New knowledge and knowledge creation are important for all innovations, not to mention radical, new-to-the-world innovations. In particular, complex radical innovations result of integration of knowledge and efforts of diverse actors and parties (e.g. Belderbos et al., 2004; Shawney, 2006, Harvey, 2014), and are therefore conducted in collaborative networks (Romero and Molina, 2011; O'Connor and DeMartino, 2006), open innovation systems (Chesbrough, 2006), innovation systems (Lancker et al., 2016) or ecosystems (Valkokari, 2015). Ecosystems are knowledge domains involving various independent parties committed to work interdependently for particular function or goal: innovation in innovation ecosystem (Valkokari, 2015), new knowledge in knowledge ecosystem (Van der Borgh et al., 2012; Valkokari, 2015) or both. As to produce radical innovations is to advance existing knowledge remarkably (e.g. Abernathy and Clard, 1985), it is appropriate to take lenses of knowledge ecosystem to study organizing knowledge creation for RI.

While ecosystems provide a rich (breadth and depth) knowledge base for radical innovations, an ability of the system to employ and use its knowledge (Dhanaraj and Parkhe, 2009; Dougherty and Dunne, 2011) is critical for the success of its function as well as for the shared goals. On the one hand, distributed knowledge among diverse independent domains is a challenge (e.g. Dougherty and Dunne, 2011). On the other hand, an ecosystem as a temporary organization and emergent form of organizing is an opportunity to build sufficient practices and processes to support joint function and goals, like innovation or new knowledge. Much of research has studied joint innovation partnerships (Tether, 2002), organizational innovation systems (Lancer et al., 2016), and ecosystems as systemic phenomena (Valkokari, 2015). However, there exist less research on convergent innovation (Phillips 2015), that is, interdependently produced innovation. Particularly, we know very little about organizing knowledge co-creation for joint innovation within knowledge ecosystems. This is surprising, as knowledge co-creation is central activity, function, and outcome in knowledge ecosystems (Valkokari, 2015), central basis of organizing (Järvi et al., 2018), and a source of interdependence. Consequently, organizing knowledge co-creation within knowledge ecosystems deserves attention, because 1) knowledge is created in social and dynamic interactions between people, when they openly explore contradictions and integrate perspectives in dialectical process (Nonaka and Toyama, 2003; Harvey, 2014) by simultaneously shaping shared goal. 2) knowledge co-creation is grounded by multiple complexities (Garud et al., 2011; Phillips 2017; Phillips et al, 2017) resulting of situational, relational and intersubjective processes (Tsoukas, 2008; Weick, 1979) that can be addressed through temporal orientations and organizing (Bakker et al., 2016; Tsoukas, 2003). To shed light on organizing knowledge creation is particularly important, because various kinds of knowledge-creation are required to achieve complex and challenging joint innovation (Nisula, Kianto and Andreeva, 2019), and because each knowledge creation process is unique (Elsbach & Kramer, 2003; Erden, von Krogh & Nonaka, 2008; Harvey, 2014; Unsworth, 2001) with varied composition of participants and varied goals.

Given the dynamics of knowledge co-creation in relation to the complex, fuzzy, and shared radical innovation outcome, it is clear that organizing knowledge co-creation becomes into highlight. Past research suggest that flexible and adaptive organizing (e.g. Kellogg, Orlikowski and Yates, 2006) better serves such conditions of complexity and volatility. This is likely to occur under limited hierarchy, horizontal relations, and interdependence (e.g. Girard and Stark, 2002; Kellogg et al., 2006). However, there exist very little research and empirical evidence on *how can knowledge co-creation for radical innovation be organized within a knowledge ecosystem?*

Building on literature on knowledge creation, innovation and organizing the present study explores organizing knowledge co-creation within one knowledge ecosystem. While doing so, we conducted a qualitative one case study, which assembled empirical evidence from one specific knowledge ecosystem constructed to bring together number of complementary parties for producing particular radical innovation.

The findings reveal that the process of knowledge co-creation is cyclic in which each cycle builds on previous one. The cyclic organizing comprises shared problem identification, shared goal setting, making experiments (testing), open demonstrations, searching internal and external feedback, and knowledge synthesis grounded by constant multidimensional orientation. Such an organizing enables integration of critical knowledge in a situational and contextual manner for the problem at hand.

2 Theoretical background

2.1. Radical innovation and knowledge co-creation

Radical innovations, as outstanding outcomes and game changers (Cooper and Kleinschmidt, 1993; Christensen et al., 2004; Schmidt and Calantone, 1998; Frederiksen and Knudsen, 2017) result of complex and multifaceted process (Van de Ven et al., 1999; Garud et al., 2011) involving diverse actors and parties. Such a non-linear and cyclic process is grounded by flexibility, emergence and learning (Arnold and Barth, 2012; Kroon et al., 2018, Lancker et al 2016). In addition to fuzzy goal of innovation, the process should address multidimensionality of innovation (Lancker et al., 2016). The cyclic processes are known among practitioners, like in start-up firms (Ries, 2011) as a pivoting or in software as agile development (Beck et al., 2001), as well as in learning as a problem based learning (Savery, 1995). However, these models lack theoretical basis and end short in addressing multidimensionality of joint innovation in knowledge ecosystem.

Knowledge creation and innovation are inherently intertwined in producing radical innovation. When innovation is conducted within knowledge ecosystem outside formal organizations, among parties who interdependently work for shared goals, knowledge creation and innovation are joint achievements. Further, as innovation comprises multiple discoveries (O'Connor and Rice, 2001; O'Connor and McDermott, 2004) throughout the process, it is clear, that various kinds of knowledge-creation in various compositions of

actors is required in addressing emerging complexities in generation of joint outcomes (Nisula, Kianto and Andreeva, 2019).

Based on literature on knowledge creation (Nonaka, 1990; Nonaka and Takeuchi, 1995; Nonaka and Toyama, 2003), collective creativity (Drazin, Glynn, Kazanjian, 1999; Harvey, 2013, 2014; Hargadon and Bechky, 2006; John-Steiner, 2000), and collaborative emergence (Sawyer and deZutter, 2009; Gray, 1989; Prince, 2009; Dougherty and Dunne, 2011) knowledge creation is inherently collaborative and collective process. We use term *knowledge co-creation*, which is a joint process to create new knowledge and understanding by integrating knowledge, expertise, and perspectives of diverse actors in situational, contextual and novel way for shared goals.

2.2. Organizing knowledge co-creation for radical innovation

Organizing knowledge co-creation for innovation within knowledge ecosystem is temporary, as it is conducted within predetermined timeframe and/or purpose (innovation), and it terminates once the goal is achieved (e.g. Bakker et al., 2016; Goodman & Goodman, 1976). It therefore differentiates from formal organization and organizing, which in general concerns division of labor and coordination of effort (e.g. Puranam et al., 2014). However, these aspects exist and are addressed differently in various types of organizing.

It is also clear that organizing multifaceted radical innovation cannot be fully planned, rather it is unfolding, characterized by emergence, uncertainty, and constant movement between complexities (temporal and relational) and synthesis (e.g. Garud et al., 2013). Therefore, an organizing, which enables flexibility, autonomy, and speed to make fast assignments, temporary agreements, shifts in accountability, roles, grouping (Kellogg et al., 2006; Girard and Stark, 2002), and in work modes (Garud et al., 2011) better address the requirements of organizing. This is likely to occur under limited hierarchy, horizontal relations and interdependence (e.g. Girard and Stark, 2002; Kellogg et al., 2006). Consequently, scholars suggest that in circumstances of complexities an unfolding organizing constitutes of set of practices (Kellogg et al., 2005; Garud et al., 2011), that is, activities and processes (Bakker et al., 2016) through which organizing is conducted and enacted (Orlikowski, 2000; Fortwengel et al., 2018). Hence, in addition to organization, we target our research to the activities and processes of organizing knowledge co-creation for radical innovation within knowledge ecosystem.

3 Methods

3.1 Research design

The present study employed a qualitative research strategy, and particularly, a single case study research approach to explore organizing knowledge co-creation for RI. As we were interested on micro-level activities of collective innovation, the case study research is well suited to investigate it. In a one case study the case itself is interesting and unique, and it can be used to analyze one or a few complex processes or phenomena when enough

cases, observations or similar types of cases do not exist at all (Yin, 1994; Gummesson, 2000; Eriksson and Kovalainen, 2016). The case was chosen as to our knowledge it is among the rare ones to consciously adopt cyclic approach in development of RI within ecosystem. Our study concerns radical innovation project during two years period in 2015-2016.

Case description

“We neither know what is the problem nor we know how to solve that problem – in this sense it is somewhat chaotic state” (respondent).

The radical innovation, “intelligent control solutions for networks and radios and related novel business models”, aimed to produce disruptive systemic technology innovation by simultaneously developing technology, changing regulation and standardization, and building novel business models (commercialization). It was conducted under the national (Finnish) research funding (TEKES) program, TRIAL, which aimed to accelerate commercialization of collaborative innovations. The ecosystem for the radical innovation was built to bring together all the critical partners (Universities, Research institutes, Applied Universities, Mobile operators, Regulatory authority, Defence forces, Technology company, and Start-up companies) required for the development of novel cognitive radio technology, to change regulation, and standardization as well as to develop novel business models. The composition of parties was unique involving academia, practitioners, and public authorities. In addition to diversity in expertise and perspectives, the actors were geographically located in different sites in Finland. Further, innovation was interdependent, because it could not have been possible by any of the partners on their own - instead it demanded an engagement and input of all actors.

As a result, the project validated the feasibility of spectrum sharing between mobile broadband networks and other types of incumbent spectrum users utilizing Finnish cognitive radio field trial environment (CORE). The project was the first to develop and validate e2e system concepts for the most prominent spectrum-sharing concepts the CBRS (FCC 2015) from the US and Europe initiated LSA (ECC 2014) in end to end field trials (Matinmikko et al. 2013, Yrjola et al. 2016, Aho et al. 2016). Validation of the sharing concepts was implemented using commercial technologies-based experimental design set-ups, wherever possible to provide practical knowledge for the selection of technology components for the next generation 5G needs while carefully considering the scalability and the total cost of ownership. Improvements in the efficiency of the spectrum usage stem from exploitation of fluctuation in the spectrum resource availability that may happen in frequency, time, space and power. The results of the project have been utilized by regulation and standardization forums not only for studying the sharing concepts themselves, but the future of spectrum management, and the evolution towards future mobile broadband systems enhanced with innovative spectrum sharing enabled business models to cope with the growing demand for capacity and new services by humans and machines.

3.2 Data collection and analysis

Altogether sixteen in-depth interviews were conducted for the present study. The informants were from variety of representatives and functional perspectives. Each interview took between 30 to 97 minutes and was recorded and transcribed. In addition, informal conversations and discussions were used as a complementary data. The use of multiple data types and data sources enables triangulation and improves reliability of findings.

For data analysis, we employed qualitative content analysis (Eriksson and Kovalainen, 2016). First, based on interview data we constructed the knowledge co-creation/innovation process. Thereafter, we fed it back to some key actors and reconstructed it based on the feedback. Second, we generated the coding scheme first inductively from data, and there after revised it with circulating between data and theory, to emphasize the contextual nature of data. As often in abductive analysis (Dubois and Gadde, (2002) the process of analysis is dynamic, proceeding iteratively between data and theory (Eriksson and Kovalainen, 2016). We used qualitative analysis software (NVIVO 2.0) to organize data. The analysis was informed by our focus on organizing knowledge co-creation, but we were also alert to emerging notions.

4 Results

4.1 Organization and underlying aspects of organizing

Radical innovation was conducted as a multiparty project around the project plan for the funding agency. The project organization involved responsible director and steering group that comprised representatives of all parties (including funding agency). The steering group was responsible for the administration of the project and it monitored the advance of the project regularly. Each party had their own research plan, which they conducted independently while simultaneously being involved into shared project plan. We target our research on the interdependent knowledge co-creation and exclude parties' independent goals. Despite the formal project organization and plan, a more sensitive and flexible organizing was consciously searched to support the sticky development of interdependent RI and to consider the multidimensionality of the RI, that is, technology, business and regulation.

For that purpose, three specialized working groups (WG) were built (technology, business, and regulation). The members and the leaders for the working groups were negotiated and collectively allocated. Two criteria guided the membership: expertise and representativeness (working groups were built to involve members of diverse parties). In addition, cross membership was also emphasized (some members were involved in two or more working group).

The working groups were non-hierarchical, meaning that there were no supervisor-employee relationship between working group members, that is, there were no defined roles within the working groups. The only exception is the leader of the working group, who was responsible about coordination within WG and between WGs.

4.2. Knowledge co-creation process

Knowledge co-creation and innovation are inherently intertwined and co-evolving, which generative dance was fostered via specific practice comprising chains of cycles (labelled as “trials”). The chain of cycles constitute a circular process, in which each cycle builds on discoveries (created knowledge), feedback, knowledge synthesis of the previous one, and thereby direct the forthcoming and future cycles and advance interdependent development of technology, regulation and business simultaneously. The circular process constituted of cycles, each of which involved five major phases (Figure 1):

1. **Problem identification and goal setting:** Problem is collectively searched and identified in relation to overall innovation by moving between problem identification and goal of the trial (public demonstration), while simultaneously amplifying between technology, business and regulation. This fuzzy orientation and ‘planning’ phase looks back (findings and results from previous trial), present and forward, while anchoring the current state and setting next steps and goal for next trial.
2. **Knowledge co-creation:** generation of new knowledge, seeking solutions and solving problem, making field test, interpreting what is found and integrating knowledge discovered.
3. **Internal knowledge sharing:** sharing results and findings within ecosystem parties and their members (who are not involved into project), by discussing about the meaning of the results.
4. **External knowledge sharing and feedback search:** Sharing findings and demonstrating (demo) for external audience in conference or other kind of forums (= goal of the trial)
5. **Knowledge synthesis:** Synthetizing knowledge gained: knowledge discovered, internal ideas, external feedback, in relation to innovation advance.

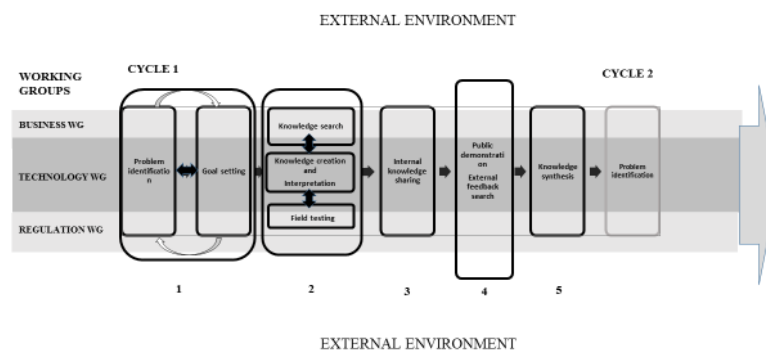

Figure 1: Knowledge co-creation/innovation process

4.2.1 Participation in knowledge co-creation

Participation in knowledge co-creation is dynamic, meaning that there were several shifts in participation within each cycle. Participation varied and was organized in changing compositions of participants along the cycle according to problem, expertise, purpose and interest.

At the beginning of each cycle (problem identification and goal setting), the participation was broad involving members from all working groups and an executive board group as well. Once the problem was identified and the goal set, the participation based on expertise and the problem at hand. In this phase, autonomous, self-organising groups around the problem took responsibility of seeking solutions. Internal knowledge sharing phase gathered a broad participation, involving members of the project parties as well as their members (who were not involved into the project, but were interested about it). Participation in the external demonstration based on expertise, experience and 'involvement' on discoveries to be demonstrated. Participation in knowledge synthesis was also broad involving members of all working groups including volunteers.

4.2.1 Coordination knowledge co-creation

Coordination knowledge co-creation was informal as there were no formal rules or decision-making processes. It also followed the cyclic process, that is, each phase in cycle is a kind of orientation (probing) and anchoring point to coordinate knowledge and activities related to innovation.

Decision-making was distributed and dynamic, ranging between decisions made by particular experts to distributed team decision making. However, decision-making based on collectively produced knowledge and understanding, that is, integration of knowledge and perspectives of diverse actors to explore and identify problems as well as to build collective sense-making. For example, regular whole day seminars were organized to gather all participants around some specific theme, like to explore *"how the business scenarios, mobile operators and their business models or ecosystems will change in future?"* (respondent).

Thus, coordination occurred through regular meetings, probing through intense dialogue and collaboration. *"Active working groups meet regularly and repeatedly, fortnightly or when needed"* (respondent). Coordination involved following types of orientations: 1) past-present-future; 2) technology-regulation-business; 3) innovation – external environment, and in knowledge co-creation 4) knowledge search - field tests - knowledge interpretation. Such a multidimensional orientation is critical, because interpretation of discoveries in relation to alternative possibilities and future direction demands thorough interpretation and integration of knowledge and expertise of diverse actors to build a shared understanding. In addition, spontaneous meetings and communication emerged according to need. *"We have a spontaneous collaboration. Once a question arises, we immediately contact (send e-mail or call) the person in charge"* Likewise, coordination practices emerged and were developed in interaction between participants according to the demands.

To support coordination several tools were employed: *E-mail*, and differentiated e-mail lists were used to leverage information either to all or to specific groups of participants and to interconnect people around a specific theme or problem. *Canvas or map* was used as a boundary object in orientation, in identifying the problem, and in visualizing the current state, advance and potential future directions of the innovation. *Databases*, to which all members had an access, were used to share documents, results, and the real time ‘roadmap’ of trials regarding the content and environment. However, documentation was not the key issue and it was kept as low as possible.

5 Discussion and conclusions

The present study examined organizing knowledge co-creation for radical innovation within knowledge ecosystem, and particularly, in one radical innovation ecosystem project.

We found that within (and despite) formal project organization organizing knowledge co-creation can, indeed, be dynamic and informal, and it seems to act as a fundamental basis of organizing knowledge ecosystem. This finding aligns with research findings by Järvi et al., (2018). Whereas the formal organization is responsible of the administrative aspects of knowledge ecosystem, it simultaneously emphasized dynamic organizing in knowledge co-creation for radical innovation. This finding is important for all types of organizations aiming to foster knowledge co-creation and innovation, as it shows that successful knowledge creation can occur under dynamic and specific kind of organizing, which can sustain also within formal organization.

Further, our findings reveal that knowledge co-creation and development of innovation are intertwined. Particularly, process of knowledge co-creation and innovation is cyclic in which each cycle builds on previous one. This refers to previous studies, which present innovation as cyclic process (Lancker et al. 2011), as well as pivoting in start-up firms (Ries, 2011) and problem based learning process (Savery, 1995). Although there exist a plan for development of innovation, it rarely is the final plan, because the process on radical innovation is grounded by emergence, setbacks, discoveries, as well as conscious decisions.

What is more, we found that when development of innovation is organized based on knowledge co-creation, it enables to capture multidimensionality of innovation (in this case orientation between technology, business, and regulation) throughout the process as well as situational and contextual complexities of innovation, while simultaneously building new knowledge. Hence, temporary, dynamic, and informal organizing enables cyclic process enacted.

Our results contribute to the research on knowledge creation (e.g. Nonaka and Toyama, 2003; Harvey, 2014) by providing a cyclic process model for dynamic knowledge co-creation within temporal and emerging collective, that is, knowledge ecosystem. Such a cyclic process enables to capture various kinds of knowledge co-creation with varied compositions of participants, which finding aligns with the recent research on knowledge creation by Nisula et al. (2019). Likewise, our findings add on

research on organizing joint innovation within temporary knowledge ecosystems, by providing empirical evidence on dynamic organizing process anchored according to the knowledge co-creation. Further, our results contribute to the literature on radical innovation, by shedding light on organizing cyclic process of innovation anchored around knowledge co-creation, which considers multidimensionality of radical innovation (e.g. Lancker et al., 2011). Further, our research contribute to the research on knowledge ecosystem function, by suggesting that knowledge co-creation process is central function in knowledge ecosystem, and a source of interdependency throughout innovation. In a broader sense, our findings contribute to the research on ecosystem capabilities (Phillips et al., 2017), by suggesting that organizing knowledge co-creation is a central function and capability in ecosystems in general, as it builds interdependence among actors as well as contributes to interdependent outcome (Tjosvold, 1989).

Abstract

Knowledge Management (KM) is vital factor to successfully undertake projects. The temporary nature of projects necessitates employing useful KM practices for tackling issues such as knowledge leakiness and rework.

The existing Project Management Maturity Models (PMMMs) have focused on discussing Project Management practices, however, the management of project knowledge is yet to be addressed, at various levels of maturity.

This research project was undertaken to investigate the mentioned gap for addressing KM practices at the existing PMMMs investigating how the knowledge being captured, managed, redistributed, shared and stored in the interviewed companies and the identification of the tools used to ensure that this occurs correctly and properly timed, to pursue continuous improvement and the success of the projects with the aim of sharing and promoting the development of the Project Management culture and Knowledge Management starting from the academic sphere, encouraging company's growth and effectiveness thanks to:

- *Improved business decisions thanks to facilitated access to expertise and to leading practices*
- *Increased efficiency, productivity and work smarter by reducing cases of "reinventing the wheel"*
- *Improved Innovation through wider and borderless collaboration.*
- *Reduced loss of know-how by capturing explicit and tacit knowledge*
- *Speeded-up productivity with on-board trainings and timely access to knowledge*
- *Increased client satisfaction by delivering value insights*
- *Enhanced quality and ability to collaborate by standardizing ways of working and enabling discussions with leading experts*

Due to the exploratory and inductive nature of this research, statistical methods were chosen as the research methodology. The web and free tool has been chosen to distribute the survey across the selected list of participants.

Keywords – Knowledge Management (KM), Project Management Office (PMO) Project-based Organization, Project Manager (PM), Project Management.

Paper Type - Academic Research Paper.

1 Introduction

A multilingual and modelled electronic questionnaire has been developed to investigate the Swiss economic context and more in particular, the maturity within Swiss Enterprises of the KM practices.

Due to multicultural environment of the Swiss enterprises reality, the electronic questionnaire has been developed in English, translated in Italian, German and French, among the Swiss national languages, and structured in four main parts:

1. Enterprise's location, size and Industrial Sector of belonging
2. Overall assessment of KM Practices
3. KM Practices
4. KM Effectiveness

To be reported the minimum threshold represented by the questions up to third, thought to determine if proceed further in the investigation of KM practices.

The survey was composed of 23 questions and focused on investigating the importance of KM practices, nowadays. The survey made it possible to get info and making consideration over 80 Swiss companies.

2 Enterprise's location, size and Industrial Sector of belonging

The survey has shown a pre-dominant participation of Italian-speaking users (80%) but also a significant participation of German-speaking users (20%). French-speaking users have been omitted, since their participation has not been considered relevant for statistical purposes.

Linguistic Region where the company is based

Considering the subject of the survey, namely the maturity of Swiss companies, "declined" in the management of knowledge, it is not surprising that as many as 74% of the people who took part in the survey are part of a big (44%) or medium (30%) company.

Company Size

In the Helvetic confederation, German-speaking Switzerland is characterized by the highest presence in the territory of large companies. Italian Switzerland emerges as a reality mainly composed of medium and micro-enterprises.

Analyzing the segmentation of the surveyed users according to the sector of belonging of their own company, we find a peculiarity of the Swiss productive fabric. Pharmaceuticals, Construction and Services are confirmed to be among the leading sectors.

3 Overall assessment of KM Practices

It is interesting to note that although knowledge management practices are recognized as value-added activities (only 7% of respondents declare the total lack of a global / local knowledge management program), their implementation according to structured practices and through appropriate tools it is far from being implemented in 31% of cases. While the large enterprise is predictable to be the most equipped with well-structured and well-defined practices for knowledge management, in the medium-sized enterprise, although acknowledged the importance of the KM topic, programs and practices for the management of it are under implementation and still not structured adequately.

1. Does your company have an enterprise-wide active, ongoing KM program, or elements of such a program, to preserve institutional memory for future use?

■ No. We have no enterprise-wide program or elements of a program.

■ Yes. We have an enterprise-wide program, but at this point it is in the "roll-out" phase and is unevenly developed among divisions.

■ Yes

As many as 62% of respondents, to a punctual question about the presence of a centralized and structured archive for knowledge management, answered affirmatively.

Percentage however destined to reach a significant 93% if within the knowledge management practices is considered a local management of it.

Finally, not considering the percentage of centralized and structured knowledge management, therefore focusing the analysis on a local knowledge management, the point of contact to access the knowledge resulted to be the teams - work units (42%) - and the individuals (18%).

3. Who or where is your institutional memory point of contact; that is, to whom do people go, or to whom are they referred, if there is a need for historical materials or documents about prior programs or projects?

As previously pointed out, 77% of respondents recognize the importance attributed in their company to the management and archiving of knowledge, answering affirmatively to question 4 related to the expectations of the company management regarding the consultation by the employee of the archived knowledge.

4. Before beginning new projects or programs, does management expect employees to consult prior organizational experience as evidenced in documents, databases, knowledgeable people, and other resources?

Transversely to the size of the company, even in the presence of a centralized and structured knowledge management, the head of department / division is identified as the element exercising authority and leadership in the KM.

5. Who exercises overall authority over KM practices?

5. Who exercises overall authority over KM practices?

Over 70% of respondents identify the management as the responsible for knowledge management. The data would seem to imply, even in the more structured company realities, the non-definition of the PMO or a questionable assignment of responsibilities related to it.

The presence of company procedures / regulations surveyed in question 8 (69%), denotes a congruity with what was surveyed in question 1 - where 62% of the interviewees confirmed the existence of a program for a centralized and structured or local knowledge management.

8. Do you have written policies or procedures for KM practices?

Where knowledge management and archiving being performed, in 7 companies out of 10 it takes place digitally. In less than 10% of cases, it only takes place on traditional media (paper, photographic, etc.).

In line with expectations, question 9 reports about digital archiving performed mainly in large and medium-sized companies and a transition phase which involves both, digital and traditional archiving, in the small enterprises.

On the contrary, a mutually exclusive choice characterizes the micro companies.

9. How do the KM practices being archived?

4 KM Practices

10. What methods are used to capture knowledge?
(Note: for this synthesis, "capturing" refers to the process of transferring knowledge from employees' minds into tangible resources, such as text documents, maps, photos, databases, websites, etc.)

In one company out of two, employees declare that they generally know what needs to be archived and how to do it and that the processes for doing so are in most of the cases well-defined. In particular, for small and micro enterprises, the processes are known more than the strategies, which are rarely present (micro company) or even absent (small companies).

13. Are practices for storing KM resources in place?

- We have a clear strategy for storing our knowledge assets.
- Employees generally understand what needs to be stored, and how to get resources from their possession into storage. The process is well-defined for most resource types.
- Storage practices are well-defined for some critical resources, such as legal or financial documents, but not necessarily for all.
- Storage practices are well-defined for physical resources but not for electronic resources
- No practices in place

14. Where are captured resources stored?

- Physical resources are stored in company-owned enterprise-level archives.
- Electronic resources are stored in an enterprise-level repository.
- We capture a lot, short-term, on personal computers or group-level servers, but we don't really have an organized way or central repository to store electronic resources long-term.
- We store our resources at another organization (i.e. state archives, museums, etc.).

What emerges in question 14, is in line with what was surveyed by question 1; one company out of two carries out a structured and centralized archiving and over the 30% of the companies performs at least a local digital archiving.

On the other hand, small enterprises outsource in 25% of cases.

Transversely to the size of the company, in over 65% of cases, the access to the knowledge is reasonably convenient and easy while in 17% of cases, the knowledge is managed locally.

18. Is there an established practice for destruction of obsolete KM resources?

In one company out of two, there is no practice for the disposal of obsolete knowledge.

On the other hand, where it is present, it is more linked to the disposal of resources stored on physical rather than electronic media.

5 KM Effectiveness

For over 7 out of 10 respondents, proper knowledge management translates into greater efficiency, productivity and better work organization. One in two interviewees considers it an element that improves business decisions.

19. What are the benefits of an effective knowledge management strategy?

20. Do KM practices enjoy continuity and persistence over time?

- The program is robust and continues through staff and administration changes.
- The program exists but is not evenly supported or well-communicated by management.
- The program may or may not survive, depending on factors such as budget cycles, administrative changes, etc.

20. Do KM practices enjoy continuity and persistence over time?

- The program is robust and continues through staff and administration changes.
- The program exists but is not evenly supported or well-communicated by management.
- The program may or may not survive, depending on factors such as budget cycles, administrative changes, etc.

The maturity of Swiss companies shows a gap when KM is probed in terms of continuity and persistence over time. In only 50% of cases, the knowledge management program is robust, well-structured and continuous over time. In the other 50% of cases it exists but is not appropriately supported by the MGMT in terms of sponsorship and continuity of the program.

21. Does your company use metrics to gauge the value-added and/or effectiveness of the KM program, or to justify costs?

21. Does your company use metrics to gauge the value-added and/or effectiveness of the KM program, or to justify costs?

Consequently, what highlighted with question 20, is further reflected in question 21, where is given evidence of a lack of metrics for the evaluation of the benefits related to knowledge management. In seven out of ten companies, there are no metrics that allow its evaluation.

6 Conclusions

Nowadays, speak about KM in a company implies a level of maturity that leads to recognize the company itself as a place of creation and accumulation of knowledge, its immaterial resources (knowledge accumulated in the organizational memory or incorporated in human resources) are the key element in the analysis of the determinants of the creation and sustainability of the competitive advantage over time.

The competitive advantage no longer consists only in providing excellent products and services in the most attractive markets but also consists in building, making operational and defending those deep competences that differentiate a company from its competitors.

To succeed in all this, organizations must realize the importance of acquiring those skills that allow them to transform business knowledge into a value, or to make of everything that the company knows, but also what it does not know to know, a competitive advantage.

Knowledge therefore represents the basis on which the specific skills of each company are built, but above all, it is the basis for taking the best decisions at every level and for reducing errors.

Competitively, what makes the difference is having an innovative knowledge management system adapted to the characteristics of the company itself.

Generating, capturing, not dispersing and operating knowledge to offer value to the customer is an essential requirement for building and sustaining competitive advantage. However, the only introduction of a management system to nothing would be worth it if it were not accompanied by a cultural change that involves every aspect of the organization. These changes must be simultaneous and interconnected.

It is therefore essential for a cultural maturation of employees towards the exchange and dissemination of knowledge, with the aim of creating a shared vision. Employee motivation for change is the key to the success of a KM process. Internal communication, rewarding systems, human resources management and working practices are the best tools to create a learning organization and to motivate employees, encouraging them to take documents to be updated and periodically checked from the company intranet.

Management have to try to eliminate the obstacles to the change - posed by those who consider it risky because of uncertainty - through the explanation of the benefits obtainable by the entire organization and by those who make it up; it has also to promote an innovative knowledge sharing culture through direct actions, staff incentives, project financing and investments in technologies aimed making people work together.

With these guidelines and with the awareness of the fundamental role played by the knowledge in the creation and maintenance of competitive advantage, we have explored the reality of Switzerland, assessing the maturity of companies respect to the implementation of practices for knowledge management.

The picture that emerged has shown a transversal awareness of employees and MGMT, regarding the importance of generating, capturing and managing knowledge, aimed to provide value added to customer.

Indeed, KM has turned out to be a current topic in all the surveyed realities, large, medium, small and micro enterprise.

In large and medium-sized enterprise, one of the two pre-conditions linked to a successful implementation of knowledge management, namely that of possessing an innovative knowledge management system adapted to the characteristics of the company, was fulfilled or, as in medium-sized companies, closed to a complete fulfillment. Large and medium-sized companies have indeed turned out to be appropriately equipped from a technological point of view. As expected, small and micro companies, suffer due to conservative company policies, showing therefore a certain delay, especially in technological terms.

Small companies, even more than micro-companies, have shown a bigger delay on the issue of the existence of an appropriate knowledge management system in the company.

However, in all the surveyed companies, a full awareness about the cultural shift needed within the organization to make effective tools and policies for knowledge management, has emerged.

Swiss productive fabric seems to have understood, even at level of small and micro enterprises, the centrality of the topic related to the knowledge management.

The cultural shift in these realities is indeed ahead respect the technological one.

In large and medium-sized enterprises, the level of acquired corporate maturity is such that it determines the shift of the focus in terms of knowledge management, from the implementation of a KM policy, to the identification of metrics that allow an appropriate assessment of the benefits related to it.

Knowledge Management to make better decisions, reduce errors and increase efficiency.

Abstract

In such a competitive world government's effort is providing an effective procedure to develop the international market and economic. Special economic zone (SEZ) is regularly used as a tool for developing economic growth, to attract more foreign direct investment, enhance international interaction and boost the national trade, especially in developing countries. On the other hand, it seems clear that governments seek more effective procedure by involving other sectors in projects of SEZs. In Policy network approach the governments involve more private sectors for solving the general problems. To perform the analysis, we study the main characteristic of special Economic zones such as geographical locations, projects, type of zones, and organizational classifications as well as indicators that reflect the institutional framework: zone's ownership, main authority, and management. The article presents a comparative analysis of SEZs institutional framework by considering the network policy approach in selected zones in Iran, UAE, and Kazakhstan. The results of this comparison between cases illustrate the main

institutional framework, governing procedure, and effect of network approach in special economic zones.

Keywords: Special Economic Zone, Policy network, comparative studies, organizational structures

Paper type: Practical Paper

1 Introduction

There are several definitions for the special economic zone, in general term, Special economic zones represent designated geographical areas within a country, where business activity is subject to different rules from those prevailing in the rest of the economy. (Farole, 2011; Zeng, 2015) Generally, the main establishers of SEZs base on their main objectives and economic targets; they design different type of zones in the countries. Overall, there are a variety of establishment classifications for special economic zone structure. World Bank (2008) categorized these zones under six main modern zones such as Export processing zones, Free trade zones, Enterprise zones, Free ports, single factory zone, and specialized zones.

By considering the important role of SEZs to attract the investors, literature reviews highlighted the studies which are a focus on the relationship between SEZs performance to attract FDI (Chakraborty, et.al, 2017; Chandrachud &Gajalakshmi, 2013). Another interesting feature of SEZ is analyzing SEZs' aspects especially on the economic situation of developing countries (Yeung, et.al.2009; Kuzmenko, et, al.2018). In respect to the main capacity of SEZ in economic growth, comparative studies on special economic zone cases are notable between these ranges of researches which are considered more the successful zones in India and China or African countries. (Roux & Schoeman, 2016; Zeng, 2015; Farole, 2011; Olga &Mayburov, 2017)

Boerzel (1997) defined the policy networks as a network of actors who have benefited by determining the policy and they provide resources (material and non-material) for adjusting, deciding and implementing of these politics. Recently, Policy network approach got also favorite concepts for researchers in policy-making process especially for analyzing its theoretical aspect (Renate & Bernd,1991; Dowding,1995; Klijn,1996; Boerzel, 1997; Moberg,2014), determining the structure of network governance(Provan &Kenis,2007), some studies take a look on the relationship between Public Management and Policy Networks (Koppenjan& Klijn,2000) other investigations explore the relationship between privatization and corporate governance (Martinez, et al, 2013) or innovative methods in management (Martinez, et, al, 2012; Grantham, 2001) .

Reviewing the background of studies on special economic zones demonstrate that most of researches design to analyze the economic aspect of these zones, therefore, few types of research have addressed the governing structure, management policy, and policy network as alternative approach to enhance the efficacy of these special zones. Many researchers compared the SEZs for understanding though there are similar works, in the

present work we have a comprehensive study on SEZs framework in selected countries (Iran, UAE, and Kazakhstan) which has never been done before. On the other hand, applying the network policy approach has never considered in previous studies for analyzing the organizational structures of SEZ in these countries. So the result will provide a range of innovative process for policymakers in special economic zones to improve the success and improve the effective operations of public and private sectors in these zones.

2 Main purpose of this study

The purpose of this study is to compare and demonstrate the similarities and differences of SEZs program, main authority and regulations, management strategies in selected countries, and to discuss the challenges of governing these zones regarding their primary organization plan and managing strategies by considering a political situation of each county.

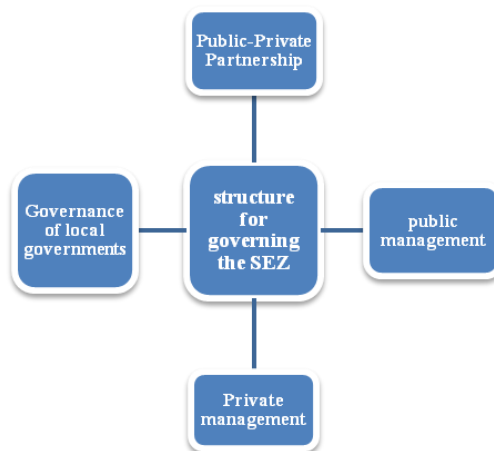

The research will respond to main questions such as:

- How institutional characteristics of SEZs' framework in different national situation conduct patterns of networking policies?
- What is the influence of the policy network process on the interactions in SEZs?

3 The institutional framework of governance in special economic zones

There is different sort of institutional adjustment to determine the authorities that include government companies, ministry, a zone-specific management board, or an investment promotion agency. (ADB, 2018)

SEZ implications are properly depend on country's specific situations and establishing these special zones are not necessarily a suitable instrument for any country(Zeng,2015) and Private sector development or public-private partnerships participations in SEZs governing cannot increase the efficiency of these zone individually, but they can help the procedure for reducing the risk of government's activities in these areas. (Farole & kweka, 2011) Base on World Bank (2017) operational review on institutional framework for governing the SEZs and FIAS's (2008) findings, in this study the special economic zones' classified in four different management structures as bellow:

(Source: Rafiee, 2009; World Bank, 2017, FIAS, 2008)

4 Theoretical framework: the policy network approach

Based on a network policy approach, an organization is considered as part of a complex arrangement that has multiple interacts with other organizations and sectors. As Rhodes(2006) definition: “Policy networks are sets of formal institutional and informal linkages between governmental and other actors structured around shared if endlessly negotiated beliefs and interests in public policymaking and implementation.(Galay&Youngs,2014)

The policy network approach designed to provide the scheme for determining the complex processes to develop management process, strategies planning and it illustrates the framework for strategic interaction processes and institutional relations in organizations. (Koppenjan& Klijn, 2000)

Background of study in policy network illustrates that the main focus in this filed was on theoretical part of governance network and political economy (Rhodes,1990; Marin & Mayntz,1992; Boerzel,1997; Klijn,1996; Grantham,2001; Provan&Kenis,2008; Galey& Youngs,2011) , inter-organizational relationships(Iacono et.al 2012; Iacono , Berni ,and Martinez,2012) and therefore there is a little attention on integration of this concept on the function of SEZ and general trade zones.

For our purpose, we consider the network as a formal and informal interaction in selected projects and different partners. Moreover, we focus on the network relation differences which are associated with the different management strategies in our case studies. The principle reason to pick up the network policy as the theoretical framework of this research is affiliated intricacy of special economic zones complex which includes a range of interaction between governments’ agencies, private sectors and also local and foreign investors at the same time.

5 Methodology

The methodology of this research comes from a combination of more qualitative and quantitative approaches. We use qualitative multiple case study design to determine a clear vision and provides a strong basis for comparing ‘how’ the SEZs authorities performance respond to the institutional framework through networking policies and what is the connived organization process for managing the SEZ in our case studies.

5.1. Data collection

We collected data through semi-structured interviews with decision makers in special economic zones; with choosing them among the domestic top and key employees of SEZ, government authorities, representatives from governmental supporting agencies and the manager in charge of the firm’s internationalization process. In addition, emails and phone calls will use to ensure that the selected cases matched the sampling. For archival data, we used resources such as websites of SEZs in selected countries, business publications, annual reports, project biographies and databases, and reports of support agencies.

6 The main feature of special economic zones in selected case studies

Reviews of the literature of studies on Special Economic Zones around the world indicate that most of them focus on cases in China, India and South Africa. In the present study, we design our case studies between some selected SEZs in developing countries such as UAE, Iran, and Kazakhstan. Regarding COMCEC report in the year 2017, UAE, Iran, Kazakhstan has a comprehensive plan to increase their zones' competitiveness between other Islamic worlds.

We choose three different economic zones relevant to their specific organizational, political characteristic, geographical position and strategic location SEZ and innovative process for developing their economic zones. We organized our research to compare the cases in selected countries base on a number of SEZs, country’s legislation and regulatory mechanisms to establish and development of SEZs, type of management, governance and institutional framework in the free trade zone, ownership structure. In this part, we take a look at selected case studies and the main comparative advantage of these areas that make each of them as a unique case.

A case study of Special economic zones in the United Arab Emirates

Base on a dataset of World Bank (2018), UAE’s GDP grew from US\$ 289.78 billion in 2010 to US\$ 382.5 billion in 2017. There are more than thirty free trade zones in UAE and they are defined as a territory which is offering special tax, customs and imports regime and they are governed by their own framework of regulations (UAE criminal law). Dubai is one successful example of FTZ in the Middle East by holding more than twenty Free zones and it is the fourth most open economy in the world and the most exposed economy in the Gulf to foreign trade and capital investment flows.

The governments of the UAE have been actively involved in the development of different economic projects in association with both local and foreign businesses, especially in free zones. Like many other global experiences, governments known as the main establisher of SEZs in UAE. Regarding the main objects of establishing the SEZ in UAE, an independent free trade zone authority governs each zone and this unit is the main responsible for issuing the licenses and operating the projects in a free zone.

Table 1 Classification of selected free zones in UAE

	Jebel Ali Free Zone	Masdar City	Dubai Airport Free Zone (DAFZ)	Dubai Multi-Commodities Centre (DMCC)	Dubai International Financial Centre (DIFC)
Year of establishment	1985	2009	1996	2002	2004
Area	Over 57 km ²	6 km ²	696,000 m ²	200-ha	110 ha
Types of ownership	-Free Zone Company (FZCO), multiple shareholding -Free Zone Establishment (FZE) -Branch of a foreign or UAE company	- Free Zone Limited Liability Company (FZ-LLC) -Branch of a foreign or UAE company	-Free Zone Company (FZCO) -Branch of a foreign or UAE company	-Free Zone Limited Liability Company (FZ-LLC) -Branch of a foreign or UAE company	-Company Limited by Shares -Branch of a foreign or UAE company
Main authority	Jebel Ali Free Zone	Abu Dhabi Future Energy Company	Authorizes by Dubai Airport Free Zone (DAFZ)	Established by government and Ahmed Bin Sulayem is the Executive Chairman of DMCC. Authorizes by Dubai Multi-Commodities Centre (DMCC)	Independent authority by Dubai International Financial Centre) DIFC has its own independent, internationally regulated regulator and judicial system

A case study of Special economic zones in Iran

With reference to Iran's geographic situation, this country has seven free-trade zones (FTZ) and 23 completed special economic zones (in form of a free port, industrial zone, Industrial Parks) and around 20 ongoing SEZs. The Main objective FTZs is attracting Foreign Direct Investment (FDI) and to increase international industrial transits by promoting Iran's non-oil exports. The history of the special economic zone in Iran back to the 1970s by developing Kish Island as a first free trade area in Iran. The FTZs are

strategically positioned for their potential international links and the SEZs for improving the country's main industry distribution system and supply network. (Hakimian, 2011)

Main structure of governing and Management of SEZ in Iran

Governing FTZs and SEZs in Iran has followed the different regulation. In order to accelerate of economic development progress and increase the investment process, create more job opportunity the government set range of regulation as the “The Law on the Administration of Free Trade-Industrial Zones ” in special economic that emphasis each zone is managed by an Authority organized as a company, with an independent legal condition that the funds belong to the government.

The Law on the Administration of Free Trade-Industrial Zones “includes 28 Articles and 8 Notes, this law gives comprehensive information about all procedures of management and governance in the zones.

Base on this law, each zone shall be administered by an authority organized as a company, with autonomous legal status, whose capital shall belong to the government. Such companies and their affiliates and subsidiaries shall be exempt from the laws and regulations governing state-owned companies and from other general regulations decreed by the government.

Management controls each zone through a Board of Directors, which consists of three to five persons who are selected by the Board of Ministers. In Iran, public-private partnership operation has been briefly mentioned in the Fifth Five Year Development Act and more details of PPPs were provided in the yearly budget. (Ministry of Industries and Mines, 2008)Special economic zone in Iran follow the different regulation that is known as “The Law on the Establishment and Administration of Economic Zones in the Islamic Republic of Iran”. This law comprises 25 Articles and 12 Notes and covers all aspects of the operation, management and governance in the zones.

Table 2 Summary on free trade zones in Iran

free trade zone in Iran:	Establishment year	Area	location	Authority	projects
Anzali port	2003	9400 ha	caspian sea /north of Iran	Ports and Shipping Organization	•Tourism industry •Agriculture and Fishery
Chabahar Free Trade-Industrial Zone (CFZ)	1992	140 ha	south east	Chabahar Free Zone Organization	•Energy hub •Food and tourism industry •Products rooted in the sea-based economy •ITC services
Kish	1989	91.5 km2	persian gulf	Kish Free Zone Organization	•Tourism industry •Banking and financial services •Electronic industries •Marine drilling technology

Arvand	2004	37,400 ha	north west of Persian Gulf	Arvand Free Zone Organization	<ul style="list-style-type: none"> •Heavy and Marine installation •oil and petrochemical industries
Qeshm Free Trade Industrial Zone	1990	480 km2	Persian Gulf and the Sea of Oman.	Qeshm Free Zone Organization	<ul style="list-style-type: none"> •Fishery industries and industrial fishing •Energy park •Oil logistic services •Transit and transportation industry
Aras	2005	9,700 ha	Northwest of Iran	Jolfa Development Company	<ul style="list-style-type: none"> •Transportation and transit industries • Expansion of agricultural, animal husbandry and transformational industries.
Makou	2010	5000 ha	northwest of Iran	Maku free zone is governed by an independent legal entity and its capital completely belongs to the government	<ul style="list-style-type: none"> •Large agricultural and industrial units. •Transportation and transit of goods

Special economic zone in Republic of Kazakhstan

Kazakhstan has been experimenting with SEZs since the early 1990s. The first free economic zone law was introduced in 1990, which was replaced by another law in 1996. In 2001, it introduced an ‘SEZ law Astana’ with a focus on constructing a capital city. In 2007, the government approved a law on SEZs again, which also met with little success. (Asian Development Bank, 2018)

The Law on special economic zones of the Republic of Kazakhstan dated July 21, 2011, defines Special economic zone (SEZ) as a territory of the Republic of Kazakhstan having precise marked borders, on which a special legal regime shall be applied to carry out priority activities. The purpose of the creation of the SEZ have accelerated construction of a new administrative and business center of the capital; the opening of new industries

About the administration of the special economic zone this law indicates that if the establishment of the special economic zone was initiated by a central executive body, administration of the special economic zone shall be carried out by the central executive body appointed by the government of Kazakhstan. Indeed, the administration of the special economic zone shall be carried out by the local authority of the administrative-territorial unit, where the SEZ is located. (chapter2, article7)

Table 3 The free trade zone characteristic in Kazakhstan

free trade zone in Kazakhstan	Establishment year	Area	location	Type of projects	Main authority
Astana	2002	7634.71 ha	Astana.	The development of Astana city, including the creation of modern infrastructure by focusing on construction field.	“Department of investment and development of Astana city” serves as the management company of SEZ Astana – New City.
SEZ Seaport Aktau	2003	2,000 ha	Aktau	It is to accelerate the development of the region by enhancing Kazakhstan’s access to the global market	Local government (akimats) is the shareholder of Management Company of SEZ Aktau Seaport
SEZ Saryarka	2011	534,9 ha	Karaganda region	It is design to develop metallurgical and metal-processing industries	Local government (akimats) Management Company of SEZ Saryarka
SEZ Ontustik (Shymkent)	2005	200 ha	Ontustik	enterprises that process cotton for the textile and garment industries;	Local government is the shareholder of management company of SEZ Ontustik
SEZ Burabay	2007	370 ha	borovoe	tourist services	Investment Committee of Ministry for Investments and Development (MID),
SEZ National Industrial Petrochemical Technoparc (Atyrau)	2007	3,476 ha	Republic of Kazakhstan Atyrau oblast	Projects in petrochemical industry for hydrocarbon processing;	The 97.5% owned by the Ministry of Energy, and 2.5% belongs to the United Chemical Company, which is fully owned by Samruk-Kazyna, a state-owned company. Ministry of Energy
SEZ Pavlodar	2011	3,300 ha	Pavlodar	chemical and petrochemical sectors, with a focus on the production of export-oriented products	Local goveremnt of Pavlodar is a shareholder of JSC «The management company of SEZ Pavlodar»

7 Main results of comparative analysis

In this section, we are discussing similarities and differences between selected SEZs in three countries. Comparative analysis indicates that the most common typology recorded within our selected case is Free Trade Zones (FTZs), Special Economic Zones (SEZs) and industrial high tech parks. Analysis of main characteristics shows that like many global trends, SEZs within these three countries were typically located close to both port and airport infrastructure. In all three countries, the governments are the main establisher of SEZs but the distributions of their power are a difference.

As can be seen from the table (above), the main difference is related to ownership of zones in the cases. Kazakhstan applies more public ownership which the government takes on the role of developer, operator, and regulator of the zones. However, a public-private partnership is actively developing recently but there is still a lack of knowledge, experience to apply PPP. The free zones in Iran are state-owned, and the administration mechanism is also state-owned, but in the special areas, the private sector is also active. For these same reasons, special economic zones are more successful than free zones.

Iran and UAE exert more privately owned zones which the companies develop, manage and operate the zones under the government's regulatory and public-private partnerships, whereby the government takes part in the zone development and operation in order to encourage private sector participation in this project. In fact, UEA follows the more liberal procedure for governing the zones to compare Iran and Kazakhstan.

8 Comparison of the key aspects of Special Economic Zones

	UAE	Kazakhstan	IRAN
Number of SEZ and FTZ	More than 40 free trade zone	10 special economic zone	six free-trade zones (FTZ) 23 special economic zones (SEZ)
Type of SEZ	Seaport free zones, airport free zones, mainland free zones. Free-trade zone	Industrial SEZ Service SEZ Technical SEZ SEZ with a combined priority activities (industrial and service	Free trade zone Seaport free zones Free Trade Industrial Zone

forms of ownership	Private and ppp	Most public ownership for SEZs	Public ownership and ppp for FTZ
Management and administration	- administered by an authority organized as a company	-Government Authorities -Ministries	- Board of Directors - administered by an authority organized as a company --Ministries
Regulator	governments	governments	governments
Developer of zone	Private sectors	governments	governments
Operator	Private sectors	Governments and private sectors	Governments and private sectors

The other notable difference is associated with main authority regulations; Iran and Kazakhstan are pursuing a more comprehensive framework that covers all zones but in the case of UAE each zone possesses different regulation.

The strategic plan of government for economic development in UAE is more related to private rather to public development of zones and they involved more foreign and private sectors in main projects by focusing on ICT and technology sectors.

Involving more the private sectors bring the necessity to design and have a more precise mechanism for simplifying the communication between government and investors and develop networking. The term of policy network and corporate governance has an important role to increase the efficacy of managing the SEZ and improve the private and public sectors.

In the case of UAE, this country takes advantage of new technologies to provide a framework for the relationship between government, state agencies and private sectors. The long term program in SEZs in UAE is improving the network approach by providing the latest technology and connectivity in legal services in zones such as world's first free zone to offer electronic signature (DMCC), Business Apps Manager for guarantee firms to compliance their activities with UAE regulations.

Regarding the governments' strong role in SEZs structure in Iran and Kazakhstan, these two countries could not improve their networking process like UAE. Kazakhstan has improved its SEZs situation by making a platform to progress academic relationship especially in R&D sectors and establish data center that helps investors to have a better connection inside SEZs. (Innovation Technology Park SEZ)

In the case of UAE, this country takes advantage of new technologies to provide a framework for the relationship between government, state agencies and private sectors. The long term program in SEZs in UAE is improving the network approach by providing the latest technology and connectivity in legal services in zones such as world's first free zone to offer electronic signature (DMCC), Business Apps Manager for guarantee firms to compliance their activities with UAE regulations.

Regarding the governments' strong role in SEZs structure in Iran and Kazakhstan, these two countries could not improve their networking process like UAE. Kazakhstan has improved its SEZs situation by making a platform to progress academic relationship

especially in R&D sectors and establish data center that helps investors to have a better connection inside SEZs.(Innovation Technology Park SEZ)

In spite of comprehensive regulation of SEZ and FTZ in Iran, the lack of coordination and network policies between the state agencies and the lack of attention to integrated management in these areas have led various agencies and organizations in free zones to implement their own laws and programs in a discrete manner and regardless of integrated zone management.

By considering the principle role of SEZs to attract FDI, foreign firms have a more effective role in special zones to transferring knowledge and advanced technology to host counties. Consequently, having an inclusive network approach can provide a flexible and effective procedure for the integration of private and not state sectors in SEZs goals.

As well as an innovative process for governing the modern SEZs it seems that corporate governance through a board of directors and local management in each zone which can balance the power in special areas. UAE successful experience represents that there is a positive relationship between independence and the level of autonomy of SEZ and the performance of firms.

Abstract

The forms of collaboration and the relationships among public and private actors are crucial to create value for regional development and to enable economic growth. Policy makers promote projects to stimulate innovation and to facilitate knowledge creation and diffusion. The paper aims to investigate the emergence of a network set up to develop a complex project. In particular, our work tries to investigate inter organizational relationships and collaboration among academic institutions, industrial organizations, researchers, policy makers and institutional actors participating to a common project to boost regional development. Firstly, our contribution focuses on the evolution of this network. Moreover, it analyses the role of different actors and the governance of the forming network studying the effects of collaborative processes on knowledge creation and diffusion.

The project was set up to introduce and create a SEZ (Special Economic Zone) in the South of Italy (Campania Region) in order to foster regional development and to boost employment as well as local and national growth. The present preliminary study is part of an ongoing program including Universities, institutional actors and organizations from different industrial sectors.

The research is based on a qualitative investigation using the case study approach. The findings could be a useful tool for institutional actors, policy makers, organizations and management to develop strategies to enhance local development. At the same time, it is essential to understand and assess the economic impact of the introduction of the SEZ, as proposed by the Regional Council (DGR No. 175 of 28/03/2018) on the entire regional economy. The observation of collaboration interactions while the network is forming is useful to understand the actors' behavior and governance mechanisms. The development of clusters is a complex process linked to actors' collaboration and to inter-organizational relationships. Integration task as well as roles in knowledge creation and collaboration among actors are key elements crucial for the development of the local areas.

Keywords – network, governance mechanisms, projects, SEZ.

Paper type – Academic Research Paper

1 Introduction

The forms of collaboration and the relationships among public and private actors are crucial to create value for regional development and to enable economic growth. Policy makers promote projects to stimulate innovation and to facilitate knowledge creation and diffusion. Recently researchers have increased their attention on the development of special economic zones (SEZ) as a tool to increase investments, to boost employment and economic growth through fiscal incentives and economic benefits (FIAS, 2008, OECD, 2009; World Investment report 2018). International experience suggests that the relationship among institutional actors such as national and local government, agencies, public and private organizations and other stakeholders are crucial to create innovation, to increase development and to improve competitiveness (Hall, Taylor 1996; Sun, Cao 2018). On one hand, most studies focus on the economic impact of SEZ; on the other hand, fewer investigate the effect of other features (i.e. management, governance, the role of actors, institutional framework etc.) on the success of these special areas. For this reason, it is interesting to study the role of actors and the governance mechanism within the network since its emergence.

The paper aims to investigate the emergence of a network set up to develop a complex project. In particular, our work tries to investigate inter organizational relationships and collaboration among academic institutions, industrial organizations, researchers, policy makers and institutional actors participating to a common project to boost regional development. Firstly, our contribution focuses on the evolution of this network. Moreover, it analyses the role of different actors and the governance of the forming network studying the effects of collaborative processes on knowledge creation and diffusion.

2 Theoretical framework

The paper contributes to the understanding of inter organizational relationship and flexible/temporary form of organizing (Bakker, 2010; Bakker et al. 2016; Sydow et al., 2004; Kenis et al., 2009 March, 1995 Ahuja 2000; Gulati, Gargiulo, 1999). The context of study regards the creation of a group of individual and collective actors who were challenged with Government Issue to set a new complex project.

2.1 The definition of Special Economic Zones

The number of special economic zones (SEZ) is rapidly growing, although the first type of free zone were set up since 1700, in the past 20 years the number of modern special economic zones has increased worldwide. Generally, SEZs are defined as specific geographical areas characterized by a particular set of incentives or economic benefits for actors who decide to locate their business in the area (World Bank 2008; Farole 2011)

The SEZ basic concept is broad¹ and includes several specific characteristics: a) a geographically delimited area usually physically secured, b) a single management or administration c) it offers benefits for investors physically within the zone d) it has a separate customs area (duty-free benefits) and streamlined procedures (FIAS 2008; World Bank 2008; Farole 2011). In addition to this, these zones have other common “special” features such as special regulation, public services, infrastructures, fiscal incentives etc. (Zeng 2016). Some studies (Zeng, 2010, 2016) confirm that successful SEZs can contribute to generate two main benefits: “direct” economic benefits, such as employment generation, export growth, government revenues, foreign currency gains; “indirect” economic benefits, such as upgrading skills, technology transfer and innovation, economic diversification and better performance of local firms.

SEZ can take a number of different forms, the most common are: Export processing zones, Free trade zones, Enterprise zones, free ports, single factory zone, specialized zones, comprehensive SEZ, bonded area and Eco industrial zones (World Bank 2008, Zeng 2016)

- Free trade zones (FTZ) are duty-free areas offering facilities for storage and distribution for trade, trans-shipment and re-export.
- Export processing zones (EPZ) are industrial zones with special incentives to attract foreign investors, in which imported materials undergo some degree of processing before being exported again (ILO) There are in general two types of EPZs: one is a comprehensive type, open to all industries; another is a specialized type, only open for certain specialized sectors/products.
- Free ports are special zones on the land area of the port cities. They host different types of activities as well as incentives and benefits to help export markets

Generally, the public opinion debates on whether SEZ have to be considered as part of economic policy reforms acting as tools for economic development or whether they are rather instruments for political purposes acting as an escape for unemployment.

Usually studies and researches classified SEZ according to different types of governance structure (World Bank 2017). The management of these special areas could be either public or private. In other cases, the management can be both public and private through partnership or a different structure such as consortium.

Another way of considering SEZ can be a broader definition: ” SEZ *are administratively defined territories, influencing interactions and competitive/co-operative behaviour of economic agents, through dynamic and interrelated cognitive, normative, regulative and organizational structures, routines, incentives and process*”(Hazakis 2014) a different concept of SEZ based on critical dimensions which are relevant to institutionalist approach. This approach highlights the complexity of the environment

¹ The core definition of a free zone, as well as proposed guidelines and standards for them, are contained in the Revised Kyoto Convention of the World Customs Organization (WCO). Annex D of the International Convention on the Harmonization and Simplification of Customs (revised in 1999) defines a free zone as “part of the territory of a Contracting Party where any goods introduced are generally regarded, insofar as import duties and taxes are concerned, as being outside the Customs territoryand not subject to the usual Customs control.”

made up of social actors, as consequences SEZ are the outcome of a socially embedded process (Hazakis 2014).

3 Methodology

The project was set up to introduce and create a SEZ¹ (Special Economic Zone) in the South of Italy (Campania Region) in order to foster regional development and to boost employment as well as local and national growth. This preliminary study is part of an ongoing program including Universities, institutional actors and organizations from different industrial sectors.

The research is based on a qualitative investigation using the case study approach, which is suitable to investigate emergent and dynamic empirical settings. The collection of empirical data is carried out using a heterogeneous plurality of instruments. The methods include document analysis, semi-structured interviews and participant observations.

The analysis focuses on collaboration by different actors involved in the process of SEZ emergence.

4 Context of study

4.1 SEZ in Italy

Currently there are four “free tax” areas (Free Port of Trieste, Venice Free Zone (VFZ Free Zone of Port of Gioia Tauro, Free Zone of Port of Taranto) in Italy. Recently, Italian Government (following European Council Law) has set up a set of measures aimed at enhancing economic growth in the South of Italy in order to create SEZ. 2The new SEZs should have the same structure and requirements (methods, time and governance, financial and economical features). This will require a high level of agreement between local, regional and national institutions as well as economic stakeholders.

Generally, according to the regulation and to the previous zones already set in Europe, the main purpose is to foster industrial growth and to increase innovation through increasing firm competitiveness and export rates, attracting foreign investment as well as boosting employment.

4.2 Case study: SEZ in Campania

According to the public actor who promote the creation of the special area in Campania the main purpose was to promote the local development helping firms already

¹ The introduction of SEZ in Campania has been proposed by the Regional Council (DGR No. 175 of 28/03/2018)

²² D.L. 20 June 2017, n. 91 art 4 c.2. definition of SEZ. The decree of the President of the Council of Ministers 25 January 2018 n. 12 defines the modalities for the establishment of SEZ, including interregional SEs; their duration; the criteria for identifying and delimiting the SEZ area; the criteria governing company access; general coordination of development objectives.

settled in the region trying to attract new actors through economic and fiscal incentives. Essentially, the first proposal includes three ports area and their surroundings.

In the first phase order to draw up the strategic development plan the regional government has been strongly engaged with stakeholders and with all actors involved in the creation of the Special Economic Zone in Campania: majors, trade unions, port Authority, Universities, trade associations, environmental associations, industrial development consortii, transport operators and associations.

At this stage, the regional government has designed the zones (table 1) according to

Table 1- List of Areas of SEZ in Campania

Areas	City/town
Port of Napoli	Napoli
Port of Castellammare di Stabia	Castellammare di Stabia
Port of Salerno	Salerno
Industrial area Napoli Est	Napoli
Area Bagnoli/Coroglio	Napoli
Airport	Napoli, Casoria
Intermodal logistic centre Campano	Nola
Industrial development consortium	Nola, Marigliano
Industrial development consortium	Pomigliano D'Arco
Industrial development consortium	Acerra
Industrial development consortium	Caivano
Industrial development consortium	Arzano, Casoria, Frattamaggiore
Intermodal logistic centre Sud Europa	Marcianise, Maddaloni
Industrial development consortium	Marcianise, San Marco Evangelista
Industrial development consortium	Teverola, Carinaro, Gricignano di Aversa
Industrial area di Castellammare "Foce Sarno"	Castellammare di Stabia, Torre Annunziata
Airport	Pontecagnano, Bellizzi
Industrial development consortium	Salerno
Industrial development consortium	Battipaglia
Industrial area Nocera	Nocera Inferiore
Industrial area Sarno	Sarno
Industrial development consortium	Fisciano, Mercato San Severino
Logistic centre di Contrada Olivola	Benevento
Industrial development consortium	Benevento
Industrial development consortium	Flumeri, Frigento
Industrial development consortium	Avellino, Grottolella, Manocalzati Montefredane, Prata di Principato Ultra, Pratola Serra, Atripalda
Industrial development consortium	Lacedonia

The management of the SEZ is public: 1) the steering committee, coordinated by the Central Tyrrhenian Port Authority, who promotes the government development strategy 2) governing body who is in charge of the coordination between local and national government.

In addition to this, a regional One-Stop Shop for Production Activities (SURAP) has been established, in order to improve the reliability of investment through fixed administrative procedures.

5 Preliminary evidences

The findings could be a useful tool for institutional actors, policy makers, organizations and management to develop strategies to enhance local development.

At the same time, it is essential to understand and assess the economic impact of the introduction of the SEZ, as proposed by the Regional Council (DGR No. 175 of 28/03/2018) on the entire regional economy. SEZ can be catalyst of development and innovation if a real integrated network exists. The challenge is to develop an interdependent co-operative group formed by SEZ actors and institutions (away from the government intervention). The observation of collaboration interactions while the network is forming is useful to understand the actors' behavior and governance mechanisms. The development of clusters is a complex process linked to actors' collaboration and to inter-organizational relationships. Integration task as well as roles in knowledge creation and collaboration among actors are key elements crucial for the development of the local areas.

Abstract

In recent years an abundant literature has been focusing on the way U-I collaborations work and on the main factors and variables that affect the process. Some studies have related to the role of proximity in explaining inter-organizational collaborations and facilitating interactions between firms and academia. Others reflected on the different mechanisms adopted in order to manage the project in a successful way. In this paper we investigate which kind of coordination mechanisms are adopted and how they influence the U-I collaboration.

Keywords – Automotive; University-Industry Partnership; Coordination mechanisms

Paper type – Academic Research Paper

1 Introduction

In recent years, universities have more and more been running research projects involving firms, also thanks to public expenditure policies that indirectly encouraged university–industry (U–I) collaborations (Giuliani and Arza, 2009). Industry–University (I–U) cooperation is not new the academic debate, and nowadays it represents an interesting stream in the managerial debate, due to the role of public research centres (and in particular of universities) in contributing to the economic development of countries or regions. Literature on knowledge and business ecosystem underline the role of these key actors in fostering knowledge creation inside a specific area. As mentioned by Järvi et al (2018; 1524): “Knowledge ecosystems have been characterized as geographically co-located hotspots, in which local universities and public research organizations are typically the central actors (Clarysse et al., 2014), and where the key activity of knowledge exploration is accomplished through collaborative research work (Valkokari, 2015)”. Industry–university interactions foster knowledge creation and innovation and are positively related to economic growth (Santoro and Chakrabarti 2002).

Recently part of the literature has investigated two different issues in I–U cooperation: one concerns the management of the project (Morandi, 2013; Rajalo and Vadi, 2017) and another deals with the process of commercialization. The latter tries to understand how it is possible to help universities in making their business ideas ready for the market (Würmseher, 2017). Particularly prolific is the topic of university spin-off, defined as new ventures initiated in an academic setting and based on university developed technology (Würmseher, 2017). Universities are heterogeneous and need differentiated technology transfer policies depending on their research intensity and other factors (Huyghe and Knockaert, 2015); similarly, at the more micro-level, the differences in scientists' attitudes to entrepreneurialism call for different policy approaches (Würmseher, 2017; p.13).

Regarding the management of the U–I collaboration, one of the main dimension concerns the knowledge transfer and in particular the firms' need of acquiring new knowledge, due to the fact that sometimes this kind of collaboration are unsuccessful. A lot of attention has been paid (Perkmann and Walsh, 2007) to the interactions taking place on the university–industry border in terms of appropriate mechanisms able to facilitate knowledge exchanges. A growing number of management studies have emphasized the relevance of linkages between universities and industry in automotive sector (e.g. Meng et al., 2019; Rasiah and Govindaraju, 2009). As argued by Steinmo and Rasmussen (2016; p. 1250): “The challenge of such knowledge transfer often relates to the development of trust and the establishment of a common understanding in communications and interactions between firms and academics”. This is why many scholars are trying to understand the way U–I collaborations work and which are the main factors and variables that affect the process. Some studies relate to the role of proximity in explaining inter-organizational collaborations and facilitating interactions between firms and academia (Steinmo and Rasmussen, 2016). Others reflect on the different mechanisms adopted in order to manage the project in a successful way (Morandi, 2013; Rajalo and Vadi, 2017). We want to go deeper in this direction and to investigate which

kind of coordination mechanisms are adopted and how they influence the U-I collaboration.

The paper sets out as follows: the next two sections review the literature on University-Industry research projects. We then analyse coordination and control mechanisms and how they relate to research projects and describe the methodology used for the empirical analysis. Finally, we present and discuss data from the empirical research before summarising the main findings and conclusions.

2 University-Industry collaborations

2.1 University-Industry collaborations: overview of organizational issues

University-Industry collaborations have been studied from a variety of perspectives and standpoints, including institutional dimensions of the collaboration, organizational culture, interorganizational relations, intermediaries and brokerage able to facilitate such collaborations. Several aspects have been incorporated in theoretical models depicting the collaborations both at meso (the dyadic relationships) and macro (the network) levels. It has also been recognised that the process of working together is not well understood at the micro level (Rigby and Edler, 2005:786).

There is little understanding of the different issues that are able to influence the collaboration process, for instance the coordination processes that may influence the U-I collaboration (Morandi, 2013). U-I collaboration has been put forward as a higher-level process that require intense teamwork and coordination. U-I collaboration has been characterised by “cultural divide” between partners in terms of goals, perspectives, motives and routines; therefore, such collaboration is highly multifaceted. The decision-making processes in collaboration are challenging (Bäck and Kohtamäki, 2015), and individual factors are bound to affect it. Amabile et al. (2001) have attributed three important features to the collaboration between academic researchers and business practitioners: 1) it involves people who are members of different professions (academia and business); 2) it is a collaboration between individuals or teams, not between organisations; and 3) the collaborators are not all members of the same organisation.

Interdependence among partners becomes key issue, related to inter-organizational streams of activities to and the extent to which partners are dependent upon one another to perform tasks. As the degree of interdependence increases, different mechanisms are needed to coordinate partners’ tasks. Coordination through standards, plans and by mutual adjustment are suitable to meet different categories of interdependence.

2.2 University-Industry collaborations: coordination issues

The need of coordination and control in a U-I collaboration represent a critical issue that could affect the final result and the way the research is conducted. In the managerial literature four different knowledge integration mechanisms are commonly identified inspired by Grant’s (1996) seminal work. They are rules and directives, sequencing, organizational routines and group problem-solving and decision-making.

Rules and directives involve “plans, schedules, forecasts, rules, policies and procedures, and standardized information and communication systems” (Van de Ven et al., 1976, p. [0].323) and may be viewed as standards which regulate the interactions between individuals. Sequencing is the organization of activities in a time-patterned sequence, so that each specialist’s input may be designed independently, receiving a separate time slot for contribution. Routines are “relatively complex patterns of behaviour [...] triggered by a relatively small number of initiating signals or choices and functioning as recognizable units in a relatively automatic fashion” (Winter, 1986, p. 165). Routines are generated by specialists in the form of sequential patterns of interaction, allowing integration of their specialized knowledge without causing knowledge transfer. Group problem-solving and decision-making require time-consuming face-to-face interaction, typically meetings. The choice of integration mechanisms depends on the characteristics of the tasks to be carried out. Less expensive mechanisms, such as rules and directives, sequencing and organizational routines, are suggested for situations with low interdependences among activities and low overall complexity. Some tasks may require more personal and communication-intensive forms of integration. Galbraith (1973) pointed to the need for “impersonal” coordination through rules and plans to be supplemented by “personal” and “group” coordination modes such as meetings.

In the literature on university–industry relationships, coordination and control issues have been considered in a few studies (Morandi, 2013; Rajalo and Vadi, 2017). Actually, the control issue is not really relevant in many U-I collaborations, because firms do not perceive the risk of a University’s opportunistic behaviour, due to the fact that University is not generally considered as a potential competitor or as a player that could acquire and transfer internal intellectual capital (Morandi, 2013). Morandi (2013) adopts a contingent approach in order to give useful insights on the adoption of different coordination mechanisms. In particular, according to her, planning is often adopted in U-I collaboration, but it has a significant role only in the initial phase of the project in order to align partners in terms of output, while mutual adjustments mechanisms are the main mechanism during the project life. As argued by Morandi (p. 84): However, despite the great effort devoted to planning activities, the initial plans do not always provide exhaustive explanations of the activities needed to reach the planned goals or a detailed description of project opportunities and challenges. The adoption of written reports is justified to control the intermediate research outputs and to transfer intermediate findings if the interdependence among partners is sequential.

Temporary group meetings of partners’ R&D staff (task forces) are also adopted. At a more general level, according to Morandi, what really matters in a U-I research project is the role of people who act as broker, liaison positions held by people with formal authority and a hub role within their organizations. In a contingent view the increase in task uncertainty in cooperative research leads to a greater decentralization of coordination and control practices (Morandi, 2013; p. 87).

Rajalo and Vadi (2017) studied the different practices adopted during the two main steps of a U-I research (initiation and implementation) in order to facilitate the

management of the project. They adopted the Rau et al. (2012) approach to define practices adopted to fill the gap between the partners in order to facilitate knowledge exchange. They refer to the boundary-crossing mechanisms and pragmatic boundary-crossing mechanisms as different practises in order to facilitate the communication and to build trust among the partners. If the general issue is to understand how it is possible to manage U-I collaborations, more light should be shed on the nature and implications of coordination mechanisms in U-I research settings. Our research question may therefore be formulated as: RQ1. What kind of coordination mechanisms are adopted in a U-I research project and how they affect the initialization and implementation phase of the research project. In particular, our aim is to investigate how the adoption of different integration mechanisms in the various steps of a typical university-industry research project overlaps with the need of establishing common ground.

3 Research Design

The empirical analysis was based on a qualitative investigation. We analysed empirical material collected within a research project originated by a partnership involving Fiat-Chrysler Automotive (FCA), a multi-brand auto manufacturer whose product range covers different market segments, and two universities: the University of Sannio (Department of Management, Italy) and the University of Portsmouth (Department of Operations & System Management, UK). The project is funded by the National Operative Programme FSE-FESR Research and Innovation, Action 1 - *“Dottorati Innovativi con caratterizzazione industriale”*. Driven by the objective of our research, in the selection phase we met the following main criteria. First, the automotive industry represents an interesting case for analysing innovation processes. In the last two decades, this industry has undergone a radical transformation. There have been three basic but intertwined structural changes. The first is that car companies have shifted their focus from national to global markets. This means changes in market scope, new competition regimes and new forms of production organization at international level. Secondly, along with this new international framework, most automotive firms have tried different organizational models for production, trying to move from the Fordist approach to newer models such as lean production. Finally, inter-company relationships have changed, because of modularization and outsourcing (Cabigiosu et al., 2012; Frigant and Layan, 2009). Second, as it is common in literature, we selected a case study in which the phenomena of interest about the use of coordination mechanisms in a University/Industry collaboration setting are transparently observable. This study used empirical material collected at FCA's Pratola Serra plant, in Avellino, Italy. Pratola Serra Plant was founded in 1991 and during these years received many certifications and awards, but it experienced also some criticalities and important organisational changes. From a performance perspective, it passed from a production of 570.000 engines in 2007 to 170.000 in 2014, to come back to 300.000 in 2015. Recent trends and forecasts are encouraging enough to think of a new increase. In 2016, FCA occupied about 1.800 people, and produced mostly diesel engines for different vehicles of different brands

(Fiat, Jeep, Alfa Romeo, Suzuki). It's a complex network made of 165 suppliers located mainly in Italy and in Europe, to supply more than 1.500 part numbers.

We carried out the analysis iteratively with a semi-grounded approach, and our data informed the selection of theory presented upfront (Van Maanen et al., 2007). The in-depth case study approach is advised when the boundaries between phenomenon and context are not entirely obvious, for example, the coordination mechanisms used within a University-Industry partnership (Dubois and Gadde, 2002). This is in line with Dyer and Wilkins (1991, p. 614), who advocated case studies, recommending that researchers should be aware of the benefits stemming from "the careful study of a single case that leads [them] to see new theoretical relationships and question old ones".

We used three data collection techniques: internal document analysis, observation/site visits and semi-structured interviews. Documentary analysis enabled understanding of the project structure and identified coordination implications. Observation was used to explore coordination mechanisms issues among partners. We carried out five semi-structured interviews with the top management of FCA and two management researchers. Each interview was conducted by at least two authors of this paper to reduce interviewer bias (such as first-impression error, non-verbal influences or negative emphasis). They used a semi-structured questionnaire designed to stimulate a narrative approach in the dialogue with the interviewees. All interviews were recorded and transcribed. They aimed at obtaining information on the adoption of different coordination mechanisms. The collection of data was carried out between October 2018 and early April 2019.

In the case study, we will focus our analysis on the relationships between FCA and the two Universities. This choice is coherent with our aim of analysing coordination mechanisms deployed on the university-industry border.

4 Case Analysis

4.1 Project description

The research project considered in the case study aims, in general, to: *a)* contribute to the development of a network of subjects involved in experimenting innovative management control systems; *b)* define new professional skills valued by the labour market; *c)* support the development of *Lean Organization* models.

At the time of drafting of the case study, the project, formally presented in December 2017, was in the initial phase (October 2018 - April 2019), which took place after the decision of the Italian Ministry of the University to finance its activities for a three-year period. This research aims at the testing of mathematical models of multi-criteria analysis in support of organizational control functions *in the automotive* sector. Within the organizational control management systems context, the research proposes the use of methods allowing a more conscious weighing of the factors that determine organizational performance, favoring organizational development, innovation and the enhancement of human capital.

The research program is divided into the following activities:

1. *Review* of the literature on control systems in the *automotive* sector;
2. Definition of knowledge gaps and the research focus;
3. Development of an experimental model for organizational performance monitoring, applicable to typical company production processes;
4. Model *testing*;
5. Experimental use of the model at the company premises, data collection and analysis.

One of the most important elements of the project is the actual use of results of the empirical research. In particular, the funding body has evaluated very positively the possibility of creating a Start-Up dedicated to the provision of management consultancy services that adopt the decision support model experienced during the project with FCA.

4.2 The stages

The universities and the company carried out different types of activities in the execution of the research project on organizational control topics. These activities can be grouped into three distinct phases: *a)* preliminary study activities; *b)* drafting the project; *c)* the launch of the project.

A) Preliminary activities

For approximately two years, the Italian university, located in the same region of the FCA plant that hosts the project, carried out together with the company study activities on the organizational control topics, which were the foundation for second phase of the project, namely the drafting. In particular, the collaboration involved the creation of three graduations theses, company visits to all production departments, the drafting of two scientific articles discussed at international conferences, holding three discussion meetings at the university and at the company. For the preparation of the theses, the company, in collaboration with the university tutor, defined the objectives of the study, provided data on the evolution of its organizational control models and facilitated five meetings between students, professors and company managers at factories in Italy - Turin, Cassino, Pomigliano d'Arco (NA), Melfi (PZ) and Pratola Serra (AV).

The role played by the World Class Project Coordinator at the global level for the FCA Group was of particular importance during this stage, who contributed, during the first study whose scope was the discussion of a graduation thesis, to defining the framework of the events that have determined the evolution of organizational control systems in the company. In fact, in 2005, following an experience in Japan and in the USA, the manager was appointed with the task of conveying and implementing the WCM method first in Fiat and subsequently in CNHInd. and Chrysler.

"To understand our need today to develop our organizational control system, we need to frame the stages of development of WCM in our company! For this reason I will be the one to provide you with the books and reports that I consider the most significant among those drafted and published over the last 10 years. Furthermore, it is necessary that you observe with your students the different levels of maturity of the organizational system at the different Italian establishments. I will accompany you!" - the manager said during the first meeting with the professors of the Italian university.

During the preliminary phase, the same group consisting of professors and managers who had already facilitated studies and company visits, organized a meeting at the Melfi Plant Academy, the modern internal training centre created in Italy and subsequently developed in a number of EMEA factories, becoming an example of excellence at a global level. During the one-day visit, accompanied by managers and specialized workers, the scholars were able to observe how in the company education and training are continuously linked to the organizational control results. The anomalies and inefficiencies detected by the organizational control system requirements automatically convey the programming of training courses, as well as with the aid of work process virtual simulation systems and the involvement of organizational design experts.

The Director of the Centre stated during the meeting: *"In the four main laboratories that make up the Plant Academy our task is to ensure the best simulation of theoretical concepts in order to increase the effectiveness of learning, research and testing innovative solutions to expand to the Plant."*

B) Drafting of the project

The most common coordination solution in the project development phase was the set of practices devised by the partners and focused on communication and on the direct comparison between them. Through recurring meetings, theoretical and operational perspectives of the study were discussed and defined; expected goals and outputs have been negotiated; and the investigation methodology was developed. The choices made in the definition of the project represented the synthesis of the needs expressed by the scholars responsible for the definition of the theoretical frame of reference and those expressed by the company management interested in the rate of application of the models and the results of the analysis to the processes of change of the company.

The company quality manager, during one of the first call conferences dedicated to the drafting of the project, was confronted with the teacher of the foreign university on the choice of the duration and the contents of the different activities: "I understand that after the collection of the set of data, you need to carry out your model testing and development activities, but the data we are considering could lose significance in such a long time and negatively reflect on the quality of the analysis!". Furthermore, the collaboration between university and business in the case under study took place through two other types of coordination mechanisms. On the one hand, the comparison between the partners has been "channeled" into a formal drafting path of the project in which an important role has been played by the tools made available to the Ministry to access the evaluation and funding. The use of a form, the access by professors and company managers to the FAQs related to the call for proposals, the criteria and the standards of access and evaluation have created a common idea among the partners within which to define the contents freely chosen for the research.

On the other hand, the collaboration on the occasion of the research project described here has benefited from the level of knowledge and trust already matured among the partners previously. The study experiences conducted to support the training of young university students or to test the organizational models devised by the company in the

context of international scientific forums have become the occasion to develop this level of trust. In particular, the company, as stated by the head of the RU during an interview: "... has been able to verify that the university did not only look for fertile land to exploit, devising complex models of interpretation of reality that cannot be used at an operational level! We were struck by the humility and patience shown by scholars in listening carefully to the starting points of the models we wanted to experiment and in having always clear that the point of arrival for all of us had to be organizational change!".

C) Launch of the project

After the positive results of the evaluation procedure by the Ministry and the consequent three-year financing of the proposed activities, the group composed of 4 university researchers and 4 company managers carried out a series of meetings aimed at defining the details of the first activities and at the start of the search. In particular, two work sessions were carried out at the Italian university in which the mathematicians for decision-making and organizational control illustrated for their areas of expertise models, expected results and necessary activity programs. Two other meetings were held at the Plant to present the project to the employees involved in the work processes being studied and to discuss the selection and data collection criteria with which to carry out the start-up phase of the theoretical decisions model.

The partners adopted a more informal approach to managing the interdependencies that emerged in the detailed design flow of the activities to be carried out.

In this sense the physical proximity of the Plant with respect to one of the two universities has facilitated the realization of a large number of meetings and contacts aimed at understanding the phenomena and the data selected to co-construct the mathematical model of decision support.

The Plant Director states in an interview: "From the beginning, I proposed to choose, as a focus of the research study, the problem related to the evaluation of improvement actions that could be designed periodically, after the detection of anomalies during engine assembly. But only after a long chat with the two professors, I realized that I should have asked a specific effort from the management to assign a weight relative to the different alternatives of choice. I also realized that the weight given to the alternatives had to be "built" by us, considering economic aspects but also elements connected to the quality of the work. Only in this way could the mathematical model give us a complete view of the most convincing possible solutions. I already knew the mathematical model adopted by the project, but talking about it calmly with my university friends, while we were running our company data, made me go much better in research! ".

5 Discussion

The collaboration university-industry relies on a variety of different coordination mechanisms. The first is identified when using formal and informal standardization mechanisms. In the Sub-Phase 2, for instance, rules and directions represent the predominant integrating mechanisms. The integration of opinions and specialist

contributions during the planning stage was facilitated by interpreting and redefining the “rules” to be followed during the project.

The template for the project (which must be adhered to obtain public funding) that had taken part in similar tenders previously, constituted the predominant frame in the implementation of this stage. Compliance regulated interactions between the management and researchers. The standardized forms for planning purposes constituted a way to specify and control the content that was to be shared among project members, also giving structure to discussions in project meetings. These factors influenced the way the group cooperated and, above all, provided constraints to the project both technically and economically. This means that partners relied on less communication and interaction-intensive mechanisms for knowledge integration and tried to structure the discussion in collective arenas, using standardized forms for reporting.

In sub-phase 1 and 3 of the WP3 common routines and sequencing were used in the management of day-to-day activities. Project members interacted extensively with members from their own departments to integrate knowledge. Physical and relational proximity increased not only the frequency of interactions but also the effectiveness of knowledge exchange through these interactions. It facilitated face-to-face contact and contributed to the emergence of cooperation.

At the same time, researchers from the same organization reactivated common previous experiences (Valentine and Edmondson, 2015), had shared experience and a common background and spoke the same language, or adopted role-based coordination.

The arrangements for managing the research project were “tried and tested”, even if the results, interactions and implications changed. The need to integrate remained significant, and every specialist had to exchange ideas with other members of the project team, both within the same fields and in different ones.

First phase was characterized by more personal and communication intensive forms of integrations. Knowledge integration in these complex phases is enabled by group problem solving and decision-making, in a collective setting. These sub-phases rely on more personal and less standardized knowledge integration mechanisms to allow project members to more freely communicate and interact to solve problems and deal with interfaces. The quest for combining scientific upgrading with process and project innovation is indicative of the final phase (dissemination) and is conducted through a dialectic process between individuals with heterogeneous core skills, mentalities and even interests.

In summary, we showed that the project was more a meta-coordination mechanism than a situated learning environment because of the need to compare and discuss the results during each sub-phase. A crucial aspect was the level of mutual understanding of specialist knowledge. When project members were derived from different sides of the university-industry border, there was a major need for recurring to more structured coordination mechanisms, even if the scientific background of participants was homogeneous. This in turn recalls the idea that soft issues such as technical jargon and similar ways of framing technical issue are not sufficient to enforce integration and more expensive coordination mechanisms (such as group problem solving and decision-

making) are to be enforced. In a nutshell, the origin of project members in terms of one side or the other of the university-industry border is more powerful than homogeneity of specialization and existence of common ground to determine the appropriate coordination mechanisms.

6 Conclusions

As shown by our case study, there are various options in terms of coordination mechanisms during the life of a university-industry research project. Our analysis shows that the choice of such mechanisms can differ across the various sub-phases of a project in relation to the organizational affiliation of project participants and the heterogeneity of their common knowledge. The study was able to expand understanding of coordination mechanisms in university-industry research settings in two respects. First, only a few studies have previously investigated such coordination mechanisms at the level of granularity we have selected. Second, the study was exploratory, which may be useful for generating research hypotheses in future work, connecting the features of interdisciplinary projects with the development of coordination mechanisms. Our results could be useful for other firms operating in the same sector, and also for policy makers wishing to stimulate this industry. The automotive industry has been involved in an extensive process of innovation within which the processes of (inter and intra) organizational coordination mechanisms have taken on a much more significant role. This study presents also limitations that have to be taken into account when evaluating its results. First, the qualitative approach here adopted is consistent with the objectives pursued and the nature of the research question, and allows us to draw insights that can be important for advances in theory. However, explanatory factors and forms of cooperation which can foster positive outcomes of interdisciplinary teams should be further analyzed. Second, as discussed before, the setting of our case study is represented by a specific context that conditions our concluding remarks; accordingly, future studies should address how integration can be achieved in practice within similar interdisciplinary research groups in this or other contexts. Finally, we should go more deeply in analyzing how the coordination mechanisms adopted in each phases of the research project actually influence final results.

Abstract

Hybridity and organizational fluidity are theoretical approaches that are increasingly challenging our thinking about management. These phenomena blur the previously clear institutional boundaries separating professions and organizational entities and will inevitably have implications for intellectual capital (IC) management as well as knowledge management (KM) more broadly. However, there has been little discussion about these implications, despite the practice of KM, and management more generally, have evolved and changed rapidly during the last decades. This paper embarks on a journey to weave connections to the theoretical discussions on hybridity and fluidity as a purpose of analysing their possible implications on management and especially managing knowledge. The research question this paper provides perspectives to is whether and how knowledge management approaches need to be adjusted to maintain their managerial relevance also when organizational environment gets hybrid and fluid. The main contribution of the paper lies in the recognition of avenues for future research in the areas of intellectual capital management and knowledge management.

Keywords – hybridity; hybrid governance; fluid organizations; knowledge; data

Paper type – Academic Research Paper

1 Introduction

Organization theorists and management scholars have been increasingly interested in hybrid organizations, hybrid governance and hybridity more generally (cf. Hansmann, 1996; Thynne, 2011; Kreps and Monin, 2011; Reay and Hinings, 2009; Pache and Santos, 2013; Ebrahim et al., 2014). Along with hybridity, organizational fluidity challenges

traditional ways of thinking about organizations (Schreyögg and Sydow, 2010). In this paper, we consider hybridity as an external, system-level characteristic and fluidity as an internal organizational feature. The underlying assumption of the paper is that these two theoretical viewpoints bring along new perspectives also to the discussions of knowledge management. Indeed, the paper aims to elaborate some of those forces that in authors' view require new kind of thinking from the knowledge management scholars in the specific context of hybridity and organizational fluidity.

In this paper, knowledge management (KM) refers to identifying and leveraging the collective knowledge in an organization to help the organization compete (von Krogh, 1998). KM involves processes such as creating, storing, transferring, and applying knowledge (Alavi and Leidner, 2001). Most importantly, knowledge management is aimed at improving an organization's overall performance (Wiig, 1997; Kalling, 2003). Knowledge management has a two-fold role in supporting performance improvement (Laihonen et al., 2015). First, knowledge assets and their management lay the foundation for competitive advantage (Grant, 1996; Sveiby, 1997; Seetharaman et al., 2002). Second, information management cycle enables efficient decision-making (Choo, 1996). This paper argues that hybridity and organizational fluidity change both the ways how valuable knowledge resources are defined and managed and what information is considered important. The results of the paper show that when the strict control relationships between the actors are missing, a need for knowledge governance arises (e.g. Peltokorpi, and Tsuyuki, 2007; Foss, 2007) to support what we have traditionally called knowledge management as an organizational function.

The paper is organized into four main sections. After the introduction, the key concepts of hybridity and organizational fluidity are defined in section two. Then, section three discusses these concepts in relation to knowledge management and recognizes some of the KM areas that on authors' view need special attention in the context of hybridity and organizational fluidity. In this phase, we are not taking a position whether they are pros or cons but that this question will provide many interesting discussion areas for future research. Finally, section four summarizes the discussion and presents some concluding remarks.

2 Hybridity and organizational fluidity

2.1. Hybridity

Hybridity has been approached from the viewpoints of institutional economics, which approaches them from the perspective of governance structures, and sees hybrids between hierarchies and markets (e.g. Powell, 1990; Williamson, 1975; Stark, 2009). For public administration theory hybridity refers to "ambiguous types of social organizing and manifests itself in institutional settings where public and private organizations operate according to public interest" (Johanson and Vakkuri, 2017). Battilana and Dorado (2010) define hybrid organizations as "organizations that combine institutional logics in unprecedented ways". According to Johanson and Vakkuri (2017) hybridity covers

situations of: 1) mixed ownership, 2) goal incongruence and competing institutional logics, 3) multiplicity of funding arrangements, and 4) public and private forms of financial and social control. Thus, in hybrids actors from diverse policy sectors with different governance modes come together to attain common goals and outcomes.

The overlapping and coexisting governance modes and especially their implications on managing knowledge make hybridity interesting from the knowledge management perspective, (cf. Lowndes and Skelcher, 1998). The central challenge both in theory and in practice lies in the unit of analysis. Whereas knowledge management literature focuses primarily to an individual organization and its objectives and business strategy (e.g., Zack, 1999; Laihonen and Mäntylä, 2018), the hybrid governance literature acknowledges the presence of goal incongruence, competing institutional logics and different forms of management control. In the latter case, the unit of analysis needs to be on the hybrid arrangement not only on an individual organization and its objectives and knowledge needs.

What becomes evident from the hybrid governance literature is that ambiguity of objectives seems to be intrinsic for a hybrid organization. In addition, hybrid governance like network governance more generally seems to rely and build on trust, mutuality and shared identity (cf. Parker, 2007). The network literature has also shown that seamless knowledge flow and shared measurement information are important determinants creating trust and commitment (Laihonen, 2012; D'Aunno et al., 2018). Therefore, it can be derived that shared knowledge base and efficient knowledge management are important performance drivers for hybrid organizations and thereby lay in the core of hybrid governance.

2.2. Organizational fluidity

Organizational fluidity refers to the increasing flexibility and dynamism and the decreasing importance of organizational boundaries, structure, and processes (Järvi, Almpantopoulou, & Ritala, 2018; Kellogg, Orlikowski, & Yates, 2006; Schreyögg & Sydow, 2010). Research suggests that the organizations are becoming more fluid to survive and thrive in the current increasingly dynamic and complex environment. Schreyögg and Sydow (2010) describe the characteristics of fluid organizations: “from hierarchies to networks, from formal programs and coordination rules to spontaneous interaction, from specialized departments and staff units to improvised processes and temporary project teams, and from vertical lines of command to lateral organization-wide communication.” Further, fluid organizations focus rather on diversity than similarity and seek speed and adaptability.

Knowledge management is at the core of what makes an organization fluid. Organizations that operate in a knowledge-based domain have two major functions. They must learn about the environment surrounding them and use this knowledge to provide value to their customers and stakeholders. These two functions, exploration and exploitation, constitute *organizational learning* (March, 1991). In a turbulent environment, the loop between exploration and exploitation must be short both in terms of organizational distance and time.

In fluid organizations, exploration and exploitation can be organized in two different ways (Schreyögg and Sydow, 2010). The first option is to dedicate organizational units to either explore or exploit. Alternatively, each individual member in an organization is expected to both explore and exploit. This dual capability is referred to as *ambidexterity* (Gupta, Smith and Shalley, 2006). While Schreyögg and Sydow (2010) conclude that ambidexterity at individual level is the optimal way to operate, Eisenhardt and Furr (2010) among others suggest a more fine-grained view to organizations that balance between efficiency and flexibility.

In knowledge-intensive organizations, information technology provides a medium for knowledge management practices and also everyday communication and interactions. Literature perceives IT as a mechanism that gives rise to organizational fluidity (Chatterjee, Sarker and Siponen, 2017). Moreover, research even suggests that information technology enables the operation of improvisational capability as the “third hand” for organizations and individuals (Pavlou and El Sawy, 2010). Radical adoption of mobile technology enables full-fledged distributed work and moves the knowledge worker to a continuous liminal state “between and betwixt” space, time, tasks, and technology (Stein, Jensen, Hekkala, 2015).

3 Hybridity, fluidity and knowledge management

In hybrid context, actors are dependent on each other’s resources in a similar manner like in networks (cf. Powell, 1990). This pooling of resources, and especially knowledge assets and decision-making information, lies in the essence of hybrid governance. However, the majority of knowledge management literature focuses on organizations and has ignored the linkages between knowledge and governance (Peltokorpi, and Tsuyuki, 2007; Eisenhardt and Santos, 2002). In this paper, we take this argument on weak linkages as an indication of the extensive focus on entities where the characteristics of hybridity or fluidity have not induced a need to focus on wider governance issues. Governance here refers to “a set of organizational mechanisms and informal practices fostering the knowledge contributions of firm members” (Peltokorpi, and Tsuyuki, 2007).

Following the above, it is argued here that the main emphasis of KM is on organization-specific knowledge, which is being acquired and gathered for the purposes of organization’s business objectives and performance management. Further, many KM models and related managerial heuristics oversimplify the world and do not recognize or consider situations where different institutional logics and forms of financial and social control come together. Similar problems relate to understanding and harnessing organizational fluidity. Inability of KM to recognize these phenomena may well be due to the weak linkage between knowledge and governance. From the hybrid governance perspective, this may mean that regarding KM, organizations within a hybrid may apply very different approaches, which makes it difficult for them to understand each other’s and define shared objectives as well as measure and report performance in a coherent way. Within a hybrid, organization-specific information can only provide a partial picture of the phenomena and may lead to sub-optimal solutions. Therefore, we call for a careful

analysis not only on hybridity as such but also the ways that hybrids understand, conceptualize and define their performance and information they base their decision-making on.

From the theoretical viewpoint, majority of knowledge management studies follow the theoretical foundations of resource-based view (Barney, 1991) and knowledge-based view (Grant, 1996; Spender, 1996). These put their emphasis on the organizational entity (firm), which is not a sufficient approach in hybrid context where actors operate in inter-organizational arrangements with different institutional logics, and where perceptions of value and performance may differ significantly. Value creation in hybrids may even call for a reconsideration of organizational boundaries. Kunttu (2017) and Santos and Eisenhardt (2005) present four distinct conceptions of organizational boundaries that each lead to different theoretical explanations of the boundary setting. Thus, each of them also leads to very different questions and expectations for knowledge management. Table 1 brings together the discussion on organizational boundaries and knowledge management.

Table 8. Organizational boundaries and knowledge management (original discussion on organizational boundaries presented by Kunttu (2017) and Santos and Eisenhardt (2005)).

	Theoretical roots	Examples of knowledge management questions in hybrids
Efficiency	Efficiency and transaction cost economy: "The boundaries should be set at the point that minimizes the cost of governing activities."	What are the costs of the new approach compared to the traditional one? Do we even know what are the costs of KM in the traditional model? How are these costs allocated in hybrids?
Power	Resource dependence and industrial organization: "Organizational boundaries should be set at the point that maximizes strategic control over crucial external forces and critical external dependencies."	Who has power over others in hybrids? Who is a legitimate actor? Who has the authority to define objectives and roles? Who is accountable for these decisions? Who defines critical knowledge? Who evaluates the risks and solves issues of data security?
Competence	Contingency theory and resource-based view: "Organizational boundaries should be set at the point that maximizes the value of the firm's resource portfolio."	What kind of competences are needed in the new world? What competences are specific to hybrids and how they differ from the traditional model? What is the value of partner's competences?
Identity	Managerial cognition and organizational identity: "Boundaries are set to achieve coherence between the identity of the organization and its activities."	How is organizational identity composed if organization boundaries get blurred and are continuously redrawn? How to solve principal-agent problems? Where are the boundaries of knowledge governance? Whose knowledge? How managers shape their actions and interpretations of the world? How values and norms are constituted?

A fluid organization that operates on digital technology and information systems both disrupts management practices and introduces new management capabilities. The disruptive aspects circle around the increasing autonomy of individual actors. The management practices that scholars (e.g., Schreyögg and Sydow, 2010) propose for fluid organizations are based on monitoring and variations of enacted sensemaking (cf., Bendoly, 2016; Weick, Sutcliffe and Obstfeld, 2005). That is, the individuals are permitted to operate autonomously and the management intervenes when they identify a behavioral pattern that insists on doing so. From a critical viewpoint ubiquitous monitoring can be perceived as panopticon-like control mechanism, inviting further research on balanced management activities (Leclercq-Vandelannoitte, Isaac and Kalika, 2014; Leclercq-Vandelannoitte, 2017). From knowledge management viewpoint, we observe fluid organizations as social structures (Borgatti and Foster, 2003; Lee and Hassard, 1999) of interconnected, ambidextrous, and autonomous individuals. Moreover, we subscribe to Ashcraft, Kuhn and Cooren (2009) in that organizations are fundamentally constituted through communication (cf. Putnam, Nicotera and McPhee, 2009).

The increased autonomy of individuals combined with the diminishing importance of the organizational envelope implies that the mechanisms that drive the formation of social networks in general come into play. The two such core mechanism are homophily and triadic closure. The homophily bias implies that forming a new connection between two individuals is more likely the more similar the individuals are—“birds of a feather flock together” (McPherson, Smith-Lovin and Cook, 2001). Triadic closure means that new connections are more likely to form among between actors that share a *strong tie*, i.e., among friends of friends (Granovetter, 1973).

When these two mechanisms unfold in unison over a period of time, the organizational social structure takes the shape of a mycelium of homogenic social groups (Kossinets and Watts, 2009), often referred to as echo chambers or silos, that connect to each other through *weak ties* (cf. Granovetter, 1973). A significant body of literature explores the importance of weak ties as potential sources of novel information (Aral, 2016). However, both strong and weak ties have their role in facilitating the flow of information within and between organizations (Aral and Van Alstyne, 2011). Professional social matching is a new academic endeavor that seeks to take advantage of the accumulating digital data and the growing importance of information technology in steering the evolution of the organizational social structure toward a beneficial direction (Olsson, Huhtamäki and Kärkkäinen, 2019). We look forward to future social matching research and development that seeks to balance diversity (weak ties) and bandwidth (strong ties) (cf. Aral and Van Alstyne, 2011).

Another interesting stream of literature from the viewpoint of this paper deals with knowledge governance (e.g. Choi, Cheng, Hilton and Russell, 2005; Foss, 2007; Zyngier and Venkitachalam, 2011; Schroeder et al., 2012; Zyngier and Burstein, 2012). This is despite the fact that its focus is in many cases narrower and focuses on governing knowledge management initiatives within an organization. However, this literature considers also the linkage between knowledge and governance as discussed in this paper.

Knowledge governance refers to choosing structures and mechanisms that can influence the processes of sharing and creating knowledge (Foss, 2007). This literature considers governance as “the distribution of decision making rights and responsibilities and the procedures and mechanisms for making and monitoring strategic decisions” (Schroeder et al., 2012; Peterson, 2004).

Considering the characteristics of hybridity and organizational fluidity, it seems inevitable that different knowledge systems will collide and new tools and methods are needed in finding a satisfying mix of governance modes, ways of organizing and knowledge management approaches. What this paper aims to postulate is that in many cases these are not primarily knowledge management discussions. Knowledge governance and integration of knowledge systems is required but before that, there are many questions to be solved that are in the hands of knowledge managers. Indeed, we believe that it is of critical importance to strengthen the link between knowledge and governance as stated by Peltokorpi, and Tsuyuki (2007). At the same time, we still believe that knowledge management can help in building a common ground for performance dialogue also in hybrid and fluid contexts (cf. Laihonon and Mäntylä, 2017; Rajala et al., 2018) if actors are willing to participate and trust each other’s enough to share their experiences and interpretations.

In addition to theoretical considerations, we believe that hybridity and organizational fluidity will also require new methods for collecting, storing, integrating and analysing data. Recently there has been significant advances in this area and many approaches are available to model hybrid systems, their structures and dynamics. Some examples of these methods are computational network analysis (Huhtamäki et al., 2015), system dynamics modelling, agent-based modelling and various machine learning approaches. To support quantitative data analytics, information visualization and visual analytics allow sense-making and storytelling, that is, gaining insights on the data and in sharing the findings (Bendoly, 2016; Bendoly and Clark, 2017; Russell et al., 2015).

4 Conclusions

The paper discussed the future of knowledge management in the specific contexts of hybridity and organizational fluidity. The aim was to recognize areas where knowledge management theory and practice needs to be re-thought. The underlying argument is that in order to develop knowledge management to better support organizational activities in these contexts we need to first understand how these phenomena change our perceptions of organizational life and then develop common ground for such knowledge management strategies and practices that would benefit all actors. We believe that this necessitates a dialogic approach and can only succeed when a mutual understanding of the shared benefits and value can be found and when a shared knowledge can be constructed to enable and support this dialogue. The presented discussion can be summarized into three arguments that provide a starting point advancing our understanding on KM and novel organization forms:

- ✓ Knowledge management for hybrid governance and fluid organizational structures require a wider theoretical standpoint than the dominant knowledge-based view.
- ✓ The essence of knowledge management in the given contexts lies in the dialogic interaction between actors as well as on recognition of mutual benefits.
- ✓ New methods and data are needed to understand and model value creation in hybrid and fluid arrangement.

The paper contributes to the knowledge management literature by opening a discussion about two timely phenomena that on authors view challenge both knowledge management theory and practice. We see a significant role for knowledge management in building organizational success in the future but also believe that hybridity and organizational fluidity will increase and require changes in how knowledge management is perceived. In our the role of knowledge management is no only technological but far more profound, which calls for a careful analysis of the organizational context where KM is to applied.

Abstract

Despite the extensive literature on the start-up, an understanding of the main factors influencing innovative performances is still lacking. Our research adds to these previous works by conducting a literature review of the main factors that intervene, at multiple levels, to improve or reduce start-up performances. The study is based on a comparison of 133 articles in the innovation management field and follow the Tranfield methodology. Results highlights a multilevel nature of the various factors that affect start-up performances. The first level explores the main factors affecting performances within the organizational boundaries (Firm Level). The other three levels (Network, Competitive, Macro environment) show that the external environment can positively or negatively affects start-ups performances. The review reveals differences among the solutions adopted in each level summarizing the current state of affairs.

Keywords – start-up; innovative performance; influencing factors; endogenous variable, exogenous variable.

Paper type – Academic Research Paper

1 Introduction

Literature on innovativeness demonstrates contrasting scenarios. Several studies suggest a positive link between innovativeness and firm survival. Innovativeness can enhance firms' market power (Schumpeter, 1934), can improve the ability to escape competition (Porter, 1990), can reduce production costs (Cohen and Klepper, 1996a, 1996b), can support dynamic capabilities (Teece et al., 1997), and can lead to enhanced absorptive capacity (Zahra and George, 2002). In other cases, less linear start-up processes, (Samuelsson and Davidsson, 2009) or more skewed returns (Scherer and Harhoff, 2000) can generate a negative link. This shows us the key role of innovation in supporting not only firms survival but mainly their performances improvement (Damanpour 1991; Smith et al. 2005). The academic literature has a long history of struggling with regards to the measurement of the performance, and in particular with regards to the innovative performance of companies (Freeman and Soete, 1997; Griliches 1998; Ernst, 2001;), even if the results of this studies have not yet led to a common view of the typologies of indicators nor a to common way to use them. While much importance has been given to the study of performances measurement, still unexplored fields remains, especially those concerning the key factors influencing firms innovative performances. Most of the literature studies have focused on the analysis of indicators: some have analyzed single indicator (R&D, patents, patent citations, or new product announcements) arguing that the specific indicator that is applied has fewer shortcomings than the other indicators; other studies used two or more indicators to generate a more complex construct. Instead, the research on factors influencing performance in new and small companies is extensive: some for example found that strategies affect industry conditions, the competitive environment, and the entrepreneur's background. Although these works provide a solid basis for understanding the dynamics of firm performance, an extensive analysis of all internal and external influencing factors is missing. Our research adds to these previous works by conducting a systematic review of contribution on the various factors that affect start-up innovative performances. Results reveals the multi-level nature of innovation, and the necessity to fully understand the determinants and dynamics of firms' innovative performance. In the next sections, we present the theoretical background and the methodological approach followed. Then, we provide an overview of key evidences regarding the main factors influencing start-up innovative performances.

