configurations	Agranoff and McGuire (1999) Hauck et al. (2015)	Management in network configurations is not based on central authority, suggesting that future research should discuss the skills development needed for network management.
	Sasaki et al. (2011)	Cluster regional policies are recognized as intensive projects to form effective knowledge networks. On other hand, the methodology for evaluating these network structures is still in development.
	Li, Li and Liu (2011)	By analyzing networks structure and interactions between networks, four stages of network evolution are identified: family networks, internal division networks, local innovation networks and global supply networks. Each stage plays a different role in cluster development.
	Schüßler et al. (2013)	Internally governed clusters networks are formed to establish links between representative clusters to share knowledge and pool resources in selected activities; Externally managed cluster networks are formed to systematically develop links and skills across clusters at different levels and are intermediated by a central inter-cluster administrative organization as well as by several leading decentralized organizations.
Innovation, cooperation, collective learning	Mackellar (2006) Eraydin and Fingleton (2006) Steinberg et al. (2010)	The results demonstrate the success of regional development cooperation and highlight the importance of developing and maintaining network relationships for collective learning and knowledge overflow

and regional development	Deas et al. (2013) Evans et al. (2015) Ansell et al. (2017) Im et al. (2017)	
	Yokura et al. (2013) Fromhold-Eisebith and Werker (2013) Meyborg (2013) Wakabayashi and Takai (2016) Snickars and Karlsson (2017)	Academic cooperation has a far greater spatial reach than cooperation with private firms, while the public sector plays an important role in local innovation processes. Universities play a key role as a platform for knowledge in regional economic development.
	Holman (2013)	Ephemeral partnerships are a problem because the knowledge generated by these partnerships can also be seen as ephemeral, increasing fatigue and cynicism among stakeholders. The structure of the network and the ability to collaborate can contribute to the depth of penetration and the longevity of the knowledge created in local partnerships.
Network Connectivity	He and Fallah (2006) Casper (2007) Sonmez (2017)	Mobility of people among their employers contributes to knowledge connectivity in the cluster.
	Van Der Valk (2007)	At the level of the network of collaborations, the research institutes have a central position.
	Fritsch and Kauffeld-Monz (2009) Kustepeli et al. (2013) Dziadkowiec et al (2015) Bauer et al. (2018)	Strong ties are more beneficial to the exchange of knowledge and information than weak ties and the positions of brokers tend to be associated with social returns rather than private benefits. Building Trust is a Key Factor for Collaboration
	Graf and Henning (2009) Schiller and Kiese (2010) Caniëls and Van den Bosch (2011) Yun and Lee (2013) Scoponi et al (2016)	Universities and non-university institutions of public research are key actors as integrators and essential elements of an effective innovation system.
	Krätke (2010) Yun and Lee (2013) Almodovar and Teixeira (2014) Calignano (2014) Makarem (2016) Noguera-Méndez et al. (2016) Lahdelma and Laakso (2016) Huggins and Prokop (2017) Rubio-Mondejar and Garrues-Irurzun (2017) Fang (2018)	Connectivity in a regional knowledge network can contribute positively to the innovation capacity of a region. Applying network theory, we can improve our knowledge of structural differences and their relationship to economic growth and regional development.
	Li et al. (2011)	Traditional production clusters are most affected by emotional connections, family relationships are the dominant channels of business, while supply and demand relationships and mobility of skilled workers are also important paths to network learning, and cooperative relationships are comparatively stable.
	Plum and Hassink (2011)	There are some key differences found in the knowledge network characteristics between knowledge base (science-based) and synthetic (engineering-based) knowledge base.

Global Networking	Eraydin and Fingleton (2006) Xu and McNaughton (2006)	The mobility of inventors between their employers and collective learning contributes to the globalization of companies.
	Varga and Sebestyen (2017)	Innovation in less developed regions tends to rely more on external knowledge to compensate for the underdevelopment of their local knowledge infrastructure.
Knowledge Based Development	Webb (2008) Chilton and Jung (2018) Galaso (2018)	It explores the social capital and knowledge networks of a region, responding to regional development agendas, identifying the need to specifically address the underlying weaknesses (participation, connectivity, and enterprise) in the regions of the city.
	Schiller and Kiese (2010) Fromhold-Eisebith and Werker (2013)	Universities and public research institutes are an important driver of innovation and knowledge-based economic development and their performance is increasingly evaluated based on their impact on regional development.
	Shapiro and Park (2012) Cabanelas et al. (2014) Wanzenbock et al (2015) Sigler and Martinus (2017) Sun and Grimes (2017) Gama et al. (2018)	Policies to encourage research specialization programs help the region become a network hub of knowledge. Public policy must be clearly committed to supporting research as a driving force in regional development.
	Emons (2012)	A better regional R & D activity to stimulate regional economic development
	Vittorio et al. (2013)	Differences in socioeconomic development can be explained by reference to some peculiarities of the knowledge economy.
Social Networking Analysis	Reid et al. (2008)	It uses a social network analysis as a method of analysis, in critique of the spatial delimitation approach, given by the clustered literature, which makes the difference between leaders, and economic development professionals and researchers.
	Russo and Rossi (2009)	Combining the tools of ethnographic research and analysis of social networks, this approach derives from the general characteristics, besides selecting methodologies for the design and evaluation of programs for innovation networks.
	Kratke and Brandt (2009)	The networks analysis of knowledge of a polycentric metropolitan region in different fields of competence produced information about the density of interconnected knowledge in the region, the degree of connectivity between the scientific institutions of the region and the companies in the private and central sector of the network. within the region.
	Brandt et al. (2009) Krebs and Latvia Univ (2013) Zhong (2018)	The analysis of networks as a thematic tool of information for knowledge management, the production of network diagrams and the parameters of network size, density, centrality, cohesion and connectivity of a large sample of actors and connections.
	Krätke (2010) Martinus (2018)	The use of a social network analysis approach can improve knowledge networks in a regional context.
	Lopes et al. (2010)	The use of social network analysis in a perspective of building communities of knowledge and adoption of ICTs.
	Kiminami et al. (2011)	The existence of a network of Small World types is considered to induce a flow of knowledge and information.
	Gopal (2012)	It serves the techniques: conceptual visualizations of trees to find patterns that affect regional development; network analysis to compare and contrast urbanization; The analysis of feelings for various sectors of development that provoke positive and negative reactions.
Social Networking Analysis	Fromhold-Eisebith and Werker (2013)	The social networks analysis and their theoretical basis offers more information on the functions of knowledge transfer of universities.

Source: Prepared by the author.

From this point on, the systematic review allows connection between selected scientific productions and research themes, identifying their contributions and raising new questions that allow the advancement in science, corroborating studies relevance that approach development based on knowledge in a approach to social network analysis.

The systematic review allow a synthesis of all studies on the subject, allowing a greater relevant results range to be incorporated, and this systematic review step presents results regarding the selected studies contributions and an advance analysis in scientific knowledge in which new studies are inserted.

3.2 Bibliometric Analysis

The Graph 1 allows a view of the temporal evolution of the studies produced and selected that contribute to the thematic of this study. The trend line shows that the productivity of studies in the subject under analysis shows an increase in the number of publications, suggesting that this is an emerging theme, especially in the last five years.

Source: Prepared by the author (2018).

Graph 1 - Time distribution of scientific production in the theme

According to Guedes and Borschiver (2006) bibliometrics is a set of laws and empirical principles that contribute to the establishment of the theoretical foundations of Information Science. The standard of distribution of bibliometric laws and principles follows the maxim "few with much and very few", known as the Matthew Effect in Science. Lotka's Law, quoted by the authors, considers that some researchers, presumably of more prestige in a certain area of knowledge, produce much and many researchers, presumably of lesser prestige, produce little.

Krätke produced three of the selected studies, two in 2009 in co-authoring with Brandt, one of which was produced only by the two authors and one co-authored by Hahn and Kiese. In 2010 Krätke produced the study Regional Knowledge Networks: A network analysis approach to the interlinking of knowledge resources published in the European Urban and Regional Studies where it employs a stakeholder networks approach for the analysis of knowledge networks in a metropolitan region of Germany to to investigate the structure and properties of regional innovation networks in a detailed and differentiated way, contributing significantly to new research.

Another bibliometric analysis mentioned by Guedes and Borschiver (2006, p.4) concerns Zipf's Laws, which allow estimating the frequencies of occurrence of the words of a given scientific text: "a small group of words occur many times and a large number of words is of small frequency of occurrence".

Figure 2 - Word cloud using the titles of the selected studies in the SLR

Following the ranking of the frequency of occurrence of words in the titles of selected studies appear the words: Regional, Innovation, Knowledge and Development. This represents the importance of considering knowledge-based regional development from the perspective of innovation. However, innovation must conceive of a perspective that transcends organizational aspects, in its process vision, products (goods and services) and marketing, these aspects are now required to be useful for human development. In this line, the ranking of frequency of occurrence of words (Table 5) presents its evidence when the word Social is above the word Economic.

Table 5 - Ranking of frequency of occurrence of words in the titles of selected studies

Ranking	Word	Frequency
1°	Network	61
2°	Analysis	21
3°	Regional	21
4°	Innovation	20
5°	Knowledge	18
6°	Development	16
7°	Social	14
8°	Economic	12
9°	Cluster	12
10°	Research	9

Source: Prepared by the author.

Another aspect to be considered in the evidence of the occurrence of words is the form of organization in Clusters, presenting itself as a significantly representative theme in the surveys between 2006 and 2016, where networking became a tool to increase the competitiveness of companies.

In 2017 and 2018 they begin studies using the network analysis approach that seeks to identify the flow of knowledge and ideas, political-institutional university-company relations and between regions, highlighting the relevance of the morphology of cities in this process of socio- sustainable economic.

4 Discussions

Emphasis is given to the contributions that future studies intend to present for advancement in knowledge-based regional development studies using a network analysis approach. In this new context of transformation of society, development must presuppose factors that move beyond the paradigm focused on economic growth, seeking the broad development of a region, from the perspective of a society based on knowledge.

However, to this end, we must understand factors that contribute to this advance in social and human factors, paying more attention to the improvement of the factors that determine the quality of life, of a more cultural and environmental nature, in which knowledge-based development using a approach to network analysis, allows you to understand the spectrum of values that an organization or a society has.

It is important to highlight that the models of analysis using probabilistic mathematics are no longer sufficient to prospect models of future scenarios. In contrast to deterministic processes, in the context of the Knowledge Age, it is necessary to apply stochastic processes, thus, network analysis seeks to establish a family of random variables representing the evolution of a value system over time.

Knowledge-based Development is the opportunity to pay more attention to the improvement of the factors that determine the quality of life, factors of a more cultural and environmental nature than those of the productive sector. However, this new context requires conditions and environments very different from those required by mass production activities. In order to survive, organizations must become more dynamic, more open and more sensitive to changing demands (changes in technology, the market, etc.)

and this requires more knowledge about all aspects of a production chain, which requires more and more customized solutions, as well as distribution, marketing, financing and flexibility aspects.

In this way, Knowledge Based Development seeks to meet the need to promote accelerated and sustained productivity growth and increase competitiveness through a new development model that privileges the use of knowledge, seeks sustainable development, through social processes of knowledge that values endogeneity, local potential and resources. It is the result of a mosaic of research and practice focused on knowledge that is shaping a multidisciplinary field that promotes decision makers and analysts with new concepts and technological tools that enable the development of appropriate frameworks and policies. Thus, Knowledge Based Development is built using social technologies that utilize the participation and engagement of the three spheres that make up the Triple Helix: Business, University and Government.

Therefore, innovation, understood in its technological, organizational and institutional dimensions, assumes an even more important importance as a strategic variable, since it causes a structural break with the technological standard, changing the status quo, giving rise to new industries, sectors and markets , or even significant reduction of costs and increase of quality in existing products, fundamental for the increase of the productivity and, consequently, of the competitiveness of a region and national.

The complexity of the innovative process requires an interorganizational network interaction, because there are relevant factors in the innovative environment where the organization is inserted and in the innovation management process, there is greater internalization through links with sources of knowledge and cooperation, generating knowledge results. Therefore, a new understanding of managerial and strategic aspects is important, where hierarchical leadership gives way to network leadership. Thus, as studies on innovation and entrepreneurship, Network Analysis also has its roots in several theoretical perspectives, and can be considered an interdisciplinary field of study. There is a rapid development of Network Analysis in recent years, leading to the resurgence of experimental and non-experimental research on the relationship between the centrality and power of social agents. Observing the contribution that an approach using the Analysis of Innovation Networks involving the spectrum of the Triple Propeller, its contributions to the diffusion of a knowledge-based economy, potentializing regional socioeconomic development.

In this sense, it is fundamental to carry out research in the field of relations between agents of an ecosystem of innovation, seeking to establish strategies of regional development based on knowledge.

5 Conclusions

The Systematic Review allowed the search of the indexed studies in the selected databases and, through explicit methods of planning and execution, these were evaluated and selected, presenting significant contributions for future studies. This process is fundamental to search for evidence regarding relevance to research topics, the evolution

and maturity of the studies already produced, as well as to limit the scope of the research, allowing to identify gaps in the theory where it is sought to explore the opportunity of new scientific contributions.

The bibliometric analysis shows that the theme is relevant for its contemporaneity, with a significant growth of studies in the last years, that future studies are added to the recent studies, allowing the scientific advance that the development of a region must understand, besides economic factors, social and human factors, paying more attention to the improvement of the factors that determine the quality of life, of a more cultural and environmental nature, that is, based on knowledge, allowing to understand the spectrum of values with which an organization counts or a society.

Another important factor is a new conception regarding the contributions to regional development from the perspective of innovation, where organizational aspects are transcended in their process design, products (goods and services) and marketing, but it is fundamental that innovation solutions to the quality of life of a society and to human development.

Abstract

As was already identified in our previous studies, managers who operate in the modern organizations should apply a new set of abilities to lead the teams (Nikitina and Lapina, 2018; 2019). Policy makers (OECD policy report, 2018) claim that entrepreneurial behaviour of employees urged to adapt to changes. There is no common opinion among researchers about similarities of managerial and entrepreneurial competencies. Some researchers point out that psychological differences between managers and entrepreneurs are insignificant in large organizations (Begley and Boyd, 1987; Sexton and Bowman, 1984; Brockhaus and Horwitz, 1986; Low and MacMillan, 1988). Other researchers report that entrepreneurs manifest more overconfidence contrary to managers (Busenitz and Barney, 1997). Other researchers assume that business owners' competencies are combined from managerial and entrepreneurial (Chandler and Hanks 1994). Recent studies emphasize that entrepreneurs are different from non-entrepreneurs in terms of the competencies they possess (e.g. Huck and McEwen, 1991; Chandler and Jansen, 1992; Minet and Morris, 2000; Baum et al., 2001; Man et al., 2002; Sony and Iman, 2005) and entrepreneurial behaviour needs to manage culture, while the non-entrepreneurial one is oriented towards performance management (Sadler-Smith et al. 2003).

Over the last decades there is a rise in the number of SME companies where people perform entrepreneurial, managerial, and operational functions (Cohen & Musson, 2000). Researchers assume that entrepreneurs have a broader scope of competencies, as they need to play the roles of the manager, owner and entrepreneur (Man, 2001). Researchers have identified a specific group of competencies relevant to development of small businesses (Smith and Morse, 2005). Addressing SME challenges, researchers define finance management, establishing good human relations and planning goals as the most important competencies needed for SME entrepreneurs (Huck and McEwen, 1991), then the list was extended with opportunity recognition, opportunity development, and strategic and decision-making skills (Herron and Robinson, 1993; Man et al., 2002). The findings correspond to the discoveries proposed by Gaile-Sarkane who introduced Semi

Management Theory addressing management functions in small and medium companies (Gaile-Sarkane, 2012).

The purpose of the research was to analyse the relationship between managerial and entrepreneurial competencies, the following hypotheses were used:

H1: Managers and entrepreneurs share the same set of competencies but the importance of the competencies varies for each of the groups.

H2: Managers and entrepreneurs acquire the competencies differently – the first set is gained via education and experience; the other set is developed due to personality and experience.

Keywords – competence, managerial competences, entrepreneurial competence, knowledge management

Paper type: Academic Research Paper

1. Literature Review

Literature review was conducted to respond to the questions whether there is change and development trend in entrepreneurial knowledge, skills sets, and competencies and whether there is a method to train and assess them in the real business environment. For the purpose of the content analysis the authors reviewed academic sources in the EBSCO database for the period from 2015 to 2018. Initially 98 articles were selected according to keywords “entrepreneurial skills”, “entrepreneurial competences”, “entrepreneur + competence”. For analysis the authors chose 70 articles where entrepreneurs were considered as subjects for investigations on entrepreneurial competences, whereas studies where organizations were assumed as subject for research were excluded from the content analysis. As per recommendations for qualitative content analysis developed by P.Mayring (2014), three segmentation rules or units of analysis were defined. The first one is the ‘coding unit’, or the smallest component of material within one category; in the study it is a specific word or phrase. The second one is the ‘context unit’, which defines the largest component in the category, a document page in the case. Finally, the third one is the ‘recording unit’ that “determines which text portions are confronted with one system of categories”, it is an article or document. The authors were interested in the changes appearing during the last three years and discovered that half of the sample were devoted to the role of higher education institutions (HEIs), competence assessment and training methods to develop entrepreneurial competences, while the other part of articles were focused on field research and case studies. The authors identified some correlation between perception about entrepreneurial competences in previous years in comparison to the latest years, as well as linkage to managerial competences. For purpose of this research the authors define the following concepts: competence (plural – competences) is a set of skills, knowledge and attitude or set of competencies (singular – competency) that include also personal behaviour or intent. A summarized output of the first part is represented below in Table 1 and Figure 1.

2. Methodology of Research

As the studies were performed as a part of ERASMUS+ KA2 project, to validate the theoretical detections EntreComp: the Entrepreneurship Framework was set as a benchmark for emerging and demanded skills in the labour market. The geographic scope is primarily Finland, Latvia and the Netherlands. A study on trans-disciplinary entrepreneurship training is considered an intellectual output of the research. Business environment trends in the demand for competences in the labour market and international business environment is one of the focuses for the researchers.

Three focus groups that consisted of 5 start-up entrepreneurs were considered as an identification method to recognize the sets of knowledge, skills and competence for further analysis. The focus group members in Finland, the Netherlands and Latvia conducted brainstorming for competences generation, and then named whether or not the competences corresponded to the ones that are enlisted in the 15 EntreComp model competences. The evaluation of the importance of the existing 15 EntreComp competences and of newly identified competences was required for the first half of the importance/performance analysis – the importance of competences necessary in the transdisciplinary entrepreneurship training methodology for entrepreneurship and management students. During the later phases of the project research the list of competences was analyzed to understand whether the performance of training meets entrepreneurs' perception about the skills importance/demand, hereafter in Table 2 it is possible to see the respondents' assessment divided per country.

Importance-Performance Analysis is a technique which visualizes an area divided into four quadrants based the values of importance and performance of different elements which are calculated in relation to each other on two-dimensional coordinate system. As per authors of the method (Martilla & James, 1977), values of different attributes are provided by respondents' assessment, calculated and represented in the coordinate system where the horizontal axis is considered as performance, and the vertical axis – importance. When conducting focus groups formed from start-up entrepreneurs, the authors asked the respondents in each country to evaluate the competences listed in the EntreComp competences list on the scale from 1 to 4 where 1 is the least important ability. Then the data from all respondents was summarized per country and its weighted values are presented in Table 2 illustrating importance of each competence to SME during its early phases.

3. Entrepreneurial competences

There are many competences, such as initiative taking, creativity, result orientation, capacity for reflection and interpersonal skills, active problem seeking and problem-solving, risk appetite, that are considered by many researchers as typical for entrepreneurs (Baert & Camertijn, 2007; Gibb, 2008; Laevers & Bertrands, 2004; Van den Berghe, 2007; Van der Kuip & Verheul, 2004, Schelfhout et al., 2016). At the same time, as already mentioned above, modern environment and policy makers are interested in

approximation of managerial and entrepreneurial competences. HEIs are concerned with developing not only skills but attitude that shapes the action of the workforce turning towards proactive entrepreneurial behaviour. For example, European Competence Framework (ECF) is used as a base for a self-assessment study to identify entrepreneurial competences acquired in entrepreneurship education courses in Estonian universities. The researchers have evaluated cognitive outcomes of the courses (knowledge about entrepreneurship), then affective outcomes (entrepreneurship-related attitudes,) and skill-based outcomes (entrepreneurial skills). To the last group of competences correspond business planning and modelling organization, project management, marketing, leadership, motivating others, team and individual work, negotiation, risk-taking, lateral thinking, commitment, managing uncertainty, solving problems, creative thinking, resolving conflicts (Kraiger et al., 1993; European Union recommendations, 2006; European Commission, 2007; Fisher et al., 2008; Kyro, 2008; ECOTEC, 2010; European Commission, 2012; Amaeshi, 2017). It was discovered that an overview of an educational program reports positive outcomes of skill-based training, although those students who come from entrepreneurial families demonstrate higher aspiration to education, a study conducted by Mets revealed that earlier orientation of students significantly influences the outcomes of the course (Mets et al., 2017). An interesting fact is that another study reported that entrepreneurial skills, such as creativity, openness to risk-taking, negotiations skills, technical knowledge and skills and marketing, are passed from generation to generation in case of a family SME (Letonja et al., 2016). Another study in the Baltics discovered creativity, communication, organiser and project manager skills, ability to plan and ability to take risk, entrepreneurial ability, and as an opportunity to acquire knowledge as a skillset for start-upers. In contrast to the previous study in the neighbouring country, it was discovered that students in Latvia have less knowledge about entrepreneurship and the demands of the labour market (Bikse et al., 2017). Similar findings were reported by researchers from Poland stating that people tend to see themselves as employees not employers, do not willing to take risks, initiative, or demonstrate creativity (Igielski, 2017). When investigating the need of entrepreneurial competences for managers and leaders another researcher discovered that entrepreneurial competences are more important for those who “need to deal with risks and challenges” (Postuła and Majczyk, 2018). Other researchers agree by pointing out that there are differences in the entrepreneurial competences between the countries depending on economic climate, i.e. passive environment or opportunity scanning (Taipale-Erävala et al, 2014).

Interestingly that a researcher from Finland emphasizes the significant role of social skills, supporting and serving society as a powerful driver to raise a responsible citizen that leads to the appearance of responsible entrepreneurial behaviour (Laalo and Heinonen, 2016). Researchers recognize the importance of network development, i.e. development of transactional and relational competences (Maksimov, 2017). There is a correlation between strong partnership management skills and sales and marketing skills (Khalid, 2015). Similar observations were made in the Netherlands where an empirical study among Master students revealed the influence of social competence and social

capital towards the raise of entrepreneurial ambitions. It was stated that social competence is a cornerstone to a range of opportunities for the entrepreneur forming a social capital for early-stage entrepreneurs (Lans et al., 2015). Dealing in uncertain situations requires a competence of crisis management; application of the competence to the context of entrepreneurial crises, such as resource shortage, dissatisfied clients or incorrect overview of financial perspective of the new venture, demands fostering the entrepreneurial competences of perceiving the critical incidents and coping with them (Heinrichs, 2016). Intriguing findings were reported by a Lithuanian researcher who proposed a technology entrepreneurship development aimed to combine techniques for launching a new business and products as well as exploring opportunities in the field of technical knowledge and science. Hereafter, it is suggested to train engineers in lean start-up methodology, business modelling, intellectual property protection and funding for a start-up in the same way that future managers and entrepreneurs are usually trained (Juceviciene et al., 2015). The author referred to previous studies (Pretorius et al., 2005) where competencies related to business management were set as complementary for an overall entrepreneurial competence. Researchers emphasize the importance of both the entrepreneurial and technical competence as preconditions for innovation and successful launch and further growth of a new SME (Ng et al., 2016). As SMEs usually operate with limited access to resources, the enterprises benefit from professional technical expertise and experience of their owners, e.g. receiving a grant at the beginning of business activities (Stenholm and Renko, 2016). Alike to the previous studies, some researchers are convinced that the abilities to plan and organize work, supervise tasks and manage people are perceived as the most important both for managers and owners of internationalized SMEs (Korsakiene, 2015).

Interestingly, the idea of gaining benefits from academic entrepreneurship, cross-disciplinary studies, entrepreneurial and operational activities is supported by researchers who write about entrepreneurial ecosystem and beneficial location of the clusters where HEIs and start-ups are collocated (Rasmussen 2011, Rao and Mulloth, 2017). Researchers (Bohdziewicz, 2016, Tuononen et al., 2016; Bravo et al., 2017; Sales et al., 2017), who explore entrepreneurial and managerial competences, refer to the concept of Career Anchors by Edgar Schein (Schein, 1985) that describes an individual's personal identity or self-image with many facets including among others technical and functional, general management and entrepreneurial creativity. Researchers found out that when comparing the entrepreneurial orientation with the managerial orientation, there is a big overlapping in the criterion variables to which each is related, hence the main difference between these two dimensions of career orientation is the desire for upward movement within the organization in the managerial orientation in contrast to a dedication for the creation of new products or processes for the entrepreneurial orientation (Bravo et al., 2017).

There are many categorizations for entrepreneurial competences, some researchers (Bird, 2002; Man et al., 2002,) divided them as 1) market exploiting opportunities; 2) interpersonal relationships; 3) conceptual abilities, such as decision-making, understanding of complex situations and innovativeness; 4) organizational skills; 5) strategic skills; 6) belonging and leading. There is another approach proposed by Le Deist

and Winterton (2005) in the context of entrepreneurial educational program development that defines entrepreneurial competence as a sum of 1) knowledge-related cognitive competence; 2) entrepreneurial skills and know-how functional competence; 3) behavioural competence.

According to the EntreComp framework (EntreComp, 2018), 15 entrepreneurial competences are divided into three areas, they are: 1) ideas and opportunities, 2) resources, and 3) into action; the full list of competences, output of content analysis and managerial competences discovered by the authors in the previous studies are compared in Table 1 below.

Table 1 Comparison of Entrepreneur's and Manager's Competences, created by the authors

EntreComp (2018)	Entrepreneurial Competences	Entrepreneurial Competences since 2015	Managerial Competences
Creativity	Creativity, creative and lateral thinking	Creativity and creative thinking	Creativity
Coping with uncertainty, ambiguity and risk	Managing uncertainty	Managing uncertainty	Ability to react and divide risks
Working with others	Team and individual work	Team and individual work	Teamwork
Self-awareness and self-efficacy	Capacity for reflection	Self-awareness	Self-organization
Mobilizing others	Interpersonal skills, incl. conflict resolution and negotiation	People management incl. Communication and Social skills, network development, partnership management, social competence	Ability for collaboration and forming relationship
Motivation and perseverance	Motivating others	Motivating others	n/a
Taking the initiative	Initiative taking	Initiative taking	n/a
Planning and management	Business planning, modelling organization, project management	Business modelling, organizing incl. specialized techniques, e.g. Lean start-up methodology	n/a
Spotting opportunities, Valuing ideas and Vision	Entrepreneurial ability	Entrepreneurial ability	n/a
Learning through experience	n/a	Ability to acquire knowledge	Willingness to learn and Erudition
n/a	Leadership	Leadership	Leadership

It was interesting to identify that three competences that are creativity, managing uncertainty, teamwork, ability for self-awareness and self-organization and strong people management competences are relevant for all researchable groups – for modern managers, entrepreneurs and the entrepreneurial educational standard as well. It is important to note that when describing entrepreneurs in the last three years researchers pay great attention to the investigation of social competence, communication and social skills, network development, and partnership management – that is a mirror image of the manager's collaboration ability and competence to form internal and external relationships.

The next group of the entrepreneurial competences identified by researchers among entrepreneurs in the last decades, including the last three years, and included in the EntreComp framework are the ability for motivating others, ability to take initiative, competence in business planning and management and ability to spot opportunities. A thought-provoking finding is that during the last couple of years, entrepreneurial competences in the field tend to be very specific, for example, a competence in business modelling, organizing incl. specialised techniques such as the lean start-up methodology. The researchers assume the change might be caused by the increasing role of start-ups as a form of SMEs and a rise in the number of business accelerators and incubators.

There are two more peculiar findings: leadership competence, which for many year was considered as an undivided part for leaders and managers, is not included in the EntreComp model, however, the ability to acquire new knowledge, which is demanded for modern entrepreneurs and managers as well as incorporated in the EU Entrepreneurship Competence Framework, is a novelty for academic research appearing recently.

The authors identified that researchers discussed the following entrepreneurial skills before and after 2015, however the competences are not reflected either in EntreComp or in managerial skills: 1) solving problems / dealing with critical incidents; 2) risk appetite and openness to risk taking / risk taking. At the same time, there are entrepreneurial skills that were discussed extensively earlier but have not been very popular in academic discussion during the last three years; they are result orientation and commitment, as well as marketing competence. Instead of it, academics utterly emphasize the significance of a) technical knowledge and skills; b) technology entrepreneurship; c) knowledge on intellectual property protection; d) competence in funding for start-ups. Probably these findings are linked with digital entrepreneurship and the notable role of ICT in the modern environment. Another interesting finding is that the EntreComp framework includes some skills that have not been widely discussed by researchers, they are:

- 1) ethical and sustainable thinking;
- 2) mobilizing resources;
- 3) financial and economic literacy.

Finally, the authors noticed that the ability to analyse and evaluate is obviously related to the managerial skills set only. A graphic representation of the findings is shown in Figure 1 below.

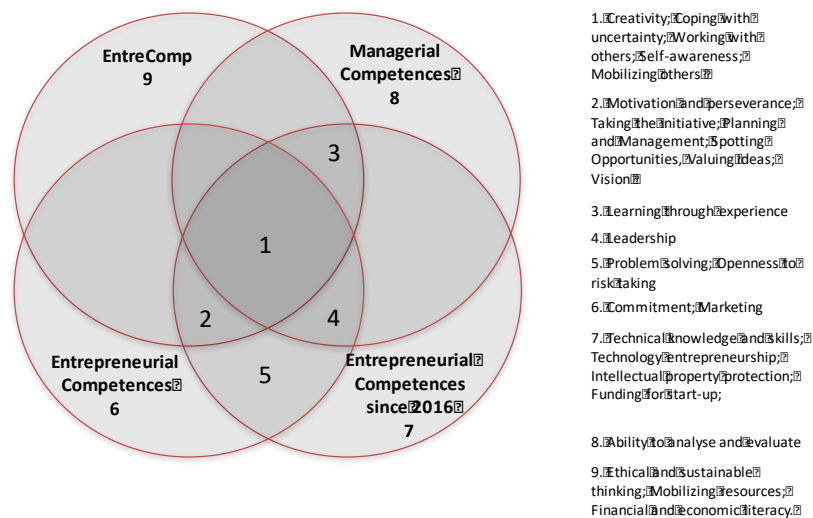

Figure 1 Entrepreneurial and Managerial Competences Model, created by the authors

4. Finding and Results

It was interesting to identify that entrepreneurs in all three countries participating in the research have a unanimous opinion about the motivation and perseverance competence as the most important to launch a business. The ability for spotting opportunities was chosen as the second most important by entrepreneurs in Finland and the Netherlands, while Latvian start-up founders ranked taking the initiative as the second most important for running a business on early stages. The third competence assumed as significant by the business persons was creativity in Finland, vision ability in the Netherlands and coping with uncertainty, ambiguity and risk in Latvia. A similar unanimous consent was demonstrated by the focus group members expressing their opinions about the least important skills for entrepreneurs: ethical and sustainable thinking, financial and economic literacy were chosen as less meaningful in all countries. In addition, the Finnish group pointed out that mobilizing others is not important for start-up companies; it might be explained by usually high motivation of the start-up team. The Dutch group also mentioned that planning and management are not so important for businesses during their early stages; it might be explained by the fact that start-ups usually focus on product development and launch, while tedious business and project planning are characteristic for firms in more mature development phases.

Comparison of the focus groups findings with previous findings of the authors lead to unexpected results, as the skills that were chosen by start-up founders as the least valuable for entrepreneurs are identical to the competences included the EU EntreComp framework but not massively investigated by other researchers from the perspective of entrepreneurial or managerial competences in modern organizations:

- 1) ethical and sustainable thinking;
- 2) mobilizing resources;

3) financial and economic literacy.

Table 2. 15 EntreComp Competences Evaluated by Start-up Entrepreneurs in Finland, the Netherlands and Latvia

EntreComp Competences	FI	NL	LV
Spotting opportunities	16	15	18
Creativity	16	13	16
Vision	8	15	17
Valuing ideas	4	10	18
Ethical and sustainable thinking	0	9,5	14
Self-awareness and self-efficacy	8	14	17
Motivation and perseverance	20	16	20
Mobilizing resources	8	13	18
Financial and economic literacy	0	7	14
Mobilizing others	4	14	17
Taking the initiative	4	14	20
Planning and management	12	8	19
Coping with uncertainty, ambiguity and risk	12	13	20
Working with others	12	10	18
Learning through experience	16	14	18

Acknowledgement

The article is written in the framework of a project that has received funding from Erasmus+ KA(203) Cooperation for innovation and the exchange of good practices Strategic partnership project No.2018-1-LV01-KA203-046974: “Augmenting academic entrepreneurial training methodology, international students’ entrepreneurship community, and fundamental entrepreneurial university network”. Project partners from Riga Technical University, South-Eastern Finland University of Applied Sciences and Hogeschool Rotterdam organized focus groups for the research purposes.

Abstract

This paper focuses on coproduction of knowledge-intensive business services (KIBS) and the impact it causes on their innovation activity. Coproduction refers to the customer engagement in one or more stages of the services production process. Although coproduction and value co-creation are close concepts and very often are used interchangeably, significant differences between these concepts exist as the latter covers a wider range of provider-client interaction during consumption and usage stages. While value co-creation is related to the development of the customer experience, coproduction is devoted to the creation of the service offering itself. According to the service-dominant logic, which is the most common framework in this field, customer is always a co-creator of value, while his involvement in coproduction is optional. This paper aims at studying whether those KIBS that involve their customers in coproduction are more innovative. The research model includes a set of innovation drivers like human capital, advertising expenditures, the existence of multiregional branch network and standardization as well as the coproduction measure. This model was empirically tested using a dataset of 441 KIBS enterprises in Russia. The results show that coproduction have a strong positive effect on the implementation of both technological and non-technological innovations in KIBS. It means that innovation-oriented KIBS may benefit from developing coproduction-based strategies. These findings contribute to both innovation management and KIBS studies and provide opportunities for future research in both fields.

Keywords – KIBS, coproduction, client involvement, innovation

Paper type – Academic Research Paper

1 Introduction

The concept of service co-production emerged in the late 1970s to describe close interactions between public services producers and the population as consumers of these services (Lehrer et al., 2012). However, since 2000s this concept has been started to be applied to the exploration of the relationships between private companies and their clients (Vieira et al., 2015). The growth of information availability, globalization and networking

in early 2000s has changed the world significantly and the research focus has shifted from producers to consumers (Vargo & Lusch, 2004). Companies' activities also moved from autonomous actions to those that involve collaborative interactions with their customers (Prahalad & Ramaswamy, 2004).

This inseparability of service production and consumption significantly enhanced the need for service producers to interact with their customers to deliver more valuable solutions (Lehrer et al., 2012). These consumer interactions are especially important for KIBS, i.e. service companies that provide knowledge-based solution at B2B markets, because they are extremely customer-oriented enterprises that develop customized services aiming at serving specific needs of each particular client (Bettencourt et al., 2002). This process requires information about the particular client rather than about the "typical customer" (den Hertog, 2001) and could be obtained only in a collaborative manner.

Despite the growing number of studies in the field of coproduction and value co-creation in a marketing and management literature, most studies cover only B2C markets and focus on customer outcomes like loyalty or satisfaction, while their impact on innovations is still being under-researched (Cui & Wu, 2016; Cabigiosu & Campagnolo, 2018). In addition, most studies in this field are conceptual in their nature and only suggest some hypotheses to be validated, but lack the empirical evidence to support them (Jouny-Rivier & Ngobo, 2016). However, with the growth of the importance of customer inputs coproduction management has become one of the most critical issues (Siahtiri, 2017), especially at emerging markets. This paper tries to fill these gaps and empirically explore the following research question: *how coproduction of KIBS influences innovation activities of these enterprises?*

The paper is structured as follows. Section 2 briefly introduces KIBS topic and presents the results of the bibliometric research. Section 3 relates to the discussion of coproduction concept and its comparison with the concept of value co-creation, following by the Section 4 which is devoted to the discussion of innovation drivers in KIBS. Sections 5 and 6 describe the methodology and the results respectively. The final section discusses the empirical findings and concludes.

2 Knowledge-Intensive Business Services

The concept of KIBS was introduced in the mid 1990s by Miles et al. (1995) who highlighted, that economic activity of a set of some service industries leads to "the creation, accumulation or dissemination of knowledge" (p. 18). Since then the research interest to these industries has grown significantly corresponded to the increase of KIBS contribution to economic growth and development (Miles et al., 2018). In innovation systems KIBS act as both knowledge intermediaries who provide required innovation inputs for their clients and innovators who develop innovative solution themselves (Shearmur & Doloreux, 2018).

Scarso (2015) highlighted that although most papers related to KIBS come from economics, in recent years management and geography scholars have also started to

contribute to KIBS studies. In addition, if earlier Muller & Doloreux (2009) suggested three main dimension for KIBS research (knowledge, innovation, and spatial proximity), Scarso (2015) add an additional “management” dimension which deals with marketing, customer relationships, new service development and human factors. To check whether the research interest in KIBS by management scholars still exists in this paper a keyword co-occurrence analysis was conducted¹. Final keyword co-occurrence network presented at figure 1 covers 125 items occurred in the selected papers at least 5 times. More recent used keywords are highlighted in yellow.

Figure 1. Keyword co-occurrence analysis of KIBS topic in WOS database

The results of the keyword co-occurrence analysis confirm that coproduction is one of the most emerging topics in KIBS literature. It is also usually co-occurred with such topics like customer interaction or value co-creation. It is in line with Lehrer et al. (2012), who highlighted that both terms “coproduction” and “co-creation” are usually used to describe the collaboration between service providers and their clients. However, very often the term “co-creation” is used without making a reference whether it relates to coproduction or to value co-creation (Mustak et al., 2013). These practices creates the ambiguity and make the differences between two concepts fuzzy (Vieira et al., 2015).

¹ The analysis is based on the published studies covered by the Web of Science database. The search query includes the following terms: “knowledge-intensive business services”, knowledge intensive business services” and “KIBS”. The analysis deals with those papers that have at least one these terms in the title or abstract. Papers that include terms like “kinetic inductance bolometers” (KIBs), “ion” or “batteries” (K-ion batteries, KIBs) were excluded. Final dataset consist of 456 publications including journal articles, conference proceedings and book chapters. The analysis of keyword co-occurrence was done using freely available VOSviewer software. Some keywords were merged manually due to the spelling issues.

3 Coproduction and Value Co-creation

Coproduction is usually recognized as one of the main feature of services (Lehrer et al., 2012). Despite the growth of research interest in this area there is still no commonly shared definition of this process. However, some core features may be derived from a wide range of approaches (Lehrer et al., 2012; Aarikka-Stenroos & Jaakkola, 2012; Leclercq et al., 2016; Ranjan & Read, 2016):

- Customers as active participants may be engaged in coproduction of service provider output at any stages of the production process preceding service consumption, including idea generation and design stages, production of related goods, service delivery, etc;
- During coproduction service providers integrates to their production processes some inputs provided by customers including intellectual (knowledge and expertise) and labor resources;
- This joint effort of both service provider and its customer is usually aimed at developing of the more optimal / effective / better quality / service solution;

The basic framework for the research of value co-creation is service-dominant logic. In their initial paper on service-dominant logic Vargo & Lusch (2004) suggested that the customer is always a coproducer of value and marks this statement as one of the fundamental premises of this theory. However, later they replace the term “coproducer” by the term “co-creator”, because coproduction relates to the service development (“making units of output”), while the process of value co-creation also includes service consumption, customer experience and perceptions (Vargo & Lusch, 2008). In their recent study Vargo & Lusch (2016) also paid attention to the importance of making a distinction between co-creation of value and customer engagement in the development of value propositions (service offerings). The comparison of two concepts is presented in Table 1.

Table 1. Comparison of “value co-creation” and “coproduction” concepts

Criteria	Concept	
	Value co-creation	Coproduction
Scope	Covers a wide range of collaborative service provider-customer relationships especially during service consumption and usage stages	Restricted to the service production and include only purposeful interactions and resource (including knowledge) sharing between service provider and its customer
Result	Value benefits for all the participants realized via interactions	Service offering (value proposition) as providers’ output that can be exchanged
Frequency	All the customers are always involved in the value co-creation as the services has no value till it is consumed	Not necessarily exist, usually is observed in interactions with experienced customers and lead users

Customer role	Leading role of the customer; Service provider helps to create or co-create his value and experience	Customer is only a contributor, leading role of the service provider
Participants	May be extended to relationships with all members of business ecosystem	Dyadic relationships between service provider and its customer
Type of value	Value-in-use	Value-in-exchange

Source: Developed by the author based on Vieira et al. (2015), Kohtamäki & Rajala (2016), Leclercq et al. (2016), Mustak et al. (2016), Mustak (2017).

Coproduction may be considered as a sub-process of value co-creation (Kohtamäki & Rajala, 2016). In addition, Leclercq et al. (2016) argued that coproduction of the service offering may lead not only to the co-creation of value, but also to the co-destruction of value. In turn, coproduction as being optional is often considered as an important process that facilitates the development of new innovative services (Greer & Lei, 2012). Miles (2008) also argued that innovative KIBS are more dependent on customer inputs than their counterparts from other industries which makes coproduction to be important innovation driver. Thus, the research hypothesis is as follows:

Research hypothesis: Coproduction is positively related to innovation activities in KIBS.

4 Innovation Drivers in KIBS

In this paper the model suggested in Chichkanov et al. (2019) is used as a baseline framework. This model covers four main innovation drivers found to be crucial in previous KIBS-related literature: human capital, access to the wider knowledge base, advertising expenditures and standardization. As the baseline model follows Gonzalez-Blanco et al. (2019) and treat both product and process innovations as a single group of technological ones, this paper also adopt this approach and additionally treat marketing and organizational innovations as a single group of “soft” or non-technological ones.

Human capital is usually considered as key production factor in KIBS as the nature of their activities is based on the tacit professional knowledge and expertise embedded in their employees (Schrike et al., 2012). In addition, most business processes in KIBS are those of the human nature, so these firms usually spend more on human resource training and development than manufacturing enterprises (Gotsch et al., 2011). Moreover, it was empirically shown that those companies that employ more qualified workforce are also better prepared to solving different issues related to innovation barriers (D’Este et al., 2014). Human capital may also be a measure of the absorptive capacity (Duchek, 2013).

According to Grandinetti (2018), absorptive capacity is important for KIBS as they are usually involved in both A- and C-networks. The latter refers to KIBS relationships with their customers, while the former is related to any other KIBS connections with competitors, research universities, etc. During their relationships with clients KIBS may either coproduce knowledge or just transfer knowledge they previously absorbed. In that case, A-networks become crucial as they provide KIBS an access to new external

knowledge that may be acquired, assimilated, transformed and applied. In that case, a multiregional branch network provides an opportunity to have an access to a wider knowledge base. In turn, this diversified knowledge base may enhance the innovation activity of KIBS by ensuring the availability of required knowledge inputs (Chichkanov et al., 2019).

In line with a “Schmooklerian” view of demand-driven innovation, the lack of demand significantly reduces the innovation activity (D’Este et al., 2012). The lack of demand is one of the biggest challenges for KIBS, especially at immature emerging markets (Lingyun et al., 2011). In developed countries KIBS also usually invest a lot in marketing and advertising to promote their innovative solutions (Asikainen, 2015). Moreover, advertising and marketing is often considered by services enterprises as an effective tool for protecting their innovations (Djellal & Gallouj, 2001).

Service solutions developed by KIBS are usually considered as highly customized and it is also described as one of the main sources of KIBS competitive advantage (Campagnolo & Cabigiosu, 2015). Bettiol et al. (2015) created an alternative taxonomy of KIBS including industrialized (provide mainly standardized solutions), bespoke (enterprises with a highly customized output) and combinatory (develop both standardized and customized solutions) KIBS and found combinatory KIBS to be the most successful in terms of revenue. Standardization may cause both positive and negative effects for innovation activities. More customized solutions are usually better suited to customer needs, while more standardized solutions are transferable from one customer to another (Cabigiosu & Campagnolo, 2018).

5 Methodology

5.1 Research Model

The research model includes four innovation drivers (expenditures on the development of the human capital, advertising expenditures, multiregional branch network and standardization) found to be significant in Chichkanov et al. (2019). In addition, coproduction measure taken from Doroshenko et al. (2013) is used. This measure reflects the average level of customer engagement in service production process and is based on the 10-grade scale where 1 refers to the lowest customer engagement (restricted by the terms of reference from the official contract) and 10 refers to the highest customer participation (collaborative activities during the whole project). Two alternative measures are dummy variables for those KIBS companies who reported that they apply the knowledge learned from or developed during the interaction with the one customer to the service development for other customers often or sometimes respectively. Descriptions for all used variables are presented in Appendix A. The final research model is as follows:

$$\log\left(\frac{P_i}{(1-P_i)}\right) = \alpha + (\beta_1 \dots \beta_4) * Innovation\ Drivers + (\gamma_1 \dots \gamma_3) * Coproduction + (\lambda_1 \dots \lambda_5) * Controls + \varepsilon_i$$

where $\log(\frac{p_i}{1-p_i})$ is the logarithm of the ratio of the probability that KIBS enterprise implements an innovation to the probability, that it does not; Innovation Drivers is a set of innovation drivers; Coproduction is a set of coproduction measures; Controls is a set of control variables, α is a constant; β, γ, λ are regression coefficients; ε is an error term.

5.2 Data

This paper uses the data from the database of the HSE ISSEK project “Monitoring of Knowledge-Intensive Business Services in Russia”. The dataset was collected in 2015 in 14 major Russian cities during two-stage sampling procedure ensuring the representativeness of the sample in terms of the geographical distribution, industry and size. After excluding observations with missing data the final dataset consists of 441 KIBS enterprises. The data was collected through structured interviews either with the owner of the KIBS company or a key-position employee like CEO.

6 Empirical Results

The results of model estimation for both technological and non-technological innovations are presented in tables 2. The results for the baseline model are presented in columns 1 and 3, while columns 2 and 4 presents the results for those models that include an additional coproduction variable. All the models are based on the robust standard errors to cope with heteroscedasticity issue. VIF values show that multicollinearity issue does not affect the results. The goodness of fit for all models is verified by Hosmer-Lemeshow statistics.

Table 2. The results of model testing for technological (1-2) and non-technological (3-4) innovations (marginal effects)

	(1)	(2)	(3)	(4)
Share of HR development expenditures	0.0167*** (0.00447)	0.0159*** (0.00449)	0.00502 (0.00438)	0.00375 (0.00449)

	(0.0594)	(0.0595)	(0.0658)	(0.0654)
C-KIBS	0.110** (0.0474)	0.119** (0.0472)	-0.0348 (0.0528)	-0.0247 (0.0529)
Age	-0.00992 (0.0329)	-0.0119 (0.0332)	-0.00679 (0.0365)	-0.0120 (0.0364)
Size	-0.0337 (0.0442)	-0.0357 (0.0450)	-0.00685 (0.0470)	-0.00545 (0.0464)

The results support the positive impact of coproduction on innovation activities in KIBS in terms of the implementation of both technological and non-technological innovations. The relationships between other innovation drivers and implementation of innovation in KIBS are in line with the baseline framework (Chichkanov et al., 2019). Thus, advertising expenditures and multiregional branch network were found to be significant drivers of both technological and non-technological innovations, while the positive impact of HR expenditures is observed only for technological ones. In addition, the relationship between standardization and technological innovations is non-linear and describes by the inverted U-shaped curve. Finally, two alternative coproduction measures are used to check the robustness of the results. The impact of coproduction on innovation activities remains positive and significant, while all other effects were also found to be stable across the specifications.

5 Discussion and Conclusions

The results support the positive view of coproduction as a mechanism that may contribute to the growth of the innovation activity of KIBS. KIBS may improve their innovation activity either by more intensive engagement of their customers into the production of services or by more frequent coproduction of knowledge. From the practical point of view these findings suggest that the development of coproduction-based strategies may help KIBS not only to improve their service offerings, but also to become more innovative.

More tight relationships with their customers help KIBS providers to enhance their innovation activity, which is in line with Greer & Lei (2012). Jouny-Rivier & Ngobo (2016) argued that developing these relationships or networks is determine the success of KIBS innovation projects as they help to integrate KIBS professional expertise and client industry-specific information. The development of KIBS also requires a lot of non-codified tacit knowledge which in turn requires deeper collaboration with the customer (Kohtamaki & Rajala, 2016).

In addition, those companies that report frequent or even occasional usage of knowledge coproduced with their customers or learned from them during the interaction also tend to implement more both technological and non-technological innovations. It is in line with den Hertog (2010) who argued that tacit knowledge developed or transferred during KIBS provider-customers interaction may enhance innovation activity not only in client firm, but also in KIBS. According to Ryzhkova (2015), these insightful customer

knowledge and expertise helps companies to discover additional opportunities at the market. In that case, KIBS often follow the market-pull approach and develop their innovative solutions in line with market insights they obtain during customer interactions (Camapagnolo & Cabigiosu, 2015).

One of the main problems is studying coproduction is its measurement. Most existing studies in this field are theoretical, while others are based on a limited amount of case studies or in-depth interviews that makes it difficult to create an appropriate tool to measure the phenomenon of coproduction (Skarzauskaite, 2013). The measures used in this paper also have some limitations and future studies will benefit by overcoming these issues.

The first used measure of coproduction is focused only on the average intensity of customer involvement and neglects some important characteristics of this process. On the one hand, the level of coproduction intensity may vary across different project stages. On the other hand, this level may also vary across different customer segments due to the client characteristics. In addition, the used measure does not focus on the duration of coproduction (Ryzhkova, 2015) and its quality. A new more sophisticated measure of coproduction intensity that covers these different contexts will be very useful for coproduction studies.

The alternative measures of coproduction look at the frequency of knowledge coproduction. Although knowledge is the most crucial production factor of KIBS by their nature, some other customer resources (labor or managerial implications) may also be exchanged during coproduction, which means additional measures that covers other types of coproduction content are required (Ryzhkova, 2015).

Finally, this study explores the link between coproduction and the implementation of technological and non-technological innovation, but it does study the commercial success of these innovations or other outcomes. In addition, comparative studies that cover different countries or longitudinal researches may also contribute to the understanding of the impact of coproduction on innovation activity in KIBS.