2 Theoretical Background

Analysing the academic literature on innovation, it is possible to observe that start-ups play a key role in the generation of radical innovations. This depends of the small size and the absence of established market positions. (Utterback 1994; Henderson 1993; Chandy and Tellis 2000) and from the necessity to create something new starting from what already exists (Hargadon 2002; Lo Storto 2006; Weiss and Gangadharan 2010). Nonetheless, it is agreed that start-ups tend to lack, the skills and routines to assemble, organize, and monitor their resources (Katila and Shane 2005), the main assets to

generates profits (Teece 1986) and consequently the sufficient capital to finance innovation. For this reason is crucial for start-ups to pursue radical innovation and scholars have started examining under which circumstances the innovation performances are enhanced (De Man and Duysters 2005). A prevailing view in literature suggests a positive link between start-up performances and innovativeness. According to Rosenbusch et al. (2011), innovation is positively associated with start-up performance and this is explained through a detailed meta-analysis of the innovation–performance relationship among small and medium-sized enterprises (SMEs). Also, Song et al. (2008) report that a positive innovativeness–performance link is found in over two-thirds of the empirical studies they review. Both of these meta-analyses also find that the results may be context-dependent and heterogeneous; Strategy can also be considered as an influencing factor that affect performance outcomes (profitability, growth, or return on asset) contingent on industry conditions (McDougall and Robinson 1988; McDougall et al. 1994; Carter et al. 1994), environmental characteristics (Covin and Slevin 1989, 1990), the entrepreneur’s background (Stuart and Abetti 1988; Sandberg 1986; Feeser and Willard 1990). Results show that particular types of strategies impact a variety of performance outcomes—profitability (McDougall and Robinson 1990), survival (Cooper, Dunkelberg, and Woo 1988), growth (McDougall and Robinson 1988), and nonfinancial measures (Stuart and Abetti 1988). Other research studies, considered innovation as an effective strategy to boost organizational performance (Butler, 1988; Drucker, 1985), and an important mechanism for a business to keep itself informed of the outer competitive environment. Moreover, Subrahmanya (2005) defined innovation as a company applying new knowledge or key techniques to development, manufacturing, or service. Besides, according to the literature review on organizational innovation and organizational performance, there is a positive and significant correlation between the two (e.g., Chen and Chen, 2006; Damanpour et al., 2009; Eddleston et al., 2008; Liao and Rice, 2010; Naranjo-Gil, 2009; Subrahmanya, 2005; Yam et al., 2004). Another important aspect regards the role of venture capitals. Some studies examined the effects of venture capital financing and strategic alliances networks on startups’ performance, highlighting that, the lack of financial resources was the most limiting factor for the growth of startups. (Boeker, 1989; Churchill and Lewis, 1983). Also, inter-firm alliances, represents a key factor for the innovative performances growth and consequently the concept of geographical proximity; a factor that tend to facilitate knowledge exchange, particularly when knowledge is complex and has a strong tacit component (Lorenzen, 2007; Zucker et al., 2002). Several studies argued that the relevance of geographical proximity lies mainly in the fact that co-location favours the development of other types of proximity – social, cognitive, organisational – which may generate significant impact on firm performance (Breschi and Lissoni, 2001; Boschma, 2005; Torre and Rallet, 2005). Specific studies also focused on the importance of Intermediary Actors and the relative impact of firm performance. They argued that for medium to low innovative firms, there is a positive correlation between firms having access to tangible and intangible resources at the STFC and their performance, while with regards to highly innovative firms, having a business partnership with incubators or universities appears to be a positively correlation with firm

performance. Other studies, in this field, instead realized that, the creation of an incubator, or the presence of a University, per se, was not sufficient for improving performance (Patton et al. 2009) and that new firms needed specialized support, especially in soft skill areas (Hindle and Yencken 2004; Colombo and Grilli 2005). The above discussion indicates that performances measurement represents a key element for firm growth and improvement. Literature mainly focused on the firm performances analysis and description (Freeman and Soete, 1997; Griliches 1998; Ernst, 2001;) and on understanding specific dynamics that lead to possible improvements. Nevertheless, an understanding of the main exogenous or endogenous factors influencing start-up performances is still lacking. Our research adds to these previous works by conducting a systematic review of the literature, analyzing the various factors that intervene, at multiple levels, to improve or reduce start-up performances, identifying the key research element.

3 Methodology

In this section we describe the methodological approach used, considering that our goal is to collect all the contributions in the literature with specific reference to factors affecting Start-up innovative performances, with the final aims to identify areas of convergence and suggest opportunities for future research on the main influencing factors.

Procedure proposed by Tranfield et al. (2003) makes it possible to identify publications of interest to researchers and then to describe the choice of relevant publications and the preparation of the research report. This procedure is systematic, transparent and replicable, in fact it consists of a series of steps that help authors define the research objective and plan the way articles are retrieved and reported):

1. The term [start-up] was used as base of the research, then a list of keywords¹ based on our prior experience was discussed with a review panel of three experienced academics in the field of innovation management.
2. We conducted Boolean searches on several combinations of the keywords identified in step 1 and discussed them with the review panel. These searches included: [start-up* OR startup* AND innovat*], [start-up* OR startup* AND performance*], [start-up* OR startup* AND endogenous variable*], [start-up* OR startup* AND exogenous variable*],
3. The review was limited to non-invited peer-reviewed journal articles published up to October 2018 (inclusive), excluding working papers, editorials, research notes and commentaries, interviews, dissertation abstracts, books, book chapters and conference proceedings (Keupp et

¹ “Innovation”, “innovative”, “performance”, “endogenous variable”, “exogenous variable”.

al. 2012); we included journals listed in the “Management” and “Business” subject category of the ISI Web of Knowledge.

4. Then we take in consideration only journal with a five-year impact factor (or the current impact for journals established later than 2014) greater than the "aggregate impact factor" value¹, ensuring the inclusion of article significantly influential in the academic debate. This choice reduced the number of journal to 15 for a total of 211 articles.

The titles, abstracts and keywords of the 211 initial articles were reviewed following a path based on the relevance of the articles to the object of our analysis and therefore we have defined specific *exclusion criteria* (Meier 2011; Pittaway *et al.* 2004; Rashman *et al.* 2009; Wang and Chugh 2014). The selection process relied on the use of more formal decision criteria to cut the broad pool of the initial list as well as on authors’ reading and understanding of the literature through textual analysis (Bakker 2010). These criteria (see Tables 1) were discussed with the review panel and subsequently used to select the relevant publications.

Table 1: Exclusion Criteria

N.	Reason of exclusion
1	Articles concerning “technology transfer” through the use of models and theories.
2	Articles concerning conceptualisation of entrepreneurial ecosystem
3	Articles focusing only on performance firms
4	Articles concerning Venture Capital
5	Articles concerning organizational management
6	Articles concerning team entrepreneurial characteristics

Of the 211 papers reviewed, 78 papers were excluded because they did not match with the aim of our research, leaving

As reported in Figure 1, the articles resulting from this methodology were published between 1990 and 2018, with more than half (65%) published since 2012, highlighting the emergent nature of the topic.

Figure 1 : Number of articles per year

¹ The aggregate impact factor is calculated by the ISI Web of Knowledge for each scientific category and takes into account the number of citations for and the number of articles of all the journals in the category. The value of the aggregate impact factor for the Business category was 2,557 and for Management was 2,393 in 2016.

Interestingly, examining the journals in which the sample articles were published reveals how widespread this topic is in the innovation management literature. Indeed, these articles appear in 15 different journals, mostly top-quality outlets such as Small Business Economics, Research Policy, Strategic Management Journal, Journal of technology transfer and Technovation (as reported in Figure 2).

Figure 2 : Number of articles per journal

In addition, in order to highlight the impact of the topic, (Figure 3) depicts that the 51% of the sample articles received between the 50 and 100 citations.

4 Analysis of the main results

The systematic review highlights a multilevel nature of the various factors that affect start-up performances. Several authors, in their works emphasized and put in light, influences coming from firm boundaries. Some of them, considered the development of innovative entrepreneurship a significant factor for the success of a start-up (Li et al., 2018), and that innovation orientation and perceived personal control, positively affects managers' tendency to rely on interpersonal ties to gather knowledge (Schierjott et al., 2018).

Different forms of capital play a significant role in the innovation and performance of start-ups (Neubert et al., 2017). Also, companies launched by a team of founders are more

likely to succeed than companies launched by individuals, in terms of, organizational innovation and organizational performance (Huang et al., 2012),

Knowledge is recognized as a key factor for economic growth, especially if it is transformed into products and services (Mueller, 2007). Firms that seek to exploit opportunities based on existing market knowledge, are more likely to attain substantial growth (Saemundsson and Dahlstrand, 2005). The role of initial worker and job characteristics (e.g., qualification, age, number of employees, marginal employment) of start-ups can determine a variation of start-up performances (Koch et al., 2013; Held et al., 2018).

Among the challenges of a team, such as creating a new venture or solving a start-up problem, hires great importance the entrepreneurship education (Dutta and Folta, 2016; Backes-Gellner and Werner, 2007). In particular, ventures cannot ignore founding team composition and expect to later professionalize their top management teams to align with their strategy and environment (Eesley et al., 2014).

Other authors put in light influences coming from external environment with a focus on network, competitive land macro environment level. Business Incubator, for example, is considered a key asset to support the commercialization of laboratory research results of innovative new science and technology-based firms (M'Chirgui et al. 2018); The technical-financial support of an incubator has a positive influence on all levels of innovation activity in all regions (Xiao et al., 2018), but effects of incubation services on the initial growth of new technology-based businesses vary according to the local context (Xiao et al., 2017). Moreover, the collaboration between incubates and incubator management also has increased incubates financial knowledge and their likelihood of raising capital (Rubin et al., 2015). Some Authors considered strategic the alliance of spin-offs with other firms (Hagedoorn et al. 2018) in order to improve resource, knowledge and competence (Parida et al., 2017).

Also, the hybrid alliances, that combine exploration and exploitation activities, can lead synergies thus to improve alliance innovation performance (Colombo et al., 2015). Therefore, the high technology start-up's innovative capability and inter-firm network (Zheng et al., 2010) bring about competitive advantage, innovations, (Littunen et al., 2003) employment growth during the early life course of firms (Stam et al., 2009) and consequently, a growing complementary effect of innovative capability and network heterogeneity on firm valuation. (Zheng et al., 2010).

Others authors considered the role of universities, as generators and disseminators of valuable knowledge (Fischer et al., 2018) and the university-industry collaboration (Chang et al., 2017) as a key asset to enhance the capabilities/efficiencies of innovation systems and to the access to financial capital (Soetanto et al., 2015; Partanen et al., 2014).

Marketing skills, through design and product innovations (Dan, 2018; Chen, 2017), the combination of different knowledge and the use of entrepreneurial strategies (Miller and Le Breton-Miller, 2017), as well as the presence of corporate structural elements (Protogerou, 2017) are considered influencing factors for start-up performances. The use and implementation of information and communication technologies (ICT) in business

management have become increasingly crucial for the growth of competitive advantage in the market (Steinfeld et al;2010).

Venture capitals are considered important factors for the financing of the knowledge-intensive enterprises (Rossi et al. 2017), creating value for the investing firms in terms of growth (Bertoni et al.,2011; Chang, ,2004).

Investors have realized that the economy of culture exists and is a field of innovation, which allows start-ups to develop a certain ability to innovate their business and management processes, making them attractive to investors (Wolf, 2012).

An important step for a start-up that operates in the innovation ecosystem is to be listed on the stock exchanges (Parhankangas, 2012). In the field of external funding, some authors point out that governmental venture capital investors (GVCs) stimulate invention and innovation and that the GVC are an ineffective substitute, but an effective complement, of IVCs (Bertoni et al.;2013). Moreover, the social capital of venture capitalists (VCs) had positive effect on the funding of start-ups, allowing superior access to information about investment objects and opportunities to leverage them in the future (Alexy et al.;2012).

Others initiatives that may contribute to the growth of a start-up in terms of profit, survival and reputation are the so-called M&A transactions (Yim, Hyung Rok;2008); but the key to economic development are the new technology ventures, which could rejuvenate industries with disruptive technologies (Song et al.;2008). Therefore, investing in an equity fund involves implicit risks and for these reasons some authors consider investment, in an arbitrage strategy on M & A transactions, as a strategic alternative (Anokhin et al;2014).

Patents and trademark have the function of facilitating relations with external partners in order to acquire financing, ensuring an increase in attractiveness for investors (Maresch et al.,2016; Block et al.,2014). To support the development of innovative products in addition to venture capital there are other forms of alternative finance for start-ups, in particular, the reward-based crowdfunding, which ignites professional investors' interest, helping secure subsequent funding (Roma et al.;2017).

The new industrial policies of governments encourage companies to invest resources in production inventions, through subsidies (Dai et al.,2015), which include access to non-financial resources (networks, business knowledge) and the reduction of administrative burdens(Patzelt et al.; 2009), improving the competitiveness of the country system.

Among the public initiatives to support of the competitiveness and successful of start-ups, some authors considered programs for technological innovation to provide indirect support, improving investment efficiency on R&D (Jun et al.,2017; Soderblom et al.,2015), as well as the international research joint ventures and their positive impact on technological assets of participants (Barajas et al.,2016). In the field of academic research, the spin-offs (RSOs)-enterprises originating from a university or research institute-appear to have higher innovative potential and capabilities than other start-ups, pursuing several business models (Lejpra,2014; Clausen and Rasmussen,2013).

5 Conclusions

The results of the analysis points out that the majority of the studies have focused on the analysis of indicators: some have analyzed single indicator, other studies used two or more indicators to generate a more complex construct.

Analyzing them in detail, however, it emerges that these indicators are strongly influenced by dynamics that operates in different way: improving the innovative performances of a start-up is the result of a set of determinants operating at different levels of analysis (Figure 4).

Figure 4: Different Levels of influence

A specific group of authors, in their works emphasized and put in light, influences coming from firm boundaries that we can call “Firm Level”.

Another set of authors put in light influences coming from external environment. This environment refers to a set of values, rules, norms, connection, relations (Edquist and Johnson, 1997) and to differences in institutional endowments (Hart, 2009) that separately or in combination can affect the growth of a company. In particular, it is possible to identify a level of influence related to factors such incubators, alliances, collaborations that we can call “Network Level”; other level that includes influencing factors as barriers, competitors, economy of scale/scope (Competitive Environment Level), and a last level that explores the influencing factors as Political, economic, social, technological, environmental, legal (Macro Environment Level).

Strategic Innovation Outcomes and Competitive Advantage: a Comparative, Empirical Study

75002 Paris / France

Abstract

This paper explores the notion of strategic innovation and examines mediating mechanisms by which it ultimately contributes to competitive advantage for the firm. The underlying premise of the study is that an innovation effort may result in a variety of outcomes. For the purpose of this study, we narrow the possible outcomes to three possible outcomes: (1) differentiation, (2) learning and new knowledge creation, and/or (3) failed innovation effort. Further, the paper argues that the three outcomes are not mutually exclusive; that is to say, an innovation outcome typically encompasses elements of all three outcomes. The three innovation outcomes exhibit varying strategic and competitive impact and time horizons. Differentiation, typically manifests in a measurable, tangible outcome (e.g. a relatively short-term outcome enabling a premium-priced product or service) and is, of course, the sought-after outcome with most immediate strategic impact. However, innovation effort may, in fact, also result in secondary intangible outcomes such as learning, knowledge creation and (intelligent) failure (failure that enables the extraction of rich learning). This paper explores the proposition that despite often overlooked, these intangible innovation outcomes can, in fact, carry greater potential competitive impact for the firm in the long term, provided they are strategically managed. A conceptual model of strategic innovation is proposed that examines the critical linkages between the three innovation outcomes and mechanisms by which learning, knowledge creation and intelligent failure ultimately can contribute to competitive advantage. The conceptual model is tested empirically using a quantitative approach. Preliminary statistical analysis (factor analysis, regression analysis) identifies some key determining factors linking the various innovation outcomes, in particular, mechanisms by which intelligent failure can contribute to learning and knowledge creation in the firm. The analysis draws on empirical data derived from three different R&D organisations –differing in research intensity, size and maturity. The findings highlight key similarities and differences in how the three organisations manage their strategic innovation. The findings of this study are shown to be consistent with current thinking that links strategic innovation with organisational knowledge, practices and culture.

Keywords – innovation, learning, knowledge, competitive advantage, failure

Paper type – Academic Research Paper

1 Introduction

Innovation, while increasingly seen to play an important strategic role in firms' competitive positioning, remains a challenge, if not an enigma, for most firms. At least in part this has to do with the various expressions of innovation found in practice. Innovation traditionally has been associated with either improvements to existing ones or radically new products or processes. Increasingly, however, innovation is being linked to learning, capability development and organizational renewal. While the traditional view affords at least some degree of measurability of the innovation outcome, the one related to learning and organizational renewal recognises the largely intangible outcome of innovation which does not readily lend itself readily to assessment and evaluation. This notwithstanding, from a strategic perspective, arguably the learning and capabilities outcome of innovation has far greater implications for the competitiveness of the firm. A basic premise taken in this paper is that any successful innovation outcome has at least two outcome dimensions: (1) An outcome that (in the case of successful innovation) can be expressed in terms of a superior value offering that leads to 'measurable' competitive differentiation in the market in the immediate term, and (2) a second, much less visible though potentially far more important long-term outcome that manifests itself in terms of an innovation capability.

In this paper we explore the learning and capability outcome of innovation that expresses itself as a transformative dynamic capability. Whilst companies are looking to innovation as means of competitive differentiation in the traditional sense, only the fewest are deliberately and purposefully harnessing the innovation outcome that expresses itself in the form of a dynamic capability.

The thinking and research discussed in this paper is still in progress. Hence the purpose of this paper is to: (1) broadly describe the conceptual framework that underlies the approach to innovation as a dynamic capability, and (2) present the research methodology used in its examination, and (3) preliminary research findings based on the analysis of both quantitative field research emerging from this investigation

2 Strategic innovation – new perspectives and strategic implications

Innovation is increasingly being seen to be a key lever to strategic growth. Yet in reality, few companies succeed in leveraging innovation consistently for competitive advantage. In reality, much of the effort invested in innovation contributes little to the business bottom line of most firms. This view rings true across many industry sectors. Companies invest in innovation with low expectations of success. From a strategic perspective, therefore, the traditional view of innovation that underpins much of today's understanding of the role and rationale for innovation is ripe for fundamental rethinking. Innovation is changing irreversibly in nature, scope and impact – and so too must our understanding of it. First, it is by no means solely the domain of the firms' research and development function. Strategic innovation clearly extends beyond the traditional notion of innovation to include significantly more encompassing view that finds expression in

business model innovation. In this way, strategic innovation increasingly is embedded not only in all of the enterprise's operations; it is deeply embedded in the firm's very culture and mindset. Second, the nature and outcomes of innovation are increasingly manifested in the form of intangibles – whether in the form of improved service offering, or simply in the form of superior knowledge embedded in a product or process that has potential for value differentiation. Last, but not least, the impact of innovation needs to be recognised not only as a 'measurable' outcome, but also as a contribution to the development of a dynamic innovation capability. The strategic implications of this latter perspective for the enterprise are immense, though largely yet neglected in practice.

Definition: *Strategic innovation* is defined to be an orientation that seeks to maximise the competitive outcome of every innovation effort, whether incremental or frame-breaking, toward creating an (ideally) unique and superior value offering targeting relevant stakeholders. Outcomes of strategic innovation might be 'measurable', such as a clearly differentiated product or service offering; however, they might also be very difficult to 'measure' in a traditional sense (such as would be the case with a dynamic capability development).

Innovation outcomes Generally, innovation outcomes can take on a range of forms. Clearly, innovation that leads to a differentiated, superior value offering of a firm in its market place is one possible outcome. This is a highly desirable innovation outcome that the market richly rewards. Indeed, the potential for competitive differentiation through innovation captures the essence of the strategic rationale for innovation. This is where most organisations' view of innovation has been in the past and where it ends for all but a few firms. In this paper we deal with an innovation outcome that is more often than not overlooked: innovation that expresses itself in the form of learning and leading to the development of a dynamic innovation capability.

Therefore, innovation leading to a position of enhanced competitiveness necessarily has two components: one that is recognized as competitive differentiation in the market place, and one that expresses itself primarily as enhanced organizational capability. Whereas the first is recognised and characteristically rewarded in the marketplace in the near- to mid-term (for example, in first-mover time-to-market advantage), the latter outcome in the form of an improved innovation capability expresses itself in terms of a mid- to long-term competitive repositioning of the firm. This latter expression of innovation is largely intangible in nature; it is difficult to measure since its competitive impact often takes time to become apparent.

The conceptual model for strategic innovation explored in this paper views innovation outcomes to consist of the *sum* of both parts:

- (a) Innovation outcomes that lend themselves to 'measurement'; this might be thought of as the result of innovation effort leading to a differentiated value offering that finds acceptance in the market. Measures might include 'time-to-market', market share increase, revenues generated in the relevant market as a result of the product / service offering.

- (b) Innovation learning and capability building that emerges through activities carried out in the course of the innovation effort describe in (a). Measures of this outcome are difficult; they are much more long-term focused and are inextricably tied into the informal organisation structures, process and culture.

Innovation as a dynamic capability By extension of the outcome (b), the question explored in this research is:

Research question: To what extent can the learning, capability development and renewal outcome of innovation be thought of as an expression of a dynamic capability?

That is to say, to what extent does this expression of innovation exhibit the capacity to support the adaptation, renewal, reconfiguration and creation of new resources in response to changes in the firm's competitive environment (Helfat et al. 2007; Eisenhardt and Martin 2000; Teece 2009; Teece et al. 1997). Moreover, to what extent does this expression of innovation resonate with earlier work on distinctive competence (Selznick 1957); core competence (Prahalad and Hamel 1990); core capability and rigidity (Leonard-Barton 1992) and combinative capability (Kogut and Zander 1992)?

Following from this, the following models frames the approach explored for the purpose of this research:

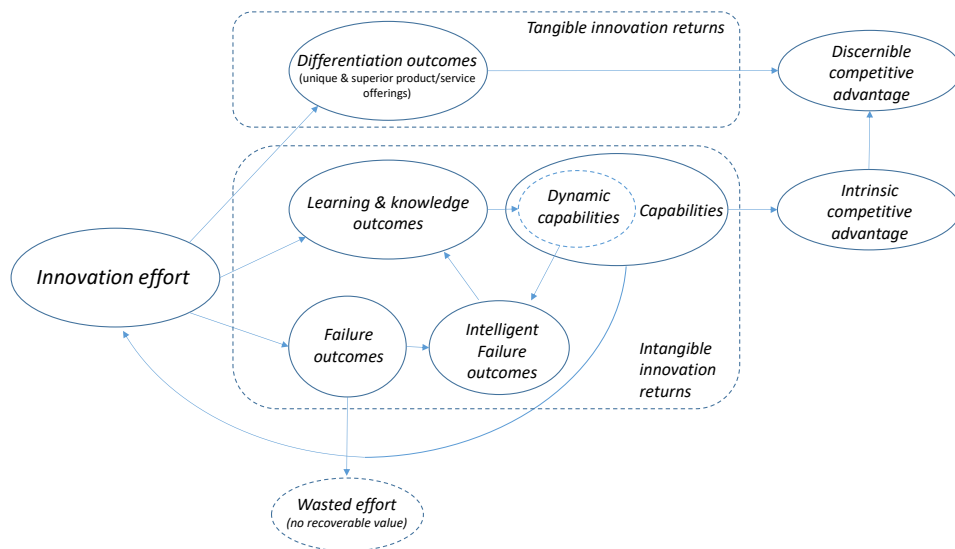

Figure 1. Innovation model: Key components linking innovation effort to competitive advantage

3 Empirical Approach

Innovation research targeting the investigation of innovation capability, particularly its expression as a dynamic capability is an emerging field of study. Some of the early studies reported include empirical research reported by Van Winkelen and Tovstiga (2010) and Tovstiga and Tulugurova (2009). In this work, innovation and its expression is tied to knowledge practices and intellectual capital practices, respectively.

3.1 Research Methodology

The exploratory research of this study is based on a quantitative analysis of data collected via a survey questionnaire that probes respondents' perceptions of innovation outcomes distributed between four possible expressions of the outcome – differentiation, neutralisation, learning, and an outcome with no discernible value.

Definitions:

Differentiation: outcome with clearly identifiable competitive impact in terms of potential for a uniquely superior value offering

Neutralisation: an outcome, while not nearly of the competitive impact of differentiation, still positive (in the sense of a 'second-mover' advantage); potential for mitigating success of a competitor's first-mover advantage

Learning: an outcome that expresses itself as benefit to the organisation; a bundling of the learning, insight and experience gained, toward building a capability that has potential for a competitive re-positioning of the firm

Failure or no-discernible value: covers innovation effort that does not lead to any identifiable value; in other words wasted effort. However, such outcomes need to be viewed critically against the possibility of an extraction of learning from that failed effort and conversion of that learning from failure to capability development.

The field investigation targeted three main sources of data; three organizations differing in size, maturity and intensity of R&D:

1. A research laboratory of a legacy, large multinational IT firm, based in Switzerland, that has brought forth four Nobel Prize – winning researchers since the research laboratory's founding in the early 1960s; 50 respondents.
2. An R&D and Technology organisation of a large UK-based telecommunications multinational; 58 respondents.
3. High-tech start-up enterprises associated with a Zurich (Switzerland) – based technology park; 84 respondents

The survey instrument developed for the empirical field research consists of a questionnaire consisting of a total of 49 items. The questionnaire consists of four main constructs; these comprise the possible outcomes of innovation: (1) differentiation, (2) neutralisation, (3) organisation learning, and (4) an outcome of no discernible value

(“wasted innovation effort”). The first four items query the estimated innovation returns in terms of a percentage distribution amongst the four possible outcomes. In a following sections of the questionnaire, 45 further items query the nature of the innovation outcomes associated with each of the four types of possible innovation returns on the basis of a 5-point Likert type scale.

The survey instrument was set up in the form of an e-survey format. Potential respondents were invited to access and respond to the survey the survey via an electronic link. In selected cases, the initial quantitative research was been followed up with qualitative research involving semi-structured interviews and workshop-type sessions with the purpose of deepening and substantiating the quantitative research findings.

Statistical analysis of the field data was carried out with the help of SPSS software. Reliability testing indicated a high degree of reliability overall. Statistical means of the scores relating to the items under each of the four main constructs were computed. Factor analysis (contributions to overall variance and factor loadings considered) was used to identify factors relating to the four main constructs. Item scores of two of the constructs (differentiation and learning) were then singled out and subjected to a joint factor analysis with the intent to identify those factors contributing to a positive innovation outcome. Some preliminary results emerging from this analysis are discussed below. In further analysis to be done, factors relating to these two constructs will be identified for further regression and correlation analyses.

4 Preliminary findings

The field research of this study has been completed; the statistical analysis of the data is still in progress. Hence this section is to provide a glimpse only of some of the results emerging from the analysis.

From the quantitative survey data the findings related to estimations of the breakdown of innovation returns between the four possible outcomes indicate that only about 30 percent of effort invested in innovation results in a differentiated product/service/concept offering. Approximately 25 percent of innovation effort results in a neutralisation outcome which, while not a differentiated outcome, is still a positive return that might, for example, challenge or mitigate a competitor’s first-mover advantage. Approximately 25 percent of innovation effort results in some form of organisational learning and capability development. Wasted effort or outcomes from investment in innovation that can be attributed to neither differentiation, neutralisation or organisation learning constitutes the remaining 20 percent. However, a comparison of this sort may be overly simplified. First, as suggested earlier, firms’ effort invested in innovation extends beyond mere R&D expenditure. Second, not everything attributed to wasted effort is necessarily that. Is a failed experiment necessarily wasted effort? Not if learning can be extracted from this ‘failed’ effort.

From the factor analysis of the construct clusters, the findings suggest some common determinants of an innovation capability; these relate to:

1. The *nature of the value offering* and the *degree of differentiation* afforded by that value offering (contributing 16.3 percent of the variance in one particular sampling of data);
2. The *strategic impact* of the value offering (15.3%)
3. *Innovation metrics* applied and *measurability* (13.2%)
4. Organisational context for the *innovation capability development* (12.7%)

Further analysis is to investigate the dependence of the differentiation outcome of innovation on the factors identified in the factor analysis.

5 Conclusions

While the analysis discussed in this paper is still in progress, preliminary findings nonetheless are consistent with recent research findings that provide empirical evidence suggestive of the link between innovation practices and organisational learning processes. Consistent with these findings, the preliminary findings of this research indicate that innovation as a learning outcome has attributes that align well with those of a firm's knowledge (or intellectual capital) base that is in turn linked to capability development and exploitation. The factor analysis suggests an approximation of some determinants that constitute the capability dimension of innovation. These provide evidence of a dynamic capability dimension of the innovation capability.

Clearly, more analysis needs to be done on the existing data set and further data needs to be gathered and analysed for confirmation of these preliminary findings. Nonetheless, the picture that emerges from the research findings of this work suggest a capability embedded in an organisation knowledge context that links innovation to knowledge in its various forms and the latter to the organisation's context such as its culture, processes and practices.

Abstract

The SNCF Group (French Railway company) splits into different small companies. One of them is “SNCF Réseau” that is in charge of the management and maintenance of the 33,000km network and the 3000 stations. SNCF Réseau is often considered as a bureaucratic and rigid system no longer responding to the changing external and internal environment. We have conducted investigations in various fields of research to understand how to turn SNCF Réseau into a hybrid and malleable system. Our literature review highlighted that organizational innovation could be a key concept in this organization's ability to evolve, renew, and perform. This paper presents the preliminary results of our study of factors influencing organizational innovation. This study is based on a systemic literature review and on an action research in collaboration with the digital direction and innovation of SNCF Réseau.

Keywords – Innovation Culture, Organizational Innovation, Multi-dimensional Framework

1 Introduction

Today, companies must innovate to exist in a volatile and moving environment (Chang and Hughes, 2010; Damanpour and Aravind, 2012; Camisón and Villar-Lopez, 2014; Iturrioz *et al.*, 2015). This quest for innovation has become an obsession: it is necessary to innovate, to transform oneself, to be digitalized, to be creative. So many injunctions that are daily present in strategies and speeches. However, it's difficult to concretize these injunctions. Beyond these injunctions and the pressure of the markets, the big companies must cope with the societal and climatic pressure: need durable and virtuous economy, scarcity of the resources, strong demographic pressure, global warming. Factors that force the implementation of many technological and non-technological innovations and a redesign of the societal role. The answers given to its stakes are mainly of a technological nature since the studies focus mainly on the role and results of technological innovations (Büschgens *et al.*, 2013; Kaur Kapoor *et al.*, 2014, Slater *et al.*, 2014; etc.). Nevertheless, non-technological innovation which contributes creating a sustainable competitive advantage that is difficult to replicate exists too (Pisano and Teece, 2007). The researches have increasingly focused on this non-technological dimension of innovation (Birkinshaw and Mol, 2006; Birkinshaw, all, 2008; Crossan and Apaydin, 2010; Damanpour and Aravind, 2012; Ganter and Hecker, 2013). The concept is called managerial innovation or administrative innovation (Birkinshaw *et al.*, 2008; Damanpour and Aravind, 2012, Kraus *et al.*, 2012). Our interdisciplinary literature review, nourished with works in management, management science, sociology, economics, information science and communication, allows us to identified a large number of factors influencing technological and non-technological innovation capacities of an enterprise. Researchers developed multidimensional framework of organizational innovation (OI) based on rigorous systematic review of the literature (Crossan and Apaydin, 2010; Khosravi, Newton and Rezvani *et al.*, 2019). These propositions are often theoretical ones and are not confronting to an empirical analysis. The purpose of the paper is to confront these models to the reality of our field of study: SNCF Réseau that is the "heart" of the French rail system with the management and maintenance of the 33,000km network and the 3000 stations. Principal objective of this research is the definition of a modelling approach of the organization to identify its strengths and limits and associated tools to allow evolution of the system (organization, management, human resources, etc.) to make the strategy of process of employees' idea generation and implementation a reality.

The main objective of this paper article is to present our first results of the using of existing models of OI (Crossan and Apaydin, 2010; Khosravi, Newton and Rezvani, 2019) in the real case study of a large company – SNCF Réseau. The paper is organized according to our scientific approach. In the first section we realize a literature analysis to define the OI concept and to identify the existing multidimensional frameworks of determinants of OI. In this section, we define the context and the elements on which we will base our research (step 1 of our approach). In the second and third sections we propose a preliminary analysis of the determinants of OI in the SNCF Réseau company in

accordance with theoretical models. The internal determinants are identified in the second section (step 2) and the external ones in the third section (step 3). This dual approach, theoretical and practical, will allow us to highlight the absence of certain factors, which can inhibit the system's ability to foster innovation. In the conclusion section, we therefore discuss about the opportunity to complete the models with new factors and open perspectives for a new definition of organizational innovation. The design of a model will perhaps allow us to have a systemic vision of the organization and the interactions between its components in order to pilot the innovation capacity of the successful company and adapted to its context. The definition of such a model, that is the last step of our research, is not presented in the paper.

2 Multidimensional Frameworks of determinants of OI

2.1 The Organizational Innovation Concept

Studies and literature on technological innovation abound mainly around three main themes: the diffusion of innovation, the adoption of innovation and the implementation of innovation. Technological innovation takes place in the technical system of the firm (Damanpour and Evan 1984; Yam, Lo, Tang and Lau, 2011). Moreover, more and more researches are also interested in non-technological innovation, particularly OI (Lam, 2005; Mol and Birkinshaw, 2009; Khosravi, Newton and Rezvani, 2019). But, the presence of works that synthesize knowledge on this concept is still lacking and accentuates the lack of knowledge on the subject (Damanpour and Aravind, 2012, Černe *et al.*, 2016). Non-technological innovation is equated with a complex social system composed of a network of actors and many internal and external relationships. Interactions occur on a daily basis in any relationship between members of the organization and between the organization and its environment. The tacit nature of these features makes the concept difficult to observe and define. Few studies have examined the diffusion, adoption and development of non-technological innovation and a great part of the research on non-technological innovation is primarily theoretical. The few empirical studies focus on the antecedents of non-technological innovations and adoption processes (Damanpour and Aravind, 2012; Volberda *et al.*, 2013). Among non-technological innovations, OI studies are recent and even contradictory. The concept is young, with several names "organizational innovation" - "managerial innovation" - "administrative innovation" (Birkinshaw *et al.*, 2008) and lacks stable references. Management studies the concept in two ways: Innovation within organizations and OI as a specific investigative object (Wolfe, 1994; Lam, 2005). Beyond the role of the OI, it is its scale of analysis and impact that are debated. Most of the time it is studied at the level of the company and its own characteristics: size, age, type of structure. But according to Damanpour (1991) this approach incorrectly uses the OI name. It should be called "organizational capacity for innovation". This confusion of names has led some authors to use the name "innovation management" (Birkinshaw *et al.*, 2008). It refers to new management practices put in place to achieve the organizational objectives of the company. This designation avoids

confusion with administrative innovation that is too restrictive. All of these variables complicate the definition of OI concept, especially since it is used without distinction in management science and management (Damanpour *et al.*, 2009, 2012). But we can rely on four characteristics:

- differs from technological innovation,
- is akin to novelty; is multidimensional,
- is systemic,
- comes from an intention to achieve a goal.

2.2 Multidimensional Framework to highlight determinant of OI in company

In the literature, innovation models and policy decisions are often focused on a single dimension or a limited number of dimensions of innovation (Rothwell, 1994; Tödtling and Trippel, 2005; Kroon *et al.* 2008; Berkhout *et al.*, 2010; Caetano and Amaral, 2011). This one-level approach does not match the reality of a company and of what could be OI. First of all, it makes complicated the construction and the analysis of the interfaces of the various levels. Second, company is a social fabric composed of individuals, groups, organizations, with a set of rules, practices, technological artifacts (ICTs) and discursive entities such as language and culture. Everything must be studied in terms of the firm's dynamic system, its strategy, its local and global context and the external environment. It is therefore necessary to have a systemic vision to develop a model of innovation multidimensional aspects. Van de Ven *et al.* (2007), considers innovation as a non-linear approach with a cycle of activities at different organizational levels. A recent study (Hughesa *et al.*, 2018) provides a more practical approach by presenting a review of empirical studies on leadership, creativity and innovation in business. This work offers a new perspective on the themes addressed and new definitions of creativity and innovation. It also highlights the main effects of leadership on creativity and innovation and that research in this area is very promising.

Based on our literature review and to consider dimensions, levels and parameters that could have an influence on OI in a company, we made the choice to work with the model built by Crossan and Apaydin (2010) (figure 1) completed with the model of Khosravi, Newton and Rezvani, 2019 (figure 2). These authors developed complete multidimensional frameworks of OI based on a review of the literature of last decades on the subject. Far from the completeness of the models, their other interest is the taking into account of the separation of the process of innovation (the how) which precedes the result (the what). This responds to the desire of (how) to create a process of organizational innovation that should lead to (what) an "innovative" system. The innovation process (how) is influenced by three main factors:

- the leadership of the organization and individuals,
- the managerial levers,
- the processes of the company (organizational learning, its knowledge management)

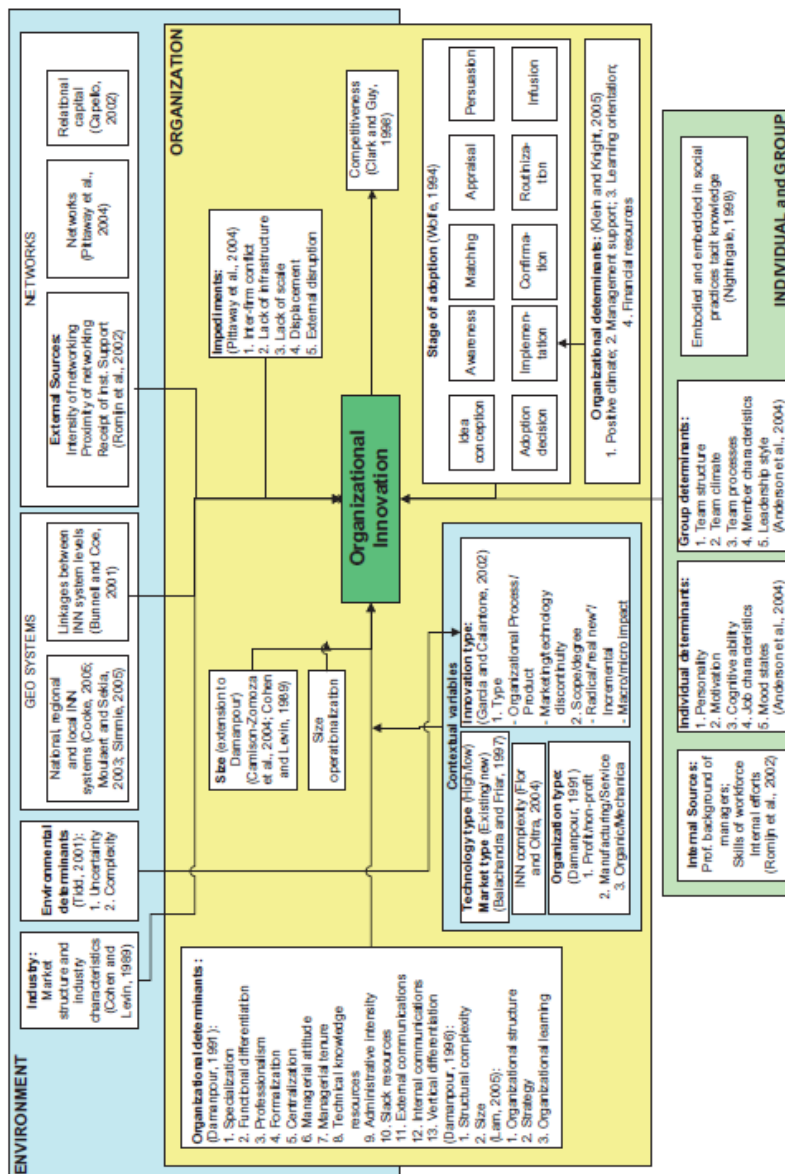

Figure 1. Determinants of OI (Crossan and Apaydin, 2010)

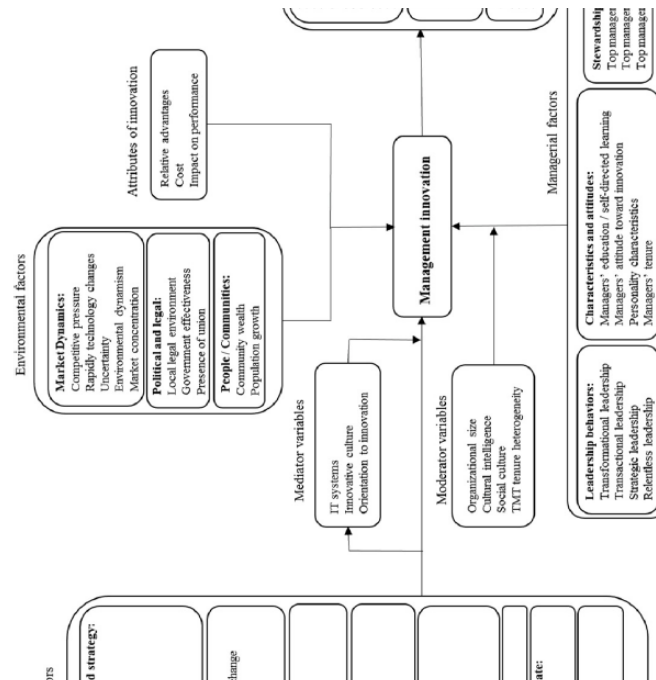

Figure 2. Drivers and outcomes on management innovation (Khosravi et al., 2019)

In the next section of the paper, we present our study within SNCF Réseau. Final objectives of our research are:

- to check if parameters defined in theoretical models in figures 1 and 2 are exploitable in real cases studies,
- to set up, thanks to the OI, a business system able to develop its innovation capabilities and fostering a culture of innovation.

In this paper, we just present the preliminary results of our study concerning the first objective of our research (to check if parameters defined in theoretical models in figures 1 and 2 are exploitable in real cases studies).

3 First step of our study – internal levels: organization and individual

3.1 Presentation of SNCF Réseau and synthesis of our observations

The French Public Rail Group is made up of SNCF, SNCF “Réseau” (Networks) and SNCF “Mobilités” (Mobilities), three public institutions that are inseparable and united. At the head of this group, SNCF provides strategic control and steering, economic coherence, industrial integration and social unity. The functions of infrastructure manager of the national rail network are entrusted to SNCF “Réseau”. Finally, SNCF “Mobilités” is responsible for all the rail transport service activities. In such a complex organization,

with a long history and specific culture and values, it is the “direction of innovation” of SNCF “Réseau” that promotes innovation and creativity strategies throughout the organization. This direction develops projects and researches focused on organizational innovation, new services, new different kinds of leadership (transformational and transactional leaderships for instance). SNCF Réseau that is the “heart” of the French rail system with the management and maintenance of the 33,000km network and the 3000 stations.

3.2 Initial internal study at organization, individual and group levels (figure 1)

Since 1938, SNCF has developed participatory innovation as about 75% of large companies in France today. This management system is very structured and generate routine (in accordance with Feldman and Pentland, 2003) and favor inertia (Montgomery, 1995). Since 2004, it is piloted at the central level that defines the rules and the procedures to all regions and institutions. It is a process that follows a precise logic: depositing ideas, instruction of the files, submission of the file to the hierarchical lines and to the technical experts then implementation of the idea with gratification. Initially it was driven by human resources and now by people who are not trained and have no time allocated to this function. This device nourishes the techno centered vision of innovation and the central place of the "expert". The setting up of such a process and its inefficiency puts into question the "process" factor. In the perspective of a new OI that allows to set up a self-adaptive system centered on humans, SNCF decided to question its model: what are the limits and benefits? Is not process operation a hindrance to innovation? How can this centralization "understand" the local context in which the idea emerges?

We began the internal initial analysis of SNCF Réseau since few months. We studied the organization of the company (hierarchical and functional organigrams, process models, etc.) and we conducted interviews of many employees. Objective was to focus on the endogenous factors mastered by the company. Preliminary results of our study highlight that:

- a. SNCF Réseau is a “bureaucratic” structure in which dominates rules, benchmarks standards, fixed and clear decision processes. Managers spend 40% of their time setting standards and controlling (Morieux, 2011). Thus, the organization develops a transactional leadership through which employees are rewarded (bonus, increase, echelons) or sanctioned. This type of leadership does not allow intrinsic motivation, and stifles creativity and innovation (Amabile, 1996).
- b. The company does not promote leadership capabilities from a collective and individual point of view. It applies a "command and control" management. This is reinforced by the supervision of the state, the main shareholder and the directives of the ministries of labor and transport which accentuate the pressure on the management and by streaming on the managers. This is a major problem when we know that managers influence the company's innovation capacities by 5% to 20% (Crossland and Hambrick, 2007), particularly by stimulating team

creativity. They also participate in the diffusion of innovations by creating favorable environments (Mumford and Licuanan 2004).

- c. We rarely talk about the organization of work and management of the company while everything is partitioned. This partitioning is due to its history, with the weight of a technical culture, disseminated by the engineers and a structured and abundant hierarchy. The set is based on several thousand standards and rules legitimized by the imperative of safety that protects agents and users. This allows each employee to know the answer to bring to a given situation when everything is "normally". The rules hamper the ability of employees and the system to cope with hazards, disrupted situations and take initiatives.
- d. In 2018, SNCR Réseau presented its new reorganization in 40 processes. The process of innovation is being thought through. In the opinion of the managers, this plan breaks a lot of questions in terms of application at the local level, strategy, vision, meaning, evolution of the business and organization. The structure continues to bear the brunt of bureaucratization because the business system does not change. Now, the question is about managers' perception of external factors and their motivation to change their approach.

Thanks to such an internal study, SNCF Réseau believes that factors influencing employee motivation are present in the company at different levels but are not explicitly mentioned:

- the organizational culture (Scott and Bruce, 1994),
- management relations (Janssen, 2005),
- the characteristics of the task (Shalley, 2008),
- relationships within the working group (Hülshwegert *et al.*, 2009),
- the differences between individuals (Raja and Johns, 2010),
- feeling of accomplishment in one's work, responding to a challenge or obtaining satisfaction in one's work (Aletraris 2010, Aselage and Eisenberger 2009),
- Extrinsic out-of-work objectives (Amabile, 1997, Malik *et al.*, 2015).

Our research seems to confirm the importance of these levers and the company continues its reflections. Nevertheless, according to the three factors described in the Crossan's model, SNCF Réseau is also interested by the influences and impacts of exogenous factors on the OI. The company asked us to particularly study these factors. So, we enlarged our scope by focusing on the external environment of SNCF Réseau, to integrate extra-organizational point of view in our study ("large-scale" notion of Armbruster *et al.*, 2008).

4 Second step of our study – high level of observation: exogenous factors

4.1 The global context of French rail transport

The opening to competition of French rail transport will be very gradually and will start in 2019 (Railway PACT). For the French Public Rail Group (SNCF) innovation and creativity in the workplace have become increasingly important determinants of

organizational performance, success, and longer-term survival in such a new competitive context. Beyond this “French” context, the new challenges for transport sector concern also climate change and societal issues. The majority of innovations that attempt to provide a sustainable solution are technological but SNCF Réseau is convinced that there are other answers. They can come from organizational, institutional and social innovations by proposing new collaborations with the aim of a transition towards a carbon-free economy for instance (Dunlap and Brulle, 2015). The climate challenge will force companies to have a long-term vision, opposed to the short-term vision (notably linked to the state). It will have to manage more uncertainties related to the climate, uncertainties in the investments, in the types of knowledge mobilized, in the crossing of the traditional horizons of management of the companies (Ageri and Cartel, 2017). Moreover, changes in societal behavior are the beginning of a profound change in society, the current paradigm and inevitably policies, corporate missions, employee behavior. Considering these changes, it is a big challenge for companies to transform themselves. They must be able to understand its external environment while meeting the expectations of its internal environment. Exogenous factors (government policy, social movements, geopolitical context, etc.) must be included in the management of the system. Even if the company cannot influence them all.

4.2 Railway PACT

The railway PACT opens to competition the transport of passengers in France. First the regions with the TER (smallest train lines connecting small towns) offer then the TGV (train lines connecting the French largest cities). SNCF will have to manage an opening to European and world competition with the emergence of China. The agents of SNCF Réseau will undergo many changes. Have a customer vision, interact with new interlocutors with different interests and requirements. His system is not ready for such rapid changes. This competition pushes the company to “innovate” in a disorganized and techno-centered way. The nature of work will change. Public service culture is being challenged in favor of profitability, efficiency and productivity.

4.3 Politic and social context

The juridical structure of SNCF will change in 2020 but it will keep a mission of public service. The presence of French State generates obligations and strong constraints for the railway group. The specifications are under the supervision of the French Ministries of Finance and Transport. The governance and strategy of the Group evolve according to policies and political parties: public tariffs, support to some agents of national economy (rail users, or its industrial suppliers), spatial planning, etc. So, the politic context influence strategy and firm system and is an important factor.

SNCF is also putting up with social pression. Two reasons: it's a very unionized company and not spared by customer dissatisfaction. Now, must review her societal role, take into account the new mobility law and the new innovation policy of the state. So many constraints to understand and master. The crisis of yellow vests questions its public service policy, its governance, its strategy of profitability classic lines, the mesh of the

territory. It is interesting to see new forms of governance emerge alongside traditional governance. These changes are also influenced by external pressures. This reinforces the hypothesis of a strong link between the company and its external ecosystem. Especially when the pressures are social. They indicate to the actors of the firm which actions envisaged in order to maintain a socioenvironmental balance. They act as governance mechanisms. The business can be likened to a network that interacts for a purpose. This network of actors makes it possible to study sustainable innovation.

The international relationships and politics have consequences too. Europe offers the possibility to have long services. SNCF should have an international destiny. But it is ahead of road transport on the European market. Freight is still not needed. Despite the creation of the EU Agency for Railways in 2006, it is difficult to organize European rail from a technical and commercial point of view. SNCF is not decided to separate from its power and keeps its industrial "protectionism".

4.3 Territorial context and OI

Study of barriers to innovation is mainly for technological innovation, with a few rare exceptions (Galia and Legros, 2004, Segarra-Blasco and Garcia-Quevedo, 2008). In the context of non-technological innovation research, the scope is the organizations, never the territory. Territory is an exogenous factor that the company needs to understand with SNCF's proximity issues. It is also an important factor in spreading and implementing an organizational innovation. The barriers are complex and numerous. The French school of proximity (Talbot, 2008) proposes a framework of study, with three components of the proximity.

- Geographic proximity to study spatial and location dimensions,
- The institutional proximity that studies the similarity of codes, rules, representations, shared values between employees. To better anticipate their respective behaviors,
- Organizational proximity, which studies the logic of belonging of employees.

According to Defélix et al. (2013), when the three proximities are combined, the adoption of innovative disposition is possible as part of joint activity. For the moment we have investigated this aspect. Nevertheless, Railway PACT will oblige SNCF to focus on territories because the company will have to decentralize its organization.

5 Conclusion

The innovation capacity of the enterprise system is a major topic within bureaucratic organizations. Beyond this capacity, innovation is too often studied through technology, the non-technological aspect is still too little present in the research. Nevertheless, some of them have been interested in organizational innovation and the factors that influence it. But few studies offer a systemic and empirical approach to the concept.

Preliminary results of our study allow us to confront the literature on the subject with a real case study. They confirm the importance of the internal factors of the organization put forward by the model and of considering influences and impacts of the external

factors. We presume that OI can only be generated and adopted by the company if the technical and social system takes into account the endogenous and exogenous factors. The new challenge of our research will be to clarify the framework of each factor and propose methodologies for the organization to seize.

Abstract

In the current political-economic scenario, creativity and innovation are even more considered as the key to the survival of organizations (Magadeley, W. & Birdy, K., 2009). Innovation is a high-risk process that hides various uncertainty factors and several barriers. The key challenge is how to innovate successfully and to cope with the innovation pace, rather than decide if it is worth innovating or not (Prajogo, D.I., & Ahmed, P.K., 2006). This paper aims to investigate the role of the creation and use of Innovation Laboratories to support companies' innovation. Drawing on a literature review, this research proposes a working definition of Innovation Laboratories and a conceptual framework that describes their key hallmarks.

This article is based on a literature review on Innovation Laboratories. Through a taxonomy it compares the most relevant studies that describe Innovation Laboratories and adopt different perspectives of analysis. The research is synthesised in a conceptual framework that helps to clarify the elusive concept of Innovation Lab and to formulate a working definition.

The interest on Innovation Lab is growing in economic markets (Burger, T., & Hermann, S., 2010). However, to date there is a lack of exhaustive studies on the topic (Meyer, L.P., 2014) and the term Innovation Lab does not have an agreed definition (Memon, A.B., et al., 2018). The paper, through a literature review, provides a clear definition of Innovation Labs. The definition does not consider, like other researches has been to date, only structural and service-based perspectives, but it considers also a scope-based one. Moreover, the paper provides insights on how Innovation Labs impact on innovation capacity development.

The paper provides a taxonomy of Innovation Labs that contributes to shed more light on a relevant phenomenon that is affecting the current innovation dynamics. Especially, the working definition of Innovation Lab offers valuable insights to all stakeholders involved in any way in building, deployment and exploitation of these peculiar innovation catalysers.

Keywords – innovation lab; innovation development; collaborative innovation, taxonomy framework

Nature of the proposed paper: Academic Research Paper

1. Introduction

In the new business landscape companies are confronted to become more and more flexible, intuitive, imaginative, resilient, and creative in order to face the increasing complexity, turbulence, unpredictability and pace of change of the competitive environment. More and more organizations have to face unexpected and unclear scenarios and to undertake unpredictable challenges. In this complex business environment organizations have to develop new competences by leveraging intuition and creative capabilities. So, both private and public organizations, independently from their for profit or not-for profit nature, have to define mechanisms and adopting approaches to support continuous learning and knowledge management for creativity and innovation. For this reason, the development of organisational innovation capacity is critical for any organisation looking to stay relevant and to be competitive and sustainable in the face of disruption and continuous turbulence of business landscape.

The organisational capacity is not simply about to decide if it is worth innovating or not and to embrace innovation, but rather than to equip the organisation with an ability for innovative thinking and successful innovation implementation (Prajogo, D.I., & Ahmed, P.K., 2006). This involves to put in place within organisations mechanisms to manage the innovation dynamics and then to face and overcome the risks associates to the innovation processes. The management literature has largely identified and discussed the factors hampering and affecting organisations' successful innovation processes. Many internal or external factors can prevent organisations' innovations, particularly in SMEs, such as the lack of qualified internal technical resources, the lack of knowledge and knowledge management practices, the difficulties in finding financial resources, the capacity of assessing the market, the conceptual barriers or dynamics that can inhibit the employees' creative thinking (Hadjimanolis, 1999; Madrid-Guijarro et al., 2009; Memon et al., 2018). In the last decade, in order to overcome some of the barriers and risks associated to the innovation management, many organisations have focuse their attention on the creation of an Innovation Lab as a way to deal with the obstacles to innovation and, particularly, create an organisational capacity for innovation. This practice is specifically characterising those organisations that are looking for new models to unpack the open

innovation paradigm and to sustain continuous innovation by shaping a resilient, proactive and creative organisational culture (Chesbrough et al., 2006).

In the academic literature the Innovation Labs can take different forms and present diverse characteristics that tend to be hydiosincritic to the context of application. There are various elusive definitions and different terms that refer to the concept of Innovation Lab (Lewis & Moultrie, 2005; Magadley, W., & Birdy, K., 2009; Gay, R., et al., 2013; Meyer, L.P., 2014; Van Golden, R., et al., 2014; Callaghan, V., et al., 2016; Schmidt, S., et al., 2016; Memon, A.B., et al., 2018).

Despite the growing attention in the business context to these kind of laboratories, the concept is still not structured and well explored (Burger, T., & Hermann, S., 2010). For this reason, this research aims to address the following leading research questions: how can an Innovation Lab be fully defined? What are the main features that characterize an Innovation Lab?

Drawing on a taxonomy of literature review, this research proposes a conceptual framework that, describing the key hallmarks of Innovation Labs, helps to advance the understanding in this field and provides a comprehensive working definition.

The paper is organized as follows. The section 2 explains the research methodology and the search strategy used. The section 3 focuses, through a taxonomy framework, on the carried out literature review and analyzes in detail the key aspects of an Innovation Lab. Then, in the section 5 a comprehensive working definition of Innovation Lab and a conceptual framework that support the theory are provided. Then insights, final remarks and possible future researches in this area are discussed.

2. Research Methodology

The objective of this paper is to identify the major works on Innovation Labs in order to categorize the key features of these kind of laboratories and to propose a comprehensive working definition. In this regard, a literature review is a valid approach, considered that it is a first essential step in structuring a field of research (Easterby-Smith, M., et al., 2002). This helps to define the conceptual content of the field (Meredith, J., 1993) and to develop the theory.

Relevant literature was identified from searches using the strings “*Innovation Laboratories*”, “*Innovation Laboratory*”, “*Innovation Lab*”. Searches were restricted to English language articles, books and or conference proceedings published within a 15-year period (2003-2018 inclusive). Studies were included in the review if they provided (1) definitions and or classification of Innovation Labs (2) empirical analysis, survey or case studies on existing Innovation Labs.

The selected studies were then categorized in a taxonomy framework (figure 1) according to *methodology* used for research, *definition* of Innovation Lab provided, *nature* (creative/physical/virtual spaces, hybrid/internal/external to an organization), *key resources* that characterize an Innovation Lab, *scope* that pushes to resort to an Innovation Labs and categories of *users* that resort to an Innovation Lab.

Then, drawing on the results of the literature review, a conceptual framework (figure 2) that organizes the key hallmarks of an Innovation Lab is proposed in order to advance understanding in this field and to provide a comprehensive working definition of Innovation Labs (par. 4).

3. Defining Innovation Lab

In the academic literature there are various definitions and different terms that refer to the concept of Innovation Lab. They can have different forms and characteristics that tend to be hydiosincrat to the context of application.

In this regard, this section shows the results of a literature review carried out by analyzing the most relevant academic studies in the field of Innovation Labs.

The results are categorized in a taxonomy framework (figure 1) according to *methodology* used for research, *definition* of Innovation Lab provided, *nature* (creative/physical/virtual spaces, hybrid/internal/external to an organization), *key resources* that characterize an Innovation Lab, *scope* that pushes to resort to an Innovation Labs and categories of *users* that resort to an Innovation Lab.

The analyzed studies are based on desk researches, case studies, surveys or interviews (Callaghan, V., et al., 2016; Gay, R., 2013; Van Golden, R., et al., 2014; Lewis, M., & Moultrie, J., 2005; Magadley, W., & Birdy, K., 2009; Memon, A.B., et al., 2018; Meyer, L.P., 2014; Schmidt, S., et al., 2016).

The review aimed to collect useful and common insights about the notion of Innovation Labs, that frequently has been fuzzy defined (Burger, T., & Hermann, S., 2010) and that is still not well and widely explored (Meyer, L.P., 2014). As shown in the Figure 1, the literature provides different but with some common features' definitions of Innovation Lab.

Below, the aspects examined in the literature review has been analyzed in detail. This in order to clearly map the State of the Art of the literature in this field, and to enable, in the next session, discussion that leads to propose a comprehensive working definition of Innovation Lab.

Therefore, considering the *scope* that an Innovation Lab aims to pursue, the literature suggests that Innovation Labs give users the possibility of enhancing their creativity and, through facilitation mechanisms, to think of problems, generate new ideas and brainstorm future opportunities in a dynamic, rapid and novel way (Callaghan, V., et al., 2016; Lewis, M., & Moultrie, J., 2005; Magadley, W., & Birdy, K., 2009). In these laboratories, institutions and organizations gain access to specialized expertise, knowledge, equipment, software, technologies and network in order to develop, test and enhance new products or services (Memon, A.B., et al., 2018; Meyer, L.P., 2014) to increase the capability of product development and decrease time to market (Gay, R., et al., 2013): Moreover organisations have the chance to stimulate business model innovation and develop a systematic approach for innovation processes (Van Golden, R., et al., 2014).

In order to fulfil the proposed aims of an Innovation Lab, the *nature*, in terms of the environment where an Innovation Lab take place, plays a relevant role. One of the

common features is that an Innovation Lab is a dedicated space (Lewis, M., & Moultrie, J., 2005; Magadley, W., & Birdy, K., 2009; Gay, R., 2013; Memon, A.B., et al., 2018) that could have a physical (Magadley, W., & Birdy, K., 2009; Meyer, L.P., 2014; Schmidt, S., et al., 2016; Memon, A.B., et al., 2018) or a virtual (Meyer, L.P., 2014) nature. In this regard, considering that one of the main purposes of an Innovation Lab is encouraging creative and innovative behaviour of people (Lewis, M., & Moultrie, J., 2005), each component of the laboratory has to be geared to this function. It is well known that layout and decor of physical environment, positively impact on creativity of people (Amabile, T.M., 1983; Gardner, G., 2001). At the same time, a physical Innovation Lab, built with the same principles and design studies aimed at eliminate the traditional environment in favour of 'creative spaces' (e.g. curved walls, moveable barriers, open spaces, etc.) positively stimulate an 'out-of-the-box' thinking (Lewis, M., & Moultrie, J., 2005; Magadley, W., & Birdy, K., 2009; Memon, A.B., et al., 2018). According to other studies (Callaghan, V., et al., 2016; Memon, A.B., et al., 2018), an Innovation Lab may also take a virtual or mobile/hybrid configuration. These location-independent forms of laboratories are oriented around technologies or people who facilitate the activities involved in the core functions of the Innovation Lab. Especially, virtual Innovation Labs, by exploiting technologies like virtual and/or immersive reality, cloud, and so on, give people the possibility of being actively involved in innovation processes directly from their own device and from anywhere in the world (Callaghan, V., et al., 2016). A mobile Innovation Lab, otherwise is an itinerant laboratory that could take place in different places, on the basis of the activity that needs to be done. For example, a brainstorming better fit with a creative space. On the contrary, an activity that requires an investigation on customer needs, could take place in a third-party site. According to Memon, A.B., et al. (2018) "*Their activities are not bounded by the lab premises rather the lab personnel carry the necessary equipment along to other sites and facilitate the innovation process therein*" (pag. 9).

Then, an Innovation Lab could be located internally or externally to an organization. Commonly big companies, multinationals, Public Institutions or those organizations that have enough resources (human and financial), build an in-house laboratory to be made available to employees. Differently, SMEs, individual entrepreneurs and those organizations that need to integrate their own resources take advantage of external Innovation Labs. Therefore, the *users* of an Innovation Lab are those public or private, profit or not for profit organizations (SMEs, firms, mass services, management team, individual employees/entrepreneurs, R&D Institutions, Academic Institutes, Universities, Government department, etc.) that aim to implement innovation dynamics in their operations (Lewis, M., & Moultrie, J., 2005; Magadley, W., & Birdy, K., 2009; Gay, R., 2013; Memon, A.B., et al., 2018).

Finally, to effectively guarantee the success of activities, *key resources* became fundamental. The literature groups the key resources of an Innovation Lab in many subcategories. Gay, R., et al., (2013) discuss on the importance of *human agents* distinguishing them in designers, operators and users. The designer is the one who imagine and design the environment and individuate the other resources needed in order

to guarantee effectiveness and efficacy of the innovation process. The operators work in the Innovation Lab and they are responsible for most of the activities conducted. There are various typologies of operators, such as functional or administrative, but the most important is the facilitator. The effectiveness of an Innovation Lab depends on the skills of the facilitator (Lewis, M., & Moultrie, J., 2005). A facilitator helps and supports people in every activity, from problem solving and brainstorming to the implementation of results (Magadley, W., & Birdy, K., 2009). Then, the users are the customers, so the people and/or organizations who need assistance and support in the development of innovation processes. According to the literature, users usually are academic or public institutions, firms (Gey, R., et al., 2013; Lewis, M., & Moultrie, J., 2005) especially SMEs (Van Golden, R., et al., 2014; Schmidt, S., et al., 2016) that generally want to innovate their business models or develop new product or services or big companies that wants to reconfigure their internal R&D department in order to stimulate employers' creativity and to develop internal innovation processes.

Human resources integrate their skills with technologies, equipment, method and tools (Memon, A.B., et al., 2018) such as brainstorming software, interactive screen, 3D oculus, whiteboards, multimedia tools, canvas, etc. This in order to improve the quality of the phases of generation, discussion and assessment of ideas (Thieme, M., & Meyer, K., 2011).

Finally, the *time* is a relevant component of an Innovation Lab. Time is one of the higher barriers to innovation for an organization, especially when they are overworked (Larsen, P., & Lewis, A., 2007). Give employees time to procrastinate and to go out from traditional boundaries of offices could be a good practice that increase creativity (West, M.A., 2000). In this regard, Innovation Labs “*give the users time for creative thinking*” (Schmidt, S., et al., 2016). (pag. 236). If continuous and repetitive interruptions may negatively affect employees' productivity, a dedicated Innovation Lab “*May clear employees' minds and allow them to focus solely on the creative task, free from disruptive interruptions*” (Magadley, W., & Birdy, K., 2009). (pag. 316).

Table 1. Taxonomy of Innovation Labs

Study	methodology	Definition	Components	Value Proposition	Users
Lewis, Moultrie 2005	Case study	An Innovation Lab is a dedicated facilities for encouraging creative behaviours and supporting innovative projects that support innovative activity through the provision of appropriate resources, visualization and model making facilities and the ability to reconfigure for new projects.	Structural and infrastructural	Create an environment in which strategies for business growth could be developed in a fun, dynamic, rapid and novel way	Mass services, government department, academic institutions
Magadley, Birdy 2009	Mixed-method approach: Case study and structured interviews	An Innovation Lab is a dedicated physical environments or facilities with collaborative workspaces in which groups and teams of	Time, Space and Technologies	Enhancing creativity and to explore user's attitudes; Facilitate individual and team creative thinking such as thinking of existing	Employees

		employees can engage with each other in order to explore and extend their creative thinking beyond and above normal boundaries		problems in a new ways, generating new ideas and thinking about how these ideas could be implemented	
Gay, Thieme 2013	Meta-structuring approach : Framework + Literature review	An Innovation Lab is a dedicated physical environment where suitable tools and methods are applied to assist in the process of idea creation or innovation development	Human agents: designer, operator, user and Material artifacts: space, tools and methods	Increase the capability of new product development and decrease time to market	Firms or Institutions
Meyer 2014	Web based study	An Innovation Lab is an ideal physical or virtual collaborative work environment where companies can develop, test and enhance innovations		Develop, test and enhance innovations	
Van Golden et al., 2014	Case-based approach	An Innovation Lab is a collaborative meeting ground between SMEs and business schools with a twofold objective: to stimulate business model innovation in SMEs and to develop a systematic approach for innovation processes		Stimulate business model innovation in SMEs; develop a systematic approach for innovation processes, adjusted to their limited financial and marketing resources	SMEs Academic Institutes
Callaghan et al., 2016	Case study	An Innovation Lab is a location-independent collaborative ideation spaces ... that requires three interlinking components namely the environment, the technology and the facilitation mechanisms to make it suitable for ideation and innovation activities	Environment, Technology and facilitation mechanisms	A specially designed environment that is conducive to creative thinking and to brainstorm future possibilities	Management team
Schmidt et al., 2016	Open and explorative desktop and online research	An Innovation Lab is a physical spaces for testing innovative ideas, alternative business models, new economic practices or flexible cooperation structures.	Spaces which temporally unite specialized competencies in a single place. Alongside technology and providing space, innovation labs also give the users time for creative thinking	Fields of experimentation and crystallization points for temporary practices that generate product, process, and organizational innovations ... New spatial configuration that gains access to specialized expertise/knowledge, equipment, software, technologies and networks	Enterprises, research and development institutions, universities

Memon, et al., 2018	In-depth expert interviews and definition of a service-based taxonomy	An Innovation Lab is a dedicated physical or mobile structure which mediates the innovation process and enables the effective development of innovations through the provision of collaborative services and necessary resources (equipment, methods and tools)'. Physical environment, Resources: soft skills such as the knowledge, technical and methodological expertise, hardware including the tangible operational and technological resources, and finance	-Enable the innovation process: generation of creative ideas; identification of the problem or need of innovation; exploration of market opportunities; assessment of end users' and/or market needs; analysis of the success or failure of innovation in marketplace -InnoLabs appear supporting innovations in three domains: product development, business processes, and service development
----------------------------	---	---	---

4. Final Remarks

The literature review highlights several definitions of Innovation Labs. Most of them present common traits, but at the same time they have many differences. Over time this ambiguity contributed to create a fuzzy overview in this field that needed further studies and considerations.

In the light of the results of literature review, the paper proposes a working definition and a conceptual framework (Figure 2) of the Innovation Lab that summarizes and contains all the perspectives addressed in the previous studies in this area.

The framework provides a picture of an ideal Innovation Lab and consider every distinguishing feature. It shows the categories of users benefiting from an Innovation Lab, the key resources that operate inside such laboratories and the type of configurations and environment and that can host an Innovation Lab.

In this regard, *an Innovation Lab is a dedicated physical, virtual and/or mobile environment, internal or external to public or private, profit or not for profit organizations, where users benefit of a set of human and technological resources for stimulate business model innovations and support innovation processes.*

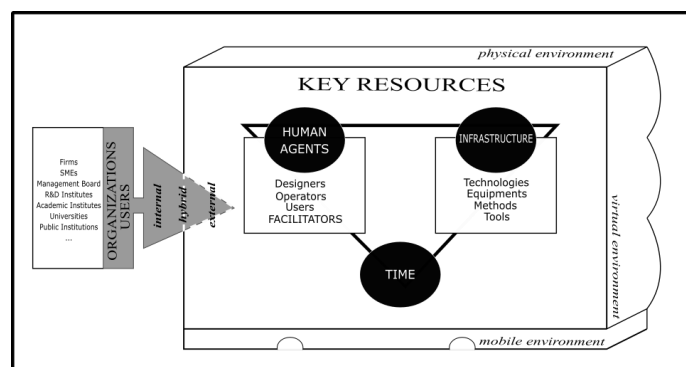

FIGURE 2. Conceptual Framework - Innovation Lab

The definition, according to the studies carried out to date, consider structural and service-based perspectives. It is about two perspectives that need to be further explored. In particular, there is a need of further studies aimed at mapping the state of the art and the presence and diffusion of Innovation Labs in local and global contexts. In this sense, some studies have already been carried out. Meyer, L.P., (2014), Schmidt, S., et al. (2016) and Memon, A.B., et al. (2018), conducted in-depth interviews and web-based studies on a relevant, but not yet representative sample. They individuate in their studies a series of service-based distinguishing categories for Innovation Labs. Schmidt, S., et al. (2016) on the basis of a research carried out among Innovation and Creative Labs in Berlin, list 5 categories: *Grassroots Lab*; *Co-working Lab*; *Firm-driven Innovation Lab*; *Academic-driven Innovation Lab* and *Incubators and Accelerators*. Memon, A.B., et al. (2018) conducted interviews with Innovation Lab facilitators. This research, based on a sample of 190 laboratories identified by Meyer, L.P., (2014) in their study, distinguish 9 not disjoint categories: *Service/Process Laboratory*; *Product/Production Laboratory*; *Consulting Laboratory*; *Co-working space*; *Business incubator*; *Network coordinator*; *Living Laboratory*; *Fabrication Laboratory* and *Research and Development Laboratory*.

Furthermore, the scope of Innovation Labs has been analysed. It can range from turning new ideas and problems into new business opportunities, to foster creative thinking to sustain organisational value creation dynamics and to develop a systematic approach for innovation processes.

This is the first attempt to define an Innovation Lab considering its scope or its intended purpose. This aspect opens the possibilities of new and in-depth research in this field, aimed at providing a scope-based categorization of Innovation Labs and to identify and define a generic and ideal *process/model/logical framework* that represents the key activities required to lead and manage an Innovation Lab.

Furthermore, this kind of categorization could also have practical implications for Innovation Lab's users, such as the possibility of helping them to better identify the best possible intervention and providers on the basis of their needs.

Abstract

In the last years the competitive landscape is experiencing a transition process from the industrial to the digital age. Digital innovations and digital transformation processes are increasingly influencing the productive system impacting in a disruptive way and revolutionizing it, modifying traditional operative system, introducing new forms of value and generating or innovating business models. Therefore, organisations that want to keep up with changing times have to implement as soon as possible digital transformation processes. So, they have to acquire culture, competence and digital skills that could allow them to continue to profitably innovate and interact with the innovative ecosystem within which they operate. In this regard, understanding what are the key factors influencing the organisation's digital innovation capacity is becoming a relevant research topic. Based on a literature review, the study describes the key factors that allow an organisation to develop its digital innovation capacity and proposes a conceptual framework describing how organisation's innovativeness turns into digital innovation capacity by leveraging and managing these key factors.

This paper is based on a literature review on the concepts of innovativeness and innovation capacity. It analyses the most relevant studies that describe these concepts and proposes a definition of digital innovation capacity and a conceptual framework that describes how to lead an organization in the process of transformation of innovativeness into digital innovation capacity.

In the current competitive scenario, the interest on digital innovation capacity is growing. However, to date there are few attempts of revising the concept of innovation capacity under a digital perspective. Based on the results of a literature review, the study proposes

a first definition of digital innovation capacity and analyses the factors underpinning its development.

The paper offers valuable insights to organisations that want to embrace digital transformation challenges and that aim to develop a digital innovation capacity.

Keywords – innovativeness; innovation capacity; digital innovation; digital innovation capacity

Nature of the proposed paper: Academic Research Paper

1. Introduction

The actual competitive scenario is characterized by continuous changes and massive competition. It is therefore essential for organisations to assume proactive and resilient attitudes, and to focus and invest in innovation in order to remain competitive. Over the years, understanding how and why an organization is more innovative than others and what are the factors affecting organisation's innovative capacity, have been topics of interest for many scholars (Hii, & Neely, 2000; McGrath, 2001; Porter & Stern, 2001; Koc, & Ceylan, 2007; Neely & Hii, 2012).

In the last years the competitive landscape is experiencing a transition process from the industrial to the digital age, where intelligent and connected products and devices are becoming increasingly popular and where data are even more accessible (Carlucci, & Schiuma, 2018). Digital innovations and digital transformation processes are increasingly influencing the productive system impacting in a disruptive way and revolutionizing it, also modifying traditional operative system, introducing new forms of value and generating or innovating business models. Therefore, organisations that want to keep up with changing times have to implement as soon as possible digital transformation processes, acquire culture, competence and digital skills that could allow to continue to profitably innovate and interact with the innovative ecosystem within which they operate.

In this regard, as the processes and operating systems must be reviewed in a digital perspective, also the innovation capacity of organisations need to be framed under a digital lens.

In the light of this, this research aims to address the following leading research questions: what are the key factors determining innovation capacity and digital innovation capacity? How to translate organisation's innovativeness in digital innovation capacity? How can an organization develop its digital innovation capacity?

Drawing on the results of a literature review, this research proposes a conceptual framework that describes the key factors that properly exploited and managed allows to turn organisation's innovativeness into a great digital innovation capacity.

The paper is organized as follows. The section 2, through a literature review, describes the concept of innovativeness. The section 3, analyses the concept of innovation capacity and those factors underpinning its development. Section 4 revises the previous concepts

under a digital perspective and then, in the section 5 a conceptual framework describing how to translate innovativeness in digital innovation capacity is provided. Then final remarks are briefly presented.

2. Innovativeness

Over the years, the concept of innovativeness has been widely addressed under different perspectives of analysis by many scholars. The first attempt of defining innovativeness was made by Rogers (1962), who considered it at the individual level as the attitude and the speed of an individual to adopt new ideas compared to others. In this regard, Rogers and Shoemaker (1971) defines innovativeness as “the degree to which an individual or other unit of adoption is relatively earlier in adopting new ideas than the other members of a system” (p. 27)

Looking at the organisation as a unit of adoption, innovativeness is considered its propensity to innovate (Neely & Hii, 2012). It is related to the organisation’s capacity to pursue innovation. This in terms of introduction of new processes, products, services and or ideas in the organisation (Hult, 2004; Kamaruddeen et al., 2010). Looking at the product, innovativeness expresses the attitude of an organisation to buy, adopt and gain acceptance for new products or services (Foxall, 1984), or ideate and disseminate them into existing or new markets (Wang & Ahmed, 2004). In this regard it is interesting to underline that the concept of innovativeness can be distinguished from entrepreneurial orientation (Lumpkin & Dess, 1996) because innovativeness not necessarily requires introduction to the market (Hult, 2004). Moreover, innovativeness can be considered as “the capacity of an organization to improve the existing products, services and/or processes, and the capacity to utilize the creative resources of the organization to the fullest” (Gebert, et al., 2003). So, incremental innovation is considered as part of firm innovativeness (Kamaruddeen, A.M., et al., 2010).

Kitchell (1995) considers innovativeness as the organization’s propensity to adopt new technologies and digital approaches, also looking at the environmental opportunities. Under this perspective, innovativeness represents a need to keep up to date and to aim to achieve a sustainable competitive advantage.

The concept of innovativeness has also and above all, a behavioural sense. In Hult et al., (2004), innovativeness is defined as cultural readiness and appreciation for innovation and considered as cultural precursor that facilitates innovative behaviour that characterizes innovative organisations. Innovative organisations are those that manage to overcome innovation barriers (D’Este et al., 2012), among which the openness to the innovation (Zaltman, 1973) that is the attention to understand the need for new ideas and strategies inside the organizations, the ability of combining new ideas with existing elements in order to create value for stakeholders (Hurley & Hult, 1998).

Innovativeness is also related to the culture of an organization aimed at promoting a shared mindset oriented to spread and support new ideas, approaches and tests (Keskin, H., 2006). Moreover, it also linked to “high tolerance for ambiguity, taking risk, and evaluating uncertain situation more favourably” (Garcí, & Calantone, 2002).

Summarising the numerous definitions and characterisation of innovativeness, it seems possible to describe the innovativeness as *the degree to which an organization is open, propense and ready to understand, adopt, stimulate and disseminate innovation*.

Innovative organisations are those that assume an innovative behaviour overtime and not just for a short period (Subramanian & Nilakanta, 1996). An organisation is considered innovative when it adopts innovation, but the magnitude to which the organisation is innovative is strictly related to the number of innovations adopted (Kamaruddeen et al., 2010).

In such a view, understanding how innovativeness translates into organisation's innovation capacity is worthwhile.

3. Innovation Capacity: definition and key factors

Avlonitis et al. (1994) assert that adopting a behavioural willingness and intention to innovate is not enough to be considered an innovative organization. Neely (2000; 2012) defines the innovation capacity of an organization as "the potential to generate new ideas, identify new market opportunities and implement marketable innovations by leveraging on existing resources and capabilities". Szeto (2000) defines innovation capacity as a continuous improvement of the overall capability of organisations to generate innovation for developing new products to meet market needs.

In a broader sense, the innovation capacity of an organization can be defined as "the potential of that organization to generate innovative outputs" (Neely, & Hii, 2012, p. 49)

Several factors affect organisation's innovative capacity (Barney, 1986; Teece & Pisano, 1994; Hii & Neely, 2000). These factors are discussed below.

First of all, the *organizational capital* (Tomer, 1987), defined as the combination of explicit and implicit knowledge that characterizes the organizational activities of an organization and its elements, including culture, structure and organizational learning, can positively affect the innovation capacity of an organization (Martin-de-Castro et al., 2006). The organizational capital "influences the way things are done within the organization" and the relationship among the stakeholders (Hii, & Neely, 2000). Innovative companies, from this point of view, are characterized by a strong openness and commitment to innovation, to the continuous improvement and also have a strong culture and a shared mission (Neely & Hii, 2012).

Another relevant aspect that can improve the innovation capacity of an organization is the *knowledge management* (Nonaka & Takeuchi, 1995; Antonelli, 1999; Carneiro, 2000; Darroch, 2005; Du Plessis, 2007; Mehrabani, 2012) because knowledge is one of the fundamental components of the innovation process which, if well managed, exploited and integrated within the organization, acts by reducing uncertainties and complexity in innovative activities and helping decision making, data integration and broad collaboration (Cong & Pandya, 2003; Cavusgil, et al., 2003). Knowledge management positively impacts on organisation's innovation capacity if considered as a continuous process that supports the organisation's needs in terms of knowledge creation, knowledge organization, knowledge dissemination, and knowledge application (Mehrabani, &

Shajari, 2012). Strictly related to knowledge management are those *competences* that can enable innovation processes within organisations (Teece & Pisano, 1994; Hii & Neely, 2000). Organisation's core competence are classified by Tidd (2000) into three categories: organizational competence, that include knowledge, innovation capabilities (e.g. creativity, idea generation capability, risk taking, problem solving, teambuilding, empowerment) value, norms and managerial systems; market competence, that refer to the ability to understand and exploit its markets and consumers' needs and habits; and technological competence that also derived from R&D activities. The role of management is to understand the scenario dynamics, employer's and consumer's needs, and market opportunities and combine them with internal competences in order to increase innovation capacity.

To really increase the organisation's innovation capacity, it is required to systematize and codify *internal processes* that also take into account the above mentioned tangible and intangible factors and that create the prerequisites to implement innovative processes. An innovative organization has to guarantee the systematic and continuous realization of internal processes, such as idea generation and capture, brainstorming sessions, performance measures and training (Hii, & Neely, 2000). This in order to facilitate the generation, adoption and dissemination of innovative outputs. This is possible by favouring the creation of an agile working climate and environment where employees scheme suggestions were widespread, successful ideas were highly thought and failure was regarded as essential to the learning process (Hii & Neely, 2000). These internal processes need to dialogue and to operate within the *innovation ecosystem*, conceived as "the complex relationships that are formed between actors or entities whose functional goal is to enable technology development and innovation" (Jackson, 2011, p. 2) and including material resources (funds, equipment, facilities, etc.) and stakeholders (customers, competitors, suppliers, strategic partners, investors, government etc.) (Neely & Hii, 2012; Oh et al., 2016). Consequently, the *stakeholder management* becomes a strategic process for improving the innovation capacity of organisations. This is possible by developing active collaborations with other organisations to share and integrate knowledge, to optimize costs and resources and to contain risks; by activating dialogues and working in partnership with investors and government and having a proactive approach with customers in order to stimulate innovations able to satisfy common and shared needs.

4. Digital Innovation Capacity: definition and key factors

Nowadays, digital innovations and digital transformation dynamics are having a disruptive impact on business performance and on traditional operating models. A recent report by MIT Sloan Management Review and Deloitte (2015) found that nearly 90% of interviewed managers state that their industry is likely to be disrupted by digital technologies. Consequently, organisations need to renew their innovation capacity (Karimi & Walter, 2015) and to develop a digital innovation capacity, in order to face this incumbent digital disruption.

According to Fichman et al., (2014), digital innovation is “a product, process, or business model that is perceived as new, requires some significant changes on the part of adopters, and is embodied or enabled by IT” (p. 330). Neely & Hii, (2012) define innovation capacity as “the potential of an organization to generate innovative outputs”.

In line with the main features associated to the concepts of innovation capacity and digital innovation in the literature, this work provides the following working definition of digital innovation capacity: it is *the potential of an organization to generate innovative outputs that are embodied or enabled by IT*.

The development of a digital innovation capacity requires the exploitation and management of several factors underpinning organisation’s innovation capacity. Especially these factors have to allow the generation of innovative outputs that are embodied or enabled by IT.

The development of a digital innovation capacity requires a balance of new and established innovation competence and skills (Svahn, et al., 2017).

Digital innovative organizations make efforts in forming IT and technical skills of employees. They invest to integrate in their staff new digital specialists, such as developers and/or data scientists to support their digital ambitions and to harness the new opportunities provided by digital technology (DeNisco Rayome, A., 2019).

To stimulate and implement digital innovation capacity, in organisation knowledge management has to be oriented towards the creation of a culture that embraces change and that looks to new digital approaches, such as for example the agile methods. Moreover, organisation needs to cross-fertilize the existing innovation ecosystem also under an open innovation approach which could allow it to acquire the needed data, technologies or services to gain more effective results (DeNisco Rayome, 2019; Svahn, et al., 2017). A profitable dialogue with the innovation ecosystem in the Digital Age is not possible without a digital infrastructure, intended as the collection of technological and human components, networks, systems, and processes that build a bridge between organization and ecosystem in order to allow open, intelligent and integrated access to the immense amount of data available nowadays and to fully exploit its potentials, opening new opportunities for innovation (Braa, et al., 2007; Tilson, et al., 2010).

5. Digital Innovation Capacity development: A Conceptual Framework

In the light of the results of literature review in the field of innovativeness, innovation capacity and digital innovation, in this section a conceptual framework (figure 1) aimed at explain how to translate innovativeness in digital innovation capacity is proposed.

Framework for Digital Innovation Capacity Development

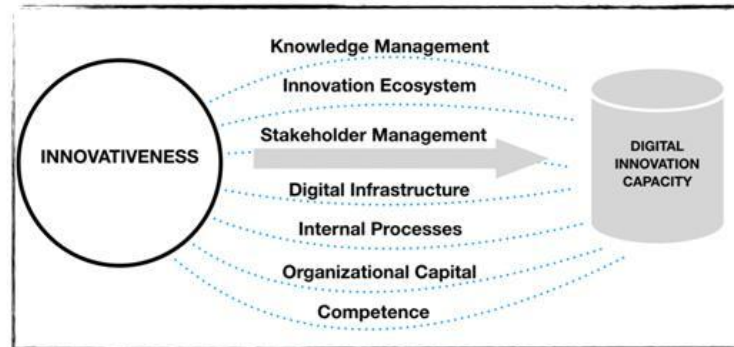

Figure 1 - source: own elaboration

The proposed conceptual framework reflects the results of the literature analysed in the previous sections and provides a picture of how the organisation's innovativeness, combined with some key factors properly deployed and exploited, i.e. knowledge management, Innovation Ecosystem, Stakeholder Management, Digital Infrastructure, Internal Processes, Organizational Culture, Competence, can contribute to the development of an organisation's digital innovation capacity.

6. Final Remarks

Drawing on the results of a literature review, the paper focuses on definitions and key factors characterizing the concepts of innovativeness, innovation capacity and digital innovation capacity.

In particular, the paper analyses factors that can help an organization to develop its digital innovation capacity and offers a conceptual framework that depicts how organisation's innovativeness can turn into digital innovative capacity by leveraging several organisational factors.

This study represents a first attempt to define the concept of digital innovation capacity, based on the recent literature. More research is needed around this topic in order to better understand, in addition to the analysed key factors, the key processes that can lead an organization to develop a digital innovation capacity.

Abstract

Consumer knowledge is a crucial organizational resource which can help advance research and development or create processes which facilitate effective management of the organization-consumer relationship. Consumer objective and subjective knowledge discrepancy is one of the critical factors influencing consumer attitudes to product / brand and buying behaviour. This study aims to reveal the consumer knowledge discrepancy about added sugar discrepancy scenarios. Knowledge discrepancy can go in two scenarios: a consumer's subjective knowledge is greater than their objective knowledge (overestimation), or their subjective knowledge is lower than their objective knowledge (underestimation). Both underestimation and overestimation may negatively affect consumer's attitudes and behaviour. Therefore, it is important for organisations to proactively identify a possible knowledge discrepancy scenario, as well as manage negative impact on consumer attitudes to product and brand and buying behaviour.

Empirical research was grounded by a positivist approach and quantitative strategy. Consistent with the quantitative, descriptive research design, a questionnaire was designed to measure the relevant constructs. The questionnaire consisted of three sections measuring objective and subjective added sugar knowledge and information related to the potential antecedent variables. Most of the variables were measured through a multi-item scale and were extracted and adapted from previous research. The data were collected from 432 residents of Lithuania. The findings have revealed that five possible knowledge discrepancy scenarios exist in the study case.

The results of research increase understanding and ability to identify and manage consumer knowledge discrepancy. Following it, organizations become more flexible and gain sustainable competitive advantage.

Keywords – objective knowledge, subjective knowledge, knowledge discrepancy, consumer behaviour, scenario.

Paper type – Academic Research Paper.

1 Introduction

A differentiation is made between subjective knowledge (what consumers believe they know) and objective knowledge (what consumers actually know). It has been theorized that these concepts have different implications on purchasing behaviour, making such a distinction necessary (Pieniak et al., 2010; House et al., 2004; Ellen, 1994). A measurement of discrepancy is also constructed to visualize the gap between consumers' subjective and objective knowledge.

According to its nature, knowledge can be objective or subjective. (Philippe & Ngobo, 1999). Carlson et al. (2009) conceptualise consumer's objective knowledge as accurate stored information, and subjective – as consumer's self-beliefs about his/her own knowledge. In other words, objective knowledge depicts what consumers know, and subjective what they think they know. Park, Garden & Thukral (1988) emphasise that empirical findings indicate that there is often a discrepancy between one's actual knowledge and one's self-assessment of that knowledge.

Knowledge discrepancy, or consumer “illusion of knowing”, as Raju et al. (1995) state, “knowledge about one's own knowledge plays an important role in a wide variety of processing tasks, including recognition, perceptual identification and insight problem solving”. To understand consumers' attitudes and buying behaviour, it is important to understand the distance between one's objective and subjective knowledge.

In research, great emphasis is put on the classification of consumer knowledge according to its nature, i.e. on subjective and objective knowledge as well as its investigation. Consumer knowledge research most often focuses on objective and subjective knowledge relation (Aertsens et al., 2011; Dodd et al., 2005), subjective knowledge impact on consumer attitude and behaviour (Selnes, Gronhaug, 1986; Feick et al., 1992; Ellen, 1994), objective and subjective knowledge influence on the sources of information relied on by consumers [14], subjective and objective knowledge as determinants of consumption (Verbeke, 2008; Pieniak et al., 2010). Ellis and Caruana (2018) point out the segments of wine consumers, based on the combination of objective and subjective consumer knowledge, etc. There is also a clear research trend on the impact of consumer personal characteristics on structural alterations of knowledge: numerous studies have found consumer knowledge and self-confidence to be influential (Flynn, Goldsmith, 1999; Alba, Hutchinson, 2000).

As Khan et al. (2017) emphasise, knowledge discrepancy can go in two scenarios: consumer's subjective knowledge is greater than their objective knowledge (overestimation), or their subjective knowledge is lower than their objective knowledge (underestimation). Both underestimation and overestimation may negatively affect consumer's attitudes and behaviour. Focusing on consumer knowledge discrepancy scenarios organizations may have a great opportunity. They can proactively identify a possible knowledge discrepancy scenario, as well as manage negative impact on consumer attitudes to product and brand and buying behaviour.

To summarize, this paper's contributions to the literature are as follows: first, it introduces the construct of consumer knowledge discrepancy and grounds a principal

methodological proposition that consumer self-confidence operates as an antecedent to subjective knowledge perception. The work substantiates the idea that consumer confidence level conditions the heterogeneity of consumer behaviour both in overestimation and underestimation of knowledge. It also demonstrates consumer discrepancy scenario definition and main scenario content characteristics. Finally, the empirical research establishes that five, not two, knowledge discrepancy scenarios may exist, depending on the degree of manifestation of knowledge discrepancy; it also outlines directions for consumer knowledge discrepancy future research.

2 Knowledge discrepancy conceptualisation

According to its nature, knowledge can be objective or subjective (Philippe & Ngobo, 1999). Carlson et al. (2009) conceptualise consumer objective knowledge as accurate stored information, and subjective – as consumer's self-beliefs about his/her own knowledge. In other words, objective knowledge depicts what consumers know, and subjective – what they think they know.

Knowledge discrepancy, or consumer “illusion of knowing”, as Raju et al., (1995) state, “knowledge about one's own knowledge plays an important role in a wide variety of processing tasks, including recognition, perceptual identification and insight problem solving”. The above definition allows for presumption that knowledge discrepancy is tightly connected with consumer self-confidence level. Veale (2008) claims that there are parallels between consumer self-confidence level and product evaluation: individuals with low level of self-confidence usually lack self-belief if faced with strong opposing opinion, and alternatively, consumers with high level of self-confidence usually possess strong attitudes that are very difficult to change. Park et al. (1994) in their theoretical and empirical research reveal that there is a positive relation between the amount of product class information stored in memory, the amount of product-related experience and level of self-assessed knowledge. Knowledge assessment is viewed as a judgement process in which individuals scan memory for cues that will help them evaluate their level of product-class knowledge (Park et al., 1994). Park et al. (1994), following DeNisi & Shaw (1977), argue that consumers knowledge assessment may be influenced by a general feeling of self-confidence, independent of what is actually known: level of general self-confidence is positively associated with level of self-assessed knowledge. These insights lead to the general statement that the consumer assesses cues in their memory subjectively as they use not the objective information in the memory, but the level of self-confidence; therefore, self-confidence operates as an antecedent to marketplace choices and subjective knowledge perceptions. This entails that self-confident customers have a high level of “illusion of knowing”, and according to Bearden et al. (2001), consumer confidence reflects subjective evaluation of one's ability to generate positive experiences as a consumer in the marketplace.

Khan et al. (2017) emphasise the idea that knowledge discrepancy can go in two scenarios: a consumer subjective knowledge is greater than their objective knowledge (overestimation), or their subjective knowledge is lower than their objective knowledge

(underestimation). Thus hypothetically a consumer with high self-confidence will overestimate, whereas that with lower self-confidence will underestimate their knowledge about products.

3 Knowledge discrepancy scenarios

3.1 Knowledge discrepancy scenario definition

Scenarios can be defined as narratives about possible future based on which future-related decisions can be taken (Ogilvy, Schwartz, 2004). In other words, a scenario in academic and practical papers is understood as a detailed and explicated possible future portrait including proactive managerial decisions adequate to such future pictures (Schwab et al., 2003). Thus knowledge discrepancy scenarios can be defined as consistent and explicated narratives about underestimation and overestimation of consumer knowledge in the future. Knowledge discrepancy scenarios should integrate customer behaviour picture and CKM decisions identifying knowledge discrepancy extent.

3.2 Knowledge discrepancy scenario content

In academic literature, characteristics of scenario content are classified into three groups: scenario goal (why?), design of scenario development process (how?) and scenario content (what?) (van Notten, 2002). This paper focuses on scenario content characteristics, those most relevant to the purpose of the work. According to van Notten (2002), in their content, scenarios should reveal instantaneous or chain events, embrace heterogeneous and homogeneous problems and, depending on how integrated they are, be integrated or fragmented.

The current external environment is characterised by turbulence, a dimension of which is complexity of continuous change. Following the insights by Levy, Lichtenstein (2011), Mason (2007), the complexity of such turbulent environment manifests itself in complex relationships between the interested parties in the external environment shaping continuous change there. As consumers interact with their environment in the context of continuous change, subjective and objective knowledge composition and knowledge assessment varies too, which affects the level of knowledge discrepancy. Thus scenarios developed in the context of current external environment cannot include only momentous pictures of the manifestation of elements expressing consumer self-confidence because knowledge creation is ongoing and cyclical (Nonaka, Konno, 1988). Content of knowledge discrepancy scenarios should be integrated as it is important not only to reveal how interacting elements develop but also to identify consumer knowledge management decisions reducing knowledge discrepancy level. Knowledge discrepancy scenarios are heterogeneous, taken globally, contemporary customers act in a turbulent external environment, which is complex, and heterogeneity is characteristic of complexity (Levy, Lichtenstein, 2011). It is also critical to identify if consumer behaviour underestimating and overestimating their knowledge is homogeneous or heterogeneous. Consumer self-

confidence is expressed by the aspects of customer behaviour distinguished by Bearden et al. (2001).

Information Acquisition and Processing reflect the individual's confidence in his or her ability to obtain needed marketplace information and to process and understand that information (Bearden et al. 2001). The construct of self-confidence in the perspective of taking a buying decision can be defined as an ability to make effective decision by acquisitive and applied information (Aghdaie, Khatami, 2014). According to Erasmus et al. (2015), self-confident consumers are selective, yet focussed on their information search because they either already possess the knowledge about product or know where to find and access the information they require. Self-confident consumers also know how to evaluate product alternatives and how to reduce purchase risk (Loibl et al., 2009). This entails that customer self-confidence is based on the ability to acquire and process market information, in order to identify selecting options, attracting positive reactions to the purchase, and effective exchange of this process, by self-preservation against misleading or unfair behaviours towards them (Aghdaie, Khatami, 2014). The ability to acquire and process the right amount of information prior to further decision making is an important antecedent to affective buying decision making (Alba, Hutchinson, 1987). Thus in the overestimation scenario, consumers experience lower risk of taking a wrong buying decision than those underestimating their knowledge. Customers tend to purchase items with the brand names they know more about, which reduces the risk of disappointment (Cheung, Chan, 2009).

Consideration-Set Formation represents confidence in one's ability to identify acceptable choice alternatives including products and brands (Bearden et al., 2001). This aspect is closely related to consumer variety-seeking behaviour in buying decisions. In knowledge discrepancy research, the concept of variety-seeking behaviour is most effectively defined by Hirschman (1980) as an internal drive or motivating force that motivates the individual to seek out novel information. Consumers' aspiration for more new information at the stage of product or brand consideration assessment becomes an internal motive to cover a wider spectrum of alternatives in the evaluation set, even if the customer was satisfied with a purchase or brand, and to be less committed and attached to definite products / brands. Ju's (2015) research shows that information scarcity is stimulating the tendency of variety seeking, so consumers with low information will show a higher tendency to pursue variety seeking than higher information group. Moreover, the assumption is made that individuals vary in confidence regarding their ability to construct consideration sets that contain choice alternatives for effectively satisfying consumption goals (Bearden et al., 2001). Thus in the overestimation scenario, variety seeking behaviour is less distinct because, as mentioned, consumers find and process more information at the second stage and are able to apply it more effectively to reduce the risk of buying decision-taking.

The link between variety-seeking behaviour and customer confidence level via knowledge discrepancy scenarios allows for more thorough analysis of personal characteristics of knowledge overestimating and underestimating consumers. Scientific works identify a number of characteristics typical of customers with variety-seeking

behaviour. Following Olsen's et al. (2015) generalisation, variety-seekers are more likely to seek change, more prone to brand switching and avoid repetitive behaviours; high sensation seeker who possesses a stronger than average need to seek out activities which are novel, complex or more intense. According to Kingent (2016), the enumerated characteristics show internal motivation of consumers to seek out a wide set of product or brand alternatives. From the perspective of socio demographic characteristics variety-seeking consumers tend to be younger, better educated and employed (Raju, Venkatesan, 1980; Wang et al., 2006), and with higher incomes (Wang et al., 2006). Deductive logic, however, raises the question whether a knowledge underestimating consumer can be characterised by a higher level of education. Olsen et al. (2015) present the assessment scale of personality trait of sensation seeking as formulated by Zuckerman et al., (1978), Zuckerman (1994), where one of assessment subscales is seeking experience. This can explain why customers with a relatively high level of education underestimate their knowledge and why they seek product or brand variety. According to the interpretation of Maslow's theory of needs, in the context of underestimation scenario, consumers seek self-esteem and its realisation through shaping subjective knowledge, i.e. through gaining experience.

Personal and Social outcomes dimension reflects confidence in one's ability to meet purchase objectives so that choices are personally satisfying and generate positive outcomes in the form of the reactions of others. The analysis of the dimensions discussed above shows that from the perspective of information acquisition and processing dimension in the overestimation scenario consumers experience lower risk of taking wrong decisions than those attributed to the underestimation scenario. Thus knowledge overestimating consumers in the post-purchase stage of buying decision-taking will have a higher level of satisfaction and receive more appreciation from the public members important to them than the knowledge underestimating consumers. Trivedi (1999) segments customers by the intensity and consistency of their variety-seeking behaviour and shows that more preferred brands were hurt the most by variety-seeking behaviour. Olsen et al. (2015) support this by stating that variety-seeking behaviour may have a negative effect on brand loyalty. Therefore, from the perspective of consideration-set formation dimension, in the underestimation scenario consumers are less satisfied with a purchase and this negatively affects their brand loyalty. In the underestimation scenario, dissatisfaction with a purchase incites cynicism toward the brand name. Academic studies define customer cynicism as dissatisfaction and disconfirmed expectations (Chylinski, Chu, 2010). Chylinski, Chu (2010) specify the concept of customer cynicism in marketing context as a process consisting of related reactions of recognition, behaviour and emotions, displayed through consumer suspicion, defence against marketing actions and non-purchase of a certain branded item or product. Yet it should be noted that empirical research by Keng, Richmond & Han (2008) shows that even self-confident customers exhibit one aspect of cynicism – greater complaint behaviour because they are self-confident enough to express their negative opinion about products and brands.

Consumer self-confidence is displayed in their ability to understand marketing actions applied by an organisation and to defend themselves against these actions (*Persuasion*

Knowledge) and to defend their values and attitudes dealing with others in marketplace (**Marketplace Interfaces**) (Bearden et al., 2001).

Within the classical marketing theory, trust between the organisation and the consumer is an essential prerequisite for long-term relationships. The use of persuasion in sales settings is a method that organizations utilize in training sales personnel, developing advertising campaigns within the promotional mix (Taylor, Barber, 2012). According to Friestad & Wright (1994), over time consumers develop personal knowledge about the tactics used in these persuasion attempts. This knowledge helps them identify how, when, and why marketers try to influence them. It also helps them adaptively respond to these persuasion attempts so as to achieve their own goals and consider possible courses of actions. According to Taylor & Barber (2012), coping behaviours assert when a consumer recognizes a marketing agent's attempt to skilfully modify their beliefs, their emotions, their attitudes, their decisions, and their thought processes, thereby altering the course of their lives.

Bell (1967) discusses Cox & Bauer's (1964) research findings which show that customers with low and high self-confidence were least affected by persuasion efforts, whereas customers with moderate self-confidence were the most susceptible to persuasion. Very confident consumers are difficult to persuade due to their positive experience in buying decision-making and therefore trust their opinion, whereas consumers who are more unconfident than confident tend to protect themselves from any influences. Since those with moderate self-confidence were neither secure with their own judgment nor highly defensive, they were the most persuadable (Bell, 1967). Boush et al. (1994) stress that customer ability to cope with persuasion efforts is a growing phenomenon because customers keep gaining new experience.

Both overestimation and underestimation scenarios of consumer knowledge discrepancy will display consumer coping behaviour against persuasion attempts, which will potentially increase their mistrust with the organisation and brand. Consumer confidence construct is critical to brand value: a consumer mistrusting a definite brand will not be loyal to it (Ball et al., 2004; Balester, Aleman, 2001). Thus an outcome of the development of these scenarios is deteriorated or lost loyalty of customers who underestimate or overestimate their knowledge.

According to Bearden et al. (2001) definition of Market Interface dimension, it can be stated that it is essentially expressed through consumer power in relation to organisations and brands. Consumer power in the digital age is inseparable from the Internet and the opportunities it provides (Knott et al., 2006; Kucuk, 2009; Labrecque et al., 2013); therefore, this paper relies on the definition by Labrecque et al. (2013): "power as the asymmetric ability to control people or valued resources in online social relations". Today's world however has seen a turnaround where consumers are driving the way marketing works. One of the main sources of contemporary consumer power is information (Labrecque et al., 2013). In the overestimation scenario, consumers are more likely to seek information on products and are more confident than in the underestimation scenario, hence the hypothetical statement that knowledge overestimating consumers

when interacting with the organisation or brand in the market are more inclined to defend their attitudes and values.

It can be concluded that two different scenarios of consumer knowledge discrepancy show through different consumer behaviours in attempting to satisfy their needs and expectations in buying decision-taking.

- The behaviour of consumers overestimating their knowledge about a product / brand is less marked by risky buying decision-taking and seeking variety before purchase. However, satisfaction and cynicism in post-purchase behaviour is more manifest. The buying behaviour of the latter consumers is sustained by persuasion knowledge and digital power.
- The behaviour of consumers underestimating their product / brand knowledge before purchase is more marked by risky prior-purchase decision-taking and seeking variety before purchase. This tendency conditions less marked consumer satisfaction and more distinctly expressed cynicism in post-purchase behaviour. The buying behaviour of the latter consumers is more supported by their persuasion knowledge and less by digital power.

4 Research methodology

Research method. Yin (2003), on the basis of constructivist paradigm, states that truth is relative and subject to perspective. According to him, as one looks for answers to questions “how” and “why” and realizes answers to these questions depend on the phenomenon researched, i.e. on contextual conditions, the best method is case study. To understand deeper the discrepancy between objective and subjective knowledge, to reveal gaps in objective knowledge, the case study method was selected for and applied to the research.

Case study. The context of added sugar was chosen as the problem of added sugar consumption is a global one. According to the current EU Labelling Regulations, consumers can determine added sugar amounts only from ingredient lists, which are complicated because food industry presents added sugars in terms unknown to consumers. Today’s nutrition environment creates a default aggravating the world-wide problem – the spread of obesity and other related medical conditions. Research show that the public understand that their nutrition is their own responsibility but say that food and drinks industry could make more effort to promote healthy nutrition (Bailey et al., 2017). Presently, consumer education and preventive measures receive considerable attention, yet few researches have been conducted on consumer understanding of added sugar (Tierney et al., 2017).

Research questionnaire. A questionnaire was used for empirical data collection. The categories of variables and measurement aspects are presented in table 1.

Table 1. Research questionnaire substantiation

Categories of variables	Measurement of variables	Authors substantiating measurement of variables
Respondents' interest in added sugar and its consumption	Respondents' interest in added sugar, attitudes and consumption.	Tierney et al. (2017)
Subjective knowledge	<ul style="list-style-type: none"> Subjective knowledge was measured by asking one general self-assessment question: "How well do you know facts and problems related to<...>?". Five-point Likert scale was used. 	House, et al. (2004), Aleksejeva (2014)
Objective knowledge	<ul style="list-style-type: none"> To identify objective knowledge a few structurally different questions suitable to check consumer knowledge were formulated. Structure of questions measuring objective knowledge was developed following consultations with a senior researcher at Kaunas University of Technologies Institute of Food Science Objective knowledge was measured as a total number of correct answers to all questions assessing objective knowledge. 	Tierney et al. (2017), Tanius, Seng (2015), Dodd et al. (2005), Bailey et al., (2017)
Independent variables	Age, education, sex, social level, family status and place of residence	-

Data collection. The research was conducted in Lithuania in April 2018. Overall, 432 respondents participated in the online survey.

Data analysis. All statistical analyses were done with SPSS software (version 17.0). a new variable was created when analysing the discrepancy between subjective and objective knowledge. Consumer subjective knowledge was measured by one question in five-point Likert scale, while objective knowledge – according to the number of correct answers to three types of questions. To compare two different measurement levels, Z estimators were calculated for each type of knowledge taking into account their deviation from mean according to the following formula (Gunne, Matto, 2017 cited from Burns, Burns, 2008):

$$Z = (x - \text{mean}) / \text{standard deviation},$$

where x means occurrence of value

Positive deviation points have shown that respondents have higher subjective knowledge than objective, whereas negative ones have indicated the opposite case.

One-way ANOVA was used to assess the impact of independent (demographic) variables on objective and subjective knowledge discrepancy, followed by a posteriori (Post-Hoc) comparison test.

Research limitations. Empirical research is limited to one country because the survey was done only in Lithuania. Analysis of demographic characteristics of the survey has revealed an uneven distribution of respondents into groups according to demographic parameters.

5 Research results

5.1. Respondents' (consumers') interest in added sugar and its consumption

The data presented in table 2 show that the participants in the survey display average interest in added sugar: always or often – 28.4% of women and 14.6% of men; never – 24.3% and 34.1% respectively. Only 2.4% of men and 5.6% of women were very strictly against consuming products with added sugar. 33 respondents stated they neither try to limit amounts of the substance nor are interested in it. Thus a rather considerable part of consumers are rather sceptical toward limiting added sugar. The findings show that a lot of consumers are not interested in choosing products labelled “no added sugar” or “unsweetened” with 43.9% of men and 38.6% of women only sometimes noticing such information on food products. Least attention is paid types of added sugar; 43.9 % of men and 43.5% of women never note it. Yet, this is quite important, for various types of sugar are used by the body differently and can increase the risk of certain diseases.

Table 2. Respondents' answers to statements about added sugar consumption and interest in it (N=432)

Statement	Sex	Never	Sometimes	Often	Always
		%	%	%	%
I strictly avoid added sugar in food products	Male	26.8	48.8	22.0	2.4
	Female	21.7	48.8	23.8	5.6
I am trying to limit consumption of added sugar	Male	19.5	31.7	41.5	7.3
	Female	14.6	35.8	34.5	15.1
I am interested in added sugar	Male	34.1	51.2	7.3	7.3
	Female	24.3	47.3	20.2	8.2
I choose products labelled “no added sugar” or “unsweetened”	Male	19.5	43.9	31.7	4.9
	Female	16.1	38.6	34.0	11.3
I choose products by the type of added sugar used	Male	43.9	41.5	9.8	4.9
	Female	43.5	32.2	16.6	7.7

5.2. Analysis of consumer subjective and objective knowledge about added sugar

Evaluation of respondents' subjective knowledge. Picture 1 shows that respondents were critical enough in assessing their knowledge about added sugar.