Appendix A. Descriptive statistics of used variables

	Description	Min	Max	Mean	St. dev.
Technological Innovation	1 if company implemented technological innovation (including innovative products and services) in the 1 st half of 2015, 0 otherwise	0	1	0.64	0.48
Non-technological innovation	1 if company implemented non-technological innovation (marketing and/or organisational) in the 1 st half of 2015, 0 otherwise	0	1	0.41	0.49
Share of HR development expenditures	Share of expenditures on recruiting and training in total expenditures of the company in the 1 st half of 2015	0	25	4.98	5.76
Share of advertising expenditures	Share of expenditures on advertising in total expenditures of the company in the 1 st half of 2015	0	40	6.73	5.59
Branches	1 if in the 1 st half of 2015 the company have branches in other regions, 0 otherwise	0	1	0.27	0.44
Standardisation	7 categories: 1 if the share of standardised services in 2014 was less than 10%, 2 for 10-20%, 3 for 21-40%, 4 for 41-60%, 5 for 61- 80%, 6 for 81-90%, 7 if the share of standardised services exceeded 90%	1	7	5.34	1.55
Standardisation ²	Square of the standardisation variable (for non-linearity testing)	1	49	30.96	14.77
Coproduction	Company's self-assessment of the average level of customer engagement in service production process from 1 (the lowest customer engagement) to 10 (the highest customer engagement).	1	10	5.93	2.80
High knowledge coproduction	1 if the company often apply the knowledge learned from or developed during the interaction with the one customer to the service development for other customers, 0 otherwise	0	1	0.08	0.27
Medium knowledge coproduction	1 if the company sometimes apply the knowledge learned from or developed during the interaction with the one customer to the service development for other customers, 0 otherwise	0	1	0.22	0.41
Control variables					
Moscow	1 if the company is located in Moscow, 0 otherwise	0	1	0.31	0.46
T-KIBS	1 if the company belongs to information technology or engineering industries, 0 otherwise	0	1	0.18	0.39
C-KIBS	1 if the company belongs to advertising, information-communication consulting or web, design and digital services industries, 0 otherwise	0	1	0.32	0.47
Size	1 for small enterprises (7-50 employees), 2 for medium-sized enterprises (51-249 employees) and 3 for large enterprises (more than 250 employees)	1	3	1.36	0.57
Age	Natural logarithm of the company age	0	4.17	2.14	0.69

In Search of Knowledge Ecosystems for Underdeveloped Countries: a Practical Case in Oncology and Complex Disease in Bolivia

Marisol Hurtado

Department of Management, Polytechnic University of Catalonia
Av. Diagonal, 647 08028 Barcelona

Abstract

This paper outlines a practical case of innovation for all in developing countries. Research focuses on innovation to support complex diseases patients. Key innovation success factors are information technologies, especially social networks; and human capital as a community of good practices (SANTI). By selecting a professional group with related knowledge in healthcare in three countries: Spain, USA, and Bolivia. Paper focuses on how to establish SANTI, with few resources and fast response, to support real cases cancer and complex patients. Research outlines a model with support of design science research, qualitative investigations and 5 cases of study with patients in Bolivia and one in Spain.

Results point to vital role of human capital and information technologies. Successful innovation relies on creating an appropriate community; strategy and values contribute positively to results.

Scholars avoid wicked problems as a hot topic in literature. Wicked problem as cancer has been avoided from an inclusive community committed to innovation with quick response to patients in developing countries. This study shows how a community of practices is capable of supporting complex patients and how it responds efficiently and fast. Innovation is possible with support of information technologies, especially social networks. Human/social process is enhanced by strategy and coach or mentor leadership. SANTI grows and evolves by open and honest communication and permission to experiment and fail. This model promotes personal health management through self-management and self-care of disease. SANTI provides resources not accessible for patients and facilitates access them through crowdfunding.

SANTI as mini-ecosystem of knowledge offers positive results in society progress, open innovation, encourage innovation of new models in health care and digital transformation. Research describes how to grow from a mini-ecosystem to provide strategic, solutions based on knowledge and how they can positively impact growth, well-being, and innovation for all. Finally, SANTI transforms the impact of current social and economic changes and challenges on positive effects on growth and well-being in chronic patients with exclusion risk. Simplicity of model makes it easily scalable to ensure growth and improve the quality life for patients in developing countries.

Keywords – Innovation for all, knowledge ecosystems, personal health management, intellectual capital management, digital healthcare transformation.

Paper type – Practical Paper

1 Introduction

The knowledge revolution brings new business models and growth to regions and cities, but it also creates new barriers, especially to groups that have no access to new technologies and specialized services and these differences become more evident in developing countries. Complex issues, such as cancer treatment, include not only medication treatment but also the follow-up in the quality of life of these patients who were already outpatients, they find a solution through advances in research and technology in the first world. However, this does not happen in developing countries as it is the case of Bolivia. In this country, there are 16 oncologists to address all cases of cancer occurring in the country, and this is due to the lack of specialized resources, the lack of training and access to scientific progress. This research aims to respond to this issue practically through knowledge ecosystems to contribute to the development of society through the elevation of health and welfare in real cases of cancer. To be able to achieve results in the short term and low cost, the research relies on the use of information technologies and in human capital, which are the primary sources to overcome the barriers of developing countries.

Another cornerstone is the creation of communities in practices and management through a coach. The research relies on the personal supervision of health from a comprehensive point of view, with the support of a vision from the intellectual capital and in the line of the concept of health proposed by the World Health Organization.

The model promotes personal health management through self-management and self-care of the disease (related to symptoms, complications and long period side effects), so the community of good practices provides resources that are not accessible to the patient and facilitates access to them through crowdfunding.

2 Theoretical background

2.1 Knowledge Ecosystem

Knowledge ecosystem is an approach to knowledge management which claims to foster the dynamic evolution of knowledge interactions between entities to improve decision-making and innovation through enhanced evolutionary networks of collaboration (Clarysse *et al.*, 2014). Concept popularity due to it frames the decisions we make affecting nature in terms of the value of life to people and makes those values more visible.

2.2 Growth and shape a sustainable future

Large clusters, cities, and metropolitan concentrate the regional development (Fagerberg and Verspagen, 2006). Regions differ each other depending on how fast is the process and the availability of resources to grow. The differences between areas make the availability of resources and services different from one region to another.

Similarly, innovation tends to cluster in specific sectors or areas, which grow faster and often require structural changes. However, sometimes there are significant differences between one industry to another. Thus, to solve complex situations, there is a need to establish links between sectors and innovation is a real solution for that.

Innovation ecosystem refers to a dynamic, interactive network that breeds innovation. It was born with industry and business clusters (Porter, 1998; Estrin, 2009) and in the Triple Helix approach to regional development and national innovation systems (Smith and Leydesdorff, 2000). In practice, the term can refer to local hubs, global networks, or technology platforms (Moore, 2006).

When ecosystems are studied frequently the goal is to emphasize on local and regional ecosystems and their development. The ecosystem approach emphasizes the position and roles of local and public actors in developing innovation activity. The ecosystem metaphor also enriches the systems model with value and culture. (Nambisan and Baron, 2013)

The continual realignment of synergistic relationships of people, knowledge, and resources for both incremental and transformational value co-creation characterizes the transformation of an ecosystem. Through links, value co-creation networks evolve from mutually beneficial relationships between people, companies, and investment organizations.

(Estrin, 2009) defines an innovation ecosystem; in her view, the innovation ecosystem is made up of communities of people with various types of expertise and skill sets. Sustainable development has economic, environmental, and social dimensions (Quinn, Doorley and Paquette, 1990). It is the emerging concept of "sustainable innovation."

Undoubtedly innovation has a crucial role in solving significant challenges such as water scarcity, climate, recycling, energy consumption (Kao, 2007). This approach could be successful for the creation of new products and services as part of the initiatives of the innovation network, but it seems different in the case of wicked problems (see Rittel & Webber, 1984) In complex issues the solution requires extensive cooperation and many actors. Wicked problems need more time for results, but when managed successfully, the solutions provide a means to tap into a significant, long-term innovation potential

In recent decades, wicked problems have been a hot topic with scholars and practitioners from different disciplines (Weber & Kahneman, 2008). In knowledge revolution organizations, companies, non-governmental organizations, and citizens are all interested in creating solutions to wicked problems. It seems that more efficient identification of issues and more collaborative approaches to building solutions are needed. Similarly, innovations are often produced through co-creation among diverse individuals and groups, not by institutions alone.

Problem solvers often possess conflicting views of the problem, of solution methods, and the legitimacy of possible solutions (Wexler, 2009). Ideation and discussions should take place in shared arenas, where organizations together with opinion leaders and other central figures guide the innovation processes and meaning creation (Luoma-aho & Vos, 2010). Inclusive innovation policy starts from the principle that all people should have the

opportunity to develop their skills and look for creative solutions to the challenges they see as necessary.

2.3 Community of practices

Communities of Practice is a term referred to how people naturally work together. It acknowledges and celebrates the power of informal communities of peers, their creativity and resourcefulness in solving problems, and inventing better, more natural ways to meet their commitments. They are peers in the execution of 'real work. What holds them together is a shared sense of purpose and a real need to know what each other knows.

A community of practice is a group of people who are informally bound to one another by exposure to a standard class of problem.

Communities of Practice Deliver their Value Proposition by developing and spreading better practices faster; connecting "islands of knowledge" into self-organizing, knowledge sharing networks of professional communities.

2.4 Building a successful team

Human capital, specifically talent, is the differential factor in organizations. Talented professional has knowledge and skills that will allow him to achieve the expected results; commitment to the project of the organization; and action. However, the most important thing is knowing how to play as a team (Bolet, 2000). The culture of an organization comprises a dynamic set of values, ideas, habits and traditions shared by the people who are part of an organization that regulates their performance. The change of culture and the elements that must be motivated and counteracted while seeking a culture oriented towards knowledge (Minsal Pérez and Pérez Rodríguez, 2007).

Talent has three main components: competence, commitment and action. Commitment is essential to achieve results. Without commitment the creation of wealth is not possible. Being fundamental to achieve results. Therefore, it is key to detect the talent that is convenient to our organizations, understand the social and economic factors that have made talent a strategic priority and measure the impact of talent management on business results(Jericó Rodríguez, 1996).

A team works if there is trust among its members. Trust is the new currency of our interdependent and collaborative world. At the same time, it is the most critical component of a successful leader and an organization (Covey and Merrill, 2006).

2.5 Supporting a wicked problem as cancer from patient centred care

It is given the name Cancer to a group of related diseases. Body cells lose cell division control and begin creating malign tissue, with the time this tissue starts to spread, and it depends on how much time that reaches more and more muscles. Physiological functions are affected by this process, and because of it the body starts working in a way it should not When the cancer is not progressing anymore, and scan tests show the disease in a stable state, clinicians consider that the condition is under control.

Nowadays there is a large group of people suffering from this disease a part of them despite having cancer under control do not have a successful cure or eliminated the entire illness and have to live their whole life with it or a long time (What Is Cancer?, 2017).

Cancer can affect a person physically, emotionally, and mentally, it can interfere with daily activities, and some degree of depression and anxiety is common in people who are coping with cancer every day. Because of, people with the disease need patient centered-care which focuses not only on relief of physical and emotional symptoms related to illness.

2.6 Intellectual capital approach for health

According to Gratton et al. there are three types of resources which make up own individual human capital (Gratton, L., & Ghoshal, 2003). Different elements of human capital are highly interrelated. Individual's sustainable competitive advantage is built from the relation of social capital elements; the combination of these elements, feedback loops, and connectivity bring individual benefit (Enache and Martí, 2007).

As well as intellectual capital refers to fundamental individual attributes highly interrelated, World Health Organization (WHO), recently proposed a basic definition of health as "a state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity." This definition suggests a holistic view of health, and it proposes a state broader than the absence of disease. More recent studies stand health is a state of both: wellness and illness. Thus, people without diagnosed disease can be ill (e.g., chronic pain sufferers). Even in the context of illness, it is possible to assist patients to achieve an optimal state of wellness through enhancements essential constituents of well-being (nutrition, exercise, sleep and rest) (Ekdahl, Andersson and Friedrichsen, 2010).

Due to the similarities in personal capital management with health management, researchers propose personal health management from the intellectual capital perspective (Hurtado Illanes and María Viedma Martí, 2018)

2.7 Specialization and accessibility of medical resources in developing countries

Bolivia only has seven machines for cancer treatments: two linear accelerators, one in a private center and the other in the Caja Petrolera; and five cobalt pumps, whose technology dates back more than 50 years and which are used in the public system and social security. According to data from the Pan American Health Organization (PAHO), in the country, there is, on average, one unit of tele-radio therapy (equipment to treat cancer with ionizing radiation) for every two million inhabitants. In addition to five radiotherapy centers, 11 oncologists, therapists, and five medical physicists. In Bolivia, there are 10,027,254 inhabitants. Making comparisons with a neighboring country, in Argentina, there are six teams for every two million people; in addition to 80 centers, 176 specialists and 98 physical doctors (Razón, 2015)

Delayed reaction to cancer affects especially women. This situation makes the health problem more expensive in this country. It is due to recent and slow handling of own information capable of orienting prevention policies and timely attention. Cancer in Bolivia is an evil that has not stopped growing and has improved especially women. Latest news systematized 2012 indicates there were 17,170 cases every year. In 2013, Pan American Health Organization estimated 6,936 people had died in the country due to cancer.

A health law from the patient perspective, is trend in world and perhaps key for medicine in Bolivia to incorporate into therapy concepts such as proper treatment, adequate time for people care, right to second medical opinion and clinical information opening of patient himself. Lack of economic resources make this model long time term; meanwhile every day some cases require urgent attention and country does not have enough funds to attend them.

In Bolivia community automatically links cancer patient with short term death and there is nothing else can be done leaving the person in a state of abandonment waiting for a final outcome. It happens because of ignorance.

3 Methodology

Theoretical development of this framework is based on Dubin's theory building model because the phenomenon under study is unstructured and requires a thorough understanding (Dubin, 1978). The case study enables the in-depth exploration of new phenomena and the identification of patterns among cases in response to how and why (Yin, 2013; Greenberg *et al.*, 2017). This approach is typically used to study and understand complex and dynamic processes on service innovation (Adams, G. R., & Schvaneveldt, 1985; Ian Stuart, 1998).

Research questions this project tries to find out are 'Complex patients in under developing countries could self-management and self-care disease with support of a community of practices?'. 'How ecosystem improves quality of life and dignity of patients, their families and their environment, achieving the postulate to live well, die with dignity'. The goal is to promote personal health management through self-management and self-care of disease. Because of lack of professionals in the area, patients need support of a community to reach this goal.

To gain more insight into the process, it has been invited complex patients to participate in case studies. There have been selected patients with different types of cancer and stages of this disease and also cases of complex diseases patients. The methodology was empirically tested by reflexive cycles proposed by Andriessen *et al.* (Andriessen, 2004). Moreover, qualitative research methods such as interviews with specialists, professionals of the community of practices and patients were useful to address a variety of evidence.

Practical methodology follows a learning by doing process through a knowledge-action ecosystem laboratory. Knowledge ecosystem has built as a community of practices, known as SANTI.

3.1 Building model

The practical methodology follows learning by doing the process. First step was the strategy formulation of SANTI. The strategy has built as a series of planned actions that help make decisions and achieve the best possible results. Those planned actions are directly related with factors to improve health (Hurtado and Viedma, 2017), The main goal of SANTI was to promote personal health management through self-management

and self-care of the disease. Patients need support of a community to achieving SANTI goal on developing countries. They also need fluent communication with members to request resources not available for them. Patients in exclusion risk need an accompaniment social network with resources to motivate emotionally, integrate patient and transmit strength to disease.

In contrast to developed countries, it is necessary to find resources compromised with patients especially in cases of exclusion risk. In this the way, patient with community help is capable of self-care and take decisions about its health process.

SANTI strategy was based on developing effective services and resources for a healthy lifestyle and coaching patients to find a personal strategy formulation to improve health

The second step was to build SANTI by inviting professional with residence in researched countries. They have been selected people matching predefined conditions. It was relevant to ensure professionals understand the strategy, mission and goals of SANTI as well as a compromise to work according to that.

The last step was to search for resources for SANTI. The premise was to explore people and resources known by SANTI members according to the following conditions: 1. Low cost. 2. Accessible easily. 3. According to values of SANTI. 4. The motivation for help with patients. 5. Identification with the mission of SANTI. 6. Compromise. Members collaborated with this step searching resources through social networks on its contact networks. Then members contacted and invited by itself collaborators to participate in SANTI.

Social networks are a critical resource to identify people who reside in areas close to patients. Thus, members can attend physically and personally to provide support to the patient accordingly needs. In this way members are capable of searching about medical specialists, take care services, diffusion and organize crowdfunding activities when are necessary. The leader must be compromised and identified with the strategy and mission of SANTI. He also is the coach of patients, introducing them to community and motivate SANTI members to include the patient as part of a big family. Leadership is a key resource for the success of the model. SANTI grows and evolves by open and honest communication and permission to experiment and fail.

There are permanent knowledge transfers between members and between community and patients. According to design science research, the model is reviewed continuously to attend needs and suggestions shared by members and patients. Internet is a critical resource, especially social networks. The communication is online for all members 24 hours, because of time differences in members countries.

It doesn't follow a capitalist model but a collaborative one. Members offer help following their values and not in search of their benefit.

4 Results

In complex medical cases, the specialization and accessibility of resources, as well as the response time, are vital to the patient's recovery. SANTI as support of complex patients in Bolivia has following results:

1. SANTI makes it possible to arrive in a timely way to resources either in the developing countries as in the developed countries in which the members reside in an agile and timely manner thanks to information technologies, especially social networks.

2. Community members living in developed countries share their know-how with the community by helping to address the situation effectively.

3. Integrate patients to the community brings other elements to the patient that are not necessarily conventional medical resources, such as how to transmit a healthy lifestyle model through changes in food, provide emotional support and motivation through the social network and a sense of belonging to a community of support to confront the disease.

4. The leader knows the model and shares it with the members of SANTI and with the patients so that together they motivate the patient to find their own model of health through changes in your lifestyle

5. Trust as a community value makes information flow and the community is perfected through the innovation that members propose.

6. The patient's emotional state is a key factor in their recovery, through the community the patient goes from feeling excluded from society to be the protagonist of a group that also contributes, in which he knows other cases and can take distance from the disease situation.

7. As new technologies allow the patient to be able to participate in the community regardless of their geographical location; SANTI is an ideal model to be able to participate and self-care at home.

4.2 Sample

To analyze SANTI services results with patients, (table xxx) describes the five cases of study.

	Nationality and sex	Age	Comments
Health and social situation	Bolivian Male	27	Osteosarcoma in the hip. Chemotherapy treatment. Orphan of father and mother. He died during the study due to nutritional conditions.
Actions			Social support to the family with information about disease and possibilities of treatment. Diffusion of family crowdfunding actions, emotional support to patient and family, nutritional suggestions, contact to health specialists. Support during the grieving process.
Patient and caregiver comments			Patient lived the process with better quality life, motivated and gratefully to the community. He participated at home with photos, audios, and videos by chat. He was happy to meet new friends around the world. Family values positively support during sickness and process. They feel grateful to SANTI members and

Health and social situation	Bolivian Female	38	continue giving support to new cases in the group. Osteosarcoma in hand and spine. She lives alone and doesn't have enough economic resources for private treatment, and social security can't support her. Chemotherapy treatment.
Actions Patient and caregiver comments			SANTI support with crowdfunding actions, emotional support to the patient, nutritional suggestions. Resident members in nearby areas assisted physically and personally with the purchase and delivery tasks according to needs. She values the help of SANTI to prepare her treatment with chemotherapy through healthy nutrition. She has also been able to contact foundations through the group. It is almost impossible to face cancer without insurance, without fixed income, and even worse being alone, thanks to SANTI it has been possible. Convalescence after chemotherapy is also hard for her. SANTI continues to offer psycho-emotional and nutritionist support since the effects are unpredictable in their duration.
Health and social situation Actions Patient and caregiver comments	Bolivian Female	40	Encephalitis in the study. Unknown causes, possibly rare autoimmune sick. On intensive care during research. Emotional support to the caregiver. SANTI through its support networks actively seeks contact with medical specialists, official media to support family crowdfunding initiatives. The caregiver, although he doesn't personally know SANTI members, has felt supported and motivated by emotional messages received. He appreciates sincerity and honesty in SANTI. He also values the leader role. He values positively: usefulness, frequency, fluid communication and group interest in patient evolution. He feels strengthened by group proximity and spirit of overcoming received. He values new friends found in SANTI to rely on and to continue the caregiver process.
Health and social situation Actions Patient and caregiver comments			Colon cancer. Chemotherapy treatment and surgery Emotional support to the patient and nutritional suggestions. Tumor has reduced enough for surgery. The patient values the information regarding a healthy and adequate diet. It has helped him be prepared for treatment. He found new ways to meditate and positive messages also helped him to face disease with optimism.
Health and social situation	Spanish Female	35	Brain cancer. Chemotherapy treatment.
Actions Patient and caregiver comments			Emotional support to the patient and nutritional suggestions. Patient feels better and more optimism respect disease. Tumor has reduced considerably. She supports treatment with nutritional changes.

5 Conclusions

Scholars researched wicked problems as a hot topic in literature. In complex issues, the solution requires extensive cooperation and many actors. Wicked problems need more time for results. Cancer as a wicked problem has been researched with real patients in Bolivia through an inclusive community committed to innovation with quick response to patients in developing countries.

SANTI as mini-ecosystem of knowledge offers positive results in society progress, open innovation, encourage innovation of new models in health care and digital transformation. Simplicity of model makes knowledge ecosystem easily scalable to ensure growth and improve the quality of life for patients in developing countries.

Cancer affects the emotional health of the person who suffers, the family of the patient and the community that surrounds it. A diagnosis of cancer can have a considerable impact on the majority of patients, families, and caregivers. The feelings of depression, anxiety and fear are very common and are normal responses to this experience that changes the life, but that are amplified by the feeling of isolation and loneliness.

Oncology patients require multi-disciplinary interventions for an extended period especially cancer survivors or complex patients. A compromised community is fundamental to support the patient on lifestyle

changes to reach states of well-being.

The most common fears that arise in these people are related to unknowledge of disease, death and economic support to pay treatment. These cancer fears are based on stories, rumors or wrong information

It usually helps to have good information to deal with fears and concerns. Most people have less fear when they know about their reality. They feel less anxiety and know what to expect.

Learning about your cancer and understanding what you can do to be an active participant in your care allows for a better lifestyle and improves the conditions you are facing

People who are well informed of their disease and treatment are more likely to follow their treatment plans and recover from cancer more quickly than those who are not.

When a person is told that their illness is terminal and that the treatment is no longer curative, but palliative, it needs great psychological, social and spiritual support, but resources are not always available to go to therapy centers, or pay for food services, expert care, and nutrition, or, as in the case of Bolivia, you cannot access these because of the lack of professionals in the area, the creation of a participatory ecosystem like the one described in the study is the opportunity to improve the conditions of people and their families by providing a simple tool to have control, information and general strategies based on the evidence and the experience of the members of this group.

The resulting social impact is promising, the low cost of implementing these strategies, the widespread use of tools such as WhatsApp or Facebook, allow based on the three postulates of "competence, commitment, and action", they allow to eliminate

distances, They transcend knowledge and allow the patient and their environment to feel part of a "something" environment that offers hope and that reducing stress will definitely improve their life strategy, feeling in control of a situation, their situation, aspect that is not possible today yet.

So definitely helping to cope with the burden of the disease by evading educational and social economic, cultural barriers in order to achieve what everything human requires: "feel part of a community even if the end is near."

Abstract

The purpose of this paper is to suggest a new approach of regional intellectual capital (further RIC) identification leading to competitive regional development. In order to make RIC management decisions leading to competitive growth, it has to be identified and its relevance for particular development purpose must be defined first. Therefore, this paper aims to reason a new RIC identification approach that takes into account strategic perspective. Suggested RIC identification approach is based on the theoretical analysis of scientific literature. According to suggested approach targeting regional intellectual resources that matter requires integration of four underpinning theories: IC theory, regional competitiveness theory, resource-based management theory and strategic management theory. Integration of these theories enriches RIC identification with strategic aspect and makes it more target-oriented. Based on the theory of regional competitiveness RIC separation into public and private dimensions is required within RIC identification process. It enables more precise distribution of responsibilities among stakeholders and makes RIC management more coordinated.

Keywords – regional intellectual capital, regional development, regional competitiveness

Paper type – Academic Research Paper

1 Introduction

Regional intellectual capital (further RIC) which is defined as hidden value of individuals, organizations, institutions and communities within region is believed to be the foundation for regional wealth and potential growth in future (Edvinsson & Stenfelt, 1999; Bontis, 2004; Lin and Edvinsson, 2008; Schiuma et al. 2008; Lin and Edvinsson,

2010). Ståhle et. al. (2015) proves that 45 % of world's GDP is generated by intellectual capital. Countries like Sweden, Finland, Denmark or Israel are recognised worldwide as the countries whose economic growth is mostly related to aspects of intellectual resources (Edvinsson, 2013). The need to understand the fundamentals of RIC becomes strong since such knowledge may bring wealth to a region or country.

Regional dimension nowadays becomes increasingly important because even in the same country, a certain level of differentiation may be observed. Some regions lag while others thrive. The European Commission has already noticed this fluctuation and has initiated monitoring of regional innovativeness and competitiveness to shape particular regional policy making, which would lead to the catching up of lagging regions and improvement of overall national competitiveness (European Union, 2017). In addition, the organizational level is explored much more thoroughly and answers to sustainable competitive advantage may be captured from the past research (Guthrie, 2001; Zickgraf, 2009; Roos et. al., 2005). Therefore, in this paper, a focus on the regional dimension is more relevant than the national or organizational.

The need to focus towards policy making has emerged which requires understanding what intangible resources are important in particular situation and why. Identification of RIC becomes a problem since region's development objectives and context differ. Orientation to practice has become a strong requirement for new methods since theoretical measurements have not been adopted in policy making. RIC importance and relevance has to be demonstrated with the purpose to reach policy makers attention. Therefore, this paper aims to suggest a new RIC identification approach leading to justifiable argumentation why some intangible resources are important for regional development. The ideas of regional competitiveness, strategic management and resources based management theories are implemented in the new approach since the lack of strategic aspect is addressed.

The results of this paper contribute to intellectual capital theory providing better understanding on RIC concept and its role in regional development. Such understanding is valuable further developing RIC management strategies focused towards regional development.

The paper is organised as follows. Section 2 provides theoretical background. Section 3 explains a suggested new approach to RIC identification. Section 4 follows with conclusions and provides future research recommendations.

2 Theoretical background

RIC definition is broad and complex leaving a lot of freedom to interpret RIC in different perspectives. Käpylä (2012) points that such indeterminacy leads to exclusion of certain knowledge like ethics, culture, history etc. from measurement indexes and results only in easily measurable indicators that may not fully reflect RIC. Some researchers who have introduced national benchmarking indexes highlight that supply of indicators is limited and a fraction of intellectual capital at national or regional level is left unmeasured (Bontis, 2004; Weziak, 2007). Usually at national level benchmarking is applied for

diagnostic purpose (Bontis, 2004; Andriessen and Stam, 2005; Weziak, 2007; Lin and Edvinsson, 2008; Lin and Edvinsson, 2011). However, relevancy of the information provided by benchmarking methods is questionable (Salonius and Lönnqvist, 2012). Therefore, in order to achieve competitive regional development, there is a need to find a way to capture relevant information and define appropriate RIC interpretation.

Issue of uniqueness of intangible resources is additional concern. Uniqueness and contextual situation is significantly stressed at organizational level by Chaminade and Johanson (2003) and Angel and Ortiz (2009). However, Schiuma et al. (2007), Kujansivu (2008), Lönnqvist et al. (2009) accept this to be true at regional level as well. Certain researches emphasize that intangible resources are unique for particular country or region and uniqueness has to be taken into account evaluating RIC (Käpylä, 2012; Yigitcanlar and Lönnqvist, 2013; Malhotra, 2003; Schneider, 2007; Käpylä, et. al., 2012). Käpylä, et al. (2012) points that regional development objectives differ in addition to regional context. Hence, RIC measurement methods should address this problem and provide a way to take uniqueness into account.

The outcome of RIC and its measurement purpose is also a question. Wealth, prosperity and economic growth are usually named as outcomes of substantial and well-developed RIC. Such viewpoint has led to researches demonstrating RIC relation to GDP. However, GDP has become a questionable indicator of prosperity and even economic development. Henderson (2008) reveals that society defines regional wellbeing beyond GDP. Delgado et al. (2012) claims that many policy makers consider competitiveness as the most important factor of regional economic policy. Definitions of regional competitiveness disclose a necessity to focus more on conditions and environment empowering economic growth rather than the final result which is demonstrated by GDP. Therefore, a demand for a new shift of RIC measurements can be observed.

Regional intellectual capital approach can be seen as more target oriented perspective which takes into consideration regional development objectives and demonstrates better orientation to practice (Viedma Martí, 2006; Medina et al., 2007; Schiuma et al., 2008; Lerro and Schiuma, 2009; Yigitcanlar and Lönnqvist, 2013; Lönnqvist et al., 2014; Kohl et al., 2015). Regional competitiveness becomes a major focus of this approach (Rodriguez and Viedma Martí, 2006; Medina et al., 2007; Lerro and Schiuma, 2009). Categorisation of regional intellectual capital becomes based on desired outcome or aspiration, for instance: sustainable development (Medina, et al., 2007), vision, core activities and capabilities (Rodriguez and Viedma Martí, 2006), social value (Lönnqvist, et al., 2014), development strategy goals (Lerro and Schiuma, 2009) (see Table 1). Kozak (2011) develops a framework for regional intellectual capital management in respect to specific strategic objectives. However, the framework is not approved yet. Nevertheless, orientation to regional objectives, competitiveness as well as intellectual capital interpretation and evaluation taking into consideration region's contextual situation is welcome in practice.

Table 14. Regional intellectual capital approaches (edited by authors).

Authors	Regional Development Goal	Intellectual Capital Dimensions
Rodriguez and Viedma Martí (2006)	Sustainable economic development	Institutions and governance Societal framework Social capital Technology Regional human capital
Medina et al. (2007)	Sustainability	Training and development Public administration Social capital Environmental capital Tourism capital Economic activity
Lerro and Schiuma (2009)	Competitive development	Human capital Structural capital Relational capital
Lönnqvist et al. (2014)	Social wellbeing	No dimensions excluded. Used indicators: Diversity of the region: Manifold knowledge Educations Universities Vitality that universities and the youth bring Very good regional image Capability for renewal Strong and varied competence of regional actors Good—open and trusting-relational actors Congenial atmosphere: willingness to seek consensus and reconciliation Eagerness for future-oriented development
Yigitcanlar et al. (2014)	Knowledge-based development	Human and social capital Environment Institutional capital Economy
Kohl et al. (2015)	Regional development	Human capital Structural capital Relational capital

It can be concluded that a new approach of RIC identification should address issues of concept indeterminacy, uniqueness, development objectives, competitiveness and relevancy of information. The next section is aimed to explain how a suggested new approach is influenced by these factors.

3 A new approach to RIC identification

Researchers (Edvinsson & Stenfelt, 1999; Malhotra, 2003; Bontis, 2004; Stam & Andriessen, 2009; Käpylä *et al.*, 2012) usually define RIC as all intangible resources available to a region including knowledge and erudition of society itself, private and public institutions' intangible resources as well as personal human knowledge. But such definition, even though reflects the true meaning of RIC, has limited value for RIC identification concerning regional development. RIC identification reveals the most important intangible resources for competitive regional growth and enables to manage them. However, management itself is inseparable from a managing body. Broad RIC

definition includes intangible resources that may be managed by different bodies: private and public institutions' intangible resources are managed respectively by private sector and public sector; personal human knowledge is managed by person himself; knowledge and erudition of society is a result of successful management of different bodies. Käpylä *et al.* (2012) research may be provided as an example of an attempt to identify RIC managing bodies in respect to RIC location: the private sector (i.e. the business sector of companies), the public sector, the third sector (i.e. civic society) and the fourth sector (i.e. family, relatives and friends). However, analysing the structure of RIC measurement approaches, it can be noticed that various indicators are included (from different RIC locations as described by Käpylä *et al.* (2012)) and there is no clarity who is responsible for the value of particular indicator. Therefore, it is difficult to create RIC management strategy based on such indexes since it is not known who is responsible for a particular resource. In order to reach competitive regional development through management of RIC, RIC identification must be carried out keeping in mind a managing body. Thus, links between resources and managing bodies have to be defined first.

Researches focused on RIC, its measurement and management usually discuss policy making perspective and dedicate findings to policy makers (Bontis, 2004; Schneider, 2007; Käpylä *et al.*, 2012; Saloniemi & Lönnqvist, 2012; Stähle, Stähle, & Lin, 2015). Such orientation towards policy making leads to understanding that managing bodies of RIC lie within a public sector. Public sector may be defined as a sector composed of all levels of government providing various governmental services and is controlled exceptionally by a state (Wegrich 2016). Further, only that part of RIC which is managed by public sector is worth investigation in respect to region's development since findings are addressed to policy makers. Private sector that can be defined as a sector controlled by individuals or group of individuals (usually business organizations) (WebFinance 2016) contain intellectual capital that cannot be directly controlled by a state. Therefore, there is no point to include intellectual capital of private sector into researches focused on RIC since it cannot be managed by public sector. Getting back to Käpylä *et al.* (2012), RIC located in civic society, family, relatives and friends or as indicated by the author third and forth sector, should be excluded from RIC identification additionally since these resources are not controlled directly by public sector as well. To conclude, RIC identification means an identification of intangible resources that are controlled by public sector and contributes to competitive regional development.

RIC managed by public sector can be structured into three typical categories of intellectual capital: human, structural and relational. Human capital is defined as publicly available human resources that include graduates, available labour force, public administrators and their competences, high skilled talents and available scientists, etc. Structural capital is defined as public intangible infrastructure including legal environment, regulations, institutional infrastructure and its efficiency, knowledge sharing networks between institutions, etc. Relational capital is defined as various relations between public sector and private sector as well as relations between institutions within a public sector. It should be emphasized that all these resources (human, structural and relational) must create value in respect to regional development in order to be considered

as capital. Within this study, RIC is defined as a composition of publicly available human, structural and relational resources that are controlled by public sector and contribute to regional growth.

A new approach to RIC identification is discussed further. Suggested solution is based on ideas of regional competitiveness, resources-based management and strategic management theories in order to provide valuable information for policy making and formation of regional development strategy. From regional competitiveness theory, public sector shapes the environment that private sector acts in (Porter, 1990). That environment empowers private sector and directly influences how successful it is. As long as competitiveness is a key concern, success of private sector is defined as its successful performance in an interregional market which demonstrates competitive advantage in respect to other market participants. Overall regional competitiveness is defined by Porter (1990) as a total success of all country's private organizations in an interregional market. Therefore, RIC identification should be based on viewpoint of private sector which actually creates a competitive advantage and defines overall regional competitiveness and leads to regional development. RIC relation to regional development is illustrated in Fig 1.

Figure 9. RIC relation to regional development.

In order to identify intangible resources that are relevant or matter the most, particular regional development objectives as well as regional context must be defined. Resources-based management theory, introduced by Wernerfelt (1995) and integrated into strategic management theory by Grant (1991), suggests that objectives indicate resources that are required to reach desired outcome. Strategic management theory suggests that particular regional context reflects specific situation, strengths and weaknesses that are inherent and must be taken into account considering development objectives. Therefore, identification of RIC is inseparable from objectives and current contextual situation.

Consequently, RIC identification focused on competitive regional development requires: (1) evaluate RIC from a viewpoint of private sector which creates competitive advantage; and (2) determine specific development objectives concerning regional competitiveness and investigate contextual situation. RIC identification factors are depicted in Fig 2.

Figure 10. Factors of RIC identification.

It has to be highlighted that development objectives concerned in this case should be specific and allow determination of public sector institutions responsible for its execution (managing body of RIC has to be clear). In addition, objectives have to contribute to regional competitiveness. Investigation of contextual situation should lead to identification of RIC elements that are present and important in current situation. RIC importance from a viewpoint of private sector can be obtained through various empirical researches that allow private sector representatives to evaluate RIC according to their business performance. According to Barney (1991), RIC identification process should be continuous as long as development objectives, contextual situation and private sector performance change throughout time and competitive advantage created by RIC is achieved just for a certain period of time.

4 Conclusions

RIC acts as a foundation for every intangible infrastructure, ecosystem, shapes the environment and determines the future success of particular initiatives. Lack of understanding of RIC prevents from strategically oriented decisions concerning RIC management and leads to performance of initiatives that do not correspond to real problems. This consequently results in money and effort wasting just because the fundamentals behind the numbers are not perceived. Therefore, RIC theory should follow the direction leading to practically oriented researches willing to reveal the fundamentals behind RIC indicators.

Conducted study demonstrates how new suggested approach for RIC identification may provide different perspective on observed problems. Suggested approach brings those problems into holistic picture and enables versatile evaluation and interpretation on relations between the problems and intangible resources that created them. This evaluation performed in the context of particular strategic goal allows better evaluation and prediction of effectiveness of public initiatives. Even though complexity becomes an issue in this case an appropriate methodological approach may solve it.

Suggested RIC identification logic could be implemented in various public organisations, but for better effectiveness and objectivity it should be performed by third party. As long as this approach investigates public RIC and challenges government and other public organisations' activity, evaluation doubtfully could be objectively performed by organisations themselves. At least supervision is needed. Private sector point of view towards public sector can be concluded to be valuable and such approach should be further maintained.

The greatest issue of suggested approach is complexity. RIC identification requires evaluation of many variables that can equally influence the final estimation. Even though the approach allows gathering versatile information, it is not easy to make sense out of it. Interpretation of results requires understanding how various components interact and there is still a lack of such kind of knowledge. Methodological implementation is also a concern. Suggested approach favours qualitative research design, however it is difficult to generalise the findings. Combined research design could provide even better insights and more rigorous results.

For future research it is recommended to specify methodological solution for implementation of suggested identification approach that would work best and determine how this logic could be applied in decision making process. Valuable information which can be provided by suggested approach should be determined and decided how it should serve for decision making.

The Arts of Cultural Ecosystem and International Fair for Global Value Creation - a Case Study of Art Revolution Taipei

Jui-ChenWang

Department of International Business Administration Master Program
of Business Administration in Practicing College of Business .
University of Chinese Culture University
No. 231, Section 2, Jianguo South Road, Taiwan (R.O.C.)

Abstract

The international art fairs enhance the cultural exchanges among different countries, not just stimulating developments of the art industry but also substantially benefiting both the host country and participating parties, as well as serving the purpose of transactions. Therefore, the art market oriented by galleries has been transforming into the economic model surrounding art expositions. It's a major issue for to explore how to have impacts on the cultural exchanges among countries by operating and developing art expositions. This study is focused on the globally renowned Art Revolution Taipei (A.R.T.), to explore from the systems thinking perspective on how the organizer of A.R.T. imbues the value concept of putting artist-centered value and front; how to create jointly a valuable business model with artists from different countries and visitors. The relevant managerial implications and suggestions will be discussed.

Keywords – art exposition、systems thinking、culture ecosystem、value creation.

Paper type – Academic Research Paper

1 Introduction

The 21st century is the era of knowledge economy; in the fierce competition in politic, economic, social and cultural relationship among countries has led to an assimilated trend for the global culture. Developments in arts are rooted in daily life, and closely related to politic and economic factors with subtle interactions. The globalization of the art market has led to a surging number of art expositions, which has increased to more than 60 of them from 10 during this decade; art expositions become an important platform for showcasing artworks from artists.

Art expositions is one of the most common model to demonstrate the standard of a country's arts and culture. The principal purpose of an exhibition is to provide an exhibition venue with educational values to the public; it may exhibit the means at man's

disposal for meeting the needs of civilization, or demonstrate the progress achieved in one or more branches of human endeavour, or show prospects for the future. (Art.1 of Convention Relating to International Exhibitions). An art exposition means to hold an event for enhancing industrial and economic developments and culture exchange through exhibiting and transact artworks in huge scale at a certain venue.

The international art expositions also serve the functions of culture promotion and exchange among different countries, not just stimulating developments of the art industry but also substantially benefiting both the host country and participating parties, as well as serving the purpose of transactions.

Art Revolution Taipei (A.R.T.) is a large-scale art event planned and launched by Taiwan International Contemporary Artist Association, a group of like-minded social elites, to promote arts and art itself in Taiwan globally without any governmental subsidy. It promotes the international image of Taiwan and democratization of arts by widely recruiting artists and buyers around the world to gather and contact directly at the A.R.T. platform; it endows a new look to art exposition by putting artists centre and front to make every booth an artist's solo exhibition, instead of following the gallery-oriented convention. The innovative and creative marketing strategies are so eye-catching that the accumulated number since 2011 to 2018 amount to 191,925 visitors; the average percentage of transaction is about 90%. In 2014, the transaction rate even reached up to 93.21%, a new record among international art fairs. In 2018, there were 471 artists from 74 countries to present more than 3,000 pieces of artworks with local features diverse styles . The detailed information of A.R.T are shown in Table 1, Table2 and Table3.

Table 1 The total number of visitors to A.R.T. for 8 editions (2011-2018)

Table 2 The number of participating artists to A.R.T. for 9 editions (2011-2019)

Table 3 The number of participating countries in the A.R.T for each edition. (2011-2019)

Source: Art Revolution Taipei

According to the conceptual framework of cultural ecosystem services (Fish, Church and Winter, 2016), the concept of cultural ecosystem services covers critical elements of hard special environment and soft cultural practice, and offers various opportunities to facilitate effects of cultural ecosystem and to deepen the recognition about the arts & culture, so more and more people would commit themselves to cultural activities and nurture their own tastes on arts and cultures. The cultural values are created under the creation, promotion and circulation of the general cultural ecosystem.

Furthermore, Giovanni Schiuma (2011) pointed out that through arts-based initiatives,

it's possible to create higher value and performance for industries. The case explored for this study, the Art Revolution Taipei (A.R.T.), is an international art platform integrating the cultural ecosystem services with the concepts of values created via arts, encompassing conceptions of art creativity, value concepts of putting artists center and front, artworks from different countries, and marketing strategies collaborated by the executive team, as well as the co-relationship and interactions among sponsors, buyers, artists and the organizer; which makes all stakeholders recognize the values created by Art Revolution Taipei with great feedbacks and self-enhancement through the experiences. In return, the cultural ecosystem services keep on expansion from the positive cycle of value-creations, and raise impacts from the A.R.T.

Peter Senge(2010) articulated the success of an organizational operation model is contributed by s series of complicate interactions among various factors; therefore, it's worthwhile to explore the reciprocal influences among stakeholders from different aspects, such as the Art Director, artist association, buyers, artists, sponsors, AD media. In this study, the perspective of systems thinking is applied to analyze the business model and strategies for Art Revolution Taipei to create values from interactions among participants in the cultural ecosystem, including the organizer, artists and visitors (buyers), hopefully to serve as a reference for other countries to plan and execute art expositions in the future.

2 Business Model

This study explores the business model of Art Revolution Taipei from the perspective of systems thinking, through literatures (Drucker,2005; Heilbrun et al., 2011; Hill et al.,2013; Kim, 1997; Mintzberg, 1977; Osterwalder,2010; Quemini, 2013 ; Sterman, 2016) and interviews with the founder and curator from the organizer, one artist in Taiwan and another one from other country, visitor, and buyers (one in Taiwan and the other one from other country) to collect data; also it attempts to find out critical factors of value creation and their interactive relationships from the main participants in the concept of cultural ecosystem, including the organizer, artists and visitors. The main models are elaborated as follows.

2.1 Values created by the organizer

- A.R.T. focuses on the “artist-centered value” and gain “core value recognition”. The higher “core value recognition,” the more “the management team's overall coherence” is. And then it can get better “overall service quality of the exhibition.” The better “overall service quality of the exhibition” leads to the more “artworks sold.” And then it will increase the “A.R.T. value and benefits, which in turn boost more “international media coverage and word of mouth”. And then it can attract more people attracted to recognize the core value of organizer.
- The casual feedback loop (shown in Figure 1) represents the “reinforcing loop,” and this feedback loop into a virtuous cycle just like snow balls either to get better and better or worse and worse.

Figure1 The casual feedback loop of value creation by organizer

2.2 Value creation from visitors and buyers

- The casual feedback loop of value creation from visitors and buyers mainly focuses on visitors. Basically, it starts from introducing the core value(artist-centered value), subsequently the acceptance and recognition of the core value increase. From its debut, the A.R.T. has pushed this feedback loop into a virtuous cycle on its own.
- The internal cycle
After the recognition of core value increases, the PR publicity for marketing activities increase accordingly, resulting in more visitors and subsequently more interactive services and communication, which includes explanation from the exhibition staff and artists from different countries; an environment and platform for cultural exchanges for multi-countries thus formed. The cultural exchanges lead to more artworks sold and enhance feeling values for visitors and buyers.
- The A.R.T.'s strategies
The left side on the figure includes "public welfare activities," "Media use," "Strategic Alliance" and other auxiliary measures, to boost the PR publicity, and further to facilitate the internal virtuous cycle. The part of "artworks sold" on the right side is accompanied with "overall service quality of the exhibition hall," which covers the A.R.T.'s key features such as the explanation from the staff, the entire logistics and cash flows. To facilitate the artworks sold efficiently, there's a package of complete logistics and cash flows in place, which impacts the number of artworks sold. The casual feedback loop of value creation for visitors and buyers is shown as Figure2.

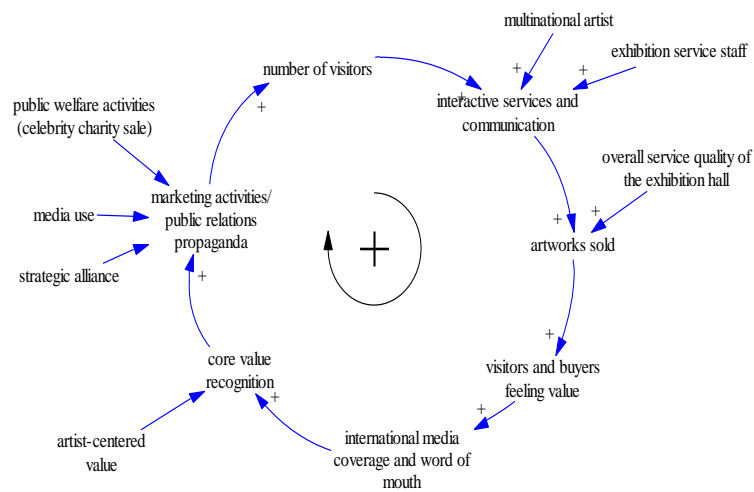

Figure 2 The casual feedback loop of value creation for visitors and buyers

2.3 Value creation for artists

- The casual feedback loop of value creation for artists

The higher core value of “artist-centered value” increases the level of value recognition, which in return attracts more good artists to exhibit their artworks; more artworks form a more healthy competition, which increases the diversity and quality in participants and artworks, then more artworks sold in return, so as the artists’ artist’s income and feeling value. The more international media coverage and reputations facilitates the level of core value recognition, which in return again to attract more excellent artists globally to participate.
- The A.R.T.’s strategies

The main purpose is expediate the virtuous cycle for a better performance, which includes a rigorous screening mechanism to present outstanding artworks to visitors by selecting excellent artists worldwide. Furthermore, in order to establish a stable market with reasonable prices, the external influential factors, such as VIP s system, previews, extended exhibitions and fixed pricing strategies, are used strategically. Please refer to the casual feedback loop of value creation for artists, shown as Figure 3.

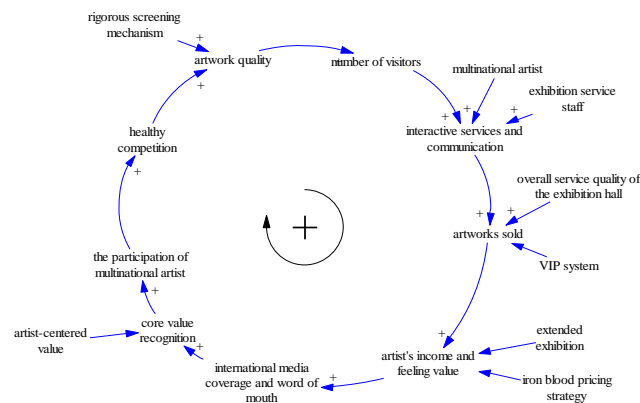

Figure 3 The casual feedback loop of value creation for artists

3 value creation about the business model of an international art exposition

Based on the literature researches, semi-structured interviews, and interviews with the A.R.T. organizer, artists and visitors-buyers, this study analyzes the business model of A.R.T. by system thinking, to construct a casual feedback loop for value creation about the business model of an international art exposition, taking Art Revolution Taipei as a study case. The conclusions we have drawn are as follows.

3.1 Combining the above-mentioned models covering interaction among the organizer, visitor and buyers for value creation

Combining the above-mentioned models covering interaction among the organizer, visitor and buyers for value creation, the general casual feedback loop is constructed shown as Figure 4.

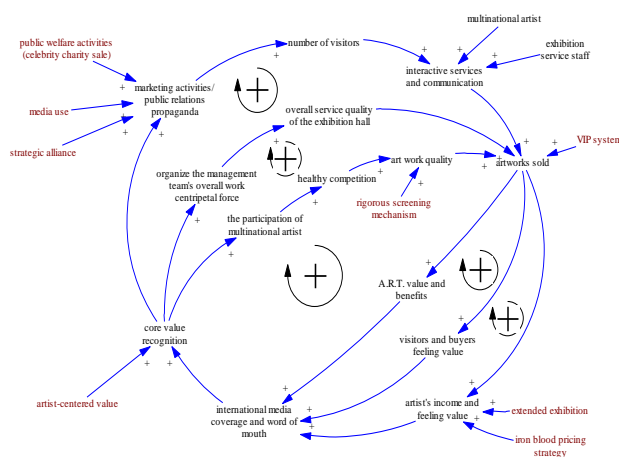

Figure 4 The general casual feedback loop of value creation From A.R.T.

3.2 Sample

In order to analyse this loop consists of three previous figures, to enhance readers' comprehension of a whole picture about the operation of A.R.T. There are many reinforcing loops and marked in red, indicating strategies introduced by A.R.T., in hope of a more smooth operation.