Picture 1. Subjective knowledge about added sugar (N=432)

The analysis of respondents' subjective knowledge established that 40.5% of them assessed their knowledge about added sugar with three points, 31% – with two points, while 11.1% said they knew nothing about it, and 17.4% assessed their knowledge as good and very good. The calculated mean of subjective knowledge is 2.66; thus it can be stated that consumers assessed their knowledge about added sugar as approximately average.

Assessment of respondents' objective knowledge. On average a respondent collected 10.3 points (standard deviation – 3.1), when the maximum total was 25 points. This means that on average respondents provided less than half correct answers to the questions on added sugar, which implies that consumers have many gaps in knowledge about it. The data analysis of the empirical study showed the following:

- Evaluation of consumer ability to classify various types of sugar and sweeteners correctly showed that only 2.5% classified all of the presented ones correctly, while 60% could identify five or fewer kinds out of 11.
- The findings demonstrated that a significant part of respondents recognise natural sugars in such products as milk (66.3%), fruit (91.5%).
- Research findings revealed the fact that about half of consumers know acceptable daily intakes of sugar recommended by the World Health Organisation and the European Union.
- Most respondents say they know that food products with added sugar often have high calorie contents but low nutrition value (89.1%). They also know that consumption of too high amounts of added sugar cause cardio-vascular diseases, Type 2 diabetes and contributes to obesity
- and 74.1% respondents believe that it is possible to feed on products with no processed sugar
- However, only 55.9% of respondents know that added sugar is more widely used than sweeteners in manufacturing food products.

5.3. Analysis of the extent of knowledge discrepancy

The analysis of research findings has shown that 25.7% of consumers underestimated their knowledge about added sugar, 28.2% overestimated their knowledge and 46.1% estimated it adequately. Consumers felt self-confident enough when expressing opinions on their knowledge about added sugar as about a third of all respondents assessed themselves better than the questionnaire results showed.

Consumer subjective and objective knowledge discrepancy varied from – 4.15 to 4.20. Based on discrepancy estimators, the respondents were grouped into categories with identical ranges. Table 3 shows five levels of discrepancy from large positive to large negative.

Table 3. Levels of consumer objective and subjective knowledge discrepancy (N=432)

Discrepancy level	Range (from-to)	Proportion of respondents	Interpretation
Large negative discrepancy	-4.2 – 2.52	5.3 %	Underestimated knowledge
Small negative discrepancy	-2.52 – 0.84	20.4 %	
No discrepancy	-0.84 – 0.84	46.1 %	No knowledge overestimation
Small positive discrepancy	0.84 - 2,52	24.5 %	Overestimated knowledge
Large positive discrepancy	2.52 – 4.2	3.7 %	

The method of one-way ANOVA was used and Tukey's post-hoc test was done to determine whether there are any statistically significant differences between objective and subjective knowledge discrepancy and demographic characteristics. The findings have established that the factors having positive impact on higher result were age ($p=0.021$) and education ($p=0.011$). Differences by sex, social level, family status and place of residence were not statistically significant.

6. Conclusions and future research

To summarise the results, it can be concluded that consumer subjective (what they think they know) and objective knowledge (what they actually know) differ; therefore, the discrepancy identified can affect selection of food products. This means that the consumer in choosing a healthier product can make a wrong decision because their subjective knowledge does not correspond to their objective knowledge.

The analysis of added sugar case in Lithuania also showed that some consumers tend to underestimate their knowledge, while others tend to overestimate it. However, they imply that there are some consumers whose objective and subjective knowledge correspond, and the extent of knowledge discrepancy can be different – knowledge underestimation and overestimation can be of lower and higher extent. These results entail that in order to identify knowledge discrepancy and its manifestation through consumer behaviour, organisations should develop scenarios for all the above-mentioned cases of knowledge discrepancy.

Future research should identify consumer behaviour in cases of each of the five possible knowledge discrepancy scenarios so that organisations could react proactively to knowledge discrepancy and make adequate product and brand development decisions using CKM. Based on Ahmad (2015), increasingly, for developing their consumers, companies are adopting extensive Consumer Knowledge Management practices that deal with knowledge for, from and about the users. Focusing on consumer knowledge management organization may have a great opportunity. They can proactively identify possible knowledge discrepancy scenarios. As well as manage negative impact on consumer attitudes about product / brand and buying behaviour.

Abstract

Active development of the digital economy influences all market agents, including consumers. Moreover, consumers become a driving force behind adoption of technology in their economic activities. They learn through this adoption process, developing both objective and subjective knowledge components. As an outcome, consumers' satisfaction, trust, value and overall perception of a win-win nature of economic interaction are affected, influencing consumer performance, e.g. causing innate dissatisfaction or stimulating inferences of manipulative intent. Current conceptual paper addresses and critically revises existing research on measuring consumer digital activities, decomposing existing indices and screening them for consumer knowledge components. Most of the indices are biased towards objective consumer knowledge, while the large body of consumer research on the relevance of subjective components, associated, for example, with the overall marketplace perception, persuasion knowledge and skepticism are omitted and thus represent potential contribution to strengthening our understanding of the knowledge perspective of consumer digital performance.

Keywords – Consumer knowledge, Digital marketplace, Consumer performance, Digital competences.

Nature of the proposed paper: Academic Research Paper

1. Introduction

The development of the digital economy requires all market agents, including those on the demand side and the supply side, to change their behavior. However, it is consumers who make an ultimate decision whether to adopt and integrate technologies into their economic activities or leave them unattended. The willingness of consumers to accept and actively use digital technologies is associated with the development of consumer resources. These resources are based upon prior consumer experiences, accumulated knowledge and abilities, as well as prevailing motivation and behavioral patterns. These internal motivational, cognitive and competence-based resources are considered the three-composite set of drivers which help consumers exhibit more confident and engaged economic behavior.

The issues of consumer engagement into the digital marketplace are being raised by researchers in various areas – information and communication technology studies, consumer research, and finally cognitive psychology. The various studies reflect on the consequences of the digital overload and technological sophistication for consumer wellbeing. The fundamental pillar of consumer wellbeing under the circumstances of digital transformation is a possibility to adjust to undergoing changes and realize consumption-related tasks in the new digital environment efficiently and effectively. This gives a rise to the notion of consumer performance, which is the quality to fulfil the consumer tasks.

Consumer performance can be defined as an integrated outcome of consumer activities in a marketplace, including satisfaction, trust, value, win-win approach in market interactions while being subject of consumption-related activities. The positive performance is associated with positive outcomes, while in case of market inefficiencies negative outcomes might include low satisfaction (e.g. innate dissatisfaction (Bearden et al., 2001)), distrust, resulting in skepticism and inferences of manipulative intent, perception of loss instead of gaining value, doubts in obtained results of market interaction. Analogous to overall consumer performance **consumer digital performance** assumes regular consumer involvement in interaction in a digital marketplace.

Current conceptual study aims to integrate existing models in the area of consumer performance research and consumer digital competences research in order to suggest a framework with attention to various types of consumer knowledge (e.g. digital literacy, marketing literacy, persuasion knowledge, etc.). The given framework is thought to provide a platform for integration of the streams of research which are currently to large extent isolated and thus provide a biased perspective on consumer behavior in the digital marketplace and its performance – assessed both through the lenses of a market/economy and consumer's own interests and motivation. An absence of such framework can lead to the situation whereas consumers are being increasingly motivated to be involved in the consumption and interaction in the digital marketplace, however do not obtain the required knowledge and skills, as well as do not perceive themselves as being able to cope with potential risks, leading to potential consumer knowledge discrimination (Pillai, Brusco, Goldsmith, & Hofacker, 2015). This approach is meant to represent a holistic

perspective on the consumer experience and implications for the market actors' strategies, reflecting on the outcomes for all the involved sides and higher consumer engagement in digital marketplace (Dessart, Veloutsou and Morgan-Thomas, 2016).

2. Existing approaches to measure consumer digital performance

Existing frameworks and indices that evaluate consumer digital performance focus on a set of activities consumers implement online suggesting that a mere fact of performance implies the presence of consumer digital knowledge (e.g. ROCIT Digital Literacy Index, Technographics model, and Euromonitor's Digital Consumer Index), however do not provide an integrative picture.

Multiple digital competence frameworks have been developed recently. Some frameworks are universal and can be applied to assess general digital competences that are necessary for individuals to realize a number of activities online. For instance, the European Digital Competence Framework for Citizens, known as DigComp, identifies five key components of digital competence—information and data literacy, communication and collaboration, digital content creation, safety, and problem solving – with 21 related competences. Consumer Savvy Index delineates six broad characteristics which enable consumers interact effectively with organizations: technological sophistication and innovative expertise, interpersonal network competence, online network competence, marketing literacy, complaining and specifying self-efficacy, and information flow expectations. The aspects of consumers' ability to adopt certain patterns of digital activities according to their psychographic profile were adopted in the Technographics model, developed by E. Forrest who suggested that the profiling of technology consumers should be based on variables which focuses on the motivations, ownership, use patterns, and attitudes toward information, communication and entertainment technologies as well as measures of a person's fundamental values and lifestyle perspective.

An overview of existing approaches to measure consumer digital performance is presented in Table 1. The comparison is based on the M-O-A framework (motivation – opportunity – ability).

Table 1. A comparative overview of existing measures of consumer digital performance

Framework	Motivation	Opportunity	Ability	Actual performance
DigCompConsumers framework			√	√
Consumer Savvy Index			√	√
Technographics model	√			√
ROCIT Digital Literacy Index		√	√	√
Digital Intelligence (World Economic Forum)	√		√	√
A Global Framework to Measure Digital Literacy (UNESCO)		√	√	√

Digital Capability Framework (JISC)	√	√	√
The Irish Digital Skills Framework		√	√

Most indices measure Internet access and track various activities that consumers undertake in the digital marketplace. However, these frameworks do not focus on the actual consumer ability to critically process the increasing information load, to feel efficient and effective as consumer in the marketplace, to be involved not only in information consumption, but also in creation or co-creation. In other words, these frameworks measure the linear progress, not the related evolution of consumer knowledge, critical thinking and resulting confusion. As T.V. Chernigovskaya (2019), everything has collapsed in our society – people hardly know what to trust, and can be named “homo confusus”.

Multiple frameworks, measuring and tracking various aspects of digital activities (such as competences, literacies and motivations), have appeared over time. Surprisingly, however, there is no consensus regarding how these aspects are related, and how they can drive or deter consumers’ digital performance. Consequently, there is a high risk that the application of the any of existing digital adoption framework without critical assessment will result in incomplete or, even worse, wrong representation of digital development stance, which can lead to wrong managerial applications of the results. Notwithstanding, while existing literature provides for a systematically evolving area of studies on consumer competences and their perception of a marketplace [Nijssen, Singh, Sirdeshmukh, & Holzmüller, 2003] and marketing literacy (Garnier & Macdonald, 2009; Macdonald & Uncles, 2007), mainstream investigation and conceptual development in the area of consumers’ digital competences and digital literacy are substantially more fragmented, overemphasize the technology aspect and fail to integrate other aspects of consumer behavior and competences, influencing how consumers think, feel and act in a digital marketplace. Still, beyond adopting the technology, consumers are using it for various purposes, integrate it in their multifaceted lives and increasingly interact in the digital marketplace. To develop an integrative framework of consumers’ digital competences, there is primarily a need to review existing frameworks of general digital competences.

To sum up, existing indices are strongly biased towards examining digital technologies access opportunities and merely tracking various types of digital behavior. The consumer research or cognitive psychology advances have hardly been considered, i.e. the lenses of consumer emotional state (e.g. skepticism), consumer beliefs, and consumer persuasion knowledge. As a result, the effect of digital technologies, information clutter, increase of information load on consumer, change in the ability to critically process information and create information due to increase passive information consumption– all of these studies are being ignored in the modern digital competence indices, which integrate all the measures through the lenses of modernism paradigm, where the progress is considered positive.

3. Consumer knowledge dimensions as a driver of consumer performance

Digitalization of the world economy brings forward the role of individuals' knowledge and competences to be successfully involved in the digital marketplace. Following the trend numerous approaches have been developed in order to investigate whether population in various countries is catching up with the opportunities, possesses basic competences, is involved in regular activities using digital technologies, understands grounds of intellectual property rights and ethical behavior (Bettiga, Lamberti, and Noci, 2018; Brečko and Ferrari, 2016).

Consumer behavior in the digital market place represents probably the largest part of all the digital activities, and while the above mentioned aspects, included in existing indices of digital competences, are crucial for the new digital global marketplace to function, the tradition of consumer research has a substantially wider perspective on conceptualizing what makes a consumption experience successful and effective, how consumers perceive their own performance in the marketplace.

This large research stream focuses on the balance between the rich stream of information, directed at consumers, and their ability to process information (e.g. marketing literacy, persuasion knowledge), their feelings and sentiment toward the marketplace (e.g. consumer skepticism, cynicism, etc.) (Macdonald and Uncles, 2007; Garnier and Macdonald, 2009). Through development of own knowledge base and a sentiments towards the marketplace, consumer experiences and service encounters consumers develop and adopt own coping strategies (Dommeyer and Gross, 2003), purchase decision styles, habitual decision making journeys (Edelman, 2010) and motivation to be engaged in various spectrum of digital activities (Fleming, Reitsma, Pappafotopoulos, Duan and Birrel, 2017). Addressing these angles constitutes actual consumer performance – both through the lenses of a wider range of stakeholders, and self-perceived consumer performance, and goes beyond the factors of adopting the use of digital technologies per se.

Consumer performance may be realized with different degrees of efficiency. Some consumers might encounter multiple troubles or spent excessive resources when undertaking digital activities, while others successfully complete digital tasks with no waste of financial, time and psychological resources. Notwithstanding, many frameworks will refer to all consumers who eventually realized those actions as literate, which definitely provides a biased estimation of digital knowledge. Adding consumer knowledge perspective to measuring consumer digital performance suggests adding the knowledge dimensions to existing framework. The proposed framework is different from existing ones in several ways. First, it goes beyond the mere registration of consumers' digital performance, but aims to estimate its efficiency.

Substantial area of consumer knowledge studies refers to shaping consumer sentiment as a result of perceived persuasion attempt, in other words – *consumer persuasion knowledge*. Consumer persuasion knowledge is activated in response to the consumer's awareness of persuasion tactics as a result of repeated exposure to the same tactic, added pressure of the salesperson's negotiation strategy, flattery of the spokesperson, excessive

use of rhetorical questions, negative comparisons, and other tactics (Main, Dahl, & Darke, 2007; Campbell & Kirmani, 2000). As an outcome, the consumer may reassess the marketer's attempts to influence him or her in deciding whether or not to purchase a product (Main, Dahl, & Darke, 2007) by regarding the marketer's claims with greater suspicion and inferring manipulative intent (Boush, Friestad, & Rose, 1994).

Consumer suspicion can be defined as a dynamic state in which a consumer considers that the marketer has an ulterior motive, such as the desire to persuade (Campbell & Kirmani, 2000). Such suspicion can be triggered by a surprising, inconsistent, or self-serving situational cue in an attempt to understand and cope with the marketer's actions, and form valid opinions about the marketer (Friestad & Wright, 1994). Once suspicion is evoked, the consumer becomes more cautious and attempts to look for alternate explanations concerning the persuader's agenda (DeCarlo, Laczniak, & Leigh, 2013). Moreover, according to Kramer (1999), if the consumer becomes overly suspicious, it can undermine information that is indicative of the truth, and lead to judgments that could verify initial suspicions (Main, Dahl, & Darke, 2007). While suspicion is a consequence of persuasion knowledge, which describes a state of mind resulting in the redistribution of attention towards brand-related information, inferences of manipulative intent describe the realization resulting in perception adjustment.

Inferences of manipulative intent are understood as consumer implications that the marketer is attempting to persuade her/him by inappropriate, unfair, or manipulative means (Campbell, 1995). As a result, such consumers are likely to detach themselves from the narrative and to evaluate the ad more analytically (Cotte, Coulter, & Moore, 2005). Studies indicate that the realization that the marketer is engaging in manipulative actions, such as creating fake positive product reviews, leads to consumers adjusting their perceptions by questioning the quality of the product (Zhuang, Cui, & Peng, 2018). This might also lead to negative behavioral responses, such as negative word of mouth and a desire for revenge (Joireman et al., 2013).

Table 2 presents results of an additional investigation of the same consumer digital performance frameworks through the lens of consumer knowledge dimensions. While cited frameworks include various elements of consumer knowledge, related to digital literacy (e.g. data, software literacy), mostly the focus is made on understanding the technical side of the usage and the variety of existing tools and opportunities. Consumer performance is thus mainly conceptualized from the perspective of potential involvement and embracing existing opportunities. The exception is represented by the need to protect consumer information and privacy, included in most of the frameworks, as well as the required understanding of the guidelines for the legal use of copyright and licenses. Probably the closest to the above mentioned classification of additional types of consumer knowledge is the Digital Intelligence (World Economic Forum), which is focused on the pace and extent of the damage to consumer choice and its performance outcomes. The central aspects for the consumer knowledge component include consumer understanding of possible online manipulation, poor awareness of one's personal data and reduced online privacy. However, the overall balance of the consumer knowledge components in already existing models provides extensive opportunities for their enrichment through

adding the consumer knowledge elements, which would reflect a balanced and holistic approach to the prospective consumer digital performance outcomes – not just involving consumers in the digital interaction, but also providing for a win-win, balanced outcomes of both consumption and co-creation processes.

Table 2. An overview of the consumer knowledge dimensions of existing consumer digital performance frameworks

Framework	Example of consumer knowledge dimensions
DigCompConsumers framework	Information and data literacy; Basic knowledge of hardware; software
Consumer Savvy Index	Digital consumption awareness & literacy
Technographics model	Knowledge on social networking, blogs and digital content creation
ROCIT Digital Literacy Index	Knowledge on digital services available to consumers
Digital Intelligence (World Economic Forum)	Understanding of possible online manipulation, poor awareness of one's personal data and reduced online privacy
A Global Framework to Measure Digital Literacy (UNESCO)	Knowledge of how to use copyright and licenses; software knowledge
Digital Capability Framework (JISC)	An understanding of basic concepts in computing, coding, and information processing/An understanding of how digital technology is changing practices at work, at home, in social and in public life
The Irish Digital Skills Framework	Knowledge on online security & consumer identity

4. Conclusion

Suggested approach assumes that measuring consumer digital performance requires inclusion of various consumer knowledge dimensions in existing indices. As most indices combine the perspective of the actual consumer behavior, existing motivation, opportunity and ability; adding consumer knowledge dimensions – e.g. persuasion knowledge, consumer skepticism and inferences of manipulative intent – will help understanding the whole range of consumer decisions on coping with existing digital opportunities. Acknowledging the variety of potential consumer coping strategies, behaviors and attitudes in the digital marketplace is required in order to develop strategies for a more successful digital interaction, including consumption of products, services, information and co-production of value, information.

Abstract

In this paper we investigate the existing limits of explanatory power of UTAUT2 as a source of consumer experiences and customer knowledge structuring. We apply a structured analysis of existing UTAUT2-based research to identify an extended conceptualization of UTAUT2 components in various contexts and with specific contextual add-ons. Based on pilot data collected in 2018 on digital wallets adoption (study 1) and barriers on musical streaming services adoption (study 2) we analyse 2 extended UTAUT2 models with PLS-SEM. The results of the analysis demonstrate consumer tendency to risk aversion (added variable) significance in the context of digital technologies usage, whereas effort expectancy and gender effects (original UTAUT2 variables) turned out insignificant in both studies. The results of the pilot studies preliminary confirm the research idea of UTAUT2 possible contextual limitations.

Keywords – UTAUT2, Consumer behaviour, Consumer knowledge, Digital marketplace

Paper type – Academic Research Paper

1 Introduction

Digitalization is reshaping the industries dramatically, leading to new consumer experiences and adoption strategies emergence. In recent years, the system of market interaction is facing new challenges, including worsen economic conditions and global

economic challenges. However, the most serious is the global technological challenge associated with the development and widespread adoption of digital technologies, which include the Internet, mobile communications, and digital manufacturing. Key elements of the digital economy are e-commerce, online banking, electronic payments, online advertising, online games, etc.

However, it is consumer who is the driving force behind the adoption of technologies and their integration into her economic activities. The dynamics of introducing digital technologies in all sectors of the economy is large-scale, which can be illustrated by the growth rate of Internet users in the world from 6.7 to 45.8 per 100 people since 2000 (World Bank, 2018). The rates of change and their scale are so great that researchers have got a good deal of investigation and interpretation of the whole range of technological influence on various spheres of human activity and its role in the development of economy and society ahead of them. The question remains open about the possibility and ability of market participants, including consumers, entrepreneurs, employees and regulators, to adapt to new requirements and receive benefits from technological changes.

2 UTAUT2 in extant research

The willingness of consumers to accept and actively use digital technologies is associated with the development of consumer knowledge, the formation of digital literacy and knowledge of the digital ecosystem. The modern toolkit for understanding of mechanisms behind technology adoption includes a wide range of theories, including Theory of Reasoned Action and Theory of Planned Behavior, Technology Acceptance Models and Unified Theory of Acceptance and Use of Technology (UTAUT) (Al-Mamary et al., 2016; Lai, 2017; Shaikh, Karjalainen, 2015; Venkatesh et al., 2012). Although original UTAUT has been widely recognized as a baseline for research on acceptance of technologies, its limitation on being more focused on organizational perspective (job performance) decreases its value to customer experiences understanding (Rondan-Cataluña, Arenas-Gaitán, and Ramírez-Correa, 2015). As a more customer-centric approach UTAUT2 relies on psychology of human behavior (Venkatesh et al., 2012), which became a baseline model for research on adoption of new technologies by end consumers.

Since UTAUT2 has been introduced in 2012 the original paper (Venkatesh et al., 2012) received more than 1500 citations in Scopus. For the purposes of our analysis we selected from the Scopus database the papers published till the end of 2017 that indicated UTAUT2 in the key words and utilized the approach in the empirical development. With that our search was limited to only 45 papers, with 35 with full text available and representing a quantitative empirical study (some papers were eliminated from the sample representing a pilot preceding a full-scale study). It should be noted that the list of selected publications was almost evenly arranged between 2015, 2016 and 2017.

Based on the conducted analysis we may divide suggestions for improvement of the UTAUT2 model into several directions. The most frequently used solution is extension of the model with variables influencing behavioral intention and/or use behavior that may

indicate either consumer trust (Slade et al., 2015; Lian, 2015; Tarhini, 2017; Alalwan et al., 2017, Trojanowski, Kułak, 2017; Shareef et al., 2017) towards provider or technology or consumer risk-related strategies and preferences, i.e. perceived risk (Slade et al., 2015; Lian, 2015; Tandon et al., 2016), security concerns (Morosan, DeFranco, 2015; Juaneda-Ayensa, 2016; Oliveira et al., 2016; Alharbi et al., 2017) and privacy concerns (Lai, Shi, 2015; Anuar et al., 2015; Morosan, DeFranco, 2015). Other studies prove that cross-cultural (Baptista, Oliveira, 2015; Khan, 2017; Blake et al., 2017) and cross-country (Tavares, Oliveira, 2017) context may also play its role in shaping the model although this type of model modification is yet not widely represented. Some authors test (however, mostly unsuccessfully) the moderating effects of educational level (Hew et al., 2015; Munyoka, Maharaj, 2017).

3 Pilot studies

In order to understand the possible directions for UTAUT2 extensions we additionally analyse 2 pilot studies on digital wallets adoption (study 1) and barriers on musical streaming services adoption (study 2) testing 2 extended UTAUT2 models using PLS-SEM. Both studies were carried out in Spring 2018 with data collected in St. Petersburg, Russia, via online questionnaires. Data was analysed using WARP-PLS.

Study 1 was focused on specificities of adoption of digital wallets by Russian consumers. Hedonic motivation, price-value and facilitating conditions were intentionally excluded from the study taking the rational nature of the service under analysis and developments of prior research. Consistently with the extant research on mobile payment technologies the security, trust and perceived risk variables were added to the model. As can be seen on figure 1, effort expectancy and social influence of the original model turned out insignificant which is quite typical and consistent with existing empirical evidence.

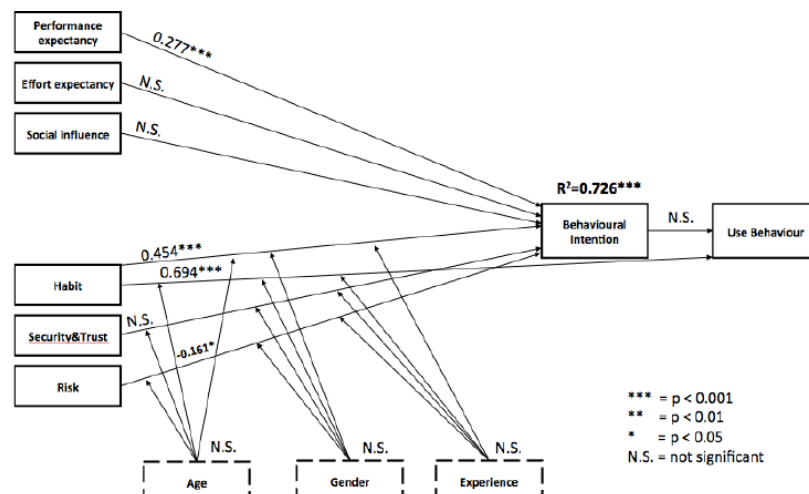

Figure 1. Pilot study on digital wallets adoption results (Voronenko, 2018)

In study 2 UTAUT2 was used to identify whether there are possible barriers that prevent adoption of the musical streaming services so tangibility preference and piracy preference were introduced by the author. As we may observe on Figure 2, the introduced variables turned out insignificant, together with the effort expectancy, facilitating conditions, hedonic motivation and price value. The study highlights the role of habit which is rarely confirmed significant in the analysed studies in forming behavioural intention and use behavior.

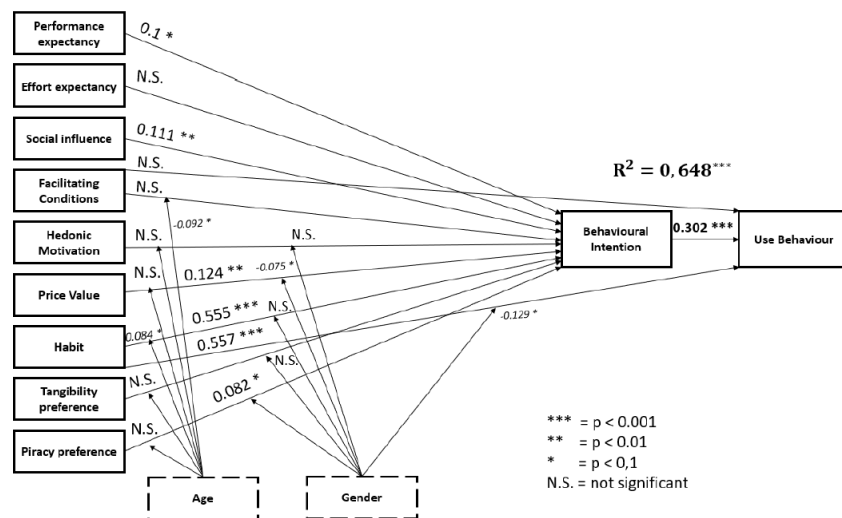

Figure 2. Pilot study on musical streaming services adoption results (Bobrov, 2018)

Both studies also show absence of moderation effects of age and gender which as well is quite typical of UTAUT2 empirical evidence observed across extant research.

4 Conclusions

This study aimed to integrate existing research experiences in UTAUT2 application in such fields as computer science, business research and engineering in order to suggest directions for improvement of UTAUT2 framework with attention to both types of consumer knowledge (e.g., digital literacy) and behavioral strategies (e.g., risk aversion), leading to implications for the market actors' strategies on introduction of new digital products to the market and improvement of consumer engagement in digital marketplace (Dessart, Veloutsou and Morgan-Thomas, 2016).

We investigate the existing limits of explanatory power of UTAUT2 as a source of consumer experiences and customer knowledge structuring. We apply a structured analysis of existing UTAUT2-based research to identify an extended conceptualization of UTAUT2 components in various contexts and with specific contextual add-ons. Based on pilot data collected in 2018 on digital wallets adoption (study 1) and barriers on musical

streaming services adoption (study 2) we test 2 extended UTAUT2 models using PLS-SEM. The results of the analysis demonstrate consumer tendency to risk aversion (added variable) significance in the context of digital technologies usage, whereas effort expectancy and gender effects (original UTAUT2 variables) turned out insignificant in both studies. The results of the pilot studies preliminary confirm the research idea of UTAUT2 possible contextual limitations.

Based on the results of the analysis of extant research we may suggest the following ideas for further development of the UTAUT2:

1. For technology-based solutions that may utilize consumer private data extension with trust, security concern and privacy concern variables will increase explanatory power of the model and may help identify consumer strategies.
2. As is proved by several studies, the results of the UTAUT2 application are subject to cultural context influence which means cultural dimensions moderators may be used to improve the model when adoption of foreign technology is considered.
3. Age and gender although initially introduced to UTAUT2 do not prove to be consistent moderators across various contexts. That

Knowledge Ecosystems and Closed Loop Supply Chain: Developing a Conceptual Model

Michal Krčál

Department of Corporate Economics
Masaryk University, Faculty of Economics and Administration
Lipová 41a, Brno, 60200, Czech Republic

Abstract

Although some researchers tried to differentiate the term knowledge ecosystem (KE) from other types of the ecosystem (such as business, innovation) the exact meaning and definition of the term remains still blurred. The indefiniteness of KE is caused partially by the fact that not much research that would specifically mention KE has been published. In WoS, only 41 articles that use the term knowledge ecosystem in the title were indexed, and only 17 from them investigate KE in the knowledge management context. When searching not only in title but more broadly in the topic, 88 articles were found, and 28 were eligible. Thus, to truly investigate KE, the focus should be on other management disciplines which are interrelated with KE through knowledge intensity. Customer Knowledge Management or Closed Loop Supply Chain are disciplines that will be used in this study to suggest how KE can be conceptualised for further research. This paper is theoretical, and the main output is a conceptual model.

Keywords – Knowledge Ecosystem, Closed Loop Supply Chain, Absorptive Capacity, Customer Knowledge Management, Reverse Logistics

Paper type – Academic Theoretical Paper

1 Introduction

With increasing virtualisation of business activities, dispersed teams, remote workplaces, and other shifts in current business, knowledge management needs to evolve together with changes in the whole economy. Since the formulation of the Knowledge-Based View (KBV) from Resource-Based View (RBV; see Curado and Bontis, 2006 for more details), the focus of organisational research was on how knowledge can be acquired, used, shared, and created. Furthermore, RBV was extended by formulating the theory of dynamic capabilities (Teece et al., 1997). Among many dynamic capabilities, absorptive capacity (AC) of the firm is the closest one to KBV (Zahra and George, 2002). Other concepts helped in the evolution of Knowledge Management (KM), such as knowledge management systems (Alavi and Leidner, 2001) or customer knowledge management (Davenport et al., 2001). Lately, it seems that further evolution of KM

theory will be through the concept of Knowledge Ecosystems (KEs) which promises to generalise the behaviour of companies connected to knowledge transfer at the inter-organisational level.

However, this concept is still novel and unresearched. In the recent extensive systematic literature review that focused on ecosystems in business, Sacringella and Radziwon (2018) identified only three articles that investigated knowledge ecosystems. Although they reviewed articles that were published before 2016 (current WoS database searches do not extend the number of studies significantly), this indicates that the research domain of KEs is significantly unexplored. Moreover, the concept of KE is not properly defined, conceptualised, and operationalised in different levels (ecosystem, firm, individual) for further analysis.

Therefore, this study starts with comparing various definitions of KE and draw conclusions which subsequently showed that absorptive capacity of the firm could be a useful bridge between KE (inter-organisational KM) and KM (intra-organizational KM). Because most of KE research is focused on the main KE nodes (usually research institutions), further development of the field should investigate different business settings where the concept of KE can be of use. Additionally, members of KE cannot efficiently function without the unobstructed flow of information inside their structure. Thus, conceptualise KE in the context of Closed Loop Supply Chain (CLSC) could allow to conduct subsequent research and bring a new understanding of how knowledge transfer in KE works.

Therefore, the goal of this study is to show how the understanding of the KE field can be extended by the research conducted in CLSC area considering knowledge and information feedback and concept of absorptive capacity of the firm. The output of this paper is a conceptual model that can be further developed and used in subsequent research. The rest of the paper describes the theoretical background in section 2, which is followed by a discussion of the conceptual paper in section 3.

2 Theoretical Background

In the following sections, the theoretical background of the presented conceptual model of CLSC Knowledge Ecosystem. First, the concept of KE, which theoretically encompasses the whole model, is introduced and discussed. The second section explains how the Absorptive Capacity, which is used as a theoretical concept for explaining how the knowledge transfers between parts of CLSC, connects Knowledge Ecosystems and the organisational processes. The third section outlines the research focusing on how the knowledge in terms of feedback is embedded in organisational processes.

2.1 Knowledge Ecosystems

Knowledge Ecosystems (KEs) were gradually derived from other ecosystems, namely business, innovation, and entrepreneurial ecosystems (Scaringella and Radziwon, 2018). Valkokari (2015) enhanced the set of different ecosystem terms by industrial and service ecosystem that partially overlap between each other. Although various scholars agree on

several specific attributes of KEs, no generally accepted definition of KE exists. Therefore, Table 1 summarises various definitions of KEs to clarify in detail what the term KE means in different studies and contexts.

Although the understanding (see Table 1) of Knowledge Ecosystem (KE) refers mainly to an inter-organisational system (Jarvi et al., 2018), the individual firm level cannot be omitted. Mainly because the processes at the individual firm level cyclically influence the processes at the ecosystem level (Borgh et al., 2012). Additionally, while specific influential parts (at the micro level) of KE can impact the whole ecosystem (e.g. Bell Labs), the way how the whole ecosystem at the macro level influences the micro level (firm level) deserves attention (Noennig et al., 2014). An example of how the macro level influences the micro level can be illustrated by the absorptive capacity of the firm.

Article	Definition
Borgh et al. (2012)	Heterogeneous set of knowledge-intensive companies and other participants that depend on each other for their effectiveness and efficiency, and as such need to be located in close proximity.
Clarysse et al. (2014)	The flow of tacit knowledge between companies and the mobility of personnel have been advanced as the main advantages of geographic colocation which characterize these hotspots. Such hotspots have been characterized as knowledge ecosystems where local universities and public research organizations play a central role in advancing technological innovation within the system.
Noennig et al. (2014)	Knowledge Ecosystems describe environments that trigger intellectual interaction and innovative production. The term indicates a dynamic relationship between knowledge work and environmental conditions, hinting at cross-scale processes between diverse agents and agencies. These actors benefit from, and contribute to, synergetic networks which continuously transform and develop the resource 'knowledge'.
Valkokari (2015)	Knowledge ecosystems have their main interest and outcome in creation of new knowledge through joint research work, collaboration, or the development of knowledge base..... knowledge ecosystems focus on the generation of new knowledge, and research institutes and innovators, such as technology entrepreneurs, play a central role in these ecosystems.
Jarvi et al. (2018)	A knowledge ecosystem consists of users and producers of knowledge, organized around joint knowledge search.... conceptualized as searching for the knowledge domain; that is, the search for the field of action where program-level knowledge creation and individual-level knowledge work will eventually take place.

2.2 Absorptive Capacity

Absorptive Capacity (AC) of the firm can be defined as: “*a set of organisational routines and strategic processes by which firms acquire, assimilate, transform, and exploit knowledge for value creation*” (Zahra and George, 2002, p. 198). The idea of absorptive capacity of the firm originated from dynamic capabilities theory formulated by Teece et al. (1997) who built it upon the Resource-Based View (RBV) of the firm (see Wernerfelt, 1984) and Knowledge-Based View (KBV) of the firm (Grant, 1996; Kogut and Zander, 1992). AC can be explained as a sponge and water which, similar to an organisation and knowledge, when released from pressure, absorbs water (Roberts et al., 2012). This absorbed knowledge allows the organisations to create value through innovation and thus to acquire the long-term competitive advantage (Zahra and George, 2002).

Although the usual focus of AC is on the individual firm's internal capability, it was shown that it could be used (together with a relational view of the firm) as a theoretical

framework on a higher level of analysis, namely in the supply chain context (Malhotra et al., 2005). Furthermore, AC promises to be a theoretical framework that can be used for conceptualising the knowledge transfer in KE. Indeed, Miller et al. (2016) investigated how knowledge transfer is performed in university (knowledge) ecosystem within the AC perspective (see their conceptual model in Figure 1). Thus, showing that AC can be used in networked companies and KE context, the research of (knowledge and information) feedback in Closed-loop Supply Chains can extend understanding of KEs and their behaviour and management (more in section 2.3).

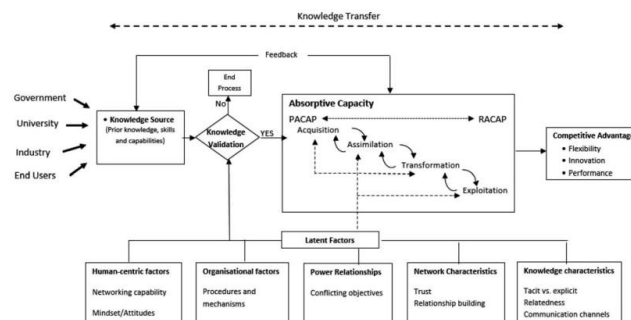

Figure 1: Absorptive capacity in Knowledge Ecosystems by Miller et al. (2016)

Besides the information and knowledge that resides within CLSC, the role of AC in CLSC can relate to Customer Knowledge Management (CKM). This concept is a combination of Customer Relationship Management (CRM) and Knowledge Management (KM) (Davenport et al., 2001). In the conceptual model, knowledge from and about customers is being absorbed by parts of the supply chain and by the producer (the main node of the KE). Incorporating CKM into KE can bring competitive advantage (Taherparvar et al., 2014). Subsequently, the customer knowledge positively influences product or service innovations (García-Murillo and Annabi, 2002), marketing results (Fidel et al., 2015), and organisational performance (Shieh, 2011).

2.3 Feedback in Closed-Loop Supply Chain

Supply Chain Management (SCM) evolved throughout the time from a “simple” logistics management into a complex management discipline. The current complex view on SCM is the concept of Closed Loop Supply Chain (CLSC) which is “the design, control, and operation of a system to maximize value creation over the entire life cycle of a product with dynamic recovery of value from different types and volumes of returns over time” (Govindan et al., 2015, p. 604). For CLSC to work, various forward and backward flows of information and knowledge need to be performed. Especially the reverse (backward) flows contain valuable information/knowledge. They are part of Reverse Logistics (RL) which is “the process of planning, implementing, and controlling the efficient, cost-effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal” (Tibben-Lembke and Rogers, 2002).

Some studies of RL showed the importance of information and knowledge that is embedded in reverse flows (Daugherty et al., 2005; Hosseini et al., 2015; Richey et al., 2005) which can be used for innovation (Krčál, 2018; Krčál and Škapa, 2017). In a recent study, the positive impact of KM on RL effectiveness was empirically demonstrated (Škapa and Klapalová, 2019). Therefore, all parts of the CLSC could benefit greatly from behaving by KE “rules”. In the conceptual model, reverse information flows are depicted as RF, and they consist of any information and knowledge that is connected to product or packaging returns (i.e. reverse logistics). The forward flows of a typical supply chain are depicted as FF, and they represent the information and knowledge connected with the product that moves forward.

When treating CLSC as a meta-organisation, the behaviour regarding knowledge transfer can be described with the help of KE findings (see Jarvi et al., 2018). Their study distinguishes between two modes of behaviour, (i) search for a knowledge domain, (ii) search within a knowledge domain. The first mode “involves probing and formulating a common goal”, the second mode “involves selectively revealing and reinforcing the common goal” (Jarvi et al., 2018, p. 1524).

3 Conceptual Model

In the following two figures, the conceptual model based on previously outlined theory depicts how knowledge transfer in CLSC can be integrated and extended by KE. Figure 2 shows how consequent research can frame the macro level of KE of CLSC together with studies that can be used for operationalising the variables. Figure 3 presents the possible conceptualisation of the micro level of KE, which is an individual firm level.

The macro level of KE of CLSC is based on the flow and seeking knowledge that originates either from the end user through customer knowledge, or the reverse flows invoked by product or package returns that contain information or knowledge about the product. The close collaboration of members of CLSC results first in a search for a common goal (e.g. why customers return products), and second in revealing the common goal (e.g. collaboratively finding the reasons for the returns and through which innovation it is possible to resolve the problem).

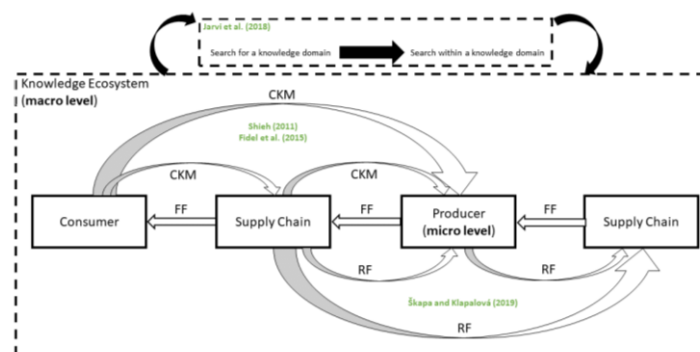

Figure 2: Conceptual model of KE macro level.

The micro level of the node in the KE is based on the previous research (Klapalová and Krčál, 2017; Krčál, 2018; Krčál and Škapa, 2017) that was conducted by a research team which the author of this study is part. Specifically, it focused on how the knowledge obtained as feedback from customers is gathered and then subsequently used. AC can be conceptualised similarly (processes of acquiring, assimilate, transform, exploit the knowledge) as was done in the study by Limaj et al. (2016).

Figure 3: Conceptual model of KE micro level.

4 Conclusions

The goal of this study was to introduce a conceptual model that will allow developing the understanding of KE both on macro and micro level. Figure 2 introduces a model that shows how KE could be conceptualised at a macro level. Figure 3 shows how knowledge transfer can be explained in the nodes of KE. Because the knowledge of KE is scattered and any unification of this concept is far from being done, the introduced conceptual models could either help with deepening the knowledge of KE or being further developed as the body of knowledge of KE will grow.

Abstract

Studies on corporate governance have undergone rapid development since the last decades of the twentieth century, when both entrepreneurs and company men began to pay considerable attention to the subject. However, the actual debate began in the early nineties when, following the numerous financial scandals, companies were forced to better define the control mechanisms within them. Most reported cases of corporate failure are attributed to corporate governance practices (Appiah, 2013). We have begun to assist on a global scale, the important role attributed to the mechanisms of Corporate Governance as their correct application is closely related to company performance (Donaldson, 2003).

On the basis of these considerations, the idea of the present work arises which, through a quantitative approach, investigates how the different composition and structure of the board influences the performance of the companies. The companies being analyzed are the mechanical companies listed on the Milan stock exchange for the three-year period 2015-2016-2017. We chose to analyze the mechanical companies thanks to the role they play in our country, in terms of employment, in terms of international trade and above all with reference to the strategic role they fulfill, strongly contributing to the development of the country and to the preservation of the levels of competition from the entire industrial sector. In the elaboration of the dataset, with regard to the governance data, the analysis of the corporate governance relations published annually by each company was used. To relate the governance variables to company performance we used a single financial statement indicator: the ROE (accounting measure), the most popular financial measure

was used.

I risultati del presente lavoro dimostrano che la dimensione del Consiglio di amministrazione ha un'influenza positiva sulla redditività delle società ed anche la maggiore presenza di donne all'interno del CdA.

This study intends to examine how board diversity in companies operating in engineering, impact on performance.

After a brief introduction to Corporate governance and firm performance, the work shows an adequate review of the most significant national and international literature on the subject. The research method used to analyze the topic is empirical using governance variable from corporate governance reports.

This work tries to study deeply the impact of board diversity on firm performance by some listed company.

Keywords – governance, board diversity, performance.

Paper: Academic Research Paper

1 Introduction

Corporate Governance is a fundamental lever for the competitiveness of companies because it represents a key through which to maximize management efficiency and more generally to optimize performance. Furthermore, it is from the corporate governance model that the level of accountability of the companies depends, that is to say the extent of responsibility given to the company decision makers and the effectiveness of the control to which they are subjected. Performance and accountability are the main key factors of business attractiveness for investors. Only in the nineties following numerous events such as the privatization process of many companies, the increase in the weight of institutional investors in the risk capital of large companies, the progressive integration of international financial markets, the failure of some important companies, the poor transparency of relations between managers, property and other stakeholders has elevated governance to a distinctive element of the company. The competitiveness of each company, regardless of the sector to which it belongs, cannot ignore clear and efficient rules on the roles and responsibilities of those who manage and above all those who invest their resources in the production system. Hence the need in many industrialized countries to seek effective models of corporate governance with related codes of conduct: the Best Practice Codes. Corporate Governance is crucial to build a trust marketplace and attract investors in the corporation, as well as corporate governance encourage investors' confidence by ensuring the existence of an independent board of directors. (Guo & Kumara, 2012).

Despite the attention received by scholars, to date there is no single definition of Corporate Governance that can be universally applied to all companies, in fact, in doctrine it is defined in numerous ways, highlighting different aspects; however, scholars and researchers generally classify corporate governance in either narrow or broad terms. The narrow view is based on shareholder satisfaction. Wider definitions extend the

objective of corporate governance to the satisfaction of all stakeholders (ie suppliers, employees and government) (Gillan 2006).

The board of directors of corporate governance is a link between those who provide capital (ie shareholders or owners) and users of that capital to create value (ie managers) Huse (2007) gives four definitions of corporate governance which provide different objectives. First, agency and stewardship theories deem that the main governance objective is to enhance shareholders 'value. Second, stakeholder theory. Reckons that corporate governance. Third, based on managerial hegemony, the objective may be regarded as "doing what is the best for management". Fourth, according to resource dependence theory, the main corporate governance objective is to do what is best for the company. Theories do not in fact, identify corporate governance objectives but the dairy are inferred from the different boards which change the basis of the theory adopted.

Corporate governance is a set of mechanisms with the help of outsiders safeguarding themselves against expropriation by the insiders. Insiders includes both managers and controlling shareholders. Or we can still define the mechanisms of corporate governance Generally when we talk about governance we analyze two dimensions that together contribute to and give rise to corporate governance mechanisms: the internal dimension and the external one. The internal dimension differs from company to company and can be defined as the set of rules, organs and activities that aims at the transparency and correctness of management's work. To carry out an analysis on governance in its internal dimension it is necessary to base the attention on the Board of Directors. External governance, on the other hand, depends on various factors such as the degree of development of the economy, of the capital market, of labor, of the legislative and regulatory system that differs between countries.

Bain and Band, (2016) explains that governance is essential for any organization that wants to maximize the firm effectiveness.

Bain, N. and Band, D. (2016) *Winning ways through corporate governance*. Springer. Metrick and Ishii (2002) for example, define corporate governance from the investor as well as the promise to repay to return on capital invested and committed to operating efficiently with a given investment. According to Mayer (1999), corporate governance is concerned with ways of bringing.

2 Governance in Italy. Origin and trend

Italy, compared to other countries, has particular characteristics of corporate governance which are to be attributed to the constant research of our country to become an economically strong and competitive international power. Because of this, many entrepreneurs have made extensive use of external indebtedness, though encountering a capital market that is little developed compared to the rest of the world. The small investors who fed our market until a few years ago were moving towards forms of investment that were certainly less profitable, but certainly more protected. There were no best practices as a governance model to refer to. Only since the nineties, following the increasing globalization of financial markets, the exchange of goods and services, the

development of technology that facilitated the communication of information, has there been a change since the legislator, the academics and the authorities supervisory authorities have begun to understand the usefulness of forming a corporate governance system.

Among the most important innovations in the legislative sphere we recall: the legislative decree n. 385/1993 the so-called Banking Consolidation Act; the law n. 332/1994 for privatizations; the legislative decree n. 58/1998, that is the Consolidated Law on Finance; the reform of company law, decree n. 6/2003; the establishment of the Corporate Governance Code for listed companies; the provisions for the protection of savings for the regulation of financial markets with the relative law n. 262/2005.

The credit intermediation sector was literally revolutionized with the Banking Consolidation Act in that the separation regime between banks and businesses was eliminated by introducing in the Italian system the "universal bank" model that allowed the establishment of bank-business relationships stronger.

The privatization law has placed restrictions on share ownership and has drawn attention to the importance of governance and shareholder protection. With the legislative decree n. 58/1998 it was decided to combine the rules and principles on financial markets and intermediaries in a single legislative text. The reform required the definition of new circumstances that could favor the development of investment demand and supply, within which corporate financiers could have the opportunity to see their interests protected.

The TUF has made several important changes, including:

The introduction of rules that protect the minority, such as the possibility for minority shareholders to be able to choose a member of the Board of Statutory Auditors, and in general the possibility of having greater consideration in the decision-making choices of the company.

The introduction of the mandatory disclosure of the existence of shareholders' agreements and the time limit of their duration.

There are no direct interventions or rules regarding the functioning or composition of the Board of Directors, but indirectly the rules on the Board of Statutory Auditors affect you. The Consolidated Law on Finance also reads about the independence of directors. In 1999, a special committee was set up whose objective was to create a report on the corporate governance of listed companies and prepare the Corporate Governance Code. The corporate law reform of 2003 essentially concerns the simplification of the regulation of corporations, the introduction of a system articulated in flexible models, the enhancement of statutory autonomy, the regulation of groups of companies.

The need for an adjustment of the legislative framework to market dynamics and developments has led our country to adopt measures aimed at restructuring the sector's top management (Law No. 262 of 2005, the "Savings Law"). The Savings Law has further extended the powers of intervention of Consob: for example the possibility of determining the limits to the accumulation of positions of the members of the control bodies of listed companies and the rules that guarantee access to such bodies of an express component by minorities or, again, the power to determine the share ownership requirements necessary for the presentation of minority lists for the election of a member

of the Board of Directors. With the Savings Law, the thesis that entrusted to the majority the appointment of the decisions and a management the relative management activity was definitively overcome, with the consequence that the powers of the minority were considered as residual, due to the mere action of opposition to resolutions of the command group. The renewed attention of the legislator has led to recognizing to minority shareholders a position of greater importance than that recognized with the Consolidated Law on Finance.

In short, the provision provides for an operation that concerns: the administrative body the control body, the publicity and disclosure on governance

In the Italian legal system there is the possibility of adopting three alternative systems of governance: the traditional, dualistic and monistic system.

3 Literature review

Although studies on corporate governance are a relatively recent phenomenon, which has experienced rapid development during the last decades of the 20th century, entrepreneurs in general and company administrators have always paid considerable attention to the issue of corporate governance. In recent times. Regardless of the particular definition, the importance of corporate governance arises in a company due to the separation between those who control it and those who own it in terms of share capital (Epps, Cereola and Ruth, 2008; (Masood Fooladi, 2012) .

Taking a historical overview, the topic of governance is already noted by the first classical economists: Adam Smith and Marshall. The evolution of corporate governance has allowed an increase in institutional communications. This for the precise purpose of establishing effective relationships with the social partners through the ability to prefigure concrete, understandable, truthful and exhaustive answers to the cognitive-evaluative requests expressed by the stakeholders. This has led companies to integrate corporate communication tools and classic accounting balance prescribed by law, and other voluntary documents have been added, such as the social report, the sustainability report, the report on corporate governance, etc. In terms of Corporate governance there are several strands of institutional theory, from sociological approaches, which focus mainly on internal organizational dynamics (DiMaggio & Powell, 1991) to economic and socio-economic approaches. The board of directors is considered to be the most powerful mechanism of corporate governance as a link between those who provide capital (ie shareholders or owners) and users of capital to create value (ie managers) (Hermanson and Rittenberg, 2003). Even more important is the c.d. board diversity, or the heterogeneity of the Board of Directors. In general, many studies refer to heterogeneity in terms of ethnicity, nationality, age and gender of the Board members. The literature generally shows (with the exception, among others, of Rose, 2007) of the existence of a positive relationship between the heterogeneity of the Board and the economic performance of companies (see Erhardt et al, 2003 and Hillman et al , 2003), social performance (Siciliano, 1996) and reputation (Miller and Triana, 2009) (Marco Fasan, 2012).

The board is expected to play an active role in the strategic process of firms, defining company purposes (Monks and Minow, 2004; Garratt, 2007a). It follows that the board's role is very complex; indeed it has to face several tensions arising from the interaction of different actors; the executives who work towards the implementation of their policies, non-executives who are there to monitor insiders, and the chairman acting as the arbiter of disputes and center of internal tensions. Some research suggests that lower-sized BODs in members may produce better corporate performances than larger BODs (Nguyen, Faff, 2006-07), but these seem to produce more stable and less variable performances (Cheng, 2008).

The empirical literature shows that a lot of studies try to measure the corporate governance influence on firm performance. Among the studies that focus, specifically on the correlation between governance and performance, we must refer to those conducted by Airoldi, Brunetti and Coda (1998), Masini (1959), Bianco and Casavola (1999). The works of the works of Bebchuk & Cohen (2004), Bebchuk, and Cohen & Ferrell (2004), show that well-governed companies perform better.

Some studies state that effective corporate governance reduces the "control rights" that shareholders and creditors give to managers, increasing the likelihood that managers will invest in projects of positive net worth, (Shleifer and Vishny, 1997). Even Antunovich et al (2000) and that of Business week (2000) show that investors are oriented in their choices towards well-governed companies.

Other studies analyze the duality of the CEO which refers to the non-separation of roles between Chief Executive Officer (CEO) and Chairman of the Board. Mohamed Moustafa Soliman, and Mohamed Abd Elsalam, 2012, show that the duality of the roles of CEO and president are apt to improve the mechanisms for monitoring performance related to business management. Other studies analyze the presence of executive administrators and while some researches come to the conclusion that the presence of the administrators contributes to increase the company performances (for example Perry, Peyer, 2005; El Mehdi, 2007; Line et al., 2009), some others arrive at opposite conclusions (eg Choi, Hasan, 2005; Cho, Kim, 2007), (Gianpaolo Abatecola, Andrea Caputo, Michela Mari, Sara Poggesi, 2011).

In summary, however, we can conclude that, on the one hand, part of the literature suggests that the overall quality of a corporate governance system, measured through the composition of specific baskets of variables, generally contributes to increasing the economic and financial value of the companies listed (Alexander et al., 2007; Schmid, Zimmermann, 2008; Renders et al., 2010). On the other hand, the understanding of the impact that the specific variables included in this system can have in more detail on company performances still seems to require a substantial deepening (Gianpaolo Abatecola, Andrea Caputo, Michela Mari, Sara Poggesi, 2011).

4 Research method

In Italy, studies on Corporate Governance are less numerous than in the other countries of the world; what has been said stems from the fact that the national literature

on the subject is quite recent. Tendentially, the studies are articulated in particular on three aspects: analysis of the problems linked to the structure of the Italian economic system; analysis on the size and composition of the Board of Directors; analysis of the correlations between governance and performance.

In recent years, several researches have been conducted aimed at verifying the hypothesis that the increase in Corporate Governance Best Practices affects corporate performance. The empirical analyzes conducted, however, did not allow us to arrive at completely unambiguous interpretations.

The dataset analyzed in the following study, examines some companies related to the engineering company sector listed on the Milan stock exchange that operate purely on the national territory in a particularly complex and engineering regulatory and competitive framework. The engineering industry plays a particularly important role in Italy both in terms of employment and international exchanges, and for the strategic role it fulfills, contributing decisively to the development of the country and to the preservation of the levels of competition of the entire industrial sector. The study conducted covers the three-year period 2015, 2016 and 2017; specifically, the sample of companies surveyed has a number of companies. In the elaboration of the dataset, as far as governance data is concerned, the analysis of the corporate governance reports published annually by each company was used, while, for the performance data, only one important financial statement indicator was used, ie the ROE; specifically, ROE is a measure that shows an investor how much profit a company generates from the money invested by its shareholders (Masood Fooladi, 2012), calculated for each company, at the end of each year.

The variables taken into consideration were divided into tables according to a criterion that led to interesting conclusions, proceeding to a regression and correlation analysis. The study also found the presence of dummy variables; in this regard, a selection was made of those variables that could be more significant than others.

For each table subsequently processed, the independent variables, ie those of corporate governance, and the dependent variable which, in this analysis, is the ROE are explained.

Research Questions

The research question put forward is to understand how in Italy the board of directors, considered a fundamental asset for company, may influence firm performance. This can be expressed as follows:

How can Board of Directors affect firm performance in Italian listed companies?

5 Results

In recent years, several researches have been carried out aimed at verifying the hypothesis that the increase in Corporate Governance best practices influence corporate performance. The empirical analyzes conducted, however, did not allow us to arrive at completely unambiguous interpretations.

The analyzed dataset examines the engineering companies listed on the Italian Stock Exchange, in particular ten of them, and covers the three-year period 2015, 2016 and 2017. The variables taken into consideration were divided into tables according to a criterion that led to interesting conclusions.

In the elaboration of the dataset, as far as governance data is concerned, the analysis of the corporate governance reports published annually by each company was used, while, for the performance data, only one important financial statement indicator was used, ie the ROE calculated for each company at the end of each year. We then proceeded with a regression and correlation analysis using excel (the data were compared with Stata13). There are also dummy variables and a selection was made of those variables that could be more significant than others.

For each table the independent variables are explained ie those of corporate governance and the dependent variable which, in this analysis, is the ROE.

For a quicker examination of each table, the relative graph is displayed as well as the summary table of the multiple regression analysis and the correlation analysis.

In the first table the regression and correlation between the size of the BoD, the number of meetings, the average age of the directors, the shares held by the first shareholder, the number of minority directors, the number of new directors appoints the newly appointed independent ones with the ROE. Following an R2 equal to 0.488 we can say that the regressors very well predict the value of the dependent variable.

The table also shows a very high significance value of the number of meetings equal to 0.888, of the minority directors equal to 0.824 and ownership equal to 0.451 compared to the other governance variables taken into consideration. The correlation between ROE and the size of the Board of Directors is positive and assumes a good value, equal to 0.278, ie the increase in the number of members of the Board increases the profitability of the companies. In fact, a larger Board has greater supervisory power over managers due to the greater number of people who control management operations and the behavior of managers. The number of meetings of -0.053 is negatively correlated to the ROE.

Even the average age correlates negatively to the dependent variable of -0.029, while minority directors positively correlate for a value of 0.132. The percentage of shares held by the first shareholder has a negative influence on the ROE for a value of -0.203.

The highest negative correlations amount to -0.441 and -0.343 and the newly appointed directors and the newly appointed independent directors and the performance variable are among the newly appointed directors. Obviously, there is a negative correlation between the two governance variables such as the first shareholder and the minority shareholder and an excellent correlation between newly appointed directors and newly appointed independent directors amounting to 0.956.

In fact, these variables affect the composition of the Board of Directors. The average age of the Board of Directors is negatively correlated with the entry of newly appointed directors and therefore with the increase of one, the other decreases.

Table 2 analyzes the governance variables such as the number of executive directors, non-executive directors, the number of independent directors, the number of managing directors, if the role of CEO is different from that of chairman or not and, if the president is an executive director. A multiple regression analysis is performed on thirty observations, placing the ROE as a dependent variable and constructing the scatter plot to see, directly and immediately, the influence that one variable has on the other.

The regression analysis leads to the achievement of homogeneous results, ie all the governance variables have very high significant values except for the variable indicating the number of executive directors.

The determination coefficient is equal to 0.117 and this means that the proportion of total variation of the dependent variable explained by the independent variable is modest.

The number of executive directors is positively correlated with the ROE and is equal to 0.133, therefore, as the number of executive directors increases, the profitability of the company increases. The number of non-executive directors is also positively correlated with $r = 0.157$. There is a positive correlation of 0.139 between the number of independent directors and the ROE. This positive influence is due to the fact that the Boards of Directors, composed of a significant number of independent members, reduce the managerial power and the information asymmetry, increasing the vigilance on any opportunistic behavior of the management and appropriately protecting the interests of all the shareholders.

Among the managing directors and the ROE, there is a positive correlation, but rather low, equal to 0.046 and therefore it is agreed that the increase in the managing directors on profitability is not particularly significant. There is a negative correlation $r = -0.042$ among managing directors who can also play the role of chairman and ROE.

This result is in line with the studies carried out in 2011 by Dey et al. which documents the lower return that is achieved by not dividing the role of chief executive officer from that of chairman, resulting in the reduced possibility of making investments to the advantage of shareholder capital.

The CEO duality, in fact, reduces the performance of the company because the CEO could filter the information available to the other members of the Board, preventing an effective control. It could also happen that the CEO duality, taking advantage of its decision-making and operational power, can undertake opportunistic behaviors in contrast with minority shareholders. There is also a negative correlation of -0.063 between the executive chair and the ROE.

Table 3 deals with the corporate governance variables relating to the presence of women at the top management related to the performance variable represented by the ROE. These governance variables, in particular, are: the number of women in the Board of Directors, the presence or not of women holding the office of president, female executive director, non-executive director and non-executive independent director. In the regression analysis, only the variable that explains the number of women on the Board of Directors is significant and this value is 0.117.

The coefficient of determination R² is equal to 0.153 and indicates an average proportion of the total variation of the performance variable explained by those of corporate governance. The presence of women on the Board of Directors is very positively correlated with the profitability of the companies for a value of r equal to 0.328.

It also experiments how, as women become more executive directors, the ROE increases, in fact, the correlation value is equal to 0.250.

This value comes out because the entry of women on the Board of Directors has brought some improvement on the boards: the female representation has brought an

increase in the percentage of graduates in addition to the decrease in the average age. But the most important consideration is precisely what this analysis revealed: the improvement in the companies' economic performance. The motivation is to be found in the fact that a selection process was carried out which did not fully take into account the gender but, rather, the competencies.

The presence of women in the family, that is related to the property, causes an increase in ROE although the coefficient is not very high, that is, equal to 0.149; likewise for the same value there is a positive correlation between women tied to the property who hold the role of executive director and the index of company profitability. From the analysis emerge many values equal to $r = 0$ that express a certain independence between the variables.

Table n. 4 shows the independent variables that concern the number of non-Italian directors, whether foreign directors are presidents, executive, non-executive and non-executive independent directors. As a dependent variable the ROE is always obtained and a regression analysis is carried out which leads to having a very high significance value for the governance variables except for the case in which the foreign administrator is chairman or executive director. The observations on which the analysis is carried out are thirty.

The coefficient of determination R² is rather small, but it is, in any case, positive. The correlation analysis shows that the number of foreign directors correlates positively with ROE for a value of 0.208.

Bringing together very different members in the Board of Directors can improve business results because it stimulates creativity, innovation and the ability to solve problems. This is what emerges from the analysis.

The non-executive directors also correlate positively with the profitability of the companies for a $r = 0.186$.

In fact, the presence of non-executive directors with different professional profiles, personal data or instructions can optimize the control capacity of the Board of Directors.

The same applies to foreign directors who hold non-executive and independent positions, the correlation that emerges from the analysis is 0.190.

However, it is analyzed, how the degree of diversity changes considerably between executive and non-executive directors, in favor of the latter and, in fact, the correlation analysis between these and the ROE is negative for a value of -0.00094.

In the companies under investigation, only one company has a foreign president in the BoD and the correlation with the ROE is negative for $r = -0.00094$.

Among the governance variables there is a strong influence between foreign directors and non-executive and non-executive independent foreign directors which is equal to as much as 0.947 in the first case and 0.833 in the second.

Table n.5 analyzes the corporate governance variables that concern the number of directors with other offices, in particular those that employ the Chairman, the executive director, the non-executive director, the non-executive and independent director. Another independent variable that has been analyzed is the average of the other tasks.

The corporate governance variables are analyzed with the performance variable which is the ROE, on a number of observations equal to thirty.

The variables that have a higher significance value are those that concern the other offices of the executive directors and the non-executive ones equal respectively to 0.948 and 0.983. The coefficient of determination is quite high, that is, equal to 0.738 and this means that the regressors well predict the value of the dependent variable.

The number of directors with other positions is very positively correlated with the ROE for a value of $r = 0.129$ while the average of the other positions negatively influences the profitability of the companies for $r = -0.303$.

The positive correlation between directors with other positions and performances is linked to the greater experience and expertise that the directors acquire from other Boards of Directors.

The possibility that presidents may have other tasks has a negative influence on the ROE of $r = -0.008$. The other positions held by the executive directors are positively correlated although of a very low value equal to 0.00047. With regard to non-executive

directors, as this governance variable increases, performance performance decreases by - 0.049. There are better performances in companies where there is a greater presence of non-executive and independent directors who have other offices, for a value of $r = 0.120$.

After having verified the research hypotheses, it is necessary to make considerations on the most important variables involved in the empirical analysis.

In the event that, both the positions of CEO and Chairman of the Board converge into a single member, we speak of CEO duality.

Although many years have passed since the first empirical study on the correlation between CEO duality and performance, this relationship is still a cause of debate in the discussions concerning corporate governance.

In the past few years, stock market management companies and companies in charge of controlling listed companies have pressed companies to avoid overlapping roles in a single person. But not all companies have highlighted these considerations as there are empirical evidences that show positive effects for the companies that adopt this governance.

This hypothesis holds that the directional unit is promoted, especially in the decision-making phase. But more recent studies (2016), as well as the aforementioned, show how the duality CEO has a negative influence on performance because the CEO could hide useful information from other members of the Board.

As for independent administrators, recent studies have begun to show different results compared to those of the past.

The empirical studies of Nguyen (2010) show that independent directors are an added value for companies and that they are capable of showing good managerial performance in the Board of Directors and shareholders.

A topic that is very interesting to scholars is that of having board members, directors who have other positions in more than one company.

Differently from what emerged years ago, more recent studies have shown a negative influence between other assignments and business value, just as this analysis demonstrates.

The size of the Board of Directors is positively correlated to the performance variable because more numerous human capital increases the skills in the company. Another point of analysis is the presence of women in the Board of Directors.

The study by Byron and Post (2016) highlights the positive correlation between women in the Board of Directors and company performance.

In fact, women are considered positively as a precious element for companies above all because they are able to provide creativity, allowing them to find innovative solutions to corporate problems.

In conclusion, from the analysis of economic literature it can be deduced, for almost all the variables taken into consideration in the analysis, the presence of often conflicting results. However, it is evident that those companies, with weak governance structures and poor shareholder protection, have agency problems. Therefore, only by having an effective Board of Directors can managers diminish or avoid opportunistic behavior, trying to outline the management's objectives with those of the stakeholders.

Among the various empirical studies, however, different results could be obtained attributable to various differences, such as, for example, the choice of the variables used to measure corporate governance, differences in the institutional context, the period under consideration or the sample of companies analyzed.

5 Limits of the research

One of the limits that the research presents is certainly the limited composition of the sample under analysis as well as the period of time taken into consideration. A longer time frame would have been more interesting.

However, we reckon that as a first study, a period of three years is sufficient to understand relations, insights and mechanisms existing within the board. Our study also does not take into consideration variables that could be just as important as the different composition of the committees that we hope to be able to investigate in the future. As we aim to investigate the percentage of properties that in this context could not be done due to the lack of information. Another interesting indicator could be that related to the level of education and / or the age of the board. Despite these limitations, it seems reasonable to assume that this research can contribute to increasing knowledge on corporate governance issues, in particular with regard to the board of directors in this particular sector where the engineering companies that are not present in Italy are included. studies in this direction.

6 Discussion and conclusion

This study can contribute to fostering an understanding and awareness of board mechanisms impacting on corporate performance and thus increase their contribution towards enhancing corporate governance

Abstract

The debate on performance evaluation of start-ups, especially the academic-based ones, is still open. The traditional assessment methods are designed for companies that operate in a structured manner, in which analysts have developed a certain experience and benchmarking capabilities.

Therefore performance measurement systems suitable for this context have to be still identified and 'calibrated': stakeholders need specific tools in evaluating investments towards a spin-off rather than another.

The paper proposes a partly qualitative and partly quantitative methodology to evaluate the performance of a spin-off. The methodology has been developed within an Erasmus+

research project, co-funded by the European Commission, called SOLA (Spin-off Lean Acceleration). The partners involved in this project are 9 European and Latin-American universities and their Technology Transfer Offices (TTOs).

A new Canvas model (the so-called LAC- Lean Acceleration Canvas) was developed and tested, more specific and suited to the context of academic spin-offs. The methodology proposes to monitor the main risk areas (market, technological, implementation, governance, and financial risk). For each of these areas, at first a framework is proposed that can support the qualitative assessment of the potential. In the second part, a set of metrics is proposed that helps to monitor the performances and to understand if the spinoff is growing in the right direction. Moreover, the methodology was applied to the spin-offs at the University of Calabria (Italy). This paper describes the first results obtained by the application of the methodology.

Keywords – Spin-off, technology transfer, canvas, performance measure, spin-off ecosystem

Paper type – Academic Research Paper

1 Introduction

The academic debate on innovation and technology transfer has underlined the role of high-tech startup companies, in particular, the academic spin-offs.

The academic spin-offs have peculiar characteristics of respect to other start-up companies: being founded within the university by researchers and teachers, they offer an innovative product/service resulting from university research. For this reason, they typically have great potential in terms of research and innovation but not management and commercial skills. The success and growth of an academic startup depends mainly on the ability: (i) to combine technological skills with the real needs of the market, (ii) to manage the relationship with stakeholders (investors, universities, commercial and industrial partners) and (iii) to develop operational and management skills that often lack the founders (typically more focused on their technical skills).

The debate on start-up performance evaluation, especially those of an academic nature, is still open. The traditional assessment methods are designed for companies that operate in a structured manner, in which analysts have developed a certain experience and benchmarking capabilities.

Therefore performance measurement systems suitable for this context have to be still identified and 'calibrated': stakeholders need specific tools in evaluating investments towards a spin-off rather than another.

The paper proposes a partly qualitative and partly quantitative methodology to evaluate the performance of a spin-off. The methodology has been developed within an Erasmus+ research project, co-funded by the European Commission, called SOLA (Spin-off Lean Acceleration). The partners involved in this project are 9 European and Latin-American universities and their Technology Transfer Offices (TTOs).

A new Canvas model (the so-called LAC- Lean Acceleration Canvas) was developed and tested, more specific and suited to the context of academic spin-offs. Moreover, the methodology was applied to the spin-offs at the University of Calabria (Italy) and the paper reports the first results obtained.

2 Literature review: measuring the performance of academic spin-offs

Literature debate on academic spin-offs, that are companies created with the aim of commercializing academic discoveries as well as developed technologies, is still open and evolving.

2.1 Factors affecting the performance of academic spin-off

A significant number of papers on the performance measurement of academic spin-offs are focused on identifying the factors that influence the performances themselves (Bigliardi et al., 2013; Hayter, 2013; Iacobucci and Micozzi 2015; Helm et al., 2016; Poponi et al. 2017).

Visintin and Pittino (2014), suggests that business performance may be affected by the composition of the entrepreneurial team (see also Rodríguez-Gulías 2017).

Evers et al. (2016) argue that the international relationships of involved researchers, typical of the academic world, strongly influence the internationalization of an academic spin-off.

Other researchers argue that the calculation of spin-off performance depends also on the technological transfer systems implemented and the ‘incubators’ available in the University of origin (Sternberg 2013; Carrasco and Aceytuno, 2015; Furlan and Grandinetti, 2014; Minguillo and Thelwall 2014; Vinig and Lips, 2015; Rodríguez-Gulías et al., 2016; Soetanto and Jack, 2016).

Poponi et al. (2017) identified nine factors associated with the performance: sustaining the start-up, the heterogeneity of the founding skills, access to finance, environmental richness, network capital, size, reliability, innovation, and motivation.

Many studies discuss the barriers and the reasons that hinder the growth of spin-offs (Ayoub et al. 2016; Galati et al. 2016; Neves and Franco 2016), taking into account that creating an academic spin-off is relatively simple, more difficult is supporting the growth, especially if the economic and social context is not favorable.

Barbieri et al. (2016) compare the work of the researchers, in terms of the number of publications made and the number of patents filed, before and after the creation of the company, as well as of the possible change of relationship with other companies.

Another critical point is to decide the right time, for a spin-off, to leave the university. The premature exit can lead to the failure of the company (Müller 2008).

Furlan and Grandinetti (2014) identify, in the early years of a start-up, two development phases: incubation and emergency phase. They focus on the factors, for each of the phases, that influence the survival and early growth of start-ups.

2.2 Methodology for measuring academic spin-off performance

Research-based spin-offs are a particular case of start-ups: they are firms strongly based on an innovative product, as it directly derives from research. Academic spin-offs are potentially the most efficient way to transfer new technological knowledge into business, i.e., into new products and services. This kind of start-ups has a great advantage, over patents or other transfer mechanisms, that the tacit knowledge of the academics, which is otherwise so difficult to transfer, is indeed transferred – straight into a new company (Sternberg, 2013)

Many scholars analyzed methods for evaluating the performance of spin-offs, as well as the impact these have on the surrounding environment both in terms of economic and social development (Cesaroni and A Piccaluga 2015; Iacobucci and Micozzi 2015; Brown 2016; Del Giudice et al. 2016; Helm, et al. 2016; Wai Fong Boh, et al. 2016; Fini et al. 2017). Some authors studied the value creation measurement in knowledge-based organizations (Iazzolino and Laise, 2016).

Helm et al. (2016) compare different kinds of indicators (not only financial and economic) to measure the performance of companies. They propose a theoretical framework for evaluating the performance from a different point of view, but it is still not clear if the spin-off classification varies according to the index used.

Cesaroni and Piccaluga (2015) identify the variables necessary to evaluate the efficiency of the KTO (Knowledge Transfer Office). They measure it in terms of the success in commercializing the generated technology and, more in general, to concretize the so-called "third mission". The amount of KT generated by Italian, European and US universities was compared.

Vinig, and Lips (2015) present an innovative approach to measuring university technology transfer performance using meta-data analysis. In particular, they use the research products (patents, licensing deals and spin-offs) as meta-data to estimate the potential for technology transfer.

However the analysis carried out shows that a methodology has not yet been developed specifically for the rating of academic spin-offs.

3 The proposed methodology for evaluating and measuring academic spin-off performance

The debate on start-up performance evaluation is still open. The traditional assessment methods are designed for companies that operate in a structured manner: vice versa startups are by definition looking for a more stable definition of the product, market, business model, organizational structure, partners. Academic startups are often more focused on the innovative technology developed by researchers and less oriented to the market.

Various kind of stakeholders are interested to understand as soon as possible which spinoffs are more promising and where to invest and allocate the resources supporting their growth: these stakeholders can be both private investors (as business angels, venture

capitalist) and public actors (as Universities interested in increasing their ‘third mission’ through, for example, the Technology Transfer Office (TTO).

Therefore these stakeholders are looking for performance measurement systems ‘calibrated’ for this context and suitable both for recognizing the potential in the early stage and for measuring if the growth is going towards a sustainable and scalable path in the next stages.

The starting point is that, before measuring quantitative performance, the critical point for an academic spin-off is to understand as soon as possible if the main typical risk areas are adequately managed. Market analysis, partnerships and managerial operating issues are frequently underestimated from researchers more oriented to technical matters.

Another critical point is to adequately consider the age class of companies, taking into account that before arriving at complete consolidation, the spin-off goes through specific stages in the first years of life (Furlan and Grandinetti, 2014) that need to be analyzed by using different indicators.

Thus, it is important to design a performance evaluation system taking into account both the potential and the actual results of an academic startup (and the lifecycle stage).

Therefore the research questions can be summarized in the following:

Q1) How to measure the performance of academic spin-offs which by their nature have different characteristics from other companies?

Q2) How to build a methodology for constructing an academic spin-off ranking?

Q3) How to evaluate the impact, from an economic and social point of view, that a spin-off has on the territory?

The methodology proposed in this paper is both *qualitative* and *quantitative*.

3.1 The first part of the proposed methodology: the fit analysis through the "Lean Acceleration Canvas" (LAC) framework

The first part of methodology (qualitative part) starts from the ‘Business Model Canvas’ proposed by Osterwalder (2004) and the ‘Lean Canvas’ proposed by Mauraya (2012) – based on ‘Lean Startup’ approach (Ries, 2011) and Blank (2013). These models allow to visually represent the way a company creates, distributes and captures value (Fig.1).

The most widespread model of Lean Canvas focuses particularly on three aspects of the risk/value of a startup: product, customer and market.

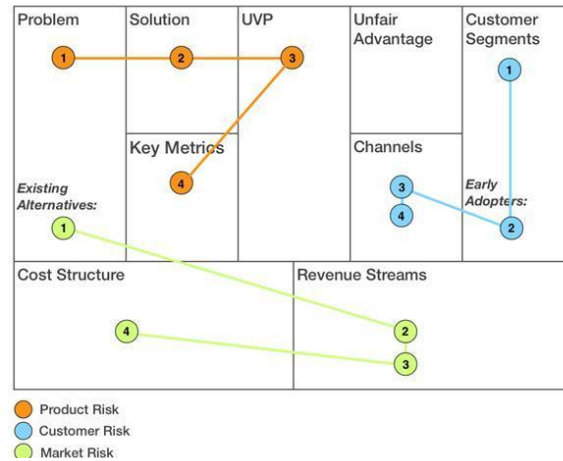

Figure 1: Lean Canvas based on Ries (2011) and Mauraya (2012).

Following an analysis carried out jointly by the TTOs involved in the project, it was found that the latter presents critical features, additional to those of the generic startups, which the general Lean model Canvas underestimate:

- *Governance and Organization*: what are the expected roles in the startup and how is the leadership distributed on the most important decisions?
- *Networking & Stakeholders*: which stakeholders are needed to make the project sustainable? How can we meet the expectations of the stakeholders involved?
- *Management skills*: what are the currently available skills and which ones are missing and should be acquired?
- *Motivation and commitment*: how much have they decided to invest the founder, not only monetarily but also in terms of commitment?
- *Scientific research and / or underlying technology*: what are the researches underlying the startup? Which intangibles are connected to the underlying research and / or technologies and how can they be valorized and defended?
- *Project Timing*: how long will it be possible to obtain a first Minimum Viable Product?

Due to the nature of the spin-offs and their characteristics, the proposed methodology is focused on a Canvas model based on 5 fundamental risk areas, 3 of which specifically cover the criticalities of the spin-offs while the remaining 2 refer to the critical risk elements already considered by the Lean Canvas:

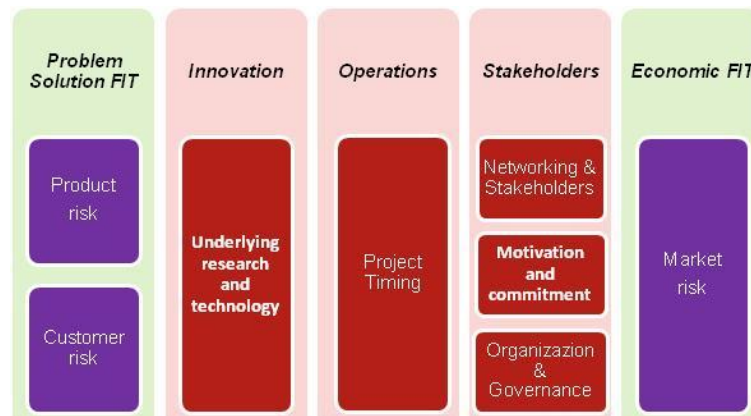

Figure 2: Lean Acceleration Canvas: the 5 risk area (Greco et al. 2016, 2017).

Therefore, to respond more directly to the spin-off ecosystem and try to provide a more exhaustive analysis and acceleration tool, the "Lean Acceleration Canvas" (LAC) has been developed (Greco et al., 2016; Greco et al. 2017), (fig. 2):

Each of the areas identified is necessary to achieve a dynamic balance in the development of the business (Fig. 3):

1. *Problem-Solution FIT*: market risk;
2. *Innovation FIT*: technological risk;
3. *Operations FIT*: risk of implementation;
4. *Stakeholders FIT*: risk of governance ;
5. *Economics FIT*: economic and financial risk.

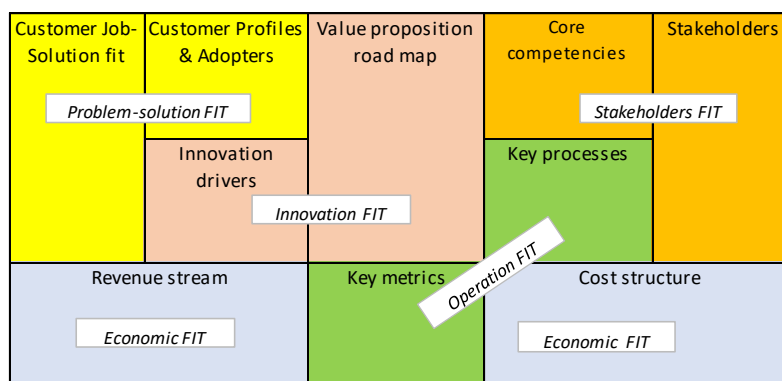

Figure 3: Lean Acceleration Canvas: the 5 FIT to be analyzed (Greco et al. 2016, 2017).

This part of the methodology has been tested through in-depth interviews with spin-offs to verify if this tool helps the founders for learning and becoming more aware of the critical aspects of their projects. The information obtained from the interviews served to provide an overview of the company situation and to know its evolution over time.

Table 1 illustrates the topics to be explored during the interviews.

The interviews have to be conducted by at least three evaluators who, first individually, and then as an evaluation group, express a qualitative judgment on each of the aspects investigated, both by giving a score from 1 to 6 and by noting relevant aspects. Table 2 and Table 3 are an example of the evaluation sheets held by the evaluators during the interview.

The weights of the various aspects considered change as the age class of the startup being evaluated varies. They are decided jointly by the team of evaluators before to start. The numerical evaluations of the individuals are appropriately normalized and summed in order to arrive at an overall score and to the overall judgments to be given to the founders.

Table 1: First part of proposed methodology: the issue to be analyzed through in-depth interview.

<i>Problem-Solution FIT</i>	<i>Innovation FIT</i>	<i>Operations FIT</i>	<i>Stakeholders FIT</i>	<i>Economics FIT</i>
Problem to be solved Solution offered Early adopters Targeting Market potential	Central innovation Mega-trends Intangibles Protectability Minimum Viable Product (MVP)	Development and prototyping Production process CRM Metrics Priority	Team skills Team compactness Partnerships The clarity in agreements and programs Involvement	Revenue Stream Cost Structure Resource Plan Business scalability The readiness of the investment

For example, the evaluators, within the SOLA project in which the methodology was developed and applied, were members of a Technology Transfer Office interested in monitoring the progress of incubated startups to support them in the growth process and the allocation of resources.

Table 2: An example of the evaluation sheet on market risk.

	1. Problem-Solution FIT: market risk	<i>Qualitative evaluation (scale from 1 to 6)</i>	<i>Weight (depending on age group)</i>
	<i>Focus on the problems to be solved</i>		
1	How good were they to identify the most important market target problems to be solved?		
	<i>Focus on the solutions to offer</i>		
2	How good they were in defining the solutions they intend to offer to solve the problems of the target		
	<i>Focus on Early Adopters</i>		
3	How good are they in defining and identifying early adopters?		
	<i>Focus on targeting</i>		
4	How well have they been able to identify and describe their market targets practically?		
	<i>Market potential</i>		
5	How important is the market potential to which the startup can aspire?		
	Total Evaluation		

Table 3: An example of the evaluation sheet on technological risk.

	2. Innovation FIT: technological risk	<i>Qualitative evaluation (scale from 1 to 6)</i>	<i>Weight (depending on age group)</i>
1	<i>Central innovations in the solution</i>		
	How do we evaluate the uniqueness of the innovations made?		
2	<i>Mega-trend</i>		
	How do we evaluate the correlation between the proposed innovation and the current social and market trends?		
3	<i>Intangibles</i>		
	How much awareness is there regarding intangibles related to innovation?		
4	<i>Protectability</i>		
	How much do we think they were good at defending innovation?		
5	<i>Minimum Viable Product (MVP)</i>		
	What skills do in predicting MVPs and the resulting iterations?		
	Total Evaluation		

3.2 The second part of the proposed methodology: the performance indicators coherent with the "Lean Acceleration Canvas" (LAC)

The second part of the methodology (quantitative part) aims to define appropriate quantitative indicators (monetary and non-monetary) that refer to the various areas identified in the LAC model.

This part aims to provide an evaluation of the sustainability and scalability of the business model pursued by the existing startups.

Coherently with the multidimensional approach before adopted, the key performance indicators and the metrics measured have been organized following a balanced scorecard approach based on the 5 dimensions identified in the LAC model (Tab. 4).

Table 5 and Table 6 are an example of the metrics considered for two of the five dimensions here proposed. Data have to be collected both through a survey and public data.

The weights of the various aspects considered change as the age class of the startup being evaluated varies. The resulting values are appropriately normalized and weighed to obtain the appropriate rankings by dimension, company and the distance from the reference threshold values.

Table 4: Second part of proposed methodology: the KPIs to be measured and monitored.

Problem-Solution FIT	Innovation FIT	Operations FIT	Stakeholders FIT	Economics FIT
Commercial independence Strong customer relationships Customer Traction Product traction	Efficiency in innovation Investment in innovation Human capital Continuity in research Implementation efficiency Validation	Efficiency in product development Customer Traction Operational growth Efficiency of HR Management	Relationship with the University Social structure Skills in spinoff	EBITDA Revenue Asset turnover Value-added % Research Capitalization Intangible assets

Table 5: KPIs and metrics for market risk.

<i>Problem-Solution FIT</i>	
<i>KPI</i>	<i>Metrics</i>
Commercial independence Strong customer relationships Customer Traction Product traction	1 /% Turnover main client % Relevant turnover Turnover last year/number of years of activity (last balance sheet) Turnover last year / no. Products TRL 5-9

Table 6: KPIs and metrics for technological risk.

<i>Innovation FIT</i>	
<i>KPI</i>	<i>Metrics</i>
Efficiency in innovation Investment in innovation Human capital Continuity in research Implementation efficiency Validation	Number of IPR titles/years of seniority Intangibles / Total Fixed Assets The number of project. funded / years of seniority Number of people employed with Ph.D. or master / total workers Number products TRL 5-9 / years of seniority N ° customers / N ° products TRL 5-9

The application of the methodology ends with a joint analysis of the qualitative and quantitative aspects, and therefore with the ranking of companies.

The qualitative first part of the proposed methodology refers to the potential of the business model the quantitative second part validates the results obtained by the considered startup.

Cross-referencing these two dimensions (qualitative-potential evaluation and quantitative-validation evaluation) we can define an overall evaluation matrix (fig. 4), that allows us to get important suggestions on how to support the growth and how to eventually correct the startup's choices.

Quantitative-validation evaluation	High	Low potential and high validation Maintain/ correct	High potential and high validation Develop
	Low	Low potential and low validation Revalue	High potential and low validation Maintain/ correct
		Low High Qualitative-potential evaluation	

Fig. 4: The overall evaluation matrix.

4. An application of the proposed methodology on spin-offs at the University of Calabria: the first results

The University of Calabria, in the south of Italy, is a medium university with near 30.000 students and 900 research assistant and professors. A TTO coordinates the technology transfer activities, and various startups can be hosted in an incubator. This methodology has been proposed to a sample represented by 37 spin-offs from the University of Calabria (of which 35% in the 0-3 years range, 19% in the 4-6 age range and the remaining 46% in the upper-end group at 6 years). Following the proposed methodology these startups have been subjected to a questionnaire aimed at investigating the data related to 2015 and a series of in-depth interviews voluntarily.

The startups completing all the process are 8 and table 7 summarizes their characteristics.

Table 7: The sample of startups analyzed

<i>Start up</i>	<i>Main activity</i>
DTOK LAB SRL	Big data analysis on the cloud
Entropica SRL	Food processing technologies
KIMICAL S.R.L.	Construction of industrial chemical additives
MACROFARM SRL	Cosmetic and pharmaceutical
NANOSILICAL DEVICES SRL	Processing of anticancer therapies
SIGMAWATER SRL	Software Innovation Engin. Modeling Analysis
SPRING RESEARCH SRL	Design of sensors for structural failure monitoring
TIFQLab SRL	Food safety testing services

Table 8: The results obtained for each area

	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7	Case 8
	<i>Qualitative evaluation</i>							
<i>Product-Market FIT</i>	0,89	0,65	0,99	0,96	1,00	1,00	0,81	0,82
<i>Innovation FIT</i>	0,76	0,54	0,91	0,99	1,00	1,00	0,56	0,65
<i>Operations FIT</i>	0,41	0,63	0,84	1,00	0,99	0,93	0,61	0,66
<i>Stakeholders FIT</i>	0,44	0,63	0,54	0,87	0,95	0,84	0,61	0,59
<i>Economics FIT</i>	0,03	0,51	0,80	0,82	1,00	0,86	0,58	0,70
	<i>Quantitative evaluation</i>							
<i>Product-Market FIT</i>	0,12	0,31	0,29	0,30	0,09	0,22	0,46	0,72
<i>Innovation FIT</i>	0,42	0,30	0,28	0,37	0,80	1,00	0,49	0,24
<i>Operations FIT</i>	0,36	0,48	0,24	0,54	0,42	0,29	1,00	0,70
<i>Stakeholders FIT</i>	0,47	0,87	0,15	0,72	1,00	0,79	0,80	0,93
<i>ECO FIT</i>	0,05	1,00	0,30	0,58	0,74	0,30	0,24	0,20

Table 8 summarizes the results obtained within the two phases of the proposed methodology (company names are hidden for confidentiality reasons). The data have been appropriately normalized so as to make them comparable by area and for an overall evaluation (Table 9).

Table 9: The overall evaluation

	<i>Qual. Score</i>	<i>Quant. Score</i>	<i>Suggestion</i>	<i>Notes</i>
Case 2	3,11	3,67	Develop	Convergent assessments High potential and good validations
Case 5	4,33	3,33		
Case 3	1,22	3,33	Maintain- correct	Prospective business model not clearly defined
Case 7	1,89	3,67		
Case 8	1,78	3,22		
Case 6	4,22	2,78	Maintain- correct	Market validations to be improved
Case 4	4	2,78		
Case 1	1,89	1,67	Revalue	Stalemate

These values can be positioned on a graph, as shown in figure 5. by positioning the axes along with the value of the medians, it can be observed that the analyzed sample of academic spin-offs is distributed among the 4 quadrants identified by the proposed overall evaluation matrix. The suggestions deriving from the application of the matrix are consistent with the qualitative evaluations emerged during the analysis phase.

Figure 5: The matrix evaluation

5 Conclusions

A new Canvas model (the so-called LAC- Lean Acceleration Canvas) was developed and tested, more specific and suited to the context of academic spin-offs.

Moreover, the methodology was applied to the spin-offs at the University of Calabria (Italy), and the paper reports the first results obtained.

The proposed methodology tries to face the typical problems that characterize the growth of an academic spin-off: (i) the excessive attention to the technological aspects with respect to the commercial and managerial ones, (ii) the need for evaluation systems that try to evaluate all risk areas and to highlight any misalignment, in particular between the market and academic research. A problematic approach to the market, in fact, leads to limited turnover which consequently limits the balanced development and the resources for becoming autonomous from the "protective" context of a university environment.

The methodology proposes to monitor the main risk areas (market, technological, implementation, governance, and economic-financial risk). For each of these areas, a framework and a checklist are proposed that first helps the qualitative assessment of the potential and of any areas not properly managed. In the second part, a set of metrics is proposed that help to monitor the performances and to understand if the spinoff is developing in the right direction.

In this context, the crucial role of TTOs emerges: they can help spinoffs in assessing the major risk areas and in focus the strategical priorities to be faced. Moreover they can offer services and advice in typically weaker areas for this type of companies.

All this is accomplished with the primary objective to support the spin-offs growth, but more deeply contributing to the economic and social growth of the territory, thus concretizing the "third mission" of the university (Brown 2016).

One of the main limitations of this work is the limited size of the analyzed sample.

This is due also because of the difficulty to collect homogeneous quantitative data, above all with companies at the first stage of their lifecycle, when the development path is often very specific.

Another critical point is the decision about the weights to give on different areas and to the different class ages: to have an overall evaluation and ranking is very useful, but the results strongly depend from these weights.

Further future development is the extent the results testing the methodology on academic spin-offs coming from other Universities, or on sample homogeneous for industry and technology.

Abstract

The essential of presented paper is to introduce the outcomes of own research based on questionnaire survey, interviews, observation, analysis of educational events and experimental lessons, which aims to understand the principles and complexity of teaching in the MBA professional study programs in the context of application of activation methods of teaching towards the support of desirable managers' competencies gaining.

Keywords – MBA professional training, manager, competences, activation teaching methods.

Paper type – Practical Paper.

1 Introduction

At present, the project has become a part of everyday life of many individuals and groups - projects are being managed to develop new products, technologies, to build highways, or to provide an education. Until recently, project management has not been practiced in the Czech Republic, but it is currently becoming more and more used in IT and automotive. Its very gradual arrival could also be due to the fact that education in the area of project management has not entered the universities too much, even where it is

very desirable - for technical and economic fields, and project management has not entered the curriculum of secondary schools at all. In recent years, project management has partially penetrated the lifelong professional training for managers, for example at the Business Institute in Prague is possible to complete the whole and in Czech Republic the only one professional training in study program Project Management and Planning.

In carrying out the research in the context of meeting the objective of the submitted paper we start from the fact that the training of the managers must correspond with the content and methodology of the complex profile of the manager. It should lead to an increase in managerial technical skills, improved leadership, communication, strategic planning, absolutely indispensable managerial competencies, especially personality profiling. To these premises are other necessary topics, depending on the situation in the enterprise, associated.

It is necessary to realize that the current labor market requires greater flexibility of employees, higher adaptability, and greater ability to learn in a rapidly changing environment. Great emphasis is placed on communication skills, knowledge of foreign languages and ability to work in a team. At the same time, there is an unprecedented increase in information technology in our lives, including education. Also, it is not to be forgotten that students attending courses of managerial professional education are coming to school with diverse expertise and skills, with diverse learning experiences with methods in teaching.

Paper's results and conclusion will help to understand the principles and complexity of teaching in MBA professional training study programs. We would like to gather sufficient and relevant information on selected learning methods, technologies and practices in the context of project management teaching in managerial professional training.

2 The current state of the problem solved

Lots of various teaching methods were described by different authors, for example by Pasternáková (2015), Kotrba and Lacina (2015), Maňák and Švec (2003), Petty (2013) or Silbermann and Lawson (1997). The lecturers are thus given the opportunity to choose from a wide range of methods those who are convinced that they will bring the best results in their conditions. *"The lecturer is fully competent to use specific teaching methods to bring the student to use his / her maximum potential. Previously, the lecturer was the only source of knowledge he gave to his students. Now there are more information resources, the lecturer should not pass the knowledge, but "accompany" the student in their acquisition"* (Malach, 2003). The primary reflection is therefore the change in the lecturer's view on the role of education at present. This brings with it the need for new methods, hence the need for a necessary and rapid identification of each lecturer with these methods. Lecturers have to reconcile diverse groups of students so that each of them can use their abilities and reach their maximum. This requires the lecturers to have not only professional erudition but also a great deal of empathy, human maturity and balanced authority, ability to resist stress, solve potential conflicts and good

pedagogical skills, including a pedagogical tact where the society rightly expects the MBA school to adapt and satisfy changing needs of groups and individuals.

The lecturer should mobilize the students, the groups to think, he should teach students to express their own opinion, to help them to build a healthy self-confidence, to rid of the stage-fright, he should teach the teamwork, to affect the ability to remember (Plamínek, 2014), i.e. exactly everything what builds the required competencies of students, future MBA graduates. Lecturer and student of the present, perhaps the future, are partners on the path to development, learning and mutual understanding.

The choice of teaching methods is based on the professional decisions of the lecturer, following the very good knowledge of the students and the state of the specific educational process. Therefore, activation methods of teaching are the right choice of contemporary and future educational process in within the framework of managerial professional training. Therefore, active problem-based and participative methods based on problem solving, accompanied by the use of modern didactic means, especially computer technology, are considered as the most suitable methods of training of managers. This helps to develop the knowledge, management activities and authority of the managerial personality, i.e. the global development of personality.

Finance spent by managers on their training is their investment for a better future and increased competitiveness. Therefore, it is necessary to develop the potential and level of managerial education for individual segments of the market, which differ with their needs and habits. It is necessary to emphasize that the provided managerial trainings should be targeted to the strategies of specific companies, segments and should be focused on the managers' business assignment. The purpose of such education is to ensure that the managers do not study for themselves but they want to develop the specific competencies that are needed for the development of their company on the basis of specific activities linked to their role.

Most professional publications such as by Bartoňková (2010), Bednaříková (2007), Horčíčka and Jelínková (2013), Mužík (2000), (2005) or Veteška and Tureckiová (2011), are filled with philosophical considerations and theoretical guidelines. If they already propose or refer to applicable learning practices and methods, they usually only describe processes that, by their functionality and content, no longer correspond to the technical level and the difficulty of spreading knowledge among MBA students.

It is undisputed that the present time makes claims and demands on the graduates of MBA study programs quite differently than in the past. Among the key competencies, that MBA graduates should acquire, belong especially required (professional economic and managerial) expression and ability to reason, to present, to communicate, to manage opposition and conflicts, to resist stress, to listen to, to ask questions, to learn new things, to perceive the needs of others empathically, to have respect for the partner's opinion, to know, how to acquire the necessary data, to do researches and analysis, to be able of independent work and team work, as is cited in Makovský (2010), Kubeš et al. (2004), Rennie (2018) or Lajčín (2014). In this context, the cardinal question, which has become the basis of our research, arises: *Does the current concept of project management*

teaching within the framework of the MBA study programs in Czech Republic focus on acquiring of these required competencies?

3 Paper Methodology

The primary goal of presented paper is to analyze the system of teaching on MBA study programs in Czech Republic focused on project management in the context of the use of activation teaching methods. The essential of the problem solving is to contribute to the pedagogical theory and practice the findings supporting the necessity of qualitative changes in the process of selection and application of teaching methods in current managerial professional training. The legitimacy and necessity of their inclusion in managerial professional training on a much wider scale than it is at present, is confirmed by the findings of available surveys, researches and experiments such as cited in Kamarudin (2018), Makovský (2010), Forwarczná (2010) or Veteška and Tureckiová (2011). We would like to collect sufficient and relevant information on selected teaching methods, technologies and practices in the context of project management teaching in MBA study programs in Czech Republic. Below we formulate the secondary goals of the research:

- **To perform an analysis of information sources related to the issues of project management teaching, adult's education, managerial education and application of activation teaching methods.** There were detected all secondary information (data) relating to knowledge on these topics, those have already been carried out by other institutions or organizations and have been also evaluated and published by other Czech and foreign authors.
- **To evaluate the practical applicability and effectiveness of activation teaching methods of project management** within the framework of managerial professional training at the Business Institute in Prague. Current status in the use of various teaching methods by project management lecturers, acting on the Project management and planning study program and on other study programs containing the module Project Management and Planning or Project Management, including the knowledge of the usability of activation teaching methods and verification of their effectiveness in fulfilling the educational objectives of the managerial professional training in comparison with traditional methods and the identification of conditions, requirements and barriers that determine the choice of activation methods of teaching, is mapped and evaluated through quantitative (structured questioning of lecturers via questionnaire) as well as qualitative (controlled interview with project management lecturers) methods of empirical pedagogical research. This represents the main part of the work for subsequent conclusions to be drawn. This reduces the absence of scientifically validated outcomes related to the problem solved. The paper further analyses and evaluates the barriers in the application of activation teaching methods to what extent these methods contribute to building the required competencies of MBA students in professional training.

- **To analyse the educational event:** An analysis of the educational event is a tool that helps to verify the quality and effectiveness of an educational event. Based on the result, we can set up measures to optimally secure the goal, which is in our case some knowledge, skill or the required behaviour. The goal of the analysis of educational event is to confirm or disprove whether the educational event, due to the lecturer, organizational form and methods used, is effective. It is about the controlling and evaluation of the monitored aspects of the lecture meetings held in within the MBA professional training at Business Institute in Prague and the analyse is implemented from two perspectives: firstly the perspective of the authors of presented paper based on the sitting in on classes and authors' own observation and secondly the lecturer meeting participant's perspective. The criteria of the control take into account the principles of effectiveness and described theoretical aspects, and point to the fact that a professionally qualified lecturer and the correct application of the methods lead to an effective set-up of educational event. We analyse the lecture meetings of MBA professional training at Business Institute in Prague, which were led by one lecturer and were focused on project management. The activation teaching methods (the experimental lesson was realised) were included in the content of the lecturer meetings, namely the Tower Challenge managerial game, the Obelisk ZIN simulation and the case study solution from the field of the project realization.

Here are the key issues of our research:

1. Do project management lecturers encourage students to develop the creativity, imagination, teamwork, ability to present and to promote their opinion?
2. Do project management lecturers use an appropriate scale of activation teaching methods to build managers' required competencies?
3. What are the most frequent barriers in the application of activation methods in project management training within the framework of managerial professional education?

Within the research methodology we used these methods:

- **Analysis:** We used the analysis to analyse the information sources, to analyse the educational event and to evaluate the practical applicability and effectiveness of the activation methods in project management teaching in within the framework of MBA professional training.
- **Observation:** Observations were carried out at lecture meetings in within to meet the identified secondary goals of presented paper. The lecturers and the students of the relevant study programs containing the module Project Management and Planning or Project Management and the students of the study program Project Management and Planning were the targeted group. We recorded the observed aspects into the pre-prepared documents. The major observations were made in experimental lessons. Experimental lessons were conducted on a total of 25 lecturers meetings (three-hour lessons in January 2016 - August 2018) by including the Obelisk ZIN simulation, the Tower Challenge managerial game, and case studies.
- **Comparison:** We used the comparison to compare our findings with the results of the analysis of information sources.

- **Synthesis:** Facts identified during the analysis of information sources and from the evaluation of practical applicability and effectiveness of activation methods in project management teaching in within the framework of MBA professional training we have synthesized into the form of suggestions and recommendations to improve the current state of the problem solved and at the same time these facts resulted into the fulfilling of the primary goal of this paper.
- **Pedagogical research:** We have chosen a method of quantitative research that works with the numerical values and determines the quantity, extent or frequency of occurrence of the analysed phenomenon, it maintains the distance from the analysed phenomenon, and the data can then be processed by mathematical and statistical methods, enabling generalization and drawing of objective conclusions, but also the realisation of consequent qualitative research.
- **Structured questioning:** Structured questioning of the lecturers was carried out in order to fulfil the formulated secondary goals and thus to evaluate the practical applicability and effectiveness of the activation methods in project management teaching in within the framework of MBA professional training at Business Institute in Prague.
- **Structured interview:** A structured interview is a qualitative research method. We conducted structured interviews with the lecturers of modules of Project Management and Project Management and Planning.

Selected and subsequently practically used methods of research work have provided sufficient data, which were then processed through the mathematical-statistically procedures with the definition of absolute frequency. Within the framework of a questionnaire survey in the team of project management lecturers, the opened and semi-closed questions were evaluated according to the frequency, expert, knowledge and logical level of answers. For the closed questions, the frequency of choice of the offered answers was evaluated with the determination of their absolute and relative extent. Data from realized interviews with project management lecturers has been carefully evaluated and summarized in response to the stated objectives and key questions and assumptions. All results were tabulated and interpreted verbally, then compared with the findings of similar researches and evaluated globally in the context of the key issues taking into account our experience.

4 Evaluation of key issues

Based on our findings, we can evaluate the formulated key issues:

Key issue 1: Do project management lecturers encourage students to develop the creativity, imagination, teamwork, ability to present and to promote their opinion? Based on the results of pedagogical research, we find that lecturers do not sufficiently motivate students to develop the creativity, imagination, teamwork, ability to present and to promote their opinion, and this in particular on the basis of the following findings:

- Just less than half of the respondents (lecturers) monitors the fulfilment of the key educational goals of the MBA professional trainings where the validity and

objectivity of this conclusion is supported by the fact that this finding was achieved on the basis of self-assessment of the lecturers and not by the controlling activity (sitting on in a class) of their teaching,

- just 29% of the respondents (lecturers) considers the activation methods to be the right methods that appropriately motivate the students, and just 10% of the responded lecturers are of the opinion that activation methods can be used more quickly and efficiently to achieve the educational goals in MBA professional training,
- responded lecturers are aware only of some effects of activation methods (the learning revival, the elimination of passivity), underlining their inexperience with wider use of these methods and active verification of their key effects in achieving of educational goals in MBA professional training. The lecturers are reluctant to change their obvious rules, they are afraid of any change, they are unwilling to invest some time and effort to innovate the methods and forms of their teaching, towards the reaching of teaching goals they still use others, often not effective, teaching methods that lead to mere memorization of the subject matter and not to a deeper understanding and adopting of solutions to managerial issues and necessary contexts. This issue results from the realised interviews with the lecturers.

Key issue 2: Do project management lecturers use an appropriate scale of activation teaching methods to build managers' required competencies? On the basis of the findings, it can be concluded that project management lecturers use the activation teaching methods to support the development of the required competencies of students only minimally, sporadically. Only 6% of lecturers stated that they frequently and actively use 6 from the 22 analysed activation methods in the project management training in within MBA study programs (brainstorming, mind maps, project learning, free writing, staging - role playing, discussion spider work), some activation methods are rarely used by lecturers, most lecturers do not use or even do not know most of the analysed activation teaching methods.

The building of the required competencies of the students is monitored by the lecturers only at the average level, which shows considerable reserves. Only 6% of the tested students stated that in the project management training the lecturer uses the mapping, learning software, in 11% the lecturer uses the simulation games, in 18% the lecturer uses the project teaching, the lecturers mostly use the group work (34%) and discussion (58%), which shows the significant reserves in the use of activation methods in project management training in within MBA study programs. This should become a signal for not only project management lecturers but also other lecturers, with the necessity to accentuate these findings and to correct the preparation and planning of teaching.

We note, therefore, that almost 94% of the analysed lecturers prefer a combined teaching unit with predominant frontal interpretation, where activation methods only play a complementary role. The traditional way of project management teaching (frontal teaching) is dominant. Only a small percentage of lecturers prefer active learning with the permanent building of a student's autonomy, supporting his / her own initiative, thus a

form of teaching based on a wide use of activation methods and targeted at fulfilling of the mandatory educational goals in managerial professional training.

Thus this empirical research has confirmed that the analysed lecturers still prefer the traditional teaching methods, especially the verbal reproduction and the activation methods are used irregularly, occasionally as a complement to traditional teaching methods.

Key issue 3: What are the most frequent barriers in the application of activation methods in project management training within the framework of managerial professional education?

Being the main barrier to the use of the activation methods, the lecturers consider the lack of time and lack of time subsidies of the subject (module). However, the objective barrier is the minimal knowledge of activation methods and their effects in teaching. A frequent argumentation of the analysed lecturers, why the activation methods cannot be used, is the difficulty of the lectured issue in their opinion. The lecturers do not understand the role and the effectiveness of activation methods in project management training. They do not know that in frame of the activation methods application, these methods are able meet the required content for the subject (module), as well as to deepen the curriculum and to achieve the required educational goals in managerial professional training. Many of the lecturers' arguments (lack of time, necessity to meet the content requirements of the module, etc.) can be considered as secondary and in no way inhibiting the inclusion of activation methods into the project management training in MBA study programs.