The main strategies include the artist-centered value, strategic alliance, media use, public welfare activities (Hundreds of Celebrities Charity event), rigorous screening mechanism, VIP system, extended exhibition, and iron blood pricing strategy. It aims at creating a win-win-win situation for the organizer, visitors and artists, then go further to establish a reputation by recognizing the core value. This in return reinforces the internal coherence of the executive team, and improve the service quality and performance; in the meantime, the PR marketing campaign could become even more powerful to attract more visitors, who would lead to more interactions with exhibiting artists and staff. Being the operational essence of A.R.T., the whole positive loop would increase the volume of artworks sold, which benefits and adds values to all parties, so as to the entire reputation.

Abstract

According to the annual pharmaceutical industry data from Ministry of Interior, Department of statistics and IQVIA Company at 2015 and 2017, Taiwan health care expenditure at 2014 is NTD933 billion (USD31 billion), GDP reaches 6.3% and the sales amount for oncology products reaches NTD4.8 billion (USD160 million). In 2016, total anti-neoplastic market reaches 8.336 billion (USD278 million), which is almost double the market size. In order to response to fast growing anti-neoplastic market, biosimilar new entries and limitation of the NHIA reimbursement, traditional marketing strategy may not fit well in this evolving pharmaceutical industry. Industrial environment change and dynamic strategy should be further considered. System dynamics management is sensitive to environment change and can mimic the result of return on investment, which can predicts a better strategic decision. This research based on system dynamics views, using marketing module of management flight simulator in system dynamic, simulating this business case in real world to produce multiple strategies and its consequences as the suggestion of future business management.

The research shows:

- 1. Use system dynamic to support decision-maker understanding the change of the environment and impact level of critical elements when making a decision*
- 2. Use flight simulator in system dynamic, identified 5-level target customers, tailored marketing strategies for each level, and simulated the result in order to get the best solution*
- 3. Validate system algorithm, external factors and internal resource allocation during simulation process, support decision-maker to understand critical elements, developing tailored strategies, forming concrete target customer structure to ensure business sustainability*

Conclusion: The research implies

- 1. Business management and decision making process*
- 2. Maximize business value and profit*
- 3. Resilience when facing competition*

Keywords Key words: System dynamics; strategy dynamic; dynamic strategy; Pharmaceutical industry

Paper type – Academic Research Paper

1.Introduction

WHO (World Health Organization) announces that cancer is the second leading cause of death in the world, causing 9.6 million deaths in 2018, which accounts for nearly one-sixth of the world's total deaths. The economic impact of cancer is tremendous and is still growing. AHRQ(The Agency for Healthcare Research and Quality) estimated the total cost of treating cancer just in the States itself is about 80.2 billion US dollars in 2015.

The number of new cancer patients and the number of deaths are increasing continuously, and the global anti-cancer drug market has maintained rapid growth in the recent years. According to IQVIA, the global expenditure for anti-cancer drugs has increased from US\$96 billion to US\$133 billion in 2013-2017. In the States, the expenditure for the cancer drug increased from US\$38 billion in 2013 to US\$61 billion in 2017, which accounted for 46% of the global market. IQVIA predicts that the global cancer treatment drug market is expected to reach US\$200 billion in 2022. However, in the pharmaceutical industry, the local laws and regulations are not the same in different countries, and the insurance payment and national policies are different. How to make use of the market research and data analysis to achieve local planning and tailored regional planning so that more patients can get more appropriate treatment.

Facing the huge market opportunities, the oncology drug market is extremely competitive. The top 10 pharmaceutical companies worldwide have about 40% of the research and development product layout is in the field of cancer treatment. Traditionally, it is no longer easy for the pharmaceutical companies to apply the promotional mode to the current environment. There must be more innovations and a quick responsive market, so that enterprises can continue to operate regardless of technological innovation and product innovation.

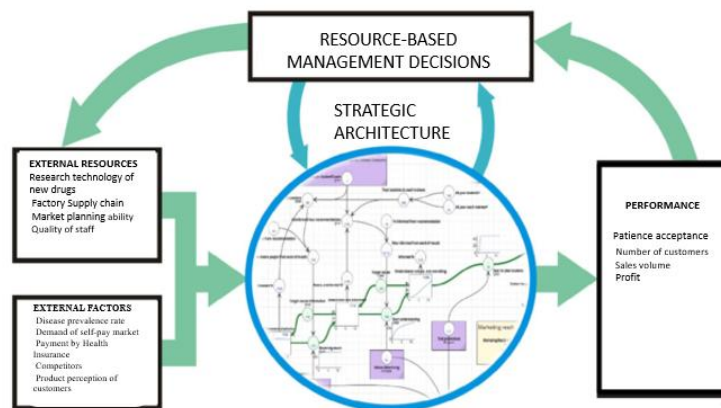

In order for the enterprises to sustain operation, there must be more innovations and possess the capability of responding quickly to the market. Regardless of technological innovation, product innovation, service innovation and business innovation, it can greatly contribute to the development of the enterprise market. Continuous service innovation can meet the needs of the existing customers, and product innovation is able to cater to the needs of customers in the future market, reducing unnecessary delivery of resources can also increase the ROI of the enterprise, process improvement and staff adjustment will also affect the product and business models, at the same time, good results are more supportive to the growth of business and revenue.

In the Yan (2018) research, it is proposed that the framework of SSDSS uses a simulation management model to establish strategic planning combined with external resources and external factors, and helps the company to examine a good decision-making business model through the customer cognitive phase and feedback mechanism.

In this case, the use of the SSDSS framework through the decision-making process, the relevant variables and feedback mechanisms can clearly outline the overall picture and diagnose the problems encountered by the corporate cases and develop relevant strategies to expand the anti-tumor market in Taiwan.

2.Strategic Framework

By importing the interview data under the SDSSS framework, it can be summarized the external resources of the medical industry including the quality of the staff, the rate at which new drugs are developed, the capability of marketing planning, the supply capacity and external factor disease prevalence rate, insurance system, the disease awareness of the customers and if the self-pay market is perfect, will affect the customer's recognition of products and enterprises.

Figure 1-1 SSDSS Decision analysis chart

According to Figure 1-1, the strategic framework illustrates the strategic results and performance, over time, changes in customer perceptions and customer inflows or outflows depend on resources, management decisions, and external factors.

In order to confirm the feasibility of the strategy, it is necessary to assess the awareness of the customers at different stages, and enterprises can apply different marketing strategies according to the different perceptions of the customers. The marketing challenge encountered by the medical industry is how to increase customer's prescription experience to accelerate customer inflows and to reduce the risk of customer outflows. This case uses SSDSS analysis to more effectively apply the method of investing in the development of customer at different stages.

Figure 1-2 Factors influencing different stages of target customer scalar quantity and flow

The customer development phase can be divided into four phases of resource allocation to maximize resource development at different stages:

(1) Unaware customers Stage of contact marketing

Increase the opportunities for the target customers to be in touch with the product and to establish brand impressions, regardless of product being advertised in the medical news magazine, or display at sponsored booth, or cooperation with the media public relations and so forth, it presents only the image of the brand logo.

(2) Aware customers Stage of experiential marketing

Allow the customers who are aware of the products but are not interested, to experience the product, besides the introduction of the products by sales representatives, invite the customers to participate in the large scale seminars, understanding the benefits of the product in detail and the treatment effect, and transform the impression of the customers' interest in the product

(3) Informed customers Stage of reciprocation marketing

To enable the target customers who have shown interest but have not consumed to become actual non-loyal consumers, invite them to attend small scale medical seminars, and consult the experts any related treatment related questions or doubts, and be invited to participate in any of the clinical trial plan to increase treatment experience and confidence.

(4) Disloyal customers Stage of testimonial marketing

At this stage, the task is to strengthen the continuous return of the customers, so that they will become devoted customers, and through the sharing of the results of large scale treatment experiments by experienced experts and arrange exchange of experience in international exchanges, so that everyone can understand more about the trend of international treatment

3. Introduction of Case Study

Roche Pharmaceuticals was founded in 1986, and the headquarters are located in Basel, Switzerland. It is the biggest biotechnology company in the world. The revenue of Roche Pharmaceuticals is 48.1 Swiss francs. Since the beginning of 21 century, the company is focusing on full development of the anti-tumor drugs. The Taiwan branch was set up in 1967, and there are about 300 employees currently, and the annual revenue is almost 270 million US dollars, which is the third biggest pharmaceutical company in Taiwan, and its anti-tumor drugs accounted for 72% of the company revenue.

The National Health Insurance implemented in Taiwan generally covers a great range of anti-tumor treatments. Because of the rapid increase of patients, many newly listed anti- cancer drugs can only be used at their own expense. For those countries relying on national health insurance, it is a very tough market, so for those managing these drugs must have a clear market research and perception of customers and big data analysis, in order to make helpful strategic planning.

In the enterprise case study, the drug, Avastin , serves as an action machine which cooperates with the chemotherapy to hinder the supply of nutrients to the cancer cells, and it can be used in the treatment of many cancers. The subject of this case study is directed at Avastin newly listed on the market for the treatment of ovarian cancer drugs. The case study is based on Avastin's new treatment of ovarian cancer drugs. Firstly, the SDSS framework is used to support management decisions and the in-depth interviews with medical experts and secondary data simulation of the amount of resources invested in the market, and to achieve changes of the dynamic equilibrium state and affecting results and to improve business performance.

Based on a total of 80 specialists of women's cancer in Taiwan, a sample interview of 30 physicians, the analysis of the target customers are as follows:

Table1. Research Approach and Sample Design

	2018 Avastin in OC survey
Sample size & target audience	n=21 Gynaecologic Oncologists n=9 Medical Oncologists
Methodology	60 minutes face to face interview with semi-structured questionnaire
Sample criteria	Practice within 3~35 years Must have at least 10 OC patients prescribed with systemic chemotherapy in past 1 year Must have at least 1 CC patients prescribed with systemic chemotherapy in past 1 year
Quota	Area - North: Central :South = 5:2:3 Medical center : Regional Hospital = 7:3 OC class - Level A:B:unclassified = 8:17:5

Scale up sample size according to the 5 stages of strategic framework, and classify them as follows:

Stage 1: Definition of unaware: Specialists of women cancer who have not heard of this product. There are about 80 Gynecology specialists in Taiwan, and approximately 20% physicians have not heard of this product.

Stage 2 Definition of Aware: Have not participated in any product presentations and those customers not fully aware of the product information accounts for 18% of the gynecology specialists.

Stage 3: Definition of informed customers: The targeted group have participated in product presentations or seminars and expressed that they have partially understood the product but have not used it before. These account for about 18% of the gynecology specialists.

Stage 4: Definition of disloyal customers: Have used the product and its substitute before, and it accounts for about 13% of the gynecology specialists.

Stage 5: Definition of loyal customers: Good experience of using the product and recommending personal treatment experience to other physicians at the large scale institutes, and this accounts for about 31% of the gynecology specialists.

According to the Ministry of Health and Welfare, the prevalence rate of ovarian cancer in Taiwan is as follows:

Table 2 Number of ovarian cancers according to clinical and pathological classification(not including 0 stage)

	Pathological stages				
Clinical stages	Stage I	Stage II	Stage III	Stage IV	Total
Stage I	311	19	22	2	354
Stage II	12	39	21	0	72
Stage III	32	18	226	9	285
Stage IV	1	0	7	134	142
Total	356	176	276	145	

Source of information: 2015 Ministry of Health and Welfare Ovarian Cancer Report.

In the case study, according to the client list of the company, the customers who are willing to recommend the patient's willingness to use and the patient's willingness to pay at their personal expense after recommendation are as follows:

Picture 3-5: Statistical ratio of phase target customer willing to recommend to patients
References : IQVIA & Roche company.

Picture: 3-6 Target customer recommendation acceptance ratio
References : IQVIA & Roche company.

3.1 Results of the analysis

Inflows and outflows are constantly alternating at the customer development stage, the scalar quantity and flow will evolve dynamically due to promotional behavior decisions or business models. Therefore, the accumulation of the target customer at the four stages is quite important. Investing resources at the four stages are used to increase the customer's awareness of the disease:

Unaware to Aware: Through large-scale broadcasting such as launching of product, medical magazine media or setting up medical clinic booths, motivate the customers to move towards customers who are recognize the product but show no interest

Aware to informed: Through small scale seminars or product presentations, the unique treatment effects and clinical trial results of the product brand are passed on to the uninterested customers.

Informed to disloyal: At this stage, the main task is to heighten the confidence of treatment and invite these customers to participate in clinical trials, and so forth.

Disloyal to loyal: The marketing task at this stage is to convert customers into product loyalists.

Therefore, the investment resources are more concentrated in strengthening the good experience of the customer and speech giving training program to increase personal influence.

Through the model framework, it can also be seen that the theory of customer development stage of the flow is subjected to dynamic changes due to the patient's self-paying ability or the ability of advisory reception or the effect of treatment is not good and the appearance of new competitors.

4. Conclusions

This case study, through SSDSS, arrives at three crucial factors to promote the business growth, firstly, to confirm changes in the mobility of customers and the five stages market development, how it can utilize the company resources to maximize the efficiency, innovation of the second business model, creates clearly the product awareness, leading customer to recognize the value of the product and increase the market share by using service innovation. Lastly, uses the strategic framework to uncover potential customers and each stage of strategic planning can assist the decision maker clearly see the whole picture and make the right decisions.

Although this study is useful for the market, but there are some restrictions.

For example, there are many factors affecting the revenue, other than the interaction between the variables, the interaction between the employees and customers will also affect the result. This encourages the study in future to continue further discussion and research.

Abstract

With the development of knowledge economy and increase of global competition, the role of university is becoming more and more critical in the development of local and national community. Besides the traditional twin missions of teaching and research, nowadays more and more emphasis has been put on the so-called third mission, i.e. social service, which commercialize generated knowledge and intellectual property. Under the New Public Management paradigm, a few performance indicators are set to make university accountable, such as number of students, amount of public and industry funding and number of transferred patents. Furthermore, a lot of rankings are introduced to compare the performance among universities. However, only a few universities meet the expectation of stakeholders. In this study, we conducted a case study in China to

investigate what is the limiting factors behind university development. First, unstructured interview towards faculties is used to investigate the limiting factors and a causal loop diagram is sketched to describe the underlying mechanism. Then a university growth strategy with executive education and industry knowledge ecosystem is proposed to alleviate the constraints and to achieve the full potential of university.

Keywords University Growth Strategy, Limits to Growth, Executive Education, Knowledge Ecosystem, Causal Loop Diagram

Paper type Academic Research Paper

1 Introduction

In the last decades, worldwide governments introduced new university reforms to respond more effectively to the changes of the economic, social and political systems (Lindstrom, 1994; Tierney, 1998; Butera, 2000). With the development of knowledge economy, university become more and more important and closely embedded in the society (Mckelvey et al 2018). Traditionally, universities are expected to create new knowledge and share it, to educate and to train people for the manufacturing and service sectors and the society at large. Compared to the twin missions of teaching and research (Etzkowitz 2004), nowadays more and more emphasis has been put on the third mission, i.e. social service, which commercialize the generated knowledge to support the development of community (Zhang et al 2018).

One of the main indicators to measure university performance is ranking, which is a weighted sum of the performance metrics. Among them, ARWU, The Times, USNews and QS university rankings are the top four. The performance metrics and respective weights of QS and The Times University Ranking can be seen in Table 1. Generally, university is evaluated based on its performance in research, teaching and reputation.

Table 15 Performance indicators and weights in QS and The Times University Ranking

Rankings	Indicators and respective weights
QS	Academic Peer Review (40%); Citations per faculty (20%); Faculty student ratio (20%); Global Employer Review (10%); International Student Ratio (5%); International Faculty Ratio (5%)
The Times	Teaching (30%); Research (30%); Citations (30%); International outlook (7.5%); Industry Income (2.5%)

In both of two rankings, research accounts more than 60% of the ranking. Indeed, among the three missions, research lies in the centre, as university is the centre of great minds and responsible for knowledge creation since it is built in the middle century, without which it cannot play a leading role in higher education. Thus in this paper, we investigate the research part of university and try to propose proper strategy to foster university growth.

2 Literature review

2.1. *University Mission and Performance Measures*

It is difficult to precisely define the universities' role in modern society. Since it is founded in the middle century, university is the centre of great minds, which creates and diffuses knowledge, delivers both knowledge and skilled students to the society. With the booming of knowledge economy and increase of global competition, universities need to reposition themselves and restructure to respond more effectively to the changing social, economic, and political forces.

It is time for universities to redesign mission. As suggested by Lindstrom (1994), this is a time of transition for everyone involved in the production of public service, internal effectiveness and external influence have been the identical standard for all organizations. The author argued that quality is the strategic factor for competition and cooperation in the university world and we need to go back to the fundamental questions, i.e., "What is meant by quality? For whom is quality intended? Who is responsible for quality? Within which areas will quality be followed up? How are quality levels followed up?" Finally Lindstrom concluded that university should engaged staff in quality evaluation and improving all areas of operations continuously. In the book titled "The Responsive University: Restructuring for High Performance", Tierney (1998) advocates reorienting basic working structures and designing more creative organizations and they argue that it is critical to find alternative ways to measure productivity and reconfigure promotion and tenure, along with academic freedom, faculty roles and rewards. Butera (2000) thinks that it is the true challenge facing the universities to contribute substantially to the development of a knowledge economy and the training of knowledge workers. Universities has assets to be successful, but also suffers severe constraints because of legacy systems rooted in organization, personnel rules, and a culture for a past era.

To define and evaluate the performance of universities is the prerequisite to achieve university mission. Sarpong et al (2015) identified three domains of practices (advanced research capabilities and external partnerships, the quantification of scientific knowledge and outputs, and collective entrepreneurship) that constitutively facilitate partnership and in turn the successful transition to a hybrid triple helix model. They also suggested integrating flexible routines and procedures into organizational processes and collaboration architectures, so as to engage productive innovation partnerships. Based on the model of collective intelligence (Boder,2006), Secundo et al (2016) proposed a three dimension framework, i.e., entrepreneurial competence development, technology transfer and innovation, social engagement and regional development, for universities to enhance their intangible resources and endorse the capacity of their "crowd", on which a profitable interaction with the external environment is based.

2.2. *System Dynamics-based University Policy Analysis*

The System dynamics (SD) methodology was found by the pioneering work of Forrester (1961), which aims at investigating complex systems through a cause-and-effect perspective. This preliminary analysis provides the basis to build simulation models oriented to supporting decision makers' learning processes. In fact, through the investigation of simulation results derived from the implementation of desired policies, decision makers can acquire a deeper knowledge on the relationship between the cause-and-effect system structure and the related main variables behaviours over time.

It was first applied in supply chain management. Nowadays, it is widely used in social science, engineering, healthcare, education, with applications in public, private and non-profit organisations (Stermann et al. 2015). The field of study related to university growth strategy, however, is not well investigated.

Richardson and Lamitie (1988) conducted a research on the increased use of school aids in Connecticut. They built a simulation model to support school's decision makers to question their thinking about target state aids, and to envisage alternative policies to effectively deal with the local districts' resistance factors. Galbraith (1998) tried to introduce system dynamics to university management by identifying system archetypes triggered by increasing competition among universities. Barlas and Diker (2000) developed an interactive simulation model named UNIGAME on which the academic aspects of university management are analysed and alternative management strategies can be tested. The use of the simulator may support decisions makers to understand the system as a whole and to make the decision process transparent.

To adapt to different situations and modelling objectives, modellers can look at the system in varied ways. At the institutional level, performance is assessed primarily in relation to the effects produced by decision makers on their own institution. At the inter-institutional level, performance is assessed in relation to the effects produced by decision makers on the wider system, e.g., either a local area or the industry to which they belong (Bianchi, 2016), such as tax contributions, increasing employment, shared knowledge with business partners, etc. Besides, there are three types of models, conceptual model, stock-and-flow model and insight model. Conceptual model depicts the feedback loops explaining system behaviour, with no quantitative data or simulation. Stock-and-flow model is quantitative which implies a level of detail, an accuracy, and an extension of explored system boundaries i.e. usually broader than in a qualitative analysis. Insight or policy-based model is built based on its usefulness to users, rather than how closely it mimics reality of historic time series. Therefore, relatively simple models might be valid, and just as effective as a highly detailed models (Lyneis, 1999; Bianchi, 2016).

2.3 Executive education and knowledge ecosystem

It has long been argued that executive education helps to build learning alliance between business and business schools (Ghoshal et al 1992). The authors proposed that instead of viewing research and teaching as independent or sequentially linked activities, such programs can make them simultaneous outputs from a shared learning experience. The executive education can close the gap between academic research and field knowledge, which will improve the productivity by increasing the relevance of research to industry. Besides, executive education provide extra funding and industry resources for further research.

Starting from its (re)introduction two decades ago by Moore (1996), the ecosystem concept has also been actively discussed in management studies, bridging, for instance, system thinking and evolutionary economics (Valkokari, 2015). Compared with business ecosystem, which focus on customer value creation and with big companies as key players, knowledge ecosystem focus on generation of new knowledge and research institutes such as universities play a central role in the system. Similar as business ecosystem, the value creation of knowledge ecosystem is two-fold: (1) facilitation of the innovation process for individual companies and (2) creation of an innovation community (Borgh et al. 2011).

3 Research method

First, the status quo is investigated by unstructured interview towards a few faculties in the selected university. Then a few limiting factors are identified and a causal loop diagram is drawn to depict the underlying mechanism. Causal loop diagram is a conceptual system dynamics tool which represents a closed loop of cause-effect linkages (causal links) as a diagram which is intended to capture how the variables interrelate (Zhu et al. 1995). Causal loop diagrams identify and label feedback loops to facilitate dynamic reasoning and formal modelling. At last, we compare the causal loop diagram with classical system archetype and a university growth strategy is proposed to achieve the full potential of university.

4 Empirical study

To investigate the development of research in university, Shanghai University of International Business and Economics, is selected as our case. Founded in 1960, the Shanghai University of International Business and Economics (SUIBE) is one of the Chinese specialized universities which is famous for economics and finance. SUIBE offers 30 undergraduate programs, covering five fields of disciplines, i.e. economics, management, literature, law and natural science.

First, an unstructured interview with faculties is conducted to investigate the critical factors that influence the research productivity and limited resources. Based on the interview, we extract cause-and-effect links from the text and develop a causal loop diagram to sketch the mental model (Doyle and Ford 2015) of faculties about research productivity. As Figure 1 shows, there are 4 reinforcing loops and 6 balancing loops, which can be described as below:

- R1 Workforce adjustment (Faculty-Publications-Projects-Desired Workforce-Recruitment-Faculty): when number of faculty increases, publications increase, which enable more projects, more faculties are required, and recruitment is adjusted to close the gap between desired workforce and current faculties.
- R2 Funding support (Research Productivity-Publications-Projects-Funding per Faculty-research productivity): when research productivity increase, publications increases, projects increases, more funding are distributed, higher funding per faculty in turn increase research productivity.
- R3 Work input (Research Productivity-Publications-Projects-Research Workload-Research Productivity): Research productivity is driven by more research workload.
- R4 Attrition Adjustment (Faculty-Attrition Rate-Recruitment-Faculty): when attrition increase, recruitment is also increased to fill the gap, faculty increases.

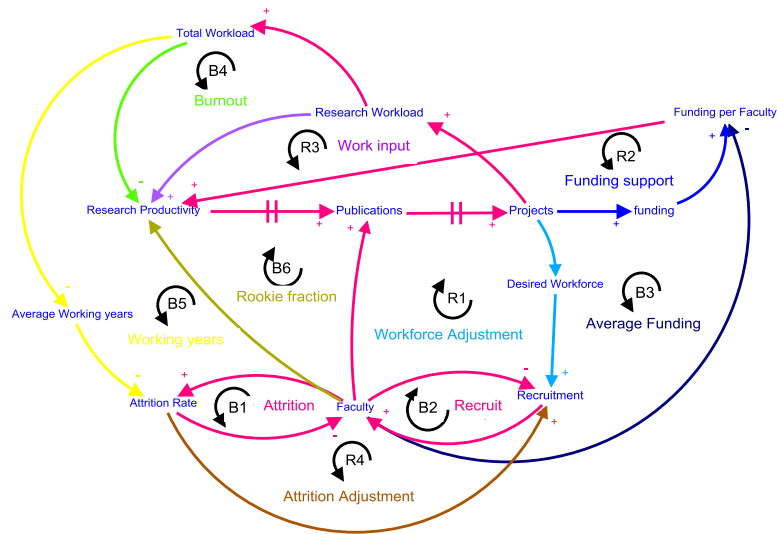

Figure 11 Causal loop diagram of university research

- B1 Attrition (Faculty-Attrition Rate-Faculty): The higher the number of faculties, the higher attrition rate, which limits the growth of faculties.
- B2 Recruitment (Faculty-Recruitment-Faculty): when number of faculties is high, recruitment is decreased, which limit the growth of faculties.
- B3 Average funding (Research Productivity-Publications-Projects-Desired Workforce-Recruitment-Faculty-Funding per Faculty-Research Productivity): Average funding is decreased because of the recruitment of faculty, which decreases research productivity.
- B4 Burnout (Research Productivity-Publications-Projects-Research Workload-Total Workload-Research Productivity): research productivity is decreased because of high total workload.
- B5 Working years (Faculty-Publications-Projects-Research Workload-Total Workload-Average Working Years-Attrition Rate-Faculty) Limit of faculty growth because of shorter average working years, which increases attrition rate.
- B6 Rookie fraction (Research Productivity-Publications-Projects-Desired Workforce-Recruitment-Faculty-Research Productivity): Limit of research productivity because when recruitment help to increase faculty number, the rookie fraction also increase, and in turn research productivity decrease.

There are four limits to growth archetype in the system, as Table 1 and Figure 2 show, for every reinforcing loop driving the development of university, there are one or two balancing loops counteracting the effect. Without the alleviation of balancing loop, it is useless to push the reinforcing loop. For example, the workforce adjustment R1 can increase the number of faculties, but B6 counteracts by increasing rookies fraction which decrease research productivity.

Figure 2 Limits to growth (Senge, 1991)

Table 16 limits to growth archetype of substructure

Substructure	Reinforcing Loops	Balancing Loops
Workforce adjustment	R1	B6
Funding support	R2	B3
Work input	R3	B4, B5
Attrition adjustment	R4	B1, B2

5 Policy analysis

As suggested by Senge (1991), with the limits to growth structure, it is useless to push the reinforcing loop without alleviating the balancing loop, thus possible policies can be addressed to overcome the effect of balancing loops. For example, increase knowledge sharing and career development to help rookies to learn faster to adjust the effect of B6. Thus we propose a university growth strategy with executive education and industry knowledge ecosystem development, which can strengthen the reinforcing loops on one hand, and alleviate the effect of balancing loops on the other hand.

Foster university growth by executive education. Executive education provides professional education and training for experienced managers, especially for senior managers. It has long been argued that executive education helps to build learning alliance between business and business schools (Ghoshal et al 1992). The executive education can close the gap between academic research and field knowledge, which will improve the productivity by increasing the relevance of research to industry. This will in turn strengthen the cooperation between university and industry, which help to attract more funding to support research.

Foster university growth by industry knowledge ecosystem development. Knowledge ecosystem becomes a buzz word recently, in which mutually complementary stake holders form a close network to share knowledge and gain competitive advantages. Based on a unique hand-collected database of 138 innovative start-ups in the region of Flanders, Clarysse et al (2014) analyse the knowledge and business ecosystem and the financial

support network. The authors find that the knowledge ecosystem is well structured and concentrated around a number of central actors while the business ecosystem is almost non-existent at the local level. University is famous for its openness and tolerance, based on which it can naturally be the central actors in the knowledge ecosystem and bridge different stakeholders, i.e. public organizations, private organizations and citizens. This will create tremendous opportunities to commercialize the generated knowledge and contribute to the development of community.

6 Conclusion

In conclusion, university is facing great challenges and it can't deal with the issues alone as there are a few limits to growth structure inside the system. Based on the analysis of system structure and investigation of latest practices, we propose a university growth strategy with executive education and industry knowledge ecosystem development. This strategy will help to strengthen the tie between university and industry and contribute to the achievement of university mission in large.

Abstract

This research is intended to theoretically investigate and analyse the characteristics of WeChat and its effect on knowledge sharing through a systems thinking approach. As one of the most popular mobile social application in China, WeChat has social attributes and the functions of multimedia interaction platform and has been gradually used in knowledge management practice. On one hand, comparing with virtual communities of practice, WeChat provides a more open and individual environment which break free the shackles of workplace relations. On the other hand, as a user-operated media and instant messaging software, WeChat has dramatically different structure with academic social network sites, such as ResearchGate and academia.edu and so on. It is found that this new emerging tool could be useful in sharing explicit and tacit knowledge through providing interactive and collaborative technologies. Meanwhile, these user-operated

media are bringing new challenges for knowledge sharing. For example, they provide a high level of convenience for the diffusion of “false knowledge”.

There is still a poverty of literature to understand how and what might be the contributions and effects of WeChat on sharing different knowledge dynamically. Therefore, the purpose of this research is to analyze the effects of social media on knowledge sharing towards a systems thinking approach in order to provide a better understanding of social media users’ knowledge sharing behavior and important practical implications for the scientific and reasonable management of knowledge sharing. By conducting a study of the characteristics of knowledge sharing on WeChat, the subject, object, content, channel, and effect of knowledge sharing were analysed. The results show that WeChat present knowledge sharing opportunity that augment personal and organizational knowledge management in terms of tacit knowledge sharing, explicit knowledge sharing and false knowledge sharing.

Keywords – WeChat; Social media; Knowledge sharing; Systems thinking

Paper type – Academic Research Paper

1 Introduction

Nowadays, social media (SM) has emerged as a valuable platform dependent on advanced information technology for facilitating knowledge sharing (KS) and communication. It becomes an important method for collecting new information, shaping new ideas, and developing new products and insight (Ogink and Dong, 2017; Ransbotham and Kane, 2011). For instance, higher education institutions have also adopted social media as a mean of inspiring learning activities (Balakrishnan and Gan, 2016; Kulakli and Mahony, 2014). The essence of these social medias is knowledge collaboration, which includes a series of activities of sharing, transfer, accumulation, and co-creation of knowledge (Faraj et al., 2011).

Social media platforms incorporate a wide range of online media, including word-of-mouth forums such as Social Networking (SNS) (like Myspace and Facebook), microblogs (like personal blogs or Twitter), pictures or video-sharing applications (like Flickr or YouTube), and collaborative websites like Wikipedia (Kaplan and Haenlein, 2010; Osatuyi, 2013; Yan et al., 2013). These types of social media tools are considered to be prominent and well-established spaces for creating knowledge sharing channels, where people are able to find other individuals with similar interests, and share their thoughts with them (Bilgihan et al., 2016). Therefore, how to facilitate knowledge sharing on social media has become a central research issue. Our study follows this research issue, aiming to fill in the gaps that come from neglecting the support of technological tools on knowledge sharing.

As the emerging social media, WeChat plays an important role in Chinese daily life since it is launched in 2011. The result of a recent research shows that: 97% of their

anticipants used WeChat every day, half of the respondents opened it at least 20 times a day, and 16.01% opened it as much as 40 to 50 times a day. Over half of the respondents stayed on WeChat for at least 1 h each day, while 18.97% used it for more than 3 h (Zhang et al., 2016). WeChat has social attributes and the functions of multimedia interaction platform and has been gradually used in knowledge management practice. For example, the WeChat service number of China Merchants Bank---official WeChat of China Merchants Bank Credit Card Centre has achieved online communication and knowledge transfer between enterprises and customers, and the WeChat subscription number of Harvard Business Review magazine has pushed and shared new knowledge on management to and with users in real time (Zheng et al., 2014). And WeChat Library was found to have many advantages, such as low development cost, automatic cross-platform service, adaptive screen, low acceptance cost, easier promotion, strong user viscosity, strong interactivity and real-time consulting (Wei and Yang, 2015). These successful examples show that WeChat plays a key role of platform in online knowledge dissemination and sharing.

The current studies mostly focus on the research of WeChat users' behaviour (Chen et al, 2018) and its motivations from the aspects of social capital (Zhang and Liu, 2018) and self-efficacy (Wang et al., 2017). There is still a lack of understanding on how social media may facilitate knowledge sharing among its users, how can maximize the benefits, and how to tailor social media platforms for the needs of knowledge sharing. Therefore, to better understanding the phenomenon of knowledge sharing in social media space, this study is intended to make a theoretical link between social media concepts and characteristics with requirements of knowledge creation and sharing to find out probable potential of social media in facilitating knowledge sharing. This research aims to answer the following questions:

- (1) What WeChat activities are used for knowledge sharing?
- (2) What are sources of knowledge sharing on WeChat?
- (3) What are effects of knowledge sharing on WeChat?
- (4) What key challenges are faced when using WeChat for knowledge sharing?

This paper is structured with five sections. Firstly, the background and objects of this research is introduced. Then the introduction of WeChat and the characteristics of WeChat is reviewed. In the third section, the role of WeChat in knowledge sharing is explained based on case study. The forth section describes a systems analysis of the relationship between WeChat and knowledge sharing. Finally, based on the research results, the fifth section presents a discussion of the review, and its conclusion.

2 WeChat and its characteristics

2.1 WeChat

WeChat (WeiXin in Chinese) is a mobile instant text and voice messaging communication service developed by Tencent Holdings Ltd. in China on January 21, 2011. It has developed from a communication tool to a platform that connects people,

service, and business. WeChat has similar features to WhatsApp to generate both text and voice messages. It is a free application program that provides an instant messaging service for intelligent terminals including iPhone, Android, and Windows Phone operating systems. WeChat supports sending text messaging, hold-to-talk voice messaging, one-to-many messaging, photo/video sharing, location sharing, and contact information exchange (Chen, 2015). WeChat is the most widely used social networking service in China and has become an important social media platform for computer-mediated communication. And WeChat is among the top App that contributes to the highest percentage of data consumption. WeChat-driven information consumption reached RMB 209.7 billion WeChat accounted for 34% of the total data traffic of users (2018 WeChat data report). With the advances in Internet connection and the popularity of smart phone, WeChat reached 1.09 billion monthly active users at the end of 2018 and is available in over 200 countries and supports 18 different languages (2018 WeChat data report). Figure 1 shows the main functions of WeChat.

	Voice Chat		Favourite Messages		Video Call		Shake
	Group Chat		Group Chat QR Code		Sticker Gallery		People Nearby
	Moments		Chat History Backup		Broadcast Messages		Walkie Talkie
	Free Call		Web WeChat		Friend Radar		

Figure 12 Main functions of WeChat (Wei and Yang, 2015)

2.2 The characteristics of WeChat

A wide variety of characteristics and capabilities have been defined for social media in the current research, including user-generated content, peer to peer communication, networking, multimedia oriented, and user friendly (Panahi et al., 2012). As one form of the social media, WeChat's characteristics are accordance with the characteristics of social media. For instance, WeChat is enabling users to store and share multiple content forms such as text, image, audio, video, and other formats in an interactive and easy way. This provides opportunity for users to easily share their own created multi-media files, tag, and comment on them. Meanwhile, like YouTube and Facebook, WeChat allows people to share variety of video and photo files with different subjects. But there's also some unique features that WeChat have. These can be categorized into three features:

Official accounts: There are two official account types on WeChat public platform, including service account and subscription account. The first one appears as friends in the "chat" section of WeChat. It is extremely visible and can only post 4 messages per month. While subscription account can send up to 1 push message per day to their followers and are grouped together in a dedicated folder. They are focused on providing users with

information by supplying media and individuals with a completely new channel for information dissemination and building improved communication and management patterns with patrons. The official account can be registered and run by individual and organization.

Equality: On WeChat, like Facebook and WhatsApp, users can easily establish a chatting room or group by adding members from their friends list. The difference is that it can add any of their friends into a WeChat chatting room without the permission of the members and the one was added. And the new members can also invite and add any friends to this chatting room from their own friends list. All the members in the same community have the equal power, which make the expansion of chatting room easier than before. WeChat group become the main form of network group life. Joining WeChat group is the routine of WeChat users.

Acquaintance network: There are obvious differences between WeChat and online community chat, especially with the so-called posting and follow-up mode, which subverts the traditional form of community life. Unlike the weak relational social networking platform, strong connectivity is the main feature of WeChat, enabling people easily to stay connected with each other in a real-time and in a global base. WeChat have provided an effective channel for social interaction and real time conversations between users in forms of chatting, video/telephone conferencing, etc.

The combination of those features and associated tools have made WeChat good channel for knowledge sharing activities. It helps people get connected, communicate with each other, build relationship, develop trust, and share their knowledge. It supports knowledge creation, distribution, and visibility of knowledge more effectively compared to traditional knowledge management systems.

3 The role of WeChat in knowledge sharing

WeChat is a virtual interactive platform based on interpersonal communication and strong relational interaction. Its media attribute is not so strong as WhatsApp. It pays more attention to pursues a kind of relationship rather than concern. WeChat group users have a higher sense of group identity and trust. The communication and discussion between users are more active and direct, forming a cultural circle with distinct topics. As collecting emotion and trust plays a direct role in inducing tacit knowledge sharing behavior, WeChat group is more recessive than other online social networks. The role of WeChat in knowledge sharing can be analyzed in the following aspects:

1) Accelerate the speed of knowledge sharing

WeChat can speed up the process of dissemination, sharing and transformation of explicit and tacit knowledge. We take the official account of Chinese Public Administration as an example. Table 1 shows the comparison of the reading numbers of the same articles posted by Chinese Public Administration on WeChat and the downloads on CNKI (China National Knowledge Infrastructure) until April 6, 2019. These articles are published in the February issue on the Journal of Chinese Public Administration. The

results indicate that the sharing speed on WeChat is more than ten times the speed on CNKI.

Table 17 Comparison of the knowledge dissemination on WeChat and on CNKI

No.	Title	WeChat	CNKI
1	Public communication, media role, and multiple consensus in social transformation: the experience and legacy of the U.S. progressive movement	642	59
2	The study of the classification system reform of Chinese civil servants from the perspective of institutional logics	1223	105
3	On the status and function of government publishing in the business climate	2028	85

2) Promote the dissemination of tacit knowledge

The role of periodicals and knowledge sharing website like ResearchGate is similar. They only can supply academic knowledge as there's a high requirement for academic rigor. This limits the knowledge sharing on these platforms are mainly explicit knowledge. The dissemination of tacit knowledge which comes from experience sharing is still very scarce. WeChat has created a new platform for informal knowledge sharing among the public. For example, in the official account of Chinese Public Administration Review, there is a special service is experience sharing of learning (Figure 2). This enriches the content of knowledge sharing and improving the dissemination of tacit knowledge.

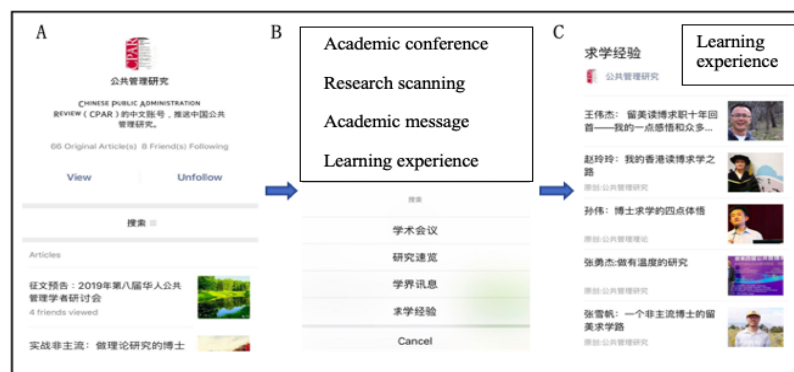

Figure 2 Application flow sheet of 'Chinese Public Administration Review' WeChat official account

3) Improve the effectiveness of knowledge sharing

Comparing with searching knowledge actively, WeChat can support a more easier and time-saving way to receive knowledge. WeChat users can achieve the latest knowledge by subscribing subscription accounts they are interested. And they could also obtain the knowledge shared by their friends and the friends of their friends. The source of knowledge is more widely. In the previous QQ group, only the group owners or authorized administrators have the right to invite new members to join. While each group member of the WeChat group can freely invite new members to join, which gather many

people in a short time. Comparing with other social media platforms, the rapid expansion of weak relationships enables knowledge in WeChat Groups to grow rapidly and increases the possibility of delivering knowledge to their potential recipients.

4) Increase the convenience of knowledge sharing

WeChat makes the access and transfer of knowledge easier. One of the most notable representative application is the usage of WeChat Library. WeChat Library is the mobile service platform developed and customized by a library based on the WeChat platform which realizes mobile service functions by connecting with the library management system, such as digital resource retrieval, OPAC retrieval, e-books and personal library (Wei and Yang, 2016). Since 2012, a lot of libraries for example Tsinghua university, opened their WeChat Library. WeChat Library realizes common mobile services, such as announcements, mobile reading, mobile consulting, recent arrivals, digital resources retrieval and items borrowed. We take Shanghai University of International Business and Economics Library as an example (Figure 3). There are three main services contents in this service account, including micro-services, cloud resource and important news. Under the cloud resource item, users can connect to the services of popular database, discovery of Chinese Periodicals, discovery of Foreign Periodicals and celebrity teacher forum. A detailed interface of discovery of Chinese Periodicals is given in figure 3.

Figure 3 Application flow sheet of 'Shanghai University of International Business and Economics Library' WeChat official account

4 System analysis of the role of WeChat in knowledge sharing

In this part, systems thinking is used to help identify and understand the relationship between WeChat and knowledge sharing from a technique support inspective. Systems thinking is a conceptual framework for problem-solving that considers problems in their entirety (P.M. Senge, 1990). Problem-solving in this research represents illustrating the mechanism of knowledge sharing on WeChat in order to enhance understanding of, and

responsiveness to, the problem. Outcomes from systems thinking depend heavily on how a system is defined because systems thinking examines relationships between the various parts of the system. Boundaries must be set to distinguish what parts of the world are contained inside the system and what parts are considered the environment of the system. The environment of the system will influence problem-solving because it influences the system, but it is not part of the system (Ackoff & Emery, 1972).

According to the definition of Davenport and Prusak's (1998), knowledge sharing includes two parts: knowledge transmission and knowledge absorption. It represents the knowledge exchange between knowledge owners and knowledge reconstructors. This knowledge sharing process can be considered as a system. The people; the knowledge people have, share, and need; the culture for knowledge sharing (or lack thereof); the technical support and the environment for knowledge sharing must all be considered for effective knowledge sharing initiatives. Systems thinking can enhance knowledge sharing through its ability to depict complex, dynamic processes and thus enhance understanding and the ability of knowledge sharing initiatives to respond to the needs of the individual and organizations (Schlange, 1995).

The feedback system of knowledge sharing is described as shown in figure 4. Five major reinforcing feedback loops and one balancing feedback loop and their effects have been identified. R1 represents a reinforcing feedback that shows in such a virtual space, WeChat users can create and display their own knowledges and exchanging their knowledge and views with others easier taking the convenience of a varied functions supported by WeChat. The diverse functions of WeChat give them the possible to quickly establish contacts, cooperate, share their views and unofficially published knowledge with people has the same research interests and fields across geographical and spatial constraints. This process accelerates the speed of tacit knowledge sharing and increase the available amount of knowledge shared on WeChat. Then the effectiveness of knowledge sharing is on the increase as WeChat users could obtain more knowledge and benefit more on WeChat. Therefore, the attractiveness of WeChat will increase and more people will tend to use WeChat as their communication tool than QQ or other social media. More WeChat users contribute to the increasement of demands. Ultimately when the demand of knowledge sharing increases, how to satisfy this demand better will become a driving force for improvement of functions. The same analysis can be applied to R4, which shows the diverse functions of WeChat accelerates the speed of explicit knowledge sharing.

R2 represents a reinforcing feedback that illustrates WeChat provides important opportunity for the dissemination of tacit knowledge. The diverse functions of WeChat, such as the subscription account, enrich the content of knowledge sharing. For example, it breaks down the barriers that academic journals can only provide professional academic knowledge. Nowadays, academic journals can also provide experience sharing through their official account. It can be concluded that WeChat plays an positive important role in exchanging and communicating tacit knowledge.

R3 represents a reinforcing feedback that good social interaction on WeChat has a positive relationship with tacit knowledge sharing. Comparing with social networking sites, such ResearchGate, WeChat has obvious advantages in the terms of interaction

between its users. The active interactions among knowledge owners and knowledge reconstructors is beneficial to tacit knowledge sharing.

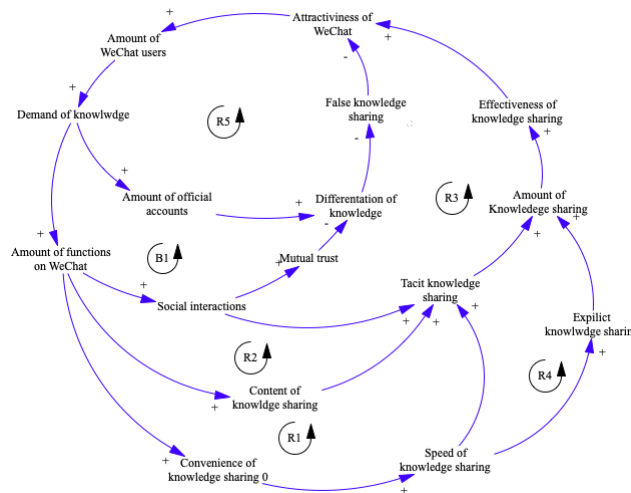

Figure 4 The eco-system of knowledge sharing on WeChat

R5 represents a reinforcing feedback that shows the usage of WeChat official account could reduce the sharing of false knowledge. WeChat official account is more authentic to users since the organization's legal name will be displayed on the information page. The knowledge provided by WeChat official account requires strict evaluation and verification. WeChat official account has strong guidance for the knowledge sharing. Therefore, WeChat users' ability to differentiate false knowledge will increase with the help of WeChat official account.

B1 is a balancing feedback that shows social interactions has positive effects on sharing false knowledge. Active social interactions could enhance the mutual trust between WeChat users, which will decrease the differentiation of knowledge. More users will share the knowledge they received without discerning between the true and the false. WeChat offers facilities for sharing false knowledge.

Based on the aforementioned feedback system, it is recognized that WeChat has the value to be an incentive to reinforce the improvement of knowledge sharing. However, improving the WeChat users' judging abilities of knowledge is one of key challenges that need to be addressed.

5 Conclusion

As an indispensable part consisting in media market, WeChat plays a more and more important role in promoting and facilitating knowledge sharing and innovation. It presents knowledge sharing opportunity that augment personal and organizational knowledge management. Although it is, yet, unable to meet all the needs of knowledge sharing, its

usage in knowledge sharing is certain to undergo further expansions along with the increasing growth of WeChat functions and the new need of the public. For example, the achievement of combining social tools with study tools makes WeChat can meet the need of fragmented learning. Future study for how WeChat augment the motivation antecedents of incentives, values, and competence-based trust will be conducted. For example, the research for studying how WeChat relate to the motivation for knowledge sharing and how WeChat affect the motivation for knowledge sharing are needed.

Abstract

In an economy such as China's with vast territory, where development differences widely exist in higher education, searching for characteristics is an inevitable choice, especially for those regional universities. The success worldwide provides experience for the regional universities to seek differentiated development by relying on the dominant disciplines with special characteristics. Using the systems science theory and ecology conceptual lens in combination with knowledge management approach, it is centring on the regional specialized university ecosystem in Shanghai. After identifying the main actors from the ecosystem theoretical framework, the characteristics and how the ecosystem is enacted are constructed. The final part is policy evaluation and discussion. Policies aim to support the effective integration of sustainable development and foster

performance in the regional higher education ecosystem. Results suggested that evaluation, regulation and funding of policy networks could aid change at higher education ecosystem.

Keywords – Higher Education Ecosystem, Strategic Knowledge Community, Regional University, Public Policy

Paper type – Academic Research Paper

1 Introduction

Regional universities refer to colleges and universities allocated funds by local administrative departments. In the higher education ecosystem in China, the number of regional universities is large, accounting for more than 95% of the total number of colleges and universities, undertaking the task of training talents for the region and serving the local economic and social development. However, compared with the universities affiliated directly to the ministry of education, the overall strength of regional ones is relatively weak, and the development is either insufficient or not fully balanced.

Specialized university is one of the important trends in the development of higher education in the modern world. For example, Babson College in the United States, as a leader in the field of entrepreneurship, has a worldwide recognized expertise in entrepreneurship. Carnegie Mellon University has made remarkable achievements in computer, robotics, software engineering, management information technology and other fields. It has rapidly developed from an ordinary regional university to a world-renowned research university. These high-end specialized universities have taken their expertise to the extreme. The success worldwide provides experience for the regional universities to seek differentiated development by relying on the dominant disciplines with special characteristics, attach importance to talent training based on local or industry, and change the construction orientation of “Go in for grandiose projects “. They will have full opportunities to be embedded in the education ecosystem to improve strengths, avoid weaknesses and win by surprise.

In order to guide the orientation on the diversified development, promote the optimization of the higher education ecosystem structure and resource allocation, it is significantly meaningful to analyze the characteristics of Shanghai regional university ecosystem, deepen the research on the application of ecology in the regional higher education field.

2 Literature review

2.1 University development and challenge

With the development of knowledge economy, universities become more and more important and closely embedded in the society (Mckelvey et al 2018). As a large

developing country, China is now faced with the dilemma of inadequate research and technology transfer capacity of research universities, weak teaching and social service level of teaching-oriented universities (Yao et al 2016). However, in many literatures analyzing the current situation and development of Chinese universities, there is a lack of research on regional specialized universities.

Butera (2000) thinks that it is the true challenge facing the universities to contribute substantially to the development of a knowledge economy and the training of knowledge workers. Besides the traditional twin missions of teaching and research, more recently universities promote and monitor results also achieved in the so-called third mission. This additional activity involves transferring and commercializing generated knowledge by interacting with key-actors of the socio-economic system (e.g., public and private organisations) and contributing to regional and national economic development (Etzkowitz, 2004, Montesinos et al., 2008). In the last twenty years, a general trend of universities adopting stronger entrepreneurship and innovation strategies has emerged giving birth to the entrepreneurial university (Clark, 1996, 1998a, 1998b, 2000; Davies, 1987; Etzkowitz, 1983), which means universities have tried to achieve the third mission. This new model of university is characterized by a more direct role in stimulating local and regional economic growth (Guerrero et al., 2014; Thorp and Goldstein, 2013).

2.2 Higher education ecosystem

An ecosystem is defined as “A biological system composed of all the organisms found in a particular physical environment, interacting with it and each other. Also in extended use: a complex system resembling this” (Oxford English Dictionary, 2017). The higher education ecosystem is an open and nonlinear complex system formed by the interaction of various elements within the higher education system with nature and social environment (Hu et al 2009).

Ecosystem researchers have continuously expanded the boundaries of their analyses (Masaharu et al 2018). Hu et al (2009) believed that it is a new attempt to study and discuss these problems by using ecological methods and principles. In recent years, the research on the ecosystem of higher education has been attached greater importance by scholars. Liu et al (2009) studied the “entrepreneurial ecosystem” advocated by MIT, which combines entrepreneurship activities with entrepreneurship education and can provide reference for the cultivation model of entrepreneurship education in Chinese universities. Taking the university of Texas at Austin and the national university of Singapore as examples, Yao et al (2016) extracted seven key elements of the entrepreneurial ecosystem of open universities. However, the research on the ecosystem of local characteristic education is missing. Moreover, nowadays, the evaluation system of higher education is not suitable for the regional specialized universities (Hu et al 2008). These universities need the new evaluation system with aim to propose the growth strategy from the perspective of the whole ecosystem.

Huang (2016) concludes that the current literatures focus on the following three aspects: University positioning research from the ecology position perspective, the

relation between ecology position and university competitiveness and specific events study of higher education by using ecology position theory.

3 Main actors and the characteristics of a regional specialized education ecosystem in Shanghai

By means of a mixed-methods approach, we identified the main actors of the regional specialized education ecosystem in Shanghai from the ecosystem theoretical framework. Following the basic structure of higher education ecosystem the connotation and extension of higher education ecosystem and its basic characteristics are analyzed.

3.1 Main actors of the regional specialized education ecosystem in Shanghai

From the perspective of ecology, higher education, like the natural world, also has a complete ecosystem. We call this system “higher education ecosystem”, which can be understood as the organic unity of internal elements of universities and their interaction with the external environment. Compared with the whole ecosystem of higher education, universities in a region or an area constitute the community ecology of higher education. This paper studies the higher education ecosystem constituted by local universities in Shanghai, especially the regional specialized universities.

The system has its own specific generation and succession process as well as structure, function, bearing capacity and productivity. It is a subsystem of the complex system of society, economy and nature. Stability and health are the key to the sustainable development of the system. The ecosystem of higher education has three functions: talent cultivation, academic research and social service in the process of material, energy and information flow and exchange.

Main body

The main body of regional specialized education ecosystem includes producer and consumer. Producers in the ecosystem refer to the regional specialized universities and their affiliated scientific research institutions, scientific and technological cultural organizations, or other organizations or individuals with higher education functions. The most important product of the ecosystem is the amount of human capital saved by individual students, followed by scientific research achievements that can directly or indirectly interact with the market and the social services provided. Consumers of the ecosystem include students, employers, beneficiaries of university culture, scientific and technological achievements and patents, and even the whole society. They receive various services from producers in different ways according to their own needs.

Decomposer

The decomposer of natural ecosystem can decompose various substances produced by producers and consumers into various elements and restore them to the environment of the ecosystem through physical, chemical or biological decomposition process, so as to provide continuous use for producers. Any material object which performs this function may be included in the category of the decomposer.

In regional specialized education ecosystem, education administrative departments such as the Shanghai educational committee and its subordinate functions as the decomposition, by performing functions, formulating related policies and regulations, implementing education funding and macro guidance and management, to ensure the stable, healthy and sustainable development of the ecosystem.

Environment

The ecological environment of the natural ecosystem is a combination of various ecological factors in the ecosystem, relative to the main body of the ecosystem. The environment of higher education ecosystem can be analyzed from three perspectives and three levels. First, it is an individual or compound higher education ecosystem, which is education-centred and combines with external natural environment, social environment and normative environment. Second, the ecosystem of higher education is formed with a certain characteristic university and a certain education level or type as the axis, which reflects the interrelationship within the education system. The knowledge community it creates from the strategic perspective is the key that leads the economy to a successful level and improves the education ecosystem development. Strategic knowledge community is a medium for knowledge exchange among members. It is a communication space formed by individuals with common interests in order to acquire the knowledge they need. The third is to study the external environment, including individual psychological and physiological factors.

Value chain and value network

The biological chain in the natural ecosystem can be equated with the value chain, and producers, consumers and decomposers of all types and levels form a chain and network through value connection, thus organically organizing the whole ecosystem. The value chain in the higher education ecosystem is the channel for the flow of material, energy and information between the inside and outside of higher education system. Because value can form new value through accumulation, the change of each link will cause the rearrangement of the whole regional specialized education ecosystem.

Higher education ecosystem emphasizes not individual elements, but the organic combination of various elements. It is a dynamic system which integrates the main body, decomposer, environment, and value chain and value network. The elements are interrelated, interdependent, interacting, motivating, complementing and restricting each other, thus constituting the whole higher education ecosystem.

3.2 Connotation and extension of higher education ecosystem and its basic characteristics

The characteristics of higher education ecosystem are the key issues concerning the stability, balance, harmony of the system and how to sustain and achieve its functions. Viewing the ecosystem as a complex actor network, each actor has a different background and attributes. In general, the system has the characteristics of focusing on the interaction between producers and consumers, playing the role of decomposers, using the comprehensive support of the environment, and forming the ecological value chain and

value network of higher education (Quan & Wang, 2017). Here we explore the basic characteristics from two aspects.

3.2.1 The intergrowth of the higher education system

Dai (2005) concludes the connotation of higher education ecosystem as the intergrowth relationship between internal and external ecology while harmonious but different. Among the 83 higher education institutions in Shanghai, all can be regarded as regional ones belonged to Shanghai local government or municipal education committee but 9 affiliated to the Ministry of Education or General Administration of Customs. Excluding private, tertiary and subordinate universities, the remaining 21 are public municipal undergraduate colleges. There are one comprehensive category, three sports and art categories, two medical departments, one public security category and two normal schools. The rest are regional specialized universities closely related to the industry. From the introduction of the characteristics of these universities, although they all aim at serving the country and Shanghai's social development and mostly adhere to career-oriented higher education, only three focus on integration with industry and nine pursue all-round development.

The intergrowth mainly includes two aspects: first, the intergrowth of homogeneity, which refers to the reciprocal cooperation between universities of the same type and at the same level, so as to avoid the duplication; second, heterogeneous intergrowth, the interaction and cooperation between different types and levels of universities. Each actor in the ecosystem has different attributes, decision-making principles, and purposes. These differences cause un-intended results at the ecosystem level, although each actor's decisions may be rational. The decision-making principle means the mechanism and priority of the decision may be very different among actors in ecosystem.

Ecology position theory emphasizes the evolution of diversity and using cooperation to avoid competition. University ecology position refers to the relatively favourable living and development space and competitive advantage formed by the interaction between universities and social environment and other higher education communities in the whole social environment (Gong et al, 2011). Individual ecology position of Shanghai regional universities reflect both this particular community and the social environment of living space occupied by it at present, also reflects its gradient formed by the various ecological factors in the environment of the position. The intergrowth relationship in the university ecosystem is conducive to the reduction of mutual functions will also have an important impact on the position of other universities in the system, and these complex influence relations will also react on the university ecosystem.

3.2.2 The overlap of higher education regulation

Higher education regulation niche overlap means that there exists a high degree of similarity or ray gap in the higher education regulation in the role played by the decomposer. The higher the degree of overlaps, the stronger it is subject to the same resources for higher education governance. Under the current situation in China's, the unbalanced distribution of higher education administrative power and resources in the

government and the universities and social organizations and the asymmetry of utilization of resources between the colleges and universities.

Starting from 1995, China launched a series of incentive projects to steer the development of universities towards expressed priorities (“211” in 1995, “985” in 1998 and “double first-rate” in 2017). These policies has formulated universities’ management strategy and generated fierce competition among universities regarding both student enrolment and research productivity. However, we found that the university in the aforementioned projects are always the same with few exceptions, which replicate the so-called “success to successful” system archetype. In this sense, what impact does these policies has on the development of universities, especially the universities that are not selected in the incentive project? How should these universities cope with the challenge to achieve university mission?

Under the higher education regulation circumstance, the government has an absolute advantage and monopolizes most of the jurisdiction and resources of education governance, so that the ecological niche of higher education governance of the government is relatively wide. The research of Liu and Qin (2013) on regional higher education governance showed that: the government monopolizes the higher education and monopolizes the regional higher education regulation system. In terms of the traditional government control system, the traces of administrative order plan control still exist, the internal and external administration of regional higher education governance is extensive, and the autonomy of colleges and universities cannot be truly implemented.

4. Mechanism of how the higher education ecosystem is enacted

In the higher education ecosystem, universities work as both the absorber and supplier of resources, surviving and developing in the interaction with various stakeholders. The effective transformation of these resources and the relationship between resources also further promote the development of the university ecosystem. The multi-actor network is not static, but dynamic. The network changes moment by moment. The purpose of this ecosystem approach is to clarify the dynamic change mechanism of the multi-actor network and find the specific patterns of evolution and extinction. If we can understand the mechanism, we will be able to design and manage the ecosystem strategically. (Tsujimoto et al, 2018)

Higher education ecosystem emphasizes not individual elements, but the organic combination of various elements. It is a dynamic system which integrates the main body, decomposer, environment, and value chain and value network. The elements are interrelated, interdependent, interacting, motivating, complementing and restricting each other, thus constituting the whole higher education ecosystem. The decision-making principle means the mechanism and priority of the decision may be very different among actors in ecosystem. To achieve the three missions of the university,

4.1 Strategy transformation and specialized development

By viewing complex processes as interdependent and intertwined systems rather than separate, single closed problems to be solved, it is possible to shed light on the way businesses can learn, grow, and sustain themselves. Regional specialized universities are special groups in the higher education ecosystem, while exploring specific development strategies is the fundamental way out to seek transformation.

Regional universities need to identify the ecology position of themselves and other universities. The strategic focus can be observed from the ecology position difference based on which to seek for their development directions. In general, regional universities need to build on themselves on a basis of regional characteristics to serve for the society progress and economic development, especially to exploit the discipline advantages to deliver qualified talents to the society and enhance the regional radiant force. Nowadays, the trend of specialized strategy formulation based on the ecology position evolution is increasingly obvious in regional universities, which proves the importance of specialized strategy.

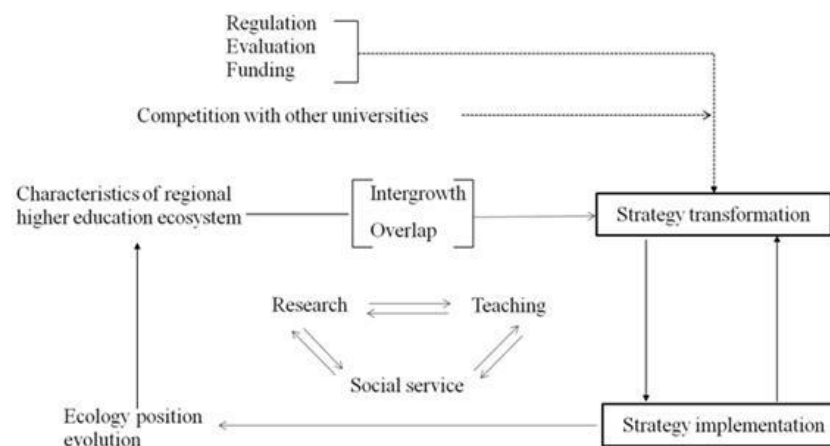

Figure 1. Strategic development of regional higher education ecosystem

In other words, the strategy transformation is embodied in the resources structure and space environment. As Figure 1 shows, under the regulation of decomposers in the ecosystem and the competition with other universities, regional universities need to consider the characteristics of the ecosystem to design the patch of strategy transformation. By taking variety of resources, regional universities form gradually the core strength, innovative capability and quality improvement, which are also the major forces to promote the development of both themselves and the external environment. Those changes are translating the ecosystem to reveal certain ecology characteristics to establish the ecology position evolution. In addition, to avoid vicious competition and keep the intergrowth relationship, regional universities need to possess specific resource

orientation and strategy space. It will serve as support and power source to felicitate the evolution of the ecology position while screening and reselecting variety of ecological factor.

4.2 Creation of strategic knowledge community

With the booming of knowledge economy, compared to the traditional twin missions of teaching and research, nowadays more and more emphasis has been put on the third mission, which involves transferring and commercializing knowledge generated within university and contributing to regional and national economic development. Results reveal that universities act as knowledge intermediaries, knowledge gatekeepers, knowledge providers, and knowledge evaluators (Ardito et al. 2018).

The scientific research of regional specialized universities pays attention to applied research, using scientific research achievements and invention patents to serve economic constructions, which is also in line with the development of university missions focusing not only on the traditional university's goals of teaching and research but also on the third mission of social service. The knowledge community it creates from the strategic perspective is the key that leads the economy to a successful level and improves the education ecosystem development. The strategic knowledge community serves as a medium for knowledge exchange among members. It is a communication space formed by individuals with common interests in order to acquire the knowledge they need. It has the basic characteristics of sociality, regionalism, knowledge and technology which are the key for the higher education ecosystem. To generate advanced knowledge needed by the society and provide high quality education serving the society, higher education should be tightly embedded in the society, which requires active partnership and interaction among different stakeholders, including profit and non-profit enterprises, public organizations and citizens, which forms the environment the ecosystem exists.

5 Policy evaluation and discussion

Any university, as an ecological body, should constantly strengthen the adaptability to the surrounding environment, which means both to make the environment conducive to its own survival by changing the environment and to adapt to environmental conditions by changing its own structural and functional mechanism. As the “success to successful” system archetype depicts that the universities in the incentive projects launched by the government are always the same with few exceptions, getting public funding for new resources is not easy for regional universities. Seeking corporate support with the strengths and experience in specialized disciplines to build strong partnerships with local corporations and other organizations is a way out.

At present, on one hand, university funding has been increasing a lot in scientific research with emerge of technological achievements, but the conversion rate is relatively low. On the other hand, the development mode of university is in the “lock-out” state of “ivory tower”, unable to establish collaborative innovation with other innovative bodies of strategic partnership and inhibit innovation cluster elements integration. The ecology

position a university occupied varies at different types and levels. It needs to relate to both internal and external ecosystem bodies to exchange resources and energies, especially in terms of knowledge transfer in the strategic knowledge community it creates. It is necessary to deregulate the mechanism of higher education ecosystem by giving colleges and universities full autonomy, under which the strategy transformation can be achieved.

The current evaluation system is not suitable for regional specialized universities, which forces them to shift to an overall development to meet the evaluation criteria instead of enhancing the specialized orientation. The strategic evaluation of universities is no longer just a summative performance evaluation, but a controlling process to realize the strategic goals of universities.

In conclusion, to support the effective integration of sustainable development in regional higher education ecosystem, it is recommended to explicit funding flows between institutions in higher education, design deregulatory mechanism to relate with other businesses beyond the ecosystem itself and adjust the higher education evaluation system to be more inclusive.

Abstract

The pharmaceutical industry is vital in taking care of the health of the people. Pharmaceutical industry that is a high-tech, and highly regulated industry has great influence over people's life and social economy. People have been pursuing a healthy life and devoting to solve the health problems by developing science and technology related to healthcare. The medical industry is improving year after year and many diseases are cured or healed. However, the development of human civilization has not only changed people's lifestyles but also damaged the environment of the world. According to this, people still need to face many health problems. As the result of this increase in medical needs pharmaceutical industry is more important to people's lives than before. The society of Taiwan is facing the problems of aging population. So the medical industry is more important to people's lives, health and safety. Nowadays, the medical market is fiercely competitive in Taiwan and people intent to pay attention to medical quality and service. Pharmaceutical companies manage to adopt newer strategies that reduce purchase costs and improve product quality to make healthcare efficient. Medical industry supply chain companies do their best to creating more corporate presence and profitability. But the most important things are the pharmaceutical companies have to considerate the people's medication safety. The choice of suppliers is one of the most important issues in the field of medical supply chain management. Choosing the right and effective pharmaceutical supplier can improve the competitiveness and greatly benefit the distributor. The main purpose of this study is to understand the role of distributors in the supply chain. The purpose is in order to achieve the good quality of pharmaceutical products, improve corporate reputation ,stable profitability and sustainable operation. This study uses literature review , expert interviews and Delphi Method to study the criteria for distributors to select their suppliers . The guidelines are expected to propose a systematic selection model for pharmaceutical suppliers. According to the study, the distributors can have more objective, fair and effective decision-making modes when conducting supplier selection. The study is expected to further improve Taiwan's pharmaceutical industry supply chain and contribute to people's health and well-being.

The research is further expected to optimize the soundness of Taiwan's pharmaceutical industry supply chain.

Keywords – Distributor, selection of supplier, Delphi Method

Paper type – Academic Research Paper / Practical Paper

1 Introduction

The medical industry is related to people's lives, health and safety. Taiwan is facing the trend of aging population. Medical needs are increasing year by year and medicinal safety is highly concerned. In the medical environment, the medical supply chain has become very important management task in the industry. The aging society is a global population trend. Almost all countries are having the problem of aging population in the world. The main expenditure of global health care has been growing due to the medical needs of the aging population.

For Asian countries, Japan is known as the fastest aging country in the world. However, Taiwan has actually stepped onto the track of an ageing population. The problem of aging population affects the entire population system, social structure, and the country's workforce. With the advent of an aging society that affect long-term care, medical treatment, drug supply, health care and other resources will continue to increase demands. This aging population problem not only affects the distribution of Taiwan's labor force but is also likely to cause serious economic problems because the huge expenditure of medical care in Taiwan. The government has responsibility to protect citizens and to solve concerned problem. The enterprises have also to make the greatest efforts to stabilize the medical industry and optimize the medical supply chains. Nowadays, the medical market is full of fierce competition. Both foreign pharmaceutical companies and domestic pharmaceutical companies are committed to improving their market competitiveness of enterprises. These companies not only devote to reducing the logistics costs but also intent to make more profits. While the corporate seek smooth functioning, it is utterly important to keep the safety of medicines and protect human health.

Medicine is a highly professional industry. The original pharmaceutical factory of Western Medicine tends to focus its resources on its specialized fields. They are willing to entrust other medicine pathway and logistics fields who are more professional distributors. Moreover, the pharmaceutical factories have to globalize to follow the rapidly changing environment that they tend to seek professional distributors as their partners in their respective countries in order to manage overseas markets with a more creative and flexible operating model. Medical suppliers and distributors have become partnerships that require teamwork. Therefore, The distributors when selecting suppliers and agents they need to understand the market demand for the drug and the financial indicators of the supplier. It is known from many documents that the selection of

suppliers is very important and requires many considerations in order to select excellent pharmaceutical supplier to help enterprises create economic benefits.

The pharmaceutical industry, particularity in life, health and safety of humans, need to comply with very strict regulations. The pharmaceutical supply chain (suppliers, logistics distributors, customers) is necessary to ensure the quality of the drug. Therefore, to optimize the management of the pharmaceutical supply chain is necessary and important. To stabilize the pharmaceutical market and guarantee the quality of medicines, which is great significance to people's life. As the result the competitiveness of distributors is directly related to the performance of suppliers. Therefore, it is necessary to regularly evaluate the suppliers of pharmaceutical companies to improve the performance of distributors. This purpose of study shows how to choose the pharmaceutical supplier and how to establish a supplier selection model. This helps to improve performance and profit of the enterprise by the way taking into account the consumer rights and drug safety to achieve sustainable business.

2 Literature reference

At this time of the fierce competition in the global market, the company hopes to create value for customers through the innovation of products and services to get outstanding performance in the competition. In Taiwan, the medical industry pharmaceutical factory has faced the impact of health care price adjustment in recent years, as well as the external environment such as the global aging phenomenon, the homogeneity of products are highly filled with the pharmaceutical market, all of that make the market price competition. In medical industry, all medical-related companies are struggling to increase their market share to achieve sales target. They are eager to seek business transformation or marketing innovations to stand out in fierce market. That is effectively linking upstream and downstream supply chains to enable suppliers and distributors to achieve win-win cooperation and alliances by sharing information and profits that has gradually become a new trend in the world today.

Enterprises hope to operate sustainably in this highly competitive market, so they not only devoted to build their core competencies but also optimize their supply chain. Effectively selecting superior suppliers and keep the long-term partnership are very important i key factors in maintaining corporate competitiveness. Michael Porter (1980) proposed supplier selection as an important consideration in the development of corporate competitiveness. The competition in the consumer market has increased and it has become an important selection condition. In successful supply chain relationship management, trust and commitment are important key factors that contribute to the long-term relationship. Dickson (1966) proposed 23 evaluation criteria for selecting suppliers, the first three of which are quality, delivery, and past performance. Weber et al. (1991) based on Dickson's (1966) 23 evaluation indicators, and the frequency of occurrence in the literature, and analysed the three important indicators of price, delivery, and quality. Desmumukh and Chaudhari (2011) studied related academic articles from 1992 to 2007 to summarize the following criteria:

Table 1 Deshmukh and Chaudhari (2011)

Dickson (1966)		Criteria	Deshmukh and Chaudhari (2011)			Weber et al. (1991)

Harris and Chernatony (2001) point out that reputation, innovation, human capital, structural capital, customer capital, organizational learning, standards, etc. Cheraghi et al. (2011) propose to focus on its future development capabilities.

3 Establishment of supplier performance evaluation model

3.1 Development of Supplier Selection Criteria

Dickson (1966) proposed the criteria for selecting suppliers, there are top three criteria quality, delivery and net price. Min (1994) proposed that in the international competition environment, in addition to finance, quality, service and performance, the selection criteria should include trade restrictions, risk indicators and cultural communication. Quality and delivery are still important for selecting suppliers in modern times, and financial status is a important indicators in supplier selection (Deshmukh and Chaudhari, 2011). The researches of Dickson and Weber.et.al. stated that communication system is an essential factor in the world today, so an effective and immediate communication system is an important evaluation index. Ellram (1990) pointed out that the choice of suppliers, in addition to the general quantitative criteria (such as cost, quality and delivery), some soft criteria should be considered, such as management compatibility and

consistent goals. Wilson (1994) believes that supplier selection should consider the four selection criteria are price, quality, delivery and service. Patton (1996) proposed seven evaluation criteria: price, quality, delivery, sales support, equipment and technology, order status, and financial status. Herbig and Milewicz (1994) propose that brand goodwill is a valuable commodity. Lambert (1997) proposes the quality, delivery and service of products in the evaluation of suppliers in the medical industry. Verma and Pullman (1998) have pointed out that in the choice of suppliers, the price and delivery time of products are the key factors affecting the choice of suppliers. Harris and Chernatony (2001) explored that reputation is a kind of capital as same as importance to innovation, human capital, structural capital, customer capital, organizational learning. Pi et al. (2004) select criteria for suppliers based on quality, price, delivery and service. According to environment changing, the select criteria of suppliers have some difference than before. Cheraghi et al. (2011) proposed that companies not only pay attention to the original quality and technology of suppliers, but also focus on their future development capabilities.

Min (1994) proposed the criteria for Financial Position is also important as quality and performance history, Attitude, Cultural and communication. D. Pi et al.(2004) article explored quality, delivery, net Price, attitude are important selection of supplier. J. Chernatony (2001) focused on reputation & Position in Industry is issue as important as other criteria. K. Chaudhuri (2002) proposed reputation and position in Industry in supplier selection.

3.2 Delphi method

1. Definition of Delphi method

The nature of Delphi method is Intuitive Forecasting. It is mainly used for insufficient data or uncertain situations or uncertain factors. Because it cannot be predicted by quantitative data. Delphi method needs to be based on the professional experience, intuition, and value judgment of the experts interviewed. The Delphi method is a forecasting process based on the results of several rounds of questionnaires sent to a group of experts.. The experts are allowed to adjust their answers in subsequent rounds, based on how they interpret the "group response" that has been provided to them. Since multiple rounds of questions are asked and the panel is told what the group thinks as a whole, the Delphi method seeks to reach the correct response through consensus.

2. Advantages and Disadvantages of the Delphi Method

The Delphi method seeks to aggregate opinions from experts, and it can be done without having to bring everyone together for a meeting. Since the responses of the participants are anonymous, individual panellist don't have to worry about repercussions for their opinions. Consensus can be reached over time as opinions are swayed, making the method very effective.

3. Key Takeaways

The Delphi method is a process used to arrive at a group opinion or decision by surveying a panel of experts. Experts respond to several rounds of questionnaires, and the responses are aggregated after each round. The experts can adjust their answer each

round, based on how they interpret the "group response" provided to them. The ultimate result is meant to be a true consensus of what the group thinks.

4 Analysis and Findings

1. *The Delphi Method questionnaire survey process.*

The questionnaire of Delphi Method was conducted and interviewed in person by experts. The study were asked experts from a drug distributor to fill out the two-round questionnaire to find out the model of the measured facet and standard indicators.

The study uses the Delphi Method to build the main and sub-criteria for the drug supplier evaluation and selection model to determine for drug distributors.

Build a model of evaluation and selection: Use the Delphi method to perform the following four steps

Step 1: Define the criteria for supplier evaluation and selection.

Step 2: Form an expert panel.

Step 3: Conduct a questionnaire survey among the experts.

Step 4: Set the standards for consensus in the expert panel.

Step 5: Build a supplier evaluation and selection model of drug distributor

2. *Build a model of evaluation and selection*

Step 1: Define the criteria for supplier evaluation and selection. This study selects 5 criteria and 26 sub-criteria from questionnaire of experts of drug distributor (as described in Table 2)

Table 2. Build selection model of main and sub-criteria.

Criteria	Sub-criteria
Product quality (D1)	C1 Quality C2 Technical Capability C3 Production Facility & Capacity C4 Operating Controls C5 Repair service
Company management (D2)	C1 Training Aids C2 Packaging Ability C3 Geographical Location C4 Procedural Compliance
Reputation and Impression (D3)	C1 Reputation & Position in Industry C2 Management & Organization C3 Labor Relations Record C4 Impression C5 Cultural and communication
Sales and Market (D4)	C1 Delivery C2 Attitude C3 Performance History C4 Communication System C5 Warranties & Claims Policies C6 Reciprocal Arrangement
Finance and Profitability (D5)	C1 Net Price C2 Financial Position C3 Amount of Past Business C4 Relationship with potential suppliers C5 Future development capabilities C6 Desire for Business

Step 2: Form an expert panel.

The experts who serve with the senior executives of various departments of the drug distributor have been working the drug distributor above 10 years. The pharmaceutical logistics company has been in Taiwan for 30 years since its establishment, and has become in the leading company for many years.

Step 3: Conduct two-round questionnaire survey among the experts.

First-round questionnaire is among the 9 experts to define and determine 5 main criteria, and second-round questionnaire is amount 14 experts to select 4 main criteria and related sub-criteria. For the two-round survey that 23 questionnaires were distributed and 23 were returned, creating a return rate of 100%.

Step 4: Set the standards for consensus in the expert panel.

Through second round of the Delphi Method questionnaires were collected. The process were collected, analysed, and screened, as the result that consolidated were four main criteria (the average percentage of consent was over 70%), and a total of 10 criteria (including a percentage of consent of more than 60%).

Table 3 The result of main criteria and sub-criteria.

Criteria	Agreed number	Agreed %	No.	Criteria	Agreed number	Agreed %	Result
Product quality (D1)	14	100%	C1	Quality	14	100%	100%
			C2	Technical Capability	11	79%	79%
			C3	Production Facility & Capacity	10	71%	71%
			C4	Operating Controls	5	36%	
			C5	Repair service	3	21%	
Company management (D2)	5	36%	C1	Training Aids	4	29%	
			C2	Packaging Ability	0	0%	
			C4	Geographical Location	0	0%	
			C5	Procedural Compliance	6	43%	
Reputation and Impression (D3)	14	100%	C1	Reputation & Position in Industry	13	93%	93%
			C2	Management & Organization	6	43%	
			C3	Labor Relations Record	1	7%	
			C4	Impression	12	86%	86%
			C5	Cultural and communication	3	21%	
Sales and Market (D4)	10	71%	C1	Delivery	10	71%	71%
			C2	Attitude	12	86%	86%
			C3	Performance History	4	29%	

			C6	Communication System	1	7%	
			C7	Warranties & Claims Policies	9	63%	63%
			C9	Reciprocal Arrangement	4	29%	
Finance and Profitability (D5)	13	93%	C1	Net Price	6	43%	
			C2	Financial Position	9	64%	64%
			C3	Amount of Past Business	8	57%	
			C4	Relationship with potential suppliers	4	29%	
			C5	Future development capabilities	10	71%	71%
			C6	Desire for Business	10	71%	

Step 5: Build a supplier evaluation and selection model of drug distributor.

The results will be included as a future study factor in the comparative weighting and mutual importance analysis of AHP (Saaty, 1980, Analytic Hierarchy Process, AHP) research analyses.

Table 4: The selection model of main criteria and sub-criteria.

Criteria	Agreed number	Agreed %	No.	Criteria	Agreed number	Agreed %	Result
Product quality (D1)	14	100%	C1	Quality	14	100%	100%
			C2	Technical Capability	11	79%	79%
			C3	Production Facility & Capacity	10	71%	71%
Reputation and Impression (D3)	14	100%	C1	Reputation & Position in Industry	13	93%	93%
			C4	Impression	12	86%	86%
Sales and Market (D4)	10	71%	C1	Delivery	10	71%	71%
			C2	Attitude	12	86%	86%
			C7	Warranties & Claims Policies	9	63%	63%
Finance and Profitability (D5)	13	93%	C2	Financial Position	9	64%	64%
			C5	Future development capabilities	10	71%	71%

5 Conclusions

Supplier selection have drawn the interest and been thought importance of researchers since 1960s. Dickson (1966) defined 23 criteria of supplier selection. Weber et al. (1991) studied 74 articles from 1966 to 1991 related supplier selection criteria. Dickson's 23 criteria have the similar analogical distributions in Weber's study.

This study consolidated the criteria and sub-criteria of supplier selection from several related articles from 1966 to 2011. Net price, quality and delivery were the most

important criteria cited, but this study concluded that quality and delivery still are the important criteria apart from net price in selection of drug supplier.

From this research, it can be concluded important criteria in the selection of pharmaceutical suppliers, which are product quality, reputation and impression, sales and market, and finance and profitability. The preliminary selection sub-criteria derived from the Delphi Method are quality, technical capability, production facility & capacity, reputation & position in industry, impression, delivery, attitude, warranties & claims policies, financial position, future development capabilities.

For future research, supplier selection criteria and methods, will continue to be the important aspects. For supplier selection criteria seems to be an important area. Some new criteria to reflect the whole supplier chain performance should be developed. This selection model is determined by experts of drug distributor. This study presents a new supplier evaluation and selection model for the pharmaceutical industry. The model is mentioned in this study have shortcomings in dealing with the selection problem. New model to develop of human decision making, such as computer programming should be also significant for supplier selection in modern era.

Abstract

Future uncertainty caused by the uniqueness of the project, all project team member all require having enough problem analysis and solving skills, The traditional project management model challenges the need for innovation and agility for project management control under the established process. There will be an accelerated shift from Waterfall to Agile Project Management in larger organizations as they realize the only way to deliver on benefits in the increasingly dynamic and complex environment is to learn and adapt quickly.

The research is to explore the relationship between the existing cognition and the development performance of new products project by introduce the agile project management in the Netcom industry, and the key factors in the introduction. For the team to accurately capture the real needs of customers and to reduce the relationship between the need for unnecessary resources and time in the project, the degree of agility of the organization and the degree of readiness for development, it is necessary to further clarification. The research utilize modified Delphi Survey to understand the mutual connections and feedback loops among the attribution of the organizational culture, the nourishing professionalism, member learning attitude, funding learning incentive factors. Then evaluate via Analytic Network Process, ANP to assess the interdependencies and feed-back issues that may exist between the guidelines, and calculations to understand the project management criteria and weights for improving agile success and for enterprise ecosystems growth of knowledge management.

From Gigabyte senior management supports, (expert samples) 15 copies of Questionnaire, to allow customer contact-employees to provide their views of organization agilization and project performance. Results of this study found, The contribution of this paper has two aspects. The theoretical: the paper can answer the research problem. The practical: this paper can offer insights into organization agilization as to how to enhance the internal project development of the organization. Technical performance and functional performance are also positively correlated. This

knowledge-based strategic, managerial and organisational solutions should be better respond to today's business and managerial challenges and how they can positively impact on growth and well-being of private and public organisations and so forth more widely, of the entire society.

Based on agile principles of acceptance of the four software development project as defined under the Scrum principles of People, Organizational, Process and Technical factor dimensions to explore their awareness of project successful, and related environmental background information analysis and discussed the relationship between Scrum and the project successful cognitive existence in Taiwan.

The research utilize modified Delphi Survey to understand the mutual connections and feedback loops among the attribution of the organizational culture, the nourishing professionalism, member learning attitude, funding learning incentive factors. Then evaluate via Analytic Network Process, ANP to assess the interdependencies and feedback issues that may exist between the guidelines, and calculations to understand the project management criteria and weights for improving agile success.

It is expected that 15 expert questionnaires will be issued for pre-questionnaire surveys and formal surveys. This research institute explores the key factors affecting the success of the Netcom industry's introduction of agile project management. Provide reference for the development direction and strategy of Netcom industry project management services.

Keywords –agile management、stakeholder、fitness、project performance.

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Facing the era of global competition, how can companies accelerate innovation, timely manage operation information, Expected to combine project management with high cost performance, punctual and flexible integration mechanism, through process design, consulting services, and system tools, assist business teams across time space constraints, comprehensive coherence and integration in operational processes and information, Helping global customers create competitive advantage in a changing market environment is an important part of today's companies to improve their business performance.

The products and services provided by the network communication industry require the stability of the products. The uninterrupted feature is a service that is highly customer-aware. Facing the high sensitivity of customers to product quality requirements. Project crews often have to be in communication and coordination between the R&D team and the customer. During the time for developing new products, project-driven quality and decision-making. It is related to whether the project manager can consider the measurement of his organizational fit in advance. In turn, project performance can be optimized. Thus, in an increasingly competitive business environment. More and more companies pay attention to the efficiency and performance of project development, Therefore, organizations have adopted an organizational optimization strategy. To

achieve positive affect on profits, improve customer satisfaction, and loyalty. (Homburg, Hoyer and Fassnacht, 2002)。

2 Introduction of Agile project management

Enterprise Project Management, EPM takes agile tool is no longer just a theory, but practice. Because information systems have a critical importance in their operations, At the same time, adopting agile management tools can help companies adapt to the changing environment., So many companies are beginning to apply agile methods to areas outside the information department (林裕丞 2018)。

Agile development uses a flexible, timely and responsive development process, while bringing customers into the team, and aggressively initiate work interaction relationship with research development , vendor. So that adaptation of project issues, relative flexibility and flexibility to update development processes in response to rapid market changes、To adopt an agile development model under common goals or concerns, Create contribution values in addition to the original development methods to enhance the performance of new product development.

Based on their combined experience of developing software and helping others do that, the seventeen signatories to the manifesto proclaimed that they value:

- Individuals and Interactions over processes and tools
- Working Software over comprehensive documentation
- Customer Collaboration over contract negotiation
- Responding to Change over following a plan

However, when more and more other countries holding agile project management, Taiwan is rather slow in this field, only software team, this is due to adopt agile practices and values improves the agility originated from software professionals, teams and organizations, almost all books or courses used massive software filed terminologies.

A common characteristic in agile software development is the daily stand-up (also known as the daily scrum). In a brief session, team members report to each other what they did the previous day toward their team's iteration goal, what they intend to do today toward the goal, and any roadblocks or impediments they can see to the goal. Let the outsiders look at it. Even, according to research, most Asian banks do not fully implement agile methods, and managers still use traditional management methods.

Enterprise intend to transform via continue to utilize promoting agile project management mode, with short-term substitution, continuous experiments, and learning, so that organization and process can be continuously improving, while these paths allows the transformation are effective and low risk, organizational metabolism employs' proactiveness, continuing product and service innovation can be achieved. 。 Even though agile can help enterprise an effective and low risk transformation, but most difficulties are leaders' need to change their concept; for example, accept failure and learn from it, accept effectiveness rather the efficiency, allows more space for employee a larger and free will (林裕丞 2018)。

When leaders willing to accept these thinking, work along with agile tool and framework, enterprise can moderate quality, make organization more

healthy, Have an independent and efficient team and provide more valuable products and services.

This research is intend to realize the recognition of agile management among netcom industry, to discuss what are the major factors would let an enterprise can successfully to implement agile methodology, and if enterprises will utilize agile management tools and frequent discussion with customers and vendors, and accurately aim at markets' need to avoid unnecessary resources and time consuming.

3 The dilemma of the introduction of innovative models

Reference to the past research in the technology industry to influence the management of innovative models, Generally, it can be roughly divided into two facets.: 「Personal facets」 and 「Organizational facets」. From 「Personal facets」's point of view, the most frequently used manners are Technology Acceptance Model, which is TAM, Judging the adoption of technology by the personal perception and attitude of policy makers, Harrison, Mykytyn, Riemenschneider (1997) found, Information technology factors for small businesses will be interfered by User's attitude, subjective consciousness and control cognition. Venkatesh and Davis (2000) proposed and proved that social affect procedures and recognition tool procedure significantly affect users' awareness of usefulness and intension to use.

From 「Organization facets」's point of view, Rubenstein-Montano et al.(2001) thinking a enterprise take steps for innovation should include, group Culture, organizational learning. Participative attitude、strategy and knowledge, especially group culture will affect further over the knowledge sharing, date storage, transmission and utilization process. Holsapple and Joshi(2000) thinking to promote success of innovation should include (1) Enterprise culture (2) Leadership (3) Science; (4) Organization adjustment (5) Knowledge management (6) Resource evaluation (7) Knowledge activities (8) Resources management (9) Motivation of occupation (10) Others. On the other hand, if the technology and organizational characteristics are used to explore the adoption of technological innovation by enterprises, Tornatzky, Fleischer and Chakrabarti (1990) think that Organizational background fact、science and external environment factors are the three major perspective affect information system to utilize this methodology.

Group Culture

If structures allow the effective use of capabilities, culture is what enables the organization to acquire the capabilities related to people. With the right kind of pro-innovation culture, the organization is much more likely to be able to recruit and keep the right people in the organization. An appropriate pro-innovation culture encourages the right kind of behavior and discourages the wrong kind. As the effects quickly cumulate, culture can make a tremendous difference for the innovativeness of an organization. Here are some of the more commonly accepted traits for an innovative culture: Emphasizes the need to always think of ways to get better, Values speed, learning and experiments, Considers failure as just a normal part of the process for creating anything new, Provides enough freedom and responsibility and is led primarily with vision and culture instead of a chain-of-command approach

Organizational Learning

On the other end of the spectrum from the phase-gate, there are people who believe that the best innovations come from simply equipping smart people with enough time and the right resources to make their ideas happen.

Participative Attitude

Empower people but hold them accountable for their work and their decisions

Have talented people on all levels of the organization

Have tools and structures in place for making sure things happen and the right things move forward Have a clear vision and a strategy that everyone understands

Are focused on implementing ideas as opposed to just talking about them

Funding Decision

In the field of innovation management, in many cases, look at risk through a broader lens, especially when it comes to innovation. The ability to tolerate risk determines both the potential downside and the potential upside of your investment.

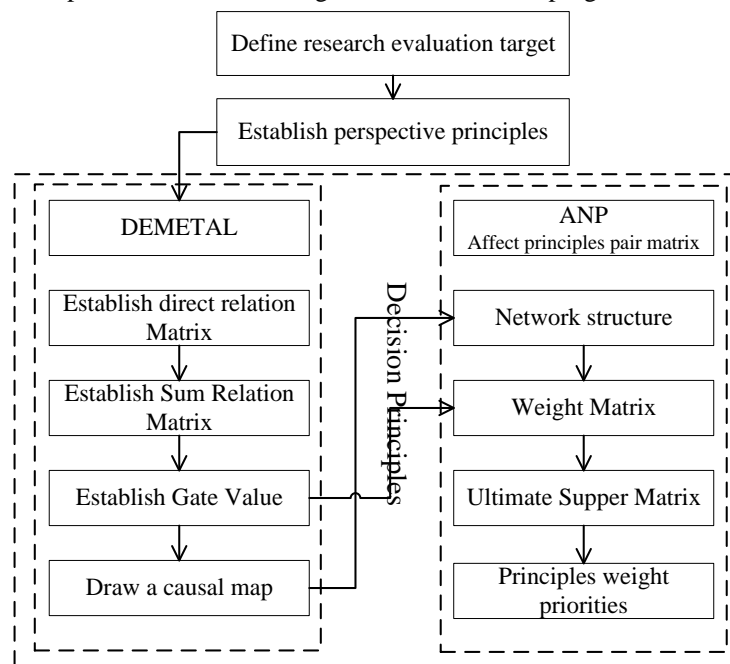

As working on innovation always involves a lot of uncertainty, look at risk as more than just something to minimize.

Incentive Program

To promote or encourage such actions or behavior by a specific group of people during a defined period of time. Incentive programs are particularly used in this

management process to motivate employees and proactively to attract and retain customers.

As above, this study based on references, would like to organize into personal perspective and organizational perspective to explore the factors of enterprise introduction of agile project management, including group Culture, organizational learning. Participative attitude、funding decision , incentive program

4 Conclusions

This study was selected to have been trained in formal project management and familiar with SCRUM agile methodology15 experts, in the netcom industry field fir initial review to conduct inquiry list content modification.。

The main research object of this research is Netcom Technology, including server , network card, STB etc. and he who needs to aware of product development process and agile management project, including manager of research and development , project manager or product manager, By the qualitative principle of Modified Delphi Method, MDM to discuss group Culture, organizational learning. Participative attitude、funding decision , incentive program inter-relationship, then Principle of quantification of Analytic Network Process, ANP to evaluate the To assess the interdependencies and feedback issues that may exist between the guidelines to calculate and weight on implementation of agile project management rules.

Abstract

With the rapid development of smart phones, innovative mobile services, constant introduction of new Apps and the facilitation of mobile networks, mobile-based payment models have gradually begun to be applied to our daily life. To make it easier for citizens to pay tax, the government also continues to promote electronic services. The available applications are getting broader, leading the payment of tax to an era of cashless transactions. People only need mobile devices and network as well as the added channels so that tax payment can improve the timeliness, convenience and information accuracy for taxpayers.

When the government introduces new services, taxpayers' intentions and attitudes toward their use are topics that researchers are concerned about and want to explore. So what do taxpayers know about "paying taxes"? Is there any willingness to use the new policies promoted by the government? And The incentives, willingness to use and key factors that make taxpayers use are also concerns and desires of researchers. Therefore, this is the main research motivation of this study.

This study attempts to analyze factors affecting the use intention of tax payment by mobile wallet for taxpayers encountering the trends of financial technology. What are the significance of these factors? What can the Ministry of Finance do to facilitate the current taxpayers switch from their old habits with tax payment to paying with mobile payment?

We summarize five main dimensions based on the past references: Mobile devices, Ease of use, Transaction security, Technology acceptance and Special offers. This research is intend to explore the key factors of taxpayers' willingness to mobile tax payment base on technology acceptance through the decision-making trial and evaluation laboratory (DEMATEL) is then used to clarify the effect and relationship between each variable. each factors or parts may exert on and obtain from other higher or lower level factors. One of excellence of this technique rather than others decision making method in applying feedback application. This study will provide recommendations based on the

analysis results, hoping that they can serve as a reference for service providers in the business of tax payment by mobile wallet and further enhance the use intention. It is expected that questionnaires will be issued for pre-questionnaire surveys and formal surveys. This research institute explores the key factors affecting the success to explore the key factors of taxpayers' willingness to mobile tax payment

Keywords – tax payment by mobile wallet, mobile payment, technology acceptance, use intention.

Paper type – Academic Research Paper / Practical Paper

1 Introduction

Depending on the growing of the smart phone technology, the latest mobile service and APPs get more and more convenient, the mobile payment affects not only the commercial action but also our daily life. McKitterick and Dowling (2003) pointed out that mobile payment is a consumer who owns a mobile device and is willing to use it to pay for a service or product. Karnouskous (2004) pointed out that in terms of consumption habits, the new type of mobile payment needs to be related to the consumer's past payment behavior, and the mobile payment systems developed by different manufacturers need to be interactive and compatible. Bai et al. (2005) believe that mobile devices can be used anytime, anywhere, regardless of space and time, because of the combination of mobile devices and the Internet. If government wants to let mobile technology more and more upgrowing and develop the relative business, promoting the mobile payment is necessary. Ministry of Finance indicates the mobile payment will let people more convenient, make the commercial business more effective, reduce the cost of cash flow handling. Base on all the reasons that the mobile payment becomes the trend of E-commerce and digital economy. To utilize the mobile payment on paying tax will realize no-cash trade off and easy paying tax on time. All of the mobile payment benefits will make the future financial technology comes true.

No matter the technology is getting more and more modern, safety of trade process is always the most important thing that buyers care about. The first untrusty of mobile payment is for taxpayers is people always think that the Hackers will try to hack the payment platform to get personal information. If Ministry of Finance promote most of people to pay the tax by mobile payment, the most important thing is how to build a safety payment platform that to prevent the hackers and other risks. Davis, Bagozzi, and Warshaw (1989) point out that potential users subjectively believe that the operation of a particular information system technology is easy to use. The easier it is to use the system, the more confidence the user will have in self-expression and the willingness to accept the system. Lee, Warkentin, and Choi (2004) argue that an individual's level of anxiety about technology affects the user's willingness to use action payments, which refers to the new technology that users generate when considering or using innovative technologies. The degree of fear. Dertouzos (2001) pointed out that the ease of use of the system is user-

oriented, and the design of the system interface is friendly and easy to operate, allowing users to work easily and happily. HSUEH-YU TSAI (2016) The future development of global e-commerce, the characteristics of the network is that consumers' online behavior is fully recorded, and various Internet giants such as Amazon, eBay, Google, and Facebook all use big data technology. Analyze all types of consumption data, explore users' various hobbies, and then use mobile devices as a media platform. With its mobile features, they can meet the needs of consumers at any time, and use smart devices or applications to serve customers. Create a brand new shopping and service experience, let customers have the feeling of customer service staff to visit the scene, and more instantly cut the real needs of consumers, and expand the future market of e-commerce. As consumers become more accustomed to mobile commerce, the number of payments and completions directly on mobile phones will naturally increase, and they will immediately enjoy the benefits and satisfaction of shopping and the entire economic market.

2 Mobile Tax Payment

In this section, to purpose how to make the tax mobile payment more popular in four parts, the mobile device, the convenience, the safety, the acceptance of tax mobile payment.

2.1 Mobile device

Guo, Ke-Yu(2012)The most using device on mobile payment is all kind of mobile device, like smart phone, pads. Buyers can downloads serval mobile payment APPs to decide which bank account to pay tax.

2.2 Convenience

This author defines that convenience of payment is buyers using the less time and spirit to get what buyer's want. Berry and Grewal (2002) This author defines that convenience of payment is the process of buying a product or service. This reference separates the convenience of service in serval type: decision convenience, access convenience, transaction convenience, benefit convenience, post benefit convenience. Chao-Jung Chang (2014) To raise buyers using rate of the mobile payment, the convenience is the most consideration in all kinds of payment tools.

Tax mobile payment is one of the mobile payments, the taxpayers can make easy tax payment, but also can share all the benefit of mobile payment. Ying-Chiang Cho (2017) This reference indicates that mobile payments can be the replacement of cash. Besides the Electronic ticket, credit card, financial apps, the mobile payment also can add more service to make it more perfect, like taxi payment, express delivery payment, Taobao, and most of small cash payment. All of these can make the mobile payment to be more wide uses and make daily life more depends on this kind of behavior.

2.3 Safety

Safety always the most important thing that buyers care about. When a successful mobile payment is built, it needs provide your personal information through internet. Li-chung Lin(2007) That the privacy and safety are the most serious consideration that buyers care. Tsao, Hsun (2012) Because the crime of cheating through internet, and share personal information without your permit. These reasons let mobile payment untrusted by buyers. Yuan-Yu Shih(2014) Now most of us have smart phone and internet service. The mobile payment becomes a part of life. The safety is the most serious consideration for buyers. Fu, Hsin-Pin(2009) indicates that when buyers use the mobile payment to pay something, except the normal access, some of emergency protect process are needed. If the buyer is paying on threatening, the buyer can enter a special code to operate his account in security mode to protect his own. This process also can contract to the bank and police to prevent extra loss.

2.4 Acceptance

Mobile payment is a new tool to handle our payment. The personal cognition and acceptance are also important elements to increase the using rate of mobile payment. Lee et al.(2004) Buyers' anxiety of mobile payment will influence their willingness to use this kind of tools. Anxiety of mobile payment is when the you use modern technology, the unbelieve level on this kind of technology. Chao-Jung Chang(2014). indicates someone who wants to use the modern technology base on how well-known about this technology.

In this section, to analysis the reference and collect the data from buyers that new technology acceptance is the main reason influence the using rate of mobile payment.

3 Conclusions

In this reference, we use strategy changing test and DEMATEL to discuss the key point the willingness of mobile payment for taxpayers. Base on the four parts are mentioned, analysis how the variables influence the buyers and decide the treatment. I

Abstract

Our government has put great efforts in promoting e-tax filing so that citizens will not be restricted by time and space constraints, thereby enjoying a "More network, less walk," barrier-free tax service environment. E-filing of taxes can correctly and quickly read report information and avoid human errors caused by the manual re-registration of the tax authorities, which greatly reduce the cost of data entry and shorten processing time. E-file is essentially an integration of an online service combined with filing taxes. Due to the strain in the operation of an online system along with the complexity of utilizing an online interface, in order to allow tax payers to overcome the difficulty in filing his/her individual income tax once a year, which affects his/her willingness to file tax online, this study uses an innovation resistance theory to explore the key factors contributing to the change in tax payment habits of taxpayers when filing their income tax.

Keywords – innovation resistance, Individual income tax, tax payment habits, manual declaration, internet declaration

1 The definition of innovation resistance

According to Rogers's (1983) theory of diffusion of innovation, innovation is delineated as when a new concept, behavior, or quality of a new thing is different from the current pattern and nature. Since new products rolled out by most companies have a high failure rate, only a few of them will be accepted by consumers. Therefore, many studies focus on the reason why innovation is successful and scrutinize the positive aspects. Innovation resistance is an act of boycott from consumers when faced with changes brought by innovations (Ram, 1987.)