The lecturers' approach to activation methods, a low level of willingness to self-educate, and subsequently to modify and to innovate the teaching, to adapt to the current needs of managerial professional training, to accept a change of the lecture's role are objective and overwhelming barrier for the activation methods application in within the managerial professional training. After all, the content requirements of the subject (module) can be fulfilled with the use of activation methods, as well as it is possible to deepen the curriculum with the using of the appropriately chosen activation methods.

The essential barrier for activation teaching methods application is the passivity of the lecturers to discover, to acquire and then to include the activation methods in active project management training or in the entire system of managerial professional training.

5 Discussion

Teaching methods are one of the most important aspects of the learning process. The ability to select adequate teaching methods and didactic means, the ability to use them efficiently and purposefully in the teaching process, including the personality integrity of the lecturer and the building of his / her authority, decides on the success of demanding pedagogical work within the framework of managerial professional training.

The research confirmed that the project management lecturers of managerial professional training are not sufficiently familiar with the activation teaching methods and are concerned about their application to project management teaching. This situation is

because of lecturers (there is a low level of willingness to change the rules and to modify the course of lecturers' meetings, to accept a change of the lecture role, to apply the activation methods to the lessons for often completely substitutive reasons - lack of time, the need to fulfil the content plans etc.), of management of educational institutions (there are reserves in motivation of lecturers, in creation of conditions for application of activation teaching methods, in evaluation criteria of teaching quality), of publication background (there is a lack of suitable publications illustrating activation teaching methods, including examples).

We also found and the experimental lessons verified that activation tasks, i.e. exercises included into the experimental lessons (Obelisk ZIN simulation, Tower Challenge managerial game, case studies) were easy to understand for the students, the lessons were fun and interesting (86% of analysed students confirmed this finding) and, above all, such lessons contributed to the students' higher level of knowledge. Thus, we can state that the effectiveness of the activation teaching methods in project management teaching in frame of the fulfilment of the educational goals of the managerial professional training significantly exceeded the traditional methods of teaching, the activation teaching methods have brought students much more enjoyment in learning, they activated and motivated them, finally students preferred them, these methods are highly effective in the concrete use of the learned curriculum, and in the persistence of the learned curriculum preservation. The legitimacy and necessity of their inclusion into the project management teaching and into the managerial professional training on a much wider scale, than it is at present, is confirmed. Our findings are validated with similar researches and experiments cited in Bickerstaffe and Ridgers (2007), Cao and Sarchutchawan (2011) or Forrssen-Nyberg and Hakamaki (1998) and Thompson and Gui (2000).

The teaching of project management within the framework of managerial professional education, which corresponds to the current demands on human resources on the labor market, is not possible without the activation methods of teaching. Our research found and in the context of findings published by Pecina and Zormanová (2009, p. 99) or Veteška and Vacínová (2011) confirmed, that the activation methods undoubtedly require intensive lecturers' work, there is more time for preparation and organization, and they require better technical equipment of classrooms than traditional methods, some are only usable on the basis of lecturer's own experience and talent to work with new methods, some methods are also associated with certain risk. The measurable effects of activation methods should become a pivotal incentive for educational institutions, lecturers and textbook authors.

6 Conclusion

The conclusions presented within this paper lead to the statement that the project management teaching in managerial professional training that corresponds to the current demands made on project managers on the labor market cannot be avoided without the use of activation teaching methods. Their successful application must be based on the

professional decisions of the lecturer, based on a very good knowledge of the activation methods, but also on the knowledge of the students, because only in such a way the good results of learning can be expected. The essential is that the lecturer is fully aware of the role he / she has in the current process of building key competencies of managers, so he / she can choose adequate teaching methods.

It is clear from our findings that not every lecturer and educational institution are capable of self-reflection and awareness of their required roles in the context of current educational needs. One of the primary factors of successful application of activation methods to the MBA trainings is the willingness of lecturers to change their attitudes, pathways, forms, and teaching methods that will lead to the current educational goals of managerial professional training. With the gradually changing lecturer's role we mean the moving of the lecturer's role from the owner of knowledge to the lecturer as a facilitator, who will support the learning process by organizing of teaching material, by highlighting of the essentials, by helping to set goals and by monitoring of goals' achievement, next to the lecturer as a coordinator who organizes the common activities of the students, creates a space for knowledge sharing and cooperation, oversees the use of the potential of the social dimension learning processes and, finally, to the lecturer who participates in the learning process, engages in learning activities, becomes a model, a model of a learner. What methods he / she chooses is, and remains, in the competence of each lecturer, when the importance and the merit of the inclusion of activation methods into the process of managerial professional training in frame of MBA study programs has proved and verified this work. The management of MBA schools and of other educational institutions, authors of textbooks and methodical aids, the universities and educational institutions preparing future teachers and lecturers, and as well the feedback from the students, who are involved in proper teaching methods application, play the strategic role in this process. It should be remembered that changes cannot happen from day to day, but it is necessary to reach them in a long and dynamic process.

The presented paper does not offer normative outputs, but represents the current level of solved problems and brings knowledge about use and effectiveness of activation teaching methods in project management in frame of managerial professional training. Selected research procedures and methods provided a relatively large amount of data, the processing of which allowed for a deeper insight into the role, effectiveness and applicability of activation teaching methods.

Abstract

Knowledge Intensive Business Services (KIBS) are private enterprises or organizations mainly concerned with providing knowledge-intensive inputs to the business processes of other organizations, including private and public sector clients, that rely heavily on professional knowledge and which involve economic activities intended to result in the creation, accumulation or dissemination of knowledge. KIBS firms, such as advertising and market research, accountancy and management consulting, IT services, engineering and technical services, represent a core feature of the knowledge-based economy functioning as innovation carriers, knowledge facilitators and innovations sources. KIBS play, also, an important role in local and regional economies as source of added value and their growing importance as emergent players is a major attribute of knowledge economy and more generally in the debate about innovation systems, knowledge driven economic dynamics and competitiveness. Their role, as co-producers of innovation, in enhancing Small and MEdium-sized enterprises (SMEs) is particularly relevant because of their prominent support in enabling SMEs to innovate in a more effective, cost-effective, and/or timely manner.

The paper investigates the application of Data Envelopment Analysis (DEA) in conjunction with Financial Ratios Analysis (FRA) to estimate and compare the performance of KIBS industry in Italy over the period 2012-2017. In particular, we evaluated the three main NACE (Nomenclature générale des Activités économiques dans les Communautés Européennes) segments that identify KIBS services: NACE 72 (computing services), NACE 73 (research and development) and NACE 74 (other professional business activities).

FRA, for its simplicity, has been achieved a widespread use in practice. A financial or accounting ratio is a relative magnitude of two selected numerical values taken from an enterprise's financial statements. DEA is a mathematical programming technique that estimates the relative efficiency of production units (Decision Making Units - DMU), computing a comparative ratio of weighted outputs to weighted inputs for each DMU and identifies best-practice frontiers over the examined data.

The results obtained from the efficiency estimates and the financial ratios are used to rate firms according to these performances. The empirical investigation proposed reveals that the results of FRA approach do not provide sufficient and complete information on the efficiency of KIBS firms, while major advantages behind using of DEA are related to its structural characteristic in measuring performance and identifying opportunities for possible efficiency improvements by looking at the differences between efficient companies and inefficient ones. The empirical results obtained from the analysis of the general sector of KIBS can be further extended and focused to the comparison of firms belonging to a more specific industry sub-sector in order to benefit managers of those companies to gain insight from the industry financial performance benchmarking process.

Keywords – Data Envelopment Analysis (DEA), Financial Ratios Analysis, Knowledge Intensive Business Services (KIBS), performance measurement.

Paper type – Academic Research Paper

1 Introduction

Knowledge Intensive Business Services (KIBS) are private enterprises or organizations mainly concerned with providing knowledge-intensive inputs to the business processes of other organizations, including private and public sector clients, that rely heavily on professional knowledge and which involve economic activities intended to result in the creation, accumulation or dissemination of knowledge (Miles et al., 1995; Hertog, 2000; Muller and Doloreux, 2009). KIBS firms, such as advertising and market research, accountancy and management consulting, IT services, engineering and technical services, represent a core feature of the knowledge-based economy functioning as innovation carriers (i.e. knowledge transfer across firms), knowledge facilitators (i.e. support for improved process or knowledge-intensive tasks) and innovations sources (i.e. co-production of innovation) (Hertog, 2000; Fischer, 2015). KIBS play, also, an important role in local and regional economies as source of added value (Toivonen, 2006; Corrocher et al., 2012; Savic, 2016) and their growing importance as emergent players is a major attribute of knowledge economy and more generally in the debate about innovation systems, knowledge driven economic dynamics and competitiveness (Ferreira

et. al., 2013; Hu et al., 2013; Pina et al., 2016). Their role, as co-producers of innovation, in enhancing Small and MEduum-sized enterprises (SMEs) is particularly relevant because of their prominent support in enabling SMEs to innovate in a more effective, cost-effective, and/or timely manner (Alvisi, 2012).

According to Corrocher et al. (2012), the three main NACE (Nomenclature générale des Activités économiques dans les Communautés Européennes) segments that identify KIBS are: NACE 72 (computing services), NACE 73 (research and development) and NACE 74 (other professional business activities).

The purpose of the paper is to evaluate the financial performances of a large sample of Italian firms, operating over the period 2012-2017 and belonging to industries commonly associated with KIBS activities, applying and comparing Data Envelopment Analysis (DEA) and Financial Ratios Analysis (FRA) approaches. This analysis has never been addressed by previous studies, and we want to fill this gap in literature.

FRA, for its simplicity, has been achieved a widespread use in practice. A financial or accounting ratio is a relative magnitude of two selected numerical values taken from an enterprise's financial statements (Heidari, 2012). It is valuable tool of interpreting the financial statements that enables analysts to conduct a certain degree of comparison across firms of different sizes and of firms related to a specific industry sector.

DEA is a mathematical programming technique that estimates the relative efficiency of production units (Decision Making Units - DMU), computing a comparative ratio of weighted outputs to weighted inputs for each DMU and identifies best-practice frontiers over the examined data. Scores equal to 1 are indicated as being technically efficient, whereas if a DMU (e.g. a firm) has a technically efficient value of less than 1, this suggests that the DMU is technically inefficient (Charnes et al., 1978).

The results obtained from the efficiency estimates and the financial ratios are used to rate firms according to these performances.

The next Section (2) describes the dataset (2.1) and discusses the methodology (2.2). Finally, Section 3 points out the results and conclusions.

2 Materials and Methods

2.1 Materials

In our analysis, DEA-based Malmquist indices are calculated at firm level to measure the change in productivity between 2012 and 2017. Thus, in a preliminary step of the overall analysis a list of KIBS companies were identified as actively operating firms during the time frame indicated. The primary source of information was the Bureau van Dijk AIDA database. AIDA contains comprehensive data about financial statement, activity, location and ownership of small, medium and large Italian companies. A preliminary group of organizations were extracted from the AIDA database matching the next selecting criteria:

- according to Corrocher et al. (2012), KIBS business activity related to three main NACE segments: NACE 72 (computing services), NACE 73 (research and development) and NACE 74 (other professional business activities);
- companies with legal status classified as active;
- firms with the complete availability of financial statement data for all the time frame proposed (2012-2017);
- companies that employed between 2 and 250 persons (Small and Medium Enterprises/SME), for all the selected periods;
- firms with value of revenues from sales and services of 100 thousand euro or more, for all the time frame used.

On the basis of the previous search strategy, the research sample was composed of 1.674 firms representative of the KIBS sector and actively operating from 2012-2017. Table 1 provides a summary of the distribution of firms among Italian regional geographical areas and their relative grouping based on the three different NACE activity code adopted.

Table 1 – Geographical distribution of KIBS sample

Regional Area	number of KIBS	%	NACE 72 (computing services)		NACE 73 (research and development)		NACE 74 (other professional business activities)	
			n.	%	n.	%	n.	%

% of KIBS per sector	1674		13.1%		38.8%		48.1%	

In order to examine the methodological issues raised in the next section, for each company, the general and financial items collected were: company name, related NACE code, geographical region in which the firms is located, number of employees, total assets, value of revenues from sales and service, Return On Equity (ROE) and Leverage Ratio.

In line of the choice of inputs and outputs adopted in some empirical studies computing firms financial performance using a combination of accounting-based income statement and balance sheet data (Oberholzer, 2014; Oberholzer, 2013; Ho et al., 2009; Lo and Lu, 2006; Tsai et al., 2006; Luo, 2003; Zhu, 2000), for each organization we defined two inputs (number of employees and total assets) and identified one output (revenues from sales and service). Total assets was defined as the year-end total amount from the balance sheet; the value of revenues from sales and service was computed as the year-end total amount of revenues income from the income statement. Table 2 exhibits some descriptive statistics of data collected (inputs, outputs and financial ratio).

Table 2 – Basic statistics of the whole sample

Item observed	Years			
	2012		2017	
	mean	sd	mean	sd
number of employees	14.3	23.3	18.4	28.7
total assets (th EUR)	3,743.7	10,653.5	4,579.0	14,309.9
revenues from sales and service (th EUR)	3,192.8	8,373.5	3,828.7	10,466.0
return on equity (%)	14.1	30.7	14.4	25.9
leverage ratio	8.5	12.3	7.2	16.6

Even if various financial ratios can be used to evaluate firm' performance from different univariate perspective (Edirisinghe et al., 2007), such as solvency, capital structure, profitability and liquidity, we selected ROE and leverage ratio in order to validate the result of the overall DEA-based Malmquist productivity analysis and to better characterize differences in financial management and efficiency among geographic-based groups of KIBS firms sampled.

As a pure bottom line measure for the shareholders (Yaw-Shun et al., 2013), ROE, defined as net income generated per unit of common shareholders equity, is the ratio that computes a firm's profitability and reveals how much profit a firm generated with the money invested in the firms stocks. The higher of this ratio the higher is the efficiency from the profitability perspective. On the other hand, the Leverage Ratio, defined as the total assets value divided by shareholders equity, is a measure used to understand a company's financial standing. A company with no debt would have a ratio of one; the higher the ratio the more is the debt used to finance the firm and, consequently, the financial leverage.

As previously stated, the linear programming model used assumed constant returns to scale and, because firms observed have a given amount of resources (employees and

assets value) and have to maximise the final results (revenues), we adopt an output orientation. The results of DEA based Malmquist productivity analysis are obtained through the use of FEAR (Wilson, 2008), a software package for frontier efficiency analysis that can be linked to the general-purpose statistical package R.

2.2 Methods

In this study we examine the efficiency of the knowledge intensive business service firms by applying constant return to scale DEA model to compute the Malmquist Productivity Index (Färe et al., 1992). The DEA-based global Malmquist productivity analysis is then used to characterize KIBS firm financial performance through the analysis of productivity patterns grouped by Italian geographical regions.

DEA is a non-parametric optimization-based method that, starting from data on inputs and outputs of a selected sample of Decision-Making Units (DMU), such in our case firms, allow to construct a piece-wise linear surface over data points named best production frontier (or envelopment). The frontier surface is defined by the solution of a sequence of linear programming problems, one for each DMU. The distance between this frontier and the observed data point (DMU input/or output) measures the relative technical efficiency. Relative efficiency ratio is expressed by a score between 0 and 1 for each decision making unit, allowing to rank the organizations on the bases of an increasing efficiency order (i.e. score of 1 for efficient units). Since the pioneer work of Charnes et al. (1978) and because its suitability for multiple-inputs multiple-outputs business context, DEA has become one of the most popular technique for benchmarking analysis. It has been developed in various extended models in many applications and extensively employed in empirical studies to assess performance in different industrial sectors in the field of industrial economics and management (e.g. Tsai et al., 2006; Yang, 2006; Zhu, 2000), and in particular has also been proposed as a model to evaluate the overall efficiency of small and medium-sized enterprises business (Marjanovic et al., 2014; Yang, 2006) and professional service firms (Hsiao et al., 2017; Hsiao et al., 2014; Wang, 2014). In order to further study changes that occurred in efficiency measures in two different time periods t and $t+1$, one of most applied extension is represented by the multi-period efficiency analysis model (e.g. Jianguo et al., 2017; Majumdar et al., 2017).

The concept of Malmquist Productivity Index (MPI) was first introduced by Malmquist (1953) and has further been studied and developed in the non-parametric framework by several authors, where the term productivity is generally used as a metric to evaluate a company's performance over a period and it is also defined as the ratio of the generated outputs to the input used (Egilmez et al., 2013). Caves et al. (1982) applied Malmquist's approach extending the MPI measure by a multi-input multi-output point of view. Combining the measurement of productivity based on MPI with basic measurement of efficiency (Farrel, 1957), Färe et al. (1992) defined an MPI directly from input and output data using DEA, and further decomposed the index into two mutually exclusive and exhaustive components: changes in productivity over time (or efficiency changes - Effch) and shifts in technology over time (or technology changes - Techch). In general terms, the relative efficiency of a decision making unit over time, defined by a relative

distance using DEA, will depend on both its position relative to the corresponding frontier (technical efficiency) and the position of the frontier itself (technological change). In other words, The Malmquist Productivity Index compute firms' deviation of productivity in two different time periods, assuming common technological involvement.

Using an output-orientated model (i.e. to measure the maximal proportional expansion of the outputs given a set of inputs), the Malmquist Productivity Index between periods t and $t + 1$, can be defined as (Färe et al., 1992, Färe et al., 1995):

$$M_{t+1}^t(y_{t+1}, y_t, x_t) = \frac{d_{t+1}(y_{t+1}, x_{t+1})}{d_t(y_t, x_t)} \times \left[\frac{d_t(y_{t+1}, x_{t+1})}{d_{t+1}(y_{t+1}, x_{t+1})} \times \frac{d_t(y_t, x_t)}{d_{t+1}(y_t, x_t)} \right]^{1/2}$$

Where d represent the distance, x and y respectively inputs and outputs, and M is the Malmquist productivity index in time $t+1$ using the $t+1$ technology relative to the production in t using the t technology. The overall equation represents the Malmquist productivity growth of a firm between two periods. A value greater than one will indicate a positive productivity growth from period t to period $t+1$ while a value lesser than one will indicate a decrease in efficiency relative to the previous year. The first term of the equation defines changes in technical efficiency (Effch) from period t and $t + 1$ and the second expression, inside the brackets, indicates changes in technology (Techch). If a firm fails to achieve an output combination on its production possibility frontier and fails beneath this frontier, it can be said to be inefficient (or technological inefficient). Over time the level of output an organization is capable of producing will increase due to technological changes. These variations cause the production possibility frontier to shift upward, as more output are obtainable from the same level of inputs. Thus, for any firm in a specific industry, productivity improvement over time may be either technical efficiency improvement or technological improvement or both.

3 Results and conclusions

The results of the analyzes were reported in Tables 3 (qualitative results) and 4 (quantitative results).

The results obtained from the efficiency estimates and the financial ratios are used to rate firms according to these performances.

The empirical investigation proposed reveals that the results of FRA approach do not provide sufficient and complete information on the efficiency of KIBS firms, while major advantages behind using of DEA are related to its structural characteristic in measuring performance and identifying opportunities for possible efficiency improvements by looking at the differences between efficient companies and inefficient ones.

The results of the analysis show, in the 2012-2017 period, average productivity values lower than one for the Italian regions having significance (or larger number of KIBS) in the examined sample (Lombardia, Lazio, Veneto and Piemonte), with the exception of Emilia Romagna (which has an average productivity value slightly greater than one), with a negative impact on the Italian national level.

The aforementioned may find justification in a poor support of technological innovation in production processes, as confirmed by the techch avg values lower than one for all regions.

The financial indicators (ROE and Leverage) show values that are not always congruent with the average productivity values detected, and for this reason specific in-depth studies are needed to better understand the regional business dynamics that can be subsequently correlated with the average productivity values obtained: this is left to future research.

The empirical results obtained from the analysis of the general sector of KIBS can be further extended and focused to the comparison of firms belonging to a more specific industry sub-sector in order to benefit managers of those companies to gain insight from the industry financial performance benchmarking process.

Abstract

The paper analyzes the VAIC (Value Added Intellectual Coefficient) and the subsequent developments 20 years after the first formulation made by Ante Pulic. The paper deeply analyzes the concept and proposes future directions for research and applications of the methodology. Three main directions for research are described: (i) value creation for stakeholders and investment in human capital; (ii) sustainability of knowledge-based strategies from an economic and social point of view; (iii) a framework for continuous increase of knowledge work productivity. Two real applications of calculation of the Knowledge Work Productivity are described.

Keywords – VAIC, Value added, Value Creation, Knowledge worker productivity, Sustainable strategies, Performance measurement

Paper type – Academic Research Paper

1. Introduction: the problem of the Knowledge worker productivity

It is generally accepted that a strategy based on investment in knowledge workers is the greatest competitive weapon of today's organizations; furthermore, it is a kind of strategy that can lead to a sustainable advantage (Grant, 2010, Ch. 6: 150-173). By sustainable growth strategies we generally mean the firm behaviors that in the long run tend to legitimize the social, environmental and economic expectations of all

stakeholders, both internal and external (Donaldson and Preston, 1995; Drucker, 1999b). The necessary condition to create wealth for all stakeholders is, according to Drucker, the growth in productivity of knowledge workers.

In fact, P. Drucker believes that “knowledge worker productivity is the biggest of the 21st-century management challenges. In the developed countries, it is their first survival requirement”. He argues that “the ability of organizations...to survive will come to depend on their comparative advantage in making the knowledge worker more productive” (Drucker, 1999b: 94). But, how can we increase the productivity of knowledge workers? Drucker sets the agenda of things to do and lists the major factors affecting the increase in the productivity of knowledge workers (Drucker, 1968; 1999a; 1999b):

- a) knowledge workers themselves have to plan what the task is or should be. In fact, in knowledge work, unlike manual work, the task does not program the worker;
- b) knowledge workers have to manage themselves (autonomy);
- c) knowledge work requires continuous innovation and learning;
- d) knowledge workers have to plan the quality of their output;
- e) knowledge workers productivity requires that the knowledge worker is seen and treated as an asset rather than a cost.

The supply and the productivity of people educated and trained for knowledge work are the only possible advantages that developed countries can hope to have.

But, can this productivity advantage be measured or is purely an “intangible thing”? Drucker does not offer an answer to this question.

The problem of measuring the productivity of knowledge workers is a very practical need for the s.c. knowledge-based firms, also in terms of incentives and rewards to be assigned to employees. But the first step is to measure the productivity of knowledge workers. How can I assign a reward to employees if I am not able to measure their productivity?

The author who accepts the challenge of measuring the productivity of knowledge workers is A. Pulic (2000; 2004; 2008). The main objective of Pulic is to find a productivity “measuring model” for the knowledge economy which will serve employees, management, investors, and business partners (Pulic, 2008: 6).

He believes that the method for measuring the productivity of knowledge workers is the same as the one used to measure the productivity of manual workers. The productivity of knowledge workers is equal to the ratio between the Value Added and the wages of workers. Other authoritative scholars share the same opinion (Kaplan and Norton, 1996).

From a methodological point of view, therefore, there is no relevant news, because everything we need is the Value Added Income Statement (VAIS). However, Pulic and Drucker think that the VAIS must be reinterpreted, and this requires a “change of mentality”, namely a new “semantic” of the value creation.

We have to start from the premise that “people are investment and not cost anymore” and that the cost of labor (intellectual), in the income statement, measures the investment in human capital rather than a cost.

If this change of mentality is accepted, then the Value Added measures the value created by knowledge workers for the whole economy, namely the value added measures the value creation from the stakeholders' point of view. Then, to increase the productivity of knowledge workers we have to increase their value added. This is Pulic's answer to the problem left open by the seminal Drucker's effort.

The original definition of the VAIC is based on variables extracted from the Value Added Income Statement as in the following table:

Tab. 1. "Value Added" Income Statement

Sales	OUT
- Costs	IN
= Value Added	VA
- Salary and wages	HC
= Structural Capital (EBITDA)	SC
- Depreciation and Amortization	D + A
= Operating Profit	P

VAIC (Value Added Income Statement) was defined as follows:

$$VAIC = HCE + SCE + CEE \quad [1]$$

where:

HCE = Human Capital Efficiency or work productivity = VA/HC

SCE = Structural Capital Efficiency = SC/VA

CEE = Capital Employed Efficiency = VA/CE (where CE = book value of Capital Employed)

In the following sections three main directions for future research and applications are described: (i) value creation for stakeholders and investment in human capital; (ii) sustainability of knowledge-based strategies from an economic and social point of view; (iii) a framework (with applications) for continuous increase of knowledge work productivity.

2. A first direction of research: value creation for stakeholders and investment in human capital

In this section an analysis of (i) value creation from the stakeholder point of view and (ii) the investment in human capital is carried out. These two items are the main theoretical topics at the basis of the VAIC concept.

2.1 Stakeholder point of view and Value Added

In the traditional way of measuring the company performance of an organization the focus is mainly on value creation for the shareholder (*shareholder point of view*) (Jensen, 2002). But, as already seen, a strategy that is socially sustainable has to create value not only for the shareholder, but also for the other stakeholders and, in particular, for the employees.

A strategy that only considers the shareholder's interests is a strategy that can only be satisfactory for a part of society. The idea underlying performance measurement in terms of satisfaction only from the point of view of the shareholder is based on the idea that by maximizing profit (NOPAT, EVA, Dividends, etc.), also social wellbeing is maximized. But it is immediately evident that the economic facts of the last twenty years, dominated by the *shareholder value analysis*, have not brought social benefits for everyone, as promised. Mass unemployment, a characteristic of the current world economy, does not confirm that the "philosophy" of *shareholder value analysis* has brought socially sustainable benefits.

The reason, as Pulic (2000; 2004; 2008) states, is that value creation has not been correctly measured. Value from the social sustainability point of view cannot be measured only by EBITDA or by other measures such as EVA which are based, on final analysis, on NOPAT which is a variant of EBITDA.

In fact, the EBITDA measures the value created for all capital investors (within which category there is also the shareholder) whereas value created for all the stakeholders is measured by Value Added. This is the fundamental criticism that Pulic (2000; 2004; 2008) makes to traditional value measurement methodologies.

According to Pulic, in addition to value created for capital investors and for the shareholder, it is necessary also to consider value created for employees, which is measured by wages and salaries, that is by the capital invested in acquiring human resources. Value Added is, therefore, the adequate measure of value creation from a stakeholder point of view.

According to Pulic (2000; 2004, 2008), from the point of view of society as a whole, value created is equal to:

$$VA = HC + EBITDA \quad [2]$$

where:

VA = Value Added

HC= Human Capital (= Cost of Employees = wages and salaries)

EBITDA = Earnings Before Interest, Taxes, Depreciation and Amortization

Expressing EBITDA in terms of its components, it holds that:

$$EBITDA = \text{Interest expenses} + \text{Taxes} + \text{Depreciation/Amortization} + \text{Net Income}.$$

The latter definition stresses the fact that in EBITDA, less taxes, there are the remunerations of various capital investors, understood in the physical sense and in the financial sense (and therefore also shareholders).

Some elucidation is needed to link the equations [2] with the themes of Knowledge Management. Knowledge that creates value is incorporated in Human Capital (people). Pulic states that: "People are the main carriers of knowledge" (Pulic, 2008). If this observation is correct then expenditure on human resources has to be seen as an investment and not as a cost: "it is only reasonable to give this resource the status it deserves of investment and not cost anymore" (Pulic, 2008). But: "employees, who are treated as investment, are the beginning and the end of the new, knowledge-based,

economy” (Pulic, 2008). The reason for investing in human resources is that they are “the main value creators of the contemporary economy” (Pulic, 2008).

Now, considering human resources as an investment and not just a cost, needs a change in managerial mentality. In fact, costs owing to their nature have to be cut and the traditional performance measurements are based on a logic of “cost cutting”. To increase the EBITDA the cost of human resources is also cut. But, if human resources are the source of value creation then cutting them can be a “short-sighted” strategy in the long term. Maybe the saying: “the lower the cost, the higher the profit” can be fine for the cost of raw materials and energy costs, but not when it refers to human resources. The reason is obvious: human resources create value.

2.2. Investment in Human Capital: a type of investment in living knowledge

Knowledge can be understood as the ability to act for survival implemented by organizations (Maturana and Varela, 1992). The actions for survival are solutions to problems and require creative thinking and ability for innovation. Knowledge is therefore a typical human characteristic that should not be confused with the knowledge embedded in machines. For this reason we distinguish the knowledge incorporated in the human mind (*living knowledge*) as distinct from the knowledge embedded in technology investments (*dead knowledge*).

The strategy based on investment in knowledge, suggested by Drucker and Pulic, can be better described by using the distinction cited above.

When investing in human resources, trust is placed in “*living knowledge*”, which is incorporated in the employees, that is, in people. It is believed that only human beings are able to create new knowledge and, therefore, produce Value Added in such a way to justify investment. Only qualified and educated human resources are, in fact, able to create patents, copyrights, know-how, etc. Moreover, only highly-trained human resources are able to increase the quality and quantity of intangible assets (organizational relations and relations with customers).

Value creation for all stakeholders therefore necessitates heavy investments in highly trained and skilled human resources. It is from this type of resource that comes value added suitable to make investment in HC convenient.

The other more traditional strategy places its trust in “*dead knowledge*” incorporated in ever more perfected machinery whose use is “labor saving”. The machine, as far as it is technologically advanced and innovative, is to be considered as an archive, a “record” of human work previously provided. It is “stored”, crystallized knowledge that is no longer vital. Furthermore, *dead knowledge* cannot self-activate but, in order to be used, it requires other *living knowledge*.

The problem with this value creation model is that it can determine problems at the overall level in terms of social sustainability.

The model based on *dead knowledge* results in a low use of workforce and in particular of skilled workforce. It can be good for the firm in itself but not for the overall economic system. The more firms using the *dead knowledge* model, the less the social

sustainability at an overall level. Therefore, there has to be a high number of industries using the *living knowledge* model in order to assure overall sustainability.

The model based on living knowledge (human resources) is the one that determines sustainability in social terms of the global system.

At a global and social level, it is necessary to understand what is the fundamental driver of value creation. That is, it is necessary to place human resources at the center of management and understand that the following factors are crucial:

1. first and foremost, it is necessary to aim at innovation, which is able to continuously increase the knowledge content of products and services. Continuous innovation is nothing other than new knowledge for the growth of value added.
2. secondly, it is necessary to develop and increase employees' skills with the aim to develop value added of products and services.

It is necessary, definitively, to abandon the idea that profits are low because the costs are high and think instead that profits are low because the Value Added is low.

3. A second direction of research: sustainability in knowledge based strategies

Using formula [3] the significance of fundamental strategies for value creation can be explained.

The basic strategies are:

1. grow the “cake” (VA) in such a way as to increase both HC and EBITDA;
2. redistribute the “cake” (VA) reducing HC and increasing EBITDA;

In the first case, the increase in work productivity is obtained with a labor intensive strategy. In the second case, on the contrary, the increase in work productivity is obtained with a labor saving strategy.

This concept can be illustrated in the following way.

Equation [3] can be rewritten in the following way in terms of variations:

$$\Delta VA = \Delta HC + \Delta EBITDA \quad [3]$$

If we invest in human resources ($\Delta HC > 0$) and if there is an increase in the VA such that $\Delta VA > \Delta HC$, then there is also an increase in working profits ($\Delta EBITDA > 0$).

Note that the condition $\Delta VA > \Delta HC$ is the main feature of investment in human capital. Note, also, that this is what Drucker and Pulic intend when saying “invest in people”.

This is an example of Economic/Social Sustainable Strategy (ESS) because it creates new value for employees ($\Delta HC > 0$) and for capital investors ($\Delta EBITDA > 0$). It could be said that such a strategy is an example of “Win-Win” strategy that does not dissatisfy anyone, since it creates new value for everyone.

In order to allow the knowledge worker productivity to be increased, the win-win strategy has to further satisfy the condition $\Delta VA\% > \Delta HC\%$. In this case, also VA/HC will be increased.

It is for this reason that it can be understood as a socially sustainable strategy. Using the metaphor of a “cake” (Pulic, 2004), it can be said that a *Win-Win* strategy does not dissatisfy anyone because there is an increase in the size of the “cake” (Value Added) and, therefore, an increase in the size of the “slice” apportioned to human resources (HC) and in the one apportioned to all investors (EBITDA).

Therefore one should ask: why is the *Win-Win* strategy not adopted by all firms?

The reason can be explained using, again, equation [3].

If one invests in human resources ($\Delta HC > 0$) which however have a low knowledge content and a low professional qualification, the growth of Value Added, as a result of investment, may be insufficient, and in particular can be lower than the investment realized ($\Delta VA < \Delta HC$). In this case there is a reduction in profits for all investors ($\Delta EBITDA < 0$). This is what happens in some sectors that, for their nature, do not invest in human resources but in machinery.

In these sectors, in order to make profits grow, there is often a reduction of the workforce (destruction of the value quota of employees) through a growth in work productivity obtained by investing in *labor saving* plants. In these cases the growth of value only for investors ($\Delta EBITDA > 0$) and the growth of the work productivity (VA/HC) is obtained by the destruction of investment in human resources ($\Delta HC < 0$) by means of reducing employment. This is an example of occupational strategy of the “*Lose-Win*” type, since there is the creation of value only for capital investors.

The “*Lose-Win*” value creation model is mainly based on *dead knowledge*, while the “*Win-Win*” model is based on *living knowledge*, as will be clarified in the next section. But the *Lose-Win* strategy is not socially sustainable in the long term since it destroys jobs and income for employees.

The characteristics of the two strategies are represented in the following table.

Tab. 2. Characteristics of the two strategies

	Shareholders	Win	Lose
Workers			
Win		<i>Win – Win</i>	<i>Win - Lose</i>
Lose		<i>Lose – Win</i>	<i>Lose-Lose</i>

where, for the strategies in the first column, we have:

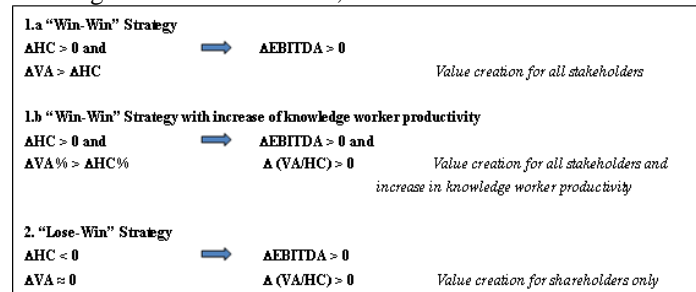

Fig. 1. The two main strategies of value creation

Note that a Win-Win strategy is not a utopian strategy. In fact, there are concrete examples of Win-Win strategy (Iazzolino et al., 2017).

4. A third direction of research: a Framework for Continuous Increase of Knowledge Work Productivity

Today, almost 20 years later the sentence by Drucker: “In terms of actual work on knowledge-worker productivity, we will be in the year 2000 roughly where we were in the year 1900 in terms of the productivity of the manual worker“ (Drucker, 1999b), the situation has not changed significantly and the same challenge is still present.

However, before a possible solution can be presented, it is necessary to clarify some facts. First, knowledge work (KW) takes place in a very different environment:

Tab. 3. From industrial to knowledge economy (Gleeson and Hargaden, 2014)

Industrial Economy	Knowledge Economy
Manufacturing Cell	Workgroup
Production Line	Business Process
Factory	Organization

What is the main difference between these two epochs? Value creation in the past was a function of economies of industrial scale: mass production and the high efficiency of repeatable tasks. **Value creation today is based on economies of creativity and innovation:** mass customization and the high value of bringing a new product or service improvement to the market. The ability to find a solution to customer’s problems or the way a new product or service is sold and delivered (Huges, 2013). All this brings the knowledge workers in foreground. They are today the dominant creators of values. Therefore, it is essential to keep track of their value creation efficiency.

There has been one big change during Taylor’s era that enabled the "productivity revolution". Namely, it was based on improving the work of the individual, manual, workers. On the other hand, today, knowledge workers create value through team work, within business processes.

Knowledge Worker Productivity can be defined as:

$$HCE = \frac{VA}{HC} \quad [4]$$

where:

HCE = Human Capital Efficiency

VA = Value Added = Sales – External Costs

HC = Human Capital, i.e. Cost of employees (Salaries and wages)

In the following two examples of calculations of KWP, on business processes and on a project team, are shown.

Case 1: Process efficiency and Knowledge Work Productivity

This process has its own input that consists of material and KW. At the end there is output whereby everything can be shown in the following way:

Fig. 2. Process of Food Safety Analysis

In order to accomplish the task, the required resources for the process are established. Since the client paid the agreed price it was possible to calculate VA and PE. So far, this data does not yet tell us whether the efficiency of the process can be improved.

Therefore, the next step would be to analyse the process from the point of view of its components or sub processes. The task was to make an analysis for the customer, in which auxiliary activities, laboratory and analytical work took place. Thus, the process was divided into three sub-processes.

Fig. 3. Sub-processes

As mentioned in the previous section for the entire process, it was necessary to first determine the required resources: material and KW and their output: revenue, value added and KWP for each sub-process. In this way we got the following amounts (all in €) and the financial results achieved.

Fig. 4. Input and output for the process and its sub-processes

After the determined results were obtained, their analysis could begin. We found out that at process level, with the material resources, consisting of the chemicals used in the analysis, some reductions that would significantly affect productivity could not be made. It is evident that this is a very small amount, which accounts for only 7% of the total input.

Therefore, in order to improve the efficiency of the process, KW had to be looked for. As can be seen, Activities 1 and 3 do not require a lot of KW, about each 14% of the total used in the process. That is why it was necessary to make a more detailed analysis of Activity 2.

Fig 5. Flow chart of Activity 2

Based on this it was determined how many knowledge work were needed:

Sub – Process Analysis	ACTIVITY 2 – KW Structure	Before	Head of Department = 2 h	Expert Worker = 3 h	Laboratory Worker = 2,5 h
		After	Head of Department = 1,5 h	Expert Worker = 2 h	Laboratory Worker = 2 h

Fig. 6. Analysis by type of knowledge work used

This is a key part of the approach. Three different types of knowledge work were involved in the analysis: routine work, mixed work, non-routine work. Sub-process (Activity 2) spent 7.5 hours of KW. After the conducted analysis, the same job was done in 5.5 hours. This means that in this sub-process there were 2 hours of non-value added work.

Fig. 7. An enhanced process with higher KWE

Thus, the reconstruction of the sub process labelled "Activity 2" achieved the same result, 1.248 created VA, but with a reduced amount of KW, resulting in an increase in productivity of PE = 2.75.

Now, it remains to be seen how the knowledge workers will be rewarded for this productivity increase. Before the process has been upgraded he made Earning Pure (EP) in the amount of 200. After the improvement, the EP was increased to 352 so the ΔEP was 152. Productivity premium (PP) is calculated: $PP = \Delta EP * KWP / 100$ (with the condition that $EP > 0$). So follows:

$$PP = 152 * 2,75 / 100$$

$$PP = 4,22$$

which is the amount that will be rewarded to the employees, who have achieved productivity gains. Although it may seem at first glance that this is a small amount, it is not the case. When the same calculation is made on an annual level, a decent amount of 13,010 is obtained (only for that process). That is why Taylor's and Drucker's requirements have been met by allowing employees to be rewarded for efficiency increases. But, it is no less important to note that PP is a motivating factor for all employees in the process to look for ways to increase overall productivity.

All of the above has been tested on a lot of examples. So I can repeat what Shiego Shingo, the master of lean manufacturing, said: "My medicine works, but only if the patient takes it"

Case 2: Knowledge Work Productivity for a project team in a knowledge-based firm

The considered firm is an Italian spin-off operating in business simulations for education and recruiting. The firm is based on scientific and professional competences of founders, academics and practitioners, in the fields of ICT and Business Economics.

The employees of the firm are 6:

- 2 Computer Engineers
- 2 Management Engineers
- 1 Project Manager
- 1 Graphic and Web Designer

The calculation of the productivity of knowledge workers has been implemented for the case of the development of a new product. The new product is an innovative software to be used in education and evaluation of human resources. It is a “web in-basket”, an individual role-playing simulating a particular organizational scenario, in which decisions are requested to be made for different levels of complexity. The following steps were implemented for the new product development:

- construction of the simulation scenario
- development of the software
- development of graphics
- launch on the market and sales

The development of the new product was assigned to a specialized project team, composed by a subset of the employees of the firm that assumed the following roles within the team:

- 1 Business Analyst (a management engineer)
- 1 Software Developer (a computer engineer)
- 1 Graphic (the graphic and web designer)
- 1 Technical-Sales person (a management engineer)

The software developer and the graphic developed respectively the software and the graphic of the product (Gui – Graphical user interface), after the business analyst has designed and implemented the scenario. The task of the technical-sales person was particularly important as he was engaged in sales. A successful approach to the customer needs the operator to be deeply aware of the technical characteristics of the product and in

particular of the innovation content of the same product, that has to be emphasized in the negotiation with the customers. The technical-sales person is able to perceive whether the sale was successful because the customer understood and appreciated the innovation embedded in the product. Therefore this allows us to determine what is the quota of sales (and also of the value added) that is attributed to the innovativeness of the new product.

In the following table the Value Added Income Statement of the firm is shown (year 2015).

Tab 4 – Value Added Income Statement year 2015

VALUE ADDED INCOME STATEMENT 2015	€	%
PRODUCTION	€ 350,958	100%
External Costs	€ 173,465	49%
VALUE ADDED (VA)	€ 177,493	51%
Cost of Employees (Human Capital)	€ 163,170	46%
EBITDA	€ 14,323	4%

The detailed Cost of employees for 2015 is included in the following table.

Tab 5 - Cost of employees

Cost of employees (overall)	No. units	Average Cost	Total Cost
Computer Engineer	2	€ 23.210	€ 46.419
Management Engineer	2	€ 34.805	€ 69.610
Project Manager	1	€ 26.854	€ 26.854
Graphic and web designer	1	€ 20.287	€ 20.287
Total cost of employees	6		€ 163.170

The components of the project team were not engaged full time in the development of the new product. In general they are assigned to different projects and teams during the year. From the analysis of workloads, the percentage of the engagement in the team was calculated for each component. In the following table the percentage of time and the total cost of the project team is shown.

Tab 6 – Cost of the project team

Cost of the project team	Cost	% engagement in the team	Cost of unit in the team
Business Analyst (a management engineer)	€ 34.805	30%	€ 10.442
Software Developer (a computer engineer)	€ 23.210	70%	€ 16.247
Graphic	€ 20.287	50%	€ 10.143
Technical-Sales person (a management engineer)	€ 34.805	50%	€ 17.403
Total cost of the project team			€ 54.234

Now it is necessary to calculate the quota of the overall Value Added attributed to the new product. This estimation was possible thanks to the technical-sales person who, as already explained, has a direct perception of the impact of the innovativeness of the new product on the customer. Therefore, the Value Added attributed to the new product was 42% of the overall value added, and then € 74.547.

Tab 7 – Value Added attributed to the new product

VA attributed to the new product	42% of the total VA	€	74.547
---	---------------------	---	---------------

Now it is possible to calculate the productivity of the new product development project team for 2015. It is given by the ratio between the Value added attributed to the new product and the cost of the project team.

Tab 8 – Productivity of the project team

PRODUCTIVITY OF THE PROJECT TEAM =	VA new product	€	74.547	1,37
	Cost of the project team	€	54.234	

The calculation of the productivity can be useful for the policy of rewarding of the firm. Let us suppose that the top management fixes a threshold for the productivity above which the team will receive a bonus. These kinds of firm mainly work basing on projects and then teams; therefore, at the starting of the year, it can be stated that the teams that will obtain a productivity above the threshold will receive a bonus, the others will not. The threshold can be chosen following subjective criteria or can be for example the average productivity of the firm. In this case study the average productivity is calculated as the overall ratio Value added / Cost of employees. In the following table the calculation is shown.

Tab 9 – Average productivity of the firm

AVERAGE PRODUCTIVITY OF THE FIRM =	VA (overall)	€	177.493	1,09
	Cost of employees (overall)	€	163.170	

Therefore, as the productivity of the project team for the new product development is greater than the average ($1,37 > 1,09$), the team will receive a bonus (to be decided) and to be equally distributed within the team.

5. Conclusion

Although nearly 20 years have passed since Drucker pointed to the obligation of raising KW productivity there is not much literature or concrete solutions. One of the most interesting attempts that has been published is the article “Productivity in Knowledge Worker Teams” (Moreno et al., 2013). This article suggests that the team should become the unit for analysis, as the team can be seen as the link between the individual and organizational frameworks, which is logical and acceptable. However, the problem is, that this productivity is expressed in a classical way: the realized profit or spent hours. Although the article provided some insight into the state of the process, it does not mention a way to improve it.

Another, a far more ambitious, attempt was made by Cintron (2013). His analysis rests on processes and their value created. The Knowledge Value Added (KVA) plus Matrix of Change (MOC) plus System Dynamics (SD) are a framework that has been presented with its utilization of knowledge as a determinant of value from execution of processes. The analysis was conducted on two specific examples, namely the UAV (Unmanned Aerial Vehicles) Case Study and the Case Study of a Shipyard. Both examples showed that measurement by VA in sub-processes provides realistic data on the success of the whole process and provides a basis for the possibility of its improvement.

The main problem is the way of calculating VA. It uses a methodology, the Knowledge Value-Added (KWA), which is relatively unknown. However, its biggest problem is the complexity of data that it calculates. It is not easier to get the other two parameters: MOC and SD. That is why the authors of this paper do not believe anyone in the business world would be interested to apply it. On the other hand, the greatest value comes from the fact, that it has been shown on realistic examples, that without measurement in processes, the efficiency of knowledge work cannot radically be increased.

The indicators VA, PE and KWP presented in this article, are an objective and useful measure for knowledge economy. VA, PE and KWP translate the knowledge applied in processes into numbers. Using these objective measurements, managers have the possibility to make scenarios for comparing the processes and technologies used to create their outputs. All this opens a way for continuous improvement of the efficiency of knowledge work.

Furthermore, there are two key reasons in favour of continuously improving the value creation efficiency of processes:

- First, because the current state of the process is never perfect. This means there is always space for improvement, that is, to increase its efficiency.
- Second, the business environment is constantly changing. This ranges from small process' improvements to disruptive technological and organizational innovations.

In the end, KW can be understood and described as something abstract but also as something very concrete. It depends on our perspective. For example, we can ask abstract questions such as "Am I right that we don't know much about knowledge work?" (Efimova, 2003). But we can also ask ourselves how much our individual, as well as our collective knowledge, has contributed to creating value for our company and our community each day. I suppose that all knowledge workers, who create value successfully, would probably be happy to get proof of their work productivity and support measurement, especially if it could result in a monthly bonus.

Abstract

An Italian company, which some years ago activated an Information Technology (IT) innovation process, has had to manage several requests pertaining to the founding of new IT projects or of introducing procedure improvements. After some years, the office in charge of this work activated an in-depth study of the procedure and its results to maximise the value of the IT implementations. Some weak points were identified and some different procedures were simulated to analyse the impact of the data and of the data treatment on the results.

A new approach, which methodologically improved the data acquisition procedure as well as the request evaluation and selection, was then defined. At the same time, the office decided to activate the knowledge resources of the organisation, in order to actually improve the whole IT innovation process and reduce or control the complaints that are inevitable after any selection activity that has to reject some proposals and fund and activate others. Some actions were implemented to involve other offices in the IT innovation process, for their competences in relation to some aspects of the innovation requests, and to facilitate cooperation and improve communication with the company sectors that were and are still used to proposing projects or procedure improvements.

After one year, the new approach produced interesting results, in relation to the IT request quality and to the reactions to the first steps of an organisational change process that was oriented towards improving knowledge sharing, cooperation and effective and transparent communication. Some procedural improvements have not yet been implemented, because such a drastic change could produce a negative reaction, and the possible consequences still need to be studied not only in relation to the quality of the request evaluation and selection, but also considering any possible organisational effects. A synthesis is here proposed of the analytical tools, which were used to methodologically and operationally analyse the past experience and to identify some weak points, and the organisational tools, which were then used to activate and share knowledge, starting from a new relationship between the involved actors, and to attempt to activate an

organisational change, that is, from a centralised activity to a shared communication space, and finally to put it to the test.

Keywords – Managerial challenge, Strategic resource, Knowledge sharing, Organizational knowledge dynamics

Paper type – Practical Paper

1 Introduction

Some years ago, an Italian company with 3200 employees arranged to stimulate requests, from the organization, of Information Technology (IT) new projects or of specific application improvements. It charged the office of IT demand management (which is shortly called DEMAND) with requirement acquisition and analysis, to map the whole company requirements and to plan the implementation of the most “interesting” and/or urgent requests.

DEMAND gathered approximately one thousand requests every year from the 15-20 sectors of the company, analysed the characteristics the proposers have indicated and the costs of each IT intervention, in order to plan and implement the most urgent requests and the others with the highest priority. Around 10 million euros were every year allocated for IT interventions.

After some years, while the request number was growing and the budget reducing, some doubts arose about the reliability of the acquired data, on costs and benefits of each IT possible intervention, and therefore about the decision. The main question was: “How can DEMAND maximize IT implementations value”. For this reason, an in-depth study of the procedure and its results was developed and some simulations were made, to analyse the impact of the data and the data treatment on the results. This study stimulated some changes that produced interesting results and the activation of an organisational change process.

The next section describes the nature of the problem and the tools, which were used to analyse the past use of the data and to identify and communicate weak points of the procedure.

The third section analyses the new approach, which was adopted to activate the knowledge resources of the organisation, in order to actually improve the whole process of IT innovation and to reduce or control the complaint that is inevitable after any selection activity that has to reject some proposals and found and activate some others.

The last section discusses the practical implications of the new approach, together with the dynamics and the risks that a new knowledge sharing vision can generate.

2 The problem and the methodological approach

Any company that stimulates IT innovation receives a growing number of proposals, year after year, and at a certain moment it has to reject some projects and application

improvement requests and to plan and implement others. This action requires a formal decision process, which is called “project selection”, in the areas of Project Management and Multicriteria Analysis. Several procedures that use economic approaches to evaluate and prioritise projects (Net Present Value, Internal Rate of Return, Benefit/Cost Ratio, Opportunity Cost, Payback Period, Economic Value Added, Initial Risk Assessment) are suggested in literature in the area of Project Management, but the values they estimate often cannot be applied to IT projects and require at least a certain minimum formalisation of the projects that have to be evaluated. Many of the costs and benefits are hidden, the lead times and pay-offs tend to be long-term and the risks are difficult to assess, all of which makes it problematic to select a proper rate of return (Milis and Mercken, 2002).

Multicriteria Analysis deals with the “project selection” problem starting from the identification of the preference system of the company. Multicriteria models and methods are used to select and exclude projects that do not present consistency with this system. This methodology can also be used in the early stages of the project definition. Relevant criteria and their weights are identified and formally defined, but the synthesis of the evaluations is not the weighted sum of the values and it depends on the specific class of multicriteria methods (Figueira et al., 2005).

The nature of a project selection problem changes in relation to the decision system (i.e. decision makers, rules and formal relationships between them and the other actors in the decision process) and to the state of knowledge that is present in the organisation or which can be activated (Norese, 2016). Several studies have analysed this kind of problem, and some methods have been proposed and used to facilitate the selection of projects, but also of offers, possible investments or programmes and, with the same logic, the management of suppliers or human resources (see, for instance, Costa et al, 2003; Norese and Viale, 2002; Norese, 2009; Viezental et al, 2010; Zopounidis and Doumpos, 2002).

DEMAND, the office that is in charge of this project selection procedure, set up good relationships with the different sectors of the company that could propose new IT projects or improvements of some IT applications and which have to document the different benefits that are associated with each project/improvement. A set of indicators has been created over the last seven years to allow all the possible benefits of these IT interventions to be appreciated. The actors of this decision process (IT intervention proponents, IT Area, DEMAND, PMO and General management) have in fact suggested these indicators year after year.

In 2017, the problem was completely reformulated, and an evaluation procedure was created to synthesize the evaluations, in relation to the set of indicators, and to rank the requests in relation to their characteristics. This new approach was adopted as a result of the need for more transparency and effectiveness of the IT implementation process.

An in-depth study of the new procedure and its results, in relation to the past and new data, was simultaneously developed. DEMAND was open to criticism, because it was evident that some requests, which were essential for the company, sometimes resulted in positions that were not so high in the ranking. Some weak points of both the indicators

and the new procedure were identified, from a methodological point of view, and some variants of the new procedure were identified and tested, in relation to certain new data treatment proposals. DEMAND considered the new proposal useful, and it stimulated some improvements of the procedure in 2018 as well as the activation and sharing of knowledge resources, in order to discuss, plan and implement a new IT demand management process.

This section describes the methodological approach that was used to analyse the evaluation procedure and to identify and communicate some possible new improvements and a multicriteria model proposal.

2.1 Methodological analysis

The first step was an analysis of the approximately one thousand requests made in the year 2017, which underlined their great dissimilarity and therefore their difficult comparison and ranking (Roy, 1996). Several different sectors in the company presented requests. Some sectors, working on the internal processes of the company (e.g. administrative planning and control, finance, compliance), proposed IT interventions to improve internal procedures (controlling operational risks, adapting procedures to new regulations, ...). The requests of other sectors (e.g. strategic marketing, claims, life insurance, ...) were of a different nature and were in general oriented towards improving communication with the present or future clients. The analysis of the requests made in the year 2017 distinguished the need for some evidently urgent interventions from the need for expensive and long procedural and technical changes, associated to some innovative projects. Some requests resulted to be clear, simple and not expensive, but their economic benefits for the company were not easily quantifiable.

The data and the implicit model the proponents had used to describe their requests were analysed, and it was evident that several possible benefits had been included by means of an often very limited and sometimes wholly absent valorisation of the benefits.

An indicator of IT intervention cost was used to analyse the complexity of the requests, to distinguish the different levels of complexity and to identify some evident outliers, which needed to be dealt with separately. Contemporarily, it was evident that the cost indicator was not often present (absent in more than 25% of the requests) because the IT Area had not been able to quickly evaluate the costs of more than one thousand requests.

As a variant of the new procedure, four different categories were proposed to distinguish the requests oriented towards:

- including new regulations in IT previous applications,
- improving internal processes,
- meeting the needs of the agencies, and
- improving the relationships with the clients.

A fifth category of transversal requests was considered. A different multicriteria model was created to rank the requests of each category. Each model included three or four specific and consistent benefits, which were extracted from the seventeen components of the original indicator set. Several simulations were implemented, and the results were

proposed to DEMAND for analysis. A cutting level was proposed for each category, in order to distinguish acceptable from unacceptable requests.

A comparison between these results and the original ranking underlined the consequences of some weak points of both the indicators and the evaluation procedure, and suggested some new models (one for each category) and some variants in the numerical or logical combinations of the data, and therefore new simulations and result analyses. As a consequence of this analysis, a new IT demand management process was outlined and proposed, to be discussed and implemented with the involvement of other company offices.

3 Knowledge resources to improve the IT innovation process

Several innovations were introduced in 2018 and communicated during some meetings in spring and summer, with the involvement of the proponents of the improvements and IT projects, in order to explain the motivations and nature of each innovation, to create new relationships between sectors and DEMAND, and therefore to facilitate the implementation of procedural and organisational changes in the following autumn.

The data acquisition procedure was changed for the first time in seven years, and other offices, with competences in relation to some data analysis and use procedures (Risk management, Compliance, Customer experience, Big Data, Lead Time, Profitability and so on), were involved in the demand management procedure. Cooperation between these offices and DEMAND improved the quality of the evaluation procedure and model. Their involvement in the meetings facilitated the communication of each change. Furthermore, their knowledge was made available to the different sectors, to facilitate them in valorising the benefits of their requests.

The new evaluation procedure reduced the workload of the IT Area, which was still involved in the cost estimation, albeit with less urgency and for a reduced number of proposals.

DEMAND also reorganised its work in order to create an institutional and operational exchange with the different sectors, along the whole IT innovation management process, and to increase reliability and effectiveness of the new data acquisition procedure. The request evaluation and priority definition procedures were changed, and several of the proposals that had been discussed during the analysis of the previous procedure were adopted.

3.1 The new procedures

The proposal of a cutting level, in order to distinguish acceptable requests from unacceptable ones, was partially accepted and this level was proposed to the proponents of the request as something that could easily be verified before the presentation of a request. This new message was combined with another indication: the need to monitor the effects of each IT innovation implied that each IT intervention proponent was required to propose a future monitoring (when, in what way, by means of what procedure). These

messages produced some interesting results, in relation to the IT demand: a 55% reduction in requests, an increase in the high-value requests from 36% to 43% and a reduction in the low-value requests from 64% to 27%.

Another new procedural element was introduced, that is, the requests were divided into seven categories, each with a different priority, and different procedures were defined to evaluate the requests and rank them, but only if needed.

The last change was a two-step evaluation procedure for the category with the maximum number of requests (371 out of the 562 requests). It allowed the benefits to be evaluated and compared with an acceptability value (the cutting level). The cost estimation was thus postponed, in order to reduce the work of the IT Area. Only the costs of the requests with benefits at least equal to the cutting level were estimated, and the combined cost/benefit indicator was used to rank the requests.

Communication of the procedure results became more transparent than in the past, in relation to both the proponent sectors and the IT Area that will implement the new projects and application improvements. The temporary and final results were communicated to the request proponents in December 2018, by means of a report (the Master Plan) on the company's intranet. This report has to be updated at least six times a year.

The Master Plan became an important communication space because it included notes and requests to some proponents (for a necessary clarification of their proposals or some new data acquisition), the category in which each proposal had been assigned, its position in the ranking and the state of the process evolution for each request ("to be evaluated", "evaluated and classified", "in the implementation plan", "implementation postponed", with the motivation for the postponement, "implementation activated" or "completed").

4 Conclusion

The improved relationship between internal offices, and a new valorisation of their knowledge, in a process in which they had not been involved in the past, were greatly appreciated by the company. DEMAND improved the quality and the results of its work, but the internal dynamics of the company also improved. This new use of organisational knowledge, together with new interactions and co-creation of value (Kohtamäki and Raiala, 2016; Ramaswamy and Ozcan, 2018), may have activated an organisational change process, from a centralised activity to a shared communication space. However, this organizational change has still to be put to the test.

This new knowledge sharing vision can generate risks. The Master Plan guarantees transparency, but can also reduce the "bargaining" space to some exceptions to be sent to an authorised management level, and can generate criticism to anything in the report or an automisation proposal of a process that now, for the first time, involves several sectors of the company. However, procedures of sharing *knowledge embedded in the interactions of people, tools and tasks provide a basis for competitive advantage in firms* (Argote and Ingram, 2000).

Some suggestions, from the analysis of the original procedure of data acquisition and request evaluation, have not yet been implemented, because a too drastic change could have produced a negative reaction. Some new model and procedure improvements will be tested this year, but the possible consequences of any new change needs to be studied, not only in relation to the quality of the request evaluation and selection, but also considering any possible organisational effects.

Abstract

The aim of this paper is to present ways to make explicit the existing knowledge of the specialty coffee agribusiness system. The recognition of agriculture as a rapidly expanding segment involving primary, secondary and tertiary sectors of the economy necessitates solutions from various areas of knowledge. Specialty coffee, among the products of the agribusiness system, will be addressed in this paper as an example due to the complexity of maintaining quality during the various stages of transformation from coffee beans into the finished product. This research is based on field visits, interactions and a systematic search of the literature. Perspectives from the agribusiness sector present managerial focuses and address critical factors for its success. It is in the novelty of generating value through knowledge as a fundamental element that the originality of this paper stands out. Explicit knowledge of the specialty coffee agribusiness system will

contribute to the evolution of the market in all links of the agribusiness system, resulting in a collaborative, knowledge-intensive agribusiness system. The results show the domains, elements and value of knowledge in the Specialty Coffee Agribusiness System (SCAS), which will serve as the basis for the elaboration of the Specialty Coffee Domain Ontology and a Conceptual Framework of SCAS.

Keywords – knowledge representation, agribusiness system, value creation, specialty coffee, conceptual framework

1 Introduction

The global food and beverage market was estimated at more than \$ 5.650 billion in 2017. This segment encompasses alcoholic beverages, non-alcoholic drinks, pet food, grain products, meat, poultry, seafood, canned fruit and vegetables, frozen foods and dairy products (Food and Beverages Global Market Report, 2018)¹. This amount reflects the economic and social importance of meeting the food needs of a growing world population.

Food derives from complex productive chains composed of numerous agents within their business unit links. The demands that the current market has generated in agriculture have entailed rapid transformations and changes in the last decades (Boehlje, Doebling, & Sonka, 2005; Margherita, Secundo, & Taurino, 2009; Sánchez & Betancur, 2016) These authors emphasize that the changes have come about not only through technology, techniques and good production practices, but also through resource management, business models, supplier linkage, and planting operations. These changes impact consumers as well as government, science, and education involved in agriculture (Margherita et al., 2009).

Agribusiness is a unique form of economic activity (Wilk & Fensterseifer, 2003), where the companies involved tend to share basic resources, technologies and similar processes, but with different objectives. “*Agribusiness analysis thus requires, in addition to an interdisciplinary approach, a dynamic and systemic, rather than a static and local, view of investments in order to achieve a long-term dynamic optimization of the system as a whole*” (Wilk & Fensterseifer, 2003, p. 100).

The concept of agribusiness recognizes that the integration of the knowledge from different areas is what determines the success of the system as a whole. This paper presents a possibility of integrating, representing and explaining the knowledge involved in the processes of the Specialty Coffee Agribusiness System (SCAS) aiming at a better quality of the final product of this system through the proposal of the Conceptual Framework of the SCAS. In fact, coffee is not born bad, it can get bad (Kasai, 2016).

2 Bibliographic Review

2.1 Agribusiness System

Food production chains have distinct denominations according to their particularities. Agroecology and organic producers can be seen as opposed to intensive agriculture, emphasize Soullignac et al. (2017). Agribusiness requires a high degree of interdependence among agricultural producers (Harling, 1995 apud Margherita et al., 2009) where the divergence between the two is in the size and use of agrochemicals in production.

The basilar concept of agribusiness was first publicized by Davis and Goldberg (1957, p. 2) as *“the sum of all operations in the manufacture and distribution of farm supplies; production operations on the farm; and the storage, processing, and distribution of farm commodities and items made from them”*.

Davis and Goldberg (1957) argue that agribusiness encompasses all the functions that the term agriculture included 210 years ago. Grynszpan (2012) treats the Agribusiness System (AGS) as a business of interdependent links that begins with the production of inputs and financing, through farms, product transportation, warehousing, processing and distribution.

Perspectives on this issue present managerial focuses and address critical factors for the success of the sector, such as the frameworks of Wilk and Fensterseifer (2003) and de Almeida and Zylbersztajn (2017), However, knowledge as a value is not explicit in these frameworks. Knowledge management is important for the generation of value in the agribusiness systems (Jatib, Vilella, Ordoñez, Napolitano, & Palau, 2003; Margherita et al., 2009; López, Hernández, & Marulanda, 2014; Ma & Huang, 2014; Bernardo, Binotto, & Farinha, 2017; Gessi et al., 2017; Horáková, Rydval, & Houška, 2017; Trauer, Valdati, Todesco, & Costa, 2018).

Problems surrounding agriculture require solutions that goes beyond biology, chemistry, and engineering (Grynszpan, 2012). Thus, the concept of agribusiness recognizes that the integration of the knowledge in the different areas is what determines the success of the system as a whole. *“Modern agriculture depends heavily on agronomy, engineering, technology, and the physical and biological sciences”* (Encarnação & Lima, 2003, p. 14, our translation).

The agribusiness system is composed of interrelated subsystems that aim to provide products and services to consumers worldwide (Biotto, De Toni, & Nonino, 2012; Gunderson, Boehlje, Neves, & Sonka, 2014; Satolo, Hiraga, Goes, & Lourenzani, 2017). These subsystems are underpinned by support services that provide logistics, coordination, financing, labour, technology, information, policies, programmes, incentives and others.

2.1.1 Specialty Coffees

Among the products of AGS is coffee, discussed in this paper as an example due to the complexity of maintaining quality during the stages of its transformation into a finished product.

Coffee is one of the most consumed beverages in the world, surpassing 3 billion cups daily (Illy, Alessandre, McDowell, & Codice, 2015). It is ingested primarily for the stimulating effects of caffeine as well as for social bonding and for its aromatic properties but is rarely drunk because of its beneficial properties to human health (Shaposhnikov et al., 2018). World coffee production forecast for 2018/2019 is 174.5 million bags of 60kg, 15.6 million more than in the last year (Trade, 2018) which is equivalent to an approximate sum of US\$ 57.9 billion only in the marketing of green coffee (not yet roasted and processed) and represents a commodity of extreme economic importance.

Before it is consumed, coffee undergoes several transformations within the Coffee Agribusiness System (CAS). In this type of system, all the producers and processors of commodities in semi-finished/finished products are linked to the suppliers of inputs and technology until reaching final consumers (Wilk & Fensterseifer, 2003; Kalaki & Neves, 2017). Non-controllable factors that encompass both the environment and policy decisions are linked to consumer decision-making regarding product choice and brand choice (Wilk & Fensterseifer, 2003).

Samoggia and Riedel (2019) after analyzing the publications of Casal et al. (2000); Gloess et al. (2013) and Parras (2007) point out that “The biochemical composition of a cup of coffee depends on the degree of roasting, the type of bean (Arabica versus Robusta), and the coffee brewing method, including grind type” (Samoggia & Riedel, 2019, p. 2). Depending on the quality of the grains used and the type of processing, coffee as the final product may have a quality disparity ranging from a product derived from blends (coffee, cereals, peels and spoiled coffee beans) to pure, well processed coffee where the preservation of its best properties is sought. It is the latter that will be called Specialty Coffee.

Although coffee seems to be a simple product, seed-to-cup transformations involve knowledge-intensive processes (Trauer, Valdati, da Costa, Trzeciak, & Varvakis, 2017) and numerous complex tasks (Hatzold, 2012). At the end of the processing, the coffee could be one of several quality standards – from coffees of a very dark roast – known as Italian or French roasted coffee (Melo, 2004; Lokker, 2016), to coffees composed of defective, green, burnt, mouldy and old harvest beans to gourmet and specialty coffees.

The final quality of this product can influence the health of its consumers, as well as scientific research that may be biased by the use of food derived from transformations that have damaged part of its substances (Mioto, 2015).

In studies involving coffee, the market, agronomy, chemistry and medicine, tend to show disciplinary interests about characteristics present in the production process that are sometimes not perceived, shared and used beyond these areas (disciplinary approach) and end up remaining implicit in the agents and activities of each sector and explicit in their areas of knowledge. It is necessary not only to explain knowledge, but also to obtain

consensus and integration on the present knowledge through agents/activities involved in the SCAS and, perhaps, to promote a transdisciplinary approach among the sectors.

2.2 Knowledge Representation

Nonaka and Takeuchi (1995) presented two types of knowledge: explicit knowledge, contained in manuals and procedures and tacit knowledge, learned only by experience and indirectly shared through metaphors and analogies. For these authors, systemic knowledge emerges from the aggregation of explicit knowledge. In the tacit dimension, Polanyi (2013, p. 4) highlights the fact that “*we can learn more than we can tell*”. This dimension of knowledge is fundamental to the development of scientific knowledge. Sharif (2004) corroborates the recognition of the tacit dimension as an indispensable part of human knowledge that is not always present at a conscious level.

In this paper, knowledge is defined through the lens of the Graduate Programme in Knowledge and Management Engineering, UFSC, Brazil: “it is content or process effected by human or artificial agents in the generation of scientific, economic, social or cultural activities” (Pacheco, 2016, p. 20, our translation).

Knowledge management makes it possible for organizations to work out strategies among the agents involved in a collaborative manner more efficiently and effectively (Hinton, 2003; Gessi et al., 2017), where knowledge is a critical factor for business survival.

SCAS can be considered as a set of several interdependent businesses throughout its chain. Thus, innumerable agents – human and non-human – make up the knowledge base of the sector. To this set it is possible to add knowledge of related scientific research. It is noteworthy that most knowledge of the organizations – in this case – of SCAS may be in the minds of the people who comprise them (Gessi et al., 2017).

The agribusiness sector demands knowledge management practices to meet knowledge gaps in the market (Nagaoka, Ensslin, Ensslin, & Nagaoka, 2011; Bernini, Nääs, Garcia, & Garcia, 2014; Bernardo et al., 2017). In this context, the importance of knowledge representation emerges to provide value generation throughout the SCAS. However, to represent knowledge only as informative content is insufficient; it is necessary to provide the understanding of this knowledge too (Sharif, 2004). Sharif stresses that the combination of context and reasoning of information content is fundamental to represent knowledge in an information system. It is understood that the combination of context and reasoning of information content is also valid for other forms of knowledge representations such as mind maps, ontologies and frameworks. The representation of knowledge contributes to the generation of value as explained by the assertion of Pacheco, Freire, and Tosta (2011) who conceive of knowledge as a generator of value.

2.2.1 Ontologies

An ontology is composed, in general terms, of concepts and relationships that can result in a knowledge base of a particular field that is modelled and explained, and can have as one of the objectives the constitution of a framework for modelling problems

(Zanni-Merk, Cavallucci, & Rousselot, 2011), as well as contributing to the collection of insights about the uniqueness of certain situations (Fernandes, Grosse, Krishnamurty, Witherell, & Wileden, 2011).

The use of ontologies is very broad in the areas of Knowledge Engineering, Artificial Intelligence, E-commerce, Computer Science, Natural Language Processing, Information Retrieval, Database Design and Integration, Bioinformatics, and Education (Simperl, 2009; Gómez-Pérez, Fernández-López, & Corcho, 2010), as well as in the context of Knowledge Management, in which "the characteristics of the development of an ontology are aligned with knowledge sharing, one of the basic processes of Knowledge Management" (Rautenberg, Todesco, & Steil, 2010, p. 171, our translation).

This paper uses the classic definition of ontology presented by Studer, Benjamins, and Fensel (1998):

An ontology is a formal, explicit specification of a shared conceptualization. Conceptualization refers to an abstract model of some phenomenon in the world by having identified the relevant concepts of that phenomenon. Explicit means that the type of concepts used, and the constraints on their use are explicitly defined. Formal refers to the fact that the ontology should be machine-readable. Shared reflects the notion that an ontology captures consensual knowledge, that is, it is not private of some individual, but accepted by a group (p. 184).

It is necessary to emphasize that the ontologies aim to represent the consensus knowledge of a given domain in a generic and formal way so that it can be reused and shared between applications and groups of people (Gómez-Pérez et al., 2010). The authors state that there is not only one ontology for each domain, but there can be several ontologies which – in different ways – model the same type of knowledge or domain.

2.2.2 Conceptual Framework

Crossan, Lane, and White (1999) based on concepts of Bacharach (1989); Whetten (1989); Sutton and Staw (1995); Weick (1995) define framework as a structure that fulfils the following fundamental requirements:

1. Identify the phenomenon of interest;
2. State the main premises or the premises underlying its structure and,
3. Describe the relationship between the elements of the structure analyzed.

The development and use of frameworks represents the most general form of theoretical analysis in which structures identify elements and general relations between them that need to be considered for institutional analysis, thus organizing diagnostic and prescriptive investigations (Ostrom, 2011).

Although they are now widely used, there is no standard definition of a framework. This paper employs the lens of the authors mentioned above, complemented by Miles and Huberman (1994) who define the Conceptual Framework as

The conceptual framework explains, either graphically or in narrative form, the main things to be studied – the key factors, constructs or variables – and the presumed relationships among them. Frameworks can be rudimentary or elaborate, theory-driven or commonsensical, descriptive or causal (p. 18).

To these definitions Shehabuddeen, Probert, Phaal, and Platts (1999) add that a Framework should:

1. Represent an issue for a defined purpose;
2. Link various elements to show a relationship;
3. Enable a holistic view of a situation to be captured;
4. Demonstrate a situation or provide a basis for solving a problem, and
5. Provide a structured approach to dealing with a particular issue (p. 9).

The Conceptual Framework represents a possibility for representation of SCAS knowledge based on the development of a Specialty Coffee Domain Ontology.

3 Research Design

The design of this research was based on stages and interactions, starting with systematic literature searches in the Scopus, Web of Science and Scielo databases supplemented by the SnowBall search technique in Google Academics, chapters of published and indexed books and technical reports in the area (Grey Literature). Key words were determined, searches of the databases were conducted, and relevant articles were selected and classified using EndNote@X9 software. Following the classification and reading of selected texts, a table containing the guiding concepts of the research and its references was developed, thus fulfilling the first step for integrating SCAS knowledge. Subsequently, guidelines for the development of the conceptual framework were presented. This knowledge representation will use knowledge engineering tools for identification of knowledge.

4 Development

With the aim of acquiring, organizing and representing knowledge of the process in SCAS to enable its sharing in this domain, the development of a Conceptual Framework will be proposed. The knowledge needed and available for this purpose is present both in SCAS agents and in related databases.

4.1 Representation of the Knowledge Context in SCAS

The various components that constitute SCAS need to be connected through relationships. Among these Wilk and Fensterseifer (2003) present in the SCAS Framework the following macro factors (here called knowledge domains): Competitive Situation; Economic Factors; Technology; Nature and Society. These macro factors can be complemented by the critical success factors defined in the Conceptual Framework of the Brazil's Coffee Industry presented by de Almeida and Zylbersztajn (2017). Figure 1 derives from this integration and in it, elements of knowledge originate from the domains,

flow smoothly and are fed by values that contribute to the understanding of the knowledge of the system. Such an understanding will enable SCAS agents to seek better results in the preparation of specialty coffee. Four components are integrated as a contribution to the above-mentioned frameworks: Knowledge Elements, Scientific Publications related to the sectors and their final products, Practical Contributions of SCAS Agents and Perceived Value for each of the components.

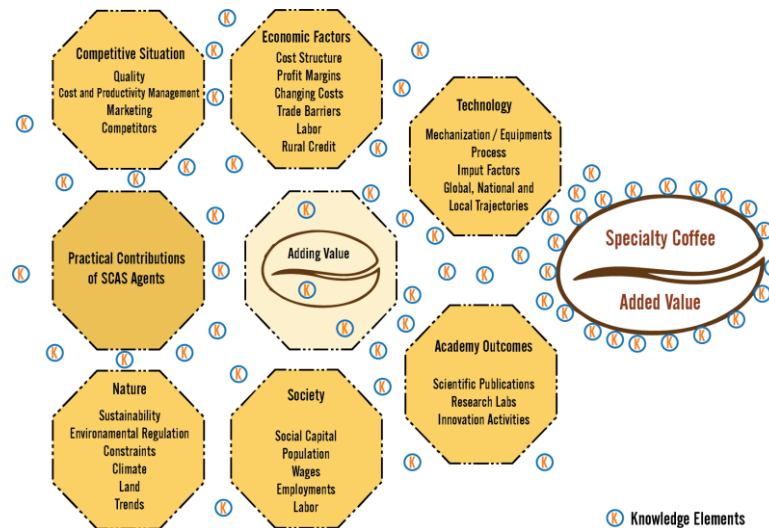

Figure 1: Domains, Elements and Value of Knowledge in SCAS. Source: Authors

Knowledge emerges in this graphic representation as a value generating factor to SCAS, encompassing scientific, economic, social and cultural aspects, according to the definition of knowledge presented by Pacheco et al. (2011), as a critical success factor in organizations (Toffler, 1991; Drucker, 1999; Porter, 2004; Stewart, 2010) and in the context of the Agribusiness Sector (Hinton, 2003; Nagaoka et al., 2011; Bernini et al., 2014; Bernardo et al., 2017; Gessi et al., 2017).

Explicit knowledge from scientific publications in the area was included because of its relevance to the sector, and because it is assumed that many SCAS agents do not have opportunities to access scientific knowledge bases, as verified in empirical interviews with specialists in the SCAS domain.

Through scientific databases it is possible to have access to knowledge such as that discussed by Hatzold (2012, p. 6): “The processing methods also influence the presence of bioactive compounds, both qualitatively and quantitatively, and therefore may influence coffee’s physiologic effects in the human body”. This author highlights the beginning of new discoveries regarding the effects of coffee on human health:

Science is only beginning to understand the relationship between coffee drinking and health and well-being. Previously, most scientific research focused on caffeine, for which there is now significant evidence describing its mild

stimulating effect. However, there are many compounds in coffee that appear to exert bioactive actions (p. 16).

The international scientific community is contributing to demystifying the notion that coffee can be harmful to human health. This product is classified as a nutraceutical beverage (nutritional and pharmaceutical), has a great variety of minerals, amino acids, lipids such as triglycerides and free fatty acids, sugars and polysaccharides, has a vitamin B complex (niacin, vitamin PP) that, when obtained from appropriate roasting processes, form chlorogenic acids – natural antioxidants – which might act to prevent depression and its consequences (Encarnação & Lima, 2003; Mito, 2015; Fischer, Victor, Robinson, Farah, & Martin, 2019).

It is important to note that of the coffee components, "only caffeine is thermostable, that is, it is not destroyed by excessive roasting. Other substances such as amino acids, sugars, lipids, niacin and chlorogenic acids can be modified, formed or even destroyed during the roasting process" (Mito, 2015, p. 4, our translation). Highly roasted coffee is essentially caffeine and ash. The aforementioned elements of knowledge are relevant to provide knowledge to SCAS agents and contribute to the generation of value of specialty coffee as final product.

Publications on the properties of coffee and their relation with human health have been presenting contradictory information over time. Fischer et al. (2019) present a historical approach to changes of conceptions about coffee consumption and its health impacts, thus reinforcing the importance of knowledge representation, having scientific bases as one of the input factors.

Many of the historical problems and controversies that were associated with the use of coffee are now linked to methodological gaps, inter- and intra-individual differences, interrelationships among food substances, form of roasting and brew preparation, and differences in coffee composition related to various aspects of growth and production (p. 14).

The form of knowledge representation that will give rise to the SCAS Conceptual Framework will be instanced by a Specialty Coffee Domain Ontology.

5 Conclusions

Ontologies and frameworks can be used to represent the integration of knowledge in formal and explicit SCAS, in which their interpretations contribute to the elaboration of referential and simplified guides available to the various SCAS agents. These representations of knowledge - among other results - present two common factors as highlighted by Pacheco (2016): "knowledge-actor relationship and its role in social co-production" (p. 11, our translation).

5.1 Theoretical Implications

This study presents four theoretical implications, the first one being in the integration of scientific academia to the proposal of the SCAS Conceptual Framework through its publications, the second in the representation of the Elements of Knowledge as actors in the integration of SCAS knowledge, the fourth with the Practical Contributions of SCAS Agents and lastly, Value Perceived in the interaction between the components of SCAS.

These implications complement the frameworks of Wilk and Fensterseifer (2003); de Almeida and Zylbersztajn (2017).

5.2 Managerial Implications

The agents and organizations that constitute the SCAS may benefit from the Conceptual Framework of SCAS as a guide for the production of products with greater added value. The framework will present motivations for transdisciplinarity in the areas that exert influence on the SCAS. Consumers of specialty coffees will benefit from shared knowledge in the market through the organizations participating in SCAS and from the possibilities of choosing coffees beneficial to human health and with particular flavours. An increase in consumption of specialty coffees could contribute to the reduction of human health expenditures¹, which in Brazil – for example – represented US\$ 140 billion² from 2010 to 2015. All these results generate wealth for society.

This paper presented ways to explain knowledge in the SCAS domain. From the evolution of this research, the proposition of the Domain Ontology of Specialty Coffee, and of the Conceptual Framework of SCAS and its respective checks with specialists will emerge.

Abstract

As citizen participation and participatory governance have become central concepts in the cultural policies at EU level, we are interested in understanding what this entails in practice. While, generally speaking, participation has been deeply scrutinized in political science and public administration literature, how citizens become participants in a process of co-creation of culture, who benefits from this participation and why is rarely discussed. By focusing on the European Capital of Culture initiative, which has become widely recognized as one of the most prominent EU cultural initiatives, we offer a thorough analysis of the participatory practices and of the challenges to participation that unfolds over the development of the ECoC projects. Adopting a Systematic Literature Review, we discuss the variety of participatory practices in real cases of ECoC, many of which, however, cannot be labelled as practices of “participatory governance”. We contribute to the stream of research on citizen participation, highlighting the selective practices that are hidden under the veil of inclusivity. These results are valuable both from a theoretical and a practical perspective.

Keywords – European Capital of Culture, citizen participation, citizen engagement, societal impact, EU policies

Paper: Academic Research Paper

1. Introduction

EU cultural programmes and policies have included the issue of citizen participation, as it is witnessed by numerous cultural policy briefs related to the European Agenda for Culture, the EU Council decisions, and documents related to cultural work programmes. More specifically, the EU has introduced the issue of participation in the WPC 2011-2014, referring to topic of “better access to and wider participation in culture, especially for socio-economically disadvantaged groups”. In the WPC 2015-2018 the EU introduced the issue of participatory governance (WPC 2015-2018). According to Fischer (2012), “participatory governance is a variant or subset of governance theory that puts emphasis on democratic engagement, in particular through deliberative practices, a form of democratic engagement to deepen citizen participation in the governmental process” (Fischer 2012: 457).

Shifting from the policies levels to the practices, the OMC report (2018) shows that there are a variety of participatory practices in cultural heritage, many of which, however, cannot be labelled as practices of “participatory governance”. In fact, although there might be a high level of involvement of citizens or communities, such practices do not necessarily foresee a system of “shared decision-making and responsibility” for the cultural sector at stake.

Numerous methods and programs in the cultural field have defined a common European approach to cultural heritage. Among these programs, the designation of selected cities as European Capital of Culture (ECoC) has received greater attention and emphasis over the last decade. The ECoC initiative has been more and more centered on participation as well. In fact, since 2000 participation has become one of the criteria to select the city to become the ECoC of the year. Nevertheless, according to Nagy (2018), the participatory governance approach is not detectable in the ECoC program. In fact, decisions and guidelines do not foresee citizen participation in public decision-making processes. Furthermore, Nagy highlights that the framing of participation in fact unveils selective practices under the “veil of inclusivity” (Nagy, 2018, p. 244).

Responding to the call for further research on this topic, we shift the level of analysis from the EU policy level to the implementation of ECoC at “the local level of city leadership” (Nagy, 2018, p. 254). The purpose of this paper is thus to scrutinize the concept of citizen participation in ECoC local initiatives and to compare it against the participatory governance approach. While generally speaking citizen participation has been deeply scrutinized in political science and public administration literature, how citizens become participants in a process of co-creation of culture, who benefits from this participation and why, is barely discussed (Cooke & Kothari, 2001; Holdgaard & Klastrup, 2014). Hence, in this paper, focusing on ECoCs, we address the following research questions: *i*) How is participation translated in ECoC initiatives?; and *ii*) Does it lead to citizen involvement in decision-making processes?

In order to answer to these questions, we adapt Nagy’s framework based on Turnhout, Van Bommel and Aarts (2010) in order to analyse three selected cases of ECoC (Aarhus, Umeå, and Matera).

By providing one of the very few studies on ECoC citizen participation we contribute to the stream of research aimed at investigating the challenges, problems and difficulties associated with the processes of evaluating, fostering and monitoring citizen participation.

Our analysis shows that: a) the various actors who take part in the ECoC initiatives perceive and interpret the concept of participation in a wide array of different modes; b) not only the framing of participation unveils selectivity, further selective practices are embedded in the mechanisms that are used to pursue community engagement and participation; c) the actual participation never translate into the decision-making processes in the development of the whole cultural project.

2. Background

Europe is facing a controversial phenomenon, as on side fewer Europeans are ‘engaging in cultural activities’ (European Commission, 2013) whereas on the other side, a greater emphasis on “audience engagement”, “audience development”, “citizen engagement”, and in general “participation” can be detected in various policy statements at EU, national, and regional levels (Jancovich & Bianchini, 2013; Bianchini & Borchini, 2018).

On the verge of the “participatory turn in EU policy” (Saurugger, 2010), cultural policies have been embracing the issue of democratic decision-making processes that can concern creation processes and/or programming choices. Indeed, cultural policies have been dealing with access and participation in culture for a long time (Tomka, 2013). Recent trends, such as the budget cuts, the digitalization, and the globalization, have emphasized the focus on participation in culture. In fact, the general understanding of cultural audience has shifted from passive to active, and to super-engaged (Tomka, 2013). Participatory Cultural Initiatives - PCIs - (Biondi et al., 2018) include a participation also of non-professionals in cultural programs and policies.

Several EU policy briefs, documents, and reports claim such emphasis on participation, by recalling various levels of participation (e.g. OMC, 2012). The concept of participation entails highly diverse cultural, psychological and social actions; thus, very different forms of promoting ways of participation can be envisioned. Within the European Agenda for Culture, the Work Plan for Culture 2015-2018 introduces the concept of participatory governance of cultural heritage as one of the topics in the priority area concerning cultural heritage. In this document, participatory governance is intended as the “multilevel governance of tangible, intangible and digital heritage”, involving the “public sector, private stakeholders and the civil society” (Council of the EU, 2014, p. 11). This concept is further explained in the Work Plan for Culture 2019-2022, where participatory governance is recalled regarding both the priority of sustainability of cultural heritage and in that of cohesion and well-being. More in details, participatory governance is envisioned as an “innovative, people-centred and forward-looking approach, introducing a real change in how cultural heritage is managed and valued” (Council of the EU, 2018, p. 9). It must be said though that none of these documents

specify in details what participatory governance entails in practice, thus leaving room for very different interpretation and implementation.

If we look more in details to a specific cultural programme, such as the ECoC initiative, we still find a background that remains vague and undefined with respect to participation. In her original scrutiny of the main policy documents related to ECoC, Nagy (2018) points out that from 1999 to 2014 an apparent shift in the official ECoC program documents took place regarding the scope of participation from the supranational level (“state level regulation”) to the regional and local levels (“multilevel governance”). In particular, in 445/2014 Decision local participation is introduced in a way that seems to overlap with Fischer’s definition: “...a form of democratic engagement to deepen citizen participation in the governmental process” (Fischer, 2012, p. 457). However, since this large scope of participatory frame is more an option rather than a requirement, the ECoC initiative contains “selectivities under the veil of inclusivity” (Nagy, 2018, p.254). In other words, in the face of an apparent openness to citizen participation addressed to the entire local community, these policies define and structure groups/segments of local population (“specific roles”) for the satisfaction of specific functions. Among these groups, in particular two groups should have a central role according to the ECoC framing: the public decision makers, and the group of local artists and cultural activists (“the experts”). The latter serve as intermediaries between the local community in which they are rooted and the ECoC board, hence they are able to represent the needs and the interest of the civil society. Furthermore, as regards more specifically the participatory governance in the different stages of the ECoC program (planning, decision making and implementation stages), the participation frame never reached the level of partnership but aimed to promote “open advice” or “consultation”. Therefore, the participatory governance framing contained in the ECoC policies only fulfills the scope of “representative democracy”.

3. Methodology

The aim of this paper is to understand how participation is addressed in the ECoC program, and to discuss the framework of citizen participation stemming from the EU policy statements against its implementation as it emerges in various experiences of ECoCs. In order to collect evidence on specific ECoC cases, we applied a Systematic Literature Review (SLR), intended as a comprehensive search for relevant studies on a specific theme and a subsequent analysis of those studies according to a predefined explicit framework (Klassen et al., 1998).

We identified the publications through searches of electronic databases, such as Google Scholar and Scopus. As regards inclusion and exclusion criteria, we included studies that: (a) use the keywords “European capital of culture” and “citizen participation”; (b) were published either in a peer-reviewed journal or in official documents, report, forum and press releases; and (c) were written in the English language. No restriction was placed on year of publication. Then, a second screening allowed to select and retrieve the full text of the eligible studies against inclusion criteria, such as: (a)

be an empirical study on a real ECoC case; (b) discuss citizen participation as the main topical theme.

4. Results

As a result of the SLR, we identified about 20 papers, among which we selected those that specifically dealt with the participatory processes in real ECoCs, and that could be analysed in terms of our proposed questions adapted from Nagy's sensitising questions for the analysis of participation (2018):

- 1) Who participated in the specific ECoC under study?
- 2) In what did they participate?
- 3) Why did they participate?

We provide an overview of the findings in the following paragraphs, per each ECoC (Umeå 2014; Aahrus 2017; Matera 2019).

4.1 Umeå 2014

For the analysis of Umeå2014 case we selected three papers: Näsholm and Blomquist (2014); Wählin (2015); Hudson, Sandberg, and Schmauch (2017).

Hudson et al. (2017) focus on the concept of co-creation and the way it was operationalized by cultural officials and the participants during the Umeå Capital of Culture development process.

The city has been designated ECoC2014 thanks to its focus on citizen participation and the "co-creation" of culture. In Umeå the first shape of participatory process is evident since the beginning of the bidding process (Autumn 2007). The municipality addressed intensive calls to local inhabitants, local cultural actors/practitioners, larger established organization and smaller organizations (*who?*) to promote their involvement in putting together the ECoC Bid, titled "Curiosity and Passion –the Art of co-creation" and in compiling the programme for the year (*in what?*). In the city official narrative, the extensive process of participation was promoted as a means to give legitimacy to the project (*why?*). There was another "partly complementary and partly divergent" narrative that saw co-creation as a "well timed marketing strategy" for selling the city (Hudson et al, 2017, p. 1544). This narrative sees "culture" as an engine of the city's growth and "voluntary participation" as the idea that everyone can contribute to creating cultural growth (*why?*). To encourage the voluntary participation of cultural actors/practitioners in producing the Bid and its programme, the city officials implemented numerous measures without providing any compensation for their participation in the belief to give participants the opportunity to maintain their independence. However, different visions emerged during the application phase between the municipality and the participants about the way to conceive the co-creation practices, and specifically about: a) whether it was appropriate or not to reward the participants for their involvement in the production of ideas; b) how to take into account the unequal power relationships between the municipality and the small independent participants; c) what possibilities existed for a small independent participant to affect a process managed and controlled by the

municipality; d) the difficulties in understanding if and in what the co-creation processes differ from the collaboration. This criticism became part of a public narrative about Umeå2014 process and illustrates dissatisfaction with how co-creation was staged.

All the three papers that are included in our sample analyse the co-creation process that took place after the designation of Umeå2014. As described in Näsholm and Blomquist (2014), the municipality actively invites the entire Umeå Community - individual artists, volunteers, small organizations and large institutions (*who?*) - to produce the content of the project and the events to be realized during the ECoC year (*what?*).

The main idea of the city officials was that most of the cultural production and events should be done by the local actors in the city in order “to investigate the most creative ideas and to get many people to be responsible in the realization of the program” (*why?*), as stated by an Official in the municipality of Umeå2014 (p. 18). To encourage the development of small projects and cultural initiatives, the Umeå2014 project team used a simplified procedure named “Cultural Boost” through which cultural actors could apply for co-funding (or funding if the request did not exceed €2.200). Over 200 applications were received and less than half were funded by Umeå2014.

This phase of the development of the program of Umeå2014 has given rise to tensions and flaws in the real participatory process. First, different interpretations emerged of the concept and practices of co-creation. As an example, a politician claimed that “Now the audience should not just be a part of it, they should be a part in creating it. They are allowed to be part of the decision-making” (Näsholm and Blomquist, 2014, p. 17), whereas a program producer reported “What’s open source? [...] What does it mean, really? It’s easy to talk about open source, loosely” (p. 19). Hence, the meaning of co-creation communicated officially was mainly a broad ideal and a value that the politicians were trying to promote, but it was understood mainly as a general invitation to participate.

Second, different actors were able to respond to the application procedure leveraging a very diverse set of resources and competencies. In fact, large cultural institutions were accustomed to these application procedures and possessed all the required resources and knowledge, whereas smaller organizations and free-lance artists were not familiar with those procedures (Näsholm and Blomquist, 2014).

Third, a grey area in participation is related to the selection process that resulted in the list of the projects that were actually funded and included in the program. The selection process, that was managed by Umeå2014 project team, was not inclusive as the applicants did not have any stake in the final decision (Wählin, 2014).

4.2 Aarhus2017

The analysis of Aarhus2017 is based on Eriksson and Stephensen (2015). In detail, this paper focuses on a micro project under the main umbrella program of the ECoC event, called “The playful society”. The ECoC organisers (the Aarhus2017 Secretariat) asked for participation in the phase of planning cultural events (*in what?*) oriented to outreach and engage young audiences (*who?*). This decision stemmed from the goal to engage young people in “culture and society” against a widespread conception that

youngsters are a “somewhat problematic segment of the population” (Eriksson and Stephensen, 2015, p. 55) to be involved in civic participation in social organizations or in cultural institutions. Hence, a call was launched directed to young cultural entrepreneurs, who, as Nagy (20018) underlines, are included in a specific cluster of citizens (local artists and cultural organisers). Indeed, young cultural entrepreneurs were supposed to be a link with the local youngsters.

What emerges from the above-mentioned study is that there were different conceptions of participations among the ECoC organisers and the young cultural entrepreneurs correlated with different rationales and expectations (*why?*). In fact, the young project initiators perceived their inclusion in the program and the funding by Aarhus2017 as an official recognition that could be added to their CVs (p. 57). However, it was also a means to change or create something new, a way “to influence the living conditions and social communities not only of themselves, but of the cities in which they live” (p.61). On the other side, the organisers had the interest of legitimization in launching a call responding to the main goal of inclusion in the ECoC motto “a project and an opportunity for everyone” (p. 53).

However, it should be said that the goal of a wide participation of young cultural entrepreneurs failed, because only 32 proposals were submitted, out of which 24 were funded. The poor interest in the call might be related to a bad communication. Moreover, in realising the cultural projects, the young participants complained the lack of supervision and follow-up by the Aarhus2017 artistic administrators, which was primarily experienced not as a liberating lack of control, but as a confusing and somewhat demotivating lack of interest and interaction. Another criticism was related to the lack of coordinating direction to foster networking across diverse youth groups.

4.3 Matera2019

Regarding the Matera2019 case, Demartini, Marchiori & Marchegiani (2018) analyse what dynamics of participation unfolds from the initial idea to the formal designation as Capital of Culture.

The authors deem that a participatory process in public decision-making emerged only in the initial phases of the initiative, when citizens and civil society were involved to gather ideas and build collective knowledge. Hence, in those phases, cultural professionals and entrepreneurs, citizens represented by their not-profit or cultural associations (*who?*) were engaged by public officials in the decision-making process. In this phase, citizens and their associations play the role of co-designer of the first cultural program (*in what?*). Participation, in fact, was one of the fundamental elements that qualified the candidacy of Matera in the competition for ECoC2019. “Together” was chosen as the brand of the Matera2019 candidacy program and it was also the title of the first Bid book prepared for the application. In this vein, citizens were considered by the organisers (public officials) as valuable partners in order to enrich the content of the first Dossier and increment the likelihood to obtain the inclusion in the short list (*why?*).

Consequently, in this phase public officials have also been interested in implementing mechanisms that facilitate their active participation such as the launch of the online

Community, through which they collected 171 projects from civil society and the encouragement of “digital” volunteers to spread the Matera2019 candidacy around the world.

On the other side, the cultural project built on the feelings of identity of the citizens to enhance their history, strengthen their values, and focus on the peculiarities of their territory (*why?*). Indeed, in the first dossier, an idea of culture prevails as a resource on which to leverage a new social project and the enhancement of the city and its inhabitants.

Once the designation in the short list of the five candidate cities to obtain ECoC title was gained, a progressive decrease in the participatory process happened. The Matera 2019 project team established the Foundation Matera Basilicata 2019 that was founded by public and private actors with the fundamental mission to compile the cultural program outlined into the second Bid book. The phase of the production of the cultural program was characterised by considerable centralisation of decision-making processes led by the public administration and by a consequent weakening of the participatory process (Demartini et al., 2018, p.531).

5. Discussion and Conclusions

The present paper aims to provide a contribution to unlock the concept of citizen participation, as it unfolds in empirical contexts against how it is envisioned at the political EU level, in the specific context of ECoC.

We focus on real case studies of ECoC in order to understand how participation is actually enacted and put into real practices. In fact, as participation in public cultural policies is by nature situated and dependent from the context, any study of the participatory practices must consider the social contexts in which they are embedded. Our analysis of the selected ECoCs confirm that co-creation emerges as something “messy, raw and context dependent” (Walmsley, 2013, p.117).

Analysing how participation is translated in ECoC, all the cases show controversial elements about how citizens participation results in co-creation of culture, who really benefits from this participation, and why. First, in terms of who is involved in the participatory practices, we show that a substantial difference exists in all the cases between the formal narrative of the participation approach and the actual practices. In some cases, whereas a broad and inclusive approach is declared, the practices indeed unveil selectivity.

Moreover, when we analyse the rationale for participation (*why?*), some elements of selectivity still persist. In fact, the intentions of the public officials/municipality/project team seem to converge into the ideals of representing many types of people and their variety and diversity. At odds, the reality shows a very different picture, where this ample representation remains at an ideal level. Minorities and sub-cultures are very unlikely to reach visibility in the actual ECoC program.

Finally, our analysis discusses in what participation is sought. First of all, a difference must be made between the very initial phases of the ECoC initiatives and their subsequent development. In fact, the Matera2019 as well as the Umeå2014 cases confirm that it is

very likely that a high level of citizen participation is reached in the initial phases of the candidacy process, when it is necessary to gather many ideas and a high level of enthusiasm is shared among all the actors to produce the first Bid . Umeå2014 and Aarhus2017 also show that the participation is high in the phase of compiling the ECoC program. In fact, a very open call for cultural ideas and cultural projects was launched in both cases. Nevertheless, we claim that the actual mechanisms that are put into practice to promote citizen participation can instil selectivity. In some cases, the application procedures bear selectivity, because they set application criteria that required a level of competencies and knowledge that was not common to all the potential applicants. In the intentions of the organizers, using the application procedures was meant as a coordinating mechanism to boost actions, it in fact lead to excluding some actors, especially volunteers and individual artists.

In other cases, the selective practices are constituted by the selection processes of the ideas that converged into the Bid (initial phase) and of the projects to be included in the program (later phase). The project team of each ECoC was in charge of the selection process, which resulted in preferring large and mainstream projects over the smaller and more original ones.

Moreover, our analysis of the cases of ECoC highlights a further critical element to enable real participation in the development of the cultural projects. In fact, some participants refer to the lack of ad “hoc mechanisms”, intended as coordinating mechanisms to help and lead young artists to perform and to establish long lasting connections among each other.

The decreasing level of participation associated with the different phases of the projects suggests that the public actors may make an instrumental use of participation, aiming to obtain legitimacy and consent that are useful solely for the purposes of candidacy.

All considered, we discuss our findings in light of the concept of participatory governance, which seems to be more and more central in the EU cultural policies. We refer to participatory governance as participation in the decision-making processes in cultural events. Against this, our discussion of the ECoCs shows that participants are involved in the decision-making process only in marginal ways. In some cases, they participate in some phases (ideas collection) but they are not involved in the whole process of developing a cultural project as part of the Capital of Culture year (including planning, sourcing, equipment, facilities, exchange of competences etc.). More importantly, citizens are never involved in the most important decisions, such as the selection processes of ideas, events, and projects.

Our study contributes to the debate on participatory governance in cultural heritage as an opportunity for economic and social development and renewal of local communities. It can offer suggestions and insights for the EU Legislator to design new rules to make citizen participation in the ECoC events more effective and for the regional public administration to define new cultural policies able to engage the local communities.

Abstract

Over recent years, in the International scenarios, very few routes have been entered to face the lack of the management dimension within Culture Sector. The contribution of economic disciplines to culture has mainly concerned political economy, rather than corporate disciplines, very often depriving the Cultural landscape of the needed profitable complementarities coming from the interaction between public and private entities. However, the very complexity of cultural heritage - for the territorial extension, to the landscape dimension, for the multiplicity of institutional levels called into question, for the intertwining of protection and valorization policies – should invoke the definition of interdisciplinary corporate operative solutions in order to respond to practical challenges and create value for all the stakeholders involved.

In this framework, the paper aims to define a theoretical and practical performance and measurement model ready to make cultural assets productive, thus demonstrate the impact of managerial private and public tools through to Cultural networks.

Without regard to any other production, authors will grade different combinations of managerial models and analysis with the view to ultimately define an innovative model in order to determine, under qualitative and quantitative terms, the consistent enhancement of artistic and cultural assets within a public-private company perspective.

The work is articulated in four steps: first, a proper analysis of existing task and general environment strategic models is in-depth; then, the assessment of a selection among those as the ideal base for Cultural Sector is shown; moreover, the definition of a new model is analyzed and its economic-financial political feasibility analysis based on a ROI outcomes quantification and Key Performance Indicators (KPIs) is tackled.

The approach undertaken appears to be totally innovative for the original definition of a new forge for the fulfillment of both companies and institutions needs and objectives, in order to fulfill the gap between theory and praxis managerial model applied to Culture. The potential of the research seems evident in consideration of the high feasibility in worldwide contextual realism and companies range, and consequent profitability of the application of the model, since the research represents a full strategic portfolio service package in order to follow the integrated Cultural investment cycle, transcending conventional indicators for the achievement of a medium and long-term economic, social and political value creation.

The attractiveness of the model is going to be crucial for the differentiation of business culture and decision makers in order to contribute to the re-launch of different territorial policies and to contribute to the development of the transparent competitive cultural performances of capital-intensive market. From this point of view, the incentives resulting from the model's application will eventually draw all different stakeholders to differently combined competences and endowments in order to undertake more collaborative and profitable action plan as to acquire a proactive role in the political decision-making, anticipating economic and occupational circumstances and needs.

Nature of the proposed paper: Practical Paper

1. Introduction

“The arts already stand naked and without defence in a world where what cannot be measured is not valued; where what cannot be predicted will not be risked; where what cannot be controlled will not be permitted; where what cannot deliver a forecast outcome is not undertaken; where what does not belong to all will be allowed to no one”
(John Tusa)

“Not everything that can be counted counts and not everything that counts can be counted”
(Albert Einstein)

Over recent years performance measurement systems have received increased attention. Those systems have been traditionally focused on financial measures such as sales, profit margin, economic value added, stock price performance or return on investment. It was since the 1990s that both practitioners and academics began to question the relevance of using solely financial performance measurement indicators, arguing that non-financial indicators, if correctly balanced with the former, would have been more deemed to indicate the real managerial efforts within the development of a medium and long-term strategy (Atkinson, Waterhouse and Wells, 1997; Kaplan and Norton, 1992, 1997; Banker, Potter and Srinivasan, 2000). Among those, Kaplan and Norton (2001) were the first to examine the application of multiple dimensions measures to not-for-profit organizations (NPOs), stressing the importance of the consideration of a multiple set of indicators for a more effective and complete evaluation of such realities.

Since then, the consistency and application of multidimensional indicators to score business performances have become increasingly relevant mainly for managers across a wide range of industries contexts characterized by the combination of knowledge and creativity in order to generate and sustain competitive advantage. This is exactly the case of the culture sector where, among others, the quality of customer satisfaction and cultural performances expressions represent the main preconditions for financial metrics. Within this scenario, culture management has to deal with the dilemma to combine ambiguity and dynamism, both of which are intrinsic to cultural goods that serve an aesthetic or expressive purpose rather than an utilitarian one (Bjorkergren 1996, Hirsch 1972, Holbrook and Hirschman 1982). Such characteristics conduct the managers involved with the creation, production, marketing and distribution of cultural goods to manage five different polarities, which shape organizational practices in cultural industries. First, managers must reconcile expression of artistic values with the economics of mass entertainment. Second, they must seek novelty that differentiates their products without making them fundamentally different in nature from others in the same category. Third, they must analyze and address existing demand while at the same time using their imagination to extend and transform the market. Fourth, they must balance the advantages of vertically integrating diverse activities under one roof against the need to maintain creative vitality through flexible specialization. And finally, they must build creative systems to support and market cultural products but not allow the system to suppress individual inspiration, which is ultimately at the root of creating value in cultural industries (Lampel, Joseph, Theresa Lant, and Jamal Shamsie, 2000).

Other academics, such as Cavalluzzo and Ittner (2004) argues as the difficulty and unpredictability of measuring qualitative emotional and expressive outcomes, the lack of clear technological capability, the weakness of the management commitment and the lack of employee training within the culture sector represent the main limit in the development of cultural performance measurement for the definition of clear standards of quality (Bjorkergren 1996, Holbrook and Hirschman 1982, Lewis 1990, Turow 1984).

The matter is therefore what can help the culture management to detect the right multidimensional indicators in order to make them more accountable for metrics purposes? Is there the possibility of finding, developing and maintaining control over resources such as talent, creativity and innovation, which are crucial for the success of a strategy of cultural industries (Jones and DeFillipi 1996, Miller and Shamsie 1996)?

Probably the best way to attempt an answer to such questions, is to focus and rely on the expertise of those sectors that are used to manage, on a daily basis, amorphous resources which cannot be clearly defined, that emerge from unexpected sources and that can lose their value for reasons that are not entirely understood similar to culture ones. One of those sectors is surely the Public Affairs one, that is, unfortunately, rarely incorporated by Culture and Arts organization. At the basis of the selection is the belief that the exploitation and mergers of the relationship between public and private interests still represents an underdeveloped ground for Culture sector, due to contextual and cultural resistances. But while Cultural business' as others, need to be answerable to society/audience for the way they conduct their activities, industries need favorable

political environments, and politicians, in return, need to rely on the expertise of cultural industry leaders to help shape policy with the aim to preserve cultural heritage, rendering the complementary exchange of views progressively mandatory. Unfortunately, despite those interdependent interactions, it happens, very often, that Cultural organizations and politics do not speak a common language. For Cultural business, as underlined, profit maximization and cost efficiency are consequences of their performances expression and are needed in order to survive and in politics, power, consensus and governance are, instead, the central concepts (Christian, 2015). The lack of a high profitable profile of culture sector therefore results in a lower reciprocal knowledge and understanding, usually implying the lost of opportunities, the slowdown of the decision-making process and a public and private waste of resources.

It is precisely to respond to such a climate of mutual incomprehension that Public Affairs and Communication specialized firms should operate, as intermediaries between societies needs, private interests and public recognition. Even because of their supporting role, over the last decades, on the public side, evaluation of advocacy and public affairs has become a new and emerging field capturing the increased attention of professional and less skeptical politicians. Their business is mainly based on the creation of common basis of communication with the attempt to overcome system boundaries that within the Culture sector could aim to render much more predictable the demand patterns, to better monitor and control production processes, to prevent the constant shifting in managerial practices and organizational forms and in shaping consumer preferences based on new methods of distribution, marketing, and promotion, striking a balance between the imperatives of creative freedom and commercial ones. The paper will therefore aim to define a theoretical and practical performance and measurement matrix model able to show the profitable impact of public affairs activities to culture organization structure.

2. Theoretical Framework

Historically literature addressed the issue of performance measurement mainly from the perspective of profit-oriented firms. As anticipated, it was only with the definition of the balanced scorecard by Johnson and Kaplan (1987) that took place the general overcoming of unidimensional approach to performance measurement, adding – for its determination - indicators as customers orientation, growth and innovation. While some saw the balanced scorecard as an innovation in performance measurement, others view it as incomplete. Sawhill and Williamson (2001), for example, argued that even with a multidimensional system very few organizations (both no-profit and profit) had linked their renewed metrics to their mission, introducing the necessity of major coherence between indicators and mission/organization identity. Successively, Atkinson, Waterhouse and Wells (1997) argued as the balanced scorecard was taking into account a limited number of stakeholders, instead fundamental for the definition of an organization, introducing the relevance of stakeholders detection for both internal and external organization expression and success. Moreover, in terms of the implementation of performance measurement systems, Ittner and Larcker (2001) argued that even if a multi-

dimensional approach provided a richer understanding of performance measurement, the practical implications of implementing such an approach limit its applicability, preventing managers from attempting to implement it mainly because of the lack of clear organization. Although criticism it seems that generally the most accepted conclusion is that organizations need to combine financial e non financial indicators selecting and linking performance measurement systems to their respective mission, as well as to their strategy for fulfilling those mission (Atkinson, Waterhouse and Wells, 1997; Sawhill and Williamson, 2001), within the detection of key stakeholders.