S. Ram (1987) proposed the innovation resistance model, claiming that innovation has its own lifecycle, during which “resistance” and “adoption” can coexist. That means there is a portion of people who accept that innovation while another portion of people exhibit actions of rejection or resistance. Therefore, conducting research on “the people who show resistance” is, in fact, a reverse approach toward the dissemination of innovation. Innovative products, services, or ideas can only be introduced to the social situation once the factors of resistance found in the people who show resistance are understood. According to the research conducted by Ram and Sheth (1989), there are two pivotal resistance barriers: Functional barrier and psychological barrier. They proposed corresponding strategies and methods to grapple with these barriers. Additionally, under the perspective of consumers’ refusal to adapt to innovation, Ram and Sheth (1987) investigated factors of consumers’ refusal to use from both functional and psychological aspects. There are three parts to “the functional aspect”: Usage barrier, value barrier, and risk barrier, and two parts to “the psychological aspect”: Image barrier and tradition barrier. Functional barrier

1. Usage barrier: Sheth (1981) proposed that when consumers are satisfied with their current life pattern, they might show resistance to innovation because it changes their habits. The more they are familiar with their current learning and behavioral habits, the greater their intensity of resistance toward the thought of changing the status quo will be, which in turn takes a long time for consumers to get accustomed to innovation.
2. Value barrier: Consumers will refuse to change unless they find out that the values and benefits of the innovative product are more than that of the currently used one after they have evaluated the values of both the innovative product and the currently used one.
3. Risk barrier: When faced with innovative technologies, consumers tend to refuse them due to the insufficiency in the understanding of them, which is result of his/her inability to evaluate the risks and uncertainties generated after using them.

(i). Psychological barrier

1. Image barrier: Psychological barrier occurs when consumers have a bad impression on the origin of the innovation.
2. Tradition barrier: The barrier occurs when a conflict exists between the innovation and the consumer’s traditional culture. The greater the conflict is, the stronger the resistance is.

According to the research conducted by Ram and Sheth (1989), there is a difference in degree in consumers’ resistance toward innovation. The pair proposed the following three forms of innovation resistance.

1. Inertia in consumers: Consumers’ refusal to adopt the innovation is due to their propensity for inertia and unwillingness to change the status quo.
2. Active resistance: Consumers’ postponement to adopt the innovation might be based on the risks they think the innovation
3. Very active resistance: Consumers might insist that the innovation is unsuitable

for them and disapprove of it.

Szmigin and Foxall (1998) suggested that there are three forms of innovation resistance.

1. Rejection: When consumers decide to reject the innovation after evaluating information.
2. Postponement: When consumers need more time and information to evaluate if the innovation is worthy of adoption. For example, the major reason why students don't use credit cards is out of the concern on income. However, after they graduate and have a steady and full-time job, most of them will choose to use this financial instrument.
3. Opposition: When consumers oppose the innovation out of their own habit or situational factors. The discrepancy between the individual recognition and the nature of the innovative product also accounts significantly for this.

Sheth (1981) looked at innovation resistance from a different angle and came up with four categories for innovation resistance based on the aspect of perceived risk and the aspect of behavioral inertia (as shown in Fig. 2-1.) We will give each category a brief introduction.

1. Dual resistance innovations: When consumers encounter innovations that are high-risk and significantly different from their previous habits at the same time, such as changes in social activities like the education system, salaries, and welfares (Sheth and Wright, 1974.)
2. Habit resistance innovations: When consumers encounter innovations that are low-risk but still need to alter their current habits to adapt to it. Continuous innovations wanting to replace current products or services but fail can be categorized under habit resistance innovations.
3. Risk resistance innovations: When consumers do not have to change their current behaviors and habits and might have the chance to form new habits. Consumers will experience very high perceived risks when faced with such innovations. Such resistance stems mainly from non-continuous innovations, like innovations derived from a breakthrough in development. For example, birth control pills, video phone calls, and others. These non-continuous innovations might persuade consumers to form new habits but will also expose them to higher perceived risks.
4. No resistance innovations: When the innovation does not require consumers to change their current habits and poses very low perceived risks.

2 Research related to the innovation resistance theory

The innovation resistance theory reveals that perceived risks will affect the extent of risk intake of trust and a relationship based on trust. Therefore, to avoid risks, organizations will opt for a more secure or safer mechanism; that is to say, the extent of perceived risks and trust of an innovative technology will affect the decision whether to adopt it. An enterprise's perception of perceived risks is best embodied in its security

awareness of trade risks. Ratnasingham (1999) thought that security and risks are not only problems caused by technologies, but are also responsibilities that an organization should tackle with management and coordination. When an enterprise is involved in commercial trading, it should properly control all risks it might face.

In the study of information management, users' resistance is defined as a reverse response, where users refuse to change (Kim and Kankanhalli, 2009). Piderit (2000) thought that users' refusal is a multi-layered personality comprised of behaviors, emotions, and cognition. Users will refuse to change if they think that the change is going to create loss, stress, or risks.

Gatignon and Robertson (1989) thought that one of the factors that causes refusal to innovation is the postponement from one side, and the refuser has to acquire more information or time to understand the new information technology. Therefore, to successfully make innovation accepted by people, one must exclude factors of refusal in consumers (Ram and Sheth, 1989).

According to the definition of innovation resistance made by Ram and Sheth (1989), there are two forms resistance barriers: Functional barrier and psychological barrier.

I. Functional barrier

(i). The aspect of computer and Information Literacy

“Information Literacy” The term “Information Literacy” refers to the cultivation of citizens' understanding of the value of information. McClure (1994) regarded Information Literacy as a concept as well as the ability to solve problems, further incorporating Computer Literacy and Internet Literacy into it.

“Computer Literacy” Abruscato (1986) pointed out that “Computer Literacy” is people's computer knowledge and skills that are used to organize and process information. Mangan's (1992) interpretation of Computer Literacy is people's proficiency in common and general computer skills and the ease they feel when using computers. According to Hunter (1983), Computer Literacy is an individual's computer knowledge and skills needed to adapt to life in this society of technology that is highly dependent on information and the solution of complex problems. Watt (1980) pointed out that Computer Literacy is an aggregate of knowledge, skills, and values, all of which can make our lives better and more convenient in this society of computer and information.

“Internet Literacy” “Internet Literacy” is the attitude to accept internet and fuse it with our daily life as well as the ability to use it to improve our lives. McClure (1994) pointed out that Internet Literacy is the fundamental ability to use the internet.

“Computer Anxiety” “Computer Anxiety,” according to Donald and Richard (1993), is a bad feeling experienced when using or communicating to a computer. The feeling will make a person afraid of using computers. It is the comprehensive response mixed with emotions such as fright, anxiety, and anticipation people expect to experience before using a computer or that actually occur during the use of a computer.

(ii). Tax-filing knowledge

The aspect of “tax system”: This includes the filing of the annual income tax return form, in which a taxpayer should calculate the annual income tax return and file it to the taxation institute before the declaration period ends. The tax system has the following characteristics: (1) Short tax season and too many taxpayers, (2) confusing and various taxing items, and (3) multiple choices of tax calculation methods.

The aspect of “tax knowledge”: This includes countless tax regulations that are highly professional, confusing, and esoteric. Taxpayers will have to compile evidence of their incomes and expenditures to continue the online declaration system.

The aspect of “system operation”: Taxpayers are required to install declaration software to finish the task online. The online declaration system imposes many limitations on data upload, and there are also internet security concerns.

II. Psychological barrier

(i). The aspect of perceived risk

Proposed by Bauer (1960), the rudimentary concept of perceived risk is derived from the development of psychology. It views consumer behavior as an instance of risk taking and can be used to explain plenty of consumers’ “switch” behaviors.

(ii). The aspect of behavioral inertia

According to Yu’s (1980) theory of habitual domains, people’s decision making is confined to their inherited habits. Once these ideas are stabilized, their response to people, matters, problems, and information, including their acknowledgment, understanding, judgment, and approach, will become habitual, turning into what we call programmed or formulated behaviors. Oliver (1999) stated that inertia reflects some behaviors that follow. Once behavioral inertia is generated, people will repeat the action habitually. Therefore, when consumers have accumulated experience of consuming a certain product or service, it will then form learning for that consumption or use of service (Assael, 1992.) In the meanwhile, consumers will gradually become familiar with information related to the product or service (Alba and Hutchinson, 1987.)

In order to gain a deeper understanding of the key factors contributing to taxpayers’ unwillingness in adopting online declaration and choosing to stay with manual declaration, this study first compiles related literature of the past on the unwillingness in using online declaration for tax filing and then builds/confirms a comprehensive research framework to understand why people are not willing to file online. In addition, the decision-making trial and evaluation laboratory (DEMATEL) method is used to understand the complex causal structure and the effects between each variable and use matrix operations to obtain the causal relationship and the strength of effect between the elements. Finally, the method of analytic network process is adopted to assign weight values of these factors to obtain the order of significance for these factors contributing to the unwillingness to file tax online. We hope that this study can understand the factors affecting the changes in tax payment habits of taxpayers and rank the factors by their significance. The results of the study can serve as a reference for the tax authorities to improve the rate of online declaration.

Abstract

In Taiwan, Electronic invoices had already been promoted since year 2000. This is to fulfill paper reduction, for the sake of environment friendly, and moving towards from less paper to paperless. How to attract more people to accept and use electronic invoices vehicle Cloud invoice is an important issue for everyone.

According to the “energy saving and carbon reduction policy” of the government it has been constantly encouraging people to act green, such as enable people to hold electronic invoice vehicles for green consumption to accelerate the use of various types of vehicles. Upload the electronic invoice data to the cloud server via these carriers. After years of hard work, the number of electronic invoices opened in the year of 106 has reached 6.8 billion sheets. More than 80% of all invoices in the year of 2017, reached planned target, but the invoice past through the vehicle (Cloud invoice), the rate of achieving true paperlessness is still low, still need to be upgraded. Therefore, most people develop the habit of taking the initiative to request paper invoices after consumption. To change people's habits, Change to electronically invoice in a paperless manner, It is not easy.

In this study, utilized from the view points of innovation resistance to explore the relationship among consumers' perception of electronic invoice carrier utilization, the behavioral inertia, and willingness of using. This study also explores interference relationship of perceptual risk behavioral inertia and willingness towards the use of incentives methods for electronic invoice vehicles

This study was conducted by questionnaire, facilitating sampling by the general public over the age of 16, The regression analysis is to verify the hypothesis. research shows

- 1 The perceived risk of the electronic invoice vehicle negatively affects the willingness to use.*
- 2 The inertia of the electronic invoice vehicle will negatively affect the willingness to use.*
- 3 The preferential measures of the electronic invoice vehicle will positively affect the willingness to use.*

4 *Preference measures, perceived inertia and use of electronic invoice vehicles willingness relationship has interference effect.*

Cloud invoices not only do our best for the planet, can also bring competitiveness to countries and enterprises, The results of this study can provide suggestions for the future research and government for reference

Keywords – electronic invoice carrier ,perceived risk, behavioural inertia, willingness of use.

Paper type – Academic Research Paper / Practical Paper

1 Introduction

The continuous opening and use of paper electronic invoices is often contrary to the government's policy of “energy saving and carbon reduction”, “green economy” and “green living”. At the same time, the store also prints such discount coupons, merchandise coupons, transaction details, credit card details, advertisements, etc. The hottest papers are more and more printed, and the environmental problems that have been created in an endless stream have further highlighted the fact that electronic invoices deviate from the original target and purpose. Therefore, when the global warming, the disappearance of rainforests, the depletion of natural resources, and the serious problem of ecological consumption, countries should not delay and vigorously promote the laws and regulations on energy conservation, carbon reduction and environmental protection.

According to data released by the Executive Yuan in 2017 to promote diversified waste disposal – making waste change resources, Taiwan's garbage collection rate reached 58%, and the resource recovery rate was higher than the world's second, second only to Germany. It shows that the environmental awareness of the people of Taiwan has reached a certain level. At the same time, whether electronic invoices can do the best for the earth, do their best for environmental protection, change the habit of requesting paper invoices, and it has become a new environmental awareness of consumers.

In the case of the government's long-term promotion of obtaining uniform invoices, consumers have developed the habit of actively requesting paper invoices after consumption for more than 60 years. Therefore, it is not easy to change the people's habits and request electronic invoices in a paperless manner.

In the process of promoting electronic invoices, the demand for paper invoices by different ethnic groups and the proficiency in the use of information by urban and rural gaps are considered. For consumers without vehicles, electronic invoice certificates are still provided for convenience. Therefore, most consumers still I am used to requesting an electronic invoice certificate. Even the electronic invoice certificate has caused some consumers to misidentify from the traditional two-way cash register invoice.

As far as the current implementation results are concerned, it is still low for consumers to obtain electronic invoices from vehicles to achieve a really small paper and paperless ratio. Although the implementation results have indeed increased year by year,

they still need to be improved. The business person prints the consumption details, coupons or marketing advertisements. When people want to use the vehicle to obtain an electronic invoice, they need to provide payment tools (cash or credit card) at the time of consumption checkout, and they must present the vehicle (such as mobile phone barcode) and tell the store service personnel to open an electronic invoice. This study suggests that consumers may feel that it is faster and more convenient to request paper invoices. Therefore, in the process of promoting electronic invoices, in order to meet the needs of different ethnic groups for paper invoices and to consider the digital gap between urban and rural information, electronic consumer invoice certificates are still given to consumers who do not have vehicles. So far, most of the consumption has been They are still accustomed to obtaining an electronic invoice certificate, and the ratio of obtaining electronic invoices to achieve true paperlessness is still low. The most important thing is to start with environmental education and change the concept and habits of consumers to obtain paper invoices.

Inertia behavior theory is often used in new product purchase decisions to explore the tendency of users (consumers) to focus on their familiar familiar product habits (Chintagunta, 1998; Ye, 2005). Inertia is also related to personal traits (perception, attitude, concept and environmental awareness) or social background (income, age and physical barriers). Consumers use the habit of cash consumption, most of which are still in cash transactions. When an electronic invoice vehicle is used, this behavior is more biased in the change of customary behavior. If this behavior change is reflected in the selection of the mode function, the effect of inertia can be measured.

Hancock and Humphrey (1997) argue that concessions are one of the key factors affecting consumer adoption barriers and adopting e-banking. Therefore, The preferential measures will cause interference between the rejection and rejection of the electronic invoice carrier. If the benefits offered by the government are more and more attractive, and can continue to implement exclusive awards. It will probably reduce the rejection and rejection of users, and thus have a willingness to use.

2 Conclusions

Sheth (1981) explores the Innovation Resistance Theory from a psychological perspective, And propose a two-dimensional facet of the degree of inertia and perceived risk of existing things. The innovation resistance is divided into four categories: double resistance innovation, custom resistance innovation, risk resistance innovation and non-resistance innovation. Difference: 1. Dual resistance innovation: refers to a consumer who is exposed to high perceived risks and is unwilling to change existing habits, causing them to resist. 2. Habit resistance innovation: refers to a consumer who is confronted with a low perceived risk but is unwilling to change existing habits. 3. Risk resistance innovation: refers to the fact that consumers face high perceived risks and do not need to change existing habits, but instead may have to accept new habits, causing them to resist. 4. Non resistance innovation: refers to the fact that consumers face low perceived risk and do not need to change existing habits, so that they do not have resistance. Ram (1987)

believes that innovation has its life cycle, and that the conditions adopted or resisted during the period may coexist at the same time. Those who accept innovation have people who have rejected or resisted. Ram and Sheth (1989) further revise and explain the definition of innovation boycotts. Consumers facing innovation may be influenced by innovations due to certain obstacles and innovation resistance. Ram and Sheth (1989) argue that these barriers are mainly due to consumer perceptions, and that resistance may be rejected or delayed. Functional barrier refers to the change that consumers feel about innovation, the inability to adapt to innovation, and the perceived barrier to functionality. Functional barriers can be seen as consumers' incompatibility with innovation. Define functional barriers: usage barrier, value barrier, risk barrier. Psychological perceptual disorder, Ram and Sheth (1989) believe that it depends on consumers' self-recognition. When innovation and original beliefs of consumers are violated, psychological barriers may arise and influence the adoption of innovation. Define psychological barriers: traditional barriers, image barriers, and propose strategies and methods for these two barriers. Consumers are not totally resistant to innovative products, ideas or services, but to the extent of resistance, as follows: 1. Inertia: Consumers come from the original lazy inertia, which makes them unwilling to change the situation and resist. 2. Subjective: Consumer subjective cognitive innovation may have a high degree of risk and make a decision to delay adoption. 3. Faith: Consumers are convinced that they are not needed or suitable for innovation and are resisted with a strong degree.

In the face of innovation, consumers may have the above five obstacles and the willingness to resist innovation will affect the willingness to adopt innovation. The overall theoretical concept is clearer and more complete.

In addition, Sheth (1981) explores the theory of innovation resistance from a psychological point of view and proposes two major facets of "perceived risk" and "behavioral inertia" of existing things. (1) Perceptual risk: It was first developed by Bauer (1960) from psychology and led to the field of sales management. It is believed that the marketing plan adopted by marketing decision makers may not predict the development of the results, so the decision makers make decisions. Behavior can be said to be the contract of risk. (2) Behavioral inertia: Sheth (1981) argues that the innate perception or perception of human beings tends to maintain consistency in current conditions rather than innovations that are inconsistent with current conditions. Ram and Sheth (1989) When the adoption of innovation must change the habits or behaviors established by the people, it takes a relatively long time to develop the acceptance process before the people accept innovation.

Inertia will reflect some of the behavior that follows, and once inertial behavior occurs, it will habitually repeat the action (Oliver, 1999). You Bolong (1980) theory of habitual domain suggests that human decision-making is subject to inherent habits. Once these ideas are stabilized, they have a habit, that is, the procedural or formulation of behaviors, in response to people, things, problems, and messages, including understanding, understanding, judgment, and practice. When consumers perceive risk, they try to delay adoption of innovation until they learn more about innovation (Ram and Sheth, 1989). In a study by Dodson et al. (1978), it was pointed out that when the margin

of a transaction increases, it will have a positive impact on the transaction, increasing the likelihood of more transactions being completed. (Andrews et al., 2010) also believes that if the content of the offer can bring value, it will be more effective for consumers, and induce consumers to generate more purchase behavior. The research mentioned that the marketers in the market spend each year. The discounted fees (for example, winning prizes, gifts) amount to billions of Taiwan dollars, and the expected purchase intention will increase with the perceived increase. Consumers must pay a considerable price when they get the value of a product or service. At this point, the consumer will have a so-called Perceived monetary sacrifice for the amount actually paid. Therefore, when the preferential rate of a product or service is higher, the actual consumer pays a drop or compensation, and the consumer's original perceived monetary sacrifice will be reduced, and the consumer's willingness to purchase the product or service will be increased (Dodds, Monroe & Grewal, 1991). In Gupta and Cooper (1992), consumers believe that consumers will influence their behavior through pre-consumer collections, and preferential information is one of the factors that influence consumer behavior.

The government's policy of energy conservation and carbon reduction continues to encourage people to act green, enable people to use electronic invoice vehicles for green consumption, and accelerate the use of various types of vehicles. The invoices are carried to the cloud through vehicles. After years of efforts, The number of electronic invoices opened in 106 has reached 6.8 billion, accounting for more than 80% of all invoices issued in the current year. It has reached the stage goal, but the invoices (cloud invoices) are used to achieve a truly paperless The ratio is still low and needs to be improved.

In this study, we use innovative resistance to theoretical perspectives to explore consumer perceptions of perceived risk, behavioral inertia, and use intentions of electronic invoice vehicles. At the same time, it also discusses the relationship between consumers' preferential measures and willingness to use electronic invoice vehicles. Finally, the relationship between the perceived risk, the behavioral inertia and the intention of use of the electronic invoice vehicle is further analyzed. Cloud invoices can not only do our best for the earth, but also bring competitiveness to the country and enterprises.

Exploring the Human Recruitment System from the Perspective of Learning Organization

Jo-chiao Cheng

Department of International Business Administration
University of Chinese Culture
55, Hwa-Kang Rd., Yang-Ming-Shan, Taipei , Taiwan 11114, R.O.C

Abstract

All activities in the organization, from the completion of simple work to the operation of the entire enterprise, require "people" to execute or manage. In a fiercely competitive environment, excellent talents are an important key factor in a company's success. From how employees enter the company, how to adapt, learn, and grow in the enterprise, and be properly used to take on tasks, human resource management plays a very important role. . Therefore, how companies can make good use of human resources at the right time, get enough manpower, quality talents, and promote their good development depends on the success of human resources. The structure of Taiwan's social population has evolved to "age", prices are getting higher and higher, and wages are not rising. As a result of the decline in fertility, various social change factors and economic problems, the vicious circle has led to the growing number of children in recent years. The impact on employment has not been found to be suitable for talents, and the development of financial owners is still to cultivate outstanding professional talents, and regard talents as a competitive advantage. In response to changes, the project is responsible for the recruitment, development and training of responsible personnel. Continue to compete for talent. The difficulty in the recruitment of human resources has increased, and in the face of severe competition in response to innovation, companies have also realized that they must change the traditional concept and nature of work. In particular, learning-oriented enterprise organizations must constantly learn, grow, change and innovate, and education and training is the driving force for improving human quality. Through the implementation of education and training, the members of the organization can have the ability to adapt. The organization can adjust the operation policy and business strategy in a timely manner, and strengthen the strength of the company's survival

Keywords –manpower recruitment system, project management, system thinking, causal feedback

Paper type – Academic Research Paper

1 Introduction

The advent of the era of knowledge economy and the continuous advancement of industrial technology have had a great impact on the learning and work of organizations.

Financial organizations must focus on the individual learning capabilities of their members to make the organization more “learning.” Employees have been seen as an asset. Whether an organization can maintain its competitive advantage and its ability to operate sustainably depends on whether the organization Get instant access to information, use information and create knowledge. Due to changes in the working environment, the organization's pre-employment conditions and work content will be continuous learning and innovation, and the "talent" will be the key. Therefore, in the economic era, all levels of the organization will challenge and develop new knowledge. One of the important duties of managers is to create a learning environment that can increase the knowledge and skills of employees, which is the birth of a learning organization.

The organization is a group of people. In order to achieve common goals, they will work horizontally and divide vertically, and be vertically stratified according to their functions. Through communication, coordination, leadership, supervision, etc., the cooperation will be achieved and the organizational goals will be achieved. The organization is also a complete organization. The organism, and self-adjustment with the changes of the times or the environment, and through the members of the organization from the psychological level of cognition, emotions and attitudes, etc., to establish group awareness. Therefore, the organization's performance, including static, dynamic, ecological, mental state and other four states, are indispensable. Organizational elements are the focus of organizational behavior. Elements determine the structure, function, nature, attributes, characteristics, etc. of the system, and at the same time determine the nature of the system. Hodgetts (1975) believes that the organization assigns its responsibilities and coordinates its work to all members of the organization, and achieves the most efficiency in achieving the goals.

The concept of "learning organization" is from the 1970s to the 1990s. It is rooted in organizational learning and its development is based on the evolution of management thoughts over the past few years. The rise of this concept pays attention to the effectiveness of teamwork and group learning among members. The enterprise is a learning organization. The organization continuously uses a single-loop learning cycle and a two-loop learning cycle to operate within the organization, progressive learning, and adjust with the evolution of the mission and competitive environment of the enterprise. In view of the significance of learning organizations, many scholars have discussed and put forward many different views. Peter Senge believes that “learning organizations” can continuously expand the ability of individuals in the organization, create truly satisfactory results, and foster new ones. And the malleable thinking style enables a shared vision to be realized, and members continue to learn how to learn together. Organizational management is to establish organizational structure, stipulate positions or positions, and clarify the relationship of rights and responsibilities, in order to play the role of the organization and accomplish the goals of the organization. In the organizational structure, the "members of the organization" are considered to be the users of the resources, and have the actual status and role. Therefore, the corporate culture is

valued by the managers of the company and plays an important role in the management of the company.

Systematic thinking about a practice of "seeing the whole", it is a framework that allows us to see interrelated rather than single events, with a causal feedback loop and time delay as the dynamic whole of the structure, the first step of thinking, It is necessary to expand the scope of time and space of thinking, and then to think in the system in which it operates, to expand the space and time of thinking of the individual, and to identify the subtle characteristics of its overall operation. Therefore, in the face of rapid response, companies must constantly review the core of internal value to respond instantly to strategic partners and customer needs, enhance competitiveness, commit to innovative services, improve quality, streamline processes, and reduce costs..

2 Literature reference

In recent years, the implementation of project management has been very fast, and it is one of the most common modes of work in most enterprises. The project management infrastructure operation method is (starting, planning, executing, monitoring, and closing five processes), and selecting tools suitable for the characteristics of the enterprise for each process, specifically, time, cost, resources, and target categories. Under the constraints, to complete the work of the established mission, and the results of the operation, naturally directly affect the competitiveness of the enterprise, to help the company achieve its goal of success. The project organization is a cross-functional team composed of executive and completion projects. Its members come from inside and outside the organization and are composed of different departments. Through horizontal cooperation, the technology of each department is integrated to reduce the level of decision-making. Make communication between related work orders smoother..

According to Kerzner's (1984) definition, the so-called project management is to plan, organize, control, and use resources to engage in relatively short-term work to achieve a clear work goal, and to manage the system in different ways. Assigned to the relevant project work. Yazici (2009) studies project management maturity and organizational performance, and organizational culture is an important key to the success of the project. Meredith & Mantel (1989) argues that a project is a special and limited task, technically complex, and continually coordinated to control schedules, processes, costs, and job performance. Project management is the application of knowledge, skills and technology to make project execution more efficient and effective, and to use organizational strategy to achieve business goals and to be more competitive in the market. Huang Zhengwei (2010) knowledge management resources have significantly improved the performance of innovation after the impact of project management capabilities. Xu Xiuying (2015) pursues the success of all projects, depending on the overall maturity of the project's project management. The high maturity means that most projects can accurately estimate the project schedule and cost, and can grasp the scope and quality of the project and achieve the expected goals. The results of the project bring the highest value to the

organization. Yazici (2009) studies project management maturity and organizational performance, and organizational culture is an important key to the success of the project.

3 Establishment of supplier performance evaluation model

3.1 Understand the overall performance of the job and the problem

This research question will first find out the past literature and grasp the phenomenon neglected in the execution of the recruitment process, and combine the system thinking mode to construct a research tool graphically, and use the causal feedback loop diagram to understand the past to find hidden key problems. The misperception of each link in each process, and the problems caused by a series of changes in the loop, followed by the results of the questionnaire, field case interviews and loop diagram analysis, and detailed enough deep mental and thinking to explore the recruitment The dynamic problem of complexity in execution and the overall thinking management strategy.

Constructing the Causal Loop Diagram (CLD) of "causal feedback and loop diagram" in the overall thinking mode of System Thinking, showing the influence of each behavioral element in dynamic change over time, and literature The discussion suggests that a systematic thinking model can influence each behavior and give back to each other, which will help to understand the dynamic behavior of the entire recruitment project. Because of the close interrelationship, it can be deeply understood. The overall operation and problems of the operation are carried out. Systematic thinking methods are used to find out the causes and solutions of the problems, and avoid the researchers' influence on the objectivity with their own ideas and opinions. Through this model, they can find the problems and feasible solutions..

This research survey method is conducted by the head office of the law collection and participates in the questionnaire survey of recruitment routines and project executives. It also conducts the same questionnaire survey of the branch business department co-organizers to understand their opinions and suggestions on recruitment and implementation. As a measure of comparison. The case study asks mainly to understand the current situation of the research object, and then conduct a preliminary analysis of the review and data collation, and thoroughly examine and ignore the existing problems and solve the improvement management strategy.

Interviews with specific people (department supervisors), through interviews with each other, to learn more about the causal development process, phenomena, and even undiscovered issues behind the specific project execution situation.

3.2 System Dynamics

1. System Dynamics Modeling Analysis Software Tool

This study uses Vensim's modeling software tool to build a dynamic model using Vensim. Through the graphical use of arrow symbols to connect various variable symbols, in the process of building a model in software, we can understand the causal relationship between input and transmission. Understand the schema architecture,

supplement the content and modify the content of the schema. System dynamics is a process of simulating internal feedback through the system, and observing how the system structure, policies, delays and other factors interact to affect the growth and stability of the system.

2. This research model is established and the program

Proposing a meaningful and worthwhile research and research is the beginning of research work. Identifying research problems or problem formulation is an important step. Researchers can explore the problems that can be studied according to their own observations or experiences; and through careful reference to relevant literature and reference experts and scholars, they will put forward the issues they want to study. (2005, Li Zenglu)

3. Dynamic planning assumptions (problem assumptions)

This study takes the hypothesis of the problem, using the Venusim software to construct the system dynamics, first based on the actual situation to create a causal feedback loop diagram for analysis, and then further identify to find the most critical issues, and related factors between each other The dynamic and complex characteristics under the interlocking relationship begin with the keyword word: (project, labor increase, time delay, overtime, error rate), and then think about the topic analysis. Therefore, this study uses Vensim to establish a dynamic model. Through the process of building a model, we can understand the causal relationship and loop between variables. In the causal relationship of project execution, find out the root cause of the original problem and think about finding the best countermeasure. , effectively solve the problem.

4 Analysis and Findings

Based on the learning organization and systematic thinking, this study identified 10 influencing factors and 10 improvement strategies. The following are the following:

1. Influencing factors:

- (1) Increase in the rate of heavy work and increase costs
- (2) Increased labor demand, resulting in work fatigue
- (3) The shortage of manpower is heavy, and the work assignment cannot be properly scheduled.
- (4) The time for supervisor communication is small, lack of listening, resulting in communication suspension, team morale is low, work enthusiasm
- (5) Talents are broken, and the company's talents cannot find suitable employees, resulting in a rising rate of work.
- (6) Increased overtime frequency, resulting in fatigue
- (7) Routine workload, time compression and rush, work without quality and efficiency, work and life imbalance.
- (8) Poor work atmosphere, affecting work efficiency
- (9) Annual budget preparation, affecting the implementation plan
- (10) The equipment is too old, the work is too cumbersome, the efficiency is poor, the execution is limited, and the quality is not good.

2. Improve strategy :

- (1) Equipment update, reduction of operations, improvement of work execution quality
- (2) Increase in the number of new students' courses and guidance
- (3) Mutual activities (physical and mental stress), employee benefits
- (4) Improve the quality of personnel, strengthen skills training and professional knowledge, and improve performance growth or competitiveness.
- (5) Reduce the chances of heavy work and ensure that the target is in line with the direction.
- (6) Increase (submerge) manpower to solve the problem of the unit's business volume and increasing threats, uneven work and rest.
- (7) Leaders care, get the approval and care of the supervisor, and the employees are focused on the organization.
- (8) Improvement of work environment quality and reasonable working environment to reduce labor fatigue and pressure
- (9) Reduce the number of overtimes, and the error rate will not occur.
- (10) Budgeting is more efficient to achieve the goal.

5 Conclusions

According to the research results, the reasons for the difficulties in the execution of the project in the manpower recruitment system are summarized into two categories, as follows:

(1) Organizational system level

The code of conduct, business philosophy and corporate culture that must be observed in the organizational system of the enterprise will affect the ideas and behaviors of employees. Competition in the environment, continuous innovation of the company, more and more employees work, everyone is under heavy time pressure, and in the case of manpower, it may need to be supported by other departments or other units. The concept of support for colleagues is not consistent, and the leader indicates that the implementation target is not clear enough, so that the work is repeated again and again, and the situation of uneven workload distribution may occur. The enthusiasm is repeatedly exhausted by excessive working hours, resulting in excessive fatigue of employees. Morale is reduced. Therefore, in the implementation, only the command can be repeated, and the personnel of each unit should be required to cooperate. The members cannot interact closely, which may delay the implementation of the project and may not be promoted smoothly.

(2) Project management issues

Successful projects require a complete management approach and processes, and carefully manage members, budgets, resources, and ensure that projects are completed before the deadline. From the case study project analysis, we can also learn that the lack of manpower for the implementation of the unit project and the high workload have led to each person having to work in multiple roles or to fight alone. Other support manpower has no project experience and it is difficult to control the project's work objectives,

content and progress, and it is impossible to achieve the goal within the specified time. Therefore, when the work item often fails, it needs to be re-started, resulting in the failure of the work to be completed smoothly.

Succession and Cultivation of Successors in SMEs in Taiwan

Ying-Hsuan Wang

Department of International Business Administration
University of Chinese Culture
No. 231, Sec. 2, Jianguo S. Rd., Da'an Dist., Taipei City
106, Taiwan (R.O.C.)

Abstract

Small and medium-sized enterprises (SMEs) provided economic benefits with Taiwan Economic boom. When SMEs faced the daunting challenge of external environment, successors of SMEs brought opportunities for creativity and innovation, but SMEs also had undergone enormous change. In Taiwan, most of SMEs were at crisis points in the succession and struggled to survive. The purpose of this study was to point out key factors of succession and cultivation of successors in SMEs. We used Delphi technique to select dimensions and criteria. When we found out dimensions and criteria, we used DEMATEL and AHP in the future to find their mutual influence degree and weighted value of key factors of succession and cultivation of successors in SMEs. We could provide this study for owners to make decisions about succession and cultivation strategies to enhance the ability and skill of successors and his performance.

Relevant researches pointed out that 53% SMEs in Taiwan were sole proprietor companies, 51% SMEs in Taiwan operated more than ten years, 53% owners of SMEs in Taiwan were over 50 years of age, but only 40% SMEs in Taiwan had succession plans. Many family businesses operated by successors reported heavy losses in Taiwan. Owners of SMEs were key factors in the initiation of succession. When owners created favorable environments for successors, and successors who made good use of knowledge and skills received social resources from owners and the companies achieved the goal of sustainable development.

This study used Delphi technique. From literature on the exploration into SMEs, owners, successors, succession and cultivation plans, and by initial interviews with two experts, we got initial dimensions and criteria. Then we chose a group of experts in this topic, and wanted anonymous experts to fill in open-ended questionnaires which we designed by using initial dimensions and criteria. According to results of first questionnaires, we set up agreed thresholds of anonymous experts. If anonymous experts reached a consensus, we got the most important dimensions and criteria. If anonymous experts failed to reach a consensus, we modified the questionnaires, and anonymous experts filled in closed questionnaires again until they reached a consensus.

This study was limited by the scope of research, research samples, data sources, and research methods, but it was expected to contribute to the key factors of succession and cultivation of successors and systematic analysis techniques for owners of SMEs to train successors.

Keywords –Small and medium-sized enterprises (SMEs), Successors, Delphi technique.

Paper type –Practical paper

1 Introduction

Small and medium-sized enterprises (SMEs) provided economic benefits with Taiwan Economic boom. SMEs stabilize the country's economic development, and create a large number of employment opportunities. When SMEs faced the daunting challenges of external environment such as globalization and the advance of science and technology, successors of SMEs brought opportunities for creativity and innovation (Kesner and Sebra, 1994; Mone, McKinley, and Barker III, 1998), but SMEs also had undergone enormous change in the structure, corporate culture, internal employee relations, and so on. Senior staff must change their mind to adapt to new environments, or they will be eliminated. Let's assume that the generation of an enterprise is 30 years, the average age of Taiwanese SMEs is 28 years, and Taiwanese SMEs are facing a large-scale succession. If owners of SME have suitable successors who can forecast trends of future, stay one step ahead of competitors, promote the upgradation and transformation of industry, and carry out diversified development of enterprises, successors of the enterprises become key indicators of the enterprises to overcome the challenges.

Family businesses account for about 75 percent of the entire global enterprises and also make up more than 73 percent of Taiwanese SMEs. Only 39.61 percent of Taiwan's enterprises have succession plans, and among them, 86.52 percent of owners divided the enterprises among his generations, 11.35 percent of owners handed over the enterprises to professional managers, and only 2.13 percent of owners sold the company. The succession of family business is a formidable challenge (Sharma and Irving, 2005). Some studies pointed out that 30 percent of companies could be transferred from the first generation to the second generation, 12 percent of companies could be successfully transferred to the third generation, but only 3 percent of companies could be passed down from generation to generation. Even though companies complete their succession plans, companies usually execute succession plans within a fairly long time frame, and there is a slight chance to succeed. 53.71 percent of Taiwanese SMEs are wholly-owned enterprises. If the company does not have succession plans in advance and successors take over companies in an emergency, companies are easily in crisis. Therefore, this study hopes to solve the succession crisis faced by Taiwanese SMEs. How to choose successors and cultivate successors as suitable successors for Taiwanese SMEs is a very important issue, and is an important driving force for the sustainable development and successful transformation into global enterprises (Lauterbach, Vu, and Weisberg, 1999).

The purposes of this study are as follows: First, there is literature on the steps and processes of SMEs' succession planning, or how to start succession planning in the past. This research is aimed at how business owners choose the company's successors to achieve the company's goals of sustainable development. Second, through qualitative interviews and quantitative analysis, we find out the dimensions and criteria between the key factors for selecting successors. Third, this study provides business owners with the methods how to choose and cultivate suitable successors. Business owners can improve the ability of successors from certain dimensions, or establish a set of priorities to enhance the ability of successors in order to improve the performance of the business.

2 Literature Review

There are 9 foreign studies among 15 researches on Taiwanese SMEs. White Paper on Small and Medium Enterprises in Taiwan (2018) pointed out that sole proprietor companies account for about 53 percent of Taiwanese SMEs, companies whose operation years more than 10 years account for 51 percent of Taiwanese SMEs, and companies whose owners' age older than 50 years old account for 53 percent of Taiwanese SMEs, but only 40 percent of Taiwanese SMEs have succession plans.

There are 8 foreign studies among 15 researches on successors of companies. The first generations of business owners who were born after 1945 have already handed over companies to the second generations, and these companies are cultivating the third or fourth generations. But Family governance review pointed out that family business which operated by the third generation in Taiwan reported heavy losses. A key factor for successors to undertake companies successfully is the attitude of business owners (De Massis, Sieger, Chua, Vismara, 2016).

There are 13 foreign studies among 21 researches on cultivating successors. Distelberg and Schwarz (2013) suggested that business owner should create favorable environments for successors who can undertake the social resources from business owners and make good use of knowledge and skills in order for sustainable development. There are four steps for Taiwanese business to select successors, including confirmation of candidates, development of educational plans, regular assessment, and promotion (Jin-Chang Zheng, 2015).

Some studies have conducted a career analysis of 100 CEOs, pointing out that business owners will pay attention to the accumulation of human capital of successors. For example, before choosing a successor, business owners will first confirm that the successor's character, ability, experience and interpersonal relationship meet their expectations. (Salvato, Minichilli, and Piccarreta, 2012). According to factors such as the degree of trust of business owners to successors (Brockhaus, 2004), the succession and performance of successors (Brun de Pontet, Wrosch, Gagne, 2007), the successor's willingness to take over the business (Sharma, Chrisman, and Chua 2003), business owners can choose the most suitable successors. After business owners transfer the control and ownership to the successors, in order to avoid the drastic changes of the business and affect the operation of the business, business owners will guide successors to ensure that successors can take over the responsibility (Distelberg and Schwarz, 2013).

3 Research Methodology

3.1 *The development background of Delphi method*

The word "Delphi" is derived from the temple of the ancient Greek god Apollo. It is the place where the gods of the future can be foreseen. The gods of "Delphi" have the meaning of prophecy and prediction. In the early 1950s, the RAND Corporation provided intelligence analysis services to the US military. The development of Delphi Technique

helped the military to develop a strategic plan for the Soviet Union. Later, that was applied to other fields, and it was used by industry, business, academics, and government agencies to evaluate matters.

3.2 The characteristics of Delphi method

1. Anonymity: Experts can freely express their opinions.
2. Iteration: The questionnaire is rounded back and forth several times. After the second questionnaire, experts can use the statistical data to correct their opinions.
3. Feedback: Experts can be modified by other experts to correct their own views.
4. Statistics: The final expert opinions are presented in a statistical manner, providing a ranking, selection or optimization of the evaluation criteria.

3.3 The implementation steps of Delphi method

The implementation steps of Delphi method are as follows:

Step 1: Set the goal and find out the possible dimensions and criteria.

From the literature, we sort out and summarize the dimensions and criteria that others have done.

Step 2: Pick the right team of experts.

The selection of the expert group is the primary task of the Delphi method, in order to make the research more forward-looking and accurate.

Step 3: The selected dimensions and criteria are open or semi-structured. We ask the anonymous experts to fill in the first questionnaire, and evaluate the importance or fill in other opinions according to the scale.

Step 4: Set the threshold based on the initial results. (e.g. 80% of the experts agree.)

(1) If there is consensus, the goal is achieved.

(2) If there is no consensus in part, they fill in the second questionnaire.

3.4 The purpose of applying Delphi method in this research

This research starts from defining the problem formulation and research purpose. As literature has suggested, we find out several relevant dimensions and criteria for SMEs choosing successors. We use the Delphi method (1950) to invite experts in the case of unknowns to provide their professional knowledge and experience to reach their consensus on the important dimensions and criteria for SMEs to choose successors. Delphi method (Gordon and Helmer, 1964; Gupta and Clarke, 1996) uses a series of systematic questionnaires to consult experts and scholars whose specialization on research issues. In the case of anonymity, we conduct a number of questionnaires to find out results that experts reach their consensus (Dalkey and Helmer, 1963; Hartman, 1981). This method will decompose complex key factors of SMEs choosing the successors into two-tier structural hierarchy (as shown in Figure 1.), so decision makers of companies can easily and clearly analysis factors of choosing successors. Through questionnaires and interviews with five experts and scholars getting their opinions, this

research finds out several dimensions and criteria for Taiwanese SMEs choosing successors and makes some very helpful suggestions for Taiwanese SMEs.

Figure 1. Two-tier structural hierarchy

4 Research Results

4.1 The analysis process

First, we obtained several dimensions and criteria from the literature and interviews. We build the research model of dimensions and criteria in the Table 1.

Table 1. Research model of dimensions and criteria

dimension	criterion
(D ₁) Professional ability	(C ₁)Strategic orientation (C ₂)Financial management ability (C ₃)Insight (C ₄)Crisis management ability (C ₅)Interpersonal communication skills (C ₆)Logical ability (C ₇)Professional technology (C ₈)Business expertise (C ₉)Education (C ₁₀)Foreign language ability (C ₁₁)Performance (C ₁₂)Industry experience (C ₁₃)Interpersonal relationship management
(D ₂) Values	(C ₁₄)Follow strong moral values (C ₁₅)Corporate culture values and strategic continuity (C ₁₆)Inheriting clear corporate core values (C ₁₇)Family tradition or previous generation of value-oriented leadership (C ₁₈)Have a recognition of the organization (C ₁₉)Have a sense of mission
(D ₃) Potential	(C ₂₀)Act decisive (C ₂₁)Positive (C ₂₂)Ability to change, learn and grow (C ₂₃)Thinking (C ₂₄)Diligent and responsible (C ₂₅)Extroverted, ambitious, persevering (C ₂₆)Affinity, cooperation (C ₂₇)Adaptability (C ₂₈)Leadership trait (C ₂₉)High EQ (C ₃₀)Active, open, curiosity

Second, we made these dimensions and criteria into a questionnaire and then asked five experts to fill it out. The content of the questionnaire contains whether the experts agree with the criterion under the dimension, and what do the experts think about the importance of the criterion under the dimension? The scale of importance is from one to five. The “1” (one) means “extremely unimportant”. The “2” (two) means “unimportant”. The “3” (three) means “ordinary”. The “4” (four) means “important”. The “5” (five) means “extremely important”.

Third, we received the questionnaires. We set the threshold of the agreement of 80% of the experts on the initial results. Because the experts reach a consensus, our research has achieved its goals. (See the (1) in the Table 2.)

Forth, we calculated the average of the scale of importance about the criterion in the dimension and then ranked them. We have the result in the (2) and (3) of the Table 2.

Table 2. The result of dimension and criterion.

Dimension	Criterion	Agreed number (1)	Average of the scale(2)	Rank (3)
(D ₁) Professional ability	(C ₁)Strategic orientation	5	4.8	2
	(C ₂)Financial management ability	5	4.2	9
	(C ₃)Insight	5	4.8	2
	(C ₄)Crisis management ability	5	4.8	2
	(C ₅)Interpersonal communication skills	5	4.7	6
	(C ₆)Logical ability	5	5	1
	(C ₇)Professional technology	4	3.8	12
	(C ₈)Business expertise	5	4.8	2
	(C ₉)Education	4	3	13
	(C ₁₀)Foreign language ability	4	4.2	9
	(C ₁₁)Performance	4	4.3	7
	(C ₁₂)Industry experience	4	4	11
	(C ₁₃)Interpersonal relationship management	4	4.3	7
(D ₂) Values	(C ₁₄)Follow strong moral values	5	4.8	1
	(C ₁₅)Corporate culture values and strategic continuity	5	4.5	5
	(C ₁₆)Inheriting clear corporate core values	5	4.6	4
	(C ₁₇)Family tradition or previous generation of value-oriented leadership	4	3.5	6
	(C ₁₈)Have a recognition of the organization	5	4.8	1
	(C ₁₉)Have a sense of mission	4	4.7	3
(D ₃) Potential	(C ₂₀)Act decisive	5	4.8	4
	(C ₂₁)Positive	5	5	1
	(C ₂₂)Ability to change, learn and grow	5	5	1
	(C ₂₃)Thinking	5	4.5	6
	(C ₂₄)Diligent and responsible	5	4.3	9
	(C ₂₅)Extroverted, ambitious, persevering	4	4.3	9
	(C ₂₆)Affinity, cooperation	5	4.5	6
	(C ₂₇)Adaptability	5	4.8	4
	(C ₂₈)Leadership trait	5	5	1
	(C ₂₉)High EQ	5	4.5	6
	(C ₃₀)Active, open, curiosity	5	4.3	9

4.2 The results

We screened the top 25% as a result for this research. (See the Table 3.)

Table 3. The result for this research

Dimension	Criterion	Agreed number (1)	Average of the scale(2)	Rank(3)
(D ₁) Professional ability	(C ₁)Strategic orientation	5	4.8	2
	(C ₃)Insight	5	4.8	2
	(C ₄)Crisis management ability	5	4.8	2
	(C ₆)Logical ability	5	5	1
	(C ₈)Business expertise	5	4.8	2
(D ₂) Values	(C ₁₄)Follow strong moral values	5	4.8	1
	(C ₁₈)Have a recognition of the organization	5	4.8	1
(D ₃) Potential	(C ₂₁)Positive	5	5	1
	(C ₂₂)Ability to change, learn and grow	5	5	1
	(C ₂₈)Leadership trait	5	5	1

The objective of this research is to explore the key influencing factors of successor's selection for Taiwanese SMEs. Using literature review and expert interviews, we find out three major dimensions, including professional competence, values, and potential. The dimension of professional competence can decompose into thirty criteria. The dimension of value can decompose into six criteria. The dimension of potential can decompose into eleven criteria. We use the Delphi method to invite five experts in the case of unknowns to provide their professional opinions by questionnaires. According to the Delphi method, with the consent of 80 percent of the experts, we reserve the top quartile for options, so we can get the three dimensions and ten criteria. We can see the research model in Figure 2. The dimension of professional competence includes five criteria, such as strategic orientation, insight, crisis management ability, logical ability, and business expertise. The dimension of value includes two criteria, such as strong moral values and recognition of the organization. The dimension of potential includes three criteria, such as positive, leadership trait, and ability to change, learn and grow. It is useful for business owners to cultivate successors from these ten criteria.

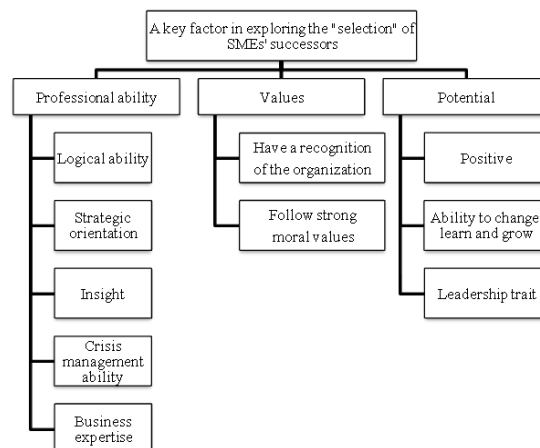

Figure 2: Research model

5 Research limits

This research is still limited by the following three limitations:

(1) A limit on scope

This research is mainly aimed at Taiwanese SMEs or experts in related fields to explore the key factors of choosing successors for business owners. Because each of the industries has the different characteristic, management model and products, the results of this study may not be applicable to all industries. Researchers can conduct follow-up studies in the future.

(2) Limits on research samples and data sources

With limited resources, samples of this research are limited to the business owners who are carrying out succession plans or who have completed successful succession to the companies in Taiwanese SMEs. Because of case interviews in this research, not random interviews or statistical sampling, we can view issues from different angles, solutions may become more obvious.

(3) Limitations of the research methodology itself

This research uses Delphi method which has limits on methodology itself. For example, when using the Delphi method, we sometimes may not get the general consensus among experts. It depends on the ratio of experts' consensus. Therefore, this research focus on screening out and analyzing key factors of successors in a systematic way, and understanding mutual influence relationship and weight of key factors to provide the dimensions and criteria for business owners to select and cultivate successors.

6 Expected contribution

This research have the following contributions to SMEs:

(1) After expert interviews, literature review and decision-making questionnaire analysis, we systematically collect, collate and analyze the experience and knowledge of experts to identify key factors of successors.

(2) This research constructs a hierarchical evaluation model to select successors for Taiwanese SMEs to select the successor as reference.

(3) This research provides Taiwanese SMEs which need succession plans. Companies select suitable successors and start to train them efficiently as soon as possible in order to achieve sustainable development for Taiwanese SMEs.

(4) After confirming successors, business owners find out criteria which are the weakness for successors and ask successors to improve their abilities in order to improve performances.

7 Conclusions

There are a large number of SMEs in Taiwan and significant differences between SMEs. No one has solved the problem of how to screen out unsuitable candidates and cultivate successors for Taiwanese SMEs. At present, there is no practical research for

Taiwanese SMEs to refer to. Therefore, how to choose and cultivate suitable successors for Taiwanese SMEs is especially worthy of notice. This study uses the Delphi method to construct the decision-making model of screening successors for Taiwanese SMEs and propose several dimensions and criteria that companies can use to improve the ability of successors, and assist companies in establishing methods for assessing and coaching successors. The later researchers will use the other research methods, such as DEMATEL (Decision-Making Trial and Evaluation Laboratory) (Tzeng and Shen, 2017) or AHP (Analytic Hierarchy Process) (Saaty, 1980, 2008), to find out the mutual influence relationship or the weight ratio between the dimensions or the criteria.

If business owners can create fruitful environments for successors to inherit, and successors are also trained and able to take responsibility, succession plans can introduce new thoughts for the company (Tirdasari and Dhewanto, 2012). Successors must successfully undertake the social networks and other resources from business owners, and make good use of management knowledge and business skills to lead the company to sustainable operation.

Abstract

In a rapidly changing world of technology, organizations need forward-thinking and insightful leaders to lead the team. Leaders can plan their vision and drive others to act, lead the organization with a positive and enthusiastic attitude, personal intuition, vision, and enthusiasm, in accordance to market trends and adapt to environmental dynamics, adjust the pace at any time., facing upcoming risk, can still hold confidence, lead the organization to move forward during uncertain times, to obtain richness and mind. Leaders expect organizations to be sustainable, so they will continue to innovate and integrate into learning organization culture, so that each member can transcend their own abilities, thinking complexity from a more comprehensive perspective point of view, and examine their own mental models. Change the original deep-rooted, share the views through deep talks, learn how to learn together, so the learning culture of the organization is considered to be a key element of business success. Take imported furniture company as an example, whether it is manufacturing for export or import for domestic sales, as it is transparent to the Internet, it faces a global market. The industrial environment is quite complicated and people's buying habits is now more different than past and more diversified. The furniture industry has been caught in a fierce price war. In order to maintain and develop unique core competitive advantages and attract consumers' attention, imported furniture companies must not only pay attention to international industry trends and fashion trends, but also provide diversified choices and innovative services in today's dynamic and complex world. To make effective decisions, you must first become a system thinker.

Therefore, outstanding leaders can lead the team with macro-thinking, so that the organization can not only continue to learn but also integrate the "collective learning" atmosphere into the organization, breaking through the growth limitation and bottlenecks.

In this study, The interview case was imported from Y Furniture Company and conducted by face-to-face interview. After observation and preliminary interview, the system based model was used as the theoretical basis, and the system thinking mode was used to draw the case system feed-back. Explore the leader-ship style of the case to assist enterprernure to convert their strategic thinking into a more wide open mind for the future of the company and come to operation model compliance and provide enterprise a reference to establish continuous learning organization culture.

Keywords –Leadership Style、Learning Organization、System thinking

1 Introduction

In today's fierce competition in the corporate environment, but also full of opportunities, leaders must play the role of pioneers on the road of changeable and unclear prospects. They don't only have good interpersonal relationships, but also need to promote cooperation, build effective teams, create an atmosphere that can play the potential of the organization, and lead the organization to climb to the peak, which is very important for organizational accomplishment. By James M. Kouzes & Barry Z. Posner, 《The Leadership Challenge》 propose that outstanding leaders must lead by example, clarify their own values, lead the organization with conviction, reform and innovation from continuous experimentation, continuous learning and progress, and understand the members and strive for their support to outline the blueprint for the future, and encourage others to act and build mutual trust. In a complex environment beyond human control, a person who evokes a shared vision and who can contribute to the organization's goals, sincerely and publicly praises, can consolidate the collective identity and community consciousness, and walk through the thorns of thorns.

By American scholar Peter M. Senge《The Fifth Discipline》It is believed that the establishment of a learning organization will be the best strategy for obtaining a competitive advantage. In this book, he proposes the management concept of a learning organization, which is characterized by rapid changes and threats in response to the external environment. Not only the ability to learn among the members of the organization, but also to learn together, share common values, develop a forward-thinking thinking model and work towards a shared vision. Therefore, in addition to the need to develop a flexible corporate strategy, leaders must also pay attention to the value of learning in the organization, and encourage the formation of a self-growth learning organization culture, so that enable each member of the organization to continually create new knowledge from work, learn from mistakes, and share what they have learned, and thus improving organizational performance and employee identification, can not only maintain the competitive advantage of the company, resolve the recession crisis, but also continue to open up the global market to achieve a common vision mission.

However, at this fast pace, it is possible to seize the business opportunities in the digital age, corporate organizations to adapt to environmental changes, continue to proliferate and grow rapidly, but unconsciously slow down, pause, or even decline, this is the "Limits to Growth" in learning organizations; Also because growth begins to slow down, leaders or high-level managers intervene directly in order to quickly resolve member errors or problems, so that members can not learn from mistakes, in addition to causing the same mistakes or problems may occur again and again, and also make members Long-term reliance on leaders or high-level managers, causing partial disability, this is the "Shifting the Burden " in learning organizations, What is worrying is that "Shifting the Burden" is accelerating the phenomenon of Limits to Growth in the organizational system, but the leader or senior manager does not know. Therefore, when leaders or senior managers do not understand the overall operation of the organization from a macro perspective, they may encounter various constraints and bottlenecks.

Therefore, the spirit of the learning organization is to help leaders or senior managers to use deeper thinking in a systematic way. A broader mindset examines the complexity issue so that the crux of the problem can be identified.

2 Research Background

Furniture has always played an important role in human life. In 1992, the average national income exceeded 10,000 US dollars. Under this rapid economic growth, the level of consumption has been continuously improved, and the comfort and exquisiteness of life have become more and more stressful, and the imported furniture market has gradually expanded.

Taking the furniture industry as an example, Taiwan's early furniture industry was originally a traditional industry. Before 1956, the furniture manufacturing and sales model was the front of the business, and the manufacturing plant was behind, saving transportation costs. After 1980, due to the development of the country's economy, the urban land was inundated, and the majority of factories gradually declined. The current furniture industry is mostly separated by production and sales. When the society begins to be rich, the people's living ,For Taiwan, which is based on foundry, in order to respond to the aggression from European and American brands, it is also actively transforming the domestic market through design innovation. However, with the advancement of technology, the transparency of online information, online stores have joined the battle, consumption patterns and never the same in the past, In order to be able to continue to be the leader in the furniture industry, whether it is furniture manufacturing or importing furniture, it is necessary to continuously develop new markets. The customers and manufacturers facing the world are more complicated, so the furniture industry practitioners Professional skills must be continuously improved and continuous learning.

This case takes the case of imported furniture company as an example, discusses leadership style and learning organization, assists leaders and high-level managers to change their thinking to think more about the future direction of the company and formulate strategies in line with the business operation mode. Explore the leadership style of case companies and the construction of learning organization culture.

3 Reserch Approach

3.1 System Theory of Rreserch

From a country, a company, a family, or even any body, it is inevitable to belong to an interdependent ecosystem. All behavioral activities are inevitably affected by the system in which each other is active. Understand the ins and outs of the overall event, and from a systemic perspective, you can have a more comprehensive insight into the root of the problem. For a complex and rapidly changing industry environment, systematic thinking for understanding dynamic complexity is a must-have core competency for leaders and supervisors.

The study interviewed the personnel of Y Import Furniture Company, based on the theory of system thinking and the current situation of the researchers through long-term observation. Conducting preliminary interviews with some supervisors and grassroots personnel in a non-structural conversation. According to the interview, the company has the phenomenon of "Limits to Growth" and "Shifting the Burden" system. Therefore, based on these two theories, the causal feedback loop graph model belonging to the case reality is drawn. The "Limits to Growth" fundamental model consists of three continuously enhanced loops and an adjustment loop. The "Shifting the Burden" model is exacerbating the regulation loop. Understand dynamic feedback relationships and design expert interview questionnaires for each variable. After collecting interview records and related company data and literature, analyze the leadership style to explore how to establish and influence the learning organization culture to explore its relevance. Hope that by systematically thinking about the theoretical basis, we will provide companies with an organizational culture of continuous learning. Leaders and department heads can avoid "Shifting the Burden" and break through the "Limits to Growth" reference proposal to achieve a sustainable business.

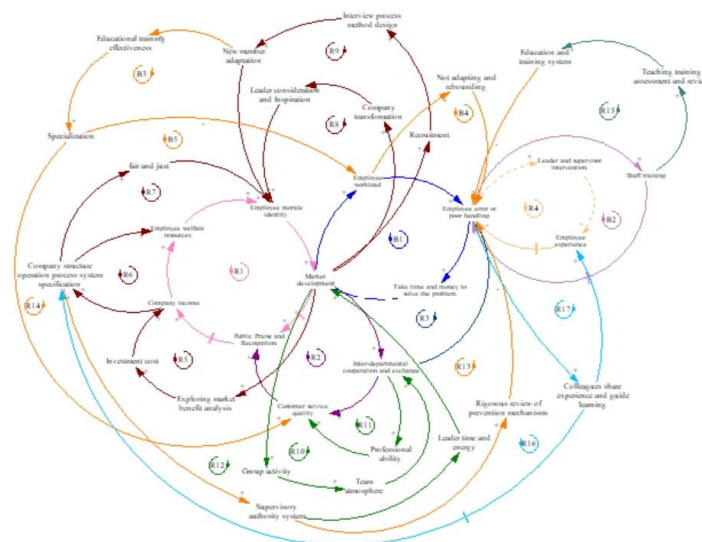

To make effective decisions in today's dynamic and complex world, companies must first become system thinkers, that is, expand the boundaries of our mental models. The basic model of by Peter Senge《The Fifth Discipline》system reveals the simple beauty behind the management of complex phenomena. The contribution of system thinking lies in the deep understanding of the counter-intuitive behavior of dynamic systems, explaining the patterns of behavior patterns through the structural causes (interaction mechanisms) behind complex behaviors, and distinguishing the differences between high-lever solutions and low-lever solutions. Assisting leaders in dealing with the linkages between multiple variables, that is, the leadership style's understanding of the relationship between organizational performance, teamwork and its learning organization culture, and integrating the continuous learning atmosphere into the organization. Therefore, the main reason for using system thinking as a research tool for this study.

3.2 Case Company Analysis

Y imported furniture was established in 2001, acting as the main consumer group of JOHN HUTTON and MOOD. With its keenness to the market and unique taste, coupled with high-standard professional services, it gradually became famous in the luxury market and introduced GIOR , RK, HH and other neo-classical European and American brands. After the market gradually stabilized, the California American style brand JRS store was established in 2005. In 2008, B&B established the Contemporary Space Pavilion to showcase the furniture configuration according to different spaces. For many years, the case has always believed in the importance of art to the aesthetics of life. Every year, domestic and foreign artists are invited to plan exhibitions. Not only do they devote themselves to Taiwan, but also to Greater China, Japan and the United States. In 2018, they entered the mainland market and established a branch in Shanghai. With the transparency of network information, the consumption pattern is gradually changing, and the industry competition is intensifying. In order to continue to consolidate the market

position, the case company develops an innovative operation mode, introduces the world famous furniture decoration brand, provides comprehensive professional integration planning proposals, and the original authorization. Perfect after-sales service.

In addition to the general store customers, they will also work with interior designers to plan projects. Therefore, it is necessary to invest a lot of business manpower and time to develop designers, provide innovative services, cross-departmental cooperation and exchange (experience sharing), and regularly arrange brand awareness and planning. Training courses can enhance the team's professional core competence and service quality. Such word-of-mouth and influence effects among customers can further promote the growth of the company, so that the morale and identity of the business manpower will increase greatly, and the market will continue to grow and expand, forming a positive cycle. However, when the market continues to develop (including the introduction of global furniture brands), in addition to maintaining customer service quality and providing multiple choices, more professional and innovative integration planning capabilities are needed. Therefore, in order to provide fast and diverse services to customers in a highly competitive environment, errors or incomplete treatment may occur, and under the consideration of time and cost, the leader or manager intervenes to solve the problem. Although the crisis situation is quickly lifted, it also reduces the ability of members to solve problems on their own, and reduces the skills that are recognized from mistakes, resulting in the same or similar mistakes in the future. If the leader or supervisor continues to intervene to solve the problem, the result is the long-term reliance of the team member on the leader or supervisor. The team member may continue to make mistakes, which in turn affects the development of the market. Therefore, leaders and managers should encourage members to think and cultivate their ability to solve problems, and to stimulate reflection and questioning with an open attitude, so as to enhance organizational learning and innovation capabilities and improve organizational effectiveness.

4 Conclusions

Based on the systemic thinking theory, the study uses the system's basic model structure to observe the case companies have the Limits to Growth and Shifting the Burden phenomenon. By drawing a questionnaire on the design of the causal feedback loop diagram design, an in-depth interview was conducted with 17 department heads and staff of the case company. The following is a summary of the content after the interview.

In such a turbulent and dynamic environment, the competitive industrial environment can continue to operate, and it is necessary to continue market development, whether it is products or customers, and to develop a sound corporate structure operation system. For the annual promotion salary reward system can be more clear, rewards and punishments are more fair, so that employee morale, identity and willingness to increase. This not only makes the products and customers more active, but also enables employees to improve their self-improvement and enrich their abilities, during this process Inter-departmental cooperation and exchange can enhance the professionalism of customer service and enhance the customer's visibility to the case company. However, the atmosphere of inter-departmental cooperation and communication is harmonious, and it requires more and more good interaction. For example: group activities. Collaboration between department heads can also contribute to this good cycle. Due to market development, both products and customers come from the global market, which is quite strange to the members of the organization. Case companies must face transformational change that causes an increase in workload and complexity. It is easy to produce unsuitable or even rebound, which may lead to errors or incomplete handling. Leadership or supervisor care and encouragement can enhance employee recognition and morale, and reduce negative atmosphere and error rate. In addition to recruiting the best talents to improve the professional division of labor by designing and improving the interview process, Conduct regular market benefit analysis to understand development effectiveness. Conducting employee training and sharing experience and learning exchanges with colleagues in the face of unfamiliar errors or incomplete management. Incorporate implicit knowledge into the company's framework of operational process systems to provide a more complete education and training system, It also enables the supervisor to follow the rules and implement the rigorous review mechanism, thereby reducing employee errors and incomplete handling, and sharing the leaders' efforts and time.

Abstract

Medical beauty is a global trend and a popular, emerging industry in development. It is believed that the integration of medical beauty sector and e-commerce platforms operated in Taiwan offering virtual reality experience supported by artificial intelligence technology would have quite a significant economic impact on the markets across the globe.

The research is to study the effects on the development of medical beauty applications, innovations, the dynamics of the incorporation of online platforms and the medical beauty sector and efficient ways of promoting sales; applying artificial intelligence and virtual reality to the products of growing e-commerce platforms, the improvement of user experience given much easier access to product information and well-designed user guidance to boost sales of products or services and strengthen the ties between industries, creating new trends to highlight the competitiveness of local merchants among competitors across the globe based on the theoretical constructs. The research also explores the business models of medical beauty industry.

The research applies Task-Technology Fit Theory (TTF), Theory of Reasoned Action (TRA) and Transaction Cost Theory (TCT) as the foundations, questionnaire as the technique and Structural Equation Modeling (SEM) to conduct the statistical analysis.

Keywords – Medical beauty, Artificial intelligence, Task-Technology Fit, Theory of Reasoned Action, Transaction Cost Theory

1 Introduction

1.1 Research Background

Medical Cosmetology, known as Medical Beauty, is medical procedures using surgery, medicine, machinery, biological material or invasive, inverse ale medical treatments to improve, repair appearance. The earliest trace of Medical Cosmetology can be found is cosmetics use by ancient Egyptian. Cosmetics was considered by ancient Egyptian a magic of beauty.

Taiwanese medical beauty research has been leading score among top competitors for cutting-edge surgical techniques. It is believed that the integration of medical beauty sector and e-commerce platforms operated in Taiwan offering virtual reality experience supported by artificial intelligence technology would have quite a significant economic impact on the markets across the globe. Dr. Chen and Dr. Tsai (2011) pointed out that the focuses on consumer relationship and user experience are left to be desired in medical beauty research such as providing distinct, innovative medical beauty services to differentiate products on Taiwanese market. Business has to pay attention to customer's needs or raise budgets to attract prospective customers (Kotler, 1997). Offering services meeting customers' needs are the keys to success of business parse.

1.2 Research Purposes

The research is to explore the implementation of AI in VR mode technology for the capabilities of e-commerce platforms and contributing factors for desired model fit. By using task-technology fit, the model should be able to predict effects of technology for consumer interests. Theory of Reasoned Action enabled the research model to predict outcomes according to Theory of Transaction Cost. After cost structure was also evaluated, the research finally moved on to validating the model to provide conclusions with sound empirical evidences.

1. Enhanced user's performance by implementing AI in VR mode for e-commerce platform of medical beauty industry.
2. Directed efficiency to the operation of AI in VR mode technology in detail based on established models.
3. The concepts of this research can be applied to other medical beauty related subjects for gaining global recognition or competitiveness of services.

2 Chapter II Literature Review

2.1 Task-Technology Fit Theory, TTF

TTF is proposed by Vessey (1991) from his research of Cognitive Fit Theory.

The individual's performance of a task could be improved with technology fit presented for the task. The relationship between technology fit and individual performance is the foundation of TTF. User's experience is directly related to the decision if incorporating technologies to tasks or not. The better the user's experience is, the more likely that the user will incorporate the technology to the task. The adaptation of

technology implies improvement of efficiency and decrease of required time of completing a task. Therefore, the Task-Technology Fit Theory proposed by Goodhue and Thompson (1995) is also supplementary to Cognitive Fit Theory.

The researcher added the factor, information security, as the seventh variable to the model based on the research conducted by Jagannathan (2018) regarding the subject. The model constructs are shown in the fig. 2.4.2.

As the fig. 2.4.2. shown, Goodhue believed that the increase of technology fit will lead to enhance of task fit, and this effect will compound to increase the demand of tasks. The increase of demand for the tasks can lower the task-technology fit. This research tested the assumed correlation between the demand of task and the increase of task-technology fit.

H1: The "Task Characteristics" by combining AI in VR mode in medical beauty related procedure has positive correlation with the "Goodness of Fit."

H2: The "Technical Characteristic" by combining AI in VR mode in medical beauty related procedure has positive correlation with the "Goodness of Fit."

H3: The "Safety" by combining AI in VR mode in medical beauty related procedure has positive correlation with the "Goodness of Fit."

H4: The "Goodness of Fit" by combining AI in VR mode in medical beauty related procedure has positive correlation with the "User's Preference."

H5: The "Goodness of Fit" by combining AI in VR mode in medical beauty related procedure has positive correlation with the "User's Utility Level."

H6: The "User's Utility Level." by combining AI in VR mode in medical beauty related procedure has positive correlation with the "User's Preference."

2.2 Theory of Reasoned Action · TRA

Theory of Reasoned Action is widely used in various subjects (Sheppard et al., 1988). Theory of Reasoned Action was studied by Fishbein and Ajzen in 1975 who thought the underlying reasons of human behaviour are all based on rational choices, and human are also capable of acting on collected information.

Extensive Research of Theory of Reasoned Action

Fishbein and Ajzen (1975) once mentioned the origin of Theory of Reasoned Action is Social Psychology. The methodology of Social Psychology has been usually deducting a complicate human behaviour from a series of events. The purpose of Social Psychology is to exploring and predicting human behaviour with assumptions of underlying human intentions. Fisher and Ajen conducted many researches about attitude, subjective norm, intention and other possible variables regarding intentions of human actions in 1970s. There were many adjustments and testing's during this period. The complete model structure was finally presented by Fisherbein and Ajzen with the theories of Attitude Toward Behaviour and Subjective Norm, to modify the previous theory of Fishbein Model. The Fishbein Model was originally based on two variables, attitude and subjective. Thus, the complete model structure was depicted as fig.

H7: The "Behavioural Belief" by combining AI with VR mode in medical beauty related procedure has positive correlation with the "Attitude Toward Behaviour."

H8: The "Normative Belief" by combining AI with VR mode in medical beauty related procedure has positive correlation with the "Subjective Norm."

H9: The “Attitude Toward Behaviour” by combining AI with VR mode in medical beauty related procedure has positive correlation with the “Behaviour Intention.”

H10: The “Subjective Norm” by combining AI with VR mode in medical beauty related procedure has positive correlation with the “Behaviour Intention.”

H11: The “Behaviour Intention” by combining AI with VR mode in medical beauty related procedure has positive correlation with the “Goodness of Fit”

2.3 Transaction Cost Theory, TCT

There are three characteristics of Transaction Cost Theory; first, Asset Specificity; second, Uncertainty; third, Frequency that are determining the transaction cost. The three characteristics are explained as below:

Williamson (1985) thought the most critical variable among the three characteristics is Asset Specificity. The more the Asset Specificity is, the less the cost of transaction would be because the organization will incline to internalize the transaction. The Asset Specificity is defined as the existence of tangible investment acquired to complete a certain transaction. There are three kinds of Asset Specificity: Site Specificity, Physical Asset Specificity, Human Asset Specificity and Dedicated Assets.

Uncertainty refers to unpredictable change from economical activities causing changes of expected outcome for the transaction. Koopmans (1965) clarified Uncertainty as two parts: the first part is unexpected events due to limited human rations; the second part is incompleteness, fabricated or twisted information due to deception or fraud. The higher the uncertainty is, the higher the cost of monitoring the transaction will be. Robertson & Gatignon (1998) further clarified the variety of Uncertainty: internal uncertainty (behaviour uncertainty) and external uncertainty (demand and technology uncertainty).

Williamson (1985) said that the transaction cost on e.g. communication, negotiation drafting contracts, etc., will rise for higher transaction frequency. Watjatrakul (2005) explained the Theory of Transaction Cost with characteristics of Asset Specificity, Uncertainty and Transaction Frequency, and specified two kinds of Uncertainty: Behavioral Uncertainty and Environmental Uncertainty (Watjatrakul 2005; Rindfleisch & Heide, 1997; Williamson, 1975). Kwon and Suh (2004) said that knowledge sharing between groups is a key factor after the supply chain partners has been determined. T.P. Liang and J.S. Huang (1998) also saw the three characteristics of Theory of Transaction Cost as factors if e-commerce platforms can make customers to decide to purchase products or not.

Transaction is the activity for all industries. The cost generated by economical activities conducted by business is transaction cost (Arrow, 1969). It is important to low the transaction cost for performance of the management and the business (Williamson, 1996). Hence, transaction cost of any activity is the top priority for business.

Transaction Cost Theory was originally proposed by Coase in 1937. According to Coase, market is imperfect instead of the then dominated theory of perfect market in economics. He pointed out that there are factors could affect transaction cost such limited human rations, uncertainty of the environment and asset specificity, and etc. Coase’s view of transaction cost was favoured by the academics at that time; hence, more specifications

had been defined until Williamson compiled organization, strategy, transaction and other related journals based on Coase's theory to create a more complete Theory of Transaction Cost. Williamson's work started to draw attention to the Theory of Transaction Cost.

The research is based on T.P. Liang & J.S. Huang's study of customer acceptance of electronic products that using Theory of Transaction Cost to propose the following assumptions:

H12: The "Asset Specificity" by combining AI with VR mode in medical beauty related procedure has positive correlation with the "Transaction Cost."

H13: The "Uncertainty" by combining AI with VR mode in medical beauty related procedure has positive correlation with the "Transaction Cost."

H14: The "Transaction Cost" by combining AI with VR mode in medical beauty related procedure has positive correlation with the "Performance."

2.4 Knowledge Sharing

Hendriks (1999) considered Knowledge Sharing as a process of communication and Reconstruction of knowledge. Reconstruction refers to knowledge receivers using collected information to learn and share knowledge. There are two essential parts of the main research structure:

1. Knowledge Owner has inclination of Externalization behaviour.
2. Knowledge Reconstruct or has Internalization behaviour.

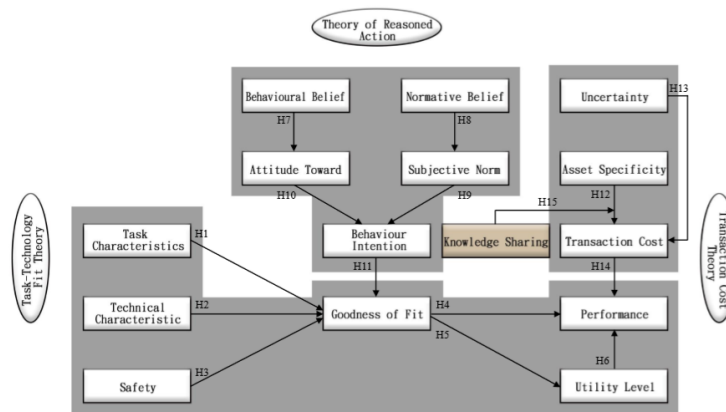

Hislop (2005) introduced the intentions of a group member sharing or hiding knowledge, and concluded the factors of the decision of sharing or hiding knowledge are: (1) Conflict of interests between groups and individuals (2) influence toward institutions (3) feeling toward justice and fairness of the group (4) trust between individuals (5) commitment between individuals (6) organization culture (7) reward system of human resource sector (8) reach and value of information sharing to the management. Corporation will keep competition edge by the active flows of knowledge in the economic system, therefore, corporation must produce knowledge to keep it as an invaluable advantage.

Petrash thought knowledge sharing between members can help improve the essential competitiveness of a corporation (Petrash, 1996). Giannetto & Wheeler said that employees should improve the process of knowledge sharing to create continuous improvement for the corporation (Giannetto & Wheeler, 2000). van den Hooff & de Ridder and Geppert & Clark also proposed the pros and cons of knowledge sharing in a corporation (Geppert & Clar, 2003; van den Hooff & de Ridder, 2004). As mentioned, studies above, business should encourage flows of knowledge among members to improve its competitiveness.

This research considered the action of knowledge sharing as a positively correlated variable of the model, and attempted to explore the influences of Attitude Toward Behaviour and Behaviour Intention to knowledge sharing. The assumptions of the above structure are as followed:

H15: The "Asset Specificity" and "Transaction Cost" in medical beauty related institution has positive correlation with "Knowledge Sharing."

3 Research Methods

3.1 Research Design

This research applied questionnaire and Structural Equation Modeling (SEM) to analysing the key variables. Structural Equation Modeling (SEM) is a statistical method consisted of sets of observed events and outcomes; usually, it is composed of multiple variables to form a theory based on “Cause and Effect” analysis (Byrne, 2010). Structural Equation Modeling (SEM) is also used to assess correlations between variables for theories in economics, social science and behavioural science (Golob, 2003). SEM combined various models to describe observed and latent variables, and also allowed quantitative tests on hypothetical models. Thus, the relationships between proposed variables of various hypothetical models can be tested to specify the model structure (Schumacker and Loman, 2004).

Adamantios Diamantopoulos, Judy A. Siguaw (2000) thought Path Analysis of Structural Equation Model (SEM) includes eight steps as followed: First, Conceptualization; second, Path Modeling; third, Confirmatory Factor Analysis; fourth, Model Specification; fifth, Factor Evaluation; sixth, Model Fit Evaluation; seventh, Model Respecification (repeat the first to the sixth step when any specification required); eighth, Cross Confirmation.

The research applied Random Sampling Method to choosing the anonymous participants by randomly giving away questionnaires. The questionnaires were collected later for further data analysis. The questionnaire was designed to understand the consumer behaviours in the medical beauty industry. The questionnaires were limited to maximum 200 questionnaires and given away to three major demographics of Northern Taiwan (55%), Central Taiwan (25%) to Southern Taiwan (20%) by proportions. The recycle rate of the questionnaires was 93%, 186 questionnaires in total; the disqualified questionnaire rate was 7%, 14 questionnaires. This questionnaire collecting was starting from January 1st, 2019 and ended on January 30th, 2019.

3.2 Research Analysis Method

The research applied statistical software, SPSS, Descriptive Statistics, the participants' information e.g., gender, age and education level from the second section of questionnaires to understanding the distribution of the samples and the recycle rate. The research also combined SEM, Regression Analysis and Cause and Effect method to analyse possible correlations between observed and latent variables and process control of deviations. PLS is a Diverse Statistical Analysis Method proposed by Herman (Herman, 1975), now to be widely used in various areas such as economics, marketing and psychology, etc. PLS is one of the model evaluation methods of SEM, using mostly Principal Components Analysis and Regression Analysis to allow the regression analysis to converge. The observed variables were evaluated before the latent variables for the step of model evaluation. This research is to illustrate the key variables influencing user's behaviours while implementing AI and VR technologies for tasks using Model Structure Diagram.

4 Research Results and Analysis

The research compiled data of qualified 186 questionnaires out of 200 questionnaires with 14 disqualified questionnaires, which made the recycle rate of the questionnaires 93%. The participants are whoever purchased medical beauty services or products in Northern, Central and Southern Taiwan.

4.1 Section I. Descriptive Statistics

The data is shown as Table 4.1. By gender, there is 76 male and 110 female participants of 186 participants that makes 40.9% of male participant and 59.1% of female participants. By age, there is 0 participant under age of 20 (0%), 54 participants between the age of 20 to 29 (29%), 40 participants between the age 30 to 39 (21.5%), 60 participants between age 40 to 49 (32.3%), 28 participants between age 50 to 59 (15.1%), 4 participants above than age 60 (2.2%). By education, there is 9 participants holding junior high degree (2.8%), 59 participants holding high school degree (18.6%), 145 participants holding bachelor's degree or equivalent (45.6%), 105 participants holding master's degree or equivalent (33%), 0 participant holding PhD degree or equivalent. By industry, there is 67 participants working in medical beauty industry (21.1%), 29 participants working in information industry (9.1%), 222 participants working in other industries (69.8%). By annual income, there is 1 participant earning annual income under NTD 290,000 (0.3%), 5 participants earning annual income between NTD 300,000 to 390,000 (1.6%), 13 participants earning annual income between NTD 400,000 to 490,000 (4.1%), 77 participants earning annual income between NTD 500,000 to 590,000 (24.2%), 222 participants earning annual income between NTD 600,000 to 690,000 (69.8%).

4.2 Section 2. Measurement Model Analysis

The research used Smart PLS 2.0 to conduct Path Analysis to test the credibility and quality of the questionnaire design. SEM and Measurement Model were tested for credibility and effectiveness. Structural Model was later validated for its variable significance and precision of predictability.

Confirmatory Factor Analysis is to test measurement model itself with PLS in the SEM to proceed the evaluation of models. Normal Distribution condition is not a requirement of PLS software nor large sample size. Minimum Square Analysis was applied to estimating measurement (Franz Michael Fischer, 2010). Thus, measurement model is composed of two parts as followed:

1. The convergence validity

Convergent Efficiency is the degree of fit of multiple variables to the same construct. The internal consistency is measured by Composite Reliability, CR.

However, the results of Composite Reliability are considered to be acceptable when the results meet the requirement CR value > 0.6 suggested by Fornell and Larcker (1981) and Cronbach's Alpha > 0.5 proposed by Nancy E. Waldeck (2000). Fornell and Larcker (1981) and Bagozzi and Yi (1988) all recognized that the ideal Average Variance Extracted, AVE value of the test results needs to be more than 0.5. However, AVE value is considered acceptable when the value is at least 0.3 or 0.4; it implied suffice Convergent Validity of the model. In short, the research results have shown there are suffice Convergent Validity of the assumed research models. See Table 4.2 for the test results.

Table 4-2 Convergence validity analysis results of measurement modes

	CR Value	Cronbach's Alpha	AVE
Task Characteristics	0.930	0.887	0.816
Technical Characteristic	0.939	0.919	0.755
Safety	0.947	0.888	0.899
Goodness of Fit	0.959	0.916	0.922
Behaviour Intention	0.904	0.840	0.758
Attitude Toward	0.887	0.807	0.725
Subjective Norm	0.885	0.806	0.720
Behavioural Belief	0.910	0.802	0.834
Normative Belief	0.923	0.833	0.857
Performance	0.940	0.872	0.887
Utility Level	0.959	0.916	0.922
Transaction Cost	0.942	0.876	0.890
Asset Specificity	0.921	0.857	0.853
Uncertainty	0.835	0.616	0.717
Knowledge Sharing	0.902	0.838	0.757

2. The discriminant validity

Joseph F. Hair (1998) suggested that the correlation coefficient between two different constructs should be smaller than the square foot of AVE value of either construct. If the

measurement of the two different constructs showed low correlation coefficient, it will mean there is Discriminant Validity between two constructs (Wu & Lin 2002).

As Table 4.3 shown the Discriminant Validity possible test results; by number, No. 1 refers to uncertainty; No. 2 refers to subjective norm; No. 3 refers to transaction cost; No. 4 refers to task fit; No. 5 refers to security; No. 6 refers to effectiveness; No. 7 refers to knowledge sharing; No. 8 refers to technology fit; No. 9 refers to performance; No. 10 refers behaviour belief; No. 11 refers to behaviour intention; No. 12 refers to attitude toward behaviour; No. 13 refers to normative belief; No. 14 refers to asset specificity; No. 15 refers to model fit.

Based on Table 4.3, the diagonal is the square foot of AVE value, non-diagonal is the correlation coefficient between variables. This research only targeted any two of different constructs with square foot of AVE value greater than the correlation coefficient. The test results showed consistency with Joseph F. Hair (1998) assumption about the correlation coefficient and square foot of AVE value.

4.3 Analysis of Structural Models

In this section, Path Coefficient is applied to analysing the statistical significance for data interpretation and the precision of outcome prediction for proposed research model. R^2 shows the precision of outcome predication by calculating the deviation percentage of Endogeneous Variable to Exogeneous Variable; the larger the value of R^2 is, the better the precision of outcome prediction is. The value of R^2 is defined to be between 0 to 1.

When T value > 1.65, it shows that the P value is possibly < than 0.05; when T value > 1.96, it shows that the P value is possibly < 0.01; when T value > 2.57, it shows that the P value is possibly < than 0.001.

Table 4-4 Study of Structural Model Hypothesis Verification Results

When T value > 1.65, it shows that the P value is possibly < than 0.05; when T value > 1.96, it shows that the P value is possibly < 0.01; when T value > 2.57, it shows that the P value is possibly < than 0.001.

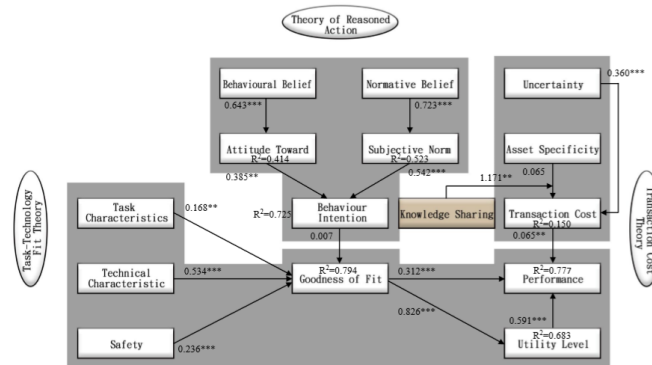

There are two kinds of moderator: mediated moderator and continuous moderator. Mediated moderator is the fixed data can be collected before the test such as gender, age, income, and etc. But it also could not be observed such as preference of product quality or price. If the variable is a mediated moderator, PLS-MGA (Keil et al., 2000) will be applied to the test. If the variable is a continuous moderator such as knowledge sharing, product-indicator approaches then the two-phase method will be applied to the test instead. If continuous moderator is affecting the correlation between two latent variables even a change of direction on such as observed value, the two latent variables will not be able to determined; yet, fluctuated with the moderator. This change or said deviation induced by the moderator is considered to be the center of the study, yet, Henseler and

Chin (Henseler & Chin 2010) thought product-indicator approaches would be a better choice unless prediction is the only goal of a study then two-phase method could take on.

If the correlation between A variable and B variable is 0.491 (the effect in the moderator mode), when the intervening variable is higher e.g. increasing one standard deviation, the dependence between A variable and B variable will weaken; on the other hand, when the intervening variable is lower e.g. decreasing one standard deviation, the dependence between A variable and B variable will strengthen. Hence, the dependence between A, B variable needs to be incorporated as a specification for model fit test (Joseph et al. 2017).

The study showed “model fit” was determined by task fit, technology fit, security and behaviour intention with the degree of dependence of 79.4%; “behaviour intention” was determined by subjective norm, behaviour belief, normative belief with the degree of dependence of 72.5%; “attitude toward behaviour” was determined by knowledge sharing with degree of dependence of 41.4%; “subjective norm” was determined by normative belief with the degree of dependence of 52.3%; “performance” was determined by attitude toward behaviour and subjective norm with degree of dependence of 77.7%; “Utility Level” was determined by normative belief with degree of dependence of 68.3%; “transaction cost” was determined by asset specificity and uncertainty with degree of dependence of 15%. The study results showed great structures of dependence between variables as Table 4.5.

5 Research Conclusions and Recommendations

5.1 Research Conclusions

The study compiled established researches to form theories and models by exploring underlying human intentions, behaviour's and contributing factors of implementing AI technology for medical beauty procedure and its potential of creating value around task-technology fit, theory of rational actions and theory of cost transaction. By adapting

research tool of PLS 2.0 (PLS-SEM), the conclusion was drawn that employees of medical beauty industry can improve performance of task and dependence between variables such as the three models of technology fit, rational behaviour, transaction cost and assumed fourteen constructs by executing task with AI in VR mode.

5.2 Research Contribution

AI in VR mode is a trendy research subject and popular topic nowadays. Breakthrough of AI and computer science could transform medical resource and digital technology around the world, and Taiwan of course will be one of the beneficiaries (John Gutttag, 2018). There is increased demand of AI technology from various industries, yet, one of the contributing factors of industry efficiency is whether or not equipping this technology. Since AI technology can help fetch the most fitting answers for the users in the enormous information database to reduce the requirements of time and slash the uncertainty during the process, the coexistence of human and AI technology is inevitably ubiquitous in modern days.

AI technology will allow the future to become “self-resolved”, and issue-oriented is not one-way transmission or old-fashioned memory testing anymore. Immersion education will be emphasized to free the learning from classrooms, yet, hands-on experience will be much valued in order to solve issues in the real world. People will be able to simulate situations with assumptions using VR technology to learn the solution with an empirical approach beforehand.

VR can be strategic to benefit and attract more users for medical beauty industry. The study concluded that VR mode in e-commerce is favored by the users, and one of the most crucial factors among all is task-technology fit. Because medical beauty procedure is very involved with issues of implemented technology and system, learning about the issues helped find their solutions. The researcher started to find the specifications by studying user’s subjective experience, needs and limitations of medical beauty products. After specified the variables, the convenience and security were further evaluated for the products. The function and efficiency were designed to meet user’s expectation of the products; therefore, technology fit has become an important reference to cope the ever-changing the economic environment for any updates of information.

The success of VR mode implementation can also be used in the subject of small business management. Disruptive innovations have brought important reform to traditional medical beauty business, not only changed its ecosystem but also directed to expansion and creativity for the industry. Small business has been proven that it can be a sustainable, explanatory business model that also create job opportunities and quality for human life. The profitability and cost level of small business hopefully can be improved by using VR mode and facial recognition with case studies of medical beauty industry.

5.3 Research Suggestions

This section continues to draw suggestions from mentioned research conclusions.

1. Management Suggestion

AI has been widely used in various areas. It is anticipated that this technology will make huge impact on the world. There are many concerns about loss of jobs by using AI technology. However, the researcher thought the implementation of AI and VR in e-commerce and medical beauty will help increase human's capacity and free people from jobs that merely repeating simply tasks. Furthermore, AI technology will also encourage people to work on innovation and creativity-cantered tasks that required human emotions. From a large picture, advance of technology improves society, economic development so it's good definitely outweighs the bad. We should wield the power of technology to improve environment for the human kind.

2. Poverty Reduction and Social Business Development

Many social entrepreneurs are trying to improve our society by exploiting their resources. Early business had hard time finding cutting-edge technologies, cultural resources, financial and medical resources. Established in 1981, the Ashoka Foundation dedicated to supporting social entrepreneurs. More than 90% of hundreds of millions of US dollars went to support the changes of national policies. They all replied on the continuous supports and strict criteria for the participants. When the leaders of the society stood out for creating more values for the society such Michael E. Porter's Creating Shared Value or Bill Gates's Creative Capitalism, it proved that business profitability and society merit are not exclusive anymore.

Social responsibility has been extended to the core values of private sector not merely a philanthropic act anymore. The Nobel Prize winner of 2007, Mohan Munasinghe, suggested ways of supporting sustainable growth of business, environment, and etc. Thus, it is utter paramount for businesses in Taiwan to support and create a better society with missions and values.

Abstract

The revolutionary changes in the financial environment in the past decade have led to changes in the convenience of information system users and the quality of the services. The investment industry fund raising fund uses the AI framework to create a smart fundraising model.

The use of AI framework by the investment fund raising foundation to create a smart model of fundraising to meet the goals set by the executives of the company will become an important issue.

This study is based on the task-technical fitness model and explores the positive growth of performance when the technical characteristics meet the goodness of fit of the task characteristics it supports.

Then, using the knowledge management system to investigate the historical fundraising model, and continue the successful knowledge management through AI, improve the user satisfaction of the information system, to achieve the company's desired fundraising goal, so that the growing performance of the fund can continue. The literature in the past does not combine the three theoretical relationships. This study combines the Task Technology Fit theory, the Knowledge Management System, and the Expectation Confirmation theory to explore the use of the AI model for the asset management industry. The key factors for the successful funds raised from the various enterprises are extracted. Through statistical analysis, these serve as a reference for relevant decision-making, increase the performance of raised funds and the efficiency of corporate organization, and to achieve the desired goal of raised funds set by the management. The subjects of this study are those who have not used the AI model structure and the users of the AI system, and use the online questionnaire to conduct convenient sampling, using questionnaires and SEM structural equation models for analysis.

The research result is to construct the AI model of fund-raising in the asset management industry, and proposes the main strategic direction for the asset management industry and the concept of the research results can be applied to the four major funds of the Taiwan government.

1 Introduction

This study holds that investment companies should develop artificial intelligence technology to replace the traditional fund-raising methods, to become a core player and possess long-term competitive advantages. Using the AI model strategy, the companies can actively monitor the market capital pulsation, aim for the future target market, and create the perspective of global investment layout.

The purpose is to investigate the funds raised by the asset management industry under the AI framework, the successful cases of fundraising of the past, the sharing of knowledge and utilizes the information system devices to extend the successful model, so that it can meet the growth expectation of the raising funds as set by the executives.

1.1 Motivation of Study

After the global financial crisis in 2008, the emergence of Financial technology ("Fintech") changes the traditional business model and financial domain, in the 2016 "FinTech 100 Financial Technology Innovator" research report by KPMG, Asia accounts for four of the top 100 companies, which is obvious that the power of continuance development in the Asia-Pacific region is strong. Closely related to Asia, we should actively expand the financial technology.

1.2 Purpose of Research

The purpose of this study:

- 1, To construct the AI mode for the asset management industry raising funds
- 2, The purpose of this study is to propose the main strategic direction for the asset management industry.
- 3, The concept of this research can be applied to the four major government funds.

2 Discussion of Literature

2.1 Task Technology Fit Theory

The Task Technology Fit (TTF) mainly originated in 1991 when Vessey mentioned the Cognitive Fit Theory. The major purpose is to understand the extension of the goodness of fit of the technological characteristics to the task characteristics it supports. When the adaptation mode between the two meets the goodness of fit, it will enhance the performance.

The study of system and performance based on goodness of fit is based on the Task Technology Fit model. The ability of Task Technology Fit technology to support tasks is represented by a formal model called TTF, which is defined as goodness of fit between the task characteristics and the technological characteristics (Goodhue, D. L. and Thompson, R. L, 1995). The TTF model holds that the goodness of fit between tasks, technology and information system users has a positive impact on the effectiveness and

performance of the system. When feature supports task, it assists the information system users to perform tasks more smoothly and the cost of performing tasks is reduced.

And when information technology supports task, users are accustomed to using new information technology. The function of information technology assists the task, which will reduce the cost of task execution and easy completion of the task.

2.1.1 Summary

In 2018, an information security incident occurred in the global semiconductor foundry leader, Taiwan Semiconductor Manufacturing Co., Ltd. The information security incident caused the company to lose NTD 5.2 billion, thus highlighting the importance of adding "safety" to the Task Technology Fit model.

The information system success model based on the results of Jagannathan et al. (2018) shows that the security and information quality of online banking applications will be the determining factor for success, thus it is extended to the model framework.

Base on the above, this study is based on the Task Technology Fit model proposed by Goodhue and Thompson (1995), and combining the concepts proposed by Jagannathan, Balasubramanian, & Natarajan in 2018, adding "safety" to the Task Technology Fit model as the third major aspect, emphasizes the importance of safety to technology.

Extend the theory mentioned above to this research, and establish the following assumptions:

- H1 The "task characteristics" of the fund raising AI model has a positive impact on the "goodness of fit" of the asset investment users.*
- H2 The "technology characteristics" of the fund raising AI model has a positive impact on the "goodness of fit" of the asset investment users.*
- H3 The "safety" of the fund raising AI model has a positive impact on the "goodness of fit" of the asset investment users.*
- H4 The "goodness of fit" of the fund raising AI model has a positive impact on the "IU satisfaction" of the asset investment users.*
- H5 The "goodness of fit" of the fund raising AI model has a positive impact on the "performance" of the asset investment users.*

2.2 Knowledge management system

Knowledge management is the academic and commercial application by Alavi and Leidner, which emerged in the mid-1990s. It is an activity that collects, stores and knowledge sharing of all organizations and members. Knowledge management is mainly a continuous process to help enterprises to enhance their performance, and by implementing knowledge management into technology to form the knowledge management system KMS (knowledge management system), providing knowledge to the information system users in need, and in turn, the knowledge of users of enterprise information systems is enhanced, and thus to improve their personal capabilities and external competitive advantages.

2.2.1 Summary

Based on the theories of all scholars, we derive at three aspects of goodness of fit of knowledge management and information systems, this paper attempts to construct a new strategic model of knowledge management system (KMS), which is based on personal traits, knowledge management system support, knowledge transfer has a positive impact on the degree of information system adaptation and continuous use of the inference.

Extend the theory mentioned above to this research, and establish the following assumptions:

H6: The fund raising AI mode uses the "personal traits" to positively influence the user's "goodness of fit".

H7: The fund raising AI mode uses the "system support" to positively influence the user's "goodness of fit".

H8: The fund raising AI mode uses the "knowledge transfer" to positively influence the user's "goodness of fit".

2.3 Expectation-Confirmation Theory

Oliver (1980) proposed the expectation confirmation theory ECT to explore the infrastructure, with expectation, confirmation, information system user satisfaction and utility level, performance has a total of five facets, and combining with "A Post Acceptance Model of IS Continuance (Bhattacharjee 2001), the proposed concept, expects to confirm that the Expectation Confirmation model ECM focuses on the variables after acceptance, and believes that the variables before acceptance are included in the degree of recognition and satisfaction; Expectation Confirmation Theory ECT only measures the pre-purchase expectations, but does not examine the consumer's subsequent expectations of the product which will change over time, so in the mode of continuous use of IS, ECM is more focused on the post-acceptance measurement model than ECT. ECM is a more suitable model for this study.

2-3-1 Summary

In summary, the effect of perceived performance is covered in the "confirmation" and this concept is defined as "after-the-event expectation". This study does not incorporate perceived performance. It attempts to construct a new theoretical model based, and base on the expectation and confirmation of the positive impact on the user satisfaction of the information system and the continuous use of the inference.

Extend the theory mentioned above to this research, and establish the following assumptions:

H9 The "expectation" of the fund raising AI mode has a positive influence on the "confirmation" of the asset management industry information system user.

H10 The "expectation" of the fund raising AI mode has a positive influence on the "goodness of fit" of the asset management industry information system user

H11 The “confirmation” of the fund raising AI mode has a positive influence on the “information system user’s satisfaction” of the asset management industry information system user

H12 The “information system user’s satisfaction” of the fund raising AI mode has a positive influence on the “utility level” of the asset management industry information system user

H13 The “utility level” of the fund raising AI mode has a positive influence on the “performance” of the asset management industry information system user

H14 The “information system user’s satisfaction” of the fund raising AI mode has a positive influence on the “performance” of the asset management industry information system user

2.4 Knowledge sharing

The aim of knowledge sharing is by organizing the exchange or discussion of knowledge between employees within the organization or between two organizations, and to create a synergy of knowledge. Nonaka & Takeuchi believe that in an uncertain economic system, knowledge is a mean of maintaining competitive advantages, and in order to uphold their superiority, enterprises must constantly create knowledge.

2.4.1 Summary

Based on the above, it can be known that knowledge sharing has a positive impact on enterprises. Therefore, this study, through the sharing of knowledge as a factor of positive adjustment effect, attempts to explore the impact of knowledge sharing on the willingness to use and satisfaction of use.

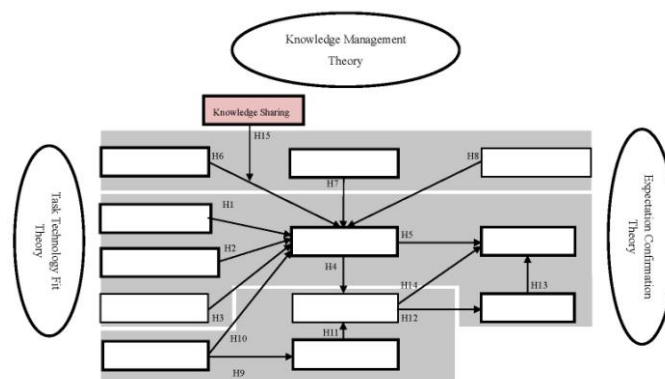

Extend the theories mentioned to this study, the following hypothesis are established:

H15 In the process of “personal traits” influencing the “goodness of fit” of the investment fundraising in the AI artificial intelligence model, knowledge sharing can have a positive adjustment effect

3 Research Method

3.1 Research framework

This section describes the exploration of the three theoretical frameworks of Task Technology Fit theory, Knowledge Management System and Expectation Confirmation Theory, and investigates the introduction of the AI model into the asset management industry, and so as to create new value of this research. The theoretical framework of the above research is drawn as the following:

1 Research Participants

In order to more objectively find out the key factors of the AI framework used in the asset management industry, the participant sample is selected as follows:

- (1) Questionnaire survey respondents are users of the asset management industry investment system, and they are picked by random.
- (2) Questionnaire survey respondents are users of the asset management related industry information system, they are picked by random.

To consider the convenience and effectiveness of sample collection, about 250 questionnaires will be distributed according to the normal distribution. The estimated effective questionnaires recovery is 77%, that is 191copies, and the invalid questionnaires are estimated at 5%, which is 9 copies, the survey will be carried out from January to March 2019.

2 Design of the Questionnaires

In order to ensure the quality of the questionnaire and the objectivity of the data, the facets and questions as designed in this study are based on the local and overseas related theories and literatures. This research questionnaire is divided into four parts and the questionnaire uses the Likert five-point scale for measurement, and uses the past literature theory as the basis for the questionnaire structure.

3.3 Research analysis method

The empirical tool for this research uses Smart PLS 2.0, with Smart PLS 2.0, the research model can be established, path coefficient and t-test can be calculated. The empirical method adopts the Structural Equation Modelling (SEM), and the structural model is to explore the causation between different latent variables and latent variables, and the “cause” assumed in the model refers to the exogenous latent variable, and the “effect” refers to the endogenous latent variable. This is to analyse and examine the relationship between the variable and the latent variable as well as to inspect the causation between latent variables, and to treat the errors of the control measurement, and so forth.