The literature on performance measurement within the culture sector is certainly not as extensive than as for others much more profitable sectors. Academics mainly focused their attention on how culture manager should measure performance rather than on how they actually do so. As Forbes (1998) assessed the performance measurement for culture sector remain an area to be explored. Morrison and Salipante (2007) argued as culture management is often very blinded in encompassing the forms of accountability that respond to explicit and objective standards of assessment without understanding that in the culture sector performance measurement implies a multidimensional concept that cannot be captured using one universal model. Also Schuster (1997), pointing out the risk of encouraging undesirable behavior, associated with using a limited number of indicators in order to monitor culture performance. The most basic guidelines concerning what principles should inspire performance measurement in the culture sector is provided by Voss and Voss (2000) who indicated as performance has to be linked to organization's values and strategic orientation to promote a clear mission statement. This principle is, however, not easily implemented by arts sector as one of the main difficulties is balancing the amount of resources needed to achieve artistic excellence with the dire need for funding (Lampel, Lant & Shamsie, 2000). Kushner and Poole (1996) suggested that effectiveness in culture performance measurement sector has four components: satisfying audiences, donors and volunteers; identifying and obtaining financial and human resources; efficiently organizing resources into technologies to present arts performances; and achieving performing arts program objectives. Gilhespy (1999, 2001) also proposed a performance measurement system for cultural institutions, arguing that external evaluation of a cultural institution's performance, including evaluation by the central government, does not take into account the distinctive objectives inherent in the arts sector, therefore suggesting a better needed relationship among public and private stakeholders to reach artistic excellence, innovation, social cohesion, public attendance and financial objectives. Generally it is recognized that weak governance typically results in a casual approach to culture performance assessment, while tighter governance mechanisms will induce performance measurement approaches that are closely tied to the organization's mission (Turbide and Laurin, 2009). When boards had no general consensus about how to measure culture organizational effectiveness, board members tended to monitor in ways that reflected their personal or professional competencies, rather than paying attention to measures needed to identify potential strengths, weaknesses and market opportunities. This result may be related to the fact that organizations do not see themselves as competing with others in terms of artistic

achievement. Activities that should, instead, be very important to the organization's survival. But in order to survive Cultural organization must be deemed legitimate by society (Ackerman, 1975). Since the public affairs function is responsible for managing the interface between the organization and its political and social stakeholders (Post, Murray, Dickie & Mahon, 1982), the way the public affairs function is conducted may be directly related to culture long-term industries survival (Meznar & Nigh, 1993). Since the 1990s the function of public affairs has been increasingly shifting from that of "improving the image" of business to that of "developing relations to consolidate reputation" (Invernizzi, 2005). Successively doctrine has been further developed and expanded, till to recognize those interpretation as restrictive and nearly overcome, considering lobbying and public affairs as one of the most important channel of sector success (Ansolabehere et al. 2003; Bennedsen and Feldman 2002; de Figueiredo and Cameron 2008; Gregor, 2011).

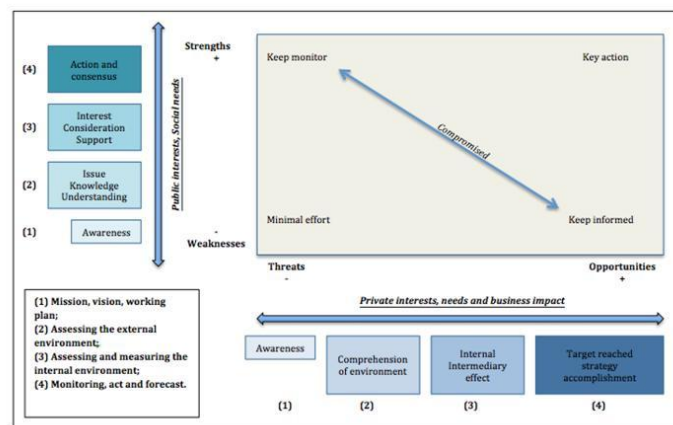

In consideration of the high levels of ambiguity and dynamism of the culture sector, which force managers to seek new models for managing their operations (Hirsch, 1972), authors will grade different combinations of managerial models and analysis with the view to ultimately define an innovative model in order to determine the consistent enhancement of artistic and cultural assets deriving from the application of Public Affairs activities in terms of freedom to operate, cost avoidance, market opportunity or advantage and reputation increasing.

3. A Public Affairs Matrix Proposal as a Culture Strategic Business Model

The role of public affairs establishment and functions is, indeed, to investigate the political groundwork structure with the attempt to recognize the opportunities for culture business coming from the legislative or regulatory interventions and stimulate the exchange of expertise and mutual recognitions. In details, the ultimate goals are: to raise public awareness on potential cultural private and public interests common grounds with the support of communication content and campaign; the identification of relevant stakeholders; the comprehension of the decision making process and the *scenario analysis*; to build a regulatory environment favorable for social, political and economic national and supranational targets; to strength the relational network and culture business external visibility; to stand private interlocutor as qualified partners as key decision makers/influencers in cultural sector policies. As evident those objectives can present themselves as a possible solution to previous theoretical observations and verified gaps and come to be essential both on a proactive and defensive way, in order to define and stimulate culture attractive economic conditions. These are just few reasons why all cultural organizations, with the initial support of a specialized firm, should dedicate, and if existing reinforced, a strategic management function to Public affairs with the task to analyze, interpret and help shaping the internal and external environment, through monitoring the political *arena*, analyzing political and social developments and, basically, representing the culture organization's interests within the political field.

On a strategic point of view, the precise knowledge of the ‘how, when and why’ of the entire decision-making processes and the identification of major decision-makers, almost inevitably gives to culture organization the possibility of easily overcoming obstacles and to anticipate the main changes of the market. Because of its peculiarities, public affairs result in being the main function able to change the fundamental course of a cultural political process already underway and headed in a certain direction. Therefore, as it aimed at detecting opportunities or preventing obstacles, it has to be part of the highest level of management in the cultural organization structure, able to exploit its value creation potential.

To this aim, authors decided to apply the following own production multi-dimensional matrix showing the importance of Public Affairs functions for business, here specifically applied to the culture sector.

The matrix results as interweave of the existing strategic business model and matrix, able to internalize almost the all mentioned variables. Initially, the matrix takes inspiration from the *SWAA matrix*, bringing together public and private needs and interests on the two dimensional axis then, inspired by the *SWOT analysis*, emphasizes actions of engagement between public and private context and cultural business, showing on the vertical axis the strengths and weakness of public intervention while on the horizontal axis the threats and opportunities coming from a private decision of a culture organization to employ public affairs actions. From the interaction of such dimensions private and public sector are immediately able to figurative realize when the collaboration and consequent actions are profitable and needed or when it's time to keep informed on the occurring progress, when it is needed to monitor and control changes and when there is the possibility to operate on a defensive or on a proactive way.

As detectable, the variables on the two axes have been putted into correlation with different action and decision consequential steps numerically and substantially corresponding to *the phases of the Allison and Kaye strategic making process (1997)*, transposable in cultural organization. In details, authors realized as in each numbered

step public affairs is able to understand which action undertake (part inside the matrix), based on the output and outcomes deliverable by the function through the different strategic phases (part outside the matrix), as follows:

(1) *Getting ready, defining mission and vision.* Private and public reconnaissance and awareness of the cultural matters. In this context, public affairs can support the portfolio analysis, to assist in the comprehension of the gaps between portfolio of services managed by the cultural organization and the expectation of its audience and stakeholders, such as donors, public funders, business sponsors, and the general public (CAIRS et al. 2004). *Measurable Output:* i.e. presentation material and strategic working and business plan definition;

(2) *Assessing the external environment.* Comprehension of environment from the private side corresponds to increased political issue, knowledge and understanding. It is evident as public affairs functions, at this level come to be climatic in mapping the operating environment through which, for instance, a stakeholder analysis model in conjunction with the Porter Five Forces model. Public affairs can identify relevant stakeholders in order to assist interests evaluating supporters and opponent and can contribute to understand the level of intensity of rivalry, understanding the threats coming from barriers and new entrants in the culture market. Moreover, within phase two it is important to *agree on priorities and actions, applying the SWOT analysis:* public affairs, being able to discern strengths and weakness and to intercept, opportunities and threats of the environment, provides the information needed to properly assess the culture organizational critical success factor, setting future agreement on priorities and goals. *Measurable Output:* i.e. list of critical issues and factors, map of competitive environment, stakeholder analysis and position papers;

(3) *Assessing and measuring the internal environment and strategic plan:* Internal intermediary effect in the private corresponds to the interest, consideration and support of the public. As shown, Public affairs also constitutes a relevant variable for the profitability analysis (i.e. ROI), the analysis of costs structures, the analysis of financing structures and for the identification of unconventional Key Performance indicator, KPI or Success critical factors (FCS). To this phase, the exiguity of outcomes concern comes to be even less substantial taking into consideration the existing *outcomes strategic-making process defined by Bryson (2004)*. Public affairs, in fact, stands on an equilibrate position between the deliberation of tangible and intangible content and process needed to succeed in the strategic change cycle. Public affairs function perfectly fits the scheme being able to deliver tangible process oriented outcomes (work, programs, stakeholders involvement and analysis, procedural requirements and expectation), intangible process such as crisis management and public relations. It provides intangible content in terms of individuation of key stakeholders and future goals, and, finally, tangible content in terms of action plans and budget saving cost. Moreover, in order to link strategy formulation to internal public affairs operating plans and budget, a *Balanced Scorecard (BSC)* can be putted in place. It permits the transformation of public affairs goals into a strategic map composed by integrated collection of objectives and performed indicators, grouped, as introduced, into four perspectives: *financial* (public affairs makes possible for culture sector to deliver

services at a lower cost and ensure trust, loyalty and affiliation), *customer* (identify targets and value propositions, ensure information, fair access and quality, satisfaction), *internal business process* (improve data-driven decision, coordination, external and internal cooperation and communication, improving public customer input process efficiency) and *learning and growing* (organizational capacity, learning and growing, improve skills, competences and resources, culture, enhancing commitment). *Measurable Output*: calculation of public affairs return on investment (ROI), impact on costs and financing structures and Key Performance indicator, KPI or Success critical factors (FCS). Identification of tangible process (i.e. work, program, stakeholders involvement, procedural requirements and expectation), intangible process (i.e. spread of appreciation, crisis management and public relations), intangible content (i.e. key relationships, future goals), tangible content (i.e. action plans and budget saving cost), definition of a *Balanced Scorecard (BSC)* for financial (cost saving), customer (trust, loyalty, affiliation, fair access and quality), internal business process (data-driven decision, coordination, cooperation, input process) and learning and growing (skills, competences, resources, culture, and commitment) indicators;

(4) *Monitoring, evaluating, act, control and forecasting future scenarios*. Target reached and strategies accomplished correspond to political collaborative action and consensus. In this phase public affairs perfectly contributes to the application of models such as the *Pest and Trend analysis*, that classified impact forces in: *political, economic, social and technological* with the support of *trend data analysis* in order to speculative combine data with evidence, probability and impact of different scenarios. Moreover, since no organization exists in a vacuum, public affairs, as anticipated, contributes to shift away from market towards service also within the *SWAA analysis of Montanari and Bracker (1986)* which is based on a two dimensional matrix: “public need support of services” and “unit capabilities needed for the service”. Public affairs function exactly fits in the forth dell of the matrix labelled “Back drawer issue” which corresponds to a function with low unit capabilities and low perceived public need - services that are not considered priorities; even though they might be very important services and they fail to be recognized as such. The matrix can therefore shows the importance of lobby/public affairs in individuate the actions involving the decisions about which cultural product or services have to be advocated, maintained, redesigned, reduced or closed down (Lega, & Cristofoli, 2009). *Measurable Output*: calculation of *Pest, Trend data and Scenario analysis* to determine whether efforts produced the desired results and decide how to alter future activities to better reach targets.

4. Results and Conclusion

Our survey thus contributes to the literature by exploring the practices in a sector that is often neglected, containing significant lessons also for similar industries. The matrix is able to focus both on political, social and technical aspects, adapting itself toward the definition of profitable public affairs actions and compromise of engagements between culture private and public context. Indeed, the research validate the possibility:

- *to establish a clearer measurable matrix capable of adapting public affairs activities to culture performance-management systems*: the matrix can be inserted on a annual time-line business planning in order to assure the budgetary framing of the function. As anticipated, authors suggest the externalization of the function to a specialized company firm, with the role to assist in the design and facilitation of the process providing expertise and external perspectives;
- *to create a link to real business outcomes – accountability*: the externalization permit do not excessively burden the budgetary adaptation of the cultural organization business.
- *to clarifying organizational support and orchestrate activities across the cultural organization business*: the support can be combined on complementary basis with both external affairs, regulatory and communication function. Moreover, the ability to convene and collaborate across functions on regulatory and communicative issues is a vital element for organizational and performance success;
- *to identify Key Performance Indicators – KPIs*, as public affairs appears fundamental in order to select the variables on which culture management can open with its decisions and which can significantly affect the competitive position of the organization, such as: *audience/stakeholders indicators* (satisfaction, awareness ratios, knowledge level, trust level, media opinion leaders contacts, number of information and relationship); *benchmark comparison indicators* (media share, share of audience, media scope, strategy success plans); *financial Indicators* (price performance, cost per program/service, return per program, cost growth); *human resources indicators* (hours per employee, growing of competences); *operational/process indicators* (program, product, service development, position papers and draft, completed project, quality performance level, volume of media released, deadlines met etc.); *quality of relationship indicator* (with investor, institutions, universities, general stakeholder, third parties; brand image and reputation; support in crisis communications and issues management; event and sponsorship);
- *to calculate public affairs return on investment (ROI)*, in order to demonstrate that business can recover investment costs and achieve measurable benefits for the function on a monetary basis. The equation for calculating Public Affairs return on investment is deceptively simple and is as follows: ROI percent= [Value of benefits generated by PA-Cost of PA] /Cost of PA x 100 percent (value received/ efforts and cost of activities).

It is therefore evident as public affairs, by preventing future levies, anticipating threats and by increasing opportunities of interaction and collaboration permits saving, cost avoidance and increased productivity within the culture sector. Such calculation is possible since outcomes became related to Public affairs activities; data are gathered during implementation thanks to the establishment of measures for each phase, able to turn data into information. In conclusion, the public affairs matrix applied to Culture can help: to anticipate and therefore shape consumer tastes; to understand if in a certain

period of time the culture organization need to drive decision making through artistic values or mass entertainment; to orient the cultural business strategy through product differentiation or market innovation; to detect problems and understand if belong to demand or market changes; to individualized a different structure of business mainly focused on vertical integration or on flexible specialization; to enchant individual inspiration or the creative system. Thanks to Public affairs culture management can be therefore able to analyze the market in order to understand what their consumers are likely to respond to, also influencing consumers by encouraging interest in attributes in which their products enjoy an advantage. From this point of view, the incentives resulting from the model's application will eventually draw all different stakeholders to differently combined competences and endowments in order to undertake more collaborative and profitable action plan as to acquire a proactive role in the political decision-making, anticipating economic and occupational circumstances and needs, representing a *benchmark* for the promotion of worldwide public affairs best practices for culture sector development.

Abstract

Sustainable competitiveness and growth of SMEs are increasingly determined by their capability to make use of digital technologies which are generating opportunities for developing new growth routes based on digitization. This paper reports the findings of a study how SMEs in the Basque region of Spain assess their digital maturity. The main purpose of this research is to gain insights into the development of digital capabilities of SMEs that support their digital based growth.

The DIGROW-Framework of digital maturity (North et al. 2018) was used to assess the digitization capabilities of SMEs in the Basque region in northern Spain. In cooperation with the regional business associations, a self-assessment questionnaire was sent to members and resulted in a return of 550 questionnaires by November 2018.

The study provides rich information on the digitization approaches of SMEs in the Basque region. It sheds light on the learning paths of digital transformation of SMEs. In particular, its originality and value resides in the application of a maturity framework based on dynamic capability theory to a wide range of SMEs. The model is easily applicable also to SMEs of other countries or regions.

Study results allow regional business associations as well as local and regional government to develop strategies and support measures to foster digital growth of SMEs. The survey also demonstrated that the applied maturity model provides guidance to SMEs to raise awareness of owners, managers and employees towards required capabilities as well as opportunities/threats, to create a shared understanding on what “digitally

enabled growth” means for the firm, to anchor pilot initiatives in an overall “picture” of digitalization and to define learning objectives.

Keywords: growth; dynamic capabilities; digital maturity; SMEs, Basque Country.

Paper type: Academic Research Paper.

1. Introduction

Sustainable competitiveness and growth of SMEs are increasingly determined by their capability to make use of digital technologies (EU 2017) which are generating opportunities for developing new growth routes based on digitization (Taruta and Gatautis, 2014). To understand how SMEs are approaching digitization we have to be aware that they are part of a heterogeneous universe of extremely diverse economic agents, whose characteristics vary depending on the business sector they operate in, the markets they serve, the products they produce and how involved and connected they are to the macroeconomic context and support institutions (Latameconomy, 2013). What SMEs have in common, however, is the need to integrate, build and reconfigure internal and external resources to adapt to rapidly changing environments (North and Varvakis 2016). These dynamic capabilities reside in skills, processes, procedures, organizational structures, decision rules and distinct disciplines that motivate and promote the detection (sensing) and capture (seizing) opportunities in order to reconfigure (transforming) their capabilities (Teece, 2007). Along these lines, several studies demonstrate that the development of dynamic capabilities contribute to SME performance and growth (He and Wong, 2004; Lubatkin et al., 2006; Macpherson and Holt; 2007; Protogerou et al., 2008).

Yeow et al. (2018) found that as an organization shifts towards a digital strategy, misalignments between the emergent strategy and resources give rise to tension and requires alignment actions, which iteratively reconfigure organizational resources and refine strategy in order to respond to both changes in the environment and internal tensions. Studies on digitization of SMEs (for an overview see North et al. 2018) suggest that in this first wave of digitisation (EU, 2017) SMEs adopt quick impact measures, experiment with new solutions, observe their peers and cautiously move forward mostly without a comprehensive vision on what digitisation means for the firm. However, we still lack consolidated evidence on the learning path of developing digitization capabilities in general and regarding SMEs in particular.

Along these lines, the main purpose of this research is to gain insights into the development of digital capabilities of SMEs that support their digital based growth. For this we apply a maturity approach based on dynamic capability theory.

Maturity models allow the assessment of the current situation of a company as well as the identification of reasonable improvement measures (Becker et al. 2009) and serve as a guide through the transformation journey (Valdez de Leon, 2016). Maturity can be defined as a measure to evaluate the capabilities of an organisation regarding a certain discipline (Paulk et al. 1993). Digital maturity means that a company has the necessary organizational capabilities to succeed in the digital transformation (Berghaus et al. 2017).

2. Methodology

2.1 The DIGROW-Framework of digital maturity

To assess the digitization capabilities of SMEs in the Basque region The DIGROW-Framework of digital maturity (North et al. 2018) was used. The theoretical foundation of the framework is Teece's (2007) model of dynamic capability development: "For analytical purposes, dynamic capabilities can be disaggregated into the capacity (1) to sense and shape opportunities and threats, (2) to seize opportunities, and (3) to maintain competitiveness through enhancing, combining, protecting and, when necessary, reconfiguring the business enterprise's intangible and tangible assets" (Teece, 2007: 1319). For the development of a practice oriented self-assessment framework a capacity of strategy development and communication was inserted between Teece's "sensing" and "seizing". This is based on findings that a particular shortcoming in SMEs is that owners and managers are aware of growth potentials but often lack an explicit strategy and if they have a strategy do not communicate that strategy to employees (North et al. 2016). It also pays tribute to Pavlou and El Sawy's (2011) argument on the importance of learning and integration in developing dynamic capabilities.

Therefore, the "DIGROW" framework contains the following four elements, which can be seen as challenges (e.g. what are our challenges to sense digitally enabled growth potentials?) or capabilities (e.g. do we have the capability to sense digitally enabled growth potentials?). Both views are useful in a self-assessment. Along the lines of Teece's (2007) microfoundations of enterprise performance, North et al. (2018) have defined four capacities for each of the four challenges or capabilities. The assessment is visualised as a "Wheel of digitally enabled growth" (Figure 1). Each of these capacities can be evaluated at five levels described by an anchor statement. In a pre-test with firms, we found that these five levels would allow a sufficient degree of differentiation. Therefore, the "DIGROW" framework is structured as follows:

1. *Sensing digitally enabled growth potentials*: Searching for digitally enabled growth opportunities, understanding and developing digital customer needs, sensing technology driven opportunities, use of external sources for digital innovation.

2. *Developing a digitally enabled growth strategy and mindset*: Digitally enabled growth strategy, digital leadership, digital mindset (attitudes & behaviors), empowered employees.

3. *Seizing digitally enabled growth potentials*: Digitally enabled business models, digital market presence, digital customer experience, agile implementation/deployment of digitalization initiatives.

4. *Managing resources for digital transformation*: Digital skills & learning, digital processes, digital technology & security, digital investments.

Table 1. provides an example how these capacities are assessed. The full framework can be downloaded from Researchgate.¹

https://www.researchgate.net/publication/326294602_Promoting_digitally_enabled_growth_in_SMEs_a_framework_proposal_-_Part_Ii_The_DIGROW-Framework_evaluation_grid

The wheel of digitally enabled growth

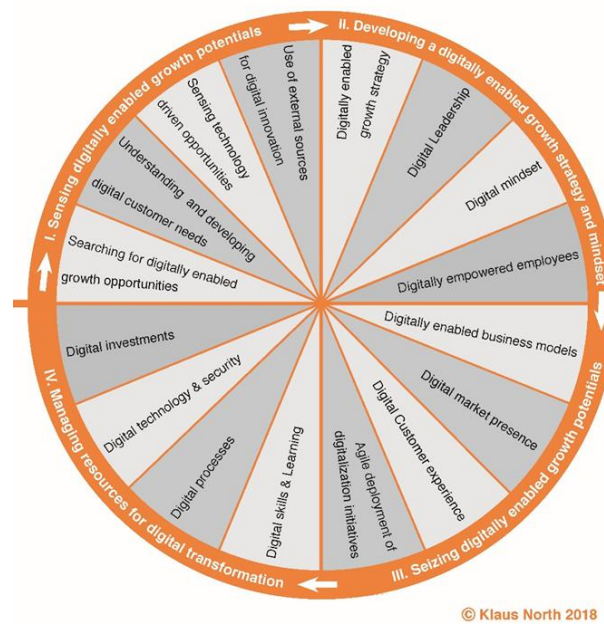

Figure 1 The wheel of digitally enabled growth (source: North et al. 2018))

Table 1: Example of the self-assessment questionnaire for the dimension “Digitally enabled business models”

Dimension	Level 0	Level 1	Level 2	Level 3	Level 4	Level 5
Digitally enabled business models	No digitally enabled business models	We have a reactive approach. First we see what competitors are doing or changing.	We are looking for new improved, innovative business models	We have started to change some components of our business model (e.g. sales channels, value proposition)	Our new business models already contribute to increased revenues	We systematically adapt our business models or create new ones for digital enabled growth, including customer segments, channels, activities/resources and the value proposition.

2.2 The survey and sample

The companies under study are small and medium-sized enterprises (SMEs) of the manufacturing and commerce sectors of the Basque Autonomous Community (CAV), characterized by having between 10 and 500 employees. According to the Basque statistics office EUSTAT the number of companies in this size range amounts to 2,599 SMEs and the number of SMEs in the commerce sector is 10170 companies. The self-assessment questionnaire was sent to 7040 firms in cooperation with the regional business associations between July and November 2018.

The number of SMEs that responded to the survey amounts to 540 (response rate 7,67%). After eliminating only partially completed or invalid questionnaires the final sample consists of 427 companies. Regarding the size of the companies, 47 firms have between 10 and 49 employees, 220 companies have between 50 and 249 employees, and 160 have between 250 and 500 employees. On the other hand, 138 firms belong to manufacturing industry, 29 to commerce sector, and the rest of the 234 companies are distributed among different types of services (i.e. education, health services, insurance, information services, transport, professional services, etc.) and building (26 firms).

3. Findings

In the following we will present the survey results, first regarding each integral dimension of the DIGROW-framework and, second, we will explore some relationships between the different dimensions and examine also other firms' characteristics (i.e. size).

1 - Sensing potential opportunities for digital growth

More than three quarters of companies (77%) search for digital growth opportunities, with more than a quarter of them (28.2%) actively working on their identification, but only 24% identify these opportunities systematically. Commerce firms identify opportunities more systematically than the manufacturing industry. In addition, a considerable percentage of them have a clear idea of the expectations and needs of their clients, although there is still a high percentage of companies that are unaware of them. Around 38% confirm that "we analyse how technology driven opportunities can create value for specific customer segments and we address them properly" and another 38% say that they appropriated some new digital technology.

However, there is still little collaboration with external agents such as potential customers, universities, research centres, "the crowd" or partners in the "eco-system" for the search of opportunities for growth and digital innovation. This sheds light on a rather closed learning path towards digitization.

2 - Developing a digital growth strategy and mindset

While many companies are sensitive to digitalisation, this does not translate into the development of strategies how to take advantage of the growth opportunities offered by digital technologies and the incorporation and application of them in the organization. Only 18% of firms claim that they have a consistent digitally enabled innovation &

growth strategy in alignment with their resources. Another 15% have updated their strategy regarding some aspects of digitally enabled growth. Commerce is more advanced than manufacturing in this respect.

The contrast between extreme positions is more accentuated in relation to digital leadership. Compared to a 14% of SMEs that count on leaders that initiate, coordinate and supervise digital initiatives, to which they assign a high priority, 30% acknowledge not having leaders that promote digital growth. The manufacturing sector is the one that concentrates the majority of companies that lack this leadership (42%).

Regarding a “digital mindset” a quarter of companies affirms that “people in our firm start thinking about digitalization and managers are developing new digital behaviours” An about 30% of SMEs situates them even higher in stating “There is a generally positive attitude towards digitalization and broad development of new behaviours”.

This emerging digital mindset has, however, a limited effect on empowering employees. While 30% of commerce firms say that employees are encouraged to experiment with digital initiatives, 40% of manufacturing deny that. This leaves still ample room for improvement and has to be seen with in connection with the very low level of agile implementation and deployment of digitalization initiatives discussed below.

3 – Seizing digitally enabled growth potentials

Although Basque SMEs, in a large percentage, are seeking opportunities for digital growth; their ability to take advantage of such opportunities and exploit them is quite limited. In this sense, although many companies are thinking of improving their business model or developing new business models based on digital technologies, few companies have taken comprehensive action. While 43% of commerce firms state that they have started to change some components of our business model (e.g. sales channels, value proposition) a similar number of manufacturing firms have done nothing so far.

Consequently, the percentage of companies actively present in the digital market is small and the interaction with customers through digital channels is limited. Also in these aspects differences are pronounced between commerce and manufacturing. Around two thirds of commerce SMEs confirm that they count with a customer-oriented website and presence in several social media or –even more advanced - continuously develop different activities to keep themselves at the top of mind (e.g. digital marketing campaigns, blogs, videos, digital communities, etc.). 44% of manufacturing have a website, which is not actively managed and some presence in social networks (e.g. Facebook or twitter). The level of a digital customer experience is quite low. Around 20% of firms say that they mainly interact with customers digitally. Some of them deliver customer service across multiple digital channels.

With their limited resources SMEs could benefit from an agile deployment of digitization initiatives. This includes methodologies such as design thinking for the development of new solutions or SCRUM for project management, small projects that lead to short-term results and that have an incremental and iterative approach to continuous improvement. Most of the companies of both sectors, however, claim not to

have projects or methodologies to implement digital initiatives. And there are few companies that systematize the use of agile technologies to implement digital initiatives.

4 - Managing resources for digital transformation

Companies still invest little in the development of digital skills and competencies as well as in digital technologies and cybersecurity. However, with regard to the digitalization of business processes, the situation is somewhat better, since almost half of the companies have begun to digitize some processes.

Digital skills include the habitual use of technology by collaborators to carry out their tasks and for the improvement and innovation of processes and / or business models. It also includes curiosity and experimentation to make improvements and the ability to be agile in order to rapidly advance at the pace of technological changes and new business models. Finally, digital skills include the capacity for continuous learning and development of teams and people to close the digital gaps. In relation to digital skills, 26% of companies say that investment to develop digital skills is low. For an additional 23% of firms the level is adequate in relation to relevant business areas. Companies that claim that their employees possess all the necessary digital skills and have formal learning and development programs are a minority, 6.7%, and represent almost the same proportion as companies that claim not to have digital skills or perform training for their development.

The implantation of technologies and the level of security of the companies is remarkably unequal. Thus, 23% of companies have incorporated digital technology in a few processes and have planned security measures, but at the same time 20 % have only minimal technology and very limited security measures. At the higher levels of maturity associated with the implementation of technologies and security measures in critical processes and / or throughout the business, the trade sector appears better positioned with 25% of companies compared to 16% of the manufacturing sector. This result may be associated with the B2C business model of the commerce sector that requires greater contact and security with the final consumer, compared to B2B relationships manufacturing.

Regarding investments in digital transformation initiatives, most companies (24%) claim to have a medium level. 15% of manufacturing firms say that they have not invested in digitization, whereas one third of commerce SMEs report a significant level of investment on digital initiatives in specific business areas.

5 Relationship between DIGROW dimensions and size effects

In order to know if there is any relationship between the different dimensions of the framework and between the different capacities making up each dimension as well, a correlation analysis has been performed. As a result of this analysis, a middle intense relationship between seizing digitally enabled growth potentials and managing resources for digital transformation dimensions is found. Regarding the relationship between the different capacities integrating both dimensions, the correlations between digital skills and learning and both digital customer experience and agile deployment for digital

initiatives are especially relevant, among others. Moreover, there are correlations between some capacities of the digitally enabled growth strategy dimension and capacities of other dimensions. In particular, the digital leadership capacity is correlated with digital business models as well as with digital skills and learning, and with digital investments.

On the other hand, and as far as the capacities of managing resources for digital transformation dimension is concerned, digital processes, digital skills & learning, digital technology & security and digital investments are quite correlated between each other (the relationship is slightly more intense between digital investment and digital processes and digital technology & security). With regard to the seizing dimension there are just two significant relationships, which are between presence in digital market and digital customer experience, and between digital enabled business model and digital market presence. In the case of developing a digitally enabled growth strategy and mindset, just one relationship is significant (the highest of all) between digital leadership and digital strategy for growth. Finally, no highly significant relationship exists between capacities related to sensing digitally enabled growth potentials dimension.

Moreover, further analysis has been carried out with the aim of testing if firm's characteristics affect digital maturity. In particular, size effect is examined. In this line, the sample has been divided into two sub-samples according to firms' size. One sub-sample is made up by firms having between 50 and 249 employees (i.e. group 1), and the other one includes companies having between 250 and 500 employees (i.e. group 2), with the purpose of comparing both sub-samples and verify if there is significant difference between them regarding the digital maturity level of companies. A mean comparative analysis has been carried out in order to test if the mean digital maturity level of firms for each capacity is significantly different or not according to size. The results of such analysis are shown in table 2 in Annex.

According to the results obtained, there is a significant difference according to the size of the firm in the case of eight capacities included in the framework over a total of sixteen (i.e. in the half of the capacities). In particular, in the case of the following capacities (the ones highlighted in red colour in the table 2): use of external sources for digital innovation, digital leadership, empowered employees, digitally enabled business models, digital market presence, digital customer experience, agile implementation/deployment of digitalization initiatives, and digital skills & learning. Therefore, it can be concluded that size is a relevant variable regarding digital maturity, since the mean digital maturity level of companies regarding each capacity is significantly different in each group of companies in the 50% of capacities the framework encompasses. Moreover, it is verified that the mean level of digital maturity is higher in the case of bigger companies in all the capacities (i.e. higher mean in the group of companies with more than 250 employees than in the group of firms having between 50 and 249 employees). This is very clearly appreciated in the table 3 in Annex which describes the mean level of digital maturity regarding each capacity in the two groups of firms distinguished.

Considering the aforementioned, it can be concluded that size is a relevant characteristic of the firm in terms of digital maturity and that, in general terms, smaller companies are less mature regarding digitalization which is probably explained by the

fact that they possess more limited capacities for enabling digitalization and digitally enabled growth than bigger ones.

4. Discussion

Our findings shed light on an experimental and less systematic learning path of digitization. Most companies surveyed do not have a digital strategy and are cautious with regard to investments. Development of digitization skills is also quite limited.

Although we currently lack consolidated evidence in this emerging field of research and practice, there is an increasing number of surveys and case studies which support our findings. The study "Impuls" (VDMA 2015) of 289 companies in the mechanical engineering sector in Germany notes that only 5.6 percent of the relatively small companies are already in the group of leaders when it comes to implementing Industry 4.0. Another 17.9 percent are beginners who work with the concepts of Industry 4.0 and are taking the first steps to make this happen. The overwhelming majority of 76.5 percent have not yet taken any systematic steps to implement Industry 4.0 and it is classified as new. In case studies of 68 German manufacturing SMEs, Müller et al (2018) illustrate that these companies generally approach Industry 4.0 with caution and still try to understand how to take advantage of the innovation of the business model in the creation of value, the offer of value and value capture. This cautious or reactive view is reflected in a survey of 300 SMEs in the US (IDC, 2017) that still consider that IT is a necessary cost (45%) instead of a driver (20%) of competitive advantage. The IDC-SAP study (2017) of 3900 SMEs in 14 countries also states that companies prefer to continue investing cautiously in small projects with a rapid impact, which lays the foundations for more ambitious and demanding projects. Observing and learning from other SMEs is a widely used approach in this gradual step towards digitization (Baker et al., 2015).

In our sample, particularly in the manufacturing sector, we witness a rather reactive approach to digitization. Employees are rarely empowered to experiment with digitization initiatives and there is a limited cooperation with outside partners. Proactive companies show strong leadership, develop a digital mindset, have well-developed sensors in terms of technology and market developments, learn from many sources, integrate into business ecosystems and actively promote their presence in the digital market (Conference Board of Canada, 2014; IDC-SAP, 2017; Sinkkilä, 2017; Müller et al., 2018).

Regarding the development of digital skills in our sample, only 23% of firms claimed that the level of training is adequate in relation to relevant business areas. This lack can be explained by the way of operating of SMEs (North and Varvakis 2016). The Interim Report of the European Pilot Project on digital skills (Bluespecs, 2018) states that the main barrier for SMEs is a lack of a long-term vision and strategy. It was argued that SMEs are not upskilling their people because by the very nature of being an SME, they are focused on delivery and the short-term. The report further argues that SMEs often are unaware of what skills they are lacking. In addition, given the scarcity of human resources, SMEs seem reluctant to have training occur during the working hours. Training is also not offered to all workers. Warnhoff and Krzywdzinski (2019) found that workers

with lower qualifications have less access to training for industry 4.0. On the other hand, successful cases demonstrate that SMEs active in non-native digital sectors acquire digital knowledge through their interaction with other SMEs specialised in offering IT services and solution, and who are able to bring skills and digitization to other SMEs in traditional sectors (Grand Coalition for Digital Jobs, no year).

On the other hand, a study of Swiss SMEs (PwC et al 2016) reveals that digital maturity correlates positively with the size of the organization and negatively with the age of its administration. This is also corroborated in the present study where it is found that also size correlates with digital maturity level, in the sense that bigger companies attain higher digital maturity levels than smaller ones.

Summing up the previous findings: in this first wave of digitalization (EU, 2017) SMEs adopt rapid impact measures, experiment with new solutions, observe their peers and move cautiously, mostly without a comprehensive vision of what the digitization for the company means.

Abstract

Collaborative applications – also known as collaborative software – are increasingly being used by companies. The applications are meant to support intensive, effortless cooperation among team members, management and clients at any place and at any time. The uniqueness is their combination with social media and Web 2.0 functionalities (McAfee, 2009). The aim of this contribution is to identify the actual, in-field benefits of software-supported collaboration for small and medium-sized enterprises (SMEs) thus far reported in the literature.

We review and summarise the findings of former research on the use of collaborative software. The term collaborative software is used to describe Web-based applications (platforms) to support communication and collaboration in enterprises. For our research of the literature we used the ProQuest and EBSCO databases, which included highly ranked journals in the field of SMEs. Only peer reviewed empirical research papers dealing with the use of collaborative software were included in the review. Our research questions were: 1. Which studies have focused on the use of collaborative software in SMEs? 2. What benefits of software-supported collaboration in SMEs have been found? 3. What were the other main findings of the studies? On the basis of the collected results we will discuss the intended vs. actual benefits software-supported collaboration have for SMEs.

To the best of our knowledge, there is no other review of the benefits of collaborative software potentially relevant for SMEs, making this review is an important addition to other contributions in the field.

The results provide valuable (albeit less comprehensive than we hoped) information to managers and practitioners in SMEs, helping them to decide their IT strategy and the importance of collaborative software therein. Knowledge about the benefits of software-supported collaboration as well as impacts on employee- and organisational-work design is useful for the effective implementation and use of collaborative software.

Keywords – collaborative software, collaboration, small and medium enterprises (SMEs), dynamic capabilities, growth

Paper Type – Academic Research Paper

1 Introduction

Information technology is seen as a major driver of business success and as a key for enabling collaboration on spatial distance (Warner and Witzel, 2004). An innovation in enterprise software, collaborative software was made possible by the introduction of Web 2.0 applications. Collaborative applications differ fundamentally from both earlier groupware applications and from classical knowledge management applications (McAfee, 2009). “However, a distinctive feature of Web 2.0 era collaboration systems is the emphasis on end user content creation; improved tools for information organisation and retrieval and the combination of existing content to deliver new information services.” (Schubert and Williams, 2012, p. 213)

In the literature, various terms are used for this type of Internet-based enterprise software: Enterprise Social Networks (Rossmann *et al.*, 2016), Enterprise Social Media (Archer-Brown and Kietzmann, 2018), Enterprise 2.0 (McAfee, 2009; Alberghini *et al.*, 2013), Emergent Social Software Platforms (McAfee, 2009), Social Software (Raeth *et al.*, 2010), Collaborative Applications (Schubert and Williams, 2012; Klötzer *et al.*, 2017), Enterprise Collaboration Systems (Cardon and Marshall, 2015; Nitschke and Williams, 2018) or Unified Communication and Collaboration Technology (Silic and Back, 2016). This variety of terms reflects both the rapid development in the field and the different perspectives from which the subject is viewed. We use the term collaborative applications in this article for applications, which connect team members via the Internet, allowing them to work anyplace and anytime. They usually include a variety of tools for communication (e.g. email, chat, online communities, Web conferencing), task

coordination (e.g. calendar, project management) and a project's knowledge management (e.g. Wiki, blog, document collaboration, social media) on a single platform ("suite").

Collaborative applications have a fast growing distribution in bigger companies (Kane, 2015) and this also applies to smaller companies (Kim *et al.*, 2013). However, there are indications that their adoption rate by small and medium-sized enterprises (SMEs) in the USA "is still much lower than that of large firms" (Kim *et al.*, 2013, p. 169) and that some SMEs in Germany have experienced difficulties in their implementation and use (Hardwig *et al.*, 2018; Paul, 2018). Overall, a very strong market potential is seen (Mikogo, 2018; Schubert and Williams, 2015).

The implementation of collaborative applications is associated with high expectations for the improvement of internal communication and collaboration. "Collaboration software enables companies to streamline their business processes, better manage projects of all sizes, and boost productivity across the board." (Mikogo, 2018, p. 2) Collaborative software has been recognised as an important enabler of productivity in enterprises (Silic and Back, 2016, p. 21). However, many of the current reports are based on market studies by consulting firms or case studies by companies reporting on their successes (see the sources in the paper of Archer-Brown and Kietzmann, 2018).

What do we really know about the real benefits of collaborative applications for companies? The aim of this paper is to identify the actual benefits of software-supported collaboration, especially for small and medium-sized enterprises (SMEs).

For this purpose we have conducted a structured literature review to find relevant studies. In the next section we present the method of the review. Then we present the results and end with a discussion of the findings and a conclusion for further research.

2 Data and Methods

We used ProQuest and EBSCO as databases to conduct the structured literature search. Since three high ranking journals are viewed to be especially relevant sources in the field of SMEs research (Durst and Edvardsson, 2012, p. 883), we ensured that these were included in our search: The International Small Business Journal, Journal of Small Business Management and Entrepreneurship Theory and Practice. We focussed our search on English-language peer reviewed empirical research papers and limited the publication time from 2009 to 2019. Based on McAfee (2009) we can assume that Web 2.0 application started to become a relevant factor for cooperation in companies about 10 years ago.

We iteratively developed a suitable search strategy for our research questions by experimenting with several search terms and combinations of terms. Due to the substantial terminological variance in the field of collaborative software (see Introduction) we examined multiple terms with regard to the number of findings and their relevance. Furthermore, we excluded the terms "education" and "corporate social responsibility" from our search, as they are not relevant to our research questions. We tried to narrow the search to studies of SMEs, but this reduced the search results too much. We therefore reversed our decision and reopened the search to all company sizes.

In the ProQuest database we achieved the most convincing results if we only searched for the applications using the different terms in the title, abstract, keywords and omitted the full text in the search.

Search term for ProQuest database:

(noft("enterprise social network") OR noft("collaborative software") OR noft("collaboration software") OR noft("social software") OR noft("unified communication") OR noft("enterprise social systems") OR noft("enterprise social media") OR noft("enterprise 2.0") OR noft("collaboration platforms")) AND (pd(20090315-20190315) AND PEER(yes))

Since there are differences in the search processes in the databases, we had to adjust our approach for EBSCO. In EBSCO the full text in the search is included. Therefore, we added different aspects (outcomes) like benefits, advantages and positive effects as well as importance and growth to focus the search on our research questions.

Search term for EBSCO database:

(enterprise social network or collaborative software or collaboration software or social software or unified communication or enterprise social systems or enterprise social media or enterprise 2.0 or collaboration platforms or enterprise collaboration system) AND (benefits or advantages or positive effects or importance or impact)

As a result, a total of 818 articles was identified. To select the relevant literature from all of our findings, we proceeded in four steps. Firstly, all 818 titles of the articles were checked for their relevance to our research questions. Over 76% of the articles did not pass the first sorting assessment. In the second step we screened the abstracts of the 193 remaining articles for their relevance. An additional 127 articles (34%) were disqualified. Although 5 articles had to be excluded because their full texts could not be procured, the full texts of the remaining 61 were subsequently read and checked with regard to their empirical method and the reported benefits of the use of software-supported collaboration. Based on this full text screening, 46 articles were disqualified, leaving 15 articles with relevant characteristics (see Table 1 in appendix).

3 Findings

Clearly, the benefits of the use of collaborative applications have not yet been thoroughly researched, demonstrated by the small number of studies found in our literature search of two large databases. Only 15 suitable studies from the last ten years were found, and they were found only because we did not limit our search to studies of collaborative software use in SMEs. The search was made more difficult by the fact that the topic is discussed using a large spectrum of different terms (see Table 2 "Type of IT System" column). In the 15 studies we analyse, 10 different terms are used, all of which refer more or less to the same subject. The only exception is the term social enterprise software, which clearly describes an add-on to existing enterprise software; the presented study by Engelstätter and Sarbu (2013) deals with customer relationship management (CRM) systems. The focus terms of the other studies are Web 2.0 and enterprise social

media. However, the concrete functionalities or products are not specified in most cases (Table 2 “Product” column).

The challenging use of collaborative applications is a global issue. The majority of the studies we found stem from Europe (8 studies), but contributions were also made in India/China (3) and Arabia (1). Three contributions analyse the situation of internationally active companies.

Most studies make no differentiation according to company size. Usually these are surveys involving a mix of company types and sizes (6), often lacking a precise description. Quite a few of the studies do not disclose their basis at all (4). Two studies are representative of the basic population (Engelstätter and Sarbu, 2013; Sarbu, 2017). One case study deals with an SME (Forsgren and Byström, 2018), one SME is represented in a multi-case study (Makkonen and Virtanen, 2015) and one study predominantly describes the situation in SMEs (Anders, 2016). More often we find studies of very large companies (4).

Not surprising is that IT companies are over-represented among the industries reported using collaborative applications. Four studies relate to the IT sector alone, and in the samples of three studies they are very strongly represented. In three surveys different industries are represented, and – as mentioned above – two analyses refer to representative samples. Three case studies add individual sectors to the list: energy sector (Alberghini *et al.*, 2013), electrical industry (Wu and Wang, 2014) and there is a collaborative application comparison of profit and non-profit companies (Trimi and Galanxhi, 2014).

Table 1 gives an overview of the methods used. Case studies (6) and surveys (5) predominate. Methodologically innovative are a multi-case study (Makkonen and Virtanen, 2015) and the content analysis of blog posts with a mixed-method approach (Anders, 2016). Econometric analyses based on representative data are carried out less frequently (3). All three analyse a regular company survey conducted by the Centre for European Economic Research (ZEW) in Germany. We also evaluate the presentation and interpretation of findings from a survey conducted by Microsoft itself (Williams and LaBrie, 2015). This study does not include a description of its method and the underlying data set, shining a light on its qualification as empirical research. We have included it because of its practical relevance.

Qualitative methods – mostly interviews – are used in case studies (Forsgren and Byström, 2018; Makkonen and Virtanen, 2015); in one case an additional survey is carried out (Trimi and Galanxhi, 2014). In these case studies, the number of respondents is between 12 and 42. In other case studies, questionnaires are used and more people are included, the amount being between 138 (Wu and Wang, 2014) and 158 (Alberghini *et al.*, 2013).

The number of cases in which company representatives are interviewed is similarly large in many surveys (between 115 and 174). Only the Czech survey achieves a large sample of 842 respondents (Skoludova, 2017). The largest samples can be found in the secondary analyses of the representative surveys (505 to 4400 respondents). Two studies do not disclose their case numbers.

The methods that were used show a relatively large number of advanced statistical approaches. There is no room here to take a closer look at whether the statistical methods match the questions used in the surveys and the data available.

What can be said about the benefits of collaborative applications based on the literature (see Table 3)?

The most noticeable result first: Only one study comes to the result that the use of social media in companies could have negative consequences. Especially the use of blogs and social media (not the use of Wiki systems) negatively correlated with labour productivity (Sarbu, 2017). The fact that the use of collaborative applications does not promise advantages under all conditions can also be taken from other studies, which we discuss later.

For the presentation of our findings on the use of collaborative software, we divide the existing contributions into four groups according to their focus on the benefits of collaborative applications:

A) The first group of four studies pursue research questions that focus on the perspective of the users of collaborative applications. What do users like about using the new tool called Slack (Anders, 2016)? What differences can be found between functional areas in a company, which are interpreted as work activities with different work related needs (Forsgren and Byström, 2018)? To what extent is the potential of such applications to generate social closeness associated with individual performance (Kügler *et al.*, 2015)? In which different dimensions (structural, relational, cognitive) do the users experience a benefit (Makkonen and Virtanen, 2015)?

These studies reveal multi-faceted effects of collaborative applications. The benefits of using collaborative applications can be summarised in four dimensions on the basis of these studies: The first is knowledge sharing (Anders, 2016) and work related information (Forsgren and Byström, 2018); the second is social benefits, comprising engagement and cohesion (Anders, 2016), the feeling of social connectedness (Kügler *et al.*, 2015) socializing (Forsgren and Byström, 2018) and the possibility to express themselves as a member of a community (Makkonen and Virtanen, 2015). The third aspect is collaboration, which comprises for instance the aspects of context awareness, collaborative workflows and avoidance of redundant work, as well as more space for collaborative discussions (Anders, 2016). The fourth dimension concerns change in the perception of events and activities within and outside the company. This dimension also includes a changed control of user awareness by the fact that independent user groups can be formed or users themselves can control which contents they want to perceive. This is described by similar terms: attention allocation (Anders, 2016) ambient awareness (Forsgren and Byström, 2018) transparency and awareness (Makkonen and Virtanen, 2015).

B) A second group of four studies surveys the benefits of collaborative applications for an entire company in the context of one (or more) case studies. They usually worked with pre-defined categories from the literature and report on very large companies. The case study of Alberghini *et al.* (2013) explores the expectations and perceptions of the employees using an enterprise 2.0 system. Another study compares management's and

employees' assessments of the benefits of a collaborative application in two large organisations, one a for-profit and one a non-profit organisation (Trimi and Galanxhi, 2014). Wu and Wang (2014) orient their evaluation towards the Balanced Scorecard system, which they operationalize with their own criteria. Williams and LaBrie (2015) do not use a specific classification system. Trimi and Galanxhi (2014) and Alberghini et al (2013) reports rather weak forms of benefits, the latter big differences between the needs of the users and the experienced reality.

Based on the above studies, three of the four dimensions of the benefits of collaborative applications can be confirmed: knowledge sharing (Alberghini *et al.*, 2013; Trimi and Galanxhi, 2014); social benefits, which includes community building, and employee engagement (Trimi and Galanxhi, 2014) as well as employee satisfaction (Williams and LaBrie, 2015); and lastly, the confirmation of collaboration (Alberghini *et al.*, 2013; Trimi and Galanxhi, 2014; Williams and LaBrie, 2015; Wu and Wang, 2014). But there are no reports of attention allocation, probably because it is not part of their given survey classifications.

Some other aspects are mentioned as benefits: better communication (Trimi and Galanxhi, 2014), competence (Alberghini *et al.*, 2013), more intensive customer relationship because of better problem handling (Wu and Wang, 2014) and organisational activities and outcomes (Trimi and Galanxhi, 2014). And last-but-not-least financial measures: Direct effects of the use of collaborative software are reduced conferencing and travel cost (Williams and LaBrie, 2015) or reduced cost of communication and reduced work hours (Wu and Wang, 2014). Other economic advantages result from the different way of working, which includes the reorganization of the work places. Williams and LaBrie (2015) report relevant reduction for real estate and operating costs and better productivity.

C) Further studies pose very specific questions regarding the benefits or drawbacks of collaborative applications. Three studies conducted econometric analyses on the basis of representative data. One (Engelstätter and Sarbu, 2013) analysed the economic effects of extending e-commerce applications with Web 2.0 functions, called social enterprise software (SES). This study reported that companies using this extension have higher revenue and labour productivity. Sarbu (2017) found that companies with a higher use of blogs and social media experience a decrease in labour productivity – the only study that reported a clear negative result of using collaboration software. The third article using der ZEW database revealed a positive relationship between the use of social media and innovation, however cause and effect were unclear (Meyer, 2010). The study from Indian IT companies found that the use of Web 2.0 applications results in significant business benefits. These effects become stronger with more advanced Web 2.0 applications (Wahi *et al.*, 2016). Skoludova (2017) found that using collaborative applications has a positive impact on managerial decisions and on all managerial functions (control, leading, organising, financial reporting).

D) The last group, including only two studies, deals with advantages of using collaborative applications almost incidentally. One used the measure of individual productivity (self-assessed job performance) as part of a model to predict the impact of

utilitarian and hedonic motivations (Aboelmaged, 2018). But he found a positive impact of the use of enterprise social networks. The other study analysed the impact of service characteristics of collaborative applications on teamwork and project success (Ulhas *et al.*, 2016). The study finds a correlation between collaborative applications and the quality of teamwork as well as the project results, which depend on how well the service quality of the collaborative applications.

4 Discussion and Conclusions

The topic of software-supported collaboration is, to date, insufficiently researched. Even once reports on the topic are identified, their focus and/or data sources tend to be narrow or even incomplete and their objectivity at times questionable. Nevertheless, important and largely consistent results are available, predominantly indicating the benefits of using collaborative applications. In our own survey of SMEs in Germany, representatives of companies reported very positive experiences with the use of collaborative applications as well (Hardwig *et al.*, 2018; Paul, 2018). Companies who have implemented collaborative applications are characterized by a requirement for high intensity of internal collaboration and the necessity to bridge spatial distances (Hardwig, 2019). A study of early adopters of collaborative applications revealed that 25% of their sample could no longer imagine working without their collaboration systems (Schubert and Williams, 2015).

In this respect, the results of this literature study are in line with other reports and allow an initial systematisation of the state of research on the subject. At the highest aggregated level, we find indications of the economic benefits of the tools for companies. The studies revealed positive effects on revenue, labour productivity (with one above-reported exception in this category), cost reductions and innovation.

These effects are probably based on the direct effects of using the tools on collaboration: The studies provide clear evidence that four central benefit dimensions can be identified:

1. Knowledge sharing
2. Social engagement and cohesion
3. Collaboration
4. Attention allocation

The first three are shown in the literature by qualitative and quantitative survey methods. The fourth dimension is above all a result of qualitative analysis. In order to identify new effects of the use of collaborative applications such as attention allocation, it seems necessary to intensify qualitative analytical research in this field.

That our literature survey confirms collaborative applications serve to improve communication, the exchange of knowledge and to foster collaboration is not surprising. What is striking, however, is how important collaborative applications seem to be for (re)creating social cohesion in the organization. Collaborative applications have been identified as a possible counteraction against the process of virtualizing the organisation (Child, 2015).

The dimension attention allocation describes probably a relatively new effect of information technology applications. Modern enterprise work redefinitions that include employees searching and organising content independently in the network (self-organised networking) is certainly noteworthy. Here, the tools provided by collaboration software apparently provide an unprecedented benefit: users no longer have to orient themselves on given structures and classifications of knowledge management (McAfee, 2009). This confirms the assumption that collaborative applications differ fundamentally from classical knowledge management (Alberghini *et al.*, 2013). Previous results regarding the benefit of knowledge management of SMEs (Durst and Edvardsson, 2012) would benefit from being systematically examined. This theoretically could be accomplished in the same way as a comparable evaluation of knowledge management benefit dimensions was conducted by Choy *et al.* (2006). However, there is currently a lack of sufficient studies on SMEs. Another shortfall of the literature is that with the ever-evolving characteristics of software-supported collaboration as their rollouts continue and their features are tweaked, it can be assumed that previously identified aspects have diminished in importance and new, unstudied aspects have emerged.

The future of the various benefits of collaborative applications depends on very different prerequisites. The properties (need vs. fit) of the applications themselves are important: on the one hand the quality of service (Ulhas *et al.*, 2016) and on the other hand the development as a Web 2.0 tool, which supports a free and intensive exchange (Wahi *et al.*, 2016).

The quality of the introduction/implementation of collaborative applications is also brought into play. Important factors here are the level of management support and the role model of new forms of collaboration (Makkonen and Virtanen, 2015). The relevant dimensions to be considered during implementation have been described (Alberghini *et al.*, 2013). Key factors are the extent to which the use of the system creates reputation for the users and how soon the implementation reaches a critical mass of convinced users, motivating other potential users to use the systems (Kügler *et al.*, 2015). And not to be underestimated is the need to redesign the entire workplace and its environment in order to harness the potential of the new forms of work these implementations create (Williams and LaBrie, 2015).

Several contributions show very clearly that collaborative application implementation challenges are not limited to known technical and organisation issues. It must be treated as a holistic approach in which structural, relational and cognitive aspects are treated integratively (Makkonen and Virtanen, 2015). The work-related interests of the various employee groups play a critical role that should not be underestimated. For instance, it cannot be assumed that collaborative applications are used in the same way by all groups (Forsgren and Byström, 2018). There are not only differences in acceptance (Trimi and Galanxhi, 2014), but also in the way applications can support the different groups' respective work.

The studies reported here do not cover all the design dimensions that have to be considered in the successful deployment of collaborative applications. But they are essentially in line with the state of research on design challenges (Greeven and Williams,

2017). We have already presented a first draft of a design model for collaborative work systems in SMEs and will continue this work (Hardwig *et al.*, 2018). An orientation framework for operational work designers dealing with how they can successfully realize a socio-technical design of the complex requirements and conditions would be of high practical value. The fact that the use of collaborative applications can bring benefits is shown by these studies, although their implementation requires critical, holistic attention to the demanding changes of individual and organisational work content and style.

Two main limitations of the results presented here must be taken into account. Firstly, we have only considered two databases and the period of ten years to date. Because extending the time period would cause the findings to become less relevant to modern SMEs than they already are, we will continue to try to identify additional, SME-relevant studies through a targeted evaluation of relevant bibliographies. The second limitation concerns the blurriness in the terminology of the tools we call collaborative applications. The various attempts to define the subject more precisely (via functionalities, possible uses, affordances, product names) have not yet been convincing. But it should be stressed that the validity of the studies would be enhanced if the subject could be better defined.

Which questions have remained unanswered? We have learned almost nothing about the specific conditions of SMEs regarding the effects of the use of collaborative applications. There are some indications that in smaller companies it might be easier to realize a successful use of collaborative applications. But whether really the specific conditions of SMEs are the cause or perhaps the context of the IT industry or other factors (i.e. implementation), cannot be decided conclusively. This is where research efforts need to be made. At present we cannot say whether and to what extent the benefits of collaborative applications in small and medium-sized enterprises differ substantially from large-scale enterprises. The studies currently available in the literature make no relevant statements on this, meaning the benefits of collaborative applications for SMEs remain a research desideratum. Another research task ahead of us is a systematic evaluation of the importance of collaborative applications for the development of dynamic capabilities and the growth of SMEs.

Table 3: Overview of the studies considered: Research aim and Main findings

Nr	Author(s)	Research aim	Main findings: Benefits of the use of collaborative applications
1	Abouelmaged 2018	This study aims to predict the impact of utilitarian and hedonic motivations on using Enterprise Social Networks for sharing internal and external knowledge, as well as their effects on employee productivity. Identifying the benefits of the tools is a minor matter.	The use of Enterprise Social Networks has a positive impact on productivity of the company. Productivity was operationalized as a self-assessment of the users' job-performance.
2	Alberghini, Cricelli and Grimaldi 2013	The aim is to demonstrate the benefits of social technologies, the major component of enterprise 2.0. Based on a bottom up framework to highlight new technology potentialities the study tries to understand how to support current users' needs. In the end the paper provides guidelines to help the management to adopt enterprise 2.0.	The benefits are described in the dimensions of Rao 2005 (but unfortunately not reported). The difference between expectations and perceptions from the users' point of view is presented. Expectations: the aspects "sharing knowledge", "collaboration" and "competence" have the highest expression. Perceptions: the aspects "collaboration" and "connectivity" are the most important. A clear difference between the perception and the degree of fulfillment calls for design measures.
3	Anders 2016	The study aims to find out why early adopter use the team platform Slack. What possibilities (affordances) that the platform offers do they value the most and how does their behaviour change through the use of Slack. Blog posts from 100 users who have talked about their experiences were examined.	The study reports new forms of collaboration enabled by teamplatforms. Rationals for adoption of the platform: virtual collaboration (34%), openness and transparency (19%), need for interoperability with external sources; centralizing communication and information (13%). Benefits are knowledge sharing (proactive knowledge aggregation 17%; recombinant idea generation 15%, vicarious learning 12%), social benefits (social engagement 17%, social cohesion 26%, virtual collaboration 34%) and collaboration (context awareness 34%, flexible roles and collaborative workflows 34%, avoidance of redundant work 28%, more space for collaborative discussions 34%, generative role taking 18%, leadership awareness 17%, context awareness for boundary work 11%) and attention allocation (engagement and presence 29%, compartmentalization 38%, synchronizing 26%).
4	Engelstätter and Sarbu 2013	This paper explores the performance impacts and benefits of the adoption of Social Enterprise Software (SES). This type of social software links and combines established enterprise software with social software applications. Focus of the research are e-commerce applications.	Companies that use Social Enterprise Software (SES) and Business to business (B2B) applications together have higher revenue and labor productivity than companies that do not use social media applications. The results offer first evidence of positive performance impacts of SES, which seem to be particularly high for firms which adopt SES in addition to already established B2B e-commerce solutions.

5	Forsgren and Byström 2018	The authors report an investigation on the use of multiple Social Media in knowledge work and explore the contribution of activity theory for such a study. Because Social Media are increasingly adopted at work, it is important to understand how they are being incorporated. The study focuses on how Social Media may improve or reduce coherence in work activities.	Social Media in general helped maintaining coherence in terms of sharing work related information, improving ambient awareness and for socialising. However there are cases where negative effects emerge, such as inconsistent use or lack of adoption. New forms of benefits in this area are informal, self-directed forms of exchange. The results reveal important differences in use: Development adopted an active and constructive approach whereas both Sales and Production Management positioned themselves in a passive, opportunistic and strategic way. Development used Social Media to build a knowledge base and solve problems, whereas Sales and Production Management focused on expanding their horizons and gathering information beyond their own immediate context.
6	Kügler, Dittes, Smolnik and Richter 2015	The paper investigates the concept of social connectedness and its antecedents, as well as its potential impact on employees' work performance. The use of Enterprise Social Software enables users to build close social relationships. To feel close to other members of the organisation (referred as social connectedness) has been shown to improve employees' work performance.	The use of Enterprise Social Software is positively related with social connectedness. The study reveals that the social connectedness impact is positively associated with individual performance impact: "employees not only feel more connected to their colleagues when using ESS, but also complete their work tasks more quickly." Important antecedens of social connectedness are reputation (quality) and critical mass (quantity) of the use of the tools in the organisation.
7	Makkonen and Virtanen 2015	Using a social capital approach, the study aims at getting a deeper understanding of Enterprise 2.0 as a holistic socio-technical phenomenon.	Enterprise 2.0 has multidimensional benefits: It provides a solid and multifunctional platform for communication and information access (structural dimension). It provides possibilities for employees to express themselves, make their work more visible to others and build their social identity as members of a particular community (relational dimension). Transparency and awareness enables users to develop shared visions and norms through the use (cognitive dimension). Management processes can be converted into a more collaboratively oriented social activity.
8	Meyer 2010	Using data from German IT companies and knowledge-intensive service firms, this paper empirically analyses whether the use of Social Software Applications triggers innovation.	"The econometric results reveal that there is a positive relationship between the use of Social Software and service innovation, measured as broadening or differentiation of the range of services offered. Firms applying at least one Social Software Application are more likely to innovate compared to firms which do not use Social Software. There is an endogeneity problem: on the one hand, it is not clear whether firms that use Social Software are more innovative or whether innovative firms tend to use new and innovative applications such as Social Software."
9	Sarbu 2017	The study analyses the relationship between social media applications and labour productivity using firm-level data of 907 German manufacturing and service firms.	The use of blogs and social networks is negativley correlated with labour productivity."In summary, firms using social media experience a decrease in labour productivity. This result is robust across all model specifications. The decrease in labour productivity is mainly driven by the social media applications blog and social network. Both applications are especially prone to the shirking of employees."
10	Skoludova 2017	The study aims at the impact of Enterprise Social Networks on the management process and on different management functions.	The responding managers assessed that the use of ESN has a positive impact on managerial decisions and on all managerial functions (controll, decions, leading, controlling, etc.). Organizing and controlling were most effected by implementing ESN.

11	Trimi and Galanxhi 2014	The study examines the hypothesis that the level of congruence of management-employees perceived benefits would affect the level of adoption of Enterprise 2.0. The study analyzed the use of Enterprise 2.0 on the basis of a case study of two large global organizations.	The study revealed that managers were more sceptical towards Enterprise 2.0 than employees. In addition there were relevant differences between the two organisations. The benefits measured on six dimensions were rated "little" by respondents (5 point likert scale): Communication (2,9), collaboration (3,0), community building (3,1), employee engagement (3,0), Knowledge management (3,2) and organisational activities and outcomes (3,2).
12	Ulhas, Lai, and Wang 2016	The study investigates the role of the Collaborative Information System (CIS) service characteristics for teamwork and software development project success using DeLone and McLean's Information System Success Model.	The service quality (performance of service) and service convenience (expense of use) of Collaborative Systems has an high impact on teamwork quality and performance. The applications "aid team members by boosting task-related and social interactions among the team members, which in turn influences teamwork performance". "The CIS provide platforms for enhancing teamwork quality, which not only enables them to communicate and coordinate, but also develops them as a social unit."
13	Wahi, Misra and Shakeel 2016	This study aims at examining the factors governing business benefits of moving to Enterprise 2.0. The study wants to develop a framework that can be used to study the readiness of an organization to implement Enterprise 2.0.	The usage of both basic and advanced Web 2.0 tools can result in significant business benefits for the organization. The impact of advanced Web 2.0 tools is higher than the impact of basic tools. The business benefits are very significant when the organization has the maturity to use both the simple/common Web tools as well as the basic and advanced Web 2.0 tools.
14	Williams and LaBrie 2015	The authors examine how advances in Unified Communications (UC) technologies are enabling radical changes in workplace redesign. The advantages of UC were presented on the basis of a case study (Microsoft) using a secondary analysis of a study conducted by Microsoft and performance measures of the company.	Workplace redesign together with the use of Unified Communication leads to a significantly better productivity. Employee satisfaction in the new work environment arose (+ 10 %), collaboration intensified and the individual effectiveness (+ 10%) increased a little more than the team effectiveness (+ 7%). Important was the cost reduction in real estate and operating costs (- 8 %), reduced space per employee, conferencing costs and relevant travel savings.
15	Wu and Wang 2014	This study investigates the benefits of a Unified Communications (UC) system for a company which is located in the electrical industry in Taiwan. The UC system would be explored from interviews with staff in the information department of the case company, and using the Technology-Organization-Environment framework.	Relevant benefits were found in all four dimensions of the balanced scorecard. The dimension "learning and growth" (improved efficiency of information exchange between employees, improved handling of problems, improved work efficiency of employees) had the highest value expression followed by the dimension "internal processes" (improved interactions between departments; improved interactions between plants; improved efficiency of work processes), the dimension "customer" (improved employees' efficiency in solving problems that must be handled immediately) and the dimension "financial" (reduced work hours of employees; reduced cost of communications). The reported means were above 3,69 (5 point-scale). Nine of twenty items ranked high. Only three items were below 3,5 in the media (customer satisfaction, improve customer trust, and the financial dimension reduced cost of buying new software).

Knowledge Management Practices Related to Organizational Resilience Capabilities

Abstract

Small and Medium Enterprises (SMEs) are highly vulnerable in times of crisis and are affected by various financial and human risks (Vargo & Servilha, 2011). One strategy for adapting and responding proactively is to develop the potential for organizational resilience. This can be understood by four capacities: to anticipate, to respond, to monitor and to learn (Hollnagel, 2010). These can be developed through the strategic management of the knowledge resource using the practices of Knowledge Management (KM). In turn, these, can be grouped according to the knowledge creation spiral of Nonaka, Takeuchi and Umemoto (1996), in actions aimed at externalization, socialization, combination and internalization. The literature addresses some KM practices related to resilience in a segmented way, such as the work of Chalfant and Comfort (2015) and Patil and Kant (2016). In this way, this study identified knowledge management practices to improve/boost resilience capabilities in the organizational environment.

The application of phase 4 of the framework developed by Fraga, Varvakis and Sell (2018) was used as a base in a small business in the information technology industry to identify practices related to resilience capabilities. Data were collected through semi-structured interviews, and knowledge management practices related to each resilience capacity were indicated.

The application of the framework allowed the connection of knowledge management practices identified through the processes of socialization, externalization, combination and internalization, making possible the understanding of the critical aspects of the resilience potential, reducing the risks of loss of knowledge and avoiding the reinvention of know-how of employees in SMEs.

It is worth noting that the use of knowledge spiral lenses to look at each resilience capacity facilitated the grouping of KM practices. It is suggested that KM techniques and tools be identified and instituted according to organizational strategies. Thus, in this study, the Nonaka and Takeuchi (1997) spiral presented an adherence to resilience capacities and their characteristics found in SMEs. This contribution is relevant, since many studies mention the importance of KM for resilience, and this research allowed the proposal of specific practices to improve the potential for resilience in this particular context.

Keywords – Organizational Resilience, Resilience Capacity, Knowledge Management, Knowledge Management Practices.

Paper type – Practical Paper

1 Introduction

Complex and turbulent environments are characterized by constant social and economic changes, disturbances, and changes in their functioning (Sahebjamnia, Torabi & Mansouri, 2015; Hosseini, Barker & Ramirez-Marquez, 2016). In view of this, with regard to constant changes in organizational environments, there are companies that do not resist or adapt to the new market realities and end up disappearing (Choo, 2006). Furthermore, complexity and turbulence also lead to uncertainties in the actions of individuals who do not know how to respond to certain situations, be they human, structural, technological or social.

Small and Medium Enterprises (SMEs) are highly vulnerable in times of crisis and are affected by various financial and human risks (Vargo & Servilha, 2011). However, to minimize and even dissolve uncertainties, organizations can develop their organizational resilience capabilities. SMEs seek to develop their resilience potential through strategic readiness, responsiveness, and knowledge creation (Pal, Torstensson & Mattila, 2014).

Resilience capabilities can be developed through strategic management of the knowledge resource, enabling organizations to be able to respond in a resilient manner to risks and changes in their environment (Rankin et al. 2014). These are understood as follows: to anticipate, to respond, to monitor and to learn (Hollnagel, Woods & Leveson, 2007).

Hollnagel and Woods (2004) add that it is not only the stocks of resources that determine resilience but also the efficient deployment of existing resources. Efficient management of available resources is required (Van Der Vorm et al., 2011). With the same line of thought, Wernke (2002) states that the differential of an organization is related not only to the quantity of equipment used in its productive processes, but also to the collective knowledge generated and acquired, to the creative abilities as well as the values, attitudes and motivation of the organization's people.

Given this context, Knowledge Management (KM) is highlighted as an essential resource for the promotion of resilience, that is, for the organization's ability to manage

the complexity and risks of its environment (Salgado, 2013). KM as a coordination mechanism through practices and tools allows the most efficient use of resources, promotes interaction, and contributes to an improvement in the organization's innovative capacity and performance (Darroch, 2005).

From the above, it can be seen that KM in organizations has a fundamental role in the context of competitiveness, complexity and changes, with the purpose of promoting organizational resilience. The literature addresses some KM practices related to resilience in a segmented way. Chalfant and Comfort (2015) discuss the importance of shared knowledge about risks to improve natural resource management. Along the same lines, the work of Patil and Kant (2016) addresses the importance of KM strategies to build a resilient supply chain. Therefore, this study aims to identify knowledge management practices to improve/boost resilience based on the analysis of their capacities in the organizational environment.

2 Theoretical Background

2.1 Knowledge as a resource

With the advancement of studies, the management of organizations has changed from the resource-based view (RBV) developed by Nelson and Winter (1982), to a knowledge-based view (KBV) studied by Grant (1996) and Sveiby (1997). The knowledge-based view considers organizational knowledge as an intangible asset as critical to respond adequately to changes in the business environment (Grant, 1996; Sveiby, 1997; Nieves, Quintana & Osorio, 2014).

In accordance with the knowledge-based view, Stewart (1998) explains that the knowledge age has the following decisive factors in its development: knowledge and relationships, both internal and external to the organization; and no longer the capital, natural resources or labor. For the author, the intangibles, present in the intellectual capital of the organization, deal with the competence and know-how in order to carry information, allowing faster reaction to the market than its competitors.

For Sabbag (2007), there are different perspectives of KM definitions as a structured process of identifying, describing and organizing the knowledge used in the organization with the objective of retaining them, multiplying them and improving them in order to leverage skills, making processes, optimizing processes, and developing the workforce. Another relevant point is cited by Fialho et al. (2010), which explains that it is through the creation and organization of his experiences that man acquires knowledge, and this can be understood as a result of his quest to contextualize and deal with the context in which he is inserted.

There are different levels of knowledge, ranging from individual to organizational. Individual knowledge is necessary to develop the basis of organizational knowledge, however, organizational knowledge is not simply the sum of individual knowledge (Bhatt, 2000; Bhatt, 2001). Organizational knowledge is formed through unique patterns of interactions between technologies, techniques and people, which can not easily be

imitated by other organizations. These interactions are shaped by the organization's history and its cultural aspects (Bhatt, 2001).

In addition, there is the distinction of knowledge of different natures: the tacit and the explicit. Authors Nonaka and Takeuchi (1997) argue that tacit knowledge is understood as the know-how of the individual that can not be verbalized and is related to the techniques and abilities that allow the individual to know how to do it. On the other hand, explicit knowledge is transmissible and allows the individual to know, in the sense of understanding and comprehension, about facts and events in their environment. Moreover, for the authors, tacit and explicit knowledge are complementary and interact with each other through a cycle of knowledge conversion, also called the knowledge spiral.

Nonaka and Takeuchi (1997) explain that an organization does not create knowledge by itself, given the fact that tacit knowledge present in the minds of individuals goes through several levels until it is expanded at organizational level. The authors argue that for the emergence of the knowledge spiral, there are four models of knowledge conversion. This conversion occurs from the interaction between tacit and explicit knowledge, known as processes of socialization, externalization, combination and internalization. These processes are represented in Figure 1 and are described by Nonaka and Takeuchi (1997) as follows:

- **Socialization:** the process of converting tacit knowledge into new tacit knowledge, that is, experiences and mental models are shared and tacit knowledge and technical skills are created. In organizational practice, socialization occurs through workplace training; informal sessions and brainstorming; interactions with customers, suppliers, etc.
- **Externalization:** the most important way of creating knowledge, by facilitating the transformation of tacit knowledge, which is personal, context-specific and difficult to formalize, into new and explicit knowledge. This process occurs through the use of metaphors, writing, analogies, concepts, hypotheses and models, which are used in dialogue and collective reflection.
- **Combination:** understood as the process of systematizing existing concepts into a new knowledge system. It is caused by the placement of newly created knowledge and existing knowledge, coming from other sections of the organization in a network, thus constituting a new product, service or management system. It means combining several sets of explicit knowledge, such as documents, meetings, telephone conversations, computerized communication networks, which can lead to new knowledge.
- **Internalization:** the existing explicit knowledge is reformulated by the individual and internalized as new tacit knowledge. Externalization becomes skills and knowledge in attitudes; internalization turns these attitudes into skills. For this, the verbalization and the diagramming of the knowledge in the form of documents; manuals or oral histories, and training programs that use simulations and experiments, which also facilitate internalization, are necessary.

Source: Adapted from Nonaka and Takeuchi (1997).

Figure 1 - Model of knowledge conversion

Therefore, socialization generates shared knowledge; explicitness generates conceptual knowledge; combination gives rise to the systemic knowledge and internalization produces the operational knowledge (Fialho et al., 2010). In addition, generating knowledge in an organization involves the creation of individual knowledge, initially, which is expanded through the interactions between individuals at different organizational levels.

These mechanisms are supported by KM practices, which are considered intentional, formal or informal activities or routines, oriented to adequately manage knowledge for efficient use and aligned with the objectives associated with a specific task (Dávila et al., 2014, Kianto & Andreeva, 2014). Examples of practices are: knowledge banks (Davenport & Prusak, 1998), coaching (Salim, 2002), practice communities (Ahmadijan, 2008), lessons learned manual (OECD, 2003), shared electronic space (Balestrin & Verschoore, 2008), prospecting scenarios (Chermack, 2004) and storytelling (Keyes, 2006). Additionally, practices can be grouped according to the knowledge creation spiral of Nonaka, Takeuchi and Umemoto (1996) in actions aimed at externalization, socialization, combination and internalization of knowledge.

2.2 Organizational resilience approach

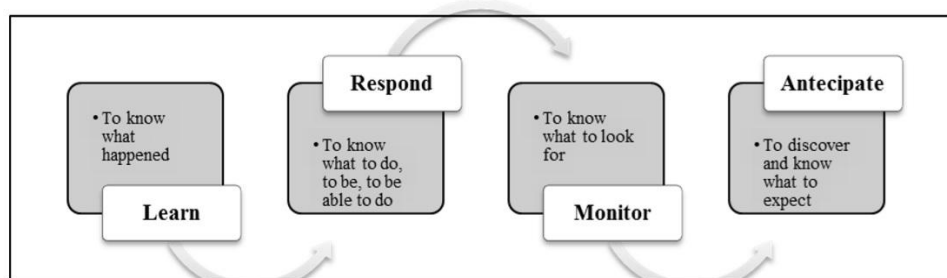

The concept of resilience is multidisciplinary and is present in several areas of knowledge, such as psychology (Coutu, 2002), ecological systems (Holling, 1973), engineering (Hollnagel & Woods, 2004) and organizational level (Hamel & Valikangas, 2003). For the purpose of this paper, we will use the concept of resilience addressed by Hollnagel (2010), in the organizational environment, with the following definition:

Resilience is the intrinsic ability of a system or an organisation to adjust its functioning prior to, during, or following changes and disturbances, so that it can sustain required operations under both expected and unexpected conditions. (HOLLNAGEL, 2010, p. 1).

In addition, it should be pointed out that this work is based on the resilience engineering approach, analyzing the organizational context, as a way of complementing the visions and elements that characterize and compose the area of resilience in the organizational context. It is important to explain that resilience engineering is not only about addressing what should have been done and explaining what happened when a failure occurs (Hollnagel et al., 2006), but learning from organizational changes and limits, to predict and anticipate possible future failures (Vargas & Guimarães, 2006).

In his research, Hollnagel (2010, 2015) points out four interdependent capacities, which form the basis of this work. If analyzed together, they make it possible to analyze the performance of an organization's resilience potential and enable it for action. These action-oriented capacities are: to respond, to anticipate, to monitor and to learn. The four capacities are represented in Figure 2 and are described by the author:

- **Anticipate:** discovering and knowing what to expect, or being able to anticipate the future, such as potential interruptions, new requirements or limitations, new opportunities, or changing operating conditions.
- **Respond:** corresponds to knowing what to do, or being able to respond to regular and irregular changes, disruptions and opportunities by activating prepared actions or adjusting the current mode of operation.
- **Monitor:** indicates what to look for, or be able to monitor what is or could seriously affect the performance of the system in a positive or negative way. Monitoring should cover the system's own performance, as well as what happens in the environment.
- **Learning:** occurs from what happened, or being able to learn from experience, specifically to learn the correct lessons from experiences, as shown in the study by Argyris and Schön (1974).

Source: adapted from Hollnagel (2010)

Figure 2 - Organizational resilience capabilities

In the area of resilience engineering, resilience capabilities are addressed in order to adapt organizations to change and also anticipate and learn from what has been experienced at a given time. Organizations should proactively develop strategies that can prevent as well as prepare them to support other forms of business disruption (Umoh, Amah & Mnim, 2014) and recovery (Bhamra, Dani & Burnard, 2011).

The choice of the four elements proposed by Hollnagel (2010), arose from empirical evidences that used them. This choice is justified by the relevance that the four elements

possess to the capacity to generate solutions, since these make possible the action and reach of resilient organizational performance. Moreover, Hollnagel (2011, 2015) argues that it is necessary to understand the definition of resilience in a more precise and operational way, considering the resources that make the performance resilient, since it is not characterized by a single characteristic or specific domain.

From this point of view, it makes sense to consider the four capabilities that provide the basis for resilient performance. However, one might ask how well a system is able to respond, monitor, anticipate, and learn. While in some cases it may be useful to approach each capability as a simple and uniform quality, understanding the set brings a complementary view on the potential for resilience.

This understanding can be accomplished, for example, by using objective-goal analysis through functional decomposition to reveal which specific functions or sub-functions are necessary to enable an organization to respond, monitor, anticipate, and learn (Hollnagel, 2015). The answers to these detailed questions can be used to develop a profile of each capability and thus serve as a (composite) measure to measure the organization's resilience potential.

3 Research Methodology

This work is a continuation of the work of Fraga, Varvakis and Sell who in 2018 developed the study entitled "Framework for Analyzing Critical Knowledge Related to the Potential of Organizational Resilience". Therefore, how they performed the research will be briefly explained, to later approach the accomplishment of the present study.

Fraga, Varvakis and Sell (2018) proposed a framework to analyze critical knowledge related to organizational resilience capabilities, which was applied through a case study in a technology-based company. The framework is composed of four phases, as explained below:

- **Phase 1** - Characterization of the context, process identification and necessary knowledge;
- **Phase 2** - Characterization of process resilience and knowledge related to its capabilities;
- **Phase 3** - Analysis of the criticality of knowledge related to resilience capabilities; and
- **Phase 4** - Identification of Knowledge Management strategies to contribute to the potential of resilience.

Regarding the main results, the authors mentioned that the application of the framework made it possible to identify and analyze critical knowledge in its value creation process, reducing the risks of loss of essential skills and avoiding the reinvention of know-how of its collaborators. These critical knowledge mapping actions are strategic to the organization's development and are supported by the analysis of their resilience capabilities and the associated critical knowledge associated with them. The perspective of this base of analysis points to KM strategies for greater capacity for action and

adequate reaction to the risks related to knowledge in a turbulent environment, as can be observed in the organization focus of this study.

It is also worth explaining that the framework was applied in a small technology-based company that can be characterized by its complex socio-technical context. This context is characterized by interaction with the environment, capability of self-regulation, and the property of equifinality, that is, it can reach the same goal from different paths and using different resources (Biazzi, 1994). Organizations of this nature are composed of two categories: the technical part that involves technologies and tasks and the social part that involves structure and people (Strauss & Porto Bellini, 2008).

Following the previous elucidations, we continue with the purpose of this study, which through the extended exploration of phase 4, intends to identify KM practices to improve/boost resilience from the analysis of capacities in the organizational environment.

Phase 4 is subdivided into two steps, each with its method of application. They are:

Step	Purpose	Method of application
1	Relate the characterization of resilience capabilities and their knowledge to the processes of knowledge management (socialization, externalization, combination, internalization).	Data collection was performed through semi-structured interviews with six company employees. The processes of the knowledge management spiral of Nonaka and Takeuchi (1997) were related as a way of structuring the analysis and indicating management strategies of the knowledge resources mapped in each capacity. This analysis was performed based on transcripts of the interviews and the results of the previous phases. It is important to note that this lens of analysis from the knowledge conversion model of Nonaka and Takeuchi (1997) does not limit future analyses from other KM frameworks.
2	Identify KM practices for each organizational resilience capacity.	KM practices related to each capacity and suggested KM process were identified. This phase analyzes the results of the previous phases together.

Figure 3 – Method of application of phase 4

5 Results

The results obtained in this research were done so by applying the framework (Fraga, Varvakis & Sell, 2018) and enabled the identification and analysis of critical knowledge in its key process of value creation in the chosen SME. It should be noted that this knowledge audit phase serves as the basis for the analysis of their resilience capabilities—to anticipate, to respond, to monitor and to learn—and critical knowledge associated with each.

This section is subdivided into two parts. The first deals with knowledge-oriented actions that are transversal to resilience capabilities, and the second refers to the analysis for each of the capabilities.

Considering the first part, figure 4 below shows the transversal knowledge next to to resilience capacities, and with each, relates them to the processes of the knowledge spiral of Nonaka and Takeuchi (1997). From this, techniques and tools for the management of critical knowledge related to each capacity are suggested.

Critical knowledge across capabilities	Processes and practices of Knowledge Management
Knowledge of programming logic. Capacities involved: respond, anticipate, monitor	<i>Characteristics:</i> explicit knowledge, combination of different knowledge, more learning time. <i>Combination and internalization practices:</i> knowledge base shared with documents and manuals on the subject; meetings with presentation of learning about scheduling among employees (pitch* weekly). * Pitch: speech or brief and objective speech that an individual uses to dialogue about a product, service or an organization demonstrating its benefits and values, arousing the interest of the interlocutor.
Knowledge of domain logic in data usage. Capacities involved: anticipate, monitor	<i>Characteristics:</i> explicit and tacit knowledge, as it involves the technical part of the domain and also the applicability of the use of the data. <i>Combination and externalization practices:</i> registration and formalization of weekly activities to document use cases; sharing of the cases in the shared knowledge base among the collaborators.
Know how to identify and correct errors when systems are out of order (e.g, Lattes Platform). Capacities involved: anticipate, respond, monitor	<i>Characteristics:</i> tacit knowledge, based on the experience of employees, more vulnerable. <i>Socialization and externalization practices:</i> access to fast electronic resources such as chats, intranets and extranets to speed up the identification process; registration and sharing of the process of correction of the error in the knowledge base with access by all collaborators.

Source: authors, based on interviews (2019).

Figure 4 - Critical cross-disciplinary knowledge and practices of knowledge management

Figure 5 shows the results obtained with the application of the framework of Fraga, Varvakis and Sell (2018) through the application of the instruments of characterization of resilience capabilities, which allowed the identification of the issues to be solved (first column). Subsequently, each of these questions was related to a process of the spiral of knowledge in the second column; and in the third column, some KM practices associated with the KM process are mentioned to solve each question.

Ability to anticipate		
Issues to be solved	KM process	KM practices
Lack of formalization of anticipatory activities.	Externalization	Prospecting scenarios, knowledge bank.
Sporadic and informal knowledge sharing.	Socialization	Mentoring, storytelling.
There is a lack of knowledge retention actions of the most experienced members.	Externalization	Coaching, personnel exchange (shukko).
Ability to respond		
Issues to be solved	KM process	KM practices
Little documentation on what is done.	Externalization	Construction of best practice manuals, bank of lessons learned.
Lack of time to document.	Socialization	Prospecting scenarios, storytelling.
Sharing of informal response knowledge.	Combination	Knowledge bank, electronic spaces.
Ability to monitor		
Issues to be solved	KM process	KM practices
Systematization of the validation process is lacking.	Externalization	Construction of best practice manuals, knowledge bank.
Low frequency of validation activities.	Socialization	Pitch for sharing of daily validations, informal meetings.
Lack of specific validation roadmap for new demands.	Combination	Internal and external benchmarking, virtual practice community, electronic spaces.
Ability to learn		
Issues to be solved	KM process	KM practices
There is a lack of documentation and formalization of the lessons learned.	Externalization	Bank of lessons learned, periodic post-action review.
Outdated and underused database.	Combination	Electronic document management.
Lack of formalized process for learning new knowledge.	Internalization	Skills and training, personnel exchange (shukko).

Figure 5 - Matrix of critical knowledge management actions related to resilience capabilities

Given the analysis presented, the externalization process emerges as a perspective of analysis which improves the development of each capacity of resilience. This is considered by Nonaka and Takeuchi (1997) as the most important method of knowledge conversion for the creation of knowledge, since it aims to facilitate the formalization of tacit and individual knowledge specific to certain technical contexts in knowledge documented and shared with all.

The second mode of conversion seen as necessary to develop resilience capabilities, was socialization, that is, the transmission of tacit to tacit knowledge. Faced with an environment that involves the structuring of technical data for systems development, many mental models of problem solving and programming are developed, but they are little disseminated. The practices that involve socialization deal with the sharing of knowledge developed by the practice of new technical skills, through actions of personal interaction between employees.

In this way, according to the analysis represented in Figure 5, it is possible to verify a series of specifications that vary according to the critical question diagnosed in each resilience capacity and its outstanding critical knowledge. The KM processes associated

with each capability as well as the practices identified correspond to suggestions for enhancing the organization's resilience.

Regarding the ability to anticipate, we identified knowledge related to identification and knowing what to expect from risks and problems. For this, practices of socialization and internalization were indicated, such as the backing up of functions, master and apprenticeship, coaching, and banking of knowledge.

Considering the ability to respond, the knowledge corresponds to knowing what to do and being able to do, and the actions of KM correspond to practices of externalization and combination, as a bank of lessons learned and formalization of emergency manuals.

With relation to the ability to monitor, which seeks to know what to look for in times of uncertainty, actions were identified to combine and socialize knowledge as updated and accessible electronic spaces, as well as daily meetings to share errors and correctness.

Finally, the ability to learn detected knowledge related to the learning process, namely what happened, making use of existing knowledge and identifying new knowledge gaps. It addresses aspects of the externalization and internalization process and indicates practices such as lessons learned banks, post-action review, knowledge mapping, and practice communities.

6 Conclusions

In this study, the extended exploration of phase 4 of the framework proposed by Fraga, Varvakis and Sell (2018) revealed strategies of KM that contribute to the development of resilience potential in the complex socio-technical context.

Authors like Mafabi, Munene and Ntayi (2012), Ose, Ramstad and Steiro (2013), and Speranza, Wiesmann and Rist (2014) highlight the importance of KM to develop resilience actions. In this study, the priority actions identified for each resilience capacity were: anticipate (externalization and socialization), respond (externalization, socialization and combination), monitor (externalization, socialization, combination) and learn (externalization, combination, internalization).

The application of phase 4 of the framework of Fraga, Varvakis and Sell (2018) allowed this alignment of KM practices with resilience capabilities through the categorization of the Nonaka and Takeuchi (1997) knowledge conversion processes.

In this way, it is emphasized that the use of knowledge spiral lenses to look at each resilience capacity facilitated the grouping of KM practices. It is suggested that KM techniques and tools be identified and instituted according to organizational strategies. Thus, in this study, the spiral of Nonaka and Takeuchi (1997) presented an adherence to resilience capacities and their characteristics found. This contribution is relevant, since many studies mention the importance of KM for resilience and this research allowed the proposition of specific practices to improve the resilience potential.

Furthermore, KM strategies generate greater capacity for action and appropriate response to the risks related to knowledge of resilience capabilities in the dynamic environment of SMEs and can be expanded to other contexts.

Thus, for future work, it is suggested that the approach proposed here be applied in other organizations that are part of the complex socio-technical context. Also, it is suggested that other perspectives of KM analysis that contribute to the development of resilience potential are used.

Abstract

The objective of this article is to identify knowledge management practices in technology-based SMEs in the South of Brazil.

This is an empirical, qualitative, and descriptive study. Data were collected in interviews with directors of technology-based SMEs in the South of Brazil, following a semi-structured interview script, adapted from Kianto and Andreeva (2014) and validated by Dávila (2016). Data were analyzed using thematic and content analysis with triangulation of evidence: bibliographic review; content from primary data sources, and data obtained from secondary sources.

This paper contributes to advancing research into knowledge management practices, which are recognized as important organizational strategies, capable of driving better performance and strengthening organizations' competitiveness. Notwithstanding, this paper's stand-out contribution is made by its empirical results. The evidence collected in technology-based SMEs in the South of Brazil demonstrates that knowledge is recognized as a strategic resource. However, these SMEs do not have management strategies for

implementation of knowledge management programs, although their practices related to organizational structure and organizational culture are better explained. This finding is attributed to the fact that the organizations analyzed are located in a technological incubator, which encourages knowledge assimilation and sharing between employees and firms, and its application to promotion of an innovation culture.

The practical results of this paper provide a basis for executives and managers interested in the subject to decide which knowledge management practices they should adopt to achieve the best strategic and operational results in Brazilian technology-based SMEs. The main findings also highlight the most important knowledge management practices that can explain the capacity that the firms studied have to share their existing knowledge among their employees, seeking to promote an innovation culture.

Keywords – Knowledge Management, Knowledge Management Practices, Brazilian SMEs.

Paper type – Academic Research Paper.

1 Introduction

The knowledge-based view (KBV) theoretical approach proposed by Grant (1996) treats knowledge as a valuable organizational resource, considered one of the most important factors of production, of capital, and of work. For Edvinsson (2013), the knowledge economy, based on the value of intangible assets, highlights the importance of managing the organizational knowledge process, because it is capable of generating competitive value, driving innovations, improving performance, and influencing organizational learning (APO, 2009).

Knowledge management (KM) practices have been defined by Inkinen, Kianto, and Vanhala (2015) as intentional organizational and management strategies or activities that enable value to be delivered from knowledge as an organizational asset. The objective is to support organizational management processes, to capture, disseminate, and promote knowledge sharing.

It has been recognized that transforming knowledge into innovative management practices and strategies is a condition for organizations to establish themselves in dynamic and competitive markets. However, this is particularly challenging for small and medium enterprises (SMEs) (Yap & Lock, 2017) and even more so in the scenarios found in developing countries, such as Brazil (Cassol, Zanesco, Martins, & Marietto, 2019).

Brazilian SMEs generate employment and revenues and develop Brazil's economy. This segment is responsible for approximately 30% of the makeup of its Gross Domestic Product (GDP), according to data from the institute for applied economic research (IPEA - *Instituto de Pesquisa Economica Aplicada*, 2018). Therefore, understanding the organizational practices and strategies implemented by these firms to keep themselves competitive in dynamic, innovative, and technological industries is an important research agenda (Koerich & Cancellier, 2017).

Dávila, Durst, and Varvakis (2018) have observed that barriers related to the economic context, to the organizational culture, and also to the limited capacity of SMEs to access and share knowledge are indicative of a need for studies of the relationship between knowledge-related capabilities and innovation in SMEs based in developing countries.

A study by Cassol et al. (2019) has contributed to discussions on the role of KM in the organizational context of Brazilian SMEs, providing insights into the need to understand the factors that drive development of practices that provide support for knowledge management to become a dynamic organizational capacity. This paper therefore contributes to filling the research gap left by the lack of studies about knowledge management practices in Brazilian SMEs, attempting to answer the following research question: What knowledge management practices can be identified in technology-based SMEs?

The paucity of empirical studies on the subject and of evidence collected in technology-based SMEs in the South of Brazil highlights the relevance of this research, since its objective is to identify knowledge management practices in technology-based Brazilian SMEs. It should be noted that, in addition to this being a recent field of study (Kianto & Andreeva, 2014; Dávila, 2016), KM practices are organizational strategies that have the capacity to foster better performance and to strengthen firm competitiveness.

2 Knowledge Management Practices

According to Wiig (1997), the ultimate objective of knowledge management practices is to ensure that the organization's knowledge-related activities are as effective as possible and provide the maximum returns, while also constantly renewing them. Therefore, to manage knowledge is "to understand, focus on, and manage systematic, explicit, and deliberate knowledge building, renewal, and application - that is, manage effective knowledge processes" (Wiig, 1997, p.9).

Davenport and Prusak (2003) recognize that in order for an organization to manage knowledge, it must develop practices based on the diversity of its employees' knowledge and experience. This requires top-management buy-in, a KM-oriented culture, the appropriate infrastructure and techniques to promote knowledge, managers who are focused on the process, a knowledge creation incentive program, and efficient communication for dissemination of knowledge.

The current discussion in the KM literature has established a number of ways to conceptualize management processes and practices. Authors such as Mckeen, Zack, and Singh (2006), Heisig (2009), Andreeva, and Kianto (2012), Dorow (2013), Kianto and Andreeva (2014), Inkien et al. (2015), Inkien (2016), and Dávila (2016), have reached consensus on the concept, creating measurable categories and employing the term knowledge management practices.

Mckeen et al. (2006), define such practices as observable activities related to KM that are executed by an organization. They analyze them using 4 dimensions: the ability to locate and share existing knowledge; the ability to experiment and create new knowledge;

a culture that encourages knowledge creation and sharing; and a regard for the strategic value of knowledge and learning.

Heisig (2009) observes that the success of KM initiatives in organizations depends on the basic conditions of their implementation. In his study, he showed that the practices central to KM are based in 4 categories: human resources factors – with its subcategories culture and organization, people, and leadership; organizational aspects of the process and structure; information technology factors; and processes for strategic management of knowledge.

Kianto and Andreeva (2014) expanded the analytical categories and defined KM practices as the set of intentional organizational and managerial activities aimed at strengthening a firm's knowledge processes. They explain them using an extended set of 27 KM practices, grouped into 5 dimensions: strategic management of knowledge, organizational culture, human resource management, organizational structure, and information and communication technologies.

Dávila (2016) adopted the Kianto and Andreeva (2014) theoretical model that considers knowledge management practices to be intentional routines for efficient management of the knowledge involved in an organization's processes, human resources, and technologies. He conducted research with 127 SMEs in the South of Brazil, finding that the flow of creation of value for organizations improved their performance and starts with contributions by two groups of KM practices. Strategic knowledge management, organizational culture, and organizational structure influenced the process of acquisition and assimilation of external knowledge. In turn, strategic knowledge management practices and information and communication technologies influenced transformation and application of knowledge within the organizations.

Dávila et al. (2018) consider that Brazilian companies have the potential to develop competitive advantages if they improve management of information and knowledge. Furthermore, as the internal information flows improve, the knowledge assimilation processes also improve. They therefore support the idea that KM practices must be implemented within firms and must be managed to improve innovation and organizational performance.

According to Dorow (2013), KM practices are important for innovation to occur, in the same way that innovation is linked with new information that will be used to create new knowledge. Finally, it has been found that use of these practices is an important driver of innovation and has been associated with organizational performance, since efficient and effective management of knowledge resources generates organizational benefits (Inkinen, 2016).

Thus, the first objective of this study is as follows: **To identify which KM practices are utilized by technology-based SMEs.**

It is clear that KM promotes and drives many different aspects of organizations. Robinson, Anumba, Carrillo, and Al-Ghassani (2006) claim that, in addition to promoting continuous improvement, enhancing stakeholder relationship management, and putting people at the center of knowledge creation processes, KM also facilitates innovation in business processes and products.

However, certain challenges faced when implementing KM programs have also been highlighted. According to Dalkir (2005), KM processes are complex, because they do not merely involve decisions related to technology, but also people and cultural elements. In turn, the second of these can create barriers to KM. A systemic perspective is needed that encompasses the organizational context, business objectives and strategies, and people, processes, and technologies.

Horta and Barbosa (2017) conducted a study that assessed the main barriers to implementation of KM programs and identified factors of the organizational context that can interfere with KM practices. According to their findings, the main barriers are a lack of support from top management, low levels of trust, and a lack of technology to support knowledge sharing.

Along similar lines, an earlier study by Ghafourian (2014) had shown that cultural aspects, individual differences, lack of vision, infrastructure, and organizational structure were the main barriers to implementation of KM programs in the context studied.

In the context of Brazilian SMEs, implementing KM systems remains a challenge. However, when KM processes are set up, these firms reap benefits such as the possibility of improving quality, efficiency, productivity, and decision-making (Yap & Lock, 2017).

Research has also highlighted the limitations of using strategic tools capable of establishing formal management processes (Cassol et al, 2019) because firms have distinct characteristics in relation to their structure and configuration (Dávila, 2016). Additionally, for firms to improve their innovation performance, it is necessary to identify and recognize the factors that drive KM and those that create obstacles to KM, which may reflect the characteristics of SMEs.

In order to guarantee that the objectives underlying implementation of KM practices will be achieved, it is necessary to identify the barriers and potential and real critical factors in each firm that can reduce the likelihood of these systems' success (Horta & Barbosa, 2017). For these reasons, and motivated by this scenario, the second research objective is as follows: **To identify the difficulties and barriers facing KM in technology-based SMEs**

3 Methodology

This is an empirical study, employing qualitative and descriptive methodology. This approach is recommended by Creswell (2010), who states that it enables the researcher to understand the experience of a given group or organization from the point of view of its members.

The strategy used to select firms for the study sample was intentional, based on criteria defined by the researchers: a) firms characterized as SMEs; b) in technology-based sectors; and c) participants of a Technology Incubator scheme. A total of twelve firms were contacted at a Technology Incubator in the South of Brazil and seven of them agreed to take part in the study. Interviews were conducted with managers, directors, and/or partners from these firms. For the purposes of this paper, these firms will be labeled 1B, 2C, 3D, 4E, 5F, 6G, and 7H.

Data were collected during semi-structured, in-depth interviews and by documentary research and non-participatory observation. The interview script was constructed by Kianto and Andreeva (2014), based on their theoretical model of KM, and was adapted for studies of Brazilian SMEs by Dávila (2016). The script covers a set of 27 KM practices grouped into 5 dimensions: strategic management of knowledge, organizational culture, human resource management, organizational structure, and information and communication technologies.

To enable analysis of the data, all of the interviews were transcribed and subjected to content and thematic analysis. According to Bardin (2010), these are a set of techniques for analysis of communication designed to overcome uncertainty and enrich readings of the data collected. Triangulation of data was also employed in the analysis, using concepts from the literature review, content from the primary data sources (interviews), and data obtained from secondary sources.

4 Data Analysis

Statements by managers of the technology-based SMEs were used to attempt to achieve the first study objective. To do so, the results were first categorized according to the 5 dimensions proposed in the Kianto and Andreeva model (2014).

Although the managers expressed doubts about the meaning and concept of knowledge management and about how it is utilized, KM practices were detectable in their organizations' practices and were cited as important, from a management perspective. They were also aligned with the strategies of the firms analyzed.

The **strategic knowledge management** dimension deals with KM initiatives within organizations' strategic planning, analyzing forms of mapping and understanding knowledge, integration of KM initiatives and plans, implementation or promotion of KM routines, and development of strategies for organizations' knowledge (Kianto & Andreeva, 2014).

Four of the seven firms studied stated that they conduct strategic planning. However, they claimed not to have explicit knowledge management plans that were aligned with their planning. All have a clear understanding of the knowledge needed to do business in the technology sector and explained some of their strategies for knowledge development, such as training and activities for acquisition of knowledge.

Our firm encourages training and learning for everybody here. We have access to courses, to universities, and to training provided by the incubator, and we also take part in projects to win funding. We are constantly monitoring the market in search of new knowledge. (Interviewee 7H)

There is no doubt that training of personnel is the most important part. Since our firm was created by a merger between three firms, each owning 33% of the new company, we don't conform to the, I'd say, prevailing, preestablished,

company model - the owner-manager-worker style. So everyone works to improve their qualifications in the best way possible. (Interviewee 2C)

Kianto and Andreeva (2014) treat the **organizational culture** dimension as one that can encourage knowledge sharing and creation, fostering, valuing, and encouraging open relationships and learner-initiated learning, with flexibility and interdepartmental cooperation.

This was one of the dimensions most often mentioned by the interviewees. The firms cited and explained practices that are initiated both by individual employees and in response to company incentives. A practice that all firms stated they use is the knowledge formalization system, which functions as a means of monitoring lessons that have been learnt

There was strong evidence of interdepartmental cooperation in the interviews, founded on open relationships between the different organizational levels. The firms also state that they value self-initiated learning, which is one of the practices in this dimension.

We believe (...) that sharing knowledge is a necessity and is part of the game. Right from the start we share knowledge ... I share my knowledge with my employees, my employees share their knowledge with me, and with each other as well, and we do the same with our customers and suppliers too (...) we share it and multiply it. (Interviewee 5F)

Our team is multidisciplinary and everyone contributes to projects. In fact, our team includes a doctor, an automation engineer, a mechanical engineer, a lawyer, and a salesman, and we have to have that for the business to work. It's good because we can think outside of the box and our management is very open. (Interviewee 4E)

Considering that the era of the Knowledge-Based Economy (Edvinsson, 2013) is replete with change, the adaptability of an organization's culture becomes an essential factor in increasing a firm's competitiveness. The study data reveal that the culture of these organizations is characterized by a horizontal structure. Decision-making is shared, with the objective of achieving the best development of innovations and the greatest possibilities for improvements.

We always share decisions, we have no resistance to that. To the extent that now we're sharing the same room (...). This type of interaction happens very frequently, both informally and formally. Twice a week we have meetings to share information and take strategic decisions. (Interviewee 2C)

(...) but really, when you're in an incubator, knowledge exchange is what you do most. What do you need help with (...) I'm in management and I can help you with this, and this, and this, and someone in the engineering department will help you with that. (Interviewee 7H)

Practices related to the human resources management dimension are assessed in terms of monetary and non-monetary forms of compensation for knowledge creation and sharing, and inclusion of these activities in the firm's performance assessments (Kianto & Andreava, 2014). With regard to the last of these items, it was found that none of the firms had performance assessments that covered knowledge creation and sharing. However, it could be considered that the streamlined structural characteristics of these firms mean that this process is not employed in a formal manner.

Nevertheless, the firms did state that they compensate employees monetarily when, by sharing and applying innovative ideas, they enable firms to achieve better performance in their markets.

We even provide incentives for our interns, who are given a percentage of the firm and become partners. For example, our engineer is an employee, but he also has a minority percentage of the firm that he was paid for a product he created. (Interviewee 2C)

If the employee solves the problems with the machine, I'll give him a 5% share of the firm. He hasn't managed it yet (...) but I hope he is able to. Less than 3 weeks after he came to the firm, I told him, if you find the answer, we'll be partners, and ever since it's been tests and trial and error - that's how development of a new product works. (Interviewee 7H).

Based on the results, it can be stated that human resources management is fundamental to reaping the benefits of KM (Kianto & Andreava, 2014). According to Dávila (2016), research has found evidence that providing people with incentives to seek and bring in external information increases innovation performance, motivates employees, and achieves efficient management.

This type of interaction, as already shown in the "organizational culture" dimension, is also a part of the **organizational structure** dimension, which is concerned with cooperation between people working in different parts of the organization (Kianto & Andreava, 2014).

The main characteristics of these firms' organizational structures were as follows: the majority had been established four years and the average number of employees was four. Management was horizontal and in the majority of the firms the employees are also partners.

It is important to note that the Technology Incubator where the firms are established provides training, promotes opportunities for information sharing, and runs programs for development of leaders and innovations.

Considering the multidisciplinary nature of their teams, the firms state that their employees cooperate actively in decision-making and in information sharing. It was therefore found that there are no barriers to collaboration between employees, because these firms are so small. Indeed, in small firms, the majority of these activities are generally informal, since the strategies and plans that are explicit in KM are not present (Dávila, 2016).

Six of the firms stated that knowledge sharing is carried out in an informal manner. This creates difficulties with relation to employee performance assessment and for formal retention of knowledge within the firm.

Knowledge sharing is not at all formal; we haven't set up daily routines or practices in the firm yet, it's totally informal. However, we treat it as a target, everybody should be sharing. That is how our structure is, (interviewee 6G).

Finally, firm practices that fall into the **information and communication technologies** (ITCs) dimension were analyzed. According to Kianto and Andreava (2014), ITCs are important strategies for supporting KM, since they contribute to storage and recovery of knowledge and also to sharing and creation of knowledge, functioning as communication channels.

The firms declared that they employ technological resources to store routines and methods, but do not have any formal KM systems implemented, which would enable them to expand on existing knowledge and create new knowledge.

We don't have any kind of a management system and no specific software. But we use freeware and some paid software that helps us with management. None of them are specifically management software, but some programs that help are part of our everyday routine at the firm. Google drive is one example. Google drive is possibly one of the best methods of sharing knowledge and information here in the firm. (Interviewee 5F)

We use certain tools, such as Drive, which is adequate for our needs for the moment. Maybe in the future, as work progresses and the firm grows, we will have to find other options for better solutions. (Interviewee 1B)

The majority of the firms studied have technological information and communication tools. However, they have no formal systems or software platforms to record and track their KM practices.

Analyses of the dimensions made it possible to identify KM practices in these firms, thereby fulfilling the first objective. Practices cited with greatest frequency include

interdepartmental cooperation and multidisciplinary teams, which are part of the organizational culture and organizational structure dimensions. These findings coincide with Dávila (2016), who has stated that creation of culture that fosters open-mindedness and multidisciplinary teams increase a firm's capacity to transform knowledge.

Moving on to the second research objective, to identify **difficulties and barriers facing KM**, it is clear that the main problems are related to Strategic Knowledge Management. The firms state that they understand what knowledge exists within their organizations, but when they were asked about methods of assessing their employees' competencies and knowledge, none of them mentioned using these practices as a strategic resource to manage their knowledge.