Partial Least Square (Partial Least Square, PLS) is a multiple statistical analysis method proposed by Herman (Herman, 1975), which is widely used in various research fields such as economics, marketing, psychology, and so forth. It is one of the ways to estimate the structural equation model which mainly uses the parameters of principal component analysis combined with multiple regressions to estimate and minimizes the residual error of the parameter of the given other parameters and repeat the estimation until convergence. When estimating the model, firstly, measure the relationship between each latent variable and the observed variable, and then measure the relationship between the latent variables.

4 Results of the research analysis

4.1 Descriptive statistics analysis

The basic data analysis of the research samples is shown in Table 4-1. In terms of gender: 72 males, accounting for 39.6%; 110 females, accounting for 60.4%, mainly are female.

In terms of age, 0 under 20 years old, accounting for 0%; 11 people in the 20 to 29 age group, accounting for 6%; 36 people in the 30 to 39 age group, accounting for 19.8%; 85 people in the 40 to 49 age group, accounting for 46.7%; 36 people in the 50~59 age group, accounting for 19.8% and 14 people over 60 years old, accounting for 7.7%, and most people are fall in the 40 to 49 age group.

In terms of education level: 0 below high school level, 0%; 5 from high school, accounting for 3.3%; 99 with general degree, accounting for 54.4%; 73 with master degree, accounting for 40.1%; 4 with doctorate degree, accounting for 2.2%, mostly are general degree. Employment: 51 in the financial sector, accounting for 28%; 50 in the service sector, accounting for 27.5%; 41 in other industry, accounting for 22.5%; 28 in commercial industry, accounting for 15.4%; 12 in the industrial , accounting for 6.6%; mostly are from financial sector.

In terms of annual income: 2 with NTD300K or less, accounting for 1.1%; 27 in the range of NTD 300K to 590K, accounting for 14.8%; 45 in the range of NTD 600K to 990K, accounting for 24.7%; 85 in the range of NTD 1000K to 1,990K, accounting for 46.7%; 23 in with more than NTD 2 million and above, accounting for 12.6%, mostly are from the group of NTD 1000K to 1.99 million.

Table 4-1 Sample basic data analysis

Total sample 182	Number of people(person)	Proportion(%)	Total sample 182	Quantity (人)	Proportion(%)
Gender			Employment sector		
Male	72	39.6%	Financial industry	51	28%
Female	110	60.4%	Service industry	50	27.5%
Age			Others	41	22.5%

Below 20	0	0	Business	28	15.4%
20~29years old	11	6%	Industrial	12	6.6%
30~39 years old	36	19.8%	Annual income		
40~49 years old	85	46.7%	Below 300K	2	1.1%
50~59 years old	36	19.8%	300K~590K	27	14.8%
Above 60 years old	14	7.7%	600K~990K	45	24.7%
Education level			1000K~1,990K	85	46.7%
Below high school level	0	0	Above 2000K	23	12.6%
High school	5	3.3%			
General degree	99	54.4%			
Master degree	73	40.1%			
Doctorate degree	4	2.2%			

4.2 Analysis of measurement method

In order to test the reliability and validity of the questionnaire, this study adopts the Smart PLS 2.0 to analyse and to further understand the path relationship and impact of this model. In order to understand the quality of the structural equation model (SEM), first of all, the reliability and validity of the Measurement Model must be tested, after which the path coefficient significance and predictive power of the Structural Model are examined.

In this section, in the analysis of the measurement mode, the Confirmatory Factor Analysis (CFA) is a test in the measurement mode. The evaluation of the measurement mode analysis uses the PLS in the structural equation to verify the mode. It is not necessary to consider the multivariate normal distribution on the PLS. It is also not necessary to consider large samples, and the estimation measurement adopts the least squares method for estimation (Franz Michael Fischer, 2010). Therefore, the reliability and validity analysis of the measurement model is divided into two parts:

1, Convergent validity

Convergence validity means that the multiple variables are measured on the same facet with the same degree of conformity. The internal consistency assessment criteria are based on the composition reliability.

When the results of Composition Reliability (CR) are in accordance with the recommended values of $CR > 0.6$ as proposed Fornell and Larcker (1981) and Cronbach's Alpha > 0.5 , proposed by Nancy E. Waldeck (2000), these can be accepted.

Fornell and Larcker (1981) and Bagozzi and Yi (1988) also suggest that the Average Variant Extracted (AVE) of individual facets should preferably be > 0.5 , but when the

average variable extraction (AVE) meets the standard of at least 0.3 or 0.4, it is generally accepted, that is, the facet has sufficient convergence validity. In summary, it shows the latent variables in the measurement mode of this study possesses good convergence validity. The analysis results are shown in the following table.

	CR Value	Cronbach's Alpha	AVE
Task features	0.906	0.792	0.827
Technology features	0.889	0.750	0.800
Safety	0.900	0.832	0.750
Goodness of fit	0.830	0.612	0.712
Personal features	0.880	0.733	0.786
Expectation	0.915	0.860	0.782
Support of system	0.898	0.773	0.815
Knowledge transfer	0.892	0.758	0.805
Knowledge sharing	0.881	0.731	0.788
Performance	0.932	0.854	0.873
Utility level	0.894	0.764	0.808
IU satisfaction	0.906	0.844	0.762
Confirmation	0.879	0.725	0.784

2, Differential validity

According to suggestion made by Joseph F. Hair (1998), the correlation coefficient between two different facets should be less than the square root of AVE of each facet. The two different facets are measured and the results are correlated. If the degree of correlation is very low, it means that the two facets have different validity (Wu Wanyi, Lin Qinghe, 2002).

As shown in the table below, the results of the differential validity analysis of each latent variable. The value of the diagonal is the square root of AVE, and the non-diagonal is the correlation coefficient between each variable. The square root values of AVE of all facets in this study are greater than the correlation coefficients between the two facets, indicates that it is compliance with the suggestion made by Joseph F. Hair (1998): the correlation coefficient between two different facets should be less than the square root of AVE of each facet.

	1	2	3	4	5	6	7	8	9	10	11	12	13
1.Task features	0.9094												
2.Personal traits	0.3825	0.7860											
3.Security	0.7365	0.4811	0.8660										
4. Utility level	0.5513	0.3298	0.5911	0.8989									
5.Expectations	0.5155	0.3448	0.4925	0.6626	0.8843								
6.IU satisfaction	0.5638	0.4141	0.6705	0.7529	0.6442	0.8729							

7.Knowledge sharing	0.4994	0.3787	0.5579	0.6082	0.5284	0.5506	0.8877						
8.Knowledge transfer	0.4571	0.2537	0.4854	0.4950	0.4920	0.4922	0.5009	0.8972					
9.Confirmation	0.4592	0.3021	0.5040	0.6419	0.7258	0.7159	0.5194	0.5244	0.8854				
10.Technology features	0.7224	0.4568	0.7394	0.5304	0.5093	0.5836	0.6004	0.4930	0.4274	0.8944			
11.System support	0.4257	0.4217	0.4710	0.5790	0.4835	0.5261	0.5412	0.6689	0.4562	0.5079	0.9028		
12.Performance	0.5936	0.3784	0.6551	0.5667	0.5208	0.5687	0.5665	0.4861	0.4208	0.6131	0.5064	0.9343	
13.Goodness of fit	0.6096	0.4266	0.5953	0.5913	0.6014	0.5337	0.5223	0.5085	0.4586	0.6269	0.5225	0.5906	0.8438

4.3 Analysis of Structural Models

There are two steps to the Structural equation modeling (SEM) analysis and interpretation:

The first step is to verify the reliability and validity of the measurement mode, and the second step is to detect the significance and predictability of the path coefficients of the structural mode.

After confirming that the reliability and validity analysis of each facet has reached a certain level, this study adopts the Smart PLS 2.0 to perform causation analysis and research hypothesis verification of the structural model latent variables, and judges the research model by R^2 explanatory power

In the analysis of structural models, this section considers whether the standardized Path Coefficient is statistically significant and to gauge the explanatory power of the model. R^2 refers to the percentage of exogenous variables which explain the variation of endogenous variables, and represents the predictive power of the research model. The value is between 0 and 1.

The bigger the value, the better is the interpretation ability of this model.

When the T value > 1.65 , it means that the significant level of P value < 0.05 has been reached, which is represented by *; when the T value is > 1.96 , it means that the significant level of P value < 0.01 has been reached, which is represented by **; when the T value is > 2.57 , it means a significant level of P value < 0.001 has been reached, which is indicated by ***.

Therefore, from the results of the verification of the overall mode relationship path, it can be found that: Except for H3 : The "safety" of the fund raising AI model has a positive impact on the "goodness of fit" of the asset investment users; H6 : The fund raising AI mode uses the "personal traits" to positively influence the user's "goodness of fit"; H7 : The fund raising AI mode uses the "system support" to positively influence the user's "goodness of fit"; H8 The fund raising AI mode uses the "knowledge transfer" to positively influence the user's "goodness of fit", the above four hypotheses did not reach $p < 0.05$ significant level. The relationships of the other ten paths are significant, and the hypotheses are valid. This is shown in the table

Interference variable H15 In the process of "personal traits" influencing the "goodness of fit" of the investment fundraising in the AI artificial intelligence model, the

hypothesis that knowledge sharing has a positive adjustment effect has not reached $p < 0.05$ significant level

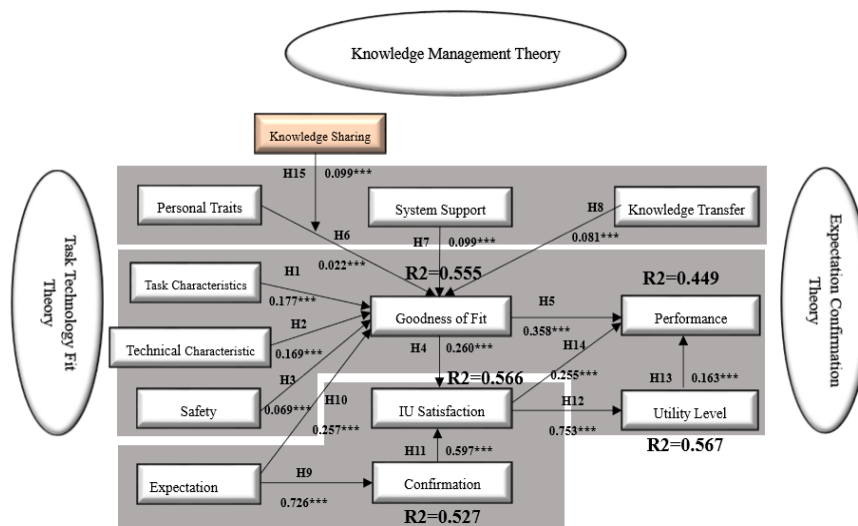

Hypothesis	Relationship	Path coefficient	T value	Significance	Verification results
H1 The "task characteristics" of the fund raising AI model has a positive impact on the "goodness of fit" of the asset investment users.	+	0.177	2.2003	**	Valid

H15 In the process of "personal traits" influencing the "goodness of fit" of the investment fundraising in the AI artificial intelligence model, knowledge sharing can have a positive adjustment effect	+	0.099	0.196		Invalid

Note: When the T value is > 1.65, it means that the significant level of P value < 0.05 has been reached, which is represented by *; when the T value is > 1.96, it means that the significant level of P value < 0.01 has been reached, which is represented by **; when the T value is > 2.57, it means A significant level of P value < 0.001 has been reached, which is indicated by ***.

Finally, the study found that the goodness of fit was affected by task technology, technology characteristics, security, personal traits, system support, knowledge transfer and expectations, and the variation of the goodness of fit is 55.5%; confirmation is affected by expectations, and the variation explanatory power for confirmation is 52.7%; "Information System User Satisfaction" was affected by confirmation and the goodness of fit, and the variation explanatory power of "Information System User Satisfaction" is 56.6%; the "utility level" is affected by the user satisfaction of the information system, and the variation explanatory power of the "utility level" is 56.7%;

"Performance" is affected by goodness of fit, information system user satisfaction and utility level, and the variation explanatory power of "performance" is 44.9%. This shows that the variation explanatory power of this research model is good, which is as shown:

This study found that the path coefficient of "personal traits" to "goodness of fit" is 0.022, and the path coefficient of the adjustment variable of "knowledge sharing" to "goodness of fit" is 0.099.

The variables of the knowledge management system are "personal traits", "system support" and "knowledge transfer", and because they do not have significant effect, the natural interference variable "knowledge sharing" also failed to achieve significant effect.

Therefore, under the premise of being invalid, there are two main reasons for analysis:

1, Knowledge Management System (KMS) is usually supported by the computer system support, which belongs to part of the technology, whereas "personal traits", "system support" and "knowledge transfer" have no such fitness with technology.

2, Knowledge management system, in the past, is the extension of academic theory applied to medical treatment, and the continuation of manufacturing know-how.

Because the asset management industry is part of the financial industry and this group of customers usually belong to the top level of the pyramid, and in recent years, under the advocacy of individual capital laws, the confidentiality of customer is very important. The use of fund raising model in the asset management industry is not applicable, therefore, the moderating effect does not have any significant adjustment effect on the relationship between the variable A and the variable B.

5 Conclusions

5.1 Research conclusion

The conclusion in this section is based on the purpose of this study, and achieves three specific research contributions:

5.1.1 Construction of a AI model for raising funds in the asset management industry

This study explores the key influencing factors for the introduction of AI models in the asset management industry. Base on the three theories of Task Technology Fit theory, Knowledge Management System, and Expectation Confirmation Theory, and combining the variables of Information Technology, variables of Management Science and variables of Psychology, to form a new structural equation model (SEM).

Furthermore, this study is based on the Task Technology Fit theory, Knowledge Management System and Expectation Confirmation theory. With these three theories as foundation, the sample questionnaire is used to modify and construct the main facet and evaluation criteria, and the structural equation model (SEM) is used as the statistical analysis. Finally, these three theoretical structural equation models (SEM) summarize the important indicators of the conclusion - the explanatory power R^2 , in the order: utility level (56.7%), information system user satisfaction (56.6%), user satisfaction (68.9%), goodness of fit(55.5%), confirmation (52.7%) and performance (44.9%). The above shows that the explanatory power of this study is good.

5.1.2 This study proposes the main strategic direction for the investment industry.

Based on the model constructed in the preceding paragraph, this study proposes the strategic direction of the AI model for investment fundraising:

The import of AI model results in the users of the information system dedicated to deep learning. The study found that the user satisfaction of the information system will positively affect the user's effectiveness in using the information system, and affect the performance of the fund-raising industry. According to the study, the asset management industry can strengthen the on-the-job training, enhance the personal computer literacy of the information systems users, enhance the self-efficacy of computer users, and enable them to fully understand the support of the information system, provide technical support and transfer of knowledge, so that task can be completed by the flexible use of the functions provided by the information system, and thus to improve the work performance.

Innovation differentiation - The extension of the positional differentiation theory from the "five competitive forces" and "three competitive strategies" proposed by Michael Porter, positioning the asset management industry AI model, in addition to reducing cost, it can also expand the services to customer base, shorten the space which affects the variables, and improving the performance of the fund-raising rate. Therefore, strengthening the core knowledge or competitiveness of the asset management industry, generate specific business models through appropriate strategic innovation, and then use information and network tools to match the physical market, to promote sales of the asset management industry.

5.1.3 The concept of this research can be applied to the four major funds of the Taiwan government.

The four major funds commissioned by the Taiwan government are the Labor Insurance trust, Labor retirement fund, pension trust and the post savings fund. In accordance with the government's decree, each affiliated institution shall, depending on the performance of each investment, the amount is adjustable or the account is discontinued each year.

To apply the research results of the AI model of the asset management industry to the application and operation of the four major funds of the government, to avoid disintermediation due to human factors, will effectively reduce the cost of commission of the four major funds. The performance of the agency assigned with the funds will be effectively achieved, and the four funds under the control of the government can be used flexibly, and the welfare of the whole nation can be recycled in the positive direction.

5.2 Research suggestions

After the specific research conclusions are obtained in this study, the research proposes that it can provide the application to the Ashoka Foundation in conjunction with social enterprises to promote public welfare.

Established in 1981, the Ashoka Foundation is dedicated to fostering social enterprises. Tens of millions US dollars have been invested and more than 90% of the social enterprises have achieved the original entrepreneurial goals. Even more than half of the social enterprises have promoted changes in national policies, which rely on the strict selection criteria and follow-up resources of the Ashoka Foundation. It shows that corporate profit and social value are no longer two strange parallel lines, so the asset

management industry can further cooperate with the Ashoka Foundation in the future, and to promote public welfare actively.

Abstract

Blockchain is the most disruptive innovative technology and application after the Internet. Acceptance of the users for blockchain technology from potential adopters to acceptance rate between real adopters, through the transaction risk, transaction cost and transaction piping, word of mouth penetration, perceived intentions and feelings after use, will affect the acceptance and the amount and speed of use of satisfaction and loyalty. The objectives of this study were to examine the perception of blockchain investors on the quality of investment relationship (integrity, commitment, and satisfaction) of virtual currency, and the impact on investors' investment behavior (behavioral loyalty) and investment intention (attitude loyalty) in virtual currency. We conducted a questionnaire survey in early 2019. After a rigorous screening of valid questionnaires and statistical analysis, 515 valid questionnaires were collected. We used SPSS statistical package to performed the multiple regression analysis to explore the multivariable analysis of relationship quality perception and customer loyalty. The regression model showed that the commitment, integrity, and satisfaction together can explain 82.6% variance of customer loyalty, while behavior loyalty and attitude loyalty are 79.9% and 80.0%, respectively. In sub-dimensions of investment relationship, integrity ($b=0.269$ to 0.540 , $p<0.001$) and satisfaction ($b=0.657$ to 1.389 , $p<0.001$) were positively associated with behavioral loyalty, attitude loyalty, and customer loyalty. The trading platform of integrity, commitment, and satisfaction for investors in the investment behavior of virtual currency — has a positive influence on behavior loyalty. This research enhanced our understanding of the determinants of consumer complaining behaviors. The study results can provide implications to the enterprise, to allocated limited resources to meet the actual needs of customers, and shorten the gap between the customer's expectation and actual perception of the service quality, and further Increase customer satisfaction and the positive image of the company.

Keywords –Virtual currency, Block chain, Relationship quality, loyalty

1 Introduction

The blockchain is a technology that connects numerous blockchains, and it is a technology that does not rely on a third party to store, verify, transmit and communicate data through distributed nodes in the network. Due to its key characteristics of disintermediation, consistency, source traceability, and unalterability, blockchain is the most disruptive innovative technology and application after the Internet. Acceptance of the users for blockchain technology from potential adopters to acceptance rate between real adopters, through the transaction risk, transaction cost and transaction piping, word of mouth penetration, perceived intentions and feelings after use, will affect the acceptance and the amount and speed of use of satisfaction and loyalty, after all is critical for the popularity of new technology. With the development of the virtual economy, the virtual business model has been evolving, which is closely related to the real economy. Therefore, in order to attract and meet the needs of investors, virtual currency platform operators must first understand the important psychological factors of different investment groups in the investment of virtual currency. In this paper, we were answering the research question: do blockchain investors' perception of the integrity, commitment, and satisfaction of the virtual currency trading platform affect their investment behaviors and intentions in the virtual currency trading platform? The objectives of the current research were: 1. To explore the perception of blockchain investors on the quality of investment relationship (integrity, commitment, and satisfaction) of virtual currency, and the impact on investors' investment behavior (behavioral loyalty) and investment intention (attitude loyalty) in virtual currency. 2. To explore the influence of investment on the characteristics of virtual currency, platform involvement and investment loyalty of investors.

1.1 Relationship quality integrity

Integrity is defined as the belief that one party's needs will be met in the future by the actions of the other party (Anderson and Weitz, 1992).

1.2 Commitment to relationship quality

Commitment to a relationship may occur only if the exchange relationship is worth the effort to maintain, and once committed relationships to occur, neither party will easily change the relationship, even if a third party offers a more valuable piece (Ulaga and Eggert, 2006).

1.3 Satisfaction with relationship quality

Customer satisfaction is defined from the two concepts of customer evaluation and comparison, which is considered as a cognitive state of whether the customer is appropriate between the purchase and payment (Hunt and Sheth, 1969).

2 Methods

In this study, we conducted a questionnaire survey, followed up and collected for nearly half a month in March 2019. The questionnaire collection was completed in early 2019. After a rigorous screening of valid questionnaires and statistical analysis, a total of 530 questionnaires were distributed and 520 were recovered (98% recovery rate). Among them, 515 valid questionnaires were collected (98% recovery rate).

We conducted the statistical analysis based on the research framework. This paper puts forward several investors involved in the relationship quality on consumer behavior loyalty and attitude loyalty of community, platform research hypothesis, to investigate whether loyalty type of RBL and RAL construction investment has positive influence on differences and relationship quality at the same time with the three dimensions (commitment, integrity, satisfaction) as the important connotation of the index, and relevance of the investment behavior loyalty and attitude loyalty, individual analysis to explore the various dimensions of relationship and interaction between possible impact. We used SPSS statistical package to performed the following analysis: (1) descriptive statistics: describe sample traits, perception of relationship quality, and customer loyalty; (2) reliability analysis: the test of the consistency of the scale; (3) independent t-test: multivariate analysis of relationship quality perception and customer; (4) correlation analysis: a bivariate analysis of relationship quality perception and customer loyalty; (5) regression analysis: to explore the multivariable analysis of relationship quality perception and customer loyalty.

3 Results

The Characteristics of the blockchain investors were shown in Table 1. In terms of the purpose, frequency, cost and method of investment of investors, the proportion (92.80%) of asking whether they have heard of virtual currency; This ratio is higher than that of those who have heard of blockchain (79.6%), indicating that some groups are still unfamiliar with the new field of blockchain (Table 2). On average, the cost of each investment in virtual currency is the highest among those who have not invested (53.6%), while the cost of those with investment experience is the highest among those who have spent more than 160,001 (15.7%). The interesting part of this option is that the groups that have not invested are relatively conservative, and those that have not been contacted have greater doubts about their risks and legitimacy. Investors who have invested in virtual currencies will spend a relatively large amount of money to make investment bets. The purpose of investing in virtual currency is to gain investment profit (43.8%) is the highest; Why the option of not investing in virtual currency is the highest with no relevant knowledge (36.1%), it can be seen that people who have not invested yet will worry about the volatility of their investment risk because they have no relevant information about blockchain.

Influence of commitment, integrity, and satisfaction on customer loyalty table shows the correlation coefficient and significance of all variables with attitude loyalty and

behavior loyalty (Table 3). The results show that all variables, including integrity, commitment, and satisfaction, have a significant and positive relationship with behavior loyalty and attitude loyalty.

As shown in Table 4, commitment, integrity, and satisfaction can explain 80.7% variance of customer loyalty, while behavior and attitude loyalty are 79.9% and 80% respectively. Meanwhile, the overall regression model has a significant effect (customer loyalty, $F=807.794$, $p<0.001$). Behavioral loyalty, $F=682.786$, $p<0.001$; Attitude loyalty, $F=678.173$, $p<0.001$). Furthermore, the parameters were positive and the sub-dimensions of customer loyalty were significantly tested, such as sub-dimension commitment (customer loyalty, $=0.934$). Behavioral loyalty, $=0.675$; Attitude loyalty, $=1.022$); Sub-dimensions of integrity (customer loyalty, $=4.241$, $p<0.001$; Behavior loyalty, $=4.09$, $p<0.001$; Attitude loyalty, $=3.714$, $p<0.001$), sub-dimension satisfaction (customer loyalty, $=12.339$, $p<0.001$). Behavioral loyalty, $=11.283$, $p<0.001$; Attitude loyalty, $=11.361$, $p<0.001$).

4 Discussion

4.1 Main findings

From the perspective of consumer behavior, this paper analyzes the platform loyalty and investment behavior of investors. The paper also discusses how virtual currency investors perceive the relationship quality of trading platforms. In addition, how the relationship quality of trading platform affects the behavior loyalty and attitude loyalty of investors is the motivation of this paper. Tarkinen & Sundqvist (2009) believes that the cognitive process of consumers' attitudes towards products is different from the actual buying process. In this context, this study intends to explore the factors of investors' participation in the cash transactions of virtual currencies and to understand the effect of the factors of loyalty dimensions through the relationship quality theory. It is expected that the results of this study can bring many valuable Suggestions to the new field of virtual currencies.

Investment for today are doing financial planning of the investing public, is not willing to contact virtual currency this reason may not be understood in the field of block smelting technology and operation principle, so can't understand the value of the virtual currency, or feel that the quality of the virtual currency risk is too high, uneven and news reports often exchange is formidable, lead to the currency is transferred and so on. The virtual currency lacks the same quality and meaningful investment analysis as stocks and funds, as well as the real-time information pipeline, which is what repealing the general public.

Through the statistical data, the operators of the blockchain virtual currency platform can better understand the investors and potential investors who have not yet been involved, and can better understand the basic demand of investors. The questionnaire platforms filled in by investors from the questionnaire samples include Bitoex, bitopro, Maicoi, niudun, ACE Exchange, huobin, Okex, Gate, Joyso, Binance, Mbaex, Wcee, Eunex, Cex, taichi, Bittrex, Hitbtc, Bibox, btc-e, Mt Gox, coinec, Ktrade, TideBit, starbit, Coinbase, Bitfinex, Bitasset, Mbaex and other virtual trading platform operators. The questionnaire respondents gave the following suggestions to the industry: user preferences become fast! Service is not good enough, it will only be replaced by the exchange of ability to provide better service, the survival of the fittest, virtual currency are often the culprit of fraud, bad image, increase service quality, investors are more at ease, no more public commentary, speed, and price transparency can sharpen and optimization, technology, can let a person more comfortable, more credit than other currencies, credit is to value, strengthen information security, more investors will be assured, eliminate the doubts of the information technology and increase the credibility of the market, we will invest, virtual currency is a great potential market, Need to do a good job of customer relations with investors and so on the virtual currency industry advice.

Further analysis, which can be found that the relationship quality and customer loyalty behavior loyalty and attitude loyalty achieves very significant positive correlation, said investors for block smelting industry promised, the greater the degree of virtual currency investors to block the affected virtual currency smelting industry in

recommended to others or continue to use the investment platform will charge. The hypothesis (the relationship quality of trading platforms has a positive impact on investors' investment behavior in virtual currency - behavioral loyalty) and the hypothesis (the relationship quality of trading platforms has a positive impact on investors' investment intention - attitude loyalty in virtual currency) is also initially supported here.

It shows that investors' trust and satisfaction positively affect their customer loyalty. However, its commitment does not reach a significant standard for investors, and its commitment does not significantly affect their loyalty. As can be seen from the table, when the constant is negative, it means that when the commitment, integrity, and satisfaction are all zero, the intention of investors is basically negative, and loyalty to the virtual currency platform will not be generated actively. When the behavior loyalty constant is positive, investors will be willing to come back and reinvest, and they will also want to continue to invest for profit. However, when the attitude loyalty constant is negative, investors are willing to invest, but they will not actively recommend it to other investors due to risks or other factors, which is also consistent with the investment environment and current situation of the entire virtual currency.

Comprehensive the above, the relationship between the overall quality of behavior loyalty and attitude loyalty, and overall customer loyalty to support, but individual dimensions observation, we for the virtual currency industry, its commitment to relative to the other sub-dimensions, the virtual platform providers are not important, operators should be more focus on investors' satisfaction first, followed by the good faith. Since the services provided by virtual platform, operators are complex and difficult to understand, and trust has the function of reducing investors' cognitive risk, the results of this study suggest that to gain investors' trust, we should first obtain their satisfaction. Finally, the more trustworthy the investor is, the higher the promise will be likely to be generated. Therefore, in order to obtain the promise of the investor, the first step is to gain his trust.

4.2 Management implications

With the rise of the virtual world and the innovative business model of the blockchain industry linking various industries and the business opportunities of the virtual currency platform, the trading mode is also between the virtual and the real. Such trading mode is not only a means but also an inevitable path. This paper discusses the relationship quality of virtual trading platform and the loyalty between investors. The statistical results prove that the relationship quality and its sub-aspects have a profound impact on investors and their sub-aspects.

After a complete analysis, the results of this study have important implications for the management practices of virtual trading platform operators, as described below. For the virtual trading platform of the blockchain, few researchers have investigated the relationship quality and loyalty of the virtual trading platform. Therefore, the research in this paper is of great significance to the sample data of the operators of the virtual trading platform. The model of relationship quality and loyalty has been widely used in academic and practical fields. In the field of the innovative blockchain, operators of virtual trading platforms should think about how to improve the relationship quality to enhance the

loyalty and integrity of investors, strengthen the commitment and obligation of virtual trading platforms to investors, and improve the satisfaction of investors in the use of virtual trading platforms.

This study confirms that relationship quality can effectively increase the willingness of investors to continue to use the virtual trading platform and promote their positive recommendation to others. For investors, the services provided by virtual currency traders will directly influence their buying intentions to consumers. The higher the perception of relationship quality, the higher the degree of potential consumer psychology. Contact and discuss with the filling volume, most of the known virtual platform trading patterns and virtual trading terms, in the actual operation situation or subsequent derived problems, there are some shortcomings, may block is a very new industry chain, this research clearly noted that the investors of risk associated with virtual platform of cognition and doubt, hope through the finishing and the results of this study, combined with the past literature evidence and information integration, allows users to further know more about the virtual trading platform operators, and further understand the importance of virtual currency trading behavior. Therefore, this research can help virtual currency managers to have a deeper understanding of investors' attitudes and behaviors, and to develop potential investors easily. It is expected that this research will provide them with practical Suggestions.

4.3 Research limitations

There are two major limitations regarding the generalizability of this study. First, this study is focused on the consumers based in the metro Taipei area, the results might not be applied to all kind of customers in the market. Second, this study is focused on one particular product and service. The study results might not generalized to all the industry.

4.4 Conclusions

The trading platform of integrity, commitment, and satisfaction for investors in the investment behavior of virtual currency — has a positive influence on behavior loyalty. This research enhanced our understanding of the determinants of consumer complaining behaviors. The study results can provide implications to the enterprise, to allocated limited resources to meet the actual needs of customers, and shorten the gap between the customer's expectation and actual perception of the service quality, and further Increase customer satisfaction and the positive image of the company.

Abstract

Facing progressively more intense competition, telecom carriers think on how to evaluate servicing business customers and optimize the relationship in between, so as to increase revenue and profits. With the Rapid development of network technology and popularization of smart phones devices, the mobile APP (Application, referred to as APP) has penetrated into our lives. Telecom service provider has launched customer service mobile Applications (for many years). In addition to save the human burden of the customer service system, more importantly, it can provide more service experience and construct new virtual channels for product sales.

There are limited studies on the comparison of technology acceptance model and switch cost among online and traditional channel while a lot of researches related to the effectiveness of switching costs was published. This study uses the Unified Theory of Acceptance and Use of Technology Model (UTAUT) as the main architecture to explain behavioral intention. The main variables are performance expectation, effort expectation, social influence and facilitating conditions, and plus conversion costs, to observe whether there is a regulatory effect between the conversion cost and the relationship between behavioral intention and usage behavior.

Keywords –unified theory of acceptance and use of technology (UTAUT), application, willingness, conversion cost

Paper type – Academic Research Paper

1 Introduction

It shows that for a long time, telecom operators have achieved stable revenues through traditional communication services. But in fact, the value of domestic telecommunications is in a recession. It shows that the global telecommunications industry is facing a transformational challenge, and it must be transformed from a pure information highway to a more Yuan service provider. According to the statistics of the National Communications and Communications Commission, the output value of Taiwan's mobile communications in the first half of 2018 has decreased by 4.67% compared with last year. In recent years, the voice income has been declining year by year, which is more than expected. Therefore, telecom operators must seek to provide differentiated services to users, trying to open up new businesses with higher margins and higher added value, in an attempt to transform into overall service providers.

With the increase in social labor costs and the rapid advancement of technology, many companies have begun to encourage the development of more technology-based services within the organization (Dabholkar, 1996). In this context, the creation of a model that allows customers to complete services without having to contact the service staff is called "self-service technologies (SSTs). The development of SSTs not only improves the efficiency of the company, but also allows Customers can flexibly choose the time of use and have more choices on service models. The telecom customer service APP proposed by various telecommunication industries is a self-service technology belonging to consumers.

The era of smart phones is also the era of APP. The mobile app has penetrated into different industries and our life scenes, such as daily shopping, transaction transfer, market intelligence and so on. For enterprises, APP is not only an interactive platform with customers, but also a strategic tool for enterprises. It can also help business owners to deepen their channel management and internal operation monitoring. Although there are many physical stores, official websites and telephone customer service, all major mobile operators also have their own customer service APP, in addition to saving the human resources of the customer service system, more importantly, it can provide users with more immediate services.

In order to make telecommunications services closer to customers and save customers' troubles, telecom operators have launched customer service APPs to provide customized and mobile service content. The 24-hour transaction has zero time difference, and the service functions provided by various telecom operators' customer service APPs are similar. However, which service functions are truly capable of generating value to the user, which cognitive values are affected by different service functions, and the impact of the user's perceived value on subsequent behaviors, using the results of this study to provide telecom operators in marketing Management decisions.

This study considers that the use of telecom customer service APP by customers is also an act of accepting new technology. Therefore, the research department combined with the integrated technology acceptance model (UTAUT) as the framework of this study plus " conversion cost " as the interference variable, and through the literature Inductively and through the distribution of questionnaires to obtain data and analysis to

explore the causal relationship between various factors affecting consumer behavior, the research conclusions provide telecommunications operators in the management and formulation strategies as a reference, so the research objectives of this study are:

1. Exploring the relationship between the UTAUT research variables and the "behaviour intentions" of the telecom customer service APP.
2. Exploring the relationship between consumers' "behavior intentions" and "actual use behaviors" of telecom customer service APP.
3. Using "conversion cost" as the interference variable, examine the interference effect of the conversion cost on the relationship between the "behavior intention" and the "actual use behavior" of the telecom customer service APP.

2. Literature research

This section collects relevant literature for the research purposes proposed in this study. The content is divided into four sub-sections, including four topics: " Unified Theory of Acceptance and Use of Technology ", "Telecom Customer Service App", " conversion cost ", and " willingness ". Discuss it.

2.1 Unified Theory of Acceptance and Use of Technology

Theory of Reasoned Action (TRA) is one of the most fundamental and influential theories of human behavior. Besides, there are seven other commonly used theories as follows: the Motiva Model (MM), the Model of PC Usage (MPCU), as well as the Social Cognitive Theory (SCT) and the Innovation Diffusion Theory (IDT). Including the famous Theory of Planned Behavior (TPB/DTPB), the Technology Acceptance Model (TAM/TAM2), and also the combination model between the Technology Acceptance Model and the Theory of Planned Behavior (C-TAM-TPB).

Unified Theory of Acceptance and Use of Technology was proposed by Vakatesh et al. (2003) in order to review and consolidate the previous eight theories, which then is referred to "the originating article" because of numerous authors cited it. The eight models were examined through four different organizations in half a year. In comparison to UTAUT, the eight models had 17% less capability to explain the variation of the same database (Abraham et al., 2016). In other words, this theory alone is capable to explain around 70 percent of the variance of behavioural intention and around 50 percent of the variance of use behavior (Abed et al., 2015). In addition, UTAUT does not only provide a useful tool to evaluate the potential success of new technology initiation, but also identify factors likely to influence adoption of technology.

UTAUT categorizes the intention of use information technology (IT) from the eight models into four main constructs: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI) and Facilitating Condition (FC). According to Vakatesh et al. (2003), definition of every construct listed below:

(1)Performance Expectancy

The degree to which an individual believes that using the system will help him or her attain gains in job performance

(2) Effort Expectancy

The degree of ease/effort associated with the use of the system. (3) Social Influence

The degree which an individual perceives the important others believe that they should use the new system.

(4) Facilitating Conditions

The degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system.

The original model of UTAUT suggested four moderators that are Gender, Age, Voluntariness of Use, and Experience. UTAUT does measure individual's intention to adopt and use the new technology.

2.2 Telecom Customer Service App

Mobile device users can download mobile software applications for free or for a fee via the wireless network to the mobile software app store. In addition to browsing and trading through a web browser such as a general online store, the mobile software app store usually also has a proprietary app that allows users to enter with one click and the interface is more convenient than the web page.

From the development of the customer service center, it can be found that the multimedia service center of the multi-service pipeline has indeed entered the service center. In addition to telephone, fax, network, MSN, and now even the development of the telecom customer service APP, the customer service center can communicate with customers. The diversification of customer service channels has also added a lot of convenience. The mobile communication industry is a representative of service and technology competition in all walks of life. He needs to face the fierce challenges of customer and service innovation. When mobile devices continue to grow, operators must care about the needs of customers. The pipeline of communication between customers and customer service personnel must also constantly seek new changes. In this era of creativity, innovative customer service is needed, and the research theme of this research is the customer service pipeline "Telecom Customer Service APP".

2.3 Conversion Cost

The conversion cost was first proposed by Porter (1980) and refers to the one-time cost incurred when a consumer moves from one provider of a product or service to another. The so-called one-time cost refers to the cost incurred in the conversion behavior, not the converted continuous cost, and includes the information search, evaluation, transaction, post-transaction learning and adaptation, etc., which is not only economically It is also time, energy and emotion, and it is an important factor that constitutes a competitive barrier for enterprises. If a customer moves from one company to another, they may lose a lot of time, effort, money, and relationships, so even if they are not completely satisfied with the company's services, they will think twice.

Most scholars agree with the existence of customer conversion costs, but different scholars have different understandings about their categories and forms of expression. In the study of customer conversion cost categories, the marketing scholars Burnham, Frels,

and Mahajan (2003) are most representative and are grouped under three broad categories of potential variables: time-dependent program-based conversion costs, Financial conversion costs related to monetary benefits, and relationship-related conversion costs related to emotions. The sub-facial aspects of the study have yielded significant results in testing both the US credit card and long-distance telephone companies. The three major facets are as follows:

1. Procedural switching costs
2. Financial switching costs
3. Relational switching cost

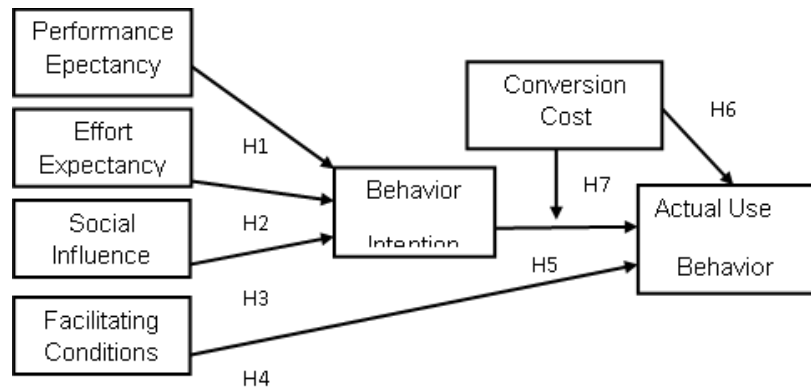

2.4 Behavior Intention

According to Ajzen (1998), behavioral intentions represent the subjective probability that an individual wants to engage in a certain behavior, the so-called behavior intention. Many studies using the theory of rational behavior (TRA) in social sciences point out that In an ethical situation, if an individual's determination of an act is correct or beneficial to oneself, it means that the individual is more likely to engage in the act; from a behavioral theory point of view, the more intention to perform an act Strong, the chances of engaging in this behavior are higher (Sheppard, Harrwick, and Warshaw, 1988; Venkatesh and Davis, 2000; Venkatesh and Agarwal, 2006). In the past, many related research paradigms have pointed out that there is a significant relationship between behavioral intentions and actual use behaviors and high explanatory power (Randall and Wolff, 1994; Sheeran and Orbell, 1998). Therefore, Peter and Olson (1987) proposed a measure of behavioral intentions that can be used to presuppose the actual use behavior and can be applied to the marketing market to predict consumer behavior. Therefore, the measurement of the actual use behavior in behavior theory by behavioral intention is also called the intention mode (Fishbein and Ajzen, 1975).

3 Research design and methodology

This chapter builds research design and methodology based on the research motivation and background, research purposes and related literature. The content is divided into five sections, including "research structure", "research hypothesis", "questionnaire design", "research distribution and research objects". "Data Analysis Methods and Tools."

This study uses (Unified Theory of Acceptance and Use of Technology, UTAUT) as the theoretical framework to explore the customer's willingness and behavior to use the telecom customer service APP with performance predictions, effort expectations, social influences, promotion conditions and behavioral intentions. And use the program-type conversion cost, financial conversion cost and relational conversion cost in the conversion cost as the interference variable to explore the influence of user behavior on the behavior of the telecom customer service APP. Research structure is as follows

The research model and research hypothesis of this study is shown in Figure 3-1, which integrates the four theoretical aspects of UTAUT: performance expectations, effort expectations, social impact, promotion conditions, and behavioral intentions and actual use behavior, plus the process of switching costs. Three types of conversion costs, financial conversion costs, and relational conversion costs.

H1: The use of the "performance expectations" of the telecom customer service app has a positive impact on "behavioral intentions".

H2: The "effort expectation" of using the telecom customer service APP has a positive impact on "behavioral intentions".

H3: The "social impact" of using the telecom customer service app has a positive impact on "behavioral intentions".

H4: The "promotional conditions" of using the telecom customer service APP have a positive impact on the "actual use behavior".

H5: The "behavior intention" of using the telecom customer service APP has a positive impact on the "actual use behavior".

H6: The higher the conversion cost of using the telecom customer service APP, the negative impact on the "actual use behavior".

H7: The "conversion cost" of using the telecom action customer service app has a regulatory effect on "behavioral intention" and "actual use behavior"

4 Conclusions

Therefore, the era of smart phones is also the era of APP. The mobile application APP has penetrated into different industries and our life scenes, such as daily shopping, transaction transfer, market intelligence and so on. For enterprises, APP is not only an interactive platform with customers, but also a strategic tool for enterprises. It can also help business owners to deepen their channel management and internal operation monitoring. Although there are many physical stores, official websites and telephone customer service, all major mobile operators also have their own customer service APP,

in addition to saving the human resources of the customer service system, more importantly, it can provide users with more immediate services.

Abstract

The purpose of this study is to illustrate the process that ended in a pilot project titled “Incubiamo Cultura” (a label playing with the words Incubator-Love and Culture), presented by some academic entrepreneurs who envisaged the possibility to create a network among public (i.e. the university, the Municipality, public cultural organisations) and private actors.

Based on a sound literature review in both the field of entrepreneurial university and cultural ecosystems, the authors adopted an action research approach to analysing a paradigmatic case study.

This paper contributes to filling a gap of research on the role of universities in a cultural ecosystem, focusing on how to design a new value chain for the launch of startups in the creative and cultural sector, where universities can play a catalyst and pivotal role.

Keywords – Cultural Startups, Entrepreneurial University, Value creation, Networking approach

Paper type – Academic Research Paper

1 Introduction

Within the field of entrepreneurial university research (Etzkowitz 2003, 2004; Guerrero & Urbano, 2012; Secundo et al. 2010, 2016), this paper investigates an issue neglected in literature concerning the role universities can play in incubating startups in the cultural and creative sectors as well as in promoting participatory cultural initiatives (Piber et al., 2019).

For this reason, this paper is the first bridge between two different streams of research, that is: “entrepreneurial university” and “cultural ecosystems”.

Research carried out in the area of cultural ecosystems has investigated under what conditions culture triggers an economically effective, socially sustainable development, and it may even be defined as “a leading growth engine” (Sacco et al., 2014). These studies share the assumption that special patterns of collaboration between diverse actors should be pursued in order to create value out of particular cultural-creative initiatives (Borin & Donato, 2015).

Supporting a networking approach in culture and creative contexts requires get together diverse actors, ranging from public to private, industrial associations, local communities, as well as citizens. The literature clarifies that, through a participatory approach, creative clusters, as well as cultural initiatives, lead to urban development (Throsby, 2010) and regeneration (Bailey et al., 2004; Sasaki, 2010).

In particular, the purpose of this study is to illustrate the process that ended in a pilot project titled “*Incubiamo Cultura*” (a label playing with the words Incubator-Love and Culture), presented by some academic entrepreneurs who envisaged the possibility to create a network among public (i.e. the university, the Municipality, public cultural organisations) and private actors. The rationale of that project is to respond to the cultural needs that emerge from the degraded and/or peripheral neighbourhoods of medium-sized Italian cities like Genoa. Despite the fact that the city holds a UNESCO heritage of great value, Genoa has undergone a strong economic and social decline in recent years and lately has represented the need of our country to invest in the regeneration of its infrastructural heritage, due to the collapse of its highway bridge.

The expected result of the *Incubiamo Cultura* project is to generate cultural and creative enterprises in urban spaces and make use of underused or abandoned cultural heritage assets. The goal can be achieved thanks to the leading role that the universities, and in particular entrepreneurial academics, can carry out through networking and training, incubation and acceleration of cultural and creative enterprises.

2 Literature Review

In the last few years, the university system has undergone a profound process of rethinking and reorganisation (Etzkowitz, 2004), and its institutional aims have also changed, including teaching, research and economic and social development (Etzkowitz, 2002; 2003). Universities should also play a role in the exploitation of research results and fostering the economic and cultural growth of regions and countries (Etzkowitz, 2002).

Our literature review focuses on the role that academic organisations can play in our society. In detail, we are interested in the role that an entrepreneurial university can play in creating and supporting a cultural ecosystem with the aim to create economic and social value. In line with the four pillar of sustainability (Hawkes, 2001) and the Sustainable Development Goals (SDG), we deem that in a knowledge economy universities might play a central role in creating societal value and fostering sustainable development goals. This is true if at least two conditions are satisfied:

- The first is that a university undergoes a strategic and managerial path to create the conditions to be systematically engaged in entrepreneurial activities;
- The second is that a university opens up to the external environment, strengthens interactions with its stakeholders and actively promotes collaborative relationships with business and institutional partners to contribute to the development of its ecosystem(s).

2.1 Entrepreneurial Universities

An entrepreneurial university can be any university that contributes and provides leadership for the creation of entrepreneurial thinking, actions, institutions and entrepreneurship capital (Audretsch et al., 2008).

Universities engage, for example, in entrepreneurial activities such as technology transfer, intellectual property management, participation in science parks, incubators, university spin-offs and other processes aimed to implement the third mission of the university (Wright, 2014). These activities can be referred to as forms of academic entrepreneurship mostly conceived as a practice performed with the intention to transfer knowledge from the university to the external environment in order to produce economic and social value.

For the sake of our research, it is important to highlight that most of the literature on academic entrepreneurial activities has investigated the issue of academic, technological spin-offs (Venturini and Verbano, 2017). Special emphasis has been put on the setup of spin-offs and factors affecting their creation, competitive success and profitability (Dameri et al., 2015; Dameri & Garelli, 2016).

Furthermore, up to this point, many scholars have delved into the topic of how a university that has included the third mission in its strategy should be managed (Etzkowitz, 2004; Secundo et al., 2016).

Academic entrepreneurship arises from internal as well as external impetuses. Referring to external drivers, scholars question how public policies have called for the growing engagement of universities within their regions and localities in the last few years (Slaughter et al., 2004).

As far as the inner impulse is concerned, some scholars have focused on how specific organisational units, such as the Technology Transfer Offices (TTO) can facilitate the commercialisation of the research output (Friedman and Silberman, 2003). Others discuss that collaborative, entrepreneurial learning processes between entrepreneurs and university students provide a coherent and systematic approach to generate, select and implement entrepreneurial practices (Simeone et al. 2018). Etzkowitz (2003) addressed the topic of how universities should support research groups that he defines as “quasi-firms”. The creation of research communities that transcend the single institution is, in fact, the first phase of a process that may subsequently result in the economic exploitation of the products of research, which Etzkowitz (2003) called the “capitalisation of knowledge”.

The decisions by individual faculty members to actively engage in technology transfer and, generally, in the third mission have been investigated by many scholars (Franklin 2001; Bercovitz & Feldman, 2008 D'este, P., & Perkmann, 2011), but, in our opinion, still deserve further consideration. Related to the last argument is the role of the academic entrepreneur. "The academic entrepreneur is a university scientist, most often a professor, sometimes a PhD student or a post-doc researcher, who sets up a business company in order to commercialise the results of his/her research" (Formica et al., 2008). However, academic entrepreneurship can also be understood as a particular behaviour to be adapted by researchers in order to modify the pattern of university research activities (Balasz, 1996). We deem that this issue is a key aspect of the existing debate in literature. We wonder whether projects concerning the third mission have to be governed by a central, top-down logic or the university should play its role in creating favourable conditions so that the so called entrepreneurial academics—thanks to their pro-activity, commitment and creativity—can develop, in a bottom-up approach, entrepreneurial initiatives and activities.

2.2 Entrepreneurial Ecosystem

Recently, the entrepreneurial ecosystem has emerged as a popular concept to explain the birth of high-growth entrepreneurship within regions. Entrepreneurial ecosystems can be defined as "the union of localised cultural outlooks, social networks, investment capital, *universities*, and active economic policies that create environments supportive of innovation-based ventures" (Spigel, 2017).

In the literature on regional development, it is well known that universities play a pivotal role in providing knowledge and innovation stimuli to the firms of the territory (Roberts and Eesley, 2011; Corbett et al. 2014).

Generally speaking, ecosystems can vary by network intensity and organizational variety. However, ecosystem conceptualisations generally focus on the role of networks and their ability to provide firms with resources and information to challenge a constantly changing competitive environment. Specifically, Autio and colleagues (2014) focused on the potential of ecosystems, among other perspectives, to provide a more nuanced understanding of entrepreneurial performance, emphasising the role of individuals and inter-organizational networks.

Referring to academic entrepreneurship, while a considerable body of literature investigates individual and firm-level characteristics associated with the success of university spinoffs, only recent works have also emphasised the importance of the ecosystem for academic entrepreneurship (Miller et al., 2017; Hayter et al. 2018).

Similarly to Autio et al. (2014), Hayter (2016) within the context of academic entrepreneurship, posits that the efficacy of academic entrepreneurship ecosystems depends on the interconnectivity of constituent elements and their collective ability to provide information and resources important for spin-offs' success.

Moreover, it is worthwhile to underline, even with reference to the field of study on ecosystems, from the meta-analysis by Hayter et al. (2018), that "hard" disciplines (i.e. Biotechnology, Engineering, Information technology, Life sciences, Physics) and

technologies transfer conditions (i.e. broad scope, patenting and licensing versus spinoff) are the variables that scholars concentrate on. To conclude, as far as we know, the role universities can play in incubating startups in the cultural and creative sectors as well as in promoting participatory cultural initiatives is neglected in the literature.