Evidence from the study conducted by Dávila (2016) indicates that there is a lack of focus on aspects related to strategic knowledge management practices, which he considers are the most important and significant practices for transforming organizational knowledge into value creation. Therefore, SMEs clearly need to create strategies to develop and implement KM as part of their strategic planning.

It was also observed that, since these are SMEs, they have not implemented KM planning, knowledge mapping, or benchmarking of external knowledge. These gaps could make it difficult for the firms to utilize strategies for technological innovation and to keep up with market tendencies. These findings are compatible with Dalkir's position (2005) that KM must be approached from a systemic perspective. Therefore, for KM to be effective, it is necessary to combine actions that cover business strategies, people, processes, and technologies.

Difficulties with Human Resources Management were also identified, with no utilization of any type of management model for performance assessment to control human resources management. According to Horta and Barbosa (2017), employees could see this barrier as a lack of incentive, causing insecurity and leading to employee turnover.

Although the firms stated that they have open organizational structures and multidisciplinary teams, they do not use coaching, a feedback culture, or mentoring, which are all actions that foster open dialogue. This could create barriers to development of teams and of individual employees, since these are founded on retaining knowledge within the organization. According to Nkomo, Thwala, and Aigbavboa (2017), practices that support knowledge transfer between people are important to ensure that firms don't lose organizational knowledge.

Considering the dynamic environment in which technology-based SMEs are inserted, and also the scarcity of resources, one starting point is to implement the KM practices that offer the greatest benefit for management strategies, thereby identifying efforts that create value for the organization, whose objective is to remain competitive in the market (Dávila, 2016).

5 Conclusions

The empirical results of this study indicate that KM practices do exist at the firms studied and, in the main, are conducted in a shared manner. However, it is also clear that these firms do not have structured and planned KM initiatives. In other words, although they have knowledge management practices, their effective implementation within the organizations remains a challenge.

Also of relevance in the findings is the observation that the practices most evident in the firms' routines were those associated with organizational structure and organizational culture. This is attributed to the fact that these organizations are located in a Technology Incubator, which is a factor that stimulates knowledge assimilation and sharing between employees and firms, applied to promotion of an innovation culture.

This paper's theoretical contribution is to extend research into KM practices in technology-based SMEs in the Brazilian setting. It also helps to fill the research gap already identified that is created by a need for more studies that deal with a pragmatic perspective on knowledge management in the organizational context of SMEs. This illustrates the importance of identifying which practices actually enable knowledge to be managed effectively.

In terms of its practical contributions, this study offers executives and managers interested in the subject a foundation for determining which KM practices could be adopted in the context studied to achieve better strategic and operational results. It also highlights the main KM practices that explain the capabilities of the firms investigated, sharing the knowledge they possess among their employees and attempting to improve their innovation culture.

With regard to the study's limitations, although much evidence of KM practices in these technology firms was observed, it was also perceived that there is a need to extend the study by conducting an analysis of KM maturity, in order to diagnose its stage of evolution and identify the next steps that these firms should take to best develop their knowledge management, in search of competitive advantages.

Finally, it is suggested that future studies could identify KM practices in organizations with a similar profile, conducting a comparative case study or even a quantitative research project. Additionally, research is needed that relates KM maturity to the practices utilized by firms.

Abstract

Despite increasing scholarly interest in the topic of innovation in the family firms, our understanding is still incomplete and inconsistent and the question of innovativeness of successors and family SMEs remains relatively unexplored (Botero et al. 2015). Our empirical research explores the relationship between the knowledge transfer in family SMEs and innovativeness of successors and of family SMEs during the succession process.

Conducting a quantitative empirical research, our research results indicate that “early inclusion into family SME” and “learning by doing” are the most valued forms of the transfer of founder’s tacit and experiential knowledge and skills to the successor and are the most important for their and the family SMEs’ innovativeness. Regarding the external knowledge transfer, our research revealed that working experiences in other firms and external training are of high importance and positively correlated with innovativeness of successors and of family SMEs.

Keywords – Family SMEs, Innovativeness, Knowledge transfer, Succession process.

Paper type – Academic Research Paper

1 Introduction

The succession (in management and ownership) in a family firm is recognized as one of the most critical period in its life cycle (Daspit et al., 2016) and therefore has been attracting the scholars’ research interest for many years (e.g., Chirico, 2008). On one hand, research findings indicate that numerous family firms do not survive the transfer especially due to badly prepared succession process (Miller et al., 2003). On the other hand, there are some indications that new generation in charge can bring new ideas and perspectives in a firm thus keeping the entrepreneurial, creative and innovative

orientation across generations (e.g., Bettinelli et al., 2017; Cabrera-Suárez et al., 2018). Due to importance of developing and selecting the most competent future family firm leader, several research studies address the education and training of successors (Le Breton-Miller et al., 2004) and the process of transferring knowledge between generations (e.g., Cabrera-Suárez et al., 2018). However, there is a lack of research addressing the succession process not only as a process of transferring knowledge between predecessors and successors but also as the process with “potentials” for enhancing successors’ and family firms’ innovativeness. If family firms want to survive across generations, there is a strong need for the ability to renew through innovations (Hauck and Prügl, 2015). Research studies deal with the entrepreneurial orientation of family firms (e.g., Barroso Martinez et al., 2016; Bettinelli et al., 2017) and their innovativeness (e.g., Brinkerink, 2018). However, research attempts have not addressed the relationship between the process of transferring and creating new knowledge during the succession and innovativeness of successors and family firms. Therefore, we address the following research question: “Is the transfer of knowledge (internal and external) into family SMEs positively related to the innovativeness of successors and family SMEs?”.

In order to bridge the identified research gap, we build our investigation on the knowledge-based view (Grant, 1996) and the organizational knowledge creating theory (Nonaka, 1994) as innovativeness of individuals and firms is influenced by their ability to acquire, assimilate, transform and exploit existent knowledge (Quintaine et al., 2011). Additionally we draw from previous studies on knowledge as a source of innovations of individuals and firms (e.g., Delgado-Verde et al., 2011) and studies on succession as we still do not dispose with succession theory (Sharma et al., 2012). We limit our research on the intrafamily succession from the first to the second generation, which can be understood as a family commitment to entrepreneurship and innovativeness by seeking for new business opportunities also when the next family generation takes over the firm (Nordquist et al., 2013). Members of the new family generation can be due to their commitment the driver of innovations in the family firm (Bettinelli et al., 2017).

The paper is divided into several sections. Following the introduction section, we review the literature and develop hypothesis in the second section. In the next sections the research method, sampling, data collection and findings are presented with a discussion of the research results. We conclude our paper with the most important conclusions and limitations of the research, and identify the future research directions.

THEORETICAL BACKGROUND AND DEVELOPMENT OF HYPOTHESES

2 Succession in family firms

We still lack a cohesive theoretical structure on the complex phenomenon of succession that affect many groups of family firms’ stakeholders (De Massis and Foss, 2018). Several research findings suggest that family firm succession still in many cases is

not solved adequately and consequently many family firms do not survive beyond the first generation (Daspit et al., 2016).

Several research works acknowledge that family business succession is rather a process than an event of transferring control to a successor (Sharma et al., 2001). It is described as a multistage process that occurs over time, starting before heirs even enter the business (Cabrera-Suárez, 2005). Since we can observe growing involvement of a (potential) successor in a family firm during the succession process (Cabrera-Suárez et al., 2001), several authors proposed multiphase models of the succession (e.g., Le Breton-Miller et al., 2004).

Most of the family firms' literature acknowledges (e.g., Cabrera-Suárez, 2005) differentiation between succession in management and in ownership. Especially the process of the leadership transfer has been viewed as the process of transferring knowledge (Duh, 2014). Since the most valuable resources and capabilities in family firms are based on information and especially tacit knowledge of the family firm leaders, the transfer of knowledge from a predecessor to a successor is of crucial importance for the family firm's success during and after the succession process (Sharma, 2004). Dynamic global environment requires successors that are able to add new knowledge and new perspectives (Barroso Martínez et al., 2016) and to seek new opportunities and foster entrepreneurship (García-Álvarez et al., 2002) thereby enhancing competitiveness and sustainability of a family firm across generations. Internal sources and transfer of knowledge should be combined with the external ones due to the importance of new knowledge for innovativeness of individuals and firms (Delgado-Verde et al., 2011).

3 Innovativeness and knowledge transfer

3.1 Innovativeness of a firm

Innovativeness is "the ability of the firm to introduce new processes, products, or ideas into a firm" (Marcati et al., 2008). Lynch et al. (2010) defined the firm's innovativeness as an expanded mindset and the attitude to innovation that all firms have to a certain extent which enables quick incorporation of changes in business practices through (early) creation and/or accepting new ideas.

The innovation ability of the firm is a prerequisite of innovativeness (Lynch et al., 2010), and is reflected in innovation. It is the ability to mobilize the knowledge that employees have in the firm (Kogut and Zander, 1992) and combine it with new knowledge that results in product and/or process innovation (Cakar and Ertuerk, 2010). Innovation abilities as a source of competitive advantage are deeply rooted in the context of an organization, and it is difficult to accurately define and imitate them (Nonaka, 1994). A firm with a high level of innovation ability is usually using a knowledge transfer method "learning by doing", which prevents competitors from accessing this knowledge in the market and imitation of knowledge is more difficult (Calantone and Zhao, 2003).

3.2 Innovativeness of individual

Hurt et al. (1977) defined individuals' innovativeness as a level to which an individual, in comparison with others in the social system, adopts relatively early something new.

Lin (2007), Liao et al. (2007) (summarized by Aulawi et al., 2009) emphasize the importance of sharing knowledge for the development of an individual's innovation ability.

The emphasis in our survey is on the innovativeness of individuals in family SMEs, the result of which is innovativeness of family SMEs. We assume that by measuring innovativeness of the family SME, we can indirectly measure innovativeness of the individual. In this assumption, we follow the definition of Tajeddini and Trueman (2005) and Verhees and Meulenbergh (2004), who claim that innovativeness is a feature of a firm or of the owner (and therefore also of the successor, note by the author).

3.3 Knowledge transfer during succession process

Knowledge and processes of knowledge creation are of crucial importance in any firm due to their direct effect on creativity and innovation (e.g., Nonaka and Von Krogh, 2009) and success of a firm (Chirico and Salvato, 2008). In family firms, knowledge “has strong tacit elements embedded in certain individuals, generally the entrepreneur/family firm founder and the successor” (Cabrera-Suárez et al., 2018, p. 181). However, there is the whole network of knowledge transfers and exchanges between successors and numerous stakeholders within and outside a family firm that should take place during the succession process (Cabrera-Suárez et al., 2018) and is of crucial importance for successors' and family firms' innovativeness.

The transfer of (tacit) knowledge can start by early inclusion of a successor into a family firm through summer and lower category jobs that present valuable experiences for successors (e.g., Cabrera-Suárez et al., 2001; Letonja and Duh, 2016). This way an important process of socialization (Nonaka et al., 2000) starts during which successors acquire founders' tacit knowledge (e.g., Cabrera-Suárez et al., 2001) and become aware of the predecessor's mental processes, ideas, and experiences (Mazzola et al., 2008). This socialization process (Nonaka et al., 2000) is an important starting point for enhancing the successor's knowledge and enabling assimilation of knowledge during succession. Creative and learning family environment importantly affects this process of early socialization and contributes to the successor's absorptive capacity that is important for future knowledge transfer processes and builds potentials for creativity and innovativeness (Cabrera-Suárez et al., 2018). The quality of the relationship between incumbent and successor is fundamental for effective succession (Daspit et al., 2016). Especially open relationship built on trust are required for optimal transfer of knowledge during the development and training of a successor (Daspit et al., 2016). Creative family environments in childhood and a family culture that stimulates innovation from the early childhood (Litz and Kleysen, 2001) influence this process of early socialization and

builds potentials for creativity and innovativeness of a successor and a family business (e.g., Cabrera-Suárez et al., 2018; Maček and Pšeničný, 2012)). Therefore, the following hypothesis is developed:

H1: Innovativeness of successors and of family SMEs are positively correlated with transfer of tacit and experiential knowledge in the form of early involvement of a successor in a company.

In order to become a qualified leader, both soft skills (e.g., personality traits, motivation and commitment) and hard skills (e.g., technical expertise, knowledge required for a job) are needed (Cabrera-Suárez et al., 2018). When successors enter the business, they should become familiar with the culture, values, mission and philosophy of a firm (Mazzola et al., 2008), acquire knowledge about different aspects of the business, and management skills (e.g., Mazzola et al., 2008). Mentoring and supervising relationships with predecessors present an important form of enhancing successors knowledge (Chirico, 2008). Mentoring by the predecessors has been recognized in the literature as suitable for development of successors (Cabrera-Suárez et al., 2018) as this way critical technical and managerial skills, knowledge on managerial systems, norms, values can be transferred (Swap et al., 2001) thus preventing the lost of predecessors' valuable knowledge (e.g., Desouza and Awazu, 2006). In the opinion of some authors (Gersick et al., 1997), family mentors are not adequate mentors as they are not able to give honest feedback to their children. Non-family mentors are proposed as very valuable in the process of successors' training and development (Daspit et al., 2016). Successors can also learn from predecessors in a learning-by-doing process that helps them to understand the technical field of family firms' operations (Chirico, 2008). Research findings indicate that a great part of learning experiences occur on the job (Cabrera-Suárez, 2005). Through socialization both mentoring and learning-by-doing (Nonaka et al, 2000) contribute significantly to successors' knowledge. Therefore, the following hypotheses were developed:

H2: Innovativeness of successors and of family SMEs are positively correlated with transfer of tacit and experiential knowledge in the form of mentoring.

H3: Innovativeness of successors and of family SMEs are positively correlated with transfer of tacit and experiential knowledge in the form of learning by doing.

Since successors' capacity to absorb knowledge, to understand and use it, is largely a function of the pre-existing stock of knowledge (Szulanski, 1996), formal academic and professional education is also of great importance (Cabrera-Suárez et al., 2018). It provides concepts and generic skills, which can be applied to most business contexts, enables development of analytical skills and abilities required for effective decision-making, and help successors to learn about new ideas and trends in management and technology (Sardeshmukh and Corbett, 2011). Barbera et al. (2015) suggest a "whole-person learning" approach in the family firm education that can foster development of a successor through development of cognitive, emotional and social skills. Therefore, we developed the following hypothesis:

H4: Innovativeness of successors and of family SMEs are positively correlated with formal education enabling knowledge in areas of critical thinking, creativity, communication, customer focus and teamwork.

Being up-to-date with recent technological, product and market developments is of crucial importance for innovativeness, competitiveness and performance of any firms. Working outside the family firm for a particular period helps successors to acquire a broader perspective of the firm's environment (Chirico, 2008) and to develop a detached view on how to manage and develop a family firm (Sardeshmukh and Corbett, 2011). Taking part in academic courses and practical training in schools and universities is of crucial importance for those successors whose family firms are active in dynamic, fast changing markets (Chirico, 2008). Training and working experiences gained outside the family firm are therefore of crucial importance for successors' and family firms' innovativeness since they expose to new ideas and situations (Sardeshmukh and Corbett, 2011) and give them access to new bodies of knowledge thus avoiding conservatism and closeness. The following hypotheses were developed:

H5: Innovativeness of successors and of family SMEs are positively correlated with work experience in another company that develops specific skills and abilities, opens different views on business operations, relevant for development of innovation skills.

H6: Innovativeness of successors and of family SMEs are positively correlated with academic and practical courses outside the family SME that allow transfer of knowledge from others to the successor, which is combined with the tacit knowledge in the family SME into new knowledge and fosters innovativeness of successors.

RESEARCH

4 Method

3.1 Approach

In order to explore how the transfer of knowledge (internal and external) relates to the innovativeness of successors (the second generation) and of family SMEs, we have carried out a quantitative research. We developed two questionnaires for the target group, one for the founders, one for the successors in family SMEs, as we have not found relevant already tested standardized measurement instruments to verify hypotheses. The final survey design was trialed from the aspect of length and validity of the content on several members of the target group. Minor adaptations had to be made. Data was analysed with help of IBM SPSS 22 and excel 2013. As we had two independent samples with (mostly) ordinal data, we used univariate (analysis of averages, variance, Cronbach alpha index, t-test) and multivariate (simultaneous analysis of several variables, correlation) statistical methods.

3.2 Data collection and sample

The questionnaires were sent to e-mail addresses of 408 family SMEs in Slovenia. The survey was conducted by the online survey tool (1KA.si).

We selected the "top management team" (TMT) approach, involving more interviewees from the company – the founder and the (or one of) successor. The first question to the founder was: "Do you consider your firm a family SME?" With this approach, used by e.g., Llach and Nordquist (2010), we avoid the danger that the answers would not be representative.

We ended up with a sample of 103 complete answers of successors and 103 answers of the founders from the same family SME (response rate 25,2%). There are 82 first generation family SMEs and 21 second generation family SMEs in our sample.

3.3 Measures

Dependent variables

Dependent variables in our research are innovativeness of successors and innovativeness of family SMEs.

Innovativeness of successors was measured with the help of Douglas N. Jackson's personality inventory (JPI) (Jackson, 1994) adapted by Mueller and Thomas (2001). JPI is a measure of the propensity to innovativeness and conceptually it is synonymous for creativity. The reliability and validity of JPI to measure the generalized risk-taking have been confirmed by different studies (e.g., Jackson, 1994).

Innovativeness of successors was measured in total by 11 variables. By the coefficient of reliability (Cronbach alpha) being 0.764, the reliability of the construct of innovativeness of successors is good (coefficient between 0.70 and 0.90).

Innovativeness of family SMEs was measured with the help of the scale, developed by Hurt and Teigen (1997), Hollenstein (1996), and it consists of 6 variables; it has been confirmed by different studies.

The coefficient of reliability (Cronbach alpha) of the construct of innovativeness of family SMEs is by 0.761 good.

Independent variables

In our research we defined four constructs (independent variables): transfer of tacit and experiential knowledge and skills of the founder as a form of internal knowledge transfer; working experiences of the successor in another company, formal education of the successor, academic and practical courses outside the family SME as external forms of knowledge transfer. Successors assessed the importance of different forms of knowledge transfer and actual experiences with them. Of total 28 variables 13 were relevant for testing our hypotheses. The reliability of the constructs is by the Cronbach alpha value of 0.891 very good.

3.4 Findings and discussion

Results of correlation between dependent variables and the importance of transferring the founder's tacit and experiential knowledge and skills to a successor, show the medium strong positive correlations between successors' and firms' innovativeness measured by "I often surprise by novel ideas/Our family SME is regularly testing new ideas" and "early involvement in family SME as a form of knowledge transfer" and "learning by doing as a form of knowledge transfer"; as well they exist between "I am a very creative person/Our family SME is creative in business methods" and "early involvement in family SME as a form of knowledge transfer".

The study of correlations between the dependent variables and actual experiences of successors with different forms of internal knowledge transfer show that successors' and firms' innovativeness measured by "In the recent 5 years I developed/started to market 0, 1, 2, 3-5, more than 5 new lines of products and services/Introduction of new products on the market has increased in our family SME in the last 5 years" "is medium strong correlated with "in my childhood I often watched parents how they run their business" and "we worked together with a parent on various activities". There are medium strong correlations between innovativeness measured by "In the recent 5 years I developed/started to market 0, 1, 2, 3-5, more than 5 new processes" and "In the recent 5 years the changes in production/services/ process lines .../Our family SME is often on the market with new products and services and "we worked together with a parent on various activities".

Therefore, our hypotheses H1 and H3, that innovativeness of successors and of family SMEs positively correlate with variables "early involvement in the company" and "learning by doing", are partly confirmed. Hypothesis H2 was not confirmed as mentoring does not correlate positively with dependent variables.

Our research revealed that early inclusion of a successor into a family SME through summer and lower category jobs is valued by successors as a factor which has the most important impact on their innovativeness and consequently innovativeness of a family SME within the process of tacit and experiential knowledge transfer. This finding is in agreement with e.g. Cabrera-Suarez et al. (2001), Letonja and Duh (2016) that early inclusion of successors in the family SMEs environment presents a valuable experience through which according to Nonaka et al. (2000) the process of socialization starts and enables absorption of the founder's tacit knowledge, ideas, experiences and builds potentials for creativity and innovativeness (Cabrera-Suarez et al., 2018). "Learning by doing" is according to the results of our research the most important actually performed form of knowledge transfer in family SMEs, which is in accordance with findings of e.g. Chirico (2008) that "learning by doing" helps successors understand the technical field of family SME operations and of Calantone and Zhao (2003) that it prevents competitors from accessing tacit knowledge in the market and imitation of knowledge is more difficult. This is positively influencing the successor's innovativeness, as well consequently innovativeness of the family SME.

The survey revealed that between the dependent variables and successor's formal education there is no positive correlation. We are surprised by the result due to relatively high educational level of successors. Therefore, the hypothesis H4 was not confirmed.

Thus our results contradict the results of previous studies by e.g. Cabrera-Suarez et al. (2001; 2018) that educational level affects the performance level of the next generation.

Research results indicate that successors' and firms' innovativeness measured by "I often surprise with novel ideas/Our family SME is testing new ideas" and by "In the recent 5 years I developed/ started to market 0, 1,2 3-5, more than 5 new processes" is correlated medium strong to working experience of successors in another company "which gives the successor a special view to the introduction and implementation of changes and innovation in the family SME" and to "working experience in another company can develop specific skills and abilities, opening different views on business operations, relevant for the development of innovation skills".

Therefore, we can partially confirm the hypothesis H5.

Our research revealed that *working experience in another company that develops specific skills and abilities, opens different views on business operations, relevant for development of innovation skills* is from the aspect of successors a very important factor for their innovativeness and consequently innovativeness of the family SMEs. This finding is in agreement with Chirico (2008).

The medium strong correlations exist between innovativeness measured by "I often surprise with novel ideas/Our family SME is regularly testing new ideas" and "I am a very creative person/Our family SME is creative in business methods" and the variable *"academic and practical courses outside the family SME that allow transfer of knowledge from others to the successor, which is combined with the tacit knowledge in the family SME into new knowledge and fosters innovativeness of successors."*

Therefore, we partially confirm the hypothesis H6.

Our research revealed that academic and practical courses of successors outside the family SMEs that allow *"transfer of knowledge from others to the successor, which is combined with the tacit knowledge in the family SME into new knowledge and fosters innovativeness of successors"* positively correlate with their innovativeness and consequently innovativeness of family SME. Our findings are in agreement with Sardesmhukh and Corbett (2011).

4 Conclusions

Our research findings filled the literature gap in the relation of internal and external knowledge transfer in family SMEs and innovativeness of successors and of family SMEs.

Our study contributes to definition of factors, which are within transfer of knowledge affecting the innovativeness of successors and of family SMEs, e.g. early inclusion in the family SME, learning by doing, working experiences in other firms and external training programs. We proved which of the variables within the construct of knowledge transfer are positively correlated to innovativeness of successors and of family SMEs.

Practical implications of our research findings are useful for founders and successors of family SMEs by demonstrating the most effective forms of transferring the existing knowledge and creating new knowledge thus fostering innovations.

Our research was limited to the smaller family firms with prevailing first generation family firms. Thus, a survey on a sample with more equal representation of family SMEs of both generations shall be considered.

Future research should address some other forms of transfer of knowledge not explored in our research, e.g. transfer of knowledge from customers, suppliers and other participants outside the family SME; exchange of knowledge through participation at meetings, in processes of strategic decision-making, which are as well important (e.g. Cabrera-Suárez et al., 2018). The challenges of future research are as well to include other variables e.g., leadership styles and psychological capital of founders and their impact on innovativeness of successors and of family SMEs; as well as the process of the leadership transfer has been viewed as the process of transferring knowledge (Duh, 2014), another interesting research direction would be how does ownership succession affect innovativeness.

Abstract

The use of Communities of Practice (CoPs) to support knowledge sharing and collaboration within organisations has been increasing over the years. Today, many different companies from various sectors are deliberately resorting to CoPs to better managing cognitive assets and improving business performance. In particular, the availability of the new web-based technologies, like for example Enterprise Social Media platforms, are promoting the widespread utilisation of virtual CoPs, i.e. CoPs that make use of ICTs to enable distant and asynchronous communications among members. Even though the “marriage” of Social Media with CoPs seems to be perfect, studies that investigate the use of the new social applications in the context of CoPs are still scarce. To contribute to fill this gap, the present paper analyses the factors that influence the frequency of CoP access by means of a Social Media platform. Specifically, the paper illustrates and discusses the results of a survey which involved 262 employees of an international engineering project-based service company that eight years ago established

several global CoPs in order to improve internal knowledge exchange and collaboration processes. At present, inside the company there are 20 active communities, involving about 1,400 project execution employees, whose functioning is supported by a Social Media platform dubbed Connect. The survey, that included 22 questions, was administered online between September and October 2018.

The findings of the survey have allowed to identify some factors that result to be strictly correlated with the frequency of use of the Social Media platform to interact with the others community members. Among others these are: position in the company, role inside the community, individual motivation, kind of use, perceived technical and organizational obstacles. The paper contributes to advance the research about the adoption of Social Media technologies as knowledge management tools by identifying some factors that influence their use inside a CoP. It also provides useful suggestions to managers who intend to promote the development of Social Media enabled virtual Communities of Practices. The main limitation of the study is that it bases on the experience of only one company working in a specific industry with specific knowledge needs and capabilities. In spite of this, the findings provide interesting insights that can be a basis for future investigations as well as suggestions to managers willing to create and sustain virtual CoPs.

Keywords – Knowledge Management, Social Media, Community of Practice, Survey

Paper type: Academic Research Paper

1 Introduction

The use of Communities of Practice (CoPs) to support knowledge sharing and collaboration within organisations has been spreading over the years (Aljuwaiber, 2016; Nithithanatchinnapat et al., 2016). Nowadays many different companies from various sectors are deliberately resorting to CoPs to better managing their cognitive assets and in this way improving their business performance. As underlined by the literature, technology is one of the key pillars of CoPs (Scarso et al., 2009; Wenger et al., 2009), since it can streamline their internal knowledge sharing processes (Hislop et al., 2018). This is particularly true in the case of virtual CoPs, i.e. communities that make use of ICTs to enable distant and asynchronous communications among members, whose rapid diffusion (Frank et al., 2017) has been favoured by the availability of new web-based tools, like for example Enterprise Social Media platforms (Leonardi et al., 2013). Such tools, in fact, enable better communication and collaboration as well as enhanced knowledge location and transfer (Mäntymäki and Riemer, 2016). However, even though the “marriage” of Social Media with CoPs seems to be perfect (Annabi and McGann, 2013), there is little research that investigates the use of the new social applications in the context of CoPs.

Considering the above, this study aims to better understand how Social Media are employed as a communication and knowledge sharing tool inside a CoP. More

specifically, the paper intends to identify and discuss the factors connected with a more or less frequent use of an Enterprise Social Media platform to access a CoP and collaborate.

The paper is articulated as follow. In the next section, the conceptual background and the rationale of the study are illustrated. Section three focuses on the research goals and method, while section four is devoted to presenting the research findings. In section five the findings are more deeply discussed; the last section offers some conclusive remarks also regarding potential and limitations of the study.

2 Background

The notion of Community of Practice was introduced almost thirty years ago by Lave and Wenger (1991) as a part of a broader conceptual framework for reflecting on learning in its social dimension. From then on, it has gained increasing popularity and found extensive practical use in so many contexts (business, government, education health, etc.) that it is difficult to list all its applications (Wenger, 2010). But it is especially in the field of Knowledge Management (KM) that CoPs have been employed as a key tool to promote collaboration and knowledge sharing among “people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis”, to recall the probably most cited definition of Wenger et al. (2002). The recent years have seen a rapid diffusion of virtual (ICT-enabled) CoPs favoured by the fact that Web 2.0 applications and especially Enterprise Social Media (ESM) platforms have increased the ease with which they can be established and sustained.

In fact, it is a widely shared opinion that ESMs can bring substantial benefits to knowledge-related processes (Bechina et al., 2012; Calero Valdez et al., 2018; Helms et al., 2017; Sankaran et al., 2018). Specifically, they are deemed to promote new ways of exchanging knowledge by employees of an organization (Razmerita et al., 2017), they can transform knowledge sharing from an intermittent and occasional process into a systematic conversation (Majchrzak et al., 2013), and they are generally less complex and more affordable than the technologies of earlier generations used to store and facilitate knowledge sharing (like, for example, big centralized databases and automated search engines). Hence not surprisingly, there are those who affirm that KM and ESM are a perfect “couple” (Helm et al., 2017), and that a perfect “marriage” exists between CoPs and ESMs (Annabi and McGann, 2013). Conversely, it is rather surprisingly that studies that investigate the use of ESMs within professional CoPs are still scarce.

The present paper intends to contribute filling this gap by identifying and analysing the factors that influence the frequency of use of an ESM platform to access a CoP and interact with its members. The assumption under this study is that understanding how to promote the sharing of knowledge within a CoP through the effective and efficient use of new social tools is not only vital for the proper functioning of the community but also for the successful adoption of the new media.

In order to perform our analysis, we mainly referred to the studies that have investigated the factors influencing knowledge sharing through ESMs. Scholars who, in

the recent literature, examined this topic tend to consider factors deriving from different conceptual perspectives (Stei et al, 2016) as follows. Nielsen and Razmerita (2014) – who recall a classification proposed by Lin (2007) – distinguish between three different classes of factors: individual factors, organizational factors, and technological factors. In a later paper (Razmerita et al., 2016), the authors provide additional specifications by distinguishing between drivers and barriers. Other scholars (Chin et al., 2015a; Lal, 2016, Harker et al., 2018), willing to underline the social nature of these technologies, add the class of social factors. Further scholars take into consideration additional factors such as: process/operational (Bolisani and Scarso, 2016; Chin et al., 2015b), economic, and cultural factors (Bolisani and Scarso, 2016). Together with the previous factors, we took into account few specific cognitive aspects that can affect how an individual use an ESM to access the knowledge resources (human and documentary, as e.g. written texts, figures, presentations, templates) made available by a CoP.

3 Research goals and methods

According to what is said above, our research aimed to examine the factors that influence the frequency of use of an ESM platform to access a CoP. More specifically it intends to identify and analyse which elements differentiate frequent users from less frequent ones. At this aim we investigated the employees of a company that have adopted an ESM platform to support their CoPs (that the company calls CoI, i.e. Community of Interest). It is an international engineering project-based service company (whose name is not indicated for reasons of confidentiality) specialized in pharmacy whose offices are in 8 different countries (Denmark, France, Belgium, Germany, Switzerland, India, Japan, and United States). At present 20 active communities involve about 1,400 employees. Their functioning is supported by ICT tools, and especially by a Social Media platform named Connect. For collecting data, we conducted a survey that included 22 questions aimed to understand how the ESM enabled CoPs of the company are supporting its knowledge management processes. The survey was administered online between September and October 2018. The present study makes use of the survey data to investigate the aspects characterizing employees who access the communities by means of the Social Media platform. For reasons of space, in the next section only a limited part of the most interesting results is illustrated and discussed.

4 Findings

4.1 The case company

The investigated enterprise is a global engineering company that specializes in the pharmaceutical industry, with around 2,000 employees in 15 offices dispersed in Europe, China, India, and USA. The company employees who are involved in the execution of the projects are expected to consult written engineering guideline when developing solutions to customers, provide feedback or suggest improvements to the guideline owner, and

participate in knowledge development discussions. Employees are also expected to leverage the globally dispersed workforce to resolve problems and find solutions by posting questions online or directly to expert colleagues. CoIs are a central part of the its strategy to become a world leading pharma engineering company that has a local presence and use the knowledge of experts around the world.

The company has organized 20 global CoIs (the first ones were established in 2008) with 1,400 project execution employees who are members of at least one CoI. Participants are voluntary practitioners that interact continuously, and the CoIs define their own task, are responsible for stewarding knowledge within the enterprise, and have a long-term focus. Each CoI represents a competence that has been identified by at least four countries as being a core competence. CoIs are responsible for writing the global engineering standards and implementing best engineering practice derived from projects throughout the world. CoIs are supported by several ICT tools including the ESM platform Connect. Each CoI has a Chairman who is overall responsible for the community and key members engagement. He/she is also responsible for the mainly administrative tasks of inviting to meetings, reporting on CoI performance, maintaining the dialogue with the CoI board, and following up on budget. A CoI has several Key members that are voluntarily appointed to the position because they are recognized experts within their field, and these are central to developing knowledge, sharing knowledge and answering questions. The CoI size ranges from 67 to 373 members. CoIs are governed by a board made up by management representatives from the countries and the board is responsible for the budget and strategy.

4.1 Characteristics of high and low frequent users

We received 262 valid answers from employees from eight countries that correspond to about 19% of CoIs members; the most frequent were Denmark (47.7%), India (13.1%) and Switzerland (12.2%).

We define a high-frequent user as a person that uses Connect for accessing his/her COI at least on a weekly basis. A low frequent user is only active on a monthly basis or even more seldom. In our dataset, we have 147 (56.1%) of high-frequent users and 115 (43.9%) low-frequent users. More specifically, only 17.6% of respondents access CoIs by means of Connect less than once a month.

Table 1: Demographic information

		All participants	High-frequent users	Low frequent users
Position	Manager	6.9%	55.6%	44.4%
	Project/Engineering Manager	19.5%	37.3%	62.7%
	Engineer/Specialist	73.6%	60.9%	39.1%
Seniority in the company	0-2 years	21.8%	64.9%	35.1%
	2-5 years	29.8%	56.4%	43.6%
	5-10 years	22.5%	54.2%	45.8%
	10-15 years	11.8%	51.6%	48.4%
	More than 15 years	13.4%	45.7%	54.3%
	Missing	0.8%		

Membership in primary CoI	0-6 months	9.5%	60.0%	40.0%
	6 month – 1 year	7.6%	85.0%	15.0%
	1-2 years	14.1%	48.6%	51.4%
	2-4 years	31.7%	50.6%	49.4%
	More than 4 years	36.6%	56.3%	43.4%
	Missing	0.4%		
Role in primary CoI	Chairman	7.3%	89.5%	10.5%
	Key member	20.2%	79.2%	20.8%
	Member	72.1%	46.6%	53.4%
	Missing	0.4%		

Table 1 shows that engineers and specialists, i.e. operative people, are more regular users than project/engineering managers. This could be ascribed to the fact that CoIs are seen as a tool to find information related to the daily work more than a coordinating tool. In any case it must be recalled that, according to some information collected by the company, project/engineering managers prefer to use other tools to coordinate their teams, as well as they are less willing to share their PM-related knowledge with other PMs. The frequency of use decreases with the seniority in the company, which indicates that more recently hired employees are also those who need it most to acquire information and knowledge about the company and their work. Instead, there is no clear relation between the frequency of use and the level of seniority, which is an aspect that would deserve further investigation. Lastly, as expected given with their role, the large majority of Chairmen and Key members are high-frequent users.

Before proceeding with analysing the results, it is needed recalling that the next figures show the percentage distribution of responses given by the two groups, where 100% corresponds to the total of valid responses of each group (between parentheses in each caption it is indicated the maximum number of possible answers).

One of the questions asked how a user interacts with his/her primary CoP. The three main ways of interacting with the primary CoI are to use content like wiki articles, to browse through content and, to a lesser extent, to contribute to conversations (Figure 1). The two groups show rather different behaviours. Specifically, high-frequent users contribute to conversations, upload articles or comment articles more than low-frequent users: in substance they show a more knowledge sharing oriented behaviour. Conversely, low-frequent users more like to browse through the content of the CoI, use relevant information and ask other users for help. To sum up, high-frequent users give a more active contribution, while low-frequent ones seem having a sort of need-driven behaviour.

Figure 1: Interaction with primary CoI (max 3 answers)

Survey participants were asked to state why their colleagues should participate in a CoI (Figure 2); this was an indirect way to ask them why they do so. While high-frequent and low-frequent users both agree that to be informed and share information are good reasons to participate in the CoIs, more high-frequent users than low-frequent users think that easier communication is a reason to use the CoIs. Both groups do not think that a CoI can replace meetings. Data confirm that CoIs are considered a tool that should be useful for the daily work, but also that at present they are not so useful for low-frequent users.

Figure 2: Participation reasons in CoIs for other colleagues (max 3 answers)

4.3 Perceived Challenges using CoIs

Both low-frequent and high-frequent users face technical challenges by using Connect as software for the CoIs. The three most named challenges independently of the user group were the difficulties to find the information in the system, the perceived usability of the system compared to other systems as well as the lack of features (Figure 3). A higher percentage of high-frequent users than low-frequent users perceived challenges, and this could be explained with their more intensive use. Especially high-frequent users complained about the insufficient technical support, while system security is not an issue at all. Interesting to note that low-frequent users more believe that other tools or solutions are quicker and /or easier to use, which could be a further reason for their sporadic use.

Figure 3: Perceived technical obstacles with Connect

Besides of technical obstacles, Connect users also face organizational ones (Figure 4). The fact that respondents indicated on average more organizational obstacles than technical ones (2.46 vs. 2.04) underline how the organizational ones are perceived as more relevant than the technical ones.

Figure 4: Perceived organizational obstacles by using Connect

The biggest organizational challenges are lack of time, too few active people and the risk of feeling distracted from the daily work. High-frequent users have a higher fear of showing that they are not knowledgeable than low-frequent users, as well as they complain a not full managerial support. More low-frequent than high-frequent users have the impression that the provided content is not relevant for them.

In line with the identified obstacles, Connect users provided ideas about how to improve knowledge sharing in the company (Figure 5). In general, employees require the allocation of time to contribute to the CoIs, knowledge sharing services and search functionality should be improved. Low frequent users are more interested in usage guidelines, better explanation of the purpose of CoIs and better integration of the Connect system with other systems than high-frequent users. High-frequent users are more interested to get a reward for their contributions, more features and better information classification than low-frequent users. Quite surprising is the fact that more high-frequency users suggest the giving of rewards than low-frequency users. It would be interesting to understand if they believe that their intense participation deserves to be rewarded, or if they think that rewards can be an effective way to motivate current sporadic users.

Figure 5: Ideas for increasing knowledge sharing in the company (max 3 answers)

5 Discussion

What emerged from the study first shows that Social Media can not only be used to support knowledge sharing processes that occur inside a community, but especially that the peculiar organizational context of a CoP appears to be particularly suitable for the successful introduction and use of these new tools. This is confirmed by the positive experience of the investigated company where more than half of the employees that answered the questionnaire access Connect frequently in order to participate to CoIs' life.

Furthermore, the findings of the survey have provided some interesting indications of general character concerning the use of an ESM platform as a tool to support a CoP, as follows:

- Communities are mainly used as virtual places where to find relevant knowledge under the form of web content, wiki articles, templates and examples.
- The most important reason to participate to a community (and hence to use Connect) is to access information and knowledge useful to the daily work.
- Technical obstacles are perceived being less important than organisational ones. Among the first ones, the difficult finding of information and the availability of easier and quicker to use alternative tools are the most named. Regarding the second ones, lack of time clearly prevails over the others.
- In accordance to the previous points, suggestions to promote a more frequent use underline the need to allocate time as well as to make the access to relevant information/knowledge easier. An element that deserves to be recalled here is the very little relevance attributed to rewards as a mean to promote knowledge sharing.

Coming to the specific issue investigated by the paper, that is which elements differentiate frequent from not frequent ESM users, the survey underlines that regular users differ from sporadic users for several aspects as e.g.: position and seniority inside the company, role within CoI, kind of use of the ESM platform, reasons to participate to a CoI, nature of perceived technical and organisational barriers. Specifically, compared to the sporadic users, frequent users seem to pay more attention to the nature of a community as a "knowledge management environment", and are particularly aware of the relevant support that Social Media can give to knowledge sharing. Conversely, sporadic users seem to show a more "opportunistic" use of the community, denoted by a very low level of personal involvement in the community.

6 Conclusion

The paper contributes to a better understanding of how Social Media-supported CoPs can promote knowledge management activities of a global company. More specifically, it investigates the factors that lead to a more frequent access to the CoP by means of Social Media. In doing this, the study reiterates the importance and usefulness of adopting a KM lens to analyse Social Media and that a very good "marriage" exists between CoP and ESM.

From the academic point of view, the study confirms the results of previous research about the existence of different classes of ESM users and the need to improve our understanding of their characteristics. It also confirms the crucial role played by some factors (as e.g. time availability, usefulness for daily work, advantages offered by alternative tools) in influencing the intensity of use of the new social platforms.

The study also offers some practical indications to managers willing to promote a more frequent use of an ESM platform in order to improve the knowledge sharing processes inside their company's CoPs. In particular, it suggests that together with some actions of general validity (as e.g. allocating time to the use of the platform) some other specific actions must be implemented that take into account the specific situations of sporadic users. In this regard, as most of the literature about ESM and CoP underlines, it is worth recalling that less frequent users are however important to keep the CoP (and the ESM platform) alive, and that therefore the first goal is to prevent their abandoning the platform.

The study is not without limitations. A first one is that it applied only descriptive analytics. Hence the next step will be to do a more sophisticated statistical elaboration of the collected data. Another limitation is that results cannot be generalised, since only one company was analysed that belongs to an industry with specific knowledge needs and capabilities. Therefore, future research should extend this analysis in other companies of different sectors. In any case, the findings of the study provide interesting insights that can be a basis for further studies.

Managing Projects and Related Knowledge at Strategic Level – a Case Study of a Hungarian IT Company

Lajos Szabó

Department of Strategy and Project Management
Corvinus University of Budapest
H-1093 Budapest, Fővám tér 8.

Abstract

The paper aims to fill in the gap of investigating the role of strategic project portfolio management and to introduce a case study that focuses on a new strategic project portfolio management model and its application at a Hungarian IT service provider company. The model integrates strategic management, project management and knowledge management in order to set up the strategic project portfolio and to support the successful planning and realization of strategic projects.

There are several approaches to create an organizational strategy (Hunger and Wheelen, 2011). However, they all share a common feature that the foundation of a successful strategy is the analysis of internal conditions and external environment. The way, how the mission and vision statements, as well as the strategic goals are formulated, the strategy for business units are defined, and the operational plans are derived, varies from organizations to organizations. Even more different is, how strategic projects are identified. The main challenge is to create a project portfolio that is aligned with the organizational strategy and provides the balance between exploration and exploitation (Kaiser et al., 2015, Kerzner, 2017, Kopmann et al., 2017, Pemsel and Wiewiora, 2013, Pinto, 2019).

The theoretical part of the paper introduces a new model of developing an organizational strategy and the strategic project portfolio. It is based on the traditional approach of strategic planning, and it is combined with the project planning processes. Scorecard systems provide the interface of these planning systems. Projects are directly linked to strategic goals and the project portfolio is managed at the strategic level.

The practical part demonstrates how this model can be applied in an organization. A Hungarian IT service provider company was selected where the model had been introduced and project management office (PMO) had been created in order to conduct the strategic project portfolio. The new model introduction, the strategic project proposal selection process as well as the project-related knowledge management practice is investigated.

Keywords – Strategy, project, portfolio, knowledge, success

Paper type – Academic Research Paper

1 Introduction

The paper aims to fill in the gap of investigating the role of strategic project portfolio management and to introduce a case study that focuses on a new strategic project portfolio management model and its application at a Hungarian IT service provider company. The model integrates strategic management, project management and knowledge management in order to set up the strategic project portfolio and to support the successful planning and realization of strategic projects.

The article begins with an overview of the evolution of strategic management. This is followed by the introduction of a new approach of developing an organizational strategy, starting from the analysis of the internal and external conditions, through the formulation of the vision and the mission, as well as the organizational goals till the definition of series of projects. The model integrates project management into strategic management.

In the practical part the paper reveals how this model has been applied to a Hungarian IT service provider. Interviews with key internal stakeholders provide a detailed analysis of the new system and lead to identify the need for further actions.

2 Evolution of strategic management

There are several theories of strategic management. The early stages of strategic management evolution concentrated on the process of strategy formulation (Chandler, 1962; Ansoff ;1965; Learned et al. 1965). Later it was investigated, what is the source of competitive advantage: the industry position that forms the space for competition (industry structure based view) or those fundamental resources and capabilities, which create the base of strategy by differentiating itself from others (resource based view). Both approaches can be considered a paradigm of strategic management, and is subject to theory and practice until today, including the Porterian industry sector analysis model's modifications, as well as the trend of emphasis shift in resource-based theory into the direction of knowledge-based dynamic capabilities (Deutsch et al, 2017; Porter, 1980, 1986; Hamel and Prahalad, 1990; Grant, 1991, 2008; Teece and Pisano, 1994; Teece et al, 1997).

Project management is one of the most dynamic fields of management science and practice. Projects are part of the organizational strategy and project management plays an increasing role in strategic management. The main challenge of project management is not limited to the successful project completion, but much more about how these projects contribute to the successful realization of organizational strategic goals (Martens et al., 2018; Pinto, 2016; Blaskovics, 2016; Cserhádi and Szabó 2014; Artto et al., 2008.).

Ambidextrous organizations try to get the balance between exploration and exploitation. Meanwhile exploitation focuses on how effectiveness of existing processes and procedures can be increased, exploration is oriented towards innovation (O'Reilly and Tushman, 2008; Birkinshaw and Gibson, 2004). Theory of ambidexterity links project management to strategic management.

3 Integration of project management into strategic management

Despite all of scientific articles and research results, there is still a lack in investigations on how project management can be integrated into the strategic management. To fill this gap, based on the model of Kessler and Winkelhofer, an integrated model was developed by the author of this article. The model relies on the traditional strategic planning process providing long term strategic and short term operational plans. This process is directly linked to the exploitation perspective of ambidexterity. Projects are platforms for exploration and the strategic project portfolio is the interface between strategic management and project management.

As it is introduced in the previous chapter, there are several approaches to create an organizational strategy (Hunger and Wheelen, 2011). However, they all share a common feature that the foundation of a successful strategy is the analysis of internal conditions and external environment. During the analysis of internal conditions, the strengths are collected and the weaknesses are faced, then an attempt is made to adjust these to market opportunities and threats. The best solution in analyzing the external environment is to have an integrated approach to examine the different environmental segments (legal, economic, political, cultural, and geographical). As the result of these analyses, a decision can be made on those business areas that the operation needs to focus on in the future (Luthans and Doh, 2012).

The next step is the formulation of the vision and the mission. The vision describes the desired future state of the organization. It does not contain numerical values to be obtained, it rather outlines those conditions the organization will endeavor to achieve in the future. The mission is the formulation of the guidelines of the core of the organizational strategy and values which is the guiding principle for managers and employees. The vision and mission are essential because during the development of strategic goals, the determination of the operational and action plans, the development of the control system, the achievement of the goals and objectives defined in the vision and mission need to be taken into consideration.

The organizational goals compared to the mission are more specifically defined. They are the core elements of the organizational management system (Luthans and Doh, 2012). During their formation their quantitative determination should be kept in mind.

The organizational strategy and thus the strategic goals are related to different areas: customers (products and services, markets or market segments), financial (profit, income, cost), internal processes (effectiveness, productivity) and learning and growth (courses, trainings) (Kaplan and Norton, 2007; Kaplan and Norton, 1996). These key areas are of high importance not only for for-profit, but also for non-profit organizations.

The strategic goals defined in the above mentioned target areas, can also be converted into specific, short-term operational plans. However, the market introduction of new products and services or the organization of an international event as projects also have a significant impact on the organization's success. Therefore, it is necessary to deal with these target areas from a strategic point of view. In these areas, the strategic goals can be accomplished as a series of projects, the purposes of which are aligned to the strategic

goals. The organizational strategic goals can be successfully achieved by the successful accomplishment of the projects conducted in the same target areas (Szabó and Csepregi, 2016).

The main challenge is to derive project goals from the organizational strategic goals (top-down approach) as well as to select project proposals which directly contribute to the realization of strategic goals (bottom-up approach). All these projects form the strategic project portfolio.

Figure 1 summarizes this integrated model for strategic project portfolio management. The model integrates project management into strategic management, therefore provides opportunity to get the balance between exploration and exploitation to ambidextrous organizations.

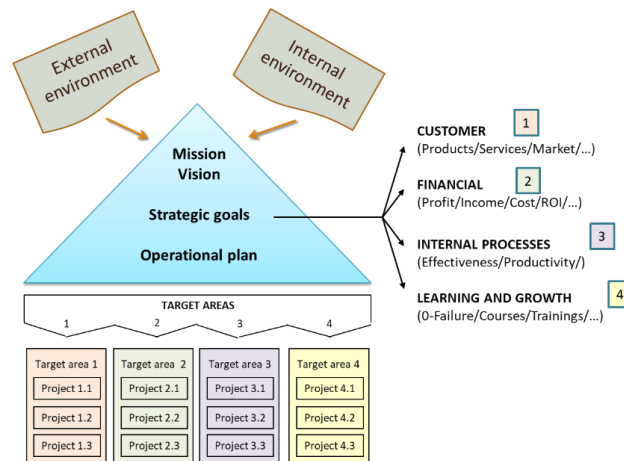

Figure 1: Integrated model for strategic project portfolio management (based on the model of Kessler and Winkelhofer, 1997)

4 Case study

The case study aims at introducing the practical application of the integrated model for strategic project portfolio management. A Hungarian IT service provider was selected in order to show how strategic project portfolio management was introduced by using the integrated model described in chapter 2.

4.1 The case: A Hungarian IT service provider

The selected company is a middle sized Hungarian IT service provider. It was founded in the middle of 90s when the first global IT companies arrived to Hungary. Over the past more than 20 years it became one of the most important local service provider of global IT companies' affiliated firms. During the past two decades, the companies' operation as well as the organizational structure went through some major changes, strategic planning system was set up and project management processes were developed. Because of the acceleration of technological development and the increased complexity of

new product and service development, increased number of project failure was realized. A consulting company was invited to identify the situation, to detect the reason of high level project failure rate and to provide solutions and recommendations for successful operation.

4.2 Applied research methodology

From methodological point of view this paper is a particular one. As an external research consultant the author was invited as subcontractor of the consulting company to take part of the screening process and support the development of the solution. After having completed the consulting process, the author carried out in-depth interviews as part of this research project. Chief Executive Officer, Head of the PMO, and 3 senior project managers were interviewed.

4.3 Result of the screening process

The organizational screening concluded with the following result. In order to increase the profitability, the company applied for many tenders and accepted lots of assignments. Many projects were launched without effective and efficient project management at the organizational level.

The most important symptoms calling for an effective strategic project portfolio management were as follows:

- Single project and process management system is operated but no organizational unit was created to provide coordination among projects.
- No project-related knowledge management system was developed. No systematic knowledge collection and knowledge sharing processes were introduced.
- Many projects were initiated without adding „strategic value” to the organization.
- Several project opportunities were taken without focusing on the strategy.
- No prioritization process was developed for business requests.
- Too many small projects were underway.
- Short term problem-solving instead of long term strategic orientation.
- Frequent change of status of projects (active – on-hold – priority – on-hold).
- Excessive project delays due to lack of resources.
- Intense competition internally with regard to financing / staffing projects.

4.3 Solution: the integrated model for strategic project management

After realizing the problems listed above, necessary conditions for strategic project portfolio management were formulated.

The solution has to fulfil requirements as follows:

- Links project selection to strategic metrics.
- Prioritizes project proposals across a common set of criteria, rather than on politics or emotion.

- Allocates resources to projects that align with strategic direction.
- Justifies killing projects that do not support organization strategy.
- Improves communication and supports agreement on project goals.
- Builds discipline into project selection process.
- Provides executive oversight of the firm.
- Provides the structure / process for project portfolio governance.
- Avoids duplication or waste.
- Supports collecting, compiling and sharing project-related knowledge.

The solution is based on three main pillars:

A/ Introduction of the integrated model for strategic project portfolio management

The integrated model for strategic project portfolio management was recommended to be introduced. Strategic project portfolio is defined as selection of projects where all projects are directly linked to the strategic goals. Strategic alignment, fitness - projects are doable with the available resources – as well as innovation are the three main features of projects of the strategic project portfolio.

B/ Converting the theoretical model into a process-based view of strategic redefinition

After deciding to introduce the new model, the next question had been raised. Although the model introduction links projects to strategic goals, the project selection process had to be developed and selection criteria had to be defined. This led to the development of process-based view of the integrated model. The new process starts with rethinking and reviewing the organizational strategy. If the review gives grounds for redefinition of the organizational strategy, strategic decision makers have to reconsider both the main pillars of the organizational strategy and the strategic project portfolio. Figure 2 shows the process-based view of strategic redefinition. The model includes the planning processes of strategic management as well as of portfolio-, program- and project management.

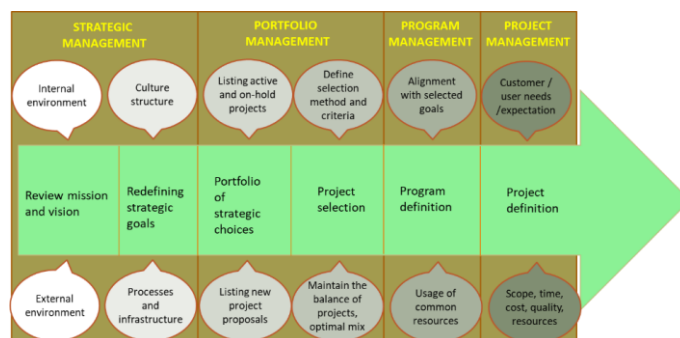

Figure 2: The process-based view of strategic redefinition

The model allows decision makers to take into consideration not only the new project proposals, but to re-evaluate on-hold and active projects when refreshing the strategic project portfolio. Listing already existing projects (active and on-hold) aims at identifying

those projects organization needs for realizing new strategic objectives, meanwhile gathering and listing new project proposals demonstrates the innovation potential of the organization. Screening models help managers pick winners from this pool of projects.

Figure 3 summarizes the most important selection criteria the company applies when selecting projects for its strategic project portfolio.

FINANCIAL	MARKET	BUSINESS BENEFIT	ORGANIZATION	CUSTOMER	FUNCTIONAL
NPV	Increasing market share	Short-term benefit	Relevance	Added value	Internal processes
Payback period	Retaining existing customers	Long-term benefit	Impact	Cost-added value ratio	Knowledge and competence
IRR	Getting new clients	Cost-benefit ratio	Sustainability	Client satisfaction	Cost management
PI			Efficiency		
			Effectiveness		

Figure 3: Criteria for strategic project selection

Financial and functional criteria represent the traditional approach of project selection and business benefit criteria indicate the new interpretation of project success. Economic, social and environmental perspectives of sustainability point out the importance of long-term orientation of project-, and portfolio management.

C/ Setting up a PMO (Project Management Office) as project-related knowledge management center

PMO as a new organizational unit was set up and head of the PMO was appointed to manage the portfolio and to direct the PMO. The new PMO has to serve as a project repository by operating as knowledge management center in terms of collecting, compiling and providing project-related information. The PMO has to provide a consultative role to projects by supplying templates, best practices, training, access to information, and lessons learned from other projects. It has to organize trainings on project management processes and tools, project management software, and project management skill development.

4.4 Assessing the result of the new model introduction

Based on the five interviews the result of the new model introduction was assessed. The assessment was divided into three main parts. The model introduction process itself as a project was evaluated. This was followed by the evaluation of the new system's operation. Finally, the project-related knowledge management conducted by the PMO was analyzed. Based on different assessment criteria, interview partners were asked to evaluate the introduction, the new system as well as the knowledge management system by using a five-grade scale with 5 being the highest and 1 being the lowest grade.

4.4.1 Assessing the new model introduction from project success perspective

Figure 4: New model introduction from project success perspective

The new model introduction was evaluated by using project success criteria as project triangle (time, budget and result), client satisfaction and client-consultant communication. Figure 4 illustrates that the introduction project was completed on time and on budget. The client representatives expressed a relatively high level of overall satisfaction. The client-consultant communication was assessed as good with an average score of 4.4. In case of communication, interview partners reported on a good partnership with the consulting company, but beside the presentations at the project milestones they expected written executive summaries as well. Executive summary and detailed written report were prepared only at the end of the introduction project. Similar score was given to the final result judgement. Components of the final result were assessed one by one in the next chapter of the interviews.

4.4.2 Assessing the new system's operation

Figure 5: Evaluation of the new system

Components of the new system which integrates projects into the organizational strategy reveal that project proposals are selected in a standardized and transparent manner, and realized based on the standards of designing, executing, closing and

evaluating projects. The introduction and application of the new system concluded with this content.

According to the interviews, the need for project portfolio risk management was identified. However, this was not incorporated into the consultant-client contract, the client realized the lack of project portfolio revision and risk evaluation. This led to a new contract and to the second phase of client-consultant cooperation which is still continuing.

4.4.3 Assessing project-related knowledge management

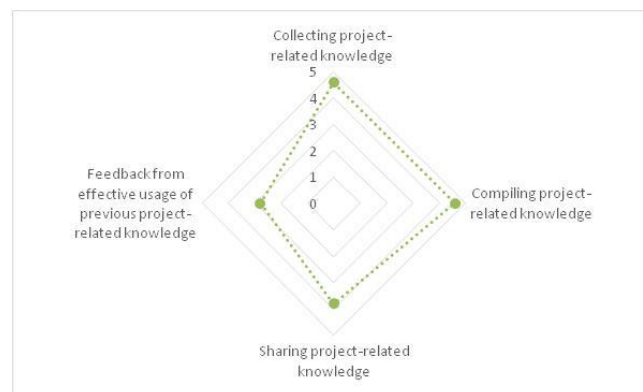

Figure 6: Analysis of the project-related knowledge management system

As an important structural development, a new organizational unit in form of project management office (PMO) was introduced. Figure 6 reveals how effectively project-related knowledge management system is operated by the PMO. Gathering, compiling and sharing functions of knowledge management are operating as expected. On the contrary, feedbacks about how knowledge of previous projects are used when initiating and realizing new projects are not collected and evaluated. Therefore, the new client-consultant contract contains assignment to work out and introduce new feedback-processes.

5 Conclusions

Strategic management and project management are often considered by scientist and practitioners as two separated disciplines and functional areas. Based on a case-study, this paper highlighted how project management can be integrated into strategic management. Through the introduction of the integrated model projects are aligned with the organizational strategy, strategic project portfolio is effectively managed and selection of project proposals goes on a transparent and standardized way. Interviews with key internal stakeholders revealed how successfully the new model was implemented and what kind of needs for further development evolved.

Abstract

The main assumption of our conference paper is that in the contemporary, ever-changing, precarious economic environment that can be described by the concept of digital transformation, it is particularly worthwhile to reintroduce the evergreen question whether traditional strategic planning and long-term strategic goal-setting, and strategic implementation based on them, are still valid concepts. We investigate this question by a brief literature review that intends to underpin the problems related to the classical models of strategic planning as well as its alternatives. Our main conclusion is that, based on the latest research results, strategy formation (and planning within it) are not outdated concepts. This is the case since 1. the implementation of a pre-defined strategy can be interpreted as a rational organizational act; 2. the failure rate of the implementation of pre-defined strategies does not disprove the validity of this traditional approach. In the discussion part of our paper we also briefly touch upon the situations in which traditional planning, to our view, can be effective, as well as on potential areas for future research related to digital transformation.

Keywords – strategy, strategy formation, strategic planning, alternative approaches, review

Paper type – Academic Research Paper

1 Introduction

The world around us is in the process of constant change at an ever-growing pace regarding nearly all aspects of life, which makes the continuous development of knowledge, skills and competences as well as the continuous adaptation to the changing environment indispensable. This is true, in particular, in the dynamic, uncertain present-

day economic environment that can be described by the notion of digital transformation. Such an environment legitimately raises concerns with regards to the effectiveness of traditional strategic planning and long-term strategic goal-setting. Can such traditional methods be effective in this modern milieu or will long-term goal setting and rigid insistence to the pre-defined plan during strategy implementation make organizational operations inflexible, thus hindering adaptation to challenges, and, ultimately, threatening the functioning and competitiveness of the organization.

In business practice we are witnessing the emergence of new management ideas both in the fields of strategy and ‘operations’. Such examples are data-driven strategy, project portfolio management, and agility, just to mention a few. In such context, exploring this fundamental question has become, once again, of central importance. Our paper intends to provide a brief overview of the conclusions that can be drawn from the related literature, putting its emphasis on the problems and alternatives to traditional strategy formation.

The theoretical approaches to strategy formation will not be covered in this paper. We only touch upon them in this paragraph, as a contextual question from the perspective of our paper, to the extent to which the basic categories need to be clarified. Thus, we need to refer to *Henry Mintzberg*, the well-known author of strategy formation, and his colleagues (Mintzberg et al., 1998), who distinguished ten schools of strategy formation. The traditional approaches, the three so-called ‘prescriptive’ schools according to Mintzbergian terminology, mainly focused on the question how strategies *should* be formed, and not so much on how they are actually formed. Contrastingly, the six other approaches, categorized as ‘descriptive’ schools, do not focus on the definition of ideal strategic behaviour, but instead focus on the ways strategies are *actually* made. Finally, the last one, the ‘Configuration School’ tries to integrate the approaches of the other nine ‘schools’ (Mintzberg et al., 1998: 6-7). Naturally, other authors have used different taxonomies. For instance, Ellen Earle Chaffe distinguished *linear*, *adaptive* and *interpretive* strategies (Chaffe, 1985). From the diversity of potential approaches, we will apply Mintzberg and colleagues’ taxonomy as a starting point.

2 Problems of classical strategy formation

The pitfalls of the traditional, ‘prescriptive’ theories of strategic planning (the design school, the planning school, and the positioning school) are related to the rigid division of planning and implementation, the formalization of the planning process, and the prior fixation and inflexibility of the strategy. For instance, just to mention a few such pitfalls, the lack of organizational commitment to the strategy (Friis et al., 2016: 1), or the fact that strategic plans in fact serve ‘symbolic goals’ and focus on the present instead of the future (Akhter, 2003: 2). In his paper about the obstacles in the way of effective strategy implementation, Hrebieniak identifies a variety of well-identifiable, cardinal problems. Among others, the disregard towards the interdependence between planning and implementation, or the fact that implementation lasts much longer than planning are worth mentioning (Hrebieniak, 2006: 12-15). A related and important problem is the fact that ‘implementers’ are often unaware of the strategy, and even in cases when they are, to

some extent, familiar with it, they tend to lack the necessary knowledge and skills required for successful implementation (Heide et al., 2002: 218).

Another important group of problems is related to the preliminary fixation of the strategy, which usually leads to the inflexibility of both the plans and the planning process, as well as to the difficulties in the adaptation to the internal and external changes (Mintzberg, 1990: 172-176). First, inaccurate identification of the internal and external factors can lead to problems even at the starting point (Hansen – Smith, 2003, cited by Arvand – Baroto, 2016: 302). Second, even for the manager who creates the strategy it is virtually impossible to collect and harmonize all the relevant factors (internal, corporate decisions, events of the external environment, actions of competitors, etc.) at the same time, ‘so that they come together at any precise moment’ (Quinn, 1978: 17). Third, and this may be the most important aspect with regards to adaptation to changes, the more clearly a strategy is articulated and the more deeply it is embedded in organizational culture, the more it will hinder necessary strategy changes in the future as well as increase resistance to such attempts (Mintzberg et al., 1998: 36).

Similar problems related to classical strategy formation (‘prescriptive’ schools) have been long and widely discussed in the literature. With regards to the *planning school*, known for its high level of formalization, Ian Wilson in his paper titled *Strategic Planning Isn’t Dead – It Changed* describes the development of strategic planning from the early 1970s. Wilson emphasizes that following the initial failures (‘seven deadly sins’) strategic planning transformed into a viable system, strategic management (Wilson, 1994: 13). Some notable debates related to this topic are well-known, such as the debate between Mintzberg and Ansoff about the design school, on the columns of the *Strategic Management Journal* (Mintzberg, 1990; Ansoff, 1991). Similarly, it is worth mentioning authors who stood out in defence of SWOT-analysis, for instance Geoffrey Bell and Linda Rochford (Bell – Rochford, 2016). However, instead of describing debates and pitfalls in more detail, in the following section we will briefly present some alternative approaches that go beyond the ‘prescriptive’ school.

3 Alternatives to traditional planning

It is important to stress that even though many authors believe that all organizations have a strategy (either explicitly or implicitly), there are some who disagree. In their paper *The seeking of strategy where it is not: towards a theory of strategy absence*, Andrew Inkpen and Nandan Choudhury concentrate on the possible reasons behind the absence of a strategy, as well as on the characteristics of such organizations. The authors emphasize that while strategic theories are becoming more and more elaborated, strategic research is presence-oriented. However, the systematic study of the *absence* of strategies could also contribute to the better understanding of how strategies work (Inkpen and Choudhury, 1995: 313-314). Inkpen and Choudhury emphasize three different approaches to this topic: 1- the absence of strategy as a negative concept: the proof of managerial *failure*; 2. the absence of strategy as a temporary, *transitional phase* in the firm’s life cycle; 3. the absence of strategy as a positive concept: the result of a *conscious, deliberate*

decision (Inkpen and Choudhury, 1995: 316-319). For the last one, the authors give two examples. In the first example, the absence of a strategy is related to the unpredictability of the environment and the intensification of competition: the lack of strategy and the conscious ambiguity integrated into the objectives may contribute to the preservation of *corporate flexibility*, to proactive and innovative decision making (Inkpen and Choudhury, 1995: 318). In the second example, the absence of a strategy is interpreted as a *symbolic message*: the organization sends a clear message to stakeholders that it does not intend to take part in 'resource-consuming ceremonies' (Inkpen and Choudhury, 1995: 319).

As has been described above, in some cases the absence of a strategy can be interpreted as a *transitional phase*. In these cases, strategy is evolving gradually, simultaneously with the increase in the firm's resources and knowledge (Inkpen and Choudhury, 1995: 317). In their paper *Of Strategies, Deliberate and Emergent*, Henry Mintzberg and James A. Waters distinguishes between deliberate and emergent strategies, which they do not consider as dichotomous categories but the *two ends of a scale*, emphasizing that observable real life strategies fall somewhere between these two ends (Mintzberg and Waters, 1985: 258-259). In relation to gradually emerging strategies, *James Brian Quinn's* name and the concept of *logical incrementalism* need to be mentioned. Quinn argues that in real life effective strategies are typically the blending of strategic subsystems focusing on specific strategic issues, however, the management and integration of these subsystems happen *incrementally*, due to the cognitive and process limits (Quinn, 1978: 8). According to his view, managers 'consciously and proactively move forward incrementally' in order to achieve such goals as the improvement of the quality of information utilized in strategic decision making, overcoming resistance against strategic change, the building of organizational awareness and commitment needed for the implementation of the strategy, and the improvement of the quality of strategic decisions themselves (Quinn, 1980: 20-21).

These concepts, emergent strategies and logical incrementalism, could be considered as the forerunners of the Mintzbergian *learning school* (one of the descriptive approaches). In addition to this school, another approach deemed desirable from many aspects by Mintzberg and his colleagues has been labelled as the *configuration school*. The main ideas of this school are organized around two central concepts: configuration and transformation. *Configuration* describes the organization and its surrounding context, while *transformation* is the strategy making process itself, the process of 'leaping from one state to another' (Mintzberg et al., 1998: 302).

From the other mainstream theories of strategic thinking C.K. Prahalad and Gary Hamel's *core competence* theory (Prahalad and Hamel, 1990) and Robert Grant's *resource-based theory* (Grant, 1991, 1996) may also be highlighted. With regards to the latter, Grant considered corporate resources and capabilities as the foundation for strategies, and, similarly to the followers of the learning school, considers organizational learning as one of the central themes. He emphasizes that *knowledge* is the most strategically-significant resource of the firm (Grant 1996: 375).

Finally, let us have a look at another possible categorization of different strategic approaches. In his paper *Strategy as practice*, Richard Whittington distinguishes four strategic perspectives based on their central issues ('dominant concerns') and the organizational level they focus on: the *planning*, the *policy*, the *process*, and the *practice* approaches (Whittington, 1996). The process-oriented approach emphasizes that the formation and implementation of a strategy is a *process*, putting great emphasis on renewal and growth, and not a static state of corporate position, resource pool, and environmental nestedness (Pettigrew, 1992, 1997). The *strategy as practice* approach focuses on the practitioner and, instead of corporate core competences, puts the emphasis on the practical competences of the manager as a strategist (Whittington, 1996: 732). The central question to this approach is how managers and consultants can act and what type of interactions they have, in other words, how strategy is actually created and operated ('doing strategy') during the process of strategy formation (Whittington, 1996: 732). Whittington emphasizes that, besides the fact that an effective strategist needs to know the analytical techniques of planning, the appropriate policy options and the organizational processes related to decision making and implementation, the strategist also draws to a great extent on the *practical knowledge and skills* obtained during the process of strategy-making. According to him, research and training should put greater emphasis on this latter area.

4 Concluding discussion

Based on the concepts and approaches described so far, the question arises whether it is worth formulating and implementing strategic goals at all. When answering this question, it is important to distinguish between the *perfect* implementation of a strategy and the *successful* performance of a firm (as a result of the strategy followed) (Lee and Puranam, 2015). Another widely discussed phenomenon in the literature related to the successfulness of strategies is the observation that a significant proportion of strategies fail or never even gets implemented (e.g. Neluheni et al., 2014; Arvand and Baroto, 2016; Hrebieniak, 2006). However, estimations and the findings of empirical research remarkably differ with regards to the size of this 'significant proportion'. Carlos Cándido and Sérgio Santos in their paper *Strategy implementation: What is the failure rate?* discuss this problem in details (Cándido and Santos, 2015). Their research findings do not support the argument that it is not worth formulating a strategy as it is not going to be implemented successfully.

However, the way and extent of strategy implementation still remains a question. Is it necessary to insist upon the pre-defined strategy planned by the management, or is it better if strategy is formed gradually with the involvement of lower levels of the organizational hierarchy? As described in this paper, the literature of strategy formation has produced basically two different answers to this cardinal question. In order to help answer this 'ultimate question', we would like to draw on the findings of an interesting computer simulation here. Eucman Lee and Phanish Puraman in their paper *The implementation imperative: Why one should implement even imperfect strategies perfectly*

emphasize that the ‘implementation imperative’ in managerial discourses is surprising for several reasons. The authors describe this phenomenon as the view according to which the improvement in the precision of strategy implementation is always desirable. In case the correct strategy were known ex ante, this would doubtlessly be the case. However, in a world of bounded rationality strategies that can be objectively called correct are rarely known (Lee and Puranam, 2015). In their paper the authors test the ‘implementation imperative’ with the help of a computational model in an environment where the optimal strategy is unknown. In this model the strategy adapts based on feedback. The two scholars found that even in such an insecure environment the ‘implementation imperative’, i.e. the precise implementation of a pre-defined strategy, is rational in cases when strategy formation and implementation are clearly separated across organizational actors.

Based on the ideas described so far, we believe that for new businesses, or businesses that intend to enter a new market, the classical strategy formation models can be useful frames. They can also be effective for small or medium-sized enterprises that work on relatively stable and predictable markets, in case their leaders are able to assess properly all the internal, firm-related and external, market-related factors and are able to collect all the relevant information related to them. (Mintzberg et al., 1998: 52-53) Naturally, in both cases employees’ understanding of the centrally-set strategy is necessary, as well as their willingness to implement it. However, in situations different from the ones described above, the risk of the appearance of problems related to classical planning increases significantly. In these cases some of the alternative approaches to strategy formation can be helpful, the main ideas of which might be worth considering for integration into the strategy formation process regardless of the situation.

The main goal of our paper was to briefly outline the most important questions related to the ‘classical’ literature of strategy formation, predominantly focusing on the problems and alternatives. We did so with the aim to review the most important findings in the field, thus enabling our forthcoming analysis of planning in a world of digital transformation. We firmly believe that in order to understand the importance of strategy formation in the world today, further research is needed. This could be extended to several aspects of planning, involving the practice of successful firms exploiting the network effect (e.g. Airbnb, Uber, eBay), or the practice of the agile small and large-sized enterprises.

Abstract

The topic of public service improvement has received great attention all over the world in recent decades, in both private and public sectors. While there is a huge literature investigating components which are critical in formulating an organization strategy for achieving service quality improvement, in both public and private organizations, namely organizational variables affecting service quality (such as resources, organizational structure, performance management system), and contextual (internal and external) factors conditioning the achievement of higher performance, there are no studies analysing how the public sectors organizations reacts to the regulation imposing performance standards and how contextual factors may affect such organization response to new performance standards. In particular, many questions posed about regulation are concerned with the extent to which it assists with or damages attempts to maintain and raise the standards of public service performance.

The aim of this paper is to contribute to the stream of public service performance (PSP) improvement by addressing the following research questions: How the organizations of public sector providers react to higher performance standards fixed by the regulators? How contextual factors affect such organization response?

With this objective, after reviewing the literature dealing with the organizational variables that are believed to be linked to quality service and performance, the areas of service quality as well as the link contextual (internal and external) factors and performance, a reference framework is developed, which is used as a guide model for the empirical analysis which was carried out on 15 public service providers in Italian water and electricity sectors.

The results of the empirical investigation indicate organizational variables mainly affected by higher performance standards imposed by the regulation are resources and performance management systems. They also reveal the existence of clusters of firms.

This will provide an interesting practical implication, by making the regulator aware that the achievement of high performances in the public service in order to be compliant with the new standards entails a change in the organizations of service providers, not so much in terms of organizational structure as in terms of the required resources and the design of the PMS. On the other hand, the study gives a number of examples about how a sample of firms has responded to the introduction of the new standards and how such response is affected by contextual factors.

Keywords – Strategic management, Performance standards, Organizational variables, Public sector.

Paper type – Academic Research Paper

1 Introduction

The topic of public service improvement has received great attention all over the world in recent decades (Boyne, 2003), in both private and public sectors. While in the private sector the use of a variety of measures of service quality as critical indicators of both organizational performance and general customer satisfaction is widely accepted (David Mc, 2013), organizations operating within the public sector have come to realize that customer service and quality are critical strategic issues only in the late 1990s (Wisniewski, 2001).

The performance of public organizations is influenced by many variables (Boyne 2003). Some of these are largely outside the control of public managers, at least in the medium term. These include the resources allocated by higher levels of government, the size and characteristics of client populations, the political ideology of national and subnational governments, and the level of support provided by political principals.

In this framework, the strategic management (SM) assumes a key role for the organizations of public sector.

SM is defined as “the conscious selection of policies, development of capacity, and interpretation of the environment by managers to focus organizational efforts toward the achievement of present objectives” (Poister, 2010).

The strategic management is important because it varies across public organizations, and it is not simply a trivial or redundant category once the impact of environmental and organizational variables is taken into account. Indeed, strategy shapes the impact of

external and internal constraints on performance, and is, in theory, both directly and indirectly linked to performance.

There is a small but growing research field (see, e.g., Andrews and Van de Walle 2012; Elbanna, Rhys, and Pollanen 2016; Ferliem and Ongaro 2015; George and Desmidt 2016; Hansen Rosenberg and Ferlie 2014) that has highlighted the importance of studying strategy and strategic thinking in public organizations for the past decade, and how public organizations apply SM in practice and which tools are used to realize a strategic intent (Hoglund et al., 2018).

Moreover, while there is a huge literature investigating components which are critical in formulating an organization strategy for achieving service quality improvement (Andrews and Boyne, 2010; Andrews et al., 2009), namely organizational variables affecting service quality (such as resources, organizational structure, performance management system), and contextual(internal and external) factors conditioning the achievement of higher performance (Capaldo et al., 2018; Andrews et al., 2005), there are no studies analysing how the public sectors organizations reacts to the regulation imposing performance standards and how contextual factors may affect such organization response to new performance standards. In particular, many questions posed about regulation are concerned with the extent to which it assists with or damages attempts to maintain and raise the standards of public service performance.

Theory and empirical evidence indicate that when a regulator chooses to regulate prices using price or revenue caps, a company's incentives to deliver efficient levels of service quality tend to drop (Giannakis et al., 2005; Pellegrino et al., 2011; Ter-Martirosyan and Kwoka, 2010). As a consequence, price cap or revenue cap regulation must be supplemented by service quality regulation (Fumagalli et al., 2007). Regulator had therefore to intervene in order to secure desirable levels of performance on the multiple dimensions of service quality. One simple regulatory instrument employed to achieve this goal is the publication of data on company performance. The dissemination of information regarding a company's performance with respect to a set of quality indicators provides unambiguous incentives for increased investments in quality (Weisman, 2005). A second relatively simple instrument is the setting of minimum quality standards (MQS). The regulator specifies performance standards in the form of a minimum level of service quality that the company is expected deliver to its customers. Non-compliance with these minimum levels of quality might entail the payment of penalties, according a predefined reward and penalty scheme for exceeding or failing to achieve these standards (Fumagalli et al., 2007).

This means that once such performance standards have been fixed by the regulators, service providers have to operate in such a way to meet them and to avoid huge penalties if they fail to do so.

Spurred by the discussed research gap and enhancing the seminal work of Capaldo et al. (2017), the aim of this paper is to contribute to the stream of public service performance (PSP) improvement by addressing the following research questions:

- How the organizations of public sector providers react to higher performance standards fixed by the regulators?

- How contextual factors affect such organization response?

The paper is organized as follows. Next section reviews the literature dealing with the organizational variables that are believed to be linked to quality service and performance, the areas of service quality as well as the link contextual (internal and external) factors and performance, and Section 3 develops the reference framework used as a guide model for the empirical analysis. Section 4 illustrates the research methodology adopted for the empirical investigation, and Section 5 discussed the result of the multiple case study. Finally, Section 6 concludes and outlines some avenues for future research.

2 Theoretical background

This section reviews the literature dealing with the organizational variables that are believed to be linked to quality service and performance, the areas of service quality as well as the link contextual (internal and external) factors and performance. The purpose is to develop a reference framework that can be used as a guide model for the subsequent empirical analysis aimed at investigating how the organizations of public sector providers react to higher performance standards fixed by the regulators and how contextual factors affect such organization response.

2.1 Organizational variables and public sector performances

The literature on PSP agrees that organizational variables, as resources, organizational structure, performance management systems, managerial capacity are critical components for achieving service delivery improvement.

Resources

The common idea that more resources will lead to better results is the basis for both the strong theory that higher public expenditure is a sufficient condition for improvement because this must result in a higher quantity and/or quality of public services, and the weak theory suggesting that greater spending is a necessary but not sufficient condition since the resources must be effectively managed in order to deliver the maximum potential benefits (Boyne 2003). On the other hand, the majority of the empirical results reveal no significant relationship between either financial resources or real resources and service performance (Bradley et al. 2001; O'Toole and Meier 2001; Meier et al. 2000). This is coherent with the theory that inefficient public managers fritter away extra money without any improvement in performance. Therefore, it is reasonable to suppose that the greater the real resources available for the organization, the higher the performance.

Organizational structure: Hierarchy of authority and degree of participation in decision-making

The literature on public service performance broadly focuses attention on the internal characteristics of public organizations that can affect service quality. In particular, it has been hypothesized by policy makers and scholars that the degree to which decision-

making is centralized or decentralized is a determinant of public service performance (Andrews et al. 2009).

For organizational theorists, the degree of centralization within an organization is indicated by the hierarchy of authority and the degree of participation in decision making, since these aspects reflect the distribution of power across the entire organization (Carter and Cullen 1984; Glisson and Martin 1980; Hage and Aiken 1967, 1969). Hierarchy of authority refers to the extent to which the power to make decisions is exercised at the upper levels of the organizational hierarchy, whereas participation in decision making pertains to the degree of staff involvement in the determination of organizational policy. There is still comparatively little research investigating the effects of the degree of centralization on public service performance (Andrews et al. 2009). Empirical studies in the private sector have failed to find a consistent or substantial relationship between centralization and performance (Wagner 1994).

Overall, theoretical arguments suggest that centralization is likely to have positive effects on performance, even though the evidence is weak or non-existent (Andrews et al. 2009).

The performance management system

Efforts to improve performance in public sector organizations have fostered the spread of performance management practices (Hood 1995) falling within the so-called New Public Management approach. Performance management practices include setting the goals to be achieved and measuring and evaluating performance (Heinrich 2002).

Despite the great attention devoted by governments to performance management practices for improving public service, a fundamental question posed by several researchers is whether performance management will actually improve public sector performance (Verbeeten, 2008). A rather limited number of empirical studies investigate the impact of PM-practices on public organizations (Van Helden, 2005) and they generally focus on the relation between one specific factor of the performance management system and performance. Some studies assert that clear goals and measurable results allow organizations to reduce ambiguity regarding objectives and to gain coherence and focus in pursuit of their mission (Rangan 2004; Kaplan 2001). Furthermore, the use of incentives may increase performance (Bonner and Sprinkle 2002). Some researchers have found that performance management may also result in unintended managerial side effects (e.g. Vakkuri and Meklin 2006; Hood and Peters 2004; De Bruijn 2002). In particular, a performance management system that does not account for difficult circumstances beyond the control of the management causing performance failure may discourage managers from performing well, thus decreasing rather than increasing the organizations' performance (Verbeeten 2008; Andrews et al. 2005; 2009). Therefore, it is reasonable to assume a positive relationship between a well-designed performance management system and performance.

2.2 Areas of service quality and performance standards

Service quality in the public service delivery covers a large number of aspects, either technical or non-technical (Fumagalli et al., 2007).

Non-technical aspects arise in the relationship between the customer and the service providers (mainly the distributor and the retailer), before the beginning of the service and during the validity of the contract.

Technical aspects of service quality are generally referred to as ‘power quality’ issues and include any variations of the characteristics of services around their ideal values.

2.3 Contextual (internal and external) factors and performances

One of the issues widely debated in the public policy literature is the relative importance of constraints and choices in the explanation of organizational processes and behaviour (Boyne 1996; Andrew et al., 2005; Capaldo et al., 2018).

Some studies stress the importance of various aspects of management for public services, such as HRM, leadership, organizational culture and strategy content (Meier and O’Toole 2002a; Brewer and Selden 2000; Zigarelli 1996). Other studies have also investigated the relationship between organizational size (e.g., number of staff, capacity, and number of service users) and performance (Boyne, 2003), revealing that the impact of size does not appear to be linked systematically to type of service or specific dimensions of performance.

Theories that emphasize the importance of external constraints imply that ‘force of circumstance’ leaves policy-makers with very limited room for manoeuvre (Andrew et al., 2005). Literature review shows that performances are significantly influenced by the characteristics of local populations and environment and that ‘poor’ performance is partly attributable to difficult circumstances rather than bad choices. Other two aspects of the local environment that have been considered as variables influencing performance are population size and population density (Boyne 1996b).

3 Reference framework

Based on the reviewed literature, we built the reference framework that served as a guide for our empirical analysis, as depicted in Figure 1. It hypothesizes that higher quality standards imposed by law impact on the organization of public service providers, specifically influencing the resources, the organizational structure and performance management system. Furthermore, it advances that the context in which the firm operates has a potential influence over the organization response to higher performance standards fixed by the regulator.

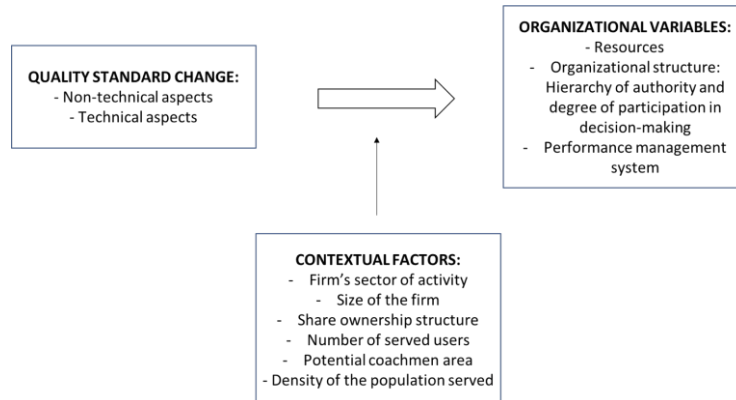

Figure 1. Reference framework

4 Research Methodology

This study uses a multiple case comparison methodology for the empirical investigation (Eisenhardt and Graebner, 2007, Yin, 2003).

The study involved 15 Italian firms, specifically 10 from the water sector and 5 from the electricity sector, that were studied during the last 2 years (see Table 1, where the identity of companies was concealed for confidentiality reasons).

Table 1. The studied firms

Firm	Sector of activity	Role of people interviewed	Firm size (No. of employees)	Share ownership structure	Number of served users	Potential coachment area (Kilometers of network)	Density of the population served*	Sold volumes	Revenues [M€]
Company A	Water	Manager of operating center	398	Public	266720	10267	25,98	39 [Mmc]	61
Company B	Water	Commercial Manager	648	Mixed (63% public share)	535234	2090	256,09	100 [Mmc]	176
Company C	Water	Administrative and customers manager	66	Mixed (52% public share)	40051	597	67,09	0,2 [Mmc]	13,5
Company D	Water	Finance and Administration manager	858	Public	594000	5368	110,66	59 [Mmc]	139,7
Company E	Water	Head of engineering and R & D department	498	Public	1650000	2500	660,00	180 [Mmc]	93
Company F	Water	Responsible for Planning and Coordination of Regulated Services	2940	mista (52% pubblica)	1450000	35096	41,32	300 [Mmc]	82,6
Company G	Water	Head of General Administrative Services	240	Public	41000	4865	8,43	71 [Mmc]	42
Company H	Water	Strategy and planning director	490	Public	2000000	2228	897,67	230 [Mmc]	72,6
Company I	Water	Responsible for Regulatory Affairs	1930	Public	1000000	21000	47,62	264 [Mmc]	550
Company L	Water	Planning and Control director	800	Public	347000	6460	53,72	250 [Mmc]	232
Company M	Water	Operative director	263	Public	450000	3370	133,53	37 [Mmc]	64
Company N	Electricity	Director	15783	Mixed (30% public share)	31500000	1.150.000	27,39	227,3 [Twh]	7591
Company O	Electricity	Technical manager	< 5	Mixed (30% public share)	970	50	19,40	0,005 [Twh]	1
Company P	Electricity	Commercial employee	<5	Mixed (25% public share)	310	14	22,14	0,013 [Twh]	<1,5
Company Q	Electricity	Responsible for Electricity Works	1.500	Mixed (52% public share)	1000000	20.000	50,00	13,23 [Twh]	600
Company R	Electricity	Responsible for the electricity grid operations	295	Mixed (85% public share)	310000	12000	25,83	2,5 [Twh]	53

* Density of the population served = Number of served users / Kilometers of network

To gather information the study followed these steps:

- We established a relationship with one of the senior managers from the selected firm.
- We used a semi-structured replicable guide to collect data, with a set of questions related to relevant constructs in our reference framework. The items investigated were measured on two Likert scales of 1-7 or 1-5,

depending on the question (with lower numbers representing “strong or totally disagree” and higher ones “strongly or totally agree”).

- Secondary information was company documentations and archival records, collected from different sources.

Data and information gathered through case studies were manipulated before their analysis.

5. Results and discussion

5.1. Service quality and performance standards change in Italian water and electricity sectors

Beginning from the year 2000 a number of EU countries, Italy too, adopted regulatory instruments that relates a company’s revenues to its performance in terms of quality: rewards and penalties scheme. Rewards/penalties schemes refer to the average level of quality, rather than to the quality level received by the individual consumer.

In the 2015, after long time compared by the electricity sector, the Authority for Electricity, Gas and the Water System approves the Integrated Text for the regulation of the contractual quality of the water system, which introduces specific quality standards, referred to the individual services provided to users, automatic compensation to be paid to users, while for general quality standards, referred to the whole of services, a penalty mechanism.

5.2. Performance standards change and organizational variables

Looking at the sample of the firms in the whole (i.e., averaging the answers of all the companies), as shown in Table 1, the response of the organizations to the new standards is mainly in terms of resources and the performance management systems, while it seems that the new higher standards have averagely less impact in terms of organizational structure.

In terms of resources, the findings indicate that to improve performance and to be compliant with the new standards, the companies invest in IT system/ informatic processes, new equipment for staff people and personnel training programs, while they less hire new employees or staff people and develop new investment plans.

In terms of PMS, the findings suggest that the companies involved in our study have registered an improvement and a diffusion of the PMS, with the adoption of incentive mechanisms that recognize premiums in case of achievement of the objectives and that consider any external factors (beyond the management control) that may undermine their achievement (Capaldo et al., 2018).

Table 1. Evidence of organizational variables affected by the new performance standards

Factors / Constructs	Item	Questionnaire Items	Mean	Std	Likert scale
Resources	New employees or staff people hired	With reference to the situation post-standard-adoption, new employees or staff people have been hired (or made available)	2,0625	0,854	5
	New personnel training programs developed	With reference to the situation post-standard-adoption, new training programs have been developed for personnel	3	1,265	5
	New equipment for staff people	With reference to the situation post standard adoption, new equipments have been provided to employees or staff people	3,3125	1,401	5
	Development of investment plans	With reference to the situation post-standard-adoption, new plans of investments have been developed	4,0625	1,482	7
	Implementation of IT system/informatic process	With reference to the situation post-standard-adoption, a new IT system or new informatic processes have been implemented	4,6875	1,957	7
Hierarchy of authority	Hierarchy levels between Top Management and lower level	With reference to the situation post-standard-adoption, the number of hierarchy levels between the top management and the lower level with power of budget / expenditure has increased	1,4375	1,031	5
	Managers reporting to the top management	With reference to the situation post-standard-adoption, the number of managers reporting to the top management has increased	1,625	1,628	5
	Strategic decisions made by the Chief Executive	Strategic decisions for our service are made by the Chief Executive more than before the new standard adoption	2,5625	1,861	5
	Strategic decisions made by the Corporate Management Team	Strategic decisions for our service are made by the Corporate Management team more than before the new standard adoption	1,125	0,342	5
Participation in decision-making	Maximum level of expenditure/investment on which the Corporate Management Team decides autonomously	With reference to the situation post-standard-adoption, the maximum level of expenditure/investment on which the Corporate Management Team decides autonomously has increased	1	0,000	5
	Level of involvement of lower levels in the strategy process of problem identification	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of problem identification	2,4375	2,097	5
	Level of involvement of lower levels in the strategy process of problem solving	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of problem solving	2,3125	2,120	5
	Level of involvement of lower levels in the strategy process of goals definition	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of goals definition	2,375	1,893	5
	Level of involvement of lower levels in the strategy process of results analysis	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of results analysis	2,3125	1,815	5
Performance management system	New standards affect the Management-by-objective	With reference to the situation post-standard-adoption, the new standards affect the Management-by-objective	4,5	1,549	7
	Adoption of performance management system	With reference to the situation post-standard-adoption, the adoption of performance management system has increased	4,5	1,751	7
	Incentives mechanisms based on goals achievement	With reference to the situation post-standard-adoption, incentives mechanisms are based on goals achievement have been introduced	4,6875	1,887	7
	External factors affecting the goal achievement	With reference to the situation post-standard-adoption, performance measurement systems take into account external factors that may affect the goal achievement	4	1,461	7

5.3. Performance standards change and organizational variables: the effect of contextual factors

In order to understand if and how contextual factors affect the response of the organizations to the new performance standards imposed by the regulators, we analyze the responses of the firms in relation to some contextual variables.

The empirical analysis reveals that the organization response to the new standards fixed by law is pursued in clusters by firms.

A first differentiation is between the cluster of firms operating in the water sector versus the one operating in the electricity sector.

The firms operating in the water sector register an organizational change in terms of resources investment and PMS improvement after the new standard adoption that is averagely higher than the one registered by the firms operating in the electricity sector, as shown in Table 2.

Table 2. The effect of firm's sector on organization response to the new standard adoption

Factors / Constructs	Item	Questionnaire Items	Water		Electricity	
			Mean	Std	Mean	Std
Resources	New employees or staff people hired	With reference to the situation post-standard-adoption, new employees or staff people have been hired (or made available)	2,273	0,7862	1,600	0,894
	New personnel training programs developed	With reference to the situation post-standard-adoption, new training programs have been developed for personnel	3,273	1,2721	2,400	1,140
	New equipment for staff people	With reference to the situation post standard adoption, new equipments have been provided to employees or staff people	3,636	1,2863	2,600	1,517
	Development of investment plans	With reference to the situation post-standard-adoption, new plans of investments have been developed	4,273	1,4894	3,600	1,517
	Implementation of IT system/informatic process	With reference to the situation post-standard-adoption, a new IT system or new informatic processes have been implemented	5,000	1,8974	4,000	2,121
Hierarchy of authority	Hierarchy levels between Top Management and lower level	With reference to the situation post-standard-adoption, the number of hierarchy levels between the top management and the lower level with power of budget / expenditure has increased	1,000	0,0000	2,400	1,517
	Managers reporting to the top management	With reference to the situation post-standard-adoption, the number of managers reporting to the top management has increased	1,000	0,0000	3,000	2,550
	Strategic decisions made by the Chief Executive	Strategic decisions for our service are made by the Chief Executive more than before the new standard adoption	1,636	1,4334	4,600	0,548
	Strategic decisions made by the Corporate Management Team	Strategic decisions for our service are made by the Corporate Management team more than before the new standard adoption	1,000	0,0000	1,400	0,548
Participation in decision-making	Maximum level of expenditure/investment on which the Corporate Management Team decides autonomously	With reference to the situation post-standard-adoption, the maximum level of expenditure/investment on which the Corporate Management Team decides autonomously has increased	1,000	0,0000	1,000	0,000
	Level of involvement of lower levels in the strategy process of problem identification	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of problem identification	1,455	1,2136	4,600	2,074
	Level of involvement of lower levels in the strategy process of problem solving	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of problem solving	1,273	0,9045	4,600	2,302
	Level of involvement of lower levels in the strategy process of goals definition	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of goals definition	1,636	1,4334	4,000	1,871
	Level of involvement of lower levels in the strategy process of results analysis	With reference to the post-standard-adoption, lower levels are more involved in the strategy process of results analysis	1,545	1,2136	4,000	1,871
Performance management system	New standards affect the Management-by-objective	With reference to the situation post-standard-adoption, the new standards affect the Management-by-objective	5,000	1,3416	3,400	1,517
	Adoption of performance management system	With reference to the situation post-standard-adoption, the adoption of performance management system has increased	4,909	1,7003	3,600	1,673
	Incentives mechanisms based on goals achievement	With reference to the situation post-standard-adoption, incentives mechanisms are based on goals achievement have been introduced	5,545	1,2136	2,800	1,789
	External factors affecting the goal achievement	With reference to the situation post-standard-adoption, performance measurement systems take into account external factors that may affect the goal achievement	4,273	1,4206	3,400	1,517

Contrarily, the firms operating in the electricity sector show a significant response of the organization to the new standards adoption in terms of organizational structure (either participation in decision making or the hierarchy of authority). As shown in Figure 2, Companies N, O, Q, and R operating in the electricity sector register the higher impact in terms of organizational structure.

Figure 2. The impact of new standards adoption on the organizational structure

A second differentiation of the firm's reaction to the new standard adoption is between companies with a lower number of employees and those with a higher number of employees. The first cluster of firms has an heterogenous response in terms of resources and PMS (in some cases the impact is high, while in other is not significant). The second cluster of firms (with a higher number of employee) highlights a significant impact of the new standards on the organization, either in terms of resources or in terms of PMS.

The same comes out by grouping the firms based on potential coachmen area (measured by the kilometers of network served by the company).

Figure 3. The effect of firm's size (number of employees) on organization response to the new standard adoption

Another difference that can be grasped in the response of companies to the new standards adoption is between fully public companies and mixed enterprises, with public-private participation. While the public companies show a heterogenous behavior in terms of resources and PMS, the companies characterized by a significant private share of

ownership (higher than 50%) register a higher change in their organizations, in terms of resources and PMS.

Figure 4. The effect of share ownership structure on the organization response to the new standards adoption

Finally, the analysis of the firms' responses show that it is not possible clustering firms based on the number of served users or kilometers of network; rather, it is possible to group firms on the basis of the density of the population served. In particular, the firms with lower density of the population served seem to record on average a higher impact of the new standards on the organization in terms of resources and PMS.

Figure 5. The effect of the density of the population served on the organization response to the new standards adoption

6. Conclusion

The theoretical and empirical evidence that the regulation of public service price often reduces a company's incentives to deliver efficient levels of service quality forced the regulator to intervene by setting minimum quality standards (MQS), namely, minimum level of service quality that the company is expected deliver to its customers.

This paper looks into the problem by exploring the interplay between performance standards, organizational variables and contextual factors through an empirical analysis carried out on 15 public service providers in Italian water and electricity sectors.

The results of the empirical investigation indicate organizational variables mainly affected by higher performance standards imposed by the regulation are resources and performance management systems.

The results also reveal the existence of clusters of firms: the firms operating in the water sector are affected by the new performance standards mainly in terms of resources and PMS, while the firms operating in the energy sector react to the new standard adoption mainly through a change in the hierarchy of authority and participation to the decision making, rather than in terms of resources and PMS.

Another cluster of firms that can be identified is the group of firms with a higher number of employees and the higher potential coachmen area (measured by the kilometers of network served by the company) which shows a significant impact of the new standards on the organization, either in terms of resources or in terms of PMS.

Companies with a significant private share of ownership (higher than 50%) register a uniform change in their organizations to respond to the new standards adoption, in terms of higher resources and improved PMS, while the public companies do not seem characterized by an homogeneous behaviour.

Finally, the firms with lower density of the population served seem to record on average a higher impact of the new standards on the organization in terms of resources and PMS.

Although the results of the study cannot be understood in the statistical sense and, consequently the results cannot yet be generalised to companies of every origin, we believe they hold valuable implications for both practitioners and academics.

The practical contribution of the paper is twofold. On the one hand, it makes the regulator aware that the achievement of high performances in the public service in order to be compliant with the new standards entails a change in the organizations of service providers, not so much in terms of organizational structure as in terms of the required resources and the design of the PMS. On the other hand, it gives a number of examples about how a sample of firms has responded to the introduction of the new standards and how such response is affected by contextual factors.

The paper contributes also to the research. It adds to our understanding of the effect of higher performances on the organization of firms because it is the first contribution, to our best knowledge, that analyses how the public sectors organizations reacts to the regulation imposing performance standards and how contextual factors may affect such organization response to new performance standards.

Despite the important contributions, the study has some methodological limitations. Because of the adopted research methodology, results cannot be statically generalized. Even though the validity and reliability of the results are ensured by the cross-case, explanation-building and patter-matching analyses, the study does not consider other contextual factors that might influence the response of the organization of public sector providers to higher performance standards imposed by the regulator for the public service

quality. Further research could be devoted to investigating the effect of other contextual factors on the reaction of organizations to higher standards.

The Relationship between the Project Management Competences and the Project Success – the Case of a Central European Oil Company

Viktória Horváth

Department of Strategy and Project Management
Corvinus University of Budapest
H-1093 Budapest, Fővám sq. 8.

Abstract

Based on the biggest project management professional association, the Project Management Institute's report (2013), the oil and gas sector considered to be one out of the seven project intensive industries besides manufacturing, business services, finance and insurance, information services, construction and utilities. Out of the three segments of the oil industry (upstream, midstream and downstream), the upstream possess the biggest complexity level regarding the size and the novelty level of the projects.

The purpose of this academic research paper is to assess the project management competencies of the different participants being involved into the project-related processes (project managers, their line managers and the staff of the project management office (PMO) in the upstream segment and to analyse the relationship between these competences and the different criteria of the project success. Bearing in mind this aim, the paper focuses on the following research questions:

- *How does the project management competence contribute to the different criteria of the project success, i.e. (a) the project triangle, (b) client satisfaction, and (c) the stakeholder satisfaction?*
- *How could the organisational context influence the project management competencies' contribution to the project success?*

Görög's (2013) hierarchical project success criteria model and the main project management competency models (e.g. Crawford, 2005) provide the theoretical background of this paper. The 4th edition of the Individual Competence Baseline for Project, Programme & Portfolio Management issued by International Project Management Association (2015) also served as a basis to assess the project management competencies of the interviewees.

Previous academic papers were not focusing on the link between the different criteria of the project success and project management competencies. In this research organisational barriers were also highlighted, which contributed to the realization of the project management competencies. They have strong impact on the actual workplace performance, thus they could block the competencies contribution to the successful completion of the projects.

Understanding the relationship between the project management competencies and the different project success criteria could contribute to the further development of the professional workplace performance of the project managers.

Keywords – project management, project management competence, project success, hierarchical success criteria

Paper: Academic Research Paper

1 Introduction

Project management is considered to be one of the most complex professions nowadays, and project related jobs could be found in almost every sector of the global economy. Organisations operating in the so-called project intensive industries should focus on the improvement of their project management performance to stay competitive and relevant in this business environment. The purpose of this academic research paper is to assess the project management competencies of the different participants being involved into the project-related processes (project managers, their line managers and the staff of the project management office, PMO) in the upstream sector of the industry and analyse the relationship between these competences and the different criteria of the project success.

Bearing this aim in mind, the paper focuses on the following research questions:

- *How does the project management competence contribute to the different criteria of the project success, i.e. (a) the project triangle, (b) client satisfaction, and (c) the stakeholder satisfaction?*
- *How could the organisational context influence the project management competencies' contribution to the project success?*

2 Literature review

2.1. Evolution of the project success criteria models

The development of the project management profession came along with the evolution of the project success determinants. The classical triple constraint model measured project success against the classical project triangle; cost, time and quality (Pinto, 2016). Later models distinguished more criteria. Shenhar *et al.* (2001) identified four dimensions of project success; (1) the first dimension was “Project efficiency”, which measured the projects against the budget and the time constraints, (2) the second was the “Impact on the Customer”, which tested how the project result meets the customer needs. (3) “Business success” serves as the third criterion, which evaluated the commercial profitability of the project. The final dimension (4) “Preparing for the future” measured the project’s impacts on the future market development or the level of technical innovation. Atkinson (1999) also created a four criteria model, in which he not only measured the project success against the (1) the classical triangle, but also against (2) the maintainability, reliability and quality of the IT system and against (3) the organisational and (4) the stakeholder benefits. The organisational benefit criterion evaluates the project

based on the efficiency, effectiveness, profit rate of the company, and how much the strategic goals were achieved by the implementation of the project. Stakeholder benefit criterion considers the satisfaction of the internal (project team) and the external stakeholders (users, social and natural environment, suppliers, etc.).

Görög's (2008) project success approach integrates the most important elements of the previously mentioned theories into a hierarchical model. The three success criteria of his model are as follows:

- project triangle,
- client satisfaction (which is the level of alignment with the organisational strategy and how the project could reach the organisational goals),
- and the stakeholder satisfaction.

Source: Görög (2013)

Figure 1. Hierarchical criteria model of project success

One of the biggest advantages of this model is that it evaluates the project success against efficiency aspects (basically the first criterion level), as well against effectiveness aspects (basically the second and third level). There is a chance to prioritise the criteria, although Lindahl and Rehn (2007) say that the upper levels in hierarchical models can be achieved, even if the project is not completed on time and to budget, so this model is really flexible in success evaluation.

2.2. Project management competency

One of most well-known project management competency approach is Crawford's (2005) integrated project management competency model. In this model the author integrates two general competency approaches; the attribute base inference of competence and the performance based inference of competence. The project management competency can be broken down into three main components; (a) the input competencies - knowledge and skills – which are also called surface competencies (Spencer & Spencer, 1993), (b) the personal competencies – motives, traits, self-concept - (Spencer & Spencer, 1993) or attitudes, personality traits, behaviours (Heywood et al., 1992), and (c) output competencies, which are measuring the demonstrable performance of the project

managers. Görög (2013) distinguishes the project manager's competencies from the project management competencies. He consider the first term as broader which includes not only all elements of the project management competency, but also the personal features and the leadership style of the project managers.

This models are focusing mainly on the different levels of the competence. The other dimension in which project management competence could be interpreted is the content aspect. El-Sabaa (2001) distinguishes three different areas of project management competency; (1) the human skills, (2) the conceptual and organisational skills and (3) the technical skills. These three main competence areas can further broken down into competence elements. The human competency area involves those competency elements which are inevitable to manage the project team and the stakeholders, the technical competencies are focusing on the classical project management tools and techniques, while the conceptual and organisational competencies are focusing on the industrial, economical and organisational context of the project. This areas could be identified in case of the most important project management competency standards as well:

- *Project Manager Competency Development Framework (PMI, 2007)* – Performance and Personal competence areas
- *Individual Competence Baseline for Project, Programme & Portfolio Management (IPMA, 2015)* – Perspective, People and Practice competence areas
- *APM Competence Framework (APM, 2015)* – contextual, technical and behavioural.

3 Empirical research

3.1 Research methodology

Considering the research questions the use of explorative research and the mixed research methodology was selected (Creswell & Clark, 2006). The research was divided into four steps: (1) preparation phase, (2) data collection and triangulation and (3) analysis and (4) evaluation.

In the *preparatory phase* several *explorative interviews* were made with the head of the company group's upstream project management office. He was the *gatekeeper* and also main contact of the researcher during this research. These interviews and the documents which were available for the researcher about the company group's organisational structure, processes, KPI system, competency development program, helped a lot to understand the operation of this special business sector and streamline the research aims and the research questions. After these meetings a *workshop* was organised for the project managers working in the upstream sector of the selected company group. During this workshop, a section was devoted to the research, which had a multifaceted aim: (a) on one hand, it highlighted the importance of the research for company group's management and for those people who were planned to be involved into the research. The researcher and the research itself was officially introduced during this event. The whole

population (all project managers of the company group) were present here. In case of an explorative research focusing on an especially sensitive topic (like the competencies) creating trust can be crucial in a situation like that. (b) On the other hand, the workshop aimed to collect general information about the population and the organisation group. In the preparatory phase the *competency self-assessment questionnaire* was also tested. This questionnaire was based on the 4th edition of the Individual Competence Baseline. The International Project Management Association's newest project management competency standard was issued in 2015. It was selected as a source of the self-assessment because it was the newest and the most complex competency system including three competency areas (Perspective, People, Practice) and which could be broken down into 28 individual competency elements. The tests served as an input for determining the length of the assessment and finalizing the English text. The assessment was conducted in English and based on the feedbacks it was decided that the researcher will be present during the whole assessment process (in person or via Skype). *Test interviews* with project managers, who were not involved into the research were also conducted, which also helped to determine the length of the interviews and the in the finalization of the interview questions.

In the *data collection and triangulation phase* included three main elements: a multilevel competency self-assessment and the semi-structured interviews with the project managers and the document analysis. Triangulation plays an important role in a qualitative research. It contributed to the information validation (Denzin 1978, 1988; Bowen, 2009; Cohen & Manion, 2000; Altrichter et al. 2008; Szokolszky, 2004). Both data and methodology triangulation was conducted. Interviews were conducted with the line managers of the project managers when they also evaluated the project managers' competencies.

The self-assessment was *analysed* based on the KPIs (key performance indicators) and measurements of the IPMA's ICB v.4. The semi-structured interviews were evaluated based on Görög's (2016) level of agreement methodology.

Before the final *evaluation* research outcomes need to be corroborated (Plutchik, R., 1983; Putnam, H. 1991), in order to achieve reliable generalization of the research results. A closing workshop was organised where the participants had the chance to give feedback to the first results of the research. Based on the feedbacks the final results were refined and finalized.

3.2 The selected company group and the research sample

The oil and gas industry is one of the classical project-intensive industries, which were defined by *Project Management Institute* (2013). The most important feature of these sectors that a broad spectrum of projects could be found in them and a significant percentage of the operation of the companies is implemented by projects.

The operation of the oil and gas industry could be divided into three sectors: upstream (E&P – exploration and production), midstream and downstream. Upstream deals with the exploration and the production of the hydrocarbon products, midstream mainly focuses on the transportation, storage and wholesale of the raw materials and refined

hydrocarbon products, while the downstream is focusing on the refinery process and the marketing and the retail of the final products (Csiszárík-Kocsir, 2015).

The research was conducted at a multinational company group, which was founded in Hungary. The company group's present in more than 30 countries and it has more than 26 000 employees. The group headquarter and those subsidiaries were involved into the research who have an active E&P activity and where actual production is also happening. Altogether seven companies were selected based on this criterion. In these companies the number project managers was 96. Altogether 25 project managers were involved into the research, which forms part 25,5 % of the whole population.

Table 1. Companies involved into the research

Company	Region
Group (headquarter)	Global
Subsidiary 1.	CEE – Hungary
Subsidiary 2.	CEE - Croatia (Egypt, Angola)
Subsidiary 3.	North Sea, UK
Subsidiary 4.	Middle East, Pakistan
Subsidiary 5.	Russia
Subsidiary 6.	Iraq

The following table provides an overview about the most important features of the project managers who were selected at random from the population.

Table 2. Sample

Average age	38,24 years	
Average project management experience	5,8 years	
Gender	Female	5 (20%)
	Male	20 (80%)
Qualification	Geologist	7 (28%)
	Geophysicist	1 (4%)
	Economist	5 (20%)
	Engineer	12 (48%)
	Hungarian	18 (72%)
Nationality	Yemeni	1 (4%)
	Pakistani	4 (16%)
	Polish	1 (4%)
	Croat	1 (4%)
Having any project management qualification (E.g. PMP, IPMA, postgraduate PM diploma etc.)		4 (16%)

4 Research results

4.1 Project success criteria and the project management competencies

This question was analysed from multiple perspectives. Based on the analysis of the documentation of the closed projects and from the interview feedbacks, it could be seen that the success of the project was mainly measured against the project triangle (92% percentage of the respondents mentioned). The client satisfaction, namely the projects

contribution to the fulfilment of the original strategic objective was not considered within the company, neither the satisfaction of the stakeholders. The project success is evaluated mainly based on the efficiency and not based on the effectiveness of the project. Even though project managers ranked people competence area as the most important, which was followed by practice and finally by the perspective competence area. The research also focused on the competency self-assessment of the project managers. They current competency level was the highest in the people competencies and the biggest lack was identified regarding the perspective competencies. Even though they confirmed that they intend to improve the people competencies the most, than the practice and they are focusing on the improvement of the perspective competencies the least.

Project managers were asked to evaluate the competence areas and elements contribution to the different project success criteria. A strong relationship was identified between the different competence areas and the success criteria. Based on the answers of the project managers 11 out of 13 practice competency element were contributing mainly to the primary project objectives, namely to the project triangle. Only the stakeholder management competency elements was matched with the stakeholder satisfaction project success criterion and the requirements and objectives competency element contributes to the client satisfaction. So the classical project management “hard skills” are contributing to the efficiency of the project.

All five perspective elements are contributing to the client satisfaction which success criterion measures the strategic alignment of the project.

7 out of 10 people competency elements were primarily mentioned at the stakeholder satisfaction success criterion. Only resourcefulness and self-reflection and self-management were contributing of the client satisfaction. Results orientation was the only people competency element which contributed to the project triangle. Table 3. introduces the results of the research.

Table 3. Competency elements and areas contribution to the project success criteria

SUCCESS CRITERIA	COMPETENCY ELEMENTS
Stakeholder satisfaction	Personal integrity and reliability (<i>People competency area</i>)
	Personal communication (<i>People competency area</i>)
	Relationships and engagement (<i>People competency area</i>)
	Leadership (<i>People competency area</i>)
	Teamwork (<i>People competency area</i>)
	Conflict and crisis (<i>People competency area</i>)
	Negotiation (<i>People competency area</i>)
	Stakeholders (<i>Practice competency area</i>)
Client satisfaction	Strategy (<i>Perspective competency area</i>)
	Governance, structure and processes (<i>Perspective competency area</i>)
	Power and interest (<i>Perspective competency area</i>)
	Culture and values (<i>Perspective competency area</i>)
	Compliance, standards and regulations (<i>Perspective competency area</i>)
	Resourcefulness (<i>People competency area</i>)
	Self-reflection and self-management (<i>People competency area</i>)
	Requirements and objectives (<i>Practice competency area</i>)
Project triangle	Project design (<i>Practice competency area</i>)
	Time (<i>Practice competency area</i>)
	Scope (<i>Practice competency area</i>)

	Quality (<i>Practice competency area</i>)
	Finance (<i>Practice competency area</i>)
	Resources (<i>Practice competency area</i>)
	Procurement (<i>Practice competency area</i>)
	Plan and control (<i>Practice competency area</i>)
	Risks and opportunities (<i>Practice competency area</i>)
	Change and transformation (<i>Practice competency area</i>)
	Results orientation (<i>People competency area</i>)

4.2 Organisational context and its effect on the project success

During the interviews the project managers highlighted a new aspect of the research field. According to their answers, the source of the project failure was not the lack of the project management competency in many cases, but it was an organisational constraint. Based on the feedbacks, four different organisational blocks were identified, which have a huge impact on the project performance and through that on the success of the projects as well. The most often mentioned constraints deriving from the organisational context are as follows: the weak authority of the project manager in the project organisational arrangement, the scarcity of the key resources in the project, the lack of integrated project control systems and the constantly changing organisational context. These organisational constraints are blocking certain competencies' effective contribution to the project success. Table 3. introduces the identified organisational constraints and the project management competencies on which they have the biggest effect on.

Table 4. The identified organisational constraints and their effect on the project management competencies

ORGANISATIONAL CONSTRAINT	PROJECT MANAGEMENT COMPETENCY
1. The weak authority of the project manager in the project organisational arrangement	LEADERSHIP (<i>People competency area</i>)
2. Scarcity of the key resources in the project	RESOURCES (<i>Practice competency area</i>)
3. Lack of integrated project control systems	PLAN & CONTROL (<i>Practice competency area</i>)
4. Constantly changing organisational context	GOVERNANCE, STRUCTURE & PROCESSES (<i>Perspective competency area</i>)

Projects were implemented most commonly in a weak matrix project organisational arrangement within the companies. In this project organisational arrangement the project manager has no line authority over the project team, so some classical tools of the leadership (*People competency area*), e.g. the task delegation, could be applied only in a limited way. It turned out that other competencies of the project manager could partly compensate this effect: personal communication (*People competency area*), negotiation (*People competency area*) and teamwork (*People competency area*) was mentioned most commonly.

Within the upstream sector there is a huge scarcity of certain human resources, especially certain field experts. Even if the project managers possess effective resource management competencies, the number of projects (the need for the special expertise) is

not in line with the demand. In these cases other competencies could contribute to the successful completion of the projects, and could “compensate” this situation, based on the feedbacks of the project managers, these are: relationship and engagement (*People competency area*), power and interest (*Perspective competency area*) and stakeholder management competency (*Practice competency area*).

Observing the actual project performance and compare it with the actual project plans is one of the most important part of the project implementation phase (*Görög and Smith, 1999*). During process control the project managers often suffered from the lack of integration between the companies’ ERP systems and the project management systems. At the company group the inputs for the project control reports were derived from the SAP system. Unfortunately, the project managers had no direct access to this system, so the data was provided by the financial department. The frequency of the data collection was not adjusted to the needs of the project but it was standardised and was available once in a month. *Görög (2013)* suggests the following regarding the frequency of the data collection in case of normal or long projects:

- *On a daily basis:* All the short time but critical activities (where the total float time of the activity is 0).
- *On a weekly basis:* All the critical activities. All those long time but non-critical activities (where the total float time of the activity is bigger than 0). that consume costly resources.
- *On a monthly basis:* All the project activities.

This could not be managed in this organisational environment, because the project managers are depending on the financial department’s monthly reports about the actual project spending. This blocks the effectiveness of the plan and control (*Practice competency area*) competency, so there other competencies, time (*Practice competency area*), finance (*Practice competency area*), and change and transformation (*Practice competency area*) could compensate the effect of it.

The organisational structure within the investigated companies are constantly changing. The organisational chart (structure) is changed frequently, the rules and regulations and the internal organisational processes also. This phenomenon has a negative effect on the governance, structure and processes (*Perspective competency*). Project managers are facing serious problems because of the changing processes, documentation, reporting etc. Those ones, who have strong competencies in requirements and objectives (*Practice competency*), change and transformation (*Practice competency*) and Compliance, standards and regulations (*Perspective competency*).

5 Conclusions

The research highlighted that the companies, which were involved into this research, are evaluating their projects mainly based on the classical project triangle even today and the other success criteria are not well-known in the given organisational context. Even though the project managers rank the human competencies to the first place over the classical technical competencies which focus on the classical project management tools

and techniques. The perspective competency area is the most underrated area, although these competencies are measuring the strategic alignment of the project.

Applying a multidimensional and hierarchical project success evaluation system could contribute to a much more detailed project success evaluation, in which the projects' strategic alignment and also the stakeholder satisfaction would be tested.

The research identified a relationship amongst the project success criteria and the different project management competency areas. This information could serve as an important input for the future competency development programs of the company group. The research also identified four organisational constraints which could block the project management competencies' contribution to the project success. The company should consider these constraints before planning the upcoming competency development programs, because in certain cases not the lack of the competence but these constraints are responsible for the project failure.

Highlighting the relationships between the project management competencies and the project success could increase the success rate within the organisations and can contribute to a better understanding of the complex nature of the project success.

Abstract

Due to accelerated structural changes in the city administration of Dresden, a new administrative center is planned for several thousands of employees. In the framework of a scientific collaboration, inter alia we researched and evaluated demands of future city administrations by way of a participative workshop-series in order to inquire the employee's and organisation's implicit knowledge as an information basis for decision making in the subsequent architectural design works.

In a series of workshops with representatives of the departments that will potentially move into the planned new building, explicit and implicit knowledge of the knowledge bearers was collected in various formats. The structure and content of the workshops was developed according to the Backcasting Method, which anticipates long-term objectives (framework specifications of the city administration and the project manager) and therefrom derives measures for achieving them. By analyzing the existing structures in the departments, discussing with the employees and validating their statements and needs made through the evaluation of references and the co-creative development of concept models, a catalogue of spatial needs was created.

By use of this preliminary planning-process we were able to set a scientific foundation for subsequent design-and-development processes for architects, civil engineers, and interior designers of the envisioned public construction project. The bottom-up-approach will ensure a sustainable design for organisational and spatial issues for the municipality by purposefully using the implicit knowledge of the prospective users. The collected data give intelligence about future office development and about specific interlinkages of the departments in regards to communication, working methods, operations and future consolidations.

The catalogue of spatial needs will be part of the architectural tender process for the “New Administration Centre” of Dresden 2019, which will be carried out in the format of a “Competitive Dialogue” between architectural offices and the city administration Dresden.

Keywords – cooperative creation workshop, knowledge based participation, future city administration, working environments, case study.

Paper type – Academic Research Paper.

1 Introduction: An architectural-administrative framework

One of the contemporary organisational challenges is the growing complexity and dynamics of organizations in private, non-profit and public sectors (Farazmand, 2002). At the same time, constantly changing constellations of actors and processes offer new change for strengthening the exchange of knowledge and information (Allen et al., 2007). Due to accelerated structural, organizational, cultural and technological changes in the city administration of Dresden, a new administrative center is planned to relocate a large amount of employees into a appropriate, contemporary work environment. Therefore, the city administration has set up two phases of demand planning that should explicitly involve the employees. Phase 1 consisted of an online survey conducted by an external consulting company. In the Phase 2, the TU Dresden WISSENSARCHITEKTUR Laboratory of Knowledge Architecture was commissioned to establish targeted and more profound requirements. Contractor for the scientific cooperation was the Construction and Property Management Office of the city administration. The content-related objective of the approach was to derive needs in terms of work processes and work contents through employee surveys, and to translate them into architectural design requirements – separately for each department, and also for the administration as a whole.

In the framework of a scientific collaboration, inter alia we evaluated demands regarding business operations of the employees in a series of participative workshops from May until November 2018 with the aim to transform the organisation's and employees' implicit knowledge into a data basis for architectural decision making. In this exploration, 13 of 36 departments of the city administration of Dresden were addressed. The preselection of the departments was made by the department of Construction and Property Management Office and can roughly be subdivided into the subsections of social departments and constructional departments. Upon the results of this study, a public tender was launched in April 2019 in the format of a "Competitive Dialogue" for general contractors (urban planners, architects and civil engineers).

2 Challenges of a future city administration

Due to cultural and technological changes, not only society and economy but also public administrations are facing new challenges. In order to outline the challenges as

well as internal and external factors that will influence the work environment of the New Administration Centre of Dresden, the so-called Backcasting Method was selected as a conceptual framework (Quist, 2008). This method appears feasible in this context, as on the one hand, changes in administration are subject to external conditions while, on the other hand, they bring along organizational, procedural, cultural, spatial and technological challenges on the side of the planners and end users of the new building. This case study will focus on a) organizational-processual, b) cultural and c) spatial challenges.

The planning project was subject to external conditions, which had to be taken into account in the overall design of the workshops to be carried out with the administration employees. First, the number of employees who were to move into the new building was set at 1,600. Second, there was a budget of 160 million Euros. Third, the size and shape of available construction space in the city center was determined by the Urban Planning Office.

A) **Organizational challenges** of future administrations partly are linked to their basic structure as defined by their organizational chart. In the case of Dresden, the chart is divided into seven “Business Areas” that cover specific topics. The business areas are divided into departments, each of which can be regarded a closed knowledge ecosystem. This ecosystem can be initially determined by knowledge exploration as baseline of the system (Valkokari, 2015). As it turned out, thematically close departments are often not co-located in the same place in the city. Here, organizational and spatial challenges overlap. Spatial distance prevents frequent, direct and informal exchanges between departments. Existing experiences cannot be shared and applied to similar issues in other departments. This means that every “ecosystem” has to go through its own experiences and learnings without being able to shorten the process through inter-department exchange. As is known from service-oriented global economies, flexible administrations need a knowledge-based fundament (Grodach, 2013). Another point of importance is the clarification of how flexible working time or mobile workplaces may play a role for the employees in future. Digitization has gradually driven analogue technologies out of work environments. The use of new communication media, EDP systems, etc. has created increasingly complex work processes which in turn lead away from traditional individual work, towards temporary project work in fast-changing teams, with a certain potential for new approaches and synergies in the work sphere (Booyesen et al., 2013).

B) **Cultural challenges** arise from the history of administrations, which formerly – according to the military models – were divided into stable units with clearly defined hierarchy (mayor > head of department > head of sub-department > head of subject area > employee. Hierarchies with sophisticated vertical specialization (Egeberg, 2003; Simon, 1957) establish strong control systems and coordination power, and thus influence directly the working environment (Christensen & Lægheid, 2010) as well as relationships and biases among employees. Hierarchy in administrations, for example, is reflected in the spatial layout by the provision of single offices for higher positions. In addition, the rising average age of employees will lead to critical demand for administrative staff in the next 10-30 years. Cultural differences due to age is especially significant in the

administrative context: the elder generation tends to rigid routine work, whereas the younger easily adopts new spatial concepts or technologies.

C) **Spatial challenges** may affect the new building in its overall structure and layout. Acute questions regard, for example, the need for citizen information, places for citizen participation, the arrangement of business areas or openness vs closeness of individual departments. Spatial requirements will change in connection with flexible working time. Depending on future activities and work processes of the respective departments, either project work or individual work will dominate, which in turn require suitable spatial solutions. Here, the distribution ratio between offices and meeting rooms becomes a key matter. One of the main reasons for the establishment of a central administrative complex was the current fragmentation and scattering of departments scattered throughout the city. This challenge, which reduces the accessibility for citizens as well as the exchange between departments, was taken as an opportunity for a spatial clustering of inter-related facilities at a central location in the city (Schlickewei et al., 2011).

3 Customized Workshop Design by Backcasting

Since the overall goal was defined by the client (Construction & Property Management Office) and by the project controller, the actual requirements in regards to workflow and spatial layout were investigated by way of bottom-up, participatory workshops with the end users, based on the Backcasting method (Quist & Vergrat, 2016). The client's specifications and input were based on best practices in administration buildings, such as Timmerhuis in Rotterdam or Coventry in London, which represent current paradigms such as open government for open source access, as well as citizen participation through new interaction and communication channels (Lathrop & Ruma, 2010). This was preceded by the requirement that the output of the workshops should contain a quantitative ratio between different room functionalities, e.g. individual office, open space offices, etc. for each department, based on the current and future work processes. With the collected requirements about spatial program, number of rooms, sizes, equipment etc. the public tender would be formulated in a later stage of the procedure.

In contrast to Phase 1 of the demand planning, in which middle managers were interviewed, the aim of the Backcasting workshops was to address a cross-section of employees, as broadly as possible. According to the bottom-up principle, all employees were thus equally involved to obtain an overall picture of the requirements and to address all key issues through co-creation activities. From these objectives, the necessary workshop activities were designed and packaged in groups activities for 10-20 participants.

Figure 1: Content-flow and structure of the workshop design

The resulting eight measures (Fig. 1) were distributed over three workshops per department. First of all, it was necessary to understand the organisation of the administration (1) and the activities taking place in it (2), both in a large and small scope. First conclusions could be drawn from gaps in knowledge (3), whereupon the individual departments were determined within the institutional context (4). From then on, it was necessary to find out which knowledge ecosystems, which are largely detached from one another, have common and specific needs for the future (5) in order to have them validated by the ecosystem itself (6). Based on the needs, common goals for the future were generated (7) and finally approaches for achieving the goals and their spatial design were designed by the participants (8).

In Phase 2 of the demand planning, a series of workshops was held with 13 departments of the city administration designated to move to the New Administrative Centre. Each department went through three differently designed workshops that thematically built upon each other. The workshop design was identical for all departments, yet results differed considerably in some cases. The following departments had participated (the Municipal Utility: Children's Day-Care Facilities and the Children's Day Care Office participated as one representative):

Name of department	Abbreviation	Average amount of participants
Economic Development Office	Economy	5
Central and Personal Office	Personal	16
Municipal Utility: IT Services	IT	17
Schools Administration Office	School	10
Youth Affairs Office	Youth	11
Municipal Utility: Children's Day-Care Facilities & Children's Day-Care Office	Children	11
Urban Planning Office	Urban Planning	16
Office for Geodata and Cadaster	Geodata	13
Construction Supervision Office	Construction	13
Construction and Property Management Office	Property	28
Street and Public Work Office	Street	14
Public Green and Waste Management Office	Public Green	15
Environmental Office	Environment	13

In total, approximately 180 employees of the city administration participated in each workshops round, thus giving an appropriate representation of the city administration as a whole.

4 Application of Workshop Design for Empirical Values

The design of the workshop series aimed at developing query methods for the administration's employees based on the outcomes requested by the city administration and the project managers. The Backcasting Method was used to create individual steps which, building on each other, could cover the organisational, procedural and spatial needs of the future end users.

4.1 Workshop I – Outlining a process network

In order to bring all participants up to the same level of knowledge, the workshop started with a general introduction of the project “New Administration Centre”. First, the participants were asked in an open question and answer session about the internal processes, which were presented on a customizable organisation chart. Connecting lines (strings, threads, etc.) were used to illustrate on the spot which sub-departments and subject areas are exchanged particularly frequently and importantly. Especially the areas of finance, secretariat and public relations turned out nodal points of internal processes.

4.2 Workshop I – Building a trend view of activities

In a next step, the participants were asked four questions to assess their working methods, which they responded on behalf of their department or subject area. The questions stated two opposing answers, whereupon participants had to decide whether and to what percentage they work one way or the other (for example: 100% working method a = 0% working method b / 75% working method a = 25% working method b / 50% working method a = 50% working method b). The four questions were asked as follows: Assessment 1: “In what proportion does your work connect internally or externally of your department?” Assessment 2: “In what proportion is your working time fix or flexible?” Assessment 3: “In what proportion is your work individual or project-related?” Assessment 4: “In what proportion does your daily work take place in a concentrated or communicative way?”

Further requests asked in which proportion the work was carried out 5-10 years ago, how it is carried out currently and how it should be carried out in 5-10 years. For this purpose, the participants located labeled each period on a "Rating Scale" (see *figure 2*) in order to make their assessment visible to all other participants. The resulting discussions between employees in the same subject area thus lead to better assessments in the making.

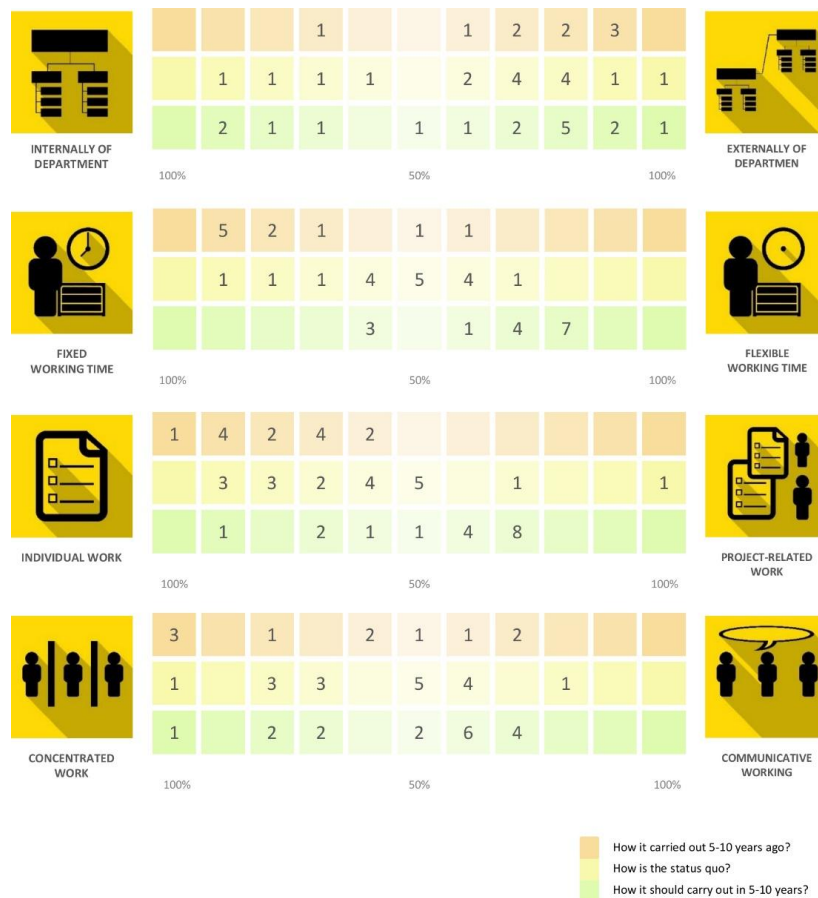

Figure 2: Example “Rating-Scale” of Urban Planning Office

The “rating-scale” of the Urban Planning Office shows by example how the results of the evaluation turned out. The numbers in the boxes mark how many participants have opted for the corresponding proposition. The red boxes indicate how the participants judge their past working method, yellow ones show the assessment of the status quo, and green ones show what the working method should look like in the future – as a potential goal to achieve in the new building. Average values were formed thereafter from the individual evaluations, which represent an overall estimate of the department. In case of the example shown above, the following average assessments are made by the representatives of the Urban Planning Office:

Average Assessments of Urban Planning Office

Assessments

- 1) Cooperation
- 2) Working Time
- 3) Activities
- 4) Working method

past (5-10 years ago)

52% internally
62% fixed
58% individual
59% concentrated

present (2018-2019)

51% internally
64% flexible
53% project related
54% communicative

future (in 5-10 years)

59% externally
76% flexible
61% project related
61% communicative

The average values of all offices were then summed up. The result is a tendency of the working methods to be translated into spatial requirements.

Average Assessments of all 13 departments

Assessments	past (5-10 years ago)	present (2018-2019)	future (in 5-10 years)
1) Cooperation	55% internally	51% internally	55% externally
2) Working Time	54% fixed	56% flexible	71% flexible
3) Activities	59% individual	51% individual	56% project related
4) Working method	56% concentrated	50:50	55% communicative

In general, it was observed that there is a desire to work more closely with other departments. This also reflects the tendency of project-related work. The communication, which is also expected to increase, makes these assumptions plausible, as there is a strong interaction between the three indicators. The greatest change can be seen in the working time or working time model. Compared to the past, this has risen to over 70%.

4.3 Workshop I – Extended demand assessment

In an open discussion with the workshop participants, questions were asked through a guided dialogue that would identify deeper needs of the employees. By using the “Programming” method, the answers were live-documented on index cards, and concerns were illustrated in real time (see Figure 3).

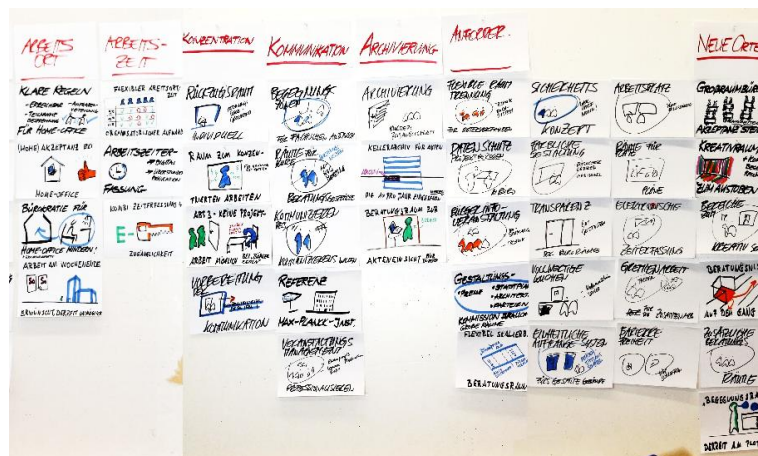

Figure 3: Output of a Programming session

The guideline divided all questions into three categories: Cross-department, Own Department and Own Workplace. Each category had sub-topics, which were asked according to the flow of conversation such as: cooperation, image of the administration, promotion of young talent, use of public areas (cross-department); cooperation, accessibility and security, processes, digitalization and electronic files, archiving and storage, visitors and citizens (own department); requirements, equipment, communication

and concentration (own working place). The evaluation and comparison of the discussion rounds of all departments served as a qualitative basis for the definition of the space required by the planned “New Administration Centre”. Approximately 90 comments, feedbacks and criticisms were documented per office, which could later be included in the architectural programme.

4.4 Workshop I – Identification of communication density

In order to determine how the departments should be located in relation to each other in the planned new building, the interfaces at which most cooperation prevails and is likely to prevail were queried. The participants filled out a survey to find out which other departments they communicate with and how often. They could choose *never*, *occasionally* or *regularly* to communicate and should rate this for the media telephone, letter/e-mail and face-to-face. In addition, a further communication medium could be added. The survey was conducted once from today's perspective, from the perspective of the past (how was it 5-10 years ago) and from the perspective of the future (what should it be like in 5-10 years). The results were brought together in a communication matrix (see figure 4).

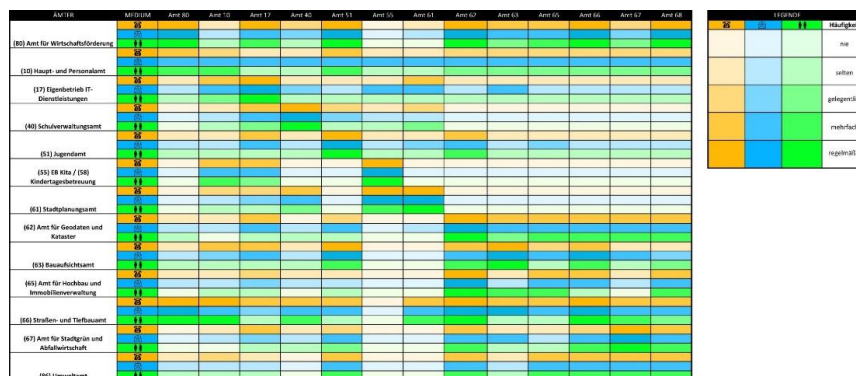

Figure 4: Communication matrix from the perspective of future demands

The yellow fields of the communication matrix stand for communication via telephone, the blue for correspondence via letter/e-mail and green for direct face-to-face exchange. The darker the fields are, the more frequently should/will communication at the corresponding interface between two offices fail in the future (5-10 years). The dark diagonal from top left to bottom right represents the internal communication, which is expected to take place regularly. It serves as a comparative value.

Compared to the communication of 5-10 years ago, the frequency of inter-department communication has generally increased today. The dense cluster of construction and environmental departments (Urban Planning, Geodata, Construction Supervision, Street and Public Work and Public Green and Waste Management) should be emphasized.

According to the workshop participants, the density of communication is expected to increase strongly over the next 5-10 years and, in addition to currently established

communication nodes, other frequently used interfaces will be added. Furthermore, it can be observed that personal conversations (face-to-face) are gaining in importance.

The following figure (see *figure 5*) shows the most important communication connections as they have been classified by the employees for the future (in 5-10 years). The figure is limited to direct communication via face-to-face. The dark connections represent the regular communication and the bright connections represent the occasional communication.

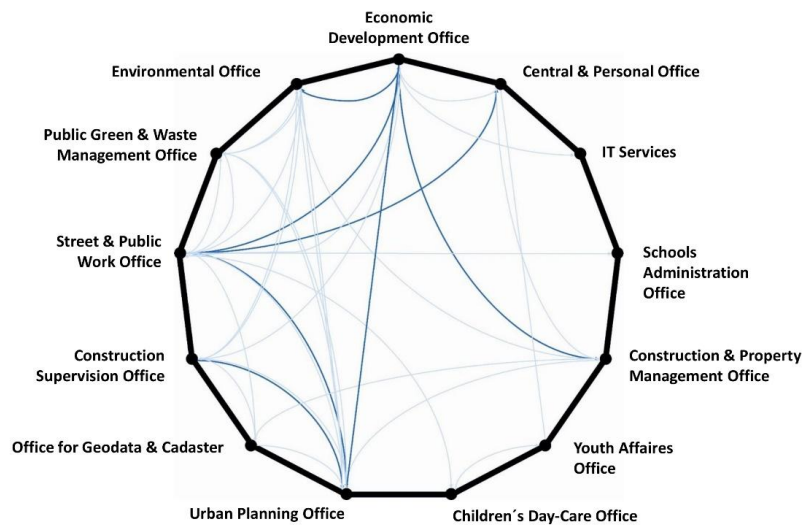

Figure 5: Tendency of expected future communication via face-to-face

Contrary to expectations, the two cross-sectional fields (Central & Personal Office and IT Services) do not provide the most regular communication to all other departments. Instead, there is a tendency for the Economic Development Office, the Urban Planning Office, the Street & Public Work Office and the Environmental Office to be the most regular providers of communication in this case.

4.5 Workshop I – Identification of Future Issues

In the last step of the first workshop, 20-30 recurring programming topics (see Chapter 4.2) were preselected. The topics with most relevance for the future operations got evaluated by the participants. Therefore, each participant was allowed to assign 5 points to one or more topics. The future related topics with the most points were integrated into the second follow-up workshop, see *figure 6* as exemplary example of voted future issues by one of the departments:

Figure 6: Exemplary future topics of a department of Dresden city administration

In this way, a total of 52 future-relevant topics were filtered out from the discussion round and get evaluated. The overall evaluation of all participating departments resulted in the following ranking and shows the most relevant needs and challenges from the perspective of the employees of the city administration:

Figure 7: Overview of future topics of all 13 participating departments

4.6 Workshop II – Validation of spatial demands

On the basis of the first workshop round, best practices of administration buildings and companies were selected for four main architectural topics: 1) reception area, 2) office, 3) meeting room and 4) social space. For each of these topics, the participants of the second round of the workshop were shown three very different references, which they were asked to evaluate. The participants were asked whether and what they liked or disliked about the a) concept, b) the function, c) the material and d) the atmosphere. The

individual comments were recorded and collected quantitatively and qualitatively, so that at the end an overall mood picture was created for each reference.

4.7 Workshop II – Develop visions to create measures

In order to describe the topic-specific requirements of employees of the city administration, visions had to be created by the workshop participants following the idea of an idea-driven knowledge ecosystem (Landry, 2008). Starting point were four topic areas, which turned out to be common denominators of all 13 departments in the first workshop: digitization, workplace, cross-office issues and adaptivity. For each department, specific sub-topics were selected for each topic area, for which the participants were asked to create visions. The topics resulted from the identification and evaluation of future topics from the first workshop (section 4.5). After describing the vision (e.g. “communication zones, public dialogue and exhibition spaces, building guidance systems for citizens”), concrete measures were lined out using the Backcasting Method. The vision was formulated as a goal and it was considered which long-term measure is necessary to achieve it (in which period, with which means, with which partners, etc.). From this, the respective initial steps could be derived, which would have to be tackled in the medium term and in the short term.

4.8 Workshop III – Co-Design for implicit knowledge request

In the first two rounds of workshops with the departments, thematic focuses were identified and organisational, procedural and spatial needs and visions were developed. In the third workshop, the resulting spatial typologies and formats were implemented by the participants alone or in groups as a built concept model and arranged in an integrative overall model. The models in their different forms and inscriptions allowed conclusions about the implicit knowledge of the knowledge carriers, which could be translated into architectural requirements. Models for the same room functions (e.g. waiting area, meeting room or creative zone) were compared and translated into spatial patterns.

5 Evaluations

In advance, it can be reported that communication within and between the individual departments is lagging behind the current needs. It could be observed that interim results were not distributed completely or at a late point in time among employees. Already the communication between planners and participants was misguided. A first publication of an architectural concept was misinterpreted by the workshop participants as a finished architectural design, which led to a need for explanation for the introduction of the first workshop. The presentation of selected reference objects to validate the architectural requirements of the employees also had to be discussed, as there was a lack of general architectural understanding and a degree of abstraction, especially for participants from departments that are not assigned to building. The understanding of terms such as

“project” and “project-related work” between the departments was also unequal and needed explanation.

The dynamically evolving departments of the city administration can be considered as closed knowledge ecosystems that live from the exchange of internal actors (Wallner & Menrad, 2011). Despite existing personnel changes between different departments, there is only a small exchange of knowledge between the individual knowledge ecosystems. On the one hand, this is due to the routine of the employees, which is based on the necessary processes, on the other hand, a direct and constant exchange is made more difficult by the geographical distance. Synergies can already be created on a small scale through the spatial proximity of departments with the same topics. One result of the Phase 2 of demand planning were proposals for the arrangement of the departments to each other. For example, it is proposed that departments that already show the same flexible working methods (see Ranking Scale status today: flexible working time and see programming: mobile workplace) be arranged in relation to each other. It is also conceivable to combine departments with similar technical backgrounds or to synchronize them by spatial proximity (e.g. Urban Planning Office, Construction Supervision Office and Street and Public Work Office).

The most frequently mentioned future topics of the participants showed a diversity of opinions on the topics of workplace and working time model between different departments. The fixed workplaces were chosen as the fourth most important topic for the future with ~40 votes, but at the same time mobile workplaces (~30 votes) and flexible workplaces (~15 votes) were also named. In addition, ~30 votes were cast in favour of flexible working time, whereas ~25 participants voted in favour of fixed working time. Spatially, the spectrum also goes in both directions, which has to be compensated by flexible, adaptable architecture in the later course of the planning project: For closed work areas such as the single office and the working space for concentration (both with ~25 voices each), open creative spaces (~35 voices) and meeting rooms (~40 voices) are opposed. This diversity is reflected in the catalogue of spatial requirements and guidelines, which was defined as a result of the workshops. Thus, depending on the statement of the departments, a percentage for concentrated and communicative work was determined and translated into architecture in the same proportion.

6 Impact & Outlook

It was found that employees were encouraged to reflect on the current working environment in terms of, for example, outdated technologies, ergonomics and lack of cooperation between departments. The architectural awareness could also be sharpened by reference buildings. In addition, within the framework of the planning project, an overview of the existing workplaces and positions available to the city administration was prepared. The results of the workshop series were brought together and compiled into a catalogue of spatial requirements and guidelines. A fact sheet was then drawn up for each office. The findings on organisational and process-related aspects of the working environment, which were queried as by-products, were iteratively integrated into the

catalogue and can be made available to the respective offices in order to analyses and, if necessary, adapt their own processes. The demand catalogue serves as a basis for the project controllers of the planning project to process the collected data. These are entered in the invitation to tender of the "Competitive Dialogue" and considerable data concerning the departments are added as an appendix. On the basis of the tender documents, the general contractor is selected who will start planning and implementing the New Administration Centre at Ferdinandplatz Dresden from 2019.

Abstract

At the present technologies have been advancing with huge steps of witch we have seen them not only in educative areas, also in the business and those are tools easy to use and they are cheaper for companies.

This has been reflected in different areas of the industry, in this research the Automotive Industry was taken.

We analysed the traditional model with the new model of the ICT application.

We use for this research a non-probabilistic sampling of conventional type, it's mixed, quantitative as qualitative, this is a consequence of technological changes as in consumer habits, for a variety of products and services with a lower cost and response time.

With this new model and the use of ICT we will have a positive result of competitiveness in the Automotive Industry area.

In the actuality technologies have grown faster, we have seen it not only in the educative area, also in the business field and those are tool easy to use and those aren't expensive for business.

This has been seen on different business areas; on this research we took the Automotive Industry.

It's important to take note about the CRM to get information about guest and we could be more competitive. It's necessary to understand the guest since the first contact, or the result of a purchase or when try to do a purchase, and more important things like to handle with complaints, and post-purchase service. (Basa, 2011)

The economy is a current environment characterized by components like the increased of competitiveness, technological innovation and the global nature of markets (Castells, 1977) We analysed different models like DEMING PRIZE, model IBEROAMERICANO of the excellence in the management (FUNDIBQ).

We used documental research, it's supported by a field research with a questionnaire, interviews, polls and observation, it's qualitative and quantitative, this is because the technological changes just as costumer habits.
With this new model and the use of ITC we will get results and could be more competitiveness on the Automotive field.

Key words: CRM, service, ITC, Competitiveness.

Paper type – Academic Research Paper

1. Introduction

The service in Automotive Industry is very important and also it's important customer satisfaction in the workshop area. It's important to listening the customers (CRM), so we could obtain a satisfactory approval in the maintenance or repair process of your unit.

Industries that don't incorporate technologies are at risk to fail, with drastic changes to stay in the market. It's important to understand who it Works ITC and their impact on real life business, companies competitiveness and workers productivities. Shutterstock. (2017).

With good use, ITC allow companies to have a bigger amount of work, with better quality on a short time.

Companies should learn to use ITC, and obtain more advantage, and try to educate their employers and customers on the right way to use them.

The American Marketing Association (AMA) acquired the concept in 1960. The Committee Definition as "Activities, benefits or satisfactions that are offers for consideration or that are provided together with the goods" This definition was refined in 1981 in the following terms "services are essentially intangible activities that can be identified in isolation, provide satisfaction and they aren't necessarily linked to sale of goods"

You have to create customer loyalty to the agency and mainly in the workshop area, so we could give confidence and consequently this will result in more units purchase. This will generate a competitive advantage towards their competitors.

Justify

It's important to integrate ICT in the workshop area, in order to provide a better service which photos of the part that needs to be repaired will be sent to you, with all the necessary information and the cost if the owner authorizes or not the repair.

The new competitiveness, with new brands and guarantee for almost 7 years, were not good for old companies, and they look for a better service on the workshop area to create more confidence with customers. We can use Whatsapp, to remind your appointment, an notification when your car is done, this can use for more personalized attention.

Other is try to train more people with ICT (tablet), train them to use tablets and recording the unit inside and outside to show to customer how it looks their unit.

2. Problem, Hypotheses and Rationale of the Study

In 2013m drastic changes took place in the Automotive Industry in which several automobile brands entered with greater technology, guarantee and proposals for the after-sale, such as service (not only to a number of kilometers) but for years. This affected some Automotive companies in the workshop area, as wall was in the purchase of new units

They came with very aggressive proposals for existing ones. This caused to the agencies to analyze and promote new strategies to continue with their clients and increase their confidence, to maintain them with their loyalty and thus attract more clients.

In which they analyzed the current ones and detected that when the car entering the workshop area they had a traditional method without the use of ICT, and this resulted in some clients abusing the service as (blows in their unit), fuel expense, damage within the unit that for some reason was omitted in the signage in document (traditional) and the client demanded a payment.

This resulted in the same customers passing the word that they didn't have 100% income control and they ware paid the damages.

Research questions.

How can ITC help at the Automotive workshop area to be more competitiveness?

Specific questions

What kind of model we can use to be in touch with the client and they could know about their car process?

Which factors are important for client loyalty to bring us their car?

Which are the reasons customers change to a new brand and new agency?

What is the reason customers come back to the Automotive agency?

General Objectives

Planning new strategies with ITC, together with the olds models to maintain customers loyalty to the brand and with the service.

Specific Objectives

Determinate which factors are importer for customers to keep their loyalty for the service.

Present a new faster, safe and reviewed model.

Base training for ITC

Analyze CRM strategies, if those are successful or fail to give a better service

Hypothesis

1. Better customer communication, more loyalty.
2. Better information and tracing about their car (e-mail, whatsapp), more reliability.
3. Better information about price for their car material, more security to pay.
4. Better post-sell service, more acceptance at the service area.

3. Literature Review

The Automotive Industry in Mexico. 2017 was full of important news for the Automotive Industry in Mexico and the rest of the world, some of them were about the beginning of the production of chine car JAC, release of the first hybrid car of KIA assembler, strikes by unions of workers of ship-owners, recruitment of human capital and renegotiation of North American Free Trade Agreement (NAFTA) that it hasn't ended yet, the cancellation of Ford plant in San Luis Potosi, the suspension of production of Corolla in the plant of Paseo el Grande, Guanajuato, and others.

On the last 5 years Automotive industry in Mexico has record numbers in production and exportation automobiles sells.

Automotive industry has been really important for the world and national economy, it has acted as a promoter of development of other sectors of high added value. Due to this fact, several countries, including Mexico seek to strengthen and develop this sector, this has been the result of events and transformations, from the evolution of globalization to the creation of industrial policies at the national level.

Currently, automotive sector contributes more than 3% of the Gross Domestic Product (GDP) and 18% of Mexico's manufacturing GDP, achieves a trade of more than 52 billion dollars a year, it has a wealth of foreign direct investment of more than 51 thousand 200 million dollars (11%) and it's responsible for about 900 thousand direct jobs.

Automotive industry in Mexico faces new challenges that could potentially changes the structure of the sector in the future. There are at least three trends that will determinate in the coming years: convergence with digital economy changes in the concept of mobility and consumption patterns, and regulatory requirements in the field of safety, environment and energy efficiency.

At 2017, investments by foreign companies in Mexico continued. However, the first days of 2017, Ford Company announced the cancellation of their plants in Villa de Reyes, San Luis Potosi. Even when the plant had more than 20% of construction.

"Although, the cancellation of investments like Ford in Mexico and others that could continue in the immediate future would have a negative impact, a massive and generalized investment cancellation" said by Oscar Silva, a leading in the firms' Global Strategy Group area, in a report published last February 2018.

Those days in Mexico, cars are produced that they are sold around the world, auto parts are successfully integrated into the value chains of the global industry and strengthened as the segment of premium vehicles. In addition, year after year the country

increases their participation in engineering, design and research and development activities.

Currently 80% of Mexico automotive production is exported, to other two members of the North American Free Trade Agreement (NAFTA). Mexico has become the seventh world producer and the fourth largest vehicle exporter in the world

Mexico has been the destination of 9 of 11 assembly plants that have been announced in North America since 2011, that's why the production of lightweight cars could increase to reach nearly 5 million units in 2020.

Until September 2017, AMIA once again reported record production and export figures for assembled automobiles in Mexico. In this accumulated figure, 2 million 829,761 cars were produced, 9.8% above the units manufactured in the country, just like last year.

In the case of exportation, it was sent to other nations 2 million 287 thousand units from Mexico, in the first nine months of the year, it was 11.5% higher than the last year 2016. This said Cluster Industry magazine (2017).

Service

There are so many definitions about service, however we take care about three things: service as a product from the industry, service as a value added, and service as a customer.

From the point of view of the authors Montoya and Boyero (2013), they said that service consists about experiences resulting from the contact between the organization and the client, which is why it's considered the best way to generate an adequate relationship. According to these authors, the satisfaction given through the service, came from company that wants to retain the client, therefore it must understand the importance of this practice.

Aguilar and Vargas (2010) considers that service consists of a process or set of actions that generally surrounds the right moment of purchase, that why those are intangible goods, that are consumed at the time of the production.

Meanwhile, Montoya and Boyero (2013) define customer service as the set of actions that a provider provides to their clients, to achieve service that it receives that means a differentiation with the rest of the organizations that offer similar services. The same is achieved through the improvement of the different aspects involved in the process to satisfy the customer.

Characteristics of customers service

1. Intangibility

According to Zeithaml and Bitner (2002), it represents the most outstanding difference between products and services, since these are not physical tangible, possible to be seen or tasted, and advantage with other tangible products. For that reason, service can't be experience before use.

In the same way, Serna (1999) considers that bases on this characteristic, the evaluation of the service depends on the perception of client and some other subjective elements.

2. Integral

All the member of the organization have to share responsibility in the production of the service, since each one intervenes in the final result that it's delivers to the customer, according to Serna (1999).

3. Heterogeneity

According this aspect, the service is not always provided in the same way, since it depends on the human resource, made up of a group of different individuals to each other, influenced by their own nature, with the changing mood at any time.

Sometimes, customer associates service directly with the employer.

4. Simultaneous production and consumption

To this characteristic, in terms of marketing services, three limitations are observed: first, there is difficulty in generating them in a massive way, Secondly their quality depends on the way it develops in the moment in front of the client, who tends to get involved, in a positive or negative way, this generate in some cases difficult users. Also Serna (1999) said, Service is a process where the supplier is also part of their production and therefore, it can't be separated from it.

5. Perishable

Serna (1999) explains in this sense, the difficulties of greater weight for he marketing of service are first of all, that it's no possible to anticipate a demand, since they cannot be stored, Secondly it's impossible to re-sell or return them, so they must have solid strategies to compensate and recover the client.

6. Basic promise

For the authors, the offer of customer service will be the standard through which it will be measured if it's accordance with their expectations. The organization must assume offer as the "hook" of their service, therefore once the client is motivated to act, this promise must be fulfilled based on their demands.

7. Satisfaction

To a large extent, their satisfaction will depend on the way in which this opportunity is used, as well as the efficiency with which it's produced and offered to the users, Serna (1999).

Added value

Serna (1999) explain that providing customer service integrally adds value, which represent a successful strategy to offer competitive advantages and it will be a differentiating factor in market, where there are large number of competitors.

From the point of view of Zeithaml and Bitner (2002), a tendency prevail in the user services, in terms of involving the attributes or components of the same way they discuss their value, because for them it's important they received based on the payment.

According to Aguilar and Vargas (2010), which are mentioned below:

- You can't be stored or accumulated

You can't see how or what happens with the products.

- You can't previously establish your final quality level.
- The basis of this process is the information.
- They aren't permanent, they are at the time of consumption.
- It depends on the individuals.
- The personnel that produces the service have contact with the users.
- Workers are responsible for the information.

To summarize, Aguilar and Vargas (2010) said that in order to develop the qualities of a good service it must be taken into account that it's not a product but a process, therefore, it can't be standardized either. This also makes control more difficult in an exact manner, making it difficult to control the process.

CRM

Pyne and Frow (2005) value that improves the development of appropriate relationship with key customers and segment customers, it unites the relationship of strategies and (IT) to create relationship with long-term customers and other key customers. CRM provides the use of data and information to understand customers as co-create value with them.

ITC Work area

In the work area, it has made it possible to streamline the automation of information, optimize good results by generating productivity in a company and improving the procedures that achieve the reduction of time in an effective way. It's important to know that ITC guarantees the work to be done and generate great opportunities in a company.

Advantages of ITC

- Guarantee more efficient procedures
- Allows the exchange of information in different areas of work
- Reduction of working time, to be able to perform other work activities.
- Increase the competitive advantage with other companies.
- Increase innovative responses to the challenges of the future.

It's a standard communication tool; it allows equal access to information and knowledge.

The right use of ITC allows companies to produce more quantity faster, better quality and less time and help to competitiveness. Ticxlabiralc. (20017).

Deming Prize model

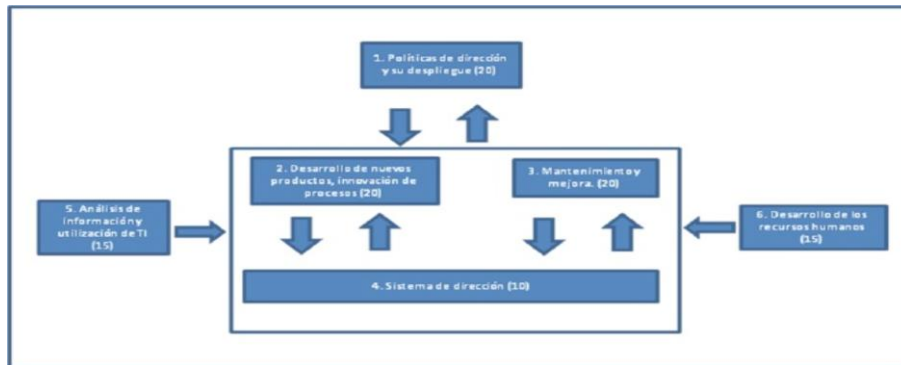

This model has been presented in Japan since 1951; it was created with becoming tool to improve the companies in that country.

This model is to promote control of quality and opportunities for excellence.

This model in 2004 had the following criteria:

- a) Management policies and their deployment in relation to the management of quality.
- b) Development of new products and/or process innovation
- c) Maintenance and improvement of operational and product quality

- d) Establishment of systems to manage quality, quantity, delivery, costs and safety and environment.
- e) Development of human resources-

The Deming Prize Guide 2004

IberoAmericano excelente management Model

This Iberoamericano excelente management model was pushed by FUNDIBEQ (Iberoamericano foundation for quality management)

FUNDIBEQ

This modal has important points like:

- I. Leadership and management style
- II. Policies and strategies
- III. Development of people
- IV. Resources and associates
- V. Customers

Criteria results with clients, development with people for a global result.

4. Analysis of Results

Methodology

Initially consists of a documentary research, supported by a field investigation with questionnaire, interviews, surveys and observation. It recommended to apply it later to the documentary to prevent duplication of information (Osirio, 2009)

A mixed research, qualitative and quantitative, on this research they survey data was analyzed as in the SPSS program to perform the crossing of variables.

The measuring instrument was divided into 6 sections.

Section	Items	Concept to size
A	6	General data
B	6	Reasons to go to the agency
C	6	Experience at the service area
D	6	Direct contact with the customer using ICT

Note: Measuring instrument. Own elaboration.

We used Likert scale with five options which they were list to 1 to 5, 1 is lower value and 5 higher value.

Hypothesis 1 Bigger communication with the customer, more loyalty

Reason to go to the agency (service area)

ANOVAS	SIG.
Security	.004

5 Conclusions

With all the transformation that we have with the comercial agreemeent and the behavior of global world, Automative field is competitive. It has been accpeted the use of ITC, which clients show more interest to their units. We noted that the result of post-sell were better.

The use of e-mail, whatsapp, photos from the begging, journey and end, it give more security and confident that the pieces are news, and this depends of the service that it's done.

One of the biggest advantage are that ITC send e-mail with photos, that was a big proposal, with the whatsapp reminder it continue with CRM

With the use of e-mail, we add comments with the photos.

6 Proposal for future research

Automative cluster is reserve in Mexico and only allow some agency to do this kind of research.

One of the biggest problems were the lack of hydrocarbons (gasoline in Mexico) affected in the sell, car manufacturing.

This gave the opportunity to the hybrids cars, which we don't know many things about them.

It has lack of catering to carring hybrids cars and Mexico is just beginning with the proposal to change and this change it will be for sell area.

We are waiting that in Mexico, they can have a better regulation and it doesn't affected produccion and economy of the country

Abstract

This paper addresses the value co-creation in homecare value networks. The paper aims to answer the following research questions: What are the fundamental elements of value from different parties' perspective? What types of practices support value co-creation among the network? What kind of outcomes can the value co-creation (inspired by the new technology) have on the network?

The paper takes advantage of a longitudinal interventionist case (2016-2019) investigating the technology implementation process in a homecare organization. The data is supported by seven other similar implementation projects concerning the same technology.

Uniquely, the article provides empirical evidence on the antecedents, roles and outcomes of the value co-creation in the homecare value networks. An in-depth access to the value network enabled capturing value elements that emerged due to the value co-creation in the customer selection, customer recruitment and service implementation phases. The article also provides examples of different types of value co-creation dynamics.

The article develops understanding of value co-creation dynamics in home care, helping homecare managers map and measure the outcome of value creation practices. The article also gives insights for managers wanting to co-create value in complex value networks.

Keywords – Value dynamics, value-in-use, value co-creation, value network, home care

Paper type – Academic Research Paper

1 Introduction

Well-being is co-created by many different parties involved in the healthcare value networks. Homecare represents an example where customers (patients), nurses,

municipalities, healthcare technology providers and many others work together in order to ensure the desired value for the customer and the society. This paper addresses the value co-creation in such a setting, with a focus on the dynamics of value creation from different parties' perspectives.

The point of departure for the paper is the value network approach (Lusch et al., 2010) that provides a basis for understanding value co-creation involving several parties. However, as a theoretical tension motivating the paper, prior research shows that whilst a value network approach is useful for studying the governance of value creation in networked operations, research does not adequately cover the responsibilities and roles of customers or value co-creation in such networks (e.g. Grönroos, 2011). In response, in-depth case examinations are desirable for unveiling the value co-creation dynamics to enable anticipating and managing such dynamics within the value networks.

In the health care context, there is the interface between the public and private sectors. Besides, both the society and individual patients can be seen as the customers of the health care processes, which increase the complexity of the research setting also regarding the value co-creation (Frow et al., 2016). Although collaboration or "co-creation" between public and private organizations can spark innovation and development (Hartley et al., 2013), there is not enough knowledge under which circumstances public-private collaboration is a usable source of innovation (Hartley et al., 2013). Unveiling the dynamics of value co-creation could help in identifying and enhancing these innovation processes as well.

To unveil the value creation especially in homecare, this paper investigates the dynamics of value creation and co-creation in value networks when a healthcare technology enables a shift towards more self-service in the value creation process of the customer. This type of change can usually occur when automation technology is introduced to the value creating process. However, it is not self-evident, how the value creation actually would change after the technology introduction, and how different parties involved in the value network would contribute to the value co-creation. Indeed, the role of some parties might change much more than the role of some others.

Altogether, the paper aims to answer the following three research questions.

1. What are the fundamental elements of value from different parties' perspective?
2. What types of practices support value co-creation among the network?
3. What kind of outcomes can the value co-creation (inspired by the new technology) have on the network?

These research questions are examined within the processes of homecare network including a technology provider inspiring change. The paper takes advantages of an interventionist cases study in homecare value networks (2016-2019), enabling an in-depth access to examine the dynamics of value creation. The empirical data of the paper consists of several meetings and discussions conducted in a longitudinal interventionist case study. The next section sets the theoretical base, on which we aim to contribute with this paper. We then present the research methodology employed to collect the empirical data of the paper. The fourth section will present the empirical case in more detail, with a

focus on different phases of value co-creation within the homecare context. Finally, empirical findings and their implications are discussed.

2 Literature on value co-creation in value networks

Addressing the dynamics of value co-creation requires understanding the value creation in general. Such approach is suggested by the service literature that places an emphasis on a thorough understanding on the elements of value and value creation in the processes (Grönroos 2008; 2011, Lusch et al., 2010; Laine et al. 2012). While value is created through the activities undertaken by the parties involved, it is not enough to embed value potentials to the characteristics of the goods and services, if they are not actually utilized in the value creation processes. Thus, we draw on the service logic where value is considered to be mainly created by customers as value-in-use (Grönroos, 2008; 2011).

According to the service logic, resources such as goods only have value potential (Grönroos, 2008). This potential, or value foundation, is utilized by the customer and transformed into value-in-use (Grönroos, 2008; 2011), which also means that often the role of supplier is to help the customers create value by providing the necessary resources or skills to do that. This distinction on who creates and who co-creates value is an important difference between the service dominant logic by Lusch and Vargo (2010; 2014) and the service logic discussed by Grönroos (2008; 2011), which we want to point out, since our paper takes the service logic approach to analysing value creation.

However, value creation and value co-creation are seldom occur with one party creating value and the other co-creating value. More often, value is created and co-created in a value network (Lusch et al., 2010). Lusch et al. (2010) see value networks as responsive and temporal structures, where different actors interact to co-create value. Our interpretation in the service logic context (Grönroos, 2008) looks at the network of stakeholder that have the temporal possibility or responsibility through interaction to help the customers create value-in-use. Due to the complexity of value especially within value networks, we also distinguish that customer value can be separated to individual value elements (e.g. Anderson et al., 2009) to better understand the dynamics in the creation of each value element

Some literature, such as Frow et al. (2016) define co-creation practices as collaborative integration of resources with the ideal outcome of having a positive impact on the ecosystem. However, we make the distinction of looking into practices, individual or collaborative that support value co-creation. Hence, these practices include but are not tied to co-creation practices only, since our focus is on both how value-in-use is created and co-created (Grönroos, 2008). The dynamic nature also suggests that value creation has temporal (Woodall, 2003; Lusch & Vargo, 2010; 2014; Grönroos, 2008; 2011), which is why we investigate the temporality of value from three dynamic temporal positions: designing, realizing and measuring value.

3 Research Methodology and Case Context

3.1. Research Methodology

We investigate the topic through a longitudinal interventionist case study (2016-2019) (Lyly-Yrjänäinen et al., 2017; Jönsson & Lukka, 2007), conducted in the homecare context. Within the interventionist approach, we utilize active participant observation as the main qualitative research method (Jönsson & Lukka, 2007; Gummesson, 2000). The topic is researched within homecare context, investigating the dynamics of customer value within the stakeholder networks involved in technology implementation pilots. Homecare context can be considered unique due to the complexity of the stakeholder network (Frow et al., 2016), and the notion of health as value (e.g. Porter, 2010). The empirical data can also be described in more detail, since the studied organizations are public organizations. As a case, the home care has some characteristics of an extreme case, providing an example of how complex can value dynamics become (Flyvbjerg, 2006), at least when examined with a uniquely in-depth, longitudinal approach.

The researchers and the homecare technology provider (from now on called TechCo) collaborate in a publicly funded research project. In the researchers study the drivers of customer value in home care in Finland. As part of the project, the researchers were invited to study the effectiveness of the service in eight different homecare organizations. Due to scarce analytics resources of municipalities, the researchers were openly invited to the field. As part of the intervention, the researchers supported the customer selection phase, by sharing findings from previous cases. They also provided analytics for the performance review by documenting the before-and-after impact and evaluating the cost effect of the robots. Figure 1 presents an overview of the steps of the interventionist case study and the longitudinal case with one of the homecare organizations (from now on called HCare), which is described as the empirical case. Regarding the case of HCare, the empirical data consisted of

- 8 meetings
- Around 100 emails, phone calls and skype calls
- 2 customer recruitment events
- 1 event for delivering the robots to customers
- 1 seminar for local municipalities

The analysis is supported by empirical data from more than 70 meetings with TechCo and its customers and over thousand emails and phone calls concerning TechCo exchanged.

Fig. 1. Timeline of the interventionist research conducted in the project.

3.2. The description of the studied technology and the homecare network

TechCo provides automated medicine-dispensing robots to homecare organizations. The robots are placed at the end customer's (i.e. patient's) home where using voice notifications they instruct the customer in taking the medicine. The robot automates most of the dose dispensing activity at the patient's home, requiring only to be filled every second week. The robot also alerts the homecare personnel, if the end customer does not take the medicine, providing additional security for the end customers. The service evolves around caregivers interacting with the customer, but the network is more complex with stakeholders such as doctors, pharmacies, relatives, other customers, suppliers and other social and health care providers. The network becomes even more complex when technology by TechCo is introduced, as illustrated in Figure 2. Hence, it becomes difficult to identify who actually creates value, how, and to whom.

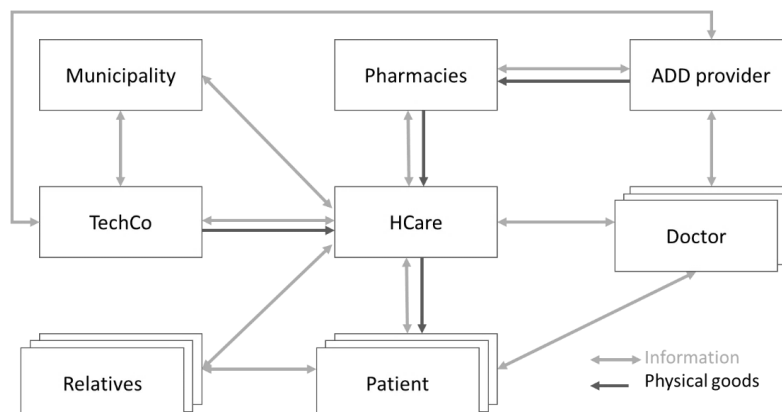

Fig. 2. The main stakeholders in the value network.

In the stakeholder network we can make a distinction between supplier level (TechCo, Pharmacies, automatic dose dispensing (ADD) -provider), service provider level (Municipality, Home care and Doctor) and customer level (Patients, Relatives and even

society). All stakeholders have their own tasks, goals and perspective on value. Table 2 shows the perspectives on the automation of medication from stakeholders that are directly involved in implementing and operating the robots.

Table 2. Stakeholders' value elements in the automation of homecare medication.

Stakeholder	Value elements in automating medication with a customer
Customer	Health outcomes, independency, social interaction and security.
Homecare organization (HCare)	Health outcomes of customers, flexibility, ability to serve customers better and reduction in workload and in work related stress.
TechCo	Growth, enabling creation of value, information, reference cases
Municipality (management)	Well-being of citizens and employees, cost-efficiency, municipality ranking

The other stakeholders naturally have their own perspectives as well, but it seemed that their role was more about approving or enabling the implementation of the robot. Additionally, the health improvement of the customer has several indirect effects that are hard to identify, but which can affect all the members in the value network. While TechCo had identified a specific demand for the robot, there was still some uncertainty in who would be the suitable end customers. To be able to use the robot, the end customer had to be open towards medication, be suitable for ADD medication and have sufficient ability to function independently. In addition, the robots had to enable creation of value by providing clear benefits for the customer and/or the homecare organization. After all, the homecare organization, the municipality and ultimately the society are expected to gain benefits from more purposeful care for end customers.

4 The Empirical Case

4.1. Presenting the technology – identification of value elements

HCare is a public organization operating in a Finnish municipality with around 20 000 residents. HCare falls under the jurisdiction of the municipality's 'services for elderly and the disabled' and they are responsible for arranging both homecare and home healthcare services in the municipality. HCare arranges around 300 homecare visits daily, with visits per customer varying up to seven visits per day. The municipality started the pilot in late 2017 and we were invited to study the pilot right from the start. Based on our experience in the previous pilots, we wanted to get understand the customer selection phase better, since it seemed to have a significant impact on the performance of the pilot. Before the customer selection, we presented discussed what kind of cooperation we could do during the pilot project. As part of the presentation, we discussed our findings and showed the performance documentation we had provided for the other municipalities. In another meeting, the representative of the TechCo presented the machine and caregivers had the possibility to try out the machine. During the event, there seemed to be certain level of

surmise towards the robot amongst the caregivers. However, the possibility to see the functionality from the perspective of the customer seemed to arouse some interest.

4.2. The customer selection – value co-creation for value realization

The customer selection -meeting was arranged two weeks after, with the objective of shortlisting customers, to whom the caregivers could start “selling” the robots. During the meeting, we discussed the ways how caregivers could create value or help create value with the customers. The emphasis of the discussion was on what types of activities help create value during the visits.

“It is the benefit of the customer, if we can sit [and talk] peacefully. Like we have flexibility on both sides and then the visits are more balanced. We can understand the memory issues and other things if there would be more discussion [with the customer].” – Caregiver, HCare

The caregivers were still uncertain about who should they deliver the robots to. We also requested to present our findings from previous cases as well as the logic of the payback period. The caregivers quite quickly identified the logic and started discussing their customers one by one with a following process: one of the caregivers brings forth the name of the customer and then the caregivers discuss about possible benefits, visit reduction potential, challenges and if the customer might be interested in using the robot. After the discussion, we asked the caregivers if we should shortlist that customer as a possible user for the robot and how many visits they estimate that could be reduced.

While most of the discussion happened in consensus, there were some points where they felt more insecure. There was also some discussion on what should be the objective of the customer selection and why they should select particular customers.

“Let us think about it the other way around so that if the customer is worried about getting his medicine, then the robot would improve his quality of life. He can feel more in control, if he can independently take care of his medication.” –Caregiver, HCare

While trying to identify potential end customers, the caregivers identified several barriers with some of the customers. Some of these related to the bundle of services that the particular customer had as illustrated by a comment by one of the caregivers.

“The night shift caregiver is required to help with support hoses and other small help. [...] The robot could make the dosing more secure, but there might not be other direct benefits.” –Caregiver, HCare

However, in most cases, the caregivers seemed to agree on particular customers and the ten-customer shortlist could be developed during the two-hour meeting. On one hand, they went quite far in making sure that the customers would be appropriate for using the robot. On the other hand, they wanted to remain flexible towards trial and error, as described by one of the caregivers during discussions about the customers’ openness towards the robot.

“We cannot know that [if the customer accepts the robot], but in that case we carry it [the robot] away from there.”

We also tried to develop an initial budget for the customer selection based on the discussion as well as the visit reduction estimations that could be used for reference later during the performance evaluation. An overview of the budget can be found on the left side in Fig 3. We also reported the initial budget to both HCare and TechCo, for further use.

Budget				Actual			
Customer selection		Implementation		Performance review		Expansion phase	
Customer	Change	Customer	Change	Customer	Change	Customer	Change
C01	-60	C11	-28	C21	-26,2	C31	-36,4
C02	-30	C12	-22	C13	-21,2	C21	-23,3
C03	-30	C13	-18	C22	-16,1	C13	-22,1
C04	-26	C14	-4	C14	-5,8	C14	-5,6
C05	-22	C15	-4	C23	-5,6	C23	-4,5
C06	-20	C07	-2	C08	-4,1	C32	-3,2
C07	-2	C08	0	C16	-3,6	C16	-3,2
C08	0	C10	0	C07	-2,1	C07	-1,9
C09	0	C09	0	C09	-2,1	C15	11,7
C10	?	C16	0	C15	-1,1	C09	17,4
						C08	21,8
						C33	34,0

Fig 3. The evolution of customer selection and the change in monthly homecare visits throughout the case.

Before the customer “recruitment”, a session with the top management of the municipality and TechCo was arranged, where the provided customer value from the perspective of health to the customers, cost savings for the municipality as well as well-being for the caregivers were discussed without the representatives of HCare. There, the management wanted to know more about the benefits or possibilities enabled by the robot, but during the discussion, they also started identifying new areas of impact that had not been brought up before, such as the high level of caregiver sick leaves that might ease out if the workload can be decreased.

4.3. Customer recruitment – enabling value-in-use

The next important phase in the implementation was customer “recruitment”, where the caregivers try to convince the customers to try out the robot. The recruitment was started just a few days after the customer selection and was conducted during scheduled homecare visits. One of the authors participated in the recruitment visits of customers C03, C07, C10, C14 and C16. During the recruitment, the caregivers presented the idea of the robot to the customers, emphasizing how it would make their life easier. They focused on the concerns that the customers might have and emphasized that you have to know your customer when “selling” something.

“For example, if you mention to him that his daughters think something then he will agree. These kinds of little things are important when you have to sell something.” – Caregiver, HCare

The caregivers also emphasized openness towards the service by encouraging customers to try the service and that it can be cancelled at any time if they wish so. Some of the customers did not seem to have a clear opinion on the robot, but were open towards trying the new way of service that the caregivers were proposing, as illustrated by the comment by another homecare customer.

“I guess I’ll have to learn to live with the mister robot then.” – Homecare customer C07

Two weeks after the recruitment, they started delivering the robots to the customers. During the deliveries, the researcher participated in the delivery for customers C03, C07 and C10. However, the robot of C03 was removed after the first day, because the customer had disconnected the robot from the power socket. During the delivery, some of the customers seemed to be a bit surprised by both the size of the robot or by the situation. However, the caregivers ensured the customers that they would not have worry since they would be there to assist with taking the medicine as long as the customers want. At this point, the budget was also updated based on the current shortlist of customers with some customers already using the robot. The changes are illustrated in Figure 3.

4.4. Performance review and 1-year after

The municipality, the homecare organization and TechCo had agreed on a six-month pilot. Already in March 2018, the homecare organization wanted to start evaluating the achieved performance. To do that they asked the researchers to analyse the impact of the robots on a more operative level by utilizing ‘enterprise resource planning’ (ERP) – information. The ERP-information from all homecare visits between August 2017 and March 2018 was gathered, which gave the possibility to inspect three months before and after. This information was analysed using spreadsheet computation to investigate the impact with customers using the robot and on the homecare organization level, and used to construct the report in Figure 4.

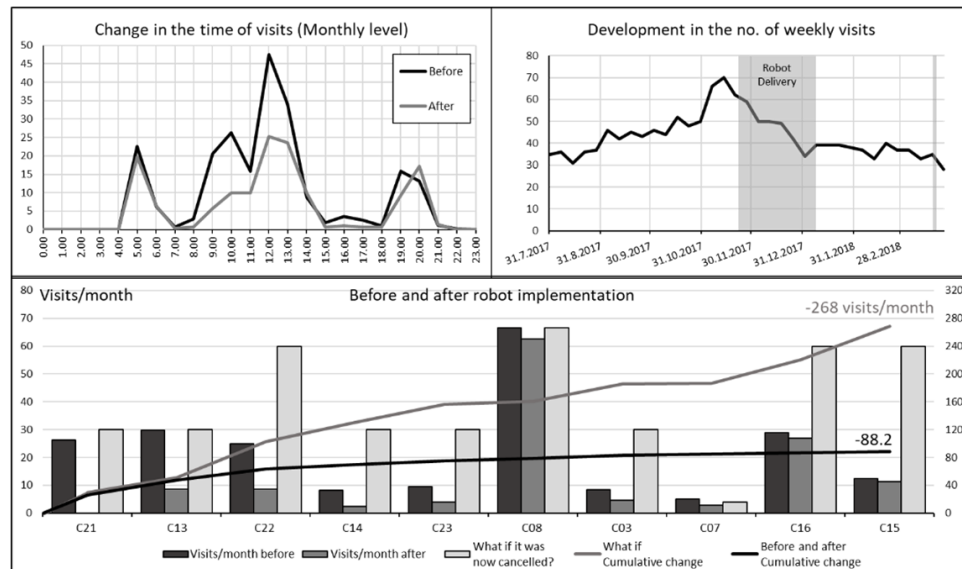

Fig 4. An overview of the performance evaluation documentation with HCare.

The documentation focused on before-and-after analysis based on the ERP-data. Based on the learnings from previous cases, we also sent a query to the homecare organization, asking the caregivers the question: how many homecare visits would be required to provide the equivalent level of care if the robot was now taken away? The role of this question was to identify changes that are not visible as operational changes, such as the possibility to keep the number of homecare visits from increasing. Due to practical reasons, the caregivers independently gathered and reported a list that was added as part of the report and discussed during the performance review discussions.

“We need something that we can use. [...] We need a good report that we can use to show that we should keep them [The robots]. We need to be able to show cost savings.” – Director of elderly care, The municipality

When asked about what kind of specific benefits there had been, they commented on the security and flexibility it brings for the caregivers. Since the robot alarms the caregiver if the customer does not take the medicine, they know more about the situation of the customers even if they cannot visit them. One of the homecare managers commented that the robot is the safe way to manage the medicine dosages.

“They said that it [ADD] would make the medicine dosing safe, but now with the robot it is actually safe.” –Homecare manager, HCare

There was also some discussion on the customer selection, since many of the originally planned customers were not included in the final customer base. While the results were positive, they were hoping for a larger operational change, measured mostly through changes in monthly homecare visits. The caregivers said that they cannot remember the specific reasons but during implementation, they ran into barriers that they

had not identified and for which they could not implement the robot with the particular customers. In these cases, they felt pressure to find someone suitable for the service and they felt more confident in choosing customers who can already operate independently. Once the customers started using the robots, it was difficult to change the customer since almost all customers learned to like the robots. One of the caregivers commented the process as an important learning objective.

“It is funny how now that the pilot is over, we know better what should be done.” – Caregiver, HCare

Hence, during the discussion they seemed to identify the role of customer selection in defining the amount of customer value that can be created using the robot. They thought about new customers with whom they could gain significant operational benefits, but at the same time, they had several other pressing matters to attend to. After the performance review, the homecare management decided to continue with the ten machines that they had, but wanted to delay the discussions on machine expansion, until they had clearer plans of developing their operations.

At the beginning of 2019, the homecare organization contacted us researchers, since they wanted to get an update on their current situation. They had been negotiating an expansion with TechCo, but wanted to still know more about their current performance and how to get the most out of the expansion. The director of elderly care emphasized the role of cost savings similarly as during the performance review half a year ago.

“If we want to expand the amount of robots, we need to be able to show that our current robots have saved costs.” –Director of elderly care, HCare

Between the previous and current discussions, the organization had also increased their installed machine base by two new robots. One of their customers had been transferred to institutionalized care, which meant they had recruited three new customers after the pilot, as seen in Figure 3. At this point, they wanted to understand the different cost effects better than before and make sure that they identify the best possible customers for the new robots. Hence, the plan was set out for spring 2019 for the new customer selection.

5 Discussion and conclusions

The empirical case represents a unique example of health care value network, with complex, dynamic value co-creation, which is as such a contribution. This contribution can be taken further by reflecting on the three research questions of the paper. First, the value creation represents different things for different parties involved in the process. While the health outcome for the customer could be seen as one of the driving value elements, other stakeholders still had their own motivations, such as the cost efficiency perspective of the municipality. This identification of value elements makes it easier to understand the value creation in total (Anderson et al., 2009), and provides a basis for understanding value co-creation practices.

However, through careful analyses and discussions, different types of value co-creation may be enabled during the implementation. As a contribution, distinction was made between customer selection to customer recruitment and performance evaluation to possible expansion plans. The role of different stakeholders varies, but the co-operation seems to have the capability of benefitting participating parties. The customer selection evolved significantly during the pilot, emphasizing the temporariness of customer value (Woodall, 2003). However, as mentioned by the homecare manager during performance evaluation, there is always some learning curve in when a new technology is adopted. Hence, the supplier can only facilitate or co-create value, but the homecare organization and the customers are still responsible for value creation (Grönroos, 2008; 2011).

Different co-creation practices occurred throughout the case. While the outcome of the pilot was favourable for the technology supplier, it is most likely that the outcomes would have evolved differently if the co-creation practices had been different. While both TechCo and the researchers supported the customer selection phase, only 40 % of the selected customers ended up even trying the robot. Thus, some level of co-creation occurs through interaction, but it is difficult to define or measure what were the outcomes of value co-creation. As a contribution, it seemed that documenting the created value with any meaningful metric can inspire discussion around value creation practices and pursued outcomes. Ironically, the measuring of outcomes and the related discussion can again also act as a significant value co-creating practice as illustrated by the discussions on expansion.

Furthermore, the case seems to support the value co-creation discussion of Grönroos (2008; 2011). For example, labelling all the rich interactions during the different steps as value co-creation takes the focus away from value creating practices. It is easy to call something value co-creation when the nature of how value is actually co-created becomes fuzzy. This can undermine the type of value co-creation in question and make the concept lose its substance (Grönroos, 2011).

Finally, our research is limited in generalization due to the rich but extreme case (Flyvbjerg, 2006). Our research also expresses the complexity of customer value dynamics, but lack in providing a general framework for them. Nevertheless, this paper can help managers facing challenges concerning technology diffusion to identify ways to co-create value. It also provides homecare professionals insight to mapping value-creating practices and measuring outcomes. We also propose that future research investigates and categorizes the types of co-creation through the analysis of empirical data. Indeed, there are more levels to value co-creation than the current literature understands and to understand the dynamics of value networks, these levels need to be identified and understood.

and Department of Management Engineering
Technical University of Denmark

Abstract

This study aims at analyzing patented innovations for blockchain applications as well as to mine cross-country creativity and knowledge flows underlying the corresponding technological trajectories. In particular, this paper aims at answering the following research questions by analyzing patent citation networks: (a) how cross-country creative/learning flows can be methodologically investigated with new algorithmic approaches; (b) whether countries of current patent owners have benefited from creative and/or knowledge flows related to patent acquisitions from abroad; (c) whether there are any country clusters with relevant country-country patenting interactions; (d) whether those clusters include or differ from the most relevant countries on the technology development of blockchain patented applications. 50,046,982 granted patents were considered initially, thus, refining the dataset based on the following constraints: (a) granting date within 2008-2018 – after Nakamoto's (2008) paper on blockchain; (b) at least one cited patent in order to ensure the analysis of patent acquisition effects without any methodological bias; (c) title/abstract including "blockchain" or related keywords; (d) further qualitative refinement by reading the main information on patents to ensure that they pertain to blockchain applications. Records with incomplete data have been eliminated after a qualitative check - including the comparison between International Patent Classification (IPC) and the Cooperative Patent Classification (CPC) codes and labels. Despite the strong multi-faceted interest - e.g. economic, business, security, societal - towards blockchain and its applications, specific studies on their technological trajectories, creative cross-country effect and knowledge transfer dynamics are still unexplored (also under the methodological perspective). Hence, this gives room studies on patent citation networks to be improved and contextualized. Findings provides an in-depth understanding of cross-country creativity and knowledge flows and the corresponding effects in terms of learning from the patent vendee's side. Findings prove to what extent the acquisition of patents from inventors' in other countries may help generating subsequent citations and affecting the technological evolution of those industries. Study relevance and implications can be summarized as follows: (a) policy-makers are provided with supporting data and guidelines to set ad hoc measures for blockchain applications in those industries deemed relevant to national interest - e.g. by nurturing the acquisition or birth of industry-strategic innovations; (b) managers of patenting firms are interested in monitoring, acquiring or anticipating possible advancements - i.e. in terms of creative concepts as well as generated knowledge and

technology -, identifying in advance potential technological innovations and recognizing evolutionary pathways in the technological scenario.

Keywords – Patent Citation Networks; Creativity; Knowledge; Innovation; Technology management

Paper type – Academic Research Paper

1 Introduction

Studies on patent citations have been extensively conducted, so far, in order to analyze both networks of patenting inventors and technological trajectories associated with the scope and intensity of knowledge and technology diffusion (Griliches, 1990; Trajtenberg, 1990; OECD, 1994; Harhoff, Narin, Scherer, and Vopel, 1999; Lanjouw and Schankerman, 2004; Breschi, Lissoni and Montobbio, 2005; Hall, Jaffe and Trajtenberg, 2005). Nonetheless, some limitations still apply with regard to the widespread literature on patent citation studies (Giglio, Musmanno and Palmieri, 2018).

First, to the best of author's knowledge, most of the studies on the flows underlying knowledge and technology diffusion did not move on to consider the peculiarity of diffusion properties (Bacchiocchi and Montobbio, 2010), like the technological field and the procedures of patent offices (also known as patent office bias) (Caballero and Jaffe, 1993; Jaffe, Trajtenberg and Henderson, 1993; Jaffe and Trajtenberg, 1999; Jaffe and Trajtenberg, 1999; Hall, Jaffe and Trajtenberg, 2001; Maruseth and Verspagen, 2002; Bottazzi and Peri, 2003; Peri, 2005; Criscuolo and Verspagen, 2008; Breschi and Lissoni, 2009; Bacchiocchi and Montobbio, 2010).

Second, extant patent citation studies dealt with a geographical perspective, identifying a predominant inclination of patent inventors towards self-citations and same-country citations, and against more relevant cross-country citations of technologically closer patents (Jaffe, Trajtenberg and Henderson, 1993; Jaffe and Trajtenberg, 1999; Maruseth and Verspagen, 2002; Bottazzi and Peri, 2003; Peri, 2005; Criscuolo and Verspagen, 2008; Breschi and Lissoni, 2009; Bacchiocchi and Montobbio, 2010).

This work is structured as follows: after the introduction, the second section provides a literature review about the analysis of cross-country creativity and knowledge flows in patent citation networks - including possible industry-specific studies, if relevant -, as well as the motivation of the paper; in the third section, the data collection and the overall methodological approach are described; the fourth section includes some discussions about results; in the last section, conclusive remarks are presented.

2 Literature review and motivation

2.1 Patent citation studies

Both a macroeconomic and microeconomic views emerge from the analysis of extant contributions on cross-country knowledge flows in literature (Griliches, 1990; Bacchiocchi and Montobbio, 2010), whilst only one work has recently tackled the analysis of “patented creativity” flows (Giglio, Musmanno and Palmieri, 2018).

The macroeconomic perspective on knowledge flows between different countries focuses on a comprehensive set of variables such as nature, type, scope and intensity of knowledge diffusion (OECD, 1997; Hu and Jaffe, 2003; Maruseth and Verspagen, 2002; Hu and Jaffe, 2003; Malerba and Montobbio, 2003; Malerba, Mancusi and Montobbio, 2007; Park, Lee and Park, 2009; Shih and Chang, 2009; Chen and Guan, 2016) as well as joint industry collaborations, social interactions, public-private co-operations (Gomes-Casseres, Hagedoorn and Jaffe, 2006; Shin and Park, 2007; Hong, 2008; Guan and Chen, 2009; Nakajima, Tamura and Hanaki, 2010; Inoue, Souma and Tamada, 2010; Chen and Guan, 2016; Stople, 2002; Fleming, King and Juda, 2007; Mina, Ramlogan, Tampubolon and Metcalfe, 2007; Verspagen, 2007; Chen and Guan, 2010; David, Fernando and Itziar, 2011; Bekkers and Martinelli, 2012).

Under the microeconomic perspective, the leadership on a technological trajectory of a minority group of countries may influence the economic value of patents, the realization of the technology potential and, finally, firms’ competitiveness within the pertaining industry (Griliches, 1990; Jaffe and Trajtenberg, 1999; Belderbos, 2001; Frietsch and Grupp, 2006; Storto, 2006; Verspagen, 2007; Deng, 2008; Ma, Lee and Chen, 2009; Chen and Guan, 2016).

Finally, macroeconomic and microeconomic perspectives, which have been adopted separately in the reviewed literature contributions, are worth being dealt with concurrently in order to derive from them some mutually reinforcing measures set by policy-makers and company managers.

2.2 Case study-related literature

As regards the case study-related literature, scientific works focusing on patent analyses (including, but not limited to patent citation studies) have not been conducted on blockchain (BC) technology. This further reinforces the motivation for a real-world application of this study as well as for comparing the findings on BC with similar studies on other technological fields (Caballero and Jaffe, 1993; Jaffe, Trajtenberg and Henderson, 1993; Jaffe and Trajtenberg, 1999; Jaffe and Trajtenberg, 1999; Jaffe, Trajtenberg and Fogarty, 2000; Hall, Jaffe and Trajtenberg, 2001; Maruseth and Verspagen, 2002; Bottazzi and Peri, 2003; Duguet and MacGarvie, 2005; Peri, 2005; Criscuolo and Verspagen, 2008; Breschi and Lissoni, 2009; Bacchiocchi and Montobbio, 2010).

Blockchain is a disruptive technology (Dutra, Tumasjan and Welp, 2018) dating back to 2008, with the potential to be applied and to act as a game changer in many

industries (Casino, Dasaklis and Patsakis, 2019; Gartner, 2018; Zhao, Fan and Yan, 2016; Swan, 2015; Veitas and Weinbaum, 2017). BC is defined as a peer-to-peer network exploiting distributed ledger technology to store and manage digital asset records (Alkudary, Brusset and Fenies, 2019; Chen, 2018; Davidson, De Filippi and Potts, 2018; Risius and Spohrer, 2017; Savelyev, 2018; Gürkaynak, Yılmaz, Yeşilaltay, and Bengi, 2018).

In one decade, BC proved to have strong relevance and implications under many perspectives – e.g. economic (World Economic Forum, 2015), business (McKinsey, 2018; CBInsights, 2018; IBM, 2016), security (World Economic Forum, 2015), societal (World Economic Forum, 2015).

Since BC was conceived by the anonymous Nakamoto in 2008 (Nakamoto, 2008), thousands of BC-based technologies have been patented¹. However, academic research on this field has not kept the pace of patenting activity and technology development (Alkudary, Brusset and Fenies, 2019; see also: Petticrew and Roberts, 2016; Thomé, Scavarda and Scavarda 2016). Hence, this gap in literature gives room alternative studies in order to shed some light on different facets of BC and its implications for managers, policy-makers, academicians and other stakeholders.

Finally, since alternative studies need alternative sources of data on the BC technology development, the aforementioned (see Section 1) noticeable amount of patented blockchain applications - i.e. 4,120 granted patents¹ in 2008-2018 - is the main unbiased alternative data source to investigate BC technology and its implications.

3 Data collection and methodological approach

3.1 Sample and methodology

A comprehensive view on the methodological approach adopted in this study is detailed in Figure 1.

¹ 4,120 patents were retrieved by searching for the following keywords in the title/abstract fields based on Alkudary, Brusset and Fenies' (2019) search strategy: "blockchain" OR "blockchains" OR "block chain" OR "Consortium Chain" OR "smart contract" OR "distributed ledger" OR "distributed ledger technology" OR "automated escrow" OR "public ledger" OR "public digital record" OR "cryptographic hash" OR "proof-of-work" OR "proof-of-stake" OR "proof-of-existence" OR Hyperledger OR "Hard Fork" OR "decentralized consensus" OR "51% attack".

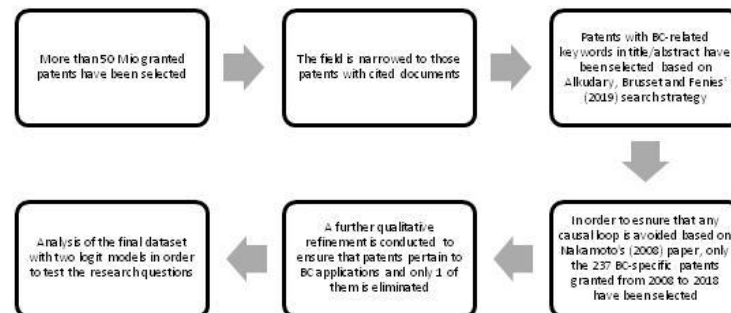

Figure 1. Methodological approach and stages.

The methodological approach relies on a single period including both cited and citing patents. This methodological choice takes into account the peculiarities of the emerging BC technology (Bacchiocchi and Montobbio, 2010), namely, BC's recent technological foundations and non-mature positioning within the Gartner Hype Cycle (Gartner, 2018). BC technology differs from the conditions under which previous patent citation studies were applied to other technologies (Giglio, Musmanno and Palmieri, 2018; Li-Ying, Wang, Salomo and Vanhaverbeke, 2013). Extant literature does not indicate a time interval for “learning-by-patent-acquisition”: literature suggests minimum 5 years (Jaffe and Trajtenberg, 1996; Jaffe and Trajtenberg, 1999; Hausman and Griliches, 1984; see also: Johnson, 2002; Ahuja and Katila, 2001; Hall, Jaffe and Trajtenberg, 1999), coherently with the proposed decade 2008-2018.

Data have been analyzed with two logit models in order to understand whether beneficial creativity and knowledge flows could be identified for owning firms - and, more broadly, for their headquarter countries, under a macroeconomic perspective.

3.2 Variables and measures

Coherently with previous methodological contributions, the analysis was conducted based on Kessler and Bierly (2000), Verspagen (2007) and Li-Ying, Wang, Salomo and Vanhaverbeke (2013). BC-related patents citing other patents are assumed to be originated from such prior arts, thus, suggesting a “learning-by-acquisition” effect enabling further technological advancements (Verspagen, 2007; Li-Ying, Wang, Salomo and Vanhaverbeke, 2013). If prior knowledge is not utilized - that is it is not cited in new patents -, hence, creativity replaces it as an innovation trigger (Verspagen, 2007; Li-Ying, Wang, Salomo and Vanhaverbeke, 2013; Giglio, Musmanno and Palmieri, 2018).

The dependent variable is defined as a binary cross-country learning variable, “DepVar” (0 = no cross-country learning, 1 = cross-country learning). The existence of a cross-country learning is reported whereas the citing patent cites one or more prior acquired patents, whereby all current owners and all inventors come from different

countries - i. e. the learning process is fostered by prior cross-country knowledge flows. The independent variable is the number of cross-country patent acquisitions, “IndVar”, that is the amount of patents with current owners’ nationalities different from inventor’s ones.

Since possible issues affecting patent citation studies - same country- and self-citations, technology- and patent office-specific aspects etc. - have been analysed in both Section 1 and 2, some control variables are considered (Li-Ying, Wang, Salomo and Vanhaverbeke, 2013), while a variant of their model is proposed for creativity flows. In detail, the methodological approach checks for technology- and firm-level as well as environmental variances. In Table 1.a and 1.b, control variables are detailed for knowledge flows and creativity flows, respectively.

Based on the binary dependent variable, the logit model is adopted (Greene, 2003; Li-Ying, Wang, Salomo and Vanhaverbeke, 2013). Two logit tests are conducted - “Knowledge Flow” and “Creativity Flow” models, respectively.

Table 1.a. Variable details for knowledge flows*.

Variables’ levels	Variables’ codes	Variables’ name	Variables’ brief description
Technology	TechAge	Technology Age	Average years between cited patent granting date and cross-country citing date
	PatCiVal	Patent Citation Value	Average citations count after cited patent granting date (within the selected time interval)
Firm	FiSize	Firm Size	Number (ln) of employees of the current owner’s firm
	AppExp	Application Experience	Number of owner-firm’s patent applications before the cross-country acquisition date (within the selected time interval)
Environment	CoPaSt	Country Patent Stock	Average number of patent applications per million people (within the selected time interval)

*All variables in Table 1.a are treated as scale variables in IBM® SPSS® Statistics 25.

Table 1.b. Variable details for creativity flows*.

Variables’ levels	Variables’ codes	Variables’ name	Variables’ brief description
Technology	PCD	Patented Creativity Degree	Number of citations by owner’s patents acquired from abroad divided by number of cited acquired patents
Firm	FiSize	Firm Size	Number (ln) of employees of the current owner’s firm
	AppExp	Application Experience	Number of owner-firm’s patent applications before the cross-country acquisition date (within the selected time interval)
Environment	CoPaSt	Country Patent Stock	Average number of patent applications per million people (within the selected time interval)

*All variables in Table 1.b are treated as scale variables in IBM® SPSS® Statistics 25.

4 Results and discussion

The statistical analysis has been conducted by means of IBM® SPSS® Statistics 25. In Table 2.a and Table 2.b, correlations among independent variables are tested in order to investigate about possible multicollinearity issues.

Table 2.a. Correlation test for the Knowledge Flow model.

*Correlation is significant at the 0.05 level (2-tailed).

In Table 2.a and Table 2.b, some variables show potential collinearity, as expected. Correlation is high between the main independent variable and the technology-level variables. In Table 2.b, the country-level analysis shows to be not significant, instead.

This may suggest that, in the BC field, the time needed to develop new patents, the amount of citations and the degree of creativity tend to affect the attractiveness of “foreign patents” to be acquired. Likewise, in both logit models, the firm-level control variables show a significant correlation with each other. This may suggest that big-sized firms in the BC field tend to have a high number of patent applications, also before the cross-country patent acquisition that calls for inclination towards knowledge absorption. Moreover, a number of employees in big firms provide highly differentiated/specialized skills, endowed with more resources boosting innovation processes. Significant cross-level correlation is found between firm- and environment-related control variables: it is lower than other correlation values in Table 1.a, whilst it is relatively high in Table 1.b. Firms are generally affected by the external environment and relevant stakeholders. National innovation systems offering a breeding environment are associated with firms with high innovation potential and knowledge generation performances, especially in creativity-based contexts: this may explain the relatively higher correlation between firm- and environment-related control variables in Table 1.b compared to Table 1.a. Results also show that the micro- and macro-economic analyses should be conducted jointly: the underexplored combined approach is one of the motivations of this work. Finally, as for the inter-level correlations, no collinearity is detected between the technology and firm levels.

In Tables 3.a, 3.b and 3.c, the results of the two logit models are shown whereas high reliability is confirmed by high overall percentages of predictability.

Table 3.a. “Knowledge Flow” logit model: classification table***.

	Observed	Predicted		Percentage Correct
		DepVar .0000	1.0000	
DepVar	.0000	33	0	100.0
	1.0000	26	0	.0
Overall Percentage				96.9

	1,0000	56	0	,0
Overall Percentage				93,7

***Constant is included in the model. The cut value is .500.

5 Conclusions

This work claims a threefold originality. Firstly, it focuses on the underexplored “learning-by-acquisition” effect in the BC field, whereas firms tend to acquire patents and hire people enabling them to further build on the acquired knowledge, finally mastering entire technological trajectories and shaping the whole industry scenario. “Learning-by-acquisition” helps understanding if and to what degree a firm is committed to further developing and shaping its own industry and technological trajectory.

Secondly, few studies have analyzed the spillover properties characterizing specific technological fields. Hence, this work enriches also this perspective of analysis.

Thirdly, studies on knowledge and creativity flows and patent citations have a two-pronged significance - macroeconomic and microeconomic -, but extant literature neglects their combination. This work fills this gap.

Under the methodological perspective, patent office bias limitations are overcome through IPC and CPC standards. In addition, the first creativity measure on patents is proposed, coherently with the methodology developed by Li-Ying, Wang, Salomo and Vanhaverbeke (2013).

As for the results, current owners operating cross-country patent acquisitions are able to internalize inventors’ knowledge and to file subsequent patents in the BC field as well as to maintain their own creativity levels. Firms increase their innovation potential and their business competitiveness, while countries strengthen their national innovation systems and foster their economic growth. Policy makers may, then, conceive measures nurturing the BC field, encouraging firms to acquire foreign patents - e.g. incentives, tax-reduction - to develop new patents or stimulate creativity. As for firms, managers should select foreign technology by strategically analyzing its age and patent citations to increase the likelihood of benefitting from the “learning-by-acquisition” effect or the creative cross-country effect. Patents with the highest innovation potential need a short time to generate new (creative) patents. The most promising patents should have high patent citation levels.

Finally, this study has some limitations. Despite both “learning-by-acquisition” and creative cross-country effects are proven, nothing can be said about to what extent owner-firms have learned/been creatively stimulated. Moreover, the whole picture is still missing: only some variables have been investigated, without testing possible moderating/mediating effects. Hence, this work paves the way for future research efforts

on knowledge and creativity flows, patent citations and both the “learning-by-acquisition” and the creative cross-country effects.

Education – Challenges in the Digital Era

Contu Eleonora Gabriela

Department of Economic and Administrative Science
University of Bucharest
36-46 Mihail Kogalniceanu, 5 district, Bucharest

Abstract

In the Digital Era, education is a complex component of human existence that must meet the challenges of contemporary society. The paper is based on a qualitative research, conducted on a sample of 100 persons (students in the first year of study at the Faculty of Administration and Business, University of Bucharest). The key questions raised at this point are: Starting from the importance of digital in the field of education what is the profile of the student of the future? How about the teacher of the future?

The research approach used emphasis on the importance of technology in academic life. In contemporary context technology should be seen as a future instrument in learning. Nowadays virtual reality creates new immediate learning experience.

This methodology highlighted the importance of knowing which teaching style should be used in an efficient instructive-teaching process. The main objectives of the study are: presenting the main education styles in virtual environment, highlighting the challenges and opportunities of education in digital era, analysing marketing research results that distinguished an innovative student profile and a successful teacher profile in the context of digitization.

The outcomes of the application underline the importance of education in digital era. The topic of the paper is popular and has potential for further research as in contemporary context students' needs and demands are changing according to New Information and Communication Technology. This fact leads to major changes in academic life. The educational context becomes more and more complex, facing challenges of contemporary realities which must not be neglected.

Keywords – education, digital era, learning styles, individual intelligences, personality traits.

Paper type – Academic Research Paper

1 Introduction

This paper sets forth to explore, surely within limits, a reality that becomes more and more present in our lives.

The present study is addressed to teachers and students / pupils, to each individual who searches throughout his/her life to understand a complex and great word, <<education>>.

The success of an instructive – educative process depends on the teachers' "craftsmanship" of using modern educational means. The successful teacher should have: ability to analyse and synthesize, flexibility, creativity, originality, clarity, expressiveness, the qualities of attention, readiness, memory qualities, pedagogical skills. Family is the exogenous variable which exerts the most powerful influence on individual behaviour. The harmonious development of the individual depends on the way in which moral education is achieved.

In present day context the role of teacher in school and society is crucial. B.F. Skinner says that the role of a teacher as a human being is amplified by the use of educational means. Augusto Cury (2011, p. 9) considers that "each individual (...) is a unique star on the life scene". Young generations should be taught how to explore a world that is waiting to be explored. And now, the role of teacher is ... crucial!

2 Literature review

In the context offered by New Information and Communication Technologies, a variety of learning styles are recognized, the roles of the teacher and learner being explicitly modified in comparison with classical roles (Ceobanu, 2016).

Literature review highlights many contemporary psychological theories that refer to different educational styles: cognitive, learning, thinking (Ceobanu, 2016). It is considered that the three educational styles are complementary, that is "it starts from a certain style of thinking, it turns into a specific cognitive style and reaches a personal learning style" (Ceobanu, 2016).

In his paper "Psychological types," Carl Jung argued that any human personality is defined in relation to three aspects: 1. introversion-extraversion; 2. intuitive personality - meticulous personality; 3. rational people (who are logical and analytical) - emotional people (who judge in terms of feelings and values) (Ceobanu, 2016).

In literature review, starting from the personality types described by Carl Jung, the Myers-Briggs Type Indicator is presented, thus highlighting four criteria for defining types of personality (Quenk, 2009; Ceobanu, 2016): 1. "Depending on where the individual focuses his attention," we distinguish the extraverted type and the introverted type; 2. "Depending on how the information is acquired", we distinguish the sensing type and the intuitive type; 3. "Depending on how the decision is made", we distinguish between the thinking type and the feeling type; 4. "Depending on how the individual orients on to the outer world" we distinguish the judging type and the perceiving type.

In this context, it is important to mention the perspective of H. Gardner who proposed eight intelligences such as: verbal intelligence, logical-mathematical intelligence, spatial intelligence, kinesthetic intelligence, musical intelligence, interpersonal intelligence, intrapersonal intelligence, ambient or naturalist intelligence (Bratianu, Dima, Vasilache and Orzea, 2011). Also, "multiple intelligences can process both explicit and tacit knowledge, both cognitive and emotional knowledge" (Brătianu, Dima, Vasilache and Orzea 2011).

3 Methodology

In order to obtain the necessary empirical information, a qualitative research was used. A sample of convenience consists of 100 students from the Faculty of Administration and Business, University of Bucharest, Romania. The data collection tool was a semi-structured questionnaire, comprising nine questions. Focus-groups consisting of 25 students were made during the seminar's meetings in March 2019. The questionnaire contains a large number of open questions.

The scope of the research consists in achieving the innovative student's profile.

According to key questions the objectives of the research are:

O₁: Identifying the learning styles in the context of virtual environment;

O₂: Shaping the innovative student's profile;

O₃: Shaping the success teacher's profile.

4 Research findings and discussion

In order to achieve a qualitative research, four groups (twenty-five students in each group) were formed. The discussion began according to an interview guide.

The interview questions were the following:

1. Mention some requirements that would make learning interactive in the classroom and / or seminar.
2. Do you think that the use of technology in the educational process can help you achieve your educational standards? Argument the answer.
3. Do you think technology is your "learning partner"? Argument the answer.
4. List the main advantages / disadvantages of using the technology in the educational / learning process.
5. What are the personality traits of the teacher of the future?
6. What about those of the student of the future?
7. What teaching method do you prefer: modern or traditional? Argument the answer.
8. What do you think are the personality traits of the teacher who practices an authoritative educational style? What about a flexible one?
9. What is the first word that comes to your mind when thinking about learning in a virtual environment?

At question 1, respondents mentioned some requirements that would make learning interactive in the classroom and / or seminar and the following points of view were highlighted: involving students in team activities and debates; performing imaginative exercises such as "What would you do if ...?"; the existence of undemanding bilateral communication; creating a pleasant environment by encouraging opinions; the existence of an empathic teacher-student relationship; including in the teaching process a session of questions-answers on the topic discussed; creating an interactive and comfortable working environment.

Question number two highlighted the following relevant responses: "I believe that the use of technology in the educational process is very useful in achieving educational

standards, because we can benefit from a great flow of information in a way that is familiar to us"; "Yes, because we are in the age of technology"; "Yes, because our generation is attracted to technology to a great extent, and its use can catch our attention easier".

Question three has provided both positive and negative answers, such as: "Yes, technology is "a learning partner" for me because I have access to extensive information in addition to the course material, and so I try to synthesize information to learn more easily"; "I think technology is "a learning partner" because it helps us find out new things"; "I consider technology "a tool" that helps us learn effectively"; "I couldn't say. I prefer more classical methods, especially handnotes. However, it is often extremely useful when I need extra information"; "In some cases, technology may even represent a disadvantage when we need to focus as it can distract us."

Question number four highlighted the following advantages and disadvantages of using the technology in the educational process, such as: advantages - speed, wide range and variety of information, easy processing of multiple data, high accessibility, time saving, it captures attention; disadvantages - some online information may be wrong, it "makes us lazy", convenience.

Question number five provided answers that outlined the following profile of the teacher of the future in the view of young students, starting from the importance of digital in the field of education. Therefore, the teacher of the future should be: flexible, calm, patient, indulgent, charismatic, happy, dedicated, open-minded, enthusiastic, cheerful, imposing, balanced, optimistic, punctual. The following interesting points of view were also highlighted: The teacher of the future must be "an open, fair and empathic person. A person who knows how to be loved and respected by his/her students, who can adapt to his/her students and make them want to know what he / she has to offer "; "The teacher of the future is a flexible teacher who combines pleasure with utility, who uses technology, but doesn't disregard old methods of teaching"; " The teacher of the future must have a strong personality, he/she must be motivated and vigilant."

Also, question number six brings forth information about the profile of the student of the future, starting from the importance of digital in education. Thus, the student of the future must be: patient, kind, hard-working, persevering, intelligent, ambitious, diligent, punctual, honest, receptive, curious, creative, responsible, cheerful, motivated, pragmatic, extraverted. He or she must engage in the learning process by searching for relevant information using technology attentively. So if he/she carefully chooses what he/she is studying, he/she will manage to learn and acquire information faster and in a pleasant way, all contributing to his/her harmonious development.

With respect to question number seven: 76% of the respondents mentioned that they prefer the modern teaching method, 5% said they prefer the traditional teaching method, and 19% mentioned that they prefer both teaching methods. The following points of view were highlighted: "The modern teaching method seems much more interactive and interesting, so you can acquire more information."; "The modern teaching method is much more accessible and flexible."; "The modern teaching method is efficient and fascinating."; The modern method of teaching is much easier and more practical for us,

the students, because we live in the century of speed, and things have to move fast."; "I personally prefer the traditional teaching method because in my case it is much safer: I have the written lesson, I pay attention to explanations, I can not lose the information and I have reliable sources that guide my learning."; "I believe that an effective teaching method is a combination of the modern and traditional teaching method."; "I prefer a combination of the two, because both have advantages and none of them should disappear or be replaced.

The next question in the questionnaire highlighted the following answers presented in the following table:

Tabel no.1 – The features of the teacher who practices different educational styles

The features of the teacher who practices an authoritative educational style	The features of the teacher who practices a flexible educational style
Authoritarian, rigid, demanding, severe, harsh, pretentious, strict, solemn, imposing, precise, serious, conservative, introverted, analytical	Patient, flexible, calm, cheerful, mild, creative, tolerant, detached, permissive

Source: personal research

The students also competed in expressing their opinion on the two teaching styles. The following views were thus outlined: "When a teacher is authoritarian, he/she lacks understanding and patience, as opposed to a flexible teacher who has more qualities and is loved by his/her students."; "A teacher who applies a flexible learning style is open-minded and closer to student requirements. On the other hand, an authoritative teacher captures students' attention quicker"; "Whether a teacher is authoritative or flexible if his/her defining features revolve on capitalizing his/her professionalism it gains the student's trust.". There was no delay in making statements such as: "When a teacher is authoritative, he/she is respected by students, and when he/she is flexible he/she is loved by students", "Teachers who practice flexible teaching can not only teach effectively but can sometimes change opinions and mentalities".

At the last question in the questionnaire respondents mentioned the following words that can characterize learning in the virtual environment: future, innovation, seriousness, interactivity, brilliance, creativity, interesting, flexible, evolution, novelty, desire.

5 Conclusions

The access to information has transformed the whole world. Great ideas are shared faster through one simple "click" that goes to an interaction between people and technology. The information "explosion" requires major changes in the sphere of education. In this context, education must be continuously revised, both at the individual and organizational level. Education takes place in space and time, it does not know limits and it is an expression of individuals' life. In this context "it is clear that the professor is playing a social role" (Bacellar and Ikeda, 2006), and more over "learning is the process of creating knowledge" (Kolb and Kolb, 2005).

Nowadays the quality of education must take into account a holistic vision that leads to a better understanding of the whole instructive-educative process. Teachers should have a strong personality. Pedagogical tact, the spirit of observation, pedagogical attitude, humanism and – the most important – love for children are just a small part of teachers' personality traits who must take responsibility for "shaping" young generations.

School, family and young generations are institutional factors that provide a social framework driven by principles, norms and values.

However, we must not forget what is essential for the educational process in order to be effective, whether we are the main educational actors or we are individuals who uninvolved, just observe this complex process: <<education>>. Therefore, "to educate means to engrain in a person the responsibility of self-reflection and self-fulfillment. Such a leaning towards yourself is the core of any true education." (Cucos, 2017).

Road Map for Creative Problem Solving Techniques

Han van der Meer

Department of Product Innovation Management of the Faculty of Industrial Design, Delft University of Technology
Landbergstraat 15, 2618 CE DELFT, The Netherlands

Katrina Heijne

** Corresponding author*

Abstract

Creativity is one of the vital skills for the 21th century as stated by the European Union. In our earlier work (Buijs et al, 2009) we gave a syntheses of the literature and practice on creativity resulting in an overall model for creative problem solving in groups. This model was called iCPS and consists of four interlinked sub processes Content Finding, Information Finding, Acceptance Finding and Project Management (Buijs & van der Meer,2013).

Building on this work the present paper focuses on techniques that can be applied within the framework of iCPS. Based on an extensive literature study combined with the experiences of over three decades training creative facilitation of groups at the Delft University of Technology all techniques found in literature were clustered to 40 specific techniques supporting the different stages of iCPS and 8 so called session duties. 5 methods significant different than iCPS were identified. For using the 40 techniques a technique selector is proposed.

The paper ends with some directions and suggestions for further research to make the shift in research on techniques for creative problem solving in groups from a merely guru driven topic to an evidence based approach.