2.3. Cultural Ecosystems

Research carried out in the area of cultural ecosystems has investigated under what conditions culture triggers an economically effective, socially sustainable development (Sacco et al., 2014).

These studies share the assumption that special patterns of collaboration between diverse actors should be pursued in order to create value out of a particular cultural-creative initiative.

The cultural initiatives promoted by institutional partners and/or public-private partnerships, as well as the creation of cultural clusters, can lead to the regeneration of the urban fabric (see the emerging literature on creative cities) and an impact on quality of life and the well-being of citizens (UNESCO, 2003).

Culture is an intangible good that comes from previous generations and represents our identity as citizens. As per the definition of Bourdieu (1986), cultural capital (a person's knowledge and intellectual skills) provides the advantage of achieving a higher social status in society. From a collective point of view, culture is the substructure of society because it gives meaning to our lives and society. Indeed, through culture, people and groups define themselves, conform to society's shared values and contribute to society.

Spreading and increasing culture is a mission for universities but, in democracy, it is also an assignment for policymakers and public officials to ensure that culture remains a common good (Gielen et al., 2015). For this reason, in recent years the United Nations has emphasised the fundamental role of culture for sustainable development, and the European Union has promoted initiatives to preserve our cultural heritage and supports cultural and creative industries (Damien & Galeazzi, 2016). However, despite this sharing of intents between institutional actors and universities, no scholar has investigated the role that universities can play in promoting a cultural ecosystem.

In conclusion, this analysis shows the following research gaps:

- The literature on entrepreneurial universities and entrepreneurial ecosystems focuses mainly on the role of universities as incubators of high-tech startups or technology transfer actors, despite the emerging relevance of creative and cultural initiatives for regeneration and local development.
- The literature on cultural ecosystems has neglected to investigate the role that an entrepreneurial university can play as a leading engine to create economic and social values.

This paper aims to contribute to filling this gap, focusing on how to design a new value chain for the launch of startups in the creative and cultural sector, where universities can play a catalyst and pivotal role.

In particular, it sheds light on:

- the process through which academic entrepreneurs can give impetus to the improvement of the University third mission;
- the catalyst role that Universities can play in activating and sticking to different resources/capital/actors/stakeholders for the success of cultural initiatives with high socio-economic impact and the birth of new ventures in the cultural and creative sector.

3 Methodology

Based on a sound literature review in both the field of entrepreneurial university and cultural ecosystems, the authors adopted an action research approach to analysing a paradigmatic case study.

3.1 Case selection

The case investigated concerns the process that ended in a pilot project titled “Incubiamo Cultura”. The latter was launched by an academic entrepreneur, who envisaged the possibility to design an initiative that leads the University of Genoa in playing a pivotal role in supporting new ventures in the cultural and creative sector. Meanwhile, it responds to the cultural needs emerging from the degraded neighbourhoods of the city in order to foster urban regeneration.

The main reasons why we selected this case are because it is an exemplary case due to the fact that the authors are directly involved in the project (one as the founder and orchestrator of the initiative and the other being involved as an observer-participant). In addition, it is a successful initiative and it is a very rare case of an Italian university acting as a leading engine actor in a cultural project for urban regeneration.

3.2 Action research approach

According to Reason and Bradbury (2006, p. 1), action research is a process that “seeks to bring together action and reflection, theory and practice”. Consistent with the interpretative approach, this is a case study whereby the researchers are involved in the initiative, offering solutions for actual problems and contributing to theory at the same time (Dumay, 2010).

Action research as a methodology considers not only the observations of the researcher but also the impact the interventions have on the real world. The researcher's main benefit is the ability to develop insights into the implementation of management actions.

There is not an agreed set of methodological protocols, or rules, shared by all researchers; however, action research usually begins with the Entry Stage, which in our case can be aligned with the launch of the initiative in 2017. Diagnosis is a pivotal stage in action research, as the researcher(s) may introduce organizational members to conceptual schemes and/or theories that enable them to reinterpret how they perceive their situation. The ultimate goal of this phase is to develop a conscious understanding

among organizational members and to co-determine and plan possible interventions. This paper, coming from a period of discussion and debate with the different stakeholders engaged, is an outcome of the diagnosis phase of the project.

The intervention stage will follow, during which both practitioners and researchers try to implement management innovation.

3.3 Data collection and data analysis

Data were collected from 2018 to 2019 by the authors, who acted as “participant-observers.”

Data used for the analysis come from different sources:

- (1) notes from meetings and discussions about the goals, opportunities and threats of the project “Incubiamo Cultura” that have been produced throughout two years, from the inception of the project so far (March 2019);
- (2) proprietary reports and documents;
- (3) No. 7 unstructured interviews with relevant stakeholders from the project (Fontana and Frey 1998). They helped the promoter of the project to reach a better understanding of the complexity of the phenomena and its dynamics (Qu and Dumay 2011). The interviewees were one manager of the University’s TTO; five experts from the commission in charge to assess the business models drawn by the students and one councillor for culture and events from the city of Genoa.

Data analysis was an ongoing process. In the first step of the data analysis, the author/founder of the project created a rich description of the case, drawing on her experience and putting together interviews and data from different sources. Then each author read the empirical material independently and categorised the stream of words into meaningful categories, via manual open coding. Subsequently, the results obtained by each author were compared and discussed to highlight the main levers of the success of the initiatives and the possibility to replicate them in other contexts.

4 Case study - the main constituent elements

Incubiamo cultura is a pilot project currently in progress in the Department of Economics and Business Administration at the University of Genoa. It was born from a successful educational experience, a Master class in Entrepreneurship for cultural heritage, which obtained a grant under the European Social Fund–Education, Skills, and Life-long learning axis. The Master class was the occasion used to observe the needs emerging from aspiring entrepreneurs and conceptualise the idea of an entrepreneurship value chain, where universities play a pivotal role in supporting new ventures, especially in the cultural and creative domain (Joglekar and Lévesque, 2013).

This program is innovative, as numerous previous actions of universities in supporting and incubating start-ups are especially focused on hi-tech companies, neglecting other business sectors and especially cultural and social entrepreneurship. In the meantime, educational initiatives in the cultural and creative sector focus mainly on management and not on entrepreneurship (Comunian and Gilmore, 2016).

Incubiamo cultura aims to create physical spaces in urban areas and neighbourhoods, where cultural and creative start-ups can work closely with citizens, to restore abandoned cultural assets and deliver cultural initiatives (Rinaldi et al., 2018). It works by carrying out initiatives for the co-working, incubation and leveraging of new companies in the cultural and creative sector.

However, the final goal of this pilot project is also (or especially) to investigate the replicability and transferability of the core constituent elements of the project and the main processes to realise it.

The peculiar aspects of this project are the processes, actors, participatory approach and values.

The core constituent elements of the project are represented in Figure 1 as they emerged gradually in the creative path underlying the project design. In detail, there is not a hierarchic logic but an increasing degree of interconnections and complexity among the different depicted elements.

Figure 1- “Incubiamo cultura” project main constituent elements

Processes

The underlying belief in planing Incubiamo cultura is that young people attending a Master class in entrepreneurship want to become entrepreneurs, but they have not got enough instruments for success in their venture. The start-up phase is a difficult path requiring mentoring and support, and also an ecosystem able to incubate the “newborn” firm.

For this reason, the Master class is only one step towards building entrepreneurial capacity in a city, neighbourhood or region. To really create value thanks to educational programs in entrepreneurship it is necessary to implement the following main processes:

- *Scouting*, that is, a selection of the best aspirant entrepreneurs and, concurrently, the best business ideas in the cultural and creative sector;
- *Education*, that is, master programs especially addressed to the selected aspiring entrepreneurs;

- *Incubation*, that is, setting up a physical place and mentoring activities that support new ventures in their first steps;
- *Dissemination*, because “one swallow does not a summer make ”: the pilot project should be communicated, participated and especially replicated thanks to a protocol that is able to reproduce the experience in different cities, urban areas and neighbourhoods to multiply the positive impacts.

Actors

To start the project the pivotal role is played by academic entrepreneurs, as they have the characteristics and capability to transform their competence into triggers for the initiative. Moreover, innovative academic entrepreneurship is the outcome of a mix of different university activities, emerging from research, education and third mission, that is, the transfer of academic knowledge into business practice. However, cultural entrepreneurship is a particular field of business, involving not only entrepreneurship *strictu sensu* but also special patterns of collaboration between diverse actors, such as local government, citizens, not-for-profit organizations, district communities, neighbourhood committees, local schools and other actors of the civil society. In a single word, it is “territory” where the physical space of Incubiamo Cultura will be settled. This peculiar aspect determines the crucial role of local networks.

Incubiamo cultura involves five main actors in a network cooperation:

- The University of Genoa that, thanks to its academic entrepreneurs, can play a catalyst and pivotal role in leading the whole project;
- the Municipality of Genoa, especially the Culture Directorate and the Real estate Directorate: the former will support the individuation of cultural needs of the neighbourhoods, the latter will provide buildings belonging to the Municipal cultural heritage, which are currently abandoned and tattered;
- Palazzo Ducale, a cultural foundation playing the role of the main partner in supporting the cultural start-ups in developing their cultural programs;
- Talent Garden, a private company leader in managing co-working space for innovative startupper, delivering courses and supporting meetings amongst potential business partners. Its role is to transfer knowledge about co-working and fostering business;
- Day One, a private company leader in cultural communication, to implement communication strategies for both start-ups and the pilot project.

It is worth underlining that the representatives of all the partners have already been involved in teaching or mentoring during the Master class, and it is thanks to the experience of Incubiamo cultura that synergies have been individuated and pursued.

Participatory Approach

Incubiamo cultura aims to create several spaces where cultural and creative firms can spring up, grow and flourish, restoring abandoned cultural assets and delivering artistic and cultural performances to citizens. This cultural profile requires the active

participation of people in defining their cultural needs, restoring the cultural heritage and enhancing the neighbourhood (Demartini et al. 2018). Therefore, a participated, bottom-up approach is required to grant the initiative success, as the initiative is carried out to respond to the cultural needs that emerge from the neighbourhoods.

Values and aims

Differently from hi-tech start-ups, cultural start-ups pursue not only financial value but also social value (Evans, 2005). Financial value is not only a driver of wellness and richness for a community but also a driver for job creation and economic development in the long term. Social value regards culture dissemination, arts promotion and civilisation. Restoration and the upgrading of cultural assets and valorisation of cultural heritage are a must. For these reasons, creating a cultural incubator is not only an economic initiative, but a complex initiative and the not-for-profit nature of universities is crucial to support and spread these values among the different actors of the network and the stakeholders involved.

5 Discussion: a lesson to be learnt

Incubiamo Cultura has been designed keeping in mind some pivotal aspects and drivers of success:

- the implementation of a set of activities linked to an “Entrepreneurial Value Chain”;
- the creation of a network of actors involving academic players, public and private bodies;
- pursuing a mix of values (i.e., cultural, social, economic and environmental);
- the sustainability and replicability of the experience, thanks to a collection of best practices to be translated in standard processes.

As far as the Entrepreneurial Value Chain is concerned, the project is mainly based on the linking of a sequence of processes—the Entrepreneurial value Chain—aiming to create a mix of economic and social values through the activities that support entrepreneurship in the creative and cultural sector. This value chain faces the main problems affecting aspiring entrepreneurs, especially in the cultural and creative sector. In a nutshell, a university can offer the education to fulfil the lack of managerial skills affecting most potential entrepreneurs, whose education has been built in the Arts and Humanities domain, services for the implementation of the business idea and networking and relationships.

The project focuses on some core processes:

1. the entrepreneurial education, conceived as leverage to settle innovative and sustainable cultural start-ups, able to overcome the seed stage of their life also thanks to mentoring (Kuhlke et al., 2015);
2. the process of incubating and accelerating new ventures, as a leverage to create economic value, skilled jobs and cultural milieus;

3. co-working, intended not only like a space or a new way to organise labour but especially like a tool to develop a cultural community of creative entrepreneurs working in the urban areas spread throughout the city (Spinuzzi, 2012; Merkel, 2015);

The main success factor of this initiative is the chain of processes, in which each process exploits the value created by its antecedent and feeds the value creation of the one that follows. As shown in Figure 2, the value creation process is an incremental path from the selection of participants to the acceleration of the created firms.

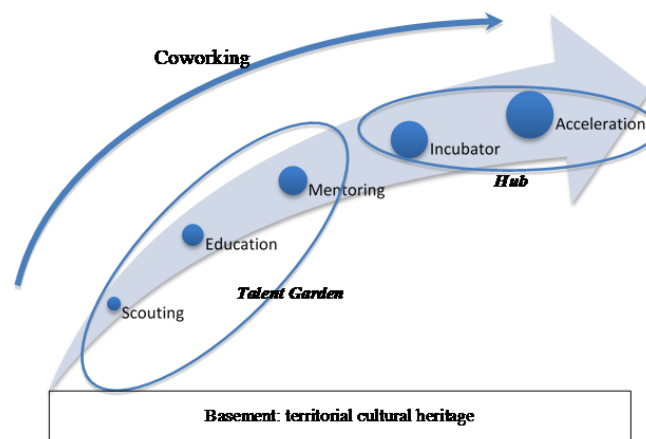

Figure 2- The Entrepreneurial Value Chain

The first three stages—scouting, education and mentoring—create a sort of Talent Garden (Mariotti et al., 2017; Bianchi et al., 2018), that is, a place where they can cultivate talents and grow. The latter two—incubation and acceleration—form a hub, where entrepreneurial activities are supported by the entrepreneurial university, delivering services and competencies.

The basis for the Entrepreneurial Value Chain of the project Incubiamo Cultura is the establishment of the cultural start-ups in tattered and abandoned locations, to exploit the city cultural heritage and favour urban regeneration.

6 Conclusions

As seen in our case study, universities can play a leading role in regenerating the cultural context of their territories.

Up to this point, many scholars have delved into the topic of how a university that has included the third mission in its strategy should be managed according to managerial logic (Etzkowitz, 2004; Secundo et al., 2015, 2016). However, today not one scholar has addressed the issue of how universities can support value creation in urban regeneration thanks to the activities of academic entrepreneurship.

Relationships and networking are the key factors for success, especially in the cultural and creative sector. Indeed, relationships can be seen as antecedent factors of a new model of iterative and collaborative innovation between entrepreneurial universities and their ecosystems.

Moreover, the specific nature of cultural and creative firms and the public value of cultural heritage define a peculiar set of processes and a different way in which the Entrepreneurial Value Chain is realised.

All these aspects are new respect to previous experiences, especially based on hi-tech ventures incubation.

Further research

This paper focuses on the design of a network and a value chain for the launching of startups in the cultural and creative sector, where universities can play an orchestrator role. Nevertheless, further research is needed on its implementation and to assess its replicability in other contexts.

As a second and noteworthy issue, we deem that evaluating the alignment between strategic orientation and performance within universities has become of paramount relevance. However, we deem that traditional indicators used to rank an entrepreneurial university (such as the no. of patents or the no of spinoffs) are not enough to account for the societal value that universities can create.

Abstract

Ageing is a relevant and urgent priority on the agenda of all the most industrialized countries. Ageing is harming the sustainability over time of the national healthcare systems as we know them nowadays. While policymakers are paying major attention to chronic care and the emerging new needs of patients who are aged 60+, less light has been shed on how to enable population-wide Healthy Ageing initiatives that offer the opportunity to postpone the need of institutionalized care and thus guarantee a longer healthy life to elderly.

This study aims at furthering the debate about Healthy Ageing initiatives for elderly aged 60+ by shedding new light on the behavioural determinants of elderly's intention to use a personalized, artificial intelligence-enabled, virtual coaching system for healthy ageing. Being the use of these systems based on individual "voluntariness", understanding what might enable or inhibit such behaviour is of paramount importance for policymakers, professionals and developers. In fact, recent evidence shows that, despite the demonstrated benefits of these systems, the level of adoption among citizens aged 60+ falls far short of the expectations.

This study develops and empirically tests an original model that, adopting the Technology Acceptance Model (TAM) as overarching theory, adds three other explanatory variables, i.e. Subjective Norm, Health Literacy and Information Technology (IT) Literacy. This study has been carried out within the NESTORE H2020 research project (ID 769643).

Data from 436 Italian citizens aged 60+ were collected to test the hypotheses via Structural Equation Modelling. Results confirmed that Intention to Use a virtual coaching system is explained by Perceived Ease of Use and Perceived Usefulness. While Subjective Norm was found to have an indirect influence. Health Literacy has a negative effect on the Perceived Usefulness. Finally, IT Literacy positively influenced Intention to Use through the partial mediation of Perceived Ease of Use.

Our results contribute to theory by unfolding the role played by Subjective Norm, Health and IT Literacy, being the last two factors at the core of numerous improvement

strategies. With respect to practice, the study offers implications to different stakeholders to facilitate the adoption of digital technologies for healthy ageing.

1 Introduction

Ageing is a significant challenge that the most industrialized countries must face seriously to guarantee the sustainability of their societies as well as of their national healthcare systems. Citizens 60+ are expected to get to 2.1 billion in 2050 and they will outnumber children aged 0-9 (World Health Organization, 2015). This global megatrend poses inevitably new challenges to policymakers. In this view, “How to enhance elderly’s ability to live a longer healthy life?”, “How to empower citizens on the engagement into healthy behaviours?” are salient and urgent questions on the agenda of both policymakers and academicians. The World Health Organization (WHO) introduced the concept of “Healthy Ageing”, intended as the process through which an individual can maintain or enhance her well-being within the ageing process. Accordingly, the WHO outlined the importance that citizens embrace a proactive approach to maintain good health conditions over the entire lifetime and it recognised the powerful role of digital technologies that can incorporate and administer the professional knowledge required.

In this regard, virtual coaching systems represents a paradigmatic example of supportive digital technologies applied to citizens’ decision-making that are based on artificial intelligence and heterogeneous sources of knowledge, such as clinical guidelines, citizens’ lifestyle behaviour, etc. These systems leverage real-time data gathering and processing capabilities to guide the user through repeated interactions, feedback and recommendations based on behavioural theories operationalized in a plan of action (Kamphorst, 2017). Virtual coaching systems, being a promising example of innovative ways to store and exploit medical knowledge, offer the potential to support healthy ageing on a population-wide scale with cost-effective solutions (Robbins et al., 2018). Despite this potential, the rate of adoption among citizens aged 60+ falls far short of the expectations (Carroll et al., 2017).

Within this background, our study aims at furthering the ongoing debate on the exploitation of heterogeneous sources of knowledge through supportive digital technologies to promote healthy ageing and thus contributing to the sustainability of the healthcare systems of the most industrialized countries. Specifically, this study sheds light on the determinants of elderly’s intention to use a virtual coach for healthy ageing, targeting people aged 60+.

2 Theoretical Framework and Hypothesis Development

We developed our theoretical framework to identify the main determinants that shape elderly's intention to adopt (and consequently to use) a virtual coaching system for engaging in healthy ageing behaviours grounding on the original formulation of the Technology Acceptance Model (TAM) by Davis (1989). We extended the original formulation by investigating the role played by three additional factors that were found significant within the literature about VCSs and are at the core of numerous improvement strategies implemented by the national healthcare systems worldwide. These factors are expected to improve the explanatory power of the original model. First, we considered the social influence exerted by people who are relevant to the individual, conceptualised as *Subjective Norm* (Venkatesh and Davis, 2000). Second, we introduced *Health Literacy*, considered as the degree to which an individual perceive to be able to find, process, and understand health-related information to ground her decisions (U.S. Department of Health and Human Services, 2010). Third, we included the individual's *Information Technology (IT) Literacy*, intended as the degree to which an individual perceives to be confident in using a technological device to perform a desired task (Lynch, 1998).

Figure 1 offers an overview of our theoretical framework with the main hypotheses that will be empirically tested. Each hypothesis will be introduced briefly in the followings.

Figure 4. Theoretical model and hypotheses (control variables are not displayed)

Past studies confirmed the underlying hypotheses of the TAM theory in healthcare, i.e. the positive influence of both PEU and PU on the Intention to adopt wellbeing, wearable technologies (e.g., Kalantari, 2017). Indeed, we proposed the following hypotheses:

H1: Perceived Ease of Use has a positive influence on the Intention to Use a virtual coaching system for healthy ageing.

H2: Perceived Usefulness has a positive influence on the Intention to Use a virtual coaching system for healthy ageing.

The positive effect of PEU on PU has been widely confirmed by previous studies in healthcare, e.g., Weng (2016) and Liu et al. (2013). Accordingly, we formulated the following hypothesis.

H3: Perceived Ease of Use has a positive influence on the Perceived Usefulness of a virtual coaching system for healthy ageing

Subjective Norm – defined as the social influence of relatives, friends, doctors and other people who are perceived as relevant by the individual – can affect significantly the intention to embrace a novel technology (e.g., Venkatesh and Davis, 2000). Subjective Norm can influence the intention to use a virtual coaching system both directly and indirectly. Especially older adults, who do not own commonly a consistent background on new digital technologies, can be influenced favourably by their family members' (e.g., Teo and Pok, 2003) as well as by doctors' (e.g., Wu et al. 2007) opinions. Other contributions (e.g., Cho et al., 2014; Kim and Park, 2012) showed that others' opinions can affect positively the intention to use health information technologies through PU and PEU, because these opinions can be useful in developing a deeper understanding of the technology (e.g., Hartwick and Barki, 1994). Accordingly, we made the following hypothesis.

H4: Subjective Norm has a positive influence on the Intention to use a virtual coaching system for healthy ageing. Perceived Usefulness and Perceived Ease of Use partially mediate the relationship.

Health Literacy refers to how an individual obtains, understands, uses and communicates health information to make informed decisions. Mackert et al. (2016) found that people with a higher health literacy perceived health information technology as more useful and easy to use. Similarly, the ability to gather and interpret health information was found to be related to the perceived easiness of using online health Apps (Cho et al., 2014). Accordingly, we hypothesized that:

H5: Health Literacy has a positive influence on the Intention to a virtual coaching system for healthy ageing through the mediation of (a) Perceived Usefulness and (b) Perceived Ease of Use.

Information Technology (IT) Literacy refers to the perception of the individual of her ability to use a digital device (Lynch, 1998). Previous studies highlighted that the capability to use digital technologies is a predictor of the adoption of a health-related digital technology (Weng, 2016). The frequency and the ability of using a personal computer influence the individual in evaluating if a computer-based technology is easy to handle or not (Princely, 2015). Similarly, another contribution by Melas et al. (2011) proved that knowledge about ICTs affects indirectly the behavioural intention to use clinical information systems through PEU. Accordingly, we hypothesized that:

H6: IT Literacy positively affects Intention to Use a virtual coaching system for healthy ageing through the mediation of Perceived Ease of Use.

3 Methods

Data were collected within the NESTORE H2020 project by means of an online survey compliant to the GDPR requirements and administered in Italy to citizens 60+ between June and August 2018. All constructs were measured by adapting previously published scales. The final sample was composed of 436 high-quality answers. Hypotheses were tested using Structural Equation Modelling in STATA14. The validity and reliability of the constructs, as well as the significance of the hypothesized

relationships among the latent variables, were verified through the output of the measurement and structural model respectively. Finally, the goodness of fit of the proposed model was assessed.

4 Results

4.1 Measurement Model

Table 1 shows the Average Variance Extracted (AVE) and the Composite Reliability (CR) for all constructs included in the model. The values are higher than commonly accepted thresholds (equal to 0.50 and 0.70 respectively), indicating a good convergent validity for all constructs.

Table 1. Confirmatory Factor Analysis

Construct	AVE	CR
Intention to Use (ITU)	0.6420	0.9146
Perceived Usefulness (PU)	0.7105	0.8303
Perceived Ease of Use (PEU)	0.5973	0.8549
Subjective Norms (SN)	0.7520	0.8746
Health Literacy (HL)	0.5227	0.8136
IT Literacy (ITL)	0.6083	0.7564

4.2 Structural Model

Table 3 reports the path coefficients and the related p-values from the Structural Model.

Table 2. Results of the Structural Model

Path	Coefficient	Std. Err.	p-value
PEU → ITU	0.1915	0.0555	***
PU → ITU	0.8563	0.0742	***
PEU → PU	0.4224	0.0452	***
SN → ITU	- 0.1187	0.0644	n.s.
SN → PU	0.5871	0.0386	***

HEA → ITU	0.0114	0.0295	n.s.
*** p ≤ 0.001; ** p ≤ 0.01; *p ≤ 0.05; n.s. p > 0.05			

4.3 Goodness of Fit

Finally, a set of indexes were computed to assess the goodness of fit of the proposed model. As anticipated, four indexes were taken into account as recommended by the academic literature, i.e., the Root Mean Square Error of Approximation (RMSEA), the Standardized Root Mean Residual (SRMR), the Comparative Fit Index (CFI), the Tucker-Lewis Index (TLI). As reported in Table 2, all indexes' values are in line with common values accepted in the literature (e.g., Hair et al., 2010).

Table 2. Goodness of Fit Indexes

Index	Value	Suggested Threshold
RMSEA	0.06	< 0.07
SRMR	0.05	< 0.08
CFI	0.91	> 0.90
TLI	0.91	> 0.90

5 Discussion

Although Virtual Coaching Systems (VCSs) proved to contribute positively to healthy ageing in elderly, their rate of adoption by citizens aged 60+ is still far short of the expectations. In this regard, this study aimed at shedding novel light on the determinants of elderly's intention to use a VCS for healthy ageing purposes. To this end, a set of hypotheses was developed for the specific case of VCS for health ageing starting from the original formulation of the TAM model (Davis, 1989). In particular, the original model has been extended by introducing three additional external variables, i.e., Subjective Norms, Health Literacy, and IT Literacy.

Our results confirm the basic linkages posited by the TAM theory. In fact, more the PEU of a VCS, more the intention to use it. Similarly, more the perception that the use of a VCS will bring effective improvements with respect to healthy ageing, more the intention to use. These findings are aligned to past studies that applied TAM to healthcare (e.g., Wang et al., 2014).

As original contribution, we found that the direct relationship between Subjective Norm and Intention to Use is not significant. This implies that the degree to which people relevant to the individual judge positively (or not) the use of a VCS does not influence directly its adoption by the individual. This result is thus not consistent with our initial hypothesis. However, we found the relationship between Subjective Norm and Intention to Use resulted to be fully mediated by PU and PEU. Given the target population and their voluntariness of using a VCS, we can assume that the positive (or not) opinions of friends, family and doctors have an impact on the intention to use a VCS only when they are fully internalized in the elderly's belief structure (Venkatesh and Davis, 2000). Additionally, the opportunity of receiving help and indications by friends, family and doctors on how to use the technology can contribute to the perception that its actual use is manageable and easy.

Contrary to expectations, our findings suggest a negative influence of Health Literacy (HL) on the PU of a VCS. Our novel evidence points out that a higher degree in HL has a negative impact on the PU of the system. One possible interpretation for this result is that if an elderly person already has a good capability to find information about her personal well-being and a good degree of understanding of this information, she would find it unnecessary and of little value added to use an additional digital tool (i.e., the VCS) to maintain her well-being.

On the other hand, our results confirm that a higher level of HL leads elderly to perceive the VCS as easier to use. This result is coherent to previous studies in the e-health field (e.g., Cho et al., 2014).

Finally, our results offer significant support of the positive relationship between IT Literacy (ITL) and PEU. This result is consistent to the theoretical arguments in literature according to which good familiarity with technological devices increases the ease of use of personal health and lifestyle digital systems (e.g., Kalantari et al., 2017).

Our results contribute to practice, too. In fact, health policymakers, healthcare professionals, and developers of digital solutions for citizens' healthy ageing might benefit from the novel evidence gathered in this study. The first suggestion deals with the design and the sponsoring of a solution that appears easy to use and in which the virtual coach is perceived as easy to follow. Indeed, when searching for a VCS, the potential user who is aged 60+ should have the perception of an easy to use tool. This goal can be achieved by showing that only a few steps are required to engage with the system as well as by communicating that only few data will be required to initiate the coaching program. Furthermore, a graphical interface that expresses an idea of simplicity could increase even more this perception. Second, developers of VCSs are advised to make the actual utility of these systems more evident to the users to increase their adoption. They should act to make elderly aware of the actual benefits of virtual coaching, for example by sponsoring successful cases of application. Similarly, about health literacy and its negative effect on the Perceived Usefulness, developers and healthcare professionals need to provide clear evidence of the effective benefits and value added driven by the ability of such systems to act upon the behaviour of a person.

6 Limitations, Future research and Conclusions

Our results should be interpreted in the light of the limitations of this study, that we suggest future research should address. First, we implemented a cross-sectional design. Consequently, we cannot offer definitive conclusions on causation, even if past contributions supported the development of our hypotheses. Future longitudinal research would be useful in establishing causality. Second, data were collected by means of an online survey. This means that seniors with limited access to the Internet or low digital skills may have been underrepresented in the final sample that may not be perfectly representative of the entire population. Moreover, our data come from a single country (Italy). Hence, the generalizability of our results should be proven by future research. In this regard, we encourage scholars of healthcare management to test our hypotheses in

different contexts (e.g., developed and developing countries). Finally, because of the unexpected negative effect of Health Literacy on the Intention to Use a VCS, and because our construct was mainly focussed on the well-being information domain, it could be interesting to further investigate the role of Health Literacy, for example considering different Health Literacy orientations.

In conclusion, despite the limitations of our study, we claim that our results shed novel light on the determinants and the inner mechanisms that shape elderly's intention to use a VCS for healthy ageing, contributing to the theoretical understanding of user discretionary acceptance of technologies as a mean for pursuing health-related goals. Moreover, our findings provide health policymakers, healthcare professionals and technology developers with evidence-based recommendations on how to promote and enable population-wide interventions about healthy ageing through digital technologies.

Assessing the Impacts of Culture and Cultural Impacts: a Planning and Evaluation Challenge

Annalisa Cicerchia

Istituto Nazionale di Statistica
Via Cesare Balbo 16 – 00184 Rome

Abstract

The increasing demand for measures of economic and social impacts of culture is somehow connected to a declining social perception of its intrinsic value. Coupled with a declining consensus on its necessity, spending on culture has increasingly been justified by a growing number of politicians and decision makers in its instrumental dimension, and its proved usefulness. This has undermined the automatic legitimacy of relevant investments in the sector, unless returns could be expected (best if economic and in the short term). In those countries where the bulk of financial resources for culture is public, scarcity, spending review, economic crisis, combined with the lowering of the social appreciation of culture, have dealt a heavy blow on the sector, but the same can be said of those countries where culture derive its main resources from private support.

Initially welcomed as a deserved acknowledgement of the collateral merits of culture, the social and economic benefits it is expected to generate have progressively outgrown and replaced its intrinsic value.

It is in this context that measurement of the social and economic impacts of the arts and culture has become a recurring topic in the literature of the last two decades or more. It is also a common aspiration of many cultural organisations that depend on public or private funding.

As instrumental approaches to culture and its role have gained a growing weight on the intrinsic ones, evidence sought to provide a sound basis and reliable information, upon which funding decision and policies are made, tends to document the benefits of culture for the local or national economy, social inclusion and cohesion, reduction of inequalities, and so on, while cultural impacts remain virtually unaccounted for.

The paper elaborates on the idea that intrinsic value is not to be underrated, and discusses why cultural impacts are worth investigating.

Keywords – Cultural impact assessment, cultural indicators, cultural participation, European Capital of Culture.

1 Introduction

The increasing demand for measures of economic and social impacts of culture is somehow connected to a declining social perception of its intrinsic value. Coupled with a declining consensus on its necessity, spending on culture has increasingly been justified by a growing number of politicians and decision makers in its instrumental dimension,

and its proved usefulness. This has undermined the automatic legitimacy of relevant investments in the sector, unless returns could be expected (best if economic and in the short term). In those countries where the bulk of financial resources for culture is public, scarcity, spending review, economic crisis, combined with the lowering of the social appreciation of culture, have dealt a heavy blow on the sector, but the same can be said of those countries where culture derive its main resources from private support.

Initially welcomed as a deserved acknowledgement of the collateral merits of culture, the social and economic benefits it is expected to generate have progressively outgrown and replaced its intrinsic value.

In the last 25 years, while its intrinsic value was progressively shrinking in the collective imagination, culture has been the object of great expectations because of its instrumental value.

During the 1990s, in Europe, potential culture-based job and business creation were a common topic of debate. This is one of the reasons why the greatest source of EU funding for culture, starting in 1994-1999, have in fact been the Structural Funds, i.e. the funding tool of the Union's economic cohesion policy. Their rate of contribution to the EU expenditure for culture reached at a certain point 83%, against 7.7% from the sectorial programmes ("Culture", "Media", etc.).

It is in this context that *measurement* of the social and economic impacts of the arts and culture has become a recurring topic in the literature of the last two decades or more. It is also a common aspiration of many cultural organisations that depend on public or private funding.

Scepticism, to various degrees, about their measurability coexists with an increasing demand of accountability, and trust in quantitative score-based methods, as in SROI (Social Return On Investments), coexists with purely qualitative or narrative-based techniques, as in MSC (Most Significant Change).

As instrumental approaches to culture and its role have gained a growing weight on the intrinsic ones, evidence sought to provide a sound basis and reliable information, upon which funding decision and policies are made, tends to document the benefits of culture for the local or national economy, social inclusion and cohesion, reduction of inequalities, and so on. But cultural activities do generate cultural impacts, after all. Alas, those cultural impacts remain virtually unaccounted for.

The paper elaborates on the idea that intrinsic value is not to be underrated, and discusses why cultural impacts are worth investigating.

It also points to the fact that often, reports of the impacts of the arts and cultural activities appear disembodied from any planning frame of reference. It is so in many ex post evaluations, where unplanned and unintended outcomes and spill-overs of cultural projects of various nature represent the most part of the report. It occurs also when the only measurables or reportables are inputs or processes, but they are disconnected from target or output indicators.

With its 30 years of existence, the European Capital of Culture Programme -ECoC has increasingly developed a praxis – not only a formal procedure – for planning, monitoring

and short term and medium term evaluating the desired impacts of the cultural investments, activities, events, etc. for candidate and selected cities to follow.

In view of this, the paper investigates the potential use of cultural impact and result indicators for Matera, the Italian 2019 ECoC, and proposes an evaluation approach focused on measuring, with appropriate indicators, changes in the levels of cultural participation, practice and consumption.

2 Defining a cultural impact

For a very long time and largely still today, in Italy, the only *cultural* indicator used to measure the impact (any kind) of projects and programmes focused on cultural heritage is the “Number of admissions to State museums, per year”. Indeed, the 478 state structures, barely 10% of the entire museum universe, attracted over 44% admissions in 2017, i.e. 53 million, with nearly 112,000 visitor on average per museum, vs. 66.2 million, on average 17,000, for the remaining 90%, the 4,411 non-State museums.

The choice of that indicator is largely data-driven, as only State museums are surveyed – if only about number of admissions and revenues from the public - every year, with time series covering over 20 years. The entire universe of museums are investigated only occasionally, alternatively with an extended questionnaire and a shorter form, about organisation, activities, services provided, etc.¹

While it can be considered an acceptable proxy of the attraction force of individual cultural sites in a given area, “Number of admissions to State museums” is by no means a measure of their individual or collective *cultural impact*, as “admissions” only count people who enter a museum, without distinction of age, gender and nationality, one-time or returning visitors, not to mention purpose, duration, content and quality of the experience.

The available data do not separate tourists from resident visitors. It is reasonable enough to suppose that, if it is a *cultural impact* what we have in mind, a cultural experience should have a minimum duration, or be repeated.

Technically speaking, an impact is a special form of change, generally fast, violent and irreversible, due to the clash between an active agent (*impactor*) on a *impacted* area. Originally, impact has been used mainly in a negative sense (as in *environmental impact*), with the induced changes mainly understood as loss or shock or collapse and subsequent positive or negative feedback on the side of the impacted system. In our case, instead, impact is instead a desirable change, due to exposition to/participation in/practice of art and culture in various forms. It is 'a dynamic concept which pre-supposes a relationship of cause and effect. It can be measured through the evaluation of the outcomes of particular actions, be that an initiative, a set of initiatives forming a policy or set of policies which form a strategy.' (Landry *et al.*, 1993).

As for culture, the pioneering work led by Matarasso (1997) listed 50 social impacts of participation in the arts and posed a set of fundamental conceptual and methodological

¹ <https://www.istat.it/it/archivio/167566>

questions. The critics of the conclusions reached by Matarasso object that, while it is difficult to disagree in principle with any of his 50 statements, his method, being, as Matarasso himself acknowledged, not fully developed, is unable to provide a conclusive evidence that they are empirically and verifiably true (Belfiore, 2006).

However, Matarasso's list does help segmenting the complexity of the specific semantic field of impacts of cultural practice. In that list, 15 pertain to the intrinsic value of culture, namely:

1. Increase people's confidence and sense of self-worth
2. Stimulate interest and confidence in the arts
3. Provide a forum for intercultural understanding and friendship
4. Promote intercultural contact and co-operation
5. Develop pride in local traditions and cultures
6. Help people feel a sense of belonging and involvement
7. Create community traditions in new towns or neighbourhoods
8. Make people feel better about where they live
9. Help people develop their creativity
10. Erode the distinction between consumer and creator
11. Allow people to explore their values, meanings and dreams
12. Help community groups raise their vision beyond the immediate
13. Raise expectations about what is possible and desirable
14. Have a positive impact on how people feel
15. Provide a unique and deep source of enjoyment.

They may be grouped into three main classes, one a) about personal and community growth, satisfaction, wellbeing and contentment; one b) about appreciation of the arts, creativity and self-expression; one c) about identities, belonging and vision:

- a) Increase people's confidence and sense of self-worth; Have a positive impact on how people feel; ; Make people feel better about where they live; Provide a unique and deep source of enjoyment;
- b) Stimulate interest and confidence in the arts; Help people develop their creativity; Erode the distinction between consumer and creator;
- c) Provide a forum for intercultural understanding and friendship; Promote intercultural contact and co-operation; Develop pride in local traditions and cultures; Help people feel a sense of belonging and involvement; Create community traditions in new towns or neighbourhood; Allow people to explore their values, meanings and dreams; Help community groups raise their vision beyond the immediate; Raise expectations about what is possible and desirable.

To the purpose of the present exercise, I propose to adopt operationally the above three conceptual clusters as basic components of a desirable *cultural impact*, and to proceed from there to elaborate a viable list of indicators.

In particular, with reference to Italy, I will distinguish two subsets of the list: available measures, related to existing datasets that only need to be adjusted from the point of view of territorial scale or updated; and additional or new measures, technically possible with

minor adjustments or targeted questionnaires. The tools I propose could be useful in assessing cultural impacts of Matera ECoC 2019.

3 Cultural impact in the ECoC planning and evaluation process

ECoC is Europe's most ambitious collaborative cultural project both in scope and scale, with budgets far exceeding those of any other cultural event. Until 2004, the designation of European Cities of Culture was an inter-governmental affair in the hands of the Council of Ministers, without the involvement of external experts or any formal assessments. In 1999, the European Parliament and the Council of the European Union decided to call the European Capital of Culture scheme a Community Action, and set up a new designation process that would apply for the 2005-2012 titles. Member States were listed in chronological order so that they could take turn to host the event. An international panel was set up to assess the suitability of cities proposed by Member States and criteria for the selection formally established. Today, a selection panel made up of experts chosen by the European institutions (Commission, Parliament, Council of Ministers and Committee of the Regions) and by the concerned Member State assesses the proposals and settles its choice. The EU Council of Ministers then officially designates the city. As well as the management of the formal selection and monitoring processes, the Commission has published a guide for candidate cities. According to Decision 445/2014/EU, a pecuniary prize of EUR 1.5 million (Melina Mercouri Prize) is awarded to all designated cities. The Prize is paid, provided that a designated city continues to honour the commitments it made at the application stage, complies with the criteria of the Decision and takes into account the recommendations contained in the selection and monitoring reports. Now in its 34th year, the ECoC programme has gradually formalised key planning concepts and methodologies for the stage of presentation of the candidate cities, their selection and the winner's four years of preparation.

The city of Liverpool, ECoC 2008, has greatly contributed to the quality of the planning/evaluation process through the Impacts 08 programme, led by the University of Liverpool, Liverpool City Council and Culture Liverpool. Impacts08 has produced a vast amount of research, data, analysis and publications and the group was subsequently involved as leading partners in the European Capitals of Culture Policy Group, funded by the European Commission's Culture Programme in 2009-2010. The Policy Group set itself the goal of sharing good practice in relation to the delivery process of the European Capital of Culture title and developing a common research framework to assess the impact of a title year (ECoC Policy Group, 2013).

The Policy Group has provided a broad research framework, with six thematic clusters that aim to encompass the broad range of potential impacts and a small core set of priority indicators supporting each theme:

1. *Cultural vibrancy and sustainability*
2. *Cultural Access and Participation*
3. *Identity, Image and Place*

4. *The Philosophy and Management of the Process*
5. *European Dimension*
6. *Economic Impacts.*

Of the six themes, only three contain direct or indirect references to cultural impacts. *Cultural vibrancy* considers the programme content of the ECoC year itself and the impact upon the vitality and sustainability of the cultural system and creative economy of the event host-city. Sub-themes include: artistic vibrancy of the year (cultural offer, innovative productions); profile of the sector (number and type of organisations, facilities and jobs); sustainability of the system (e.g. skill development in the cultural sector); the ECoC contribution (e.g. direct investment/funding of the city's cultural system) and contribution of other relevant regional, national or international institutions. *Cultural Access and Participation* attempts to understand: what is the cultural offer; how access to it is encouraged; who is accessing it; why are they accessing it; and what value do they derive from it. Answering these questions requires the assessment of demographic and geographic data on participants and non-participants in cultural activities, and access to opportunities for cultural involvement. In addition, it focuses on particular sub-cultures and groups and explores experiences, cultural values, changing levels of participation and interests, and reasons for participation. *Identity, Image and Place* explores the perceptions and awareness of both the ECoC programme and the host city, and how these change as a result of the ECoC year. The sub-themes for this area include the positioning/repositioning of the host-city before and after becoming ECoC, the changing perceptions of the city by local communities, event visitors, and non-visitors; and the strength of local identity and self-confidence.

4 Matera, ECoC2019

The final Matera 2019 Bidbook¹ is the official source to identify measures of expected cultural impacts, as well as other kind of impacts.

At the time of the candidacy, the indicators for the Basilicata Region of the BES - Benessere equo e sostenibile, the national project of wellbeing measures by the National Statistical Institute, ranked quite poorly in the area of culture. The index of cultural participation (percentage of people aged 6 and over who had participated at least in three cultural activities - going once to museums/archaeological sites, theatre, concerts; going at least four times to the cinema; reading newspapers at least three times a week; reading at least four books in one year -) was declining, from 23.2% in 2009 (was 30% at the national level) to 18.9% (25.9% at the national level). Even worse in 2014, with 15.6%. The rise in 2015 (20.1%) and 2016 (24.7%) could be ascribed as a positive effect of the successful process of ECoC candidacy, but in 2017 the value fell again as low as 19.7% (in Italy was 25.8%).

The final Matera 2019 Bidbook lists the City's expectations about culture for the Capital year:

¹ <https://www.matera-basilicata2019.it/en/matera-2019/bid-book.html>

- To strengthen broad-ranging, open and diversified cultural citizenship;
- To transform Matera into the most important platform of open culture in Southern Europe;
- The propellant to imagine a future in which they will not be forced to quit their native land, a future in which their hopes can be nurtured and expanded.
- To strengthen the breadth and diversity of citizens who actively participate in the cultural programme, encourage them to learn and infuse them with a sense of ownership and responsibility for the care, protection and regeneration of our culture”.

The Bidbook sets out a few target indicators for that:

- Prepare infrastructure and actions in the sphere of open design, culturally motivated social innovation, digital storytelling to fully leverage heritage, involving at least 5.000 between 2015 and 2020 and fostering the establishment of 25 new economic entities.
- By 2020, 70% of people will say that Matera is a city attractive to young people.
- By 2020, 90% of people will believe culture has a very important role in the economy of the future.
- By 2020, 70% of people will say that Matera is an innovative and creative city.
- 80% of the cultural programme must provide for the direct involvement of citizens through co-creation and co-production of projects.
- All elementary and junior high schools of Matera and Basilicata will be directly involved in the implementation of the cultural projects.
- By 2017, 60% of citizens will declare themselves willing to do volunteer work for Matera 2019.
- By 2017, 60% of citizens will declare themselves willing to act personally to make the city more beautiful.
- By 2019, Matera will have expanded its web of international and European relations by consolidating its network presence, by intensifying the inward and outward flow of people and projects, by encouraging the internationalization of operators in creative innovation and cultural development, and by bringing online a broadcasting service dedicated to culture and events.

Two relevant questions the selected city must answer are “What are the enduring aspects of the event, and how can it become an integral part of cultural and social development of the city in the long term?” and ” Are any parts of the proposed Project aimed at specific groups (young people, minorities, etc.)? If so, what are they?”. Here is what the Bidbook proposes: “A fundamental requirement for the cultural development of Basilicata is to increase capacities (among socio-cultural operators, public officials and citizens) as well as a sense of personal civic responsibility, also with a view to stimulating innovation. (...) Improving access to and participation in culture for all people who live in Matera and Basilicata is one of the primary aims of the candidature. Statistics show that the consumption of culture in Italy is one of the lowest in Europe, and Basilicata has traditionally lagged farthest behind. It is not, however, merely a question of increasing the consumption of culture. Rather, the concept of “inhabiting culture” postulates that culture

must be understood as consisting of a diversified array of options that also and especially includes the effective practice of the same and the full immersion of those who “consume” it. Rather than objectives, these are preconditions for a programme such as ours that is underpinned by belief in community involvement and the co-generation of processes and recognizes that a considerable time may have to elapse before aspirations can be turned into reality. Capacity-building activities will also serve to improve the planning skills of Basilicata operators with regard to accessibility, understood in its broadest sense.

As 129 out of 131 municipalities in Basilicata have fewer than 10,000 inhabitants, an objective problem exists regarding the scarcity of demand, which often makes it impossible to maintain a diffuse supply of culture throughout the territory. This is a problem that affects not only Basilicata, but many areas of Europe, and the candidature has opened the door to innovative outreach initiatives for areas with low-density populations and reduced opportunities. (...). Matera 2019 legacy: one of the most important legacies of Matera 2019 will leave to the city itself and all Basilicata will be immaterial: a revived self-confidence in its own potential. After decades of disgrace, marginalisation and closure, Matera will finally look to Europe with renewed self-esteem; its younger generations will set foot on the European stage not as migrant escaping the impoverished provinces but as proud citizens of a city that has had the strength to reinvent itself by continuing to innovate”.

The excerpts from the Bidbook reveal a strong convergence with the three key dimensions of cultural impact that I proposed earlier: a) personal and community growth, satisfaction, wellbeing and contentment; b) appreciation of the arts, creativity and self-expression; and c) identities, belonging and vision.

5 Measuring cultural impact: a modest proposal.

In this section, I propose three feasible sets of indicators of cultural impact, relating to the three dimensions I described earlier (Tab.1).

Tab.1. Proposed measures of cultural impact			
	Personal and community growth, satisfaction, wellbeing	Appreciation of the arts, creativity and self-expression	Identities, belonging and vision
Available	Level of life satisfaction (subjective indicator) of resident people with varying intensity of cultural participation (per age and gender), per year	Intensity of cultural participation of resident people (per age and gender), per year	Percentage of resident people (per age and gender) who think cultural heritage is important for themselves personally

	Percentage of resident people (per age and gender) who think that living close to places related to Europe's cultural heritage can improve people's quality of life	Current public expenditure for cultural heritage, city level, per year	Percentage of resident people (per age and gender) who think cultural heritage is important for their local community
		Percentage of resident people (per age and gender) who are involved at least in three ways in cultural heritage.	Percentage of resident people (per age and gender) who feel pride in a historical monument or site, work of art or tradition (e.g. crafts, festivals, music, dance etc.) from their region or from their country
Additional	Varying levels of cortisol prior and after cultural activities (museum visits, participation in shows or concerts, etc.)	Duration of museum visits - electronic check of entrance and exit via barcoded admission tickets	Targeted questionnaires
	Targeted questionnaires	Targeted questionnaires	

Own elaboration, on Istat and Eurobarometer 466 metadata

They are divided in two subsets: one is made of existing indicators that need adjusting their territorial detail, as at present their data (the source is in parenthesis) only cover national or regional levels¹:

- Intensity of cultural participation of resident people (per age and gender), per year (Istat);
- Level of life satisfaction (subjective indicator) of resident people with varying intensity of cultural participation (per age and gender), per year (Istat);
- Current public expenditure for cultural heritage, city level, per year (Istat)²
- Percentage of resident people (per age and gender) who think that living close to places related to Europe's cultural heritage can improve people's quality of life (Eurobarometer 466);
- Percentage of resident people (per age and gender) who are involved at least in three ways in cultural heritage (Eurobarometer 466);
- Percentage of resident people (per age and gender) who think cultural heritage is important for themselves personally (Eurobarometer 466);
- Percentage of resident people (per age and gender) who think cultural heritage is important for their local community (Eurobarometer 466);
- Percentage of resident people (per age and gender) who feel pride in a historical monument or site, work of art or tradition (e.g. crafts, festivals, music, dance etc.) from their region or from their country
- Index for positive attitude towards cultural heritage (Eurobarometer 466);

¹ Istat data are collected on a yearly basis, while Eurobarometer 466 is so far a single data collection.

² Note that this is an indicator of public appreciation of the strategic relevance of culture, not a financial indicator. Detailed financial measures are well developed within the proceedings of ECoC.

- Proportion of people indicating lack of interest as the main barrier to access cultural heritage sites or activities (Eurobarometer 466)

The second subset is of additional measures, technically possible, but not implemented yet:

- Duration of museum visits - electronic check of entrance and exit via barcoded admission tickets (MiBAC);
- Targeted questionnaires for participants in cultural activities, aimed at investigate self-perceived changes in the three key cultural dimensions;
- Varying levels of cortisol prior and after cultural activities (museum visits, participation in shows or concerts, etc.).

The proposed set of measures could be applied, with appropriate samples, to the desired territorial scale in two waves: one prior the beginning of the planned cultural activities and events, and one 12 months after. The targeted questionnaires could help focusing, where needed, on specific events, programmes or places. The output of the proposed list is a simple dashboard. Of course, synthetic indexes could be calculated for each of the three dimensions of cultural impacts.