Keywords: Creativity, Group sessions, Creative Problem Solving

Type of paper: Practical paper

1 Introduction

Creativity is a complex and complicated phenomenon (Runco et al,1999). It has to do with talent and traits of people, it has to do with surprising new solutions, it has to do with specific actions people take, and it has to do with circumstances and situations. Rhodes (1961) divided the research in creativity into four specific aspects. Since all aspects have a label beginning with a P his work is referred to as the *4P theory on Creativity: Person, Process, Press and Product*. Since in practice we only find the Process part useful when

we design tools for creative sessions (Buijs & van der Meer, 2013) we use the working definition of the most cited author on creativity Theresa Amabile:

“Creativity is the process that leads to novel and useful solutions to given problems”. (Amabile, 1996)

Creative Facilitation is not suited for all types of problems. Usually two types of problems are distinguished: close-ended and open-ended problems (Rickards, 1974). In the rest of the text we will focus on open problems thus leading to our working definition of creativity:

“Creativity is the process that leads to novel and useful solutions to given open problems.”

2 History of Creative Problem Solving

One of the oldest descriptions of the creative process in stages has been given by Wallas (1926 in Vernon 1970). In the first stage the problem is "investigated ...in all directions" (page 91). In the second stage the problem solver is not consciously thinking about the problem. In the third stage suddenly the "happy idea" appears (page 92). And in stage four the idea is checked for its proper value. Although in later works a fifth and even sixth step can be found the four stage representation of the creative process is still the most used (Sadler-Smith, 2015).

The research in creativity made a major leap when Guilford (1950) delivers his acceptance speech as the new president of the American Psychological Association. In this speech he proposes to separate the diverging and converging capacity of the brain. Ever since, stimulating creativity and supporting people in Creative Problem Solving (CPS) has become an explicit academic and professional domain.

Diverging is at the heart of CPS. Getting many options in order to get one or two good ones for further development is the basic line of reasoning. The option generating technique *Brainstorming* (Osborn, 1953) made this way of thinking popular. The core message of diverging in brainstorming is “postponing judgment” and “quantity breeds quality”, so generating lots of options without judging any of them. The consequence of diverging is that you also have to converge later in the process. If you produce hundreds of options, you have to select a couple of good ones to continue with since it is impossible to develop all of them. This sequence of divergence (generating) and convergence (selecting) led to the well-known ‘*creative diamond*’: an expanding diverging phase followed by a narrowing converging phase. See figure 1.

Figure 1: Modelling the sequence of diverging and converging thinking in the form of the "Creative Diamond". Horizontal the number of ideas, vertical the time. Based on Guilford's and Osborn's thinking.

In those early days of creativity research the emphasis was on diverging: if you could produce many ideas you were a creative potential. Torrance (1974) developed different tests to measure people's ability to diverge, among which the well-known TTCT: Torrance Tests of Creative Thinking. The four main aspects to judge divergence are according to him:

1. *fluency* (the number of options per time unit),
2. *flexibility* (the number of categories the options are based on or fit in),
3. *elaboration* (the depth or filling out of the option) and
4. *originality* (the degree of newness of the options)

One of the presuppositions of our approach to Creative Facilitation (Buijs & vander Meer 2013) is that you can influence *Fluency* and *Flexibility* by using techniques and this will then lead to *Originality*. A good facilitated creative process will subsequently protect *Originality* and foster *Elaboration*.

Whereas Osborn and his followers of the Buffalo school focused on *Fluency* and came from the advertising world another group active in the 1950s focused on *Flexibility* and *Elaboration* and came from the technical invention world. Training groups of mainly technicians to come up with technological breakthroughs they experienced the power of *Metaphors* and the mechanism of *Forced Fitting* options from a completely different field to the problem at hand. Their approach to creativity is often referred to as 'Synectics' (Gordon, 1961).

The Brainstorming and Synectics practices are the main foundations of what is now referred to as CPS or Creative Problem Solving (Parnes et al, 1977, Isaksen et al, 2000). Other well known authors in the CPS tradition are de Bono (1971) and Van Gundy (1988). An important aspect of CPS is that it is always intended to be a group activity. Small groups of people execute the CPS-process. From now on we will refer to this group as the Resource Group.

Part of this group process is the particular task or role of the so-called *Facilitator*. This person is responsible for organizing and managing the CPS-group process. There is

consensus among the academics and practitioners in the field of CPS that the ideal size of a Resource Group should be 5 – 8 persons to work effectively under the guidance of one facilitator. Larger groups should be split up and thus need more facilitators (Isaksen et al, 2000).

In the CPS tradition (Parnes, 1967) the process the Resource Group will follow is not limited to one single creative diamond but consists of a sequential series of five separate diamond shaped steps:

Figure 2: The five CPS-stages based on Parnes, 1967

3 iCPS: Delft's expansion of the classical CPS-approach

Since the roots of Creative Problem Solving can be found in the USA and is as such rather USA culture biased while the classical (linear) CPS approach remains a challenge for European CPS practitioners. *Integrated Creative Problem Solving (iCPS)* is the attempt of the Delft University of Technology (DUT) to cope with these challenges (Buijs & van der Meer, 2013). The main characteristics of *iCPS* will be elaborated in the following paragraphs in four steps:

1. *The four sub-processes of iCPS:* Instead of concentrating on the *Content Finding* process only, *iCPS* consist of four interdependent sub-processes: Project Management, Information Finding, Acceptance Finding and Content Finding (see figure below)

Figure 3: The basics of iCPS

This leaves for the Content Finding sub-process only 3 diamonds as shown in the following figure.

Figure 4. The 3 diamonds of the Content Finding sub process

2. *Creative Diamond 2.0*: *iCPS* added a step of Reverting in the traditional two-step Creative Diamond of a Diverging followed by Converging step. This three-step Creative Diamond is called Creative Diamond 2.0.

Figure 5 The Creative Diamond 2.0

3. *iCPS basic module*: *iCPS* expanded the Creative Diamond 2.0 into the *iCPS basic module*. On top of Creative Diamond 2.0 a step called *Task Appraising* is added. After the converging step a *Reflecting* step is added. Thus the *iCPS basic module* consists of five steps: (1) Task Appraising – (2) Diverging – (3) Reverting – (4) Converging – (5) Reflecting.

Figure 6. The iCPS Basic Module

4. *The active role of the Facilitator in both process and content: iCPS put emphasis on the active role of the Facilitator and the need of content knowledge to be a good leader in the creative process.*

4 Methods besides iCPS

Besides CPS there are other methods known for complete problem solving processes. Aristotle provides us with a basic framework for our thinking on problem solving. First he separates essential knowledge (or closed problems as we suggest) from inessential knowledge (or open problems as we suggest). For essential knowledge Aristotle proposes one instrument: *analitica* we now know as *logica* or logical reasoning. For the inessential knowledge Aristotle proposes two instruments *rhetorica* and *dialectica*. The first being the art of persuasiveness in (oral) presentations and debates the latter being inquiry in a topic by dialogue. The rules for a good dialogue (see for instant the rules of Socratic inquiry; Jackson, 2001) show remarkably resemblance with iCPS.

In the following picture we place the essence of iCPS and the other methods in a matrix using the insights of Aristotle and whether the method is designed for groups or for individuals.

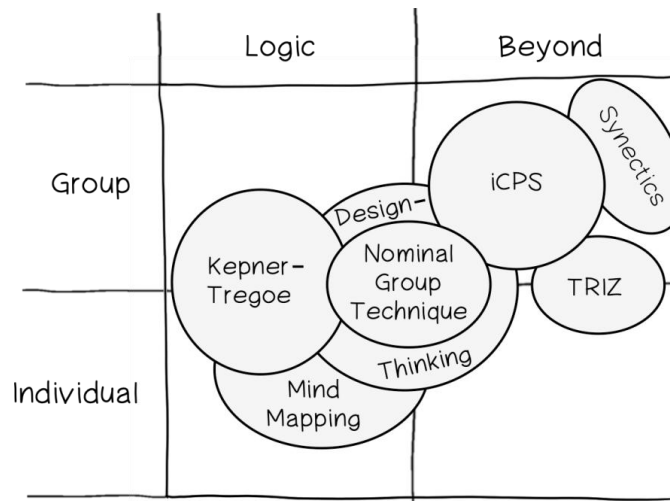

figure 7: An overview of methods

4.1 Kepner-Tregoe Method

The K(epner-)T(regoe) Method was developed in the 1960s by Charles H. Kepner and Benjamin B. Tregoe (1965), two social scientists conducting research on breakdowns in decision making at the Strategic Air Command. The KT-Method aims at rational analyses and decision-making. This method is used to solve problems in the logical domain aiming at implementing trouble shooting and to make a solid problem analysis. It is still one of the most used and trained method of rational problem solving in corporate settings (Spitzer & Evans, 1997). It is a rich source for techniques in the Problem Finding stage and for all convergent stages.

To break through the traditional patterns of long processes and indecision Kepner and Tregoe (1965) provide a series of four rational processes in which four fundamental questions are reflected:

- *Situation appraisal*: This clarifies the problem situation (what's going on?).
- *Problem analysis*: Here the actual cause of the problem and the relationship between cause and effect are searched for (why did this happen?).
- *Decision analysis*: Based on the decision-making criteria, choices are made to arrive at potential problem resolutions (which course of action should we take?).
- *Potential Problem analysis*: Here potential future problems are anticipated and preventive actions are developed (what lies ahead?).

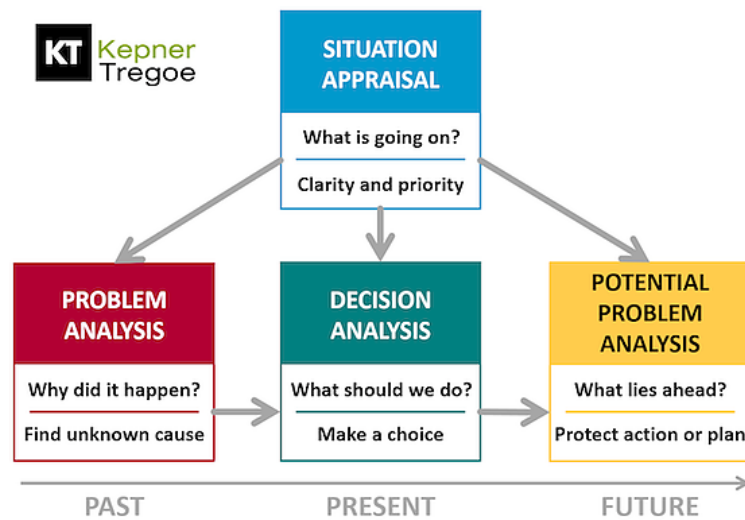

Figure 8: KT-Method (based on Kepner & Tregoe, 1965)

4.2 TRIZ

TRIZ a Russian acronym for Theory of Inventive Problem Solving was developed by Altshuller [Altshuller, 1984] and is continually being developed and modified. Genrich Altshuller (1926-1998) was a Russian researcher with German roots working at the Russian navy on the Caspian Sea shortly after the Second World War. He had an office job preparing patents for inventions made there by the military and surrounding services. From that position he had to go through dozens of patents every day to see if something had not been invented before. Slowly but gradually he got a view of the underlying patterns in all those patents. Even though it involved very different types of inventions, from new materials to engine parts it turned out to having a number of common elements. After criticism on the soviet regime he was send to the Gulag but was released after the death of Stalin. Unfortunately . A few years later he wrote his first articles and books on "TRIZ", a theory of creative problem solving (Altshuller & Shapiro, 1956) .

TRIZ is composed of a few distinct problem-solving and problem-definition procedures and principles as well as a unifying algorithm called ARIZ (Horowitz ,1999). The two most used procedures are:

Contradiction table. In this table the knowledge on solutions found in patents is represented. It is a two dimensional look-up matrix that connects pairs of physical attributes representing physical contradictions (e.g. length and weight) to operators that are known from past experience to be capable of resolving the specific contradiction.

Principles. Based on the specific type of contradiction, defined by the variables involved, that a case can potentially resolve. For example, if a problem involves a conflict between the *length of a mechanical element* and its *strength* (increasing length deteriorates the strength), the method directs the problem-solver to look at relevant principles f.i. principle 40 "Replace homogeneous materials by composite ones".

TRIZ has proven to be a strong method to provide for Flexibility (compare also Synectics).

figure 9: TRIZ is an Invention Machine

4.3 Nominal Group Technique

One of the challenges of Traditional Brainstorming is about sharing out loud options. Some Resource Group members may feel limited in their participation because of these distractions. Similarly, during the converging stage, some individuals may be too influential as well, due to personality or hierarchy. In the 70s Delbecq and van de Ven developed a group approach to minimize these influences: the Nominal Group Technique (1971).

Nominal groups are groups in which individuals work in the presence of one another but do not actively interact. As such, the Nominal Group Technique is a highly structured method used to build consensus in a group during diverging, reverging and converging, while minimizing bias and influence of individuals in the group. The Resource Group is asked to write down multiple options in silence. In turn, the options will be shared with the group, one option at a time, without discussion. Once all ideas are listed (and numbered) the ideas will be discussed for clarification (not for evaluation). Again in silence, a first round of independent voting or ranking will be conducted. After counting the votes, the results will be discussed plenary. If desired, another round of voting will be done. NGT is highly appreciated for setting up studies in the social domain (see also Engaged Scholarship by Van de Ven, 2007).

4.4 Mind Mapping

The original use of Mind Maps was for studying and memorising lectures and books and preparing papers. It is a system “to organise knowledge”(Buzan, 1974; p. 12). In the

later use of the method we see also mind maps for analyzing situations and preparing speeches or other actions.

Mind mapping is about finding keywords to describe the topic at hand. In the original version one should start with the central theme in the form of picture. From this central theme one should add associations (or connected keywords) on lines by words or pictures. For words one should use PRINT and the use of colours is promoted to highlight or structure. Adding two more rules the "Seven Laws of Mind Mapping" than are (Buzan, 1973):

1. Image in the centre
2. Words on connected lines
3. One word per line
4. WORDS IN PRINT
5. Colours
6. More images
7. Free Flowing Mind

In the work of Buzan (1974, 1993) the way to get a Free Flowing Mind is not explained although in his first works he combines it with physical exercise and a short interval of concentrated work and a long interval of break. Only a couple of pages in the work are devoted to the use of Mind Maps in groups and even then it starts with individually making mind maps and sharing them in an effort to make one big mind map. The method emphasis on diverging or "radiant thinking" as Buzan (1993) calls it and is very shallow on converging.

4.5 Design Thinking

Most of the methods on problem solving date back 50 years or more. A rather recently advocated method is Design Thinking. According to Dorst (2009) the term 'Design Thinking' has been part of the collective consciousness of design researchers since Rowe used it as the title of his 1987 book (Rowe, 1987). Tim Brown of the American design agency IDEO popularized Design Thinking in a highly cited article in Harvard Business Review (Brown, 2008). Studying the way designers work and adopting some designerly practices can be interesting to other fields because designers have been dealing with open, complex problems for many years, and the designing disciplines have developed elaborate professional practices to do this. Multiple models of design thinking have emerged since 1990, based on widely different ways of viewing design situations and using theories and models from design methodology, psychology, education.

Design thinking is build up from diverging and converging stages like our three diamond iCPS content finding model. Special attention is given to Information Finding for our first diamond (Problem Finding). An often used technique here is the Customer Journey (see f.i. Van Boeijen et al, 2013). We found no other techniques for ideation in the design thinking community than Traditional Brainstorming, Brainstorming with Post Its and Interactive Brainsketching. For our last diamond (Solution Finding) design thinking proposes Fast Prototyping & Testing and the techniques used here are depending

on the domain the design thinking is applied for. Since the method is often used in the development of digital tools for the web, A/B testing can be found regular. It seems too early to conclude upon the contribution of Design Thinking for the Creative Problem Solving field but in using it in other fields than strict design one should cope for the possible lack of designer knowledge and experience in the Resource Group. The criticism that starts on Design Thinking lately could stem from underestimating the necessity of these special qualities in other members in the RG than educated and experienced designers.

5. iCPS Techniques Categorized

In the methods many techniques can be found. Since the field of CPS is rather guru biased and each guru added some specific smaller or larger variants of these techniques (see f.i. de Bono 1971; VanGundy 1998; Van Leeuwen & Terhürne, 2010; Aznar & Bléas, 2018) are presented as “new” techniques. In total we found over 500 techniques in literature. Most techniques presented concentrate on the diverging stages. Only a few authors put also emphasis on techniques for converging (see f.i. Isaksen et al, 2000; Byttebier et al, 2007) and hardly any technique on reverging can be found (Heijne & Smit, 2018). Removing all doubles in these techniques we suggest a set of 40 essential techniques characterized by the following:

Type of problem (Divergent techniques only): iCPS can be applied to a wide variety of themes, such as thinking of new products or services, developing a commercial, thinking of new applications of existing products or technologies, developing a vision for a joint venture etc. It is found that some techniques are more suitable to certain themes than others. However, in essence, it is about two things: Is the Problem as Given (PaG) Complex or Single. This classification factor builds on what Souder and Ziegler (1977) refer to as ‘Ill-defined’ versus ‘well-defined’ problem statement and whether it is ‘well-understood’ versus ‘not well-understood’. Complex problems benefit from techniques with a more holistic approach and provide for some deep thinking. While Single problems thrive best on fluency and/or high energy techniques.

Type of options (Divergent techniques only): This classification factor is closely linked to ‘type of problem’ and depends on what the Problem Owner is aiming for: are ‘obvious’ options desired or is there a specific need to aim for options ‘beyond the obvious’? In many situations obvious options will be satisfying, especially if the aim of the session is to harvest existing options from a Resource Group or to build consensus about an intended decision. When truly new ideas, solutions or opportunities are desired or when a shift in paradigm is needed, it is recommended to choose a technique that is designed for generating options beyond the obvious.

Number of options (Revergent and Convergent and Acceptance Finding techniques only): Once a set of options is generated, it is time for reverging, followed by converging. The amount of options is essential for choosing an appropriate technique. Some reverging and converging techniques take more time and energy than others. Acceptance Finding techniques are also included in this classification factor, since it is a valuable indicator.

Instead of providing exact numbers, we created the following ranges: suitable for 1-3 options, up till 5 options, up till 10 options, up till 50 options or up till 100+ options. These ranges mean that techniques that are suitable for 100+ options can also be selected for reverging or converging 20 options.

Level of Experience (Facilitator and Resource Group): Traditional Brainstorming is an example of a technique that seems quite easy, since a lot of people claim to apply it often. In fact, it is one of the most difficult techniques in our collection to apply. The Facilitator needs a lot of expertise, and in addition, the Resource Group should have quite some experience and/or training as well. Other techniques are easier to apply, and require less rigid facilitation, like Brainwriting 6.3.5.. We suggest to classify all iCPS techniques, Session Duties and Methods into three buckets to indicate the level of experience required to apply them effectively: Novice, Intermediate and Expert.

Time: This factor is indicating the minimum amount of time required for an activity during the creative session.

Fun Factor: A scale of 1-5 (1 is low, 5 is high) is suggested to indicate the fun factor. Some techniques provoke a fun environment, which may foster both fluency and flexibility. The techniques with a high fun factor are beneficial for creating a positive and open climate and are particularly suitable for team building purposes. The fun factor is often linked to the group energy level, but not in all cases. It is a subjective factor we based on student ratings.

Other factors that are relevant for selecting and using the 40 techniques are:

Size Resource Group: The ideal size of a Resource Group is between 5 and 9 participants, given that there is one Facilitator. All iCPS techniques and Session Duties described in this paper are suitable for 5-9 participants. With larger groups, it is wise to split up the group into subgroups and involve more Facilitators.

On- or offline: The approach and techniques described in this paper are mainly focused on Resource Groups working in a face-to-face setting. However, sometimes a creative session is needed with participants who are working at different locations. Online sessions could be a solution, in which participants can work remotely, and in some situations even asynchronous (e.g. Collective Notebook). Although there are plenty of attempts to take (parts) of creative sessions online, it remains a challenge to respect the basic principles of good facilitation. Some interesting attempts are being developed at Stormz.me and Nureva.

In the table below the 40 essential techniques are presented. Since a lot of the materials presented in the literature on creativity techniques are more general in nature and cannot be represented in the techniques nor in the iCPS framework we suggest to represented these in so called session duties. We came to 6 clusters as represented in the table below.

Table 1 the 40 techniques and 6 Session Duties

Content Finding - Problem Finding

Figure 10 Techniques in iCPS

6 Conclusions and recommendations for further research

Guru driven

Most of the works on creativity techniques are guru driven and their books do not stand in an academic tradition. Similar techniques are presented with new names or slightly changed principles as complete new insights. The set of 40 techniques and 6 session duties within the iCPS framework is a first attempt to come to a standardized B(ody) O(f) K(nowledge). This BOK can be used to position the claims of new guru's.

From practitioners rule of thumb to evidence based

Techniques and methods in creative problem solving come from practice. Hardly any attempt is made to prove the efficiency and efficacy of the claims the authors of the various techniques and methods make. An exception can be made on the claims of the training in CPS. These claims are evidence based. Future research should try to fill the gap between the claims and evidence on technique and methods. A standard set of techniques (f.i. problem finding with 5W1H and restating the problem with H2's; idea finding diverging with a purge using Brainstorming with Post Its combined with a Creative Confrontation approach with a simple excursion like "What thoughts do a Blue Banana provoke in you" , reverging with Spontaneous Clustering and converging with Hits and Dots; Making a Poster for solution finding) could be the standard for a double blind procedure.

Abstract

This paper discusses arts as practice for business and society studies. Given that arts are necessary to develop business and society; how can valuable arts practices be learned? This conceptual paper is investigating how collective knowing develops in business contexts using art by unconventional painters such as Edvard Munch as examples of this process. The necessity of art is giving us a societal meaning of the process of knowing or a scripted story for enterprise action based upon the knowledge of art. The reflection and dialogue based on art might contribute to creativity and innovation in the business process. The paper develops a theoretical framework and theory for how this works.

Key words – Art management, Ideas, Creativity, Knowledge management, Innovation

Type of paper – Academic research paper

1. Introduction

This paper adopts a view that artwork can offer significant ways of experiencing and knowing that they can become of practical interest for business and society. The artwork at the University of Oslo became significant for manifesting Edvard Munch's paintings as a lasting value for Society (Ydstie, 2011).

As already contended by the philosopher David Hume (1739/1969), exciting experiences are fundamental for human understanding. However, a rich understanding of human knowledge and experiential capacities has tended to become lost in mainstream management studies, control of knowledge is stressed rather than its creation (Von Krogh, Ichijo and Nonaka, 2000). The process of working greener and smarter through new practices require time for reflection, learning and knowledge sharing. The slowness in adapting to emerging ecosystems might be found in hierarchical, top-down management

systems not allowing ordinary people to deliver extraordinary results based upon art, new cultural and social meanings.

We will in this paper investigate how collective knowing develops in art and business contexts giving us an expanded meaning of the process of knowing in practice. Our primary interest lies in how collective knowing develops based on art and culture experiences. Related research questions are what kind of understanding do we share, what means that are used to enable this development and at what pace this development takes place. We also need to account for the simultaneous existence of less known aspects or even non-knowing, when facing new or unfamiliar matters or concepts.

To illuminate arts as ongoing practices of knowing and non-knowing, we draw on works in two periods of the painter Edvard Munch. Born in Norway, Munch worked and exhibited in several European countries, he self-reflected in both visual artworks and poetic texts and took part in public exhibitions and debating with others. Although being met with much skepticism, he created seminal works for the future.

By addressing arts as a practice of both collective knowing and non-knowing in performances of high interest for society, our paper seeks to contribute to the future of businesses for society. The implication of art as practice in the knowledge process in businesses is an ambitious task, but we aim to find a theoretical framework for how this works and to state our point of view.

The remainder of this paper first explores modes of knowing and forms of representability as two fundamental notions in the art as practice. The paper then describes the emergence of particular artistic ways of illuminating and gaining new perspectives on collective knowledge. We are anticipating that the modes of knowing and non-knowing are resonating with on-going individuated and collective processes in art and business. The knowledge dynamics of art and business and an expanded dialogue might thus give meaning both to arts and business.

2. Methodology

We base the methodology of the paper on an exploration of clarified subjectivity concepts. We are exploring the concepts of knowledge together with the concepts of art and business. Our concepts are sensitizing seeking directions along which to look as opposed to definitive concepts seeking already predefined directions. We are further exploring the connections between art and businesses. We are not explaining the connections. We are instead using logic and clarification through our argumentation. We define this as a clarified subjectivity as opposed to pure subjectivity. Our methodological support is found in Feyerabend's book "Against methodology" (1993). Feyerabend argues that any pure falsification and a pure logic process will destroy any creativity or novelty in any science. We are not falsifying anything, but instead exploring possible directions along which to look for art and business. We draw on examples from unconventional artists like Edvard Munch. He explored new ways of painting and printing throughout his lifetime and became influential for international art practices as well as for

arts concerning business and society. Munch's art practices are thus of interest for both arts and business.

3. Modes of knowing

Rather than talking about types of knowledge, we will discuss ways of knowing as it is our perception that understanding is an always ongoing process. Types of knowledge only provide us with a snapshot of this process and thus give a static image of expertise. Hence, our modes of knowing model consist of a fluid scale from non-representable knowing to non-representative making the knowledge into representable knowing, where the boundaries between the aspects or levels are unclear. Non-representable and non-representative knowledge might also be labeled tacit knowledge, and the representative knowledge might be labeled explicit knowledge (Polyani, 1959). The tacit aspects of the knowledge process are challenging to explore. To explain the process towards the concrete result might be impossible both in art and business. Rotating professional roles and observation might give others the possibility to deliver similar results or knowledge about the imitation of the tacit process. The management process is also tacit in the way that we cannot say what works in different situations. When Thompsen (2019) summarized management to "all you need is love" that also pinpointed the subjectivity of what works in management. The processes of love, emotions, and intuition are indeed working, but how and when to use them remain a part of the tacit experienced way of leadership. There are also composition rules to follow and learn in art practices, but how to make them into high art remain a tacit process. Take the process of simplification of anything. There is nothing more challenging and difficult demanding professional knowledge, experiences and attitudes in all crafts, art, and businesses. The Japanese artist making the sea wave made it in a couple of hours, and it is spread all over the world as better than the reality (Gombrich, 1986).

Table 1 The different modes of knowing in art and business

Knowledge perspectives	Individual	Collective Group or Organization
Expressive theories Unfolded origins Nonrepresentative tacit knowledge	Immanent Subjective Original Human "Core"	Latent Unique Core (possibly distinguished) competences Access to talented people
Transformative theories Interplay and co-creation Experience as creation Representative knowledge	Creating Experiencing Feeling intelligence Participating	Performative as process and product Encounter in communication. Enlivened experience in a collective
Mimetic theories Influencers Representative knowledge	Absorbing Imitating role models Rehearsals	Sharing intentions, exemplary works Copying with others Inspiration and imitative exercises
Non-knowledge and ignorance theories Nonrepresentable tacit knowledge	Not-sensing Overlooking Imagining from invisible sources	Blindfolded organizing Performing outside the standard operating procedures Sharing situations of new or unfamiliar practices

Representability refers to what degree knowledge creations visualized or externalized and represented in texts, art, and metaphors. We have chosen to name three knowing modes. One is named non-representable knowing, which refers to the fact that it is impossible to represent. Another is named non-represented, which means that through specific processes or means it is possible to externalize parts of the knowledge. Finally, representable knowing is externalized and represented in art and texts, videos or other media. We can refer to, explain and help transfer or progress this knowledge through different forms of representations. Representable knowledge is the junior professional knowledge used in any training and is the foundation for the superior professional knowledge incorporating knowledge, experiences, and attitudes into own wisdom as an artist, designer or leader.

4. Non-representable knowing

Non-representable knowing is a mode that individuals or groups develop over time and that cannot be made explicit. Non-representable knowing itself thus takes place as individuals or groups gain experience, but it remains non-representable. Examples of non-representable knowing on an individual level are intuition, imagination, and emotions. It may not be easy to express why we make a particular decision, but our "gut-feeling" tells you that it is the right thing to do either you are in business or the arts.

We define non-representable knowing as "What we do not know that we do not know" and "What we do not know that we know." We will be striving to work with this knowing/non-knowing, which involve tacit and less articulable aspects, but from any great piece of art and a great piece of science and innovation, we know that suddenly one day we feel that we see the light.

5. Non-represented knowing

The scale of representability flows on towards non-represented knowing. This mode resonates with the tacit knowledge that Nonaka and Takeuchi (1995) saw as transferable through observation. It can be seen as implicit know-how and is a result of experiences that individuals, groups or societies have. Studying manuals or texts do not lead to this non-represented knowing – it also requires practical experience. Orr explained this mode of knowing as "both the ability to do things without being able to explain them completely and also the inability to learn to do them from a theoretical and a craft understanding of the task" (1990: 170).

6. Representable knowing

Towards the end of the scale, we find modes of knowing that we are more easily expressing or representing. We may communicate representable remembering through art, texts, symbols, and products. It recognizes that individuals and collectives rapidly can share and exchange. An example of representable knowing is what we are expressing in

this paper. What we can read is however only a snapshot of our knowing. Hence, we see one state of our work printed on paper, whereas it may have developed somewhere else – on paper, in our computer or our mind. These snapshots may be an art exhibition, a piece of literature, a business decision, a service or a product.

We define representable knowing as "What we know." This explicit knowing might be communicated as state-of-the-art knowledge and explained.

Figure 2: Modes of knowing

Figure 1 illustrates the modes of knowing that we have discussed above. The model visualizes how the different styles interact with each other and how they can shift from one degree of representability to another as we can see in the figure non-representable knowing only tangents the other modes. The little interaction intends to illustrate that the non-representable style of understanding has an impact on the different patterns, but it is difficult to shift it into more representable modes. The style impression has an impact on any piece of art. We experience it as the art of Edvard Munch or Hakon Bleken (see later sections). How do we make it non-representative and representative for businesses?

The ellipse with an arrow in on each end illustrates that knowing can shift in both directions, e.g., both towards, from, and within a mode. Missing in the figure are the linkages between individual and collective knowledge. This is the linkage that we would like to explore next.

7. Knowing and non-knowing as a collective activity

Sharing or appreciating unfamiliar knowing is not necessarily something that happens. From common sense, observations and articles we can conclude that shared knowledge is a result of a long and continuously ongoing process of uncertainty, conflict, needs and wants. There must be some prerequisites for collective intelligence to take place, and there also seems to be a need for a matter, means or tools that enable shared knowing. What these are and how they support shared knowing is the next thing we will try to establish.

Blackler argued (1995) that knowing both in art and businesses are purposive and object-orientated, which could limit specific knowing merely to clear aims. The existence of a purpose – whether articulated or habitually taken for granted – may be beneficial when seeking to enable the actual sharing of knowledge. A purpose does however not just arise out of nowhere. There must be a context or a situation in which identify a need or desire for knowledge.

Even experts may tend to stay in their current position doing more of what they have been doing before although they may have the possibility to explore the anomalies or unexpected phenomena. Kuhn (1962) describes how scientists are doing whatever they can to keep their paradigm as a normal science even if the paradigm is outdated.

Art may thus help us appreciate the knowledge gap and non-knowing but how? Through the socialization of art and businesses, we may get art to talk to us in a different way giving our business more creativity and an ability to walk in another direction. Individuals are often not aware of their own, deeply rooted, assumptions until a situation occurs where the assumptions surface and are made conscious in an interaction between individuals. Thus taking part in interactive and unfamiliar situations can create an opportunity for non-representable knowing to move into other known modes.

8. Illumination: Munch's art practices

In the following, we shall draw on research and arts-based texts grounded in art practices of Edvard Munch (1863-1944), an internationally renowned painter and graphic artist born in Norway. Munch worked for more than sixty years and produced a rich variety and quantity of paintings and prints. He is most famous for a few of his iconic paints such as *The Scream*, *Madonna*, *Vampire*, and *the Sick Child*. *The Scream* has become one of the most iconic images of world art, and one of four original versions was sold at Sotheby's in 2012 for a price of 120 mills. USD.

Beyond Christiania Munch came to spend time in nearby regions. He painted and sought inspiration outdoors. He traveled especially to Germany and France which offered artistic stimulations, places to exhibit, cafés, friends as well as enemies. The provincial town Christiania had artists like Henrik Ibsen, Edvard Grieg, Gustav Vigeland, Ludvig Karsten, Knut Hamsun (later Nobel prize winner), Harald Sohlberg, Nikolai Astrup, Bjornstjerne Bjornson (later Nobel prize winner). All of them were in opposition to the accepted paradigms within their arts. The contemporary European art, literature and classical music were through them present in Christiania. Explorers like Roald Amundsen and Fridtjof Nansen and new industrial businesses were also forming the city. Art, literature, music, and businesses were transforming Christiania in a new democratic nation striving to find an identity.

9. Vignette 1: The Life Frieze

Several of Munch's most famous paintings – called *The Life Frieze* – reveal inner states of anxiety and illness and they are often linked what has been called the symbolism

period, which also inspired German expressionism. Particular anxiety and strangeness associated with *The Scream* (1893) originated in Munch's walk outdoors in Oslo and a sudden moment of visual and emotional impressions. It is however not an explicit self-portrait or another recognizable person portrayed when walking in the sunset. Instead, it is depicted through a highly abstracted man or creature's apparent scream coming towards us in scenery where the whole landscape is in a whole disturbing move. Munch himself recalled that he had been out for a walk at sunset when he suddenly sensed "an infinite scream passing through nature" (Stang, 1977).

10. Vignette 2: The university paintings

The Aula decorations and Laboratory materials thus enable us to revisit an artist's work as well as his reflexive writings. Munch was breaking away from the Greek assumptions of what and how to portray in mural decorations and worked hard to find other radical ways of representing knowledge and non-knowledge. The works are a part of expressive German art. The expressionism is evident in Munch's decoration of the University Hall. Munch, who had gained fame in 1892 through his "scandal" exhibition in Berlin, discussed his drafts with German art friends and presented them at the exhibition in Berlin 1913. Highly acclaimed, they contributed to ensuring Munch the commission of decorating the University Hall. He created his paintings between 1909 and 1916 dedicated to representative and non-representative knowing of the past, present, and future melting together in a search for the unknown light.

11. Towards understanding arts as a practice

From Munch's art practices, we can learn how the shared context and situations matter in nontrivial ways. His difficult childhood did not merely harm this artist; Munch found several ways of dealing with and transgressing the dark sides when he painted and repainted *The Sick Child* in a close up more direct fashion that broke away from the conventional images. Knausgård (2017) underlines that Munch is expressing the presence of the death itself.

Interestingly, the contemporary Norwegian painter Håkon Bleken – who also experienced a challenging childhood and ambiguous relation with his father – also excels by zooming in on the dark sides including painting his dying father and mother in close-up, unconventional ways. In an interview Bleken explains how pace was an enabling factor; in fact, he painted very quickly with few broad strokes to avoid the conventional assumptions. In retrospect, he felt it had opened up for a better portrayal (Bleken, 2018). He also feels that painting fast give a better expression of the Holocaust, the Utoya and the Middle East tragedies. The fastness is not representable, and non-representative knowledge was becoming representative to paintings that question the essential existential situation for how we are willing to meet the tragedies of today and yesterday. Bleken paints them as ever existing situations we always have to handle. Bleken paints the

climate crisis as an invitation to recreate businesses and societies as sustainable ecosystems. The black death is meeting the blue survival.

Looking afresh at Munch's *Scream* painting reveals that the human creature approaching has the mouth wide open and with hands running up quickly as in a shocking inner state to embrace the head. The agonized face in the middle of this painting has become an iconic image of art seen as symbolizing the anxiety and uncertainty of modern man. What we are seeing make us scream.

We are moving from individual to collective knowing and vice versa. Munch engaged in various relations with significant others. The arts circles and café encounters offered some highly skilled and engaged people recurrent possibilities to share and debate contemporary artwork. Munch's way of evoking another presence in a variety of daily situations breaks with earlier artistic practices, for example, making a crowd appear ugly and hostile rather than beautifully painted. In this manner, the artist opens up for another proximity and even darker sides of human encounters. This darker side compares to Bleken's darker sides and presents an engaged art talking to us and confronting us with a life and death situation that does not leave us.

12. Opening up for new mental models

There are individual and shared mental models (Kim, 1993). In a socialization process, an individual's conceptions, understanding, and mental models change. However, the redefinition of the individual mental models can only take place when the individuals face a situation that is relevant to them (Richmond, 2000).

Trying to make mental models representable may however not be easy. It may also be an uncomfortable process because by expressing our deeply rooted assumptions we also expose them to critique and revision. Blackler (1995) argued that it is incoherencies, inconsistencies, and conflicts that offer learning opportunities. By facing incoherencies, disagreements, and disputes an individual is exposed to alternative assumptions and can thereby choose to adopt these or stick to the old ones. Bleken and Munch might give assumptions on sustainable and engaged businesses.

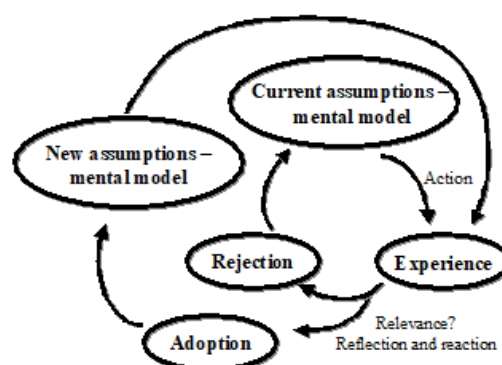

Figure 3: Development of new assumptions and mental models

13. Communication, language, and metaphors

Weick (1995) stated that "language is both the tool and the repository of learning. It is the critical tool for reflection, both at the inter- and intra-personal level. Also, language is a social phenomenon or stated differently, learning is embedded in relationships or relating learning is an inherent property not of an individual or an organization, but rather resides in the quality and the nature of the relationship, between levels of consciousness" (1991:18). From Munch, we may learn that both visual arts and poetic language can support individuals and collectives to make their knowing representable. When the Christiania Bohemians were talking with each other, writing and painting, some of their knowing/non-knowing became expressed and materialized. Their art became a manifest in a variety of ways of representing and non-representing knowing. Moving into non-representable knowing also means that metaphors partly determine the future collective knowing; "Metaphor is not merely the first step of transforming tacit knowledge into explicit knowledge; it constituted an important method of creating a network of concepts which can help to generate knowledge about the future by using expressions from any existing knowledge" Nonaka (1994:21). These expressions are a part of Munch and Bleken's paintings.

14. Observation and imitations

Figure 3 below illustrates the dynamics of knowledge between individuals and collectives and within a collective. The ellipses with the arrows in both ends visualize knowing moves within as well as between the modes and organizations. As in figure 1, non-representable knowing serves as a basis for the other knowing styles, since it filters what impressions, alternative assumptions and mental models that a group adapts.

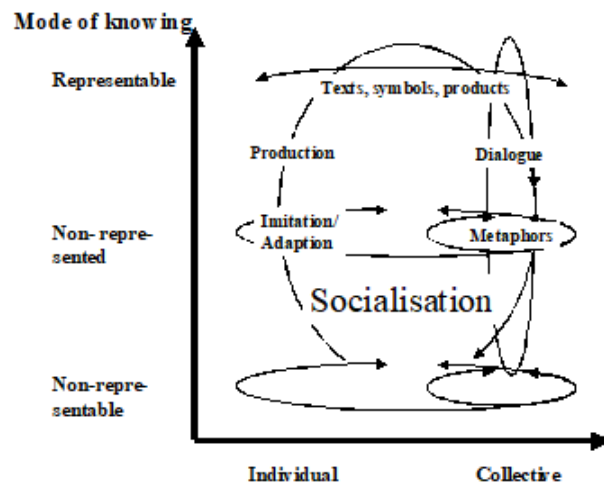

Figure 4: Knowing as a collective project activity

In the figure we also find the means or tools that enable and support the link between individual and collective knowledge. Socialisation contributes to all modes of knowing, but is especially crucial for non-represented and non-representative knowing. We have illustrated this with the horizontal ellipse that connects individual knowing to collective non-represented and non-representable knowing. Socialization contributes to both individual and collective knowledge since it provides a context within which both personal and shared mental models are challenged. Socialization and dialogue also give individuals an opportunity to develop and share metaphors and stories, which links non-represented knowing to non-representable knowing (illustrated by the vertical ellipse that flows through all three knowing modes). We use art and texts as a means for distributing metaphors and stories. However, because documents are static, only a one-way link is enabled, from representable to non-represented knowing. Dialogues, on the other hand, allow the interactive development of a story. In figure 4, the line that links the individual to collective representable knowing illustrates this.

The question often posed is if art can change the world or the actual behaviour. The traditional way of thinking is that art cannot transform businesses and society. Ideas and concepts can only do this transformation. We propose that art may also be converting the business community like the works of Munch. The conversion might be instantly or continuous. The Life magazine photo of the American soldier killing a pregnant woman in the Vietnam war changed the attitudes instantly. The Munch Scream describes the anxiety of modern times anytime. Picasso's Guernica changed the way we were and are looking upon the Spanish Civil War (Gombrich, 1986). Art is in transit between the non-representative and representative and might of this reason change an individual and collective perspective. Bleken's picture "Living the sales" shows the "best" in life is to save money on every seasonal sale. Having seen it, we reflect upon our life. We are concluding that art certainly can change perspectives, attitudes, and behaviour. Art may be vital for any business.

15. The pace of sharing knowledge: a proposed conceptual framework

What we have not accounted for hitherto is the pace at which knowing takes place. Knowing takes place and is shared at a different speed depending on what mode it is in, that means that we use and on the individuals involved. We can for example almost instantly share representable knowing, whereas non-representable knowing can take years to share.

All knowing takes place over time but at what pace is determined by how well the individuals know each other and what kinds of means they use to support recognizing. Our understanding is that the more time individuals spend together, the faster is the pace at which knowledge becomes collective. On the other hand, a problem can be that after a while collective non-representable knowing becomes so strong that it may be difficult for the group to adopt new assumptions and mental models.

Finally, the pace at which knowing shifts between the different modes depends on the circumstances under which knowing takes place. If the knower is contributing necessary

ingredients or a leader in a collective, it is more likely that knowing is adopted than if the knower is at a lower level or working in unrecognized enclaves of the organization. Art may influence what we think about the knower. In figure 4, we have illustrated the dynamics of knowing within a team and between individuals and organizations.

Figure 5: Pace of change within a collective and between individuals and collectives

The greyed-out lines in the figure illustrate that there are no absolute ends on the scales. In a new team, it takes some time to get to know each other, define the individual roles, and to develop a shared culture and shared mental models. The black circle in the lower right corner illustrates this. Further, at this early stage of the establishment of a team, the influence of new members is faster than it is when the team becomes more established. The lack of a strong-shared culture makes it easier to influence the development of a collective culture. The black line that goes from individual to collective non-representable knowing illustrates this. The lower grey line, on the other hand, demonstrates that, once the team culture is becoming established, the team tends to be critical towards new ideas and assumptions, which also makes it slower to change. As team members get to know each other better the pace of non-representable knowing is faster than in new teams.

16. Conclusion

Firstly, we identified three similar modes of knowing in art and businesses. The non-representable knowledge is what we do not know that we do not know and what we do not know that we know. We can thus not make the knowledge representable, but suddenly we will know that this is the painting, the book or innovation to be made. Non-Representative knowledge is what we do not know. We are still able to see or feel or make a kind of representation. Munch made multiple sketches and recurred to motives.

The representative knowledge is what we know and how we can represent the knowledge through a piece of art, a book or a product. In the making, we revisit our tacit knowing and non-knowing and explore their boundaries further in process and product. A piece of art might then start as well as nurture the process of a business idea or an innovation.

Secondly, we recognized that what makes theory and a piece of art exciting and influential is that it challenges our assumptions in some significant way. The piece of art or theory talks to us in a way which we can use it in our daily life.

What is it that people (re)present in the present and the future? Collective knowing are ideas and concepts that a collective and its interests engage in and develop over time, and that guides and give meaning to actions in a specific context. However, collective knowledge with its implicit shadowing may need confrontation and illumination of possibly veiled non-knowing of dark or ignored sides to test and renew our assumptions of true beliefs. We have revealed that art practices and their collective apprehension can become transformed into new meanings of societal importance, as exemplified in the paintings of Munch and Bleken.

Thirdly, the boundaries between individual and collective knowing are blurred, and it is difficult to determine how they affect each other. Everyone has individual mental models, but also share assumptions and mental models with others, and this implies that art unfolds and travels between individuals and groups. Art is vital for creative and innovative mental models.

Finally, art might also start a process of business and societal responsibility looking at Bleken's picture of the tragedies of Utoya, Holocaust, the Middle-East and the Climate. Art represents a form of its ecosystem where Bleken's tragedies and Much's actual Aula pictures might be the start of thinking about sustainable ecosystems in businesses. These eco-systems are today represented in the way that we know that we are reaching a global warming crisis, but we do not know how to recreate businesses into eco-friendly systems and by that the survival of the earth.

Abstract

The purpose this paper is analysing and comparing all the papers in the proceedings of IFKAD in 2016 (Dresden), 2017, (St. Petersburg) and in 2018 (Delft). The study is classifying the papers according to methodology, analysis, discussion and conclusion regarding their contribution placing them into the four paradigmatic boxes. The approach is to use a philosophy of science framework and compare this to the content of the research papers. We will use the findings in four representations of knowledge, two typologies of concepts, four paradigmatic classifications and in the concluding framework for knowledge management research.

All three conferences have a heavy emphasis upon knowledge-itis and instrumental-itis and much less emphasis upon problem-itis. The papers are mostly centred around existing knowledge and accepted methodology and less related to new problems.

The IFKAD studies both in 2016 and 2017 have rather low complexity presented in an empirical and materialistic paradigmatic framework through definitive concepts representing a form of atomistic research. The complexity to more problem based studies are increasing slowly in 2018. The 2018 conference represented a more inductive research based upon sensitizing concepts and action paradigms. The progress is however slow. What would IFKAD have been with a higher degree of complexity in action and subjective paradigmatic frameworks through sensitizing concepts representing a form of holistic research? Probably a more creative, engaged and relevant conference. Objectivity is in demand, but subjectivity is needed to come up with proposals for working greener and smarter.

To move ahead for better quality in the research it is necessary to break free from the empirical paradigm and the materialistic paradigm and move into the clarified subjectivity and action paradigm. Paradigmatic ecumenism will tend to a fiercer, but an idea-generating debate. This pluralistic approach will give more engaged practical research representing more sustainable societies and businesses.

Keywords - Paradigms, Concepts, Perspectives, Knowledge creation, Knowledge accumulation

Paper type –Academic research paper

1 Introduction

Tornebohm (1983) conceives social science as a sequence of partly cumulative and partly non-cumulative transformations of knowledge (K), problems (P) and instruments(I). Tornebohm (1983) argued that if the sciences and social sciences are going to progress there has to be a balance between K, P and I. An overemphasis on any of them will hinder a free scientific discourse and by that the development of any scientific field. A central notion for instance from the compound (K1, P1, I 1) to (K2, P1, I2) occur when the problems P1 are solved to increase the stock of knowledge from K1 to K2. In the problem-solving process, new instruments may be developed or borrowed from other disciplines, at this moment changing I1 to I2. If one of the three aspects is allowed to dominate the other two, the discipline becomes less relevant. Overemphasis on knowledge ("knowledge-itis") may result in empirically empty structures irrelevant to the problems. Empty content structures are the case for business school research in general (VendeVen 2007, Olaisen and Revang 2017) where business schools are producing more and "better" research than ever, but the practical business world finds the results less relevant than ever. Preoccupation with problems ("problem-itis") may mean shallow pragmatism and conceptual malnutrition. Finally, too much attention to instruments ("instrument-itis") may erode the substantive core of a discipline. The focus of the studies is how to practice the research methodology in itself. The researchers end up testing themselves if they can master the instruments and not the theories. Tornebohm (1983) identifies these imbalances in the researcher's orientation as a lack of commonly agreed upon perspectives and something less than social science and something more than fiction. Kuhn(1970) identifies it as a pre-scientific situation where any discipline might remain until the discipline dies or advances a new paradigm.

The initial KPI maps the aspect of interest (in this case feature of knowledge structures or processes). The KPI compound in this process filters through what is called the "researchers orientation and worldview" or perspectives in Tornebohm's words (1983) or paradigms in Kuhn's words (1970) or research domains in Olaisen's words (1985). These authors are all referring to the fact that there are alternative ways of approaching the social sciences and by that also knowledge management research. The aspects studied are not given once and for all. New knowledge widens the boundaries, as might happen after the broadening of the knowledge management research. Thornebohm's idea is that pluralism is needed in any discipline to get an accumulation of knowledge and if this pluralism is lacking over time any discipline will erode and be a form of mechanistic puzzle solving of more and more irrelevant problems. The relevance will be found in other disciplines replacing a discipline over time. Kuhn (1970) labeled this as normal

science activities where the scientists agree upon what is good science reproducing obvious results in quasi scientific ways to gain respect within a smaller and smaller circle.

Galtung's (1972) idea was to identify four ways of approaching the social sciences in a triangle of theory, data and values:

- (1) Empiricism – is what we are presenting true or false (if true consonance if false dissonance)
- (2) Criticism – is what we are presenting acceptable or not acceptable (if acceptable consonance if not acceptable dissonance)
- (3) Constructivism – is what we are presenting adequate or inadequate (if adequate consonance if not adequate dissonance)
- (4) Pluralism – a triangulation of empiricism, criticism and constructivism (if congruence consonance if not congruence dissonance)

Galtung (1972) assumes that a common goal of all social sciences is to establish what is called sentences dichotomizing their "world space" by including some defining the empirical world by including some "world points" and excluding others. Hence, data sentences are reports explaining the empirical world by including what they observe and eliminate what they do not see or imagine. Theory-sentences (hypotheses or propositions) on the other hand, define the foreseen world, including aspects which are predicted by the underlying theory. Finally, value sentences refer to the preferred world, including what is accepted and excluding what is rejected. Galtung's idea was that all the social sciences could be analysed according to this framework. This is the first time Galtung's and Tornebohm's approaches are used to analyse knowledge management research.

Blumer (1969) argued that research concepts in any of the social sciences might be divided into definitive concepts and sensitizing concepts. The concepts have an essential role in any scientific inquiry. They are usually the anchor point in the interpretation of findings.

The purpose of the definitive concept is to:

Describe-Explain-Predict and Control and Rule (A definitive and objective process).

Bunge (1967) named this process as "the process of all serious systematic research".

The sensitizing concepts have another purpose:

Describe-Explore-Reflect-Participate and Change (A subjective and relative process).

Glaser and Strauss (1967) named this process "Grounded-theory-research".

Olaisen (1985) divided any kind of knowledge into four types of knowledge:

- (1) What we know defining
- (2) What we don't know implying
- (3) What we don't know that we know as a part of
- (4) What we don't know that we don't know

According to Olaisen to get a scientific, intuitive and creative movement between these four types of knowing represent the essence of representable and non-representable knowing modes in any science and social science.

Olaisen (1985) divided the social sciences into four paradigms in a quadrate of harmony versus conflict and objectivity versus subjectivity:

- (1) The empirical paradigm
- (2) The materialistic political paradigm
- (3) The clarified subjective paradigm
- (4) The action paradigm

2 Methodology

The purpose this paper is analysing and comparing all the papers in the proceedings of IFKAD in 2016(156 papers), 2017(164 papers) and 2018 (171 papers). A total of 491 academic research papers within a framework of 5000 words for each paper. The approach is to use a philosophy of science framework and compare this to the content of the research papers.

We have used five philosophy of science frameworks to analyse all the papers:

- (1) Tornebohm's knowledge, problem and instrument description (1983)
- (2) Galtung's scientific perspective triangle (1972)
- (3) Olaisen's four kinds of knowledge identification (1985)
- (4) Blumer's two kinds of scientific concepts (1969)
- (5) Olaisen's four kinds of paradigms identification (1985)

This paper has combined (4) and (5) as a pluralistic proposal for future the progress for knowledge management research.

Each paper has been classified according to:

- (1) Problem
- (2) Methodology
- (3) Theoretical foundation
- (4) Propositions and/or hypotheses
- (5) Analyse
- (6) Discussion of results
- (7) Conclusions
- (8) Theoretical and practical implications

For each academic paper a decision has been made for each of the five frameworks according to which format the paper fits into. The decision is based upon the reading of the paper. For two thirds of the papers the decision of placing them into a category was clear. For one third of the papers we had to make a subjective decision for which category we placed them into. The decision is based upon our notes from each paper and if in doubt we have reread the paper.

3 Knowledge-it is, instrument-it is and problem-it is

The papers are suffering from "instrument-it is" and to some extent from "knowledge-it is," but they are certainly not suffering from "problem-it is." Problem-oriented research is demanding and require systematic and logic argumentation (Lawrence 1992). Problem-orientated research might be a weakness for knowledge management researchers. The researchers do the statistical tests well and the researchers present the data in "nice" total packages as a form of truth. Very few results are however in conflict with existing results or anything at all. 2 of 3 hypotheses are found to be correct and 1 of 3 hypotheses are found to be incorrect. In papers dealing with knowledge sharing and knowledge management there are many similar hypotheses/propositions (44%) while 51% reach the same result and 49% reach a different result for similar propositions and hypotheses. The Popperian falsification process (1973) are used for both explicit and tacit knowledge processes even if 82% in 2017 and 84% in 2018 of the papers do not make any distinction between tacit and explicit knowledge processes. This might represent a lack of theoretical sophistication. Two third of the papers lack a definition of knowledge, information, management, leadership or the situations these concepts are used in. The lack of definitions give a kind of storytelling where a story exemplified with statistics is told. This is what Kuhn (1970) named a pre-scientific situation where anything might be equal in importance or what Popper (1973) described as the situation for psychology as a field. Kuhn (1970) called this "something less than research". The lack of problem-it is makes it difficult to make progress. There is an improvement in 2018 where as much as 18% of the papers are concentrated upon the problem itself and not the instruments, data or solutions.

More than 50% of the papers write about the need for new ways of knowledge leadership, knowledge management, and knowledge organizing. The papers however are centred around traditional leadership, management and organization issues. The papers label and marketing that they are proposing new ways of leadership, management and organizing, but they do neither define the situation today compared with the situation tomorrow nor how we are going to take us to tomorrow. The problems in the papers are centred around solvable matters and very seldom if anytime related to unsolvable problems. We are defining such "instrument-it is" and "knowledge-it is" in knowledge management research as a misdirecting striving for respectability. Twenty-one of 491 papers discuss the problems of our ecological systems and what we need to do to solve the climate crisis through sustainable businesses. These green ecological papers ask a number of questions they are not able to answer and are thus speculative and are all conceptual papers without any empirical basis.

4 The aspects of the world studied

We are making a distinction between four areas of knowledge in management research: "What we know"(1), "What we know that we don't know"(2) and "What we don't know that we know (3) and What we don't know that we don't know"(4). Area (1)

will define the area (2) while there will be a misinterpretation and bias towards area (3) and area (4).

(1) WHAT WE KNOW	(4) WHAT WE DON'T KNOW THAT WE DON'T KNOW
(2) WHAT WE DON'T KNOW	
(3) WHAT WE DON'T KNOW THAT WE KNOW	

Figure 1 Knowledge representations (Olaisen 1985)

For area (3) and area (4) will imagination and intuition be necessary f

If we want to move between area one and two the logical, empirical studies ("secure and clean studies") will be ideal, but the source of bias and misinterpretations start as soon as we move into what we do not know anything experienced. We will here begin to involve imagination and intuition. Experience-based intuition is the start point of any essential research effort while the movement from area one to area two is only instrumental puzzle-solving most often without any knowledge accumulation (Minzberg 1979, Morgan 1980). The way to improve our technique is not to attempt to analyse things into their elements, reduce them to measure and determine functional relations, but to educate and train our intuitive powers (Knight 1936). If our role is only to produce some publishable or travelable research, then we are reduced to mechanic puzzle solving demonstrating that we can master the techniques we were learning in our Ph. D's. Between 80 and 90% of the research papers in 2016 and 2017 represent this kind of mechanic puzzle solving (Morgan 1980). We are sending out a questionnaire to a large sample getting a response rate of 5-20% applying statistics and getting a classification of research results in nice tables, diagrams and figures getting more of the same trivial already known knowledge. In the 2018 conference the mechanic puzzle solving is reduced to 70%, but the response rate is at the same low level.

5 Scientific orientations

Galtung (1972) assumes that a common goal of all social sciences is to establish what is called sentences dichotomizing their "world space" by including some defining the empirical world by including some "world points" and excluding others. Hence, data sentences are reports explaining the empirical world by including what is observed and excluding what is non-observed. Theory-sentences (hypotheses or propositions) on the other hand, define the foreseen world, including aspects which are predicted by the underlying theory. Finally, value sentences refer to the preferred world, including what is accepted and excluding what is rejected. Most of the papers (65%) in 2016 and 63% in 2017 do not develop hypotheses but do only describe the findings of the theory without

concluding it into hypotheses for testing (Bunge 1967). This is increasing to 72% in 2018. The research is, however, comparing data-sentences with theory-sentences without using Poppers falsification principle (Popper 1972). A dissonance does not result in producing new theory sentences while a consonance occurs in noting that the research results are in line with mainstream knowledge management research. Criticism is the type of scientific activity where data-sentences are confronted with value-sentences. By the tenets of this orientation, consonance is created by producing new data sentences by changing the aspect of reality into an acceptable condition. Criticism is not a large part of the IFKAD 2016, 2017 and 2018 papers (15% versus 16% versus 18%). Criticism is needed through values, speculations and ad hoc methods to advance a field even if the validity and reliability are low.

Constructivism implies comparing theory sentences with value sentences to see to what extent the foreseen world is also the preferred world. Consonance refers to what is adequate and dissonance to what is inadequate. In the case of dissonance, theory and value sentences are about equal in priority, and both might be changed in knowledge management research. Constructivism represents around 20% of the papers. The business reality is today complex and global. A combination of the understanding of both wholisms and atomisms is needed in a good research strategy (Minzberg 1979) and for actionable puzzle solving (Morgan 1980). Imagination and intuition are required for this process (Bunge 1967, Alvesson and Skjoldberg 2009). The intuitive powers seem to be less trained among the IFKAD researchers. Intuition, imagination and creativity is needed to handle a high degree of complexity like scenarios for the business future or the green environmental future. Such complex scenarios are only handled in 11 of the papers (5%) where both criticism and constructivism are handled at the same time to come up with what is acceptable and not acceptable for the society going on with what is further adequate and what is inadequate for the businesses. This might as a result give us a greener, smarter and safer world where the businesses and societies walk hand-in-hand. This subjective and actionable research for a better future is missed in the IFKAD papers. Also missed is what kind of leadership will take us into a more responsible sustainable world.

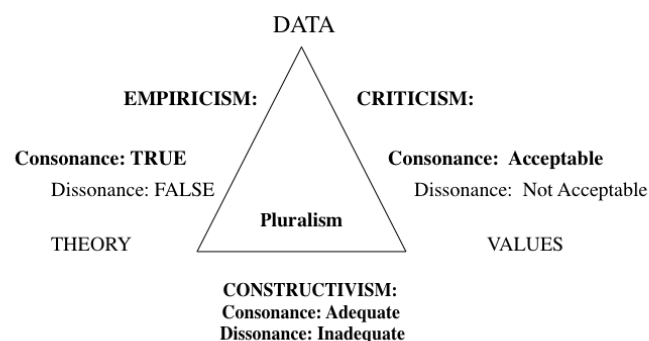

Figure 2 Empiricism, criticism and constructivism

6 The rise and fall of paradigms

The essence of Kuhn's position (1970) is that paradigms serve a normative and conserving function. When a standard prevails in a discipline, so-called "normal" science practice evolve as the puzzle-solving activity. During normal science, the scientific community works under the assumption that "it knows what the world is like," and is prepared to defend this assumption "at any cost." (Kuhn 1970: 5). Very often normal science suppresses "major novelties, conceptual or phenomenal" (Kuhn 1970:36). Thus scientists are only preoccupied with solving problems/puzzles according to accepted specific rules that are according to the traditional viewpoint or preconception.

Kuhn writes that "there can be a sort of scientific research without paradigms, schools, perspectives" ... (1970:11), in such research "... though the field's practitioners were scientists, the new findings of their activity were something less than science or social science" (1970:13). He further notes that "... every individual researcher starts over again from the beginning" (1970: 13), that some competing schools are directing their publications where they may be published, and a continued discussions over the same fundamentals and no progress is made at all" (1970: 159).

We may sum up Kuhn (1970) in this way:

1. Only readily available facts are collected.
2. At this stage, all facts seem equally relevant.
3. The instruments are overemphasized and often presented in "quasi-fanciful" ways to get "false" respect.

If we look at knowledge management research at IFKAD, we conclude that this is the situation for more than 80% of the papers. In fact, the 2017 papers were slightly less scientific than the 2016 papers – 81% versus 83%. While the 2018 papers improved to be to 76%. There is some progress in making knowledge management more scientific and robust. We found that Kuhn's description fit the situation in knowledge management research very well. It looks like every researcher starts over again from the beginning was easily collected survey, and case data are assembled and presented in fancy scientific ways.

For Feyerabend (1974), this was the situation in the management literature where one case description follows the other case report without any accumulation of knowledge. According to Feyerabend, this is a storytelling tradition where the marketplace gives new stories all the time. The faster the marketplace develops, the more the researchers will be in dissonance with the market. They will according to Feyerabend (1987) produce more and more "hard science" stories without basis in reality, but with a kind of basics in business schools further and further from the firm itself. The businesses itself will find the highest rated research less and less relevant (Van-de-Ven 2012, Olaisen and Revang 2017). The ruling group in business schools is its own exclusively audience and often behaves like a mob against revolutionary thoughts. The group is dogmatic, authoritarian and narrow-minded. They represent a groupthink. The mind is with other words temporary closed. The highest aim is to control the field and the rules for the accepted puzzle-solving activity. The rules of the puzzle solving activity become the most

important issue. There is a Matthew effect in work – those who do it the most accepted way shall get more, and those who do not do it the accepted way shall not be published or getting tenure (Merton 1968). Most researchers in knowledge research are trained in Ph. D. programs with an emphasis on empirical studies. They know that to get papers accepted, they have to follow the "correct" researchers, have a representative sample and use a proper statistical package to prove your results and end up with decent results or a proposal for another knowledge framework.

7 Alternative concepts

The concepts have an essential role in any scientific inquiry. They are usually the anchor point in the interpretation of findings (Blumer 1969 and Baugh 1990). The concepts are the glasses we have used since we got our Ph.D's. We discuss two different worlds of ideas. The definitive concept is based on empirical data or "evidence" and often with the search for causal relationships.

The more definitive concepts are linked to "what we know and "what we know that we do not know, while the more sensitizing concepts will be related to "what don't know that we know and "what we do not know that we do not know." Sensitizing concepts will advise where to look and will set up and compare alternative views. They will be more indications on relationships, and they will be dependent on inductive research methods and precise descriptions. Definitive concepts represent deductive quantitative research methods. For induction, the sample of 0 (imagined sample) or 1 might be good enough while deduction requires large samples. Induction is closeness while deduction is distance. Induction is participation and involvement while we do not interfere at any price. Induction might be exploring, and actionable while deduction might be explaining without action.

In knowledge management studies, the definitive concepts are taking over the ground of the sensitizing concepts. Taking all the papers and dividing them into one of these ideas around 70% of the studies rely on definitive deductive theories while 30% rely on inductive sensitizing concepts. In the IFKAD 2018 about 65% rely upon definitive concepts while 35% rely upon inductive sensitizing concepts. The induction process described as "directions along which to look and use intuition and curiosity" instead of facts or data is less used. Intellectual curiosity might be the path to choose for creative scholars. The papers are becoming more deductive and definitive in the 2017 conference compared to the 2016 conference. While the papers are becoming slightly more inductive in the 2018 conference.

8. Alternative research paradigms

It is here proposed to analyse knowledge management research in four main perspectives. These alternative realities are different meta-theoretical assumptions about the nature of social science. The empirical paradigm where its explanatory power consists of establishing causal variables between variables. The knowledge systems and the

knowledge technology relations have a concrete, real existence and systematic character producing quantitative and qualitative findings according to the need for the societies and businesses. The business world is considered primarily as conflict-free and harmonious at a higher level of aggregation. 50% of the studies in 2016 versus 45% of the 2017 papers versus 40% of the 2018 papers belong here.

The materialistic political paradigm is physical events and behaviour where the surface is manifestations of underlying mechanisms. The materialistic paradigm relies on the assumption of predictable uniformities in the knowledge systems. The world of knowledge systems exchanges is defined by concrete, measurable, ontologically real structures and the interdependencies in knowledge systems. 20 % of the studies in all three conferences are found here.

The clarified subjectivity paradigm holds social reality does not exist in any concrete sense but is the product of the subjective and inter-subjective experience of individuals and organizations. According to this paradigm; knowledge behaviour must be understood from the viewpoint of the employee and organization rather than from the outside observer. We can only get such understanding by direct, give-and-take interaction with the employees and organizations. We can, of course, get in surveys as questionnaires, but then we are defining the questions and the business situation. 25% of the studies in 2016 are here versus 27% of the 2017 studies and 30% of the 2018 studies. The action paradigm (5% of the studies in 2016 and 8% of the studies in 2017 against 10% in 2018) also assumes that what passes for reality is socially determined. The role of knowledge research is to identify the stakeholders in the systems, their goals, interests and power bases to describe the conflicts and contradictions of the knowledge systems and also show the way to emancipation, for instance, working smarter or greener. Knowledge management researchers inspired by the action paradigm are concerned with discovering how individuals can link thought and action as a means of transcending their alienation. The papers often analyse the situation where the author is a consultant, owner or employee. The relationship to the investigated firm is close. The results are own experiences, knowledge, and attitudes from the actual situation resulting in practical and theoretical recommendations.

Figure 3 Research paradigms

9 The fall of knowledge management as objective research?

The action-driven and the clarified subjectivity paradigms represent a different degree of complexity and subjectivity. They represent both harmony and conflict. Various levels of complexity require different research paradigms; Pluralism is demanded to catch different aspects of reality. Subjectivism is necessary to capture complexity.

As a consequence, we will have to define this discipline as a subjective multidiscipline, and we will have to innovate, simulate an experiment to a much higher degree. We will have to accept ad-hoc hypotheses and ad-hoc methodological solutions and the clarified subjectivity. We need to cooperate with businesses and the society to participate in getting research from sustainable societies and businesses supporting a greener, smarter and safer solutions. A more engaged knowledge management research field is needed to be a part of the sustainable, global and digital businesses replacing traditional businesses.

Feyerabend (1974,1987) represents this anarchistic, irrational and artistic view of science and social science. However, in reality, scientists follow "irrational" rules in any science, and there is progress. Therefore it is not needed any rules and a research strategy supporting this (Minzberg 1979). As a consequence, we will have to define this discipline as a subjective multidiscipline, and we will have to explore, innovate, simulate and experiment to a much higher degree. We need more subjectivity, conflicts and less harmony and objectivity in our research. There is a movement in leadership and organizational methodology towards phenomenon research taking research out of the iron jacket into a flexible and soft jacket opening up for alternative realities (Doh 2015, Schwartz and Stensaker 2014, von Krogh et al. 2012).

10 Synthesis and conclusion

Figure 4 presents a form of synthesis of our reflections. One of the axes represents the degree of complexity and the other the level of subjectivity. The definitive concepts represent a small degree of subjectivity (i.e., the high degree of objectivity if that is possible) while the sensitizing concepts express a high degree of subjectivity. The four paradigms might be subjective or objective. Objectivity does not exist any longer. The problematic question is: if we choose one model, will it then be possible to move on from a low degree of complexity to a higher level of complexity (i.e., can we generalize from a tiny part of reality to a more substantial portion of the fact). Are the models interchangeable? It might be impossible or desperate to move up the line from origo to a higher degree of complexity and also from the top to Origo (Alvesson and Skjolberg 2009, Bunge 1967). The knowledge research reality in both businesses and climate conflicts offer global complexity. To understand this, we have to apply subjective paradigms combined with empirical investigations. Eisenhardt and Grabner (2007) describe this kind of theory building. We have to use sensitizing concepts coupled with actionable definitive ideas. We have a field like knowledge research to understand whatever we are applying it is subjective, but it is systematic and logical rigid.

Abstract

Working in collaborative groups and teams now represents the practice predominantly adopted by organizations aspiring to create innovation and to remain competitive (Korde & Paulus, 2017; Paulus, 2000). However, this trend towards boundless collaboration at work is harshly criticized by a theory called the “New Groupthink”, which argues for a resulting discrimination of introverted employees (Cain, 2012, 2013). According to this perspective, introverts suffer from working conditions that inhibit individual and quiet work. The theory consequently argues that the current shift towards limitless collaboration overall elicits lower creativity and achievement levels due to the resulting suppression of introverts (Cain, 2013). Provided that the “New Groupthink’s” claim is reasonable, this inefficiency hence depicts a relevant issue for companies by reason of creativity and innovation’s decisive stake in today’s turbulent environments.

This paper examines the existing performance gap between introverts and extraverts in group brainstorming. This research aims at assessing whether hybrid brainstorming can equate introverts with extraverts by balancing their idea contribution and therewith lower the effect theorized by the “New Groupthink”. It is intended to suggest solutions to both introverts, with regards to enhancing their stake in brainstorming, and companies, with regards to how to apply this ideation method in its most efficient way.

The research at hand is of quantitative nature, whereas the methodological approach selected constitutes an experimental study. The sample consists of a total of 87 business students; personality types are differentiated according to the introversion-extraversion dimension. Based on the obtained results, inferences can be made about the effectiveness and suitability of the traditional and hybrid brainstorming methods considering the proportionate idea-contribution and post-brainstorming satisfaction levels of the two personality types. Results indicate that applying hybrid brainstorming is suggested to be

suitable for both introverts, who feel omitted in traditional brainstorming, and companies, to better include introverts' ideas and to enhance overall results. The study adds original contributions to the creativity and brainstorming literature by providing first suggestions of how to counter the "New Groupthink" effect. It emphasizes the need to further explore the scarcely researched factor of personality in brainstorming and to search for solutions to strengthen the contribution of introverts. Further studies are required to elaborate on the hybrid methods' potential with regards to the empowerment of introverts in ideation.

Keywords – New Groupthink, Brainstorming, Creativity, Introverts vs. Extroverts

1 Introduction

Today, increasingly globalized competition, new possibilities for production, as well as fast-paced technological developments jointly force companies to find strategies to assure their competitive advantage and long-term survival (Mumford, Scott, Gaddis, & Strange, 2002; Tang, 2016). Resulting therefrom, creativity and innovation have become central areas of interest as well as key success factors (Anderson, Potočnik, & Zhou, 2014; Mumford et al., 2002; Tang, 2016). In this context, working in collaborative groups and teams now represents the practice predominantly adopted by organizations aspiring to remain competitive (Korde & Paulus, 2017; Paulus, 2000). However, this trend towards boundless collaboration at work is harshly criticized by a theory called the "New Groupthink", which argues for a resulting discrimination of introverted employees (Cain, 2012, 2013). According to this perspective, introverts suffer from working conditions that inhibit individual and quiet work. The theory consequently argues that the current shift towards limitless collaboration overall elicits lower creativity and achievement levels due to the resulting suppression of introverts (Cain, 2013). Provided that the "New Groupthink's" claim is reasonable, this inefficiency hence depicts a relevant issue for companies by reason of creativity and innovation's decisive stake in today's turbulent environments.

In this regard, another focus of criticism by the "New Groupthink" theory is the most widely applied collaborative ideation method of group brainstorming. Since this prominent method normally does not allow for individual and quiet ideation, introverts are supposed to fall behind extraverts in this form of idea generation (Cain, 2013). Apart from the claims of this critical theory, the application of traditional group brainstorming was effectively found to bear several shortcomings that can be ascribed to multiple factors (Diehl & Stroebe, 1987, 1991; Lamm & Trommsdorff, 1973; Mullen, Johnson, & Salas, 1991; Paulus, Larey, & Ortega, 1995; Rietzschel, Nijstad, & Stroebe, 2006; Taylor, Berry, & Block, 1958). Indeed, one of the factors that cause restriction, constitutes the factor of participants' personalities, although it has only sparsely been scientifically explored so far (Callaghan, 2009; Camacho & Paulus, 1995; Furnham & Yazdanpanahi, 1995; Jung, Lee, & Karsten, 2012). In particular, earlier research accredited variations in performance levels of introverts and extraverts by indicating that introverts generally tend

to fall behind extraverts with regards to idea generation in traditional group brainstorming (Bradshaw, Stasson, & Alexander, 1999; Callaghan, 2009; Camacho & Paulus, 1995). This finding consequently supports the claims made by the “New Groupthink” theory. However, existing research on the actual impact that limitless collaboration has on introverted employees is limited and so are findings on the impact of personality differences in brainstorming. Accordingly, by now there do not exist any solutions for closing the performance gap between introverts and extraverts in group brainstorming and therewith for limiting the effect supposed by the “New Groupthink”.

Although this problem has yet to be scientifically approached, there are some indications for potential solutions. One flexible method, namely hybrid brainstorming, that consists of an alternation between individual and group brainstorming, was already shown to possess the power to enhance overall brainstorming performance (Korde & Paulus, 2017). Since introverts were generally found to prefer quiet ideation time (Callaghan, 2009; Culp & Smith, 2005), an alternating brainstorming method could be favorable to their performance. However, no research has yet investigated whether hybrid brainstorming helps to overcome the discrepancy between introverts’ and extraverts’ contributions in group brainstorming. Therefore, the fundamental aim of this research is to ascertain whether hybrid group brainstorming can empower introverts in brainstorming by balancing the idea contribution of introverts and extraverts.

This paper is structured as follows. Chapter 2 will review the existing body of literature, which serves as the theoretical framework for this research. This includes a discussion of the “New Groupthink” theory and a review on brainstorming with regards to both the methods’ advantages and inefficiencies as well as the link between personality and brainstorming performance. It concludes with the concept of hybrid brainstorming and a derivation of hypotheses. Subsequently, chapter 3 will introduce the methodological approach selected in this research. Next, chapter 4 encompasses the depiction of the obtained results and an outline of the hypotheses tests. In this turn, the fundamental research question is answered. Finally, chapter 5 includes a discussion of the results and chapter 6 contains the study’s overall conclusions and its major limitations, implications and recommendations for further research.

2 Theoretical background

2.1 Collaborative creativity and the “New Groupthink”

Business and society are experiencing a shift from the “Information Age” towards the “Creativity Age”, where economies classify “creativity” as their core characteristic and the production of ideas is valued over that of things (Dubina, Carayannis, & Campbell, 2012; Sawyer, 2012). For these reasons, creativity and innovation are moving into the center of organizational settings and are increasingly seen as vital for organizational performance, competitive advantage, and long-term survival (Anderson et al., 2014; Mumford, Hester, & Robledo, 2012; Tang, 2016; West, 2002). One widely-adopted approach in this regard is to refrain from rigid, hierarchical structures and move towards

more organic and flexible organizational forms. In doing so, the team rather than the individual becomes the basic building block of companies and collaboration moves in the center of work (Tjosvold, West, & Smith, 2003). Recent management literature places its major focus on collaborative forms of creativity and promotes the establishing of teamwork with regard to innovation (Anderson et al., 2014; Hülsheger, Anderson, & Salgado, 2009; Kozlowski & Ilgen, 2006; Paulus & Nijstad, 2003; West, 2003; West & Altink, 1996). Group work is seen to increase the effectiveness of the growingly complex organizations and the adaptability to their fast-changing environments (Kozlowski & Ilgen, 2006; West & Altink, 1996).

However, this all-encompassing, dominating thought of collaboration is not without controversy. Likewise, the continuing development towards boundless collaboration in every aspect of work is criticized as being counterproductive for introverted employees, i.e. for individuals who oftentimes enjoy solitude, need to consider ideas individually before discussing them in groups, and prefer depth over superficiality (Cain, 2013; Deresiewicz, 2009; Dossey, 2016). (Cain, 2012, 2013) argues against the rising notion of collaboration being the sole key to creativity and innovation. In this regard, she criticizes the elevation of teamwork above everything else, as well as the widespread belief that exclusively gregarious places allow for creativity to take place. Cain (2013) raises concern over the effectiveness of today's development towards compelled collaboration and vouches for the consideration and recognition of introverts, by calling this phenomenon the "New Groupthink". According to Jung's publication "Psychological Types" (1921, reprinted 2017), Cain (2013) characterizes introverts as individuals drawn to their inner world, who try to make meaning of the happenings around them and who reenergize through solitude. Other publications confirm this arguments, where introverts are oftentimes described as quiet, reserved, retiring, shy, silent, and with-drawn (Culp & Smith, 2005; McCrae & John, 1992). Cain (2012) furthermore states that introverts oftentimes show higher creativity levels compared to extraverts and refers to several studies demonstrating this causality (Feist, 1998, 1999). However, this argument is not universally valid. In fact, findings on the creative personality revealed that creative people can be both extraverted and introverted (Eysenck, 1995). Studies with reference to the widely-adopted five-factor model of personality (Goldberg, 1990) found that individuals high on openness to experience and low on conscientiousness, are the most creative (Batey, Chamorro-Premuzic, & Furnham, 2010). Since both factors represent subscales of the introversion-extraversion scale, introversion cannot be a reliable indicator for creativity by default. However, based on the former characterization of introverts and findings on their creativity levels, Cain (2013) conclusively argues that introverts need silence and privacy to perform at their best and therefore claims that solitude, on the contrary to contemporary claims, can be a vital key to creativity. In her point of view, "collaboration kills creativity" (Cain, 2013, p. 71); resulting therefrom, she proposes to find the right balance and to create conditions that allows both for individual and group work in order to accommodate extraverts as well as introverts.

Existent studies indicate poor performances when using group brainstorming (Dunnette, Campbell, & Jaastad, 1963; Furnham, 2000), showing that group

brainstorming lacks effectivity. One reason might be the fear of judgement by others, also known as evaluation apprehension (Diehl & Stroebe, 1987). Dossey (2016, p. 157) also calls for more individual work in ideation phases by stating that “brainstorming is an extroverted strategy par excellence”. He argues that in order to understand the inefficiencies of group brainstorming, one has to understand the differences between introverts and extraverts. However, none of the authors conducted own research to legitimate their arguments but availed themselves of other scholar’s findings.

2.2 Advantages and inefficiencies of brainstorming

Brainstorming is regarded as the most commonly adopted approach for generating creative ideas and maintains widespread acceptance (Rietzschel et al., 2006). In this regard, it is generally assumed that sharing ideas in groups increases both the number and novelty of ideas generated (Korde & Paulus, 2017). Brainstorming can correspondingly be defined as a “problem solving technique that involves the spontaneous distribution of ideas from all members of a group” (Furnham, 2000, p. 23). Its underlying purpose is to produce as many different ideas as possible, while relieving participants from inhibition, self-criticism, and criticism by third persons (Taylor et al., 1958). The method was first introduced by Osborn (1957, reprinted 2013), who argued for its outstanding effectiveness in terms of quantity and quality of ideas generated, compared with individual brainstorming. He introduced four basic rules that characterize the traditional-, interactive group brainstorming method (called “traditional group brainstorming” hereafter), namely (1) any criticism is ruled out, (2) lateral thinking is welcomed, (3) quantity is wanted, and (4) combinations and improvements of ideas are sought.

Nonetheless, Osborn did not scientifically prove the method’s effectiveness (Henningsen & Henningsen, 2013). Notwithstanding, there are scholars who found brainstorming to be an important source of creativity and underpin its positive effects on performance outcomes. To illustrate, Paulus (2000), discovered that a certain extent of excitement and synergy, which is commonly present during brainstorming, can facilitate idea generation. Further advantages are social and cognitive stimulation, since participants benefit from mutual stimulation of associations that go beyond individual imagination. However, it is assumed that exclusively under certain conditions can idea sharing in groups be productive. Only if participants pay attention, i.e. follow their colleagues as well as incubate and reflect on ideas, can the idea exchange process in groups lead to enhanced performance (Heslin, 2009; Paulus & Yang, 2000). Furthermore, Sutton and Hargadon (1996) demonstrated that the use of traditional group brainstorming can have positive effects on organizations that go beyond classic measures of productivity, such as the quantity of ideas. In this regard, also an increase in group cohesiveness can be observed over time within brainstorming groups, which is believed to bring about socioemotional advantages to the organization (Henningsen & Henningsen, 2013).

On the contrary, a number of scholars found traditional group brainstorming to be less productive in comparison to an equal number of individuals brainstorming alone, so-called nominal groups, and consequently raise concern over its widespread utilization.

Taylor, Berry and Block (1958) were the first authors to demonstrate that nominal brainstorming groups outperform interactive groups in terms of the number of ideas generated. By means of an experiment comparing both types of brainstorming groups, they concluded that “group participation when using brainstorming inhibits creative thinking” (Taylor et al., 1958, p. 43). Ever since, multiple researchers replicated the finding of interactive brainstorming groups being less productive in terms of both quantitative and qualitative measures, compared to nominal groups (Diehl & Stroebe, 1987, 1991; Lamm & Trommsdorff, 1973; Mullen et al., 1991; Paulus et al., 1995; Rietzschel et al., 2006). Despite all evidence for its ineffectiveness, traditional group brainstorming persists in being a commonly used practice and popular method for idea generation in organizations (Callaghan, 2009; Diehl & Stroebe, 1991). As a result, a central issue in brainstorming literature has been the identification of factors that inhibit the performance in interactive brainstorming groups (Camacho & Paulus, 1995). Three of these are primarily discussed in literature, namely (1) social loafing, i.e. some individuals rest while others do the work, (2) production blocking, i.e. only one person is able to talk at a time and (3) evaluation apprehension, i.e. the fear to disgrace oneself in front of other group members (Diehl & Stroebe, 1987). Referring to more recent literature, Paulus, Dzindolet and Kohn (2012) underpin that psychological or participative safety as well as cohesion and trust are factors that influence general team creativity.

2.3 Personality and brainstorming

Personality traits are defined as “consistent patterns in the way individuals behave, feel, and think” (Pervin & Cervone, 2010, p. 228). The scholarly field on personality traits is approaching consensus on a general taxonomy, namely the “Big Five” personality dimensions. This model is a joint work of researchers developed over time, representing a common framework of diverse perspectives (John & Srivastava, 2001). One of the model’s dimensions is the personality trait of extraversion (McCrae & John, 1992). As a higher-order personality trait, it is composed of several more specific traits and can be understood as a broad continuum that reflects the dimension of individual differences, ranging from introversion to extraversion (Watson & Clark, 2007). Basically, it can be interpreted as the general level of sociability. Individuals who are high in extraversion, were found to be active, assertive, energetic, enthusiastic, outgoing and talkative, whereas individuals low in extraversion are rather quiet, reserved, retiring, shy, silent, and withdrawn (McCrae & John, 1992). In addition, extraverts prefer to generate ideas in groups and express their thoughts in front of others, while introverts excel when they have quiet time to think things through and process their thoughts before speaking (Culp & Smith, 2005).

Since individual personality was found to affect team creativity, the factor of personality increasingly gained significance within the brainstorming literature (Hoff, Carlsson, & Smith, 2012; Paulus et al., 2012). However, to date, only a comparatively small body of research concerning the connection between personality and brainstorming performance is available (Callaghan, 2009; Camacho & Paulus, 1995; Furnham & Yazdanpanahi, 1995; Jung et al., 2012). In this regard, it was found that group members’

personalities generally affect the overall group performance by influencing individual creativity levels and thinking styles (Bolin & Neuman, 2006; Hoff et al., 2012; Jung et al., 2012). Previous research provides evidence that particularly differences in the introversion-extraversion dimension can play a significant role in brainstorming. Primarily, introverts seem to produce fewer ideas when compared to extraverts in traditional group brainstorming. Callaghan (2009), for instance, conducted an experiment with undergraduate students exploring the connection between brainstorming performance and personality type in cross functional, new product development teams. By means of the MBTI® personality test (Briggs Myers, 1995), she found that introverts were generally less involved than extraverts in brainstorming rounds. This agrees with Dossey (2016), who affirms that when involved in group idea-generation, introverts usually fall behind extraverts regarding idea expression. In addition, Aguilar-Alonso (1996) pointed out that extraverts produce more original outcomes in brainstorming. Jung et al. (2012) further reinforced this finding by confirming significant performance differences between extraverts and introverts in terms of unique and diverse ideas. In accordance, Bradshaw et al. (1999) demonstrated that one single introverted group member leads to lower productivity and increased evaluation apprehension. Camacho and Paulus (1995) were the first scholars to indicate that individual differences could actually be accountable for the performance gap between nominal and interactive brainstorming groups. This underpins Dossey's (2016) opinion that in order to understand the reasons for brainstorming inefficiencies, one has to understand the differences between introverts and extraverts. Taken as a whole, the findings obtained in these studies point to the critical conclusion that the involvement of introverted group members in traditional group brainstorming entails productivity impairment. Even though Camacho and Paulus (1995) have already discovered personality differences as being key in solving the performance gap between interactive and nominal brainstorming groups, no research has yet to find ways to empower introverts in group brainstorming and therewith enhance overall productivity. Accordingly, no solution was found that can overcome the effect of the "New Groupthink" on ideation.

Therefore, the following is hypothesized (H1): In traditional interactive group brainstorming, introverted group members contribute significantly less to the total amount of ideas generated, compared to extraverted group members.

2.4 Hybrid brainstorming

2.4.1 Development of hybrid brainstorming

Apart from investigating the factor of personality, some authors have already discovered brainstorming methods which generally help to bridge the performance gap between interactive and nominal brainstorming groups. Still, no research has proved these methods to overcome the inequalities in brainstorming performance between introverts and extraverts. First, there is the so-called "brainwriting" method, which is "the silent, written generation of ideas by a group of people" (VanGundy, 1984, p. 68). This method entails several forms and can overcome various inefficiencies such as minimizing status

differences between participants. Furthermore, research has revealed that it leads to superior idea generation compared with both non-sharing or nominal brainstorming groups (Paulus & Yang, 2000). Nevertheless, social interaction and active discussions are oftentimes critical for group success, which is why brainwriting cannot always be selected as an alternative to interactive group brainstorming (VanGundy, 1984). Second, there is the method of electronic brainstorming, which is an “e-collaboration method that employs networked computer terminals and software designed to allow group members to communicate electronically during idea generation exercises” (DeRosa, Smith, & Hantula, 2007, p. 1550). On the one hand, electronic brainstorming was found to both increase productivity and satisfaction with the interaction process compared with traditional face-to-face brainstorming. On the other hand, overall benefits of this method were found to be limited and electronic brainstorming groups had to consist of more than 7 people to outperform nominal groups (DeRosa et al., 2007). Besides, the synergistic effect of group collaboration was missing, which made the method unsuitable to apply universally (Korde & Paulus, 2017). Third, the so-called “hybrid brainstorming” method, which combines individual and group brainstorming phases by switching between individual brainwriting and group brainstorming. This method was likewise found to overcome several productivity barriers and enhance the overall effectivity of the brainstorming process (Korde & Paulus, 2017). Some early findings have already indicated that an alternation between the conditions makes sense and therewith provided first hints concerning the method’s advantages over traditional group brainstorming. In fact, Osborn (1957, reprinted 2013) already noted that an alternation between group and individual ideation has the power to produce maximum results, although not empirically verifying his argument. Subsequently, several studies suggested that the exposure to other persons’ ideas may enhance brainstorming performance (Jung et al., 2012). Likewise Paulus et al. (1995) stated that “group brainstorming may be most useful after individuals have generated ideas individually for a period of time and need the additional social stimulation” (p. 252). Girotra, Terwiesch and Ulrich (2010) conducted an experiment to assess two brainstorming conditions, namely a group and a hybrid condition, where individuals initially brainstormed alone and then together. The authors found strong support that the best ideas generated in the hybrid condition were better than those generated in the group condition. Besides, the hybrid groups generated three times as many ideas as the traditional groups. Accordingly, Korde (2014) conducted studies to achieve better performance by means of hybrid brainwriting methods. She found that the hybrid condition outperformed the traditional group condition. In addition, hybrid brainwriting was experimentally tested in an industrial setting at an international company and again, the hybrid condition yielded more ideas than the group condition. Therefore, the authors recommend alternating group review sessions with private idea generation when brainwriting (Paulus, Korde, Dickson, Carmeli, & Cohen-Meitar, 2015). The most recent experiment by Korde and Paulus (2017) once again demonstrated the benefits of hybrid brainwriting compared to alone and group brainwriting reflected in the number of ideas generated. Still, these findings of Korde and Paulus (2014; 2017) are exclusively

valid for the hybrid brainwriting method, which does not involve interactive group discussions, but brainwriting as such.

2.4.2 Personality and hybrid brainstorming

Since hybrid brainstorming was found to narrow the general productivity gap between nominal and interactive brainstorming groups, it can be questioned whether this method likewise helps overcome the performance gap between introverts and extraverts in group brainstorming. However, hardly any studies have investigated the effect of personality type on hybrid brainstorming to date. Nevertheless, some of the studies previously discussed, provide first hints that hybrid brainstorming could be favorable for introverts' enhanced contribution to ideation. Camacho and Paulus (1995) have indicated that interactive group brainstorming would be best suited for individuals low in social anxiety since introverts might be too concerned about the reactions of others. Correspondingly, evaluation apprehension, i.e. the fear to disgrace oneself in front of other group members, has been identified as one major factor inhibiting brainstorming performance early on (Diehl & Stroebe, 1987). Furthermore, it was found that the minor performance in interactive brainstorming groups can be assigned to differences in personality types (Camacho & Paulus, 1995), mainly due to the underperformance of introverts. Since introverts usually prefer to think quietly before talking, e.g. reaching conclusions before discussing their thoughts, and need time to recharge their energy (Callaghan, 2009; Culp & Smith, 2005), an alternating brainstorming process could be favorable to their performance. Hence, hybrid brainstorming, which includes individual phases that allow for quiet thinking before discussing the ideas as a group, could potentially narrow the performance gap between introverts and extra-verts in group brainstorming.

Based thereupon, the following is hypothesized (H2): In hybrid brainstorming, introverted group members contribute significantly more to the total amount of ideas generated, compared to traditional interactive group brainstorming.

Furthermore, Korde (2014) strived to investigate the general increase in performance in hybrid brainwriting. Hence, she hypothesized that participants high in extraversion will generate the most ideas within the hybrid condition. However, this hypothesis was not supported, even though the hybrid method did yield an increase in overall brainstorming performance. Since extraverts do not necessarily exhibit an increased performance in hybrid conditions, the increase in overall performance could be ascribed to the improved performance of introverts. This could implicate that extraverts do not fundamentally perform in a superior manner, but that the brainstorming method as such causes the performance gap between the personality types. If hybrid brainstorming can overcome this gap, the contributions of extraverts and introverts should converge accordingly. A similar effect was noted by Camacho and Paulus (1995) for the general productivity gap between nominal and real groups in brainstorming. They noted that if social anxiousness and hence individual differences are minimized, group brainstorming can be as productive as nominal group brainstorming.

Therefore, the following hypothesis (H3) is stated: In hybrid brainstorming, introverted and extraverted group members contribute equal shares to the total amount of ideas generated

In addition, Korde and Paulus (2017) have already established that the order of individual and group phases in hybrid brainstorming is of minor significance to the outcome. However, neither has a study investigated the effect of the number of changes between the two conditions nor its impact on the performance of introverts compared to extraverts. Some studies on hybrid brainstorming have utilized one individual and one group phase (Girotra et al., 2010; Paulus, Larey, & Dzindolet, 2000; Paulus et al., 2015), others employed experimental designs with two aligned sequences of individual and group phases, i.e. four phases per group (Korde, 2014; Korde & Paulus, 2017). However, these scholars did not argue for the number of switches between the two conditions. Nevertheless, the general exposure to the ideas of others can lead to an overall increase in ideas generated (Paulus et al., 2015). In this regard, it was shown that individual reflection after group discussion leads to associations and the further development of others' ideas (Paulus et al., 2015; Paulus & Yang, 2000). On the contrary, if phases last too long or if only brainstorming as a group without individual phases, a steady decline of generated ideas can be observed (Korde & Paulus, 2017). Besides, Kasof (1997) argued that introverts have a narrower attention span than extraverts. Therefore, the involvement of frequent individual phases allows them to recharge their energy for the subsequent group discussion (Callaghan, 2009; Culp & Smith, 2005).

Hence, the following is hypothesized (H4): In hybrid brainstorming, introverted group members contribute significantly more ideas if frequent changes between individual and group phases are included, compared to less frequent changes.

2.4.3 Individual satisfaction in hybrid brainstorming

Although satisfaction was found to be an important factor for understanding overall brainstorming performance, metrics in brainstorming experiments oftentimes exclusively focus on the quantity of ideas generated (Bolin & Neuman, 2006; Callaghan, 2009). However, despite all scientifically proven inefficiencies, the general satisfaction with brainstorming remains repeatedly named as one reason for its widespread utilization. In fact, people seem to enjoy brainstorming, since it satisfies their need for social interaction (Heslin, 2009; Paulus, 2000; VanGundy, 1984). Besides, group brainstorming leads to more favorable perceptions of individual performance (Paulus et al., 2000). However, hardly any studies have investigated satisfaction levels of introverts compared to extraverts after traditional group brainstorming or hybrid brainstorming. Callaghan (2009) conducted one of the rare studies exploring satisfaction levels of introverts and extraverts, although she did not involve any hybrid methods. In two out of three brainstorming sessions, a lower satisfaction level was measured for introverts. The only case in which introverts reported a slightly higher satisfaction level compared to extraverts, involved a brainstorming method that allowed introverts to think longer and to be introspective. In addition, introverts oftentimes perceive meetings and group discussions, such as

interactive brainstorming, to be an energy drain, since they commonly reenergize through being alone (Cain, 2013; Culp & Smith, 2005).

Based thereupon, the following is hypothesized (H5): Introverted group members show a lower satisfaction-level after traditional interactive group brainstorming compared to extraverted group members.

As already stated above, no study has investigated participants' satisfaction after hybrid brainstorming rounds, regarding their personality type. However, since hybrid brainstorming entails individual reflection phases, it can be assumed that introverts enjoy hybrid brainstorming over traditional group brainstorming. This is underlined by their general preference of having quiet time to think things through (Culp & Smith, 2005). Callaghan's finding (2009) that a method which allows introverts to think more leads to increased satisfaction levels, already provides a first hint that introverts may prefer hybrid brainstorming over traditional methods.

Accordingly, the following is hypothesized (H6): Introverted group members show a higher satisfaction-level after hybrid brainstorming compared to traditional brainstorming.

3 Methodology

3.1 Research methodology

This research is of quantitative nature, following a deductive approach while testing 6 hypotheses (H1a-H2b) that were derived from prior scientific findings (see table 1 for an overview). Accordingly, the research is based upon the fundamental philosophy of postpositivism, common for experimental designs and surveys. This perspective holds that causes determine certain effects or outcomes (Creswell, 2008). In this research, a relationship between the independent variables (IV) personality type and brainstorming methods and the dependent variables (DV) brainstorming outcome and post brainstorming satisfaction is advanced in form of hypotheses. Correspondingly, since this research is based upon objective scientific observation and empirical enquiry by means of a controlled experiment, the postpositivistic perspective frames the present study. However, absolute truth cannot be found at any point, which differentiates postpositivism from the traditional positivistic perspective (Creswell, 2008).

Table 1: Overview of tested hypotheses.

Hypotheses	
H1	<i>In traditional interactive group brainstorming, introverted group members contribute significantly less to the total amount of ideas generated, compared to extraverted group members</i>
H2	<i>In hybrid brainstorming, introverted group members contribute significantly more to the total amount of ideas generated, compared to traditional interactive group brainstorming</i>
H3	<i>In hybrid brainstorming, introverted and extraverted group members contribute equal shares to the total amount of ideas generated</i>

- H4 *In hybrid brainstorming, introverted group members contribute significantly more ideas if frequent changes between individual and group phases are included, compared to less frequent changes*
 - H5 *Introverted group members show a lower satisfaction-level after traditional interactive group brainstorming compared to extraverted group members*
 - H6 *Introverted group members show a higher satisfaction-level after hybrid brainstorming compared to traditional brainstorming*
-

The methodology of this thesis consists of two elements. In the first instance, the underlying research methodology is an experimental design for testing the hypotheses H1-H4. This method entails “manipulating levels or amounts of selected independent variables (causes) to examine their influence on dependent variables (effects)” (Brown & Melamed, 1990, p. 1). Such causal conclusions can be drawn most appropriately within experimental research, since variables other than the variables of interest, are controlled (Kirk, 2013). In the case of this research, the influence of personality types (introverted, extraverted) and selected brainstorming methods (traditional group brainstorming and two hybrid brainstorming methods) on the outcome of brainstorming, will be investigated. Since the impact of changes in two causes, i.e. personality type and brainstorming methods, are explored, this research employs a factorial design (Gray, 2004). Selfsame methodology is well-suited for such research since it allows to test the hypothesized relationship between personality type and brainstorming method on brainstorming outcome while controlling for nuisance variables (Kirk, 2013). Besides, scholars who conducted previous studies that investigated the relationship between brainstorming and personality types, likewise applied the methodological approach of experiments (Bolin & Neuman, 2006; Callaghan, 2009; Furnham & Yazdanpanahi, 1995; Jung et al., 2012; Korde & Paulus, 2017). This makes it reasonable to continue the research stream by choosing a comparable approach. By these means, the results of this re-search can directly be compared to and be discussed in light of earlier findings as laid out in chapter 2. Furthermore, the general intention of experimental research is to generate objective, valid and replicable results (Gray, 2004), which is likewise highly strived for within this study. Therefore, data derived from the experiment is subject to valid statistical analysis.

In addition, a second methodological element in form of a survey is utilized to test the hypotheses H5-H6. This methodology involves a systematic, highly standardized collection of data by means of data collection methods, such as questionnaires (Sapsford, 2007). These characteristics allow a statistical analysis of survey data, suitable for quantitative research. The conducted survey aims at measuring and comparing satisfaction levels of introverted and extraverted participants after each brainstorming round. This approach is in line with one prime purpose of surveys, namely to make planned comparisons between several groups (Sapsford, 2007). Hence, a survey suits the purpose of studying satisfaction levels and making statistical inferences about the difference between the perceptions of the two personality types well. In addition, previously conducted studies have chosen the same methodological approach, such as Korde (2014)

or Camacho and Paulus (1995). Selecting the same approach allows for a better comparability to previous literature and hence a constructive discussion of findings.

3.2 Sample

The sample of the present study consisted of business students from Germany, which were selected by applying a convenience sampling method (Quinlan, 2011). The total sample hence consisted of 87 participants, whereof 54 were male and 30 were female students; three participants did not indicate their gender. The age ranged from 19 to 32 years, with a mean of 22 years. During the course of the study, the sample was divided into three subsets: (1) introverted participants ($N = 16$), (2) extraverted participants ($N = 46$) and (3) average participants ($N = 25$), i.e. participants that rather fall into the middle of both personality types and could not be assigned to one of them. To include those participants classified as average in the later statistical analysis could have falsified the results, as they do not show distinct enough extraverted or introverted behavior. Therefore, these participants were not taken into consideration (see Table 2 for descriptive sample data).

Table 2: Descriptive sample data.

		Male	Female	Not indicated	Sum
Introverted	Day 1	3	1	1	5
	Day 2	4	3	-	7
	Day 3	2	2	-	4
	Sum	9	6	1	16
Extraverted	Day 1	8	5	-	13
	Day 2	11	8	2	21
	Day 3	8	4	-	12
	Sum	27	17	2	46
Average	Day 1	3	2	-	5
	Day 2	7	5	-	12
	Day 3	8	0	-	8
	Sum	18	7	-	25
Sum		54	30	3	87

Based on their personality type, the participants were randomly divided in a total of 23 brainstorming groups. A general group size of four was chosen because previous studies have chosen the same size (Bolin & Neuman, 2006; Callaghan, 2009; Henningsen & Henningsen, 2013). However, two groups consisted of three participants only, whereof one was subject of subsequent analysis. Besides, one group consisted of two participants only, however not being subject for analysis. The reason for their exclusion is that seven of the 23 brainstorming groups consisted of students classified as average within the personality test and were not taken into consideration. All remaining brainstorming groups were formed of one participant classified as introverted and two to three participants classified as extraverted. Conclusively, 62 participants (16 introverted, 46 extraverted), equalling 16 brainstorming groups, were taken into consideration for statistical analysis.

3.3 Measures and instrumentation

This research employs a 2 x 3 factorial design, crossing personality type (introverted, extraverted) with brainstorming method (traditional group brainstorming, hybrid method 1, hybrid method 2) to test the defined hypotheses H1-H4. This is complemented by a survey to test H5-H6. In order to test the research design in practice before carrying out the experiments, a pilot study was conducted upfront.

The first independent variable is personality type (IV-I), which includes the two levels of introverted and extraverted personality type. The classification and belonging of participants to one of these two levels is defined by means of a personality test, namely IPIP-NEO-120, developed by Johnson (2014). The test was developed as the short version of the initial IPIP-NEO-300 by Goldberg (1999), which is a 300-item inventory that measures personality constructs. The IPIP-NEO-120 is a 120-item inventory that can be administered on the World Wide Web and measures the five broad domains of the Five-Factor Model (Goldberg, 1990). These domains consist of Neuroticism, Extraversion, Conscientiousness, Agreeableness and Openness to Experience (Johnson, 2014), whereof Extraversion is the scale of interest to this study. The score ranges from 0-100, 100 being extremely extraverted. Students with a score below 40 are categorized as introverts, above 60 as extraverts and between 40 and 60 as average. The scores are reported as percentile estimates. To illustrate, a score of 70 means that the level on extraversion is estimated to be higher than 70% of persons of the same sex and age (Johnson, 2014). Cronbach's alpha reliability estimates are available for all IPIP scales, whereof the scales measuring extraversion yield a mean score of .84 to .89, depending on the sample the estimates were based upon. One determinant of the test's validity are the correlation coefficients to constructs similar to the IPIP-NEO-120, whereof the correlation to the NEO-PI-R totals .85 (Johnson, 2014).

The second independent variable is brainstorming method (IV-II), including the three levels of traditional group brainstorming, hybrid method 1 and hybrid method 2. These brainstorming methods entail three different conditions. First, the condition of the traditional group brainstorming method (G), which encompasses brainstorming in a group for a time of eight minutes. Second, the condition of hybrid method 1 entails first brainstorming individually for half of the time, i.e. four minutes, and consecutively, in a group for four minutes (IG). The third method, namely hybrid method 2, entails first brainstorming individually, then in a group, then again individually and then in a group for two minutes each (IGIG).

The dependent variable of the experimental design is defined as the average quantitative, non-redundant ideas generated per participant and personality type per group (DV- I), called "average ideas generated" hereafter, for reasons of simplicity. This implies that two scores are assigned to every brainstorming group after each of the three brainstorming rounds. First, one average score of non-redundant ideas produced by introverted, and second, one average score produced by extraverted group members. Since the underlying research question asks whether hybrid brainstorming can empower introverts to contribute an assimilable amount of ideas compared to extraverts, the focus of this research solely lies on the quantity of ideas produced. The quality of ideas is

neglected at this point. The dependent variable is measured by counting the numbers of ideas produced per group and personality type. Therefore, all participants receive sticky notes in different colors according to a predefined color code, so that ideas produced by introverts and extraverts can be differentiated.

The dependent variable of the survey is post-brainstorming satisfaction (DV-II). This construct is measured by the following four items: Were you satisfied with the (1) process, (2) the results, (3) your own contribution to this brainstorming round and (4) how satisfied were you overall. These items are measured using a questionnaire with 5-point Likert Scales, ranging from very unsatisfied (1) to very satisfied (5). The average of these four items is reported per participant. The short questionnaire, which includes four questions only, was partly adopted from Valacich, Dennis and Nunamaker (1992), who measured post-brainstorming satisfaction in computer-mediated groups. However, the questionnaire was tailored to the demands of this particular study. Overall, the scale was reliable (Cronbach's alpha: .74).

3.4 Data collection

The experiment was conducted during three different days (see figure 1 for an overview of the process of experiment). As a first step, test persons were asked to complete the online personality test IPIP-NEO-120 (Johnson 2014) using fictitious nicknames. Next, they were sorted into three subgroups (1) introverted (extraversion score below 40), (2) extraverted (score above 60), and (3) average (score between 40 and 60). Based on a provided list including their nicknames and their personality types, the test persons were assigned to one of the brainstorming groups, consisting of one introverted and two to three extraverted each. Thereafter, the participants received an introduction on the general procedure, including the idea generation and coding in brainstorming. The coding was based sticky notes in different colors in order to assign the ideas to different group members.

After having received the instructions, the participants conducted a small test-round to become familiar with the procedure. The first brainstorming round used the traditional group brainstorming method according to the rules of Osborn (called "G-condition"). Therefore, the participants were asked to brainstorm as a group for eight minutes. At day 1, their task was to consider possible product differentiations of a chocolate brand (the task is called "chocolate"). Since counterbalancing was used in this study, the order of tasks varied on each day (see figure 1). On day 2, the first task was to think of possible marketing actions for the promotion of a new product of smoothie brand (called "smoothie"), and on day 3, their first task was to think of products that could be sold under a newly introduced product line of a supermarket (called "supermarket"). After eight minutes, all ideas (sticky notes) were collected. Thereafter, the participants were asked to fill in the satisfaction questionnaires for round 1. Next, the second brainstorming round was conducted, employing hybrid method 1. This entails switching from individual phases to group phases. Therefore, the students first brainstormed individually (I) for four minutes and then in a group (G) for four minutes (called "IG-condition"). The final brainstorming round used hybrid method 2. The process first entailed an individual phase

(I), followed by a group phase (G), an individual phase (I) and a group phase (G) another group phase for 2 minutes each (called “IGIG-condition”).

The collected data hence consisted of two components. First, the sticky notes that are used to measure the DV-I, namely the average ideas generated and second, questionnaires that are used to measure the DV-II, namely post-brainstorming satisfaction. The data collected from groups with participants classified as average were disregarded for analysis.

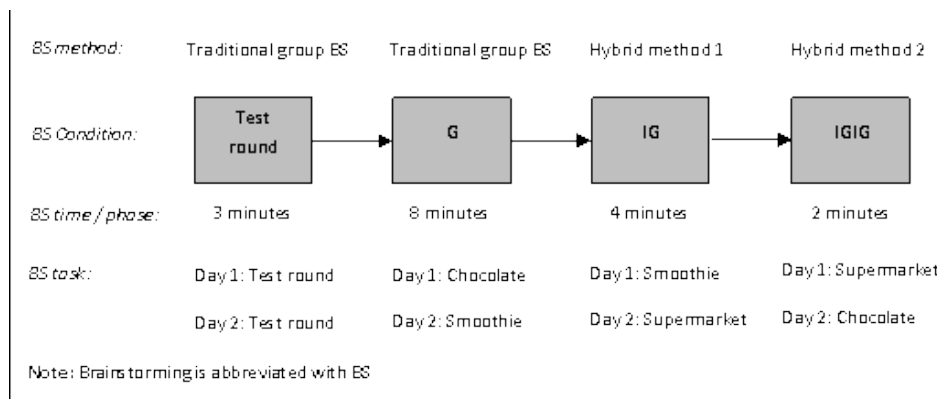

Figure 1: Process of experiment.

3.5 Data analysis methods

The primary hypotheses were tested using a two-way mixed design ANOVA, followed by several post-hoc tests. The statistical test of a two-way mixed design ANOVA compares the differences in means between groups that are split on two independent variables, as in the case of this research. These variables comprise one between-subjects factor that has two independent groups, i.e. introverted or extraverted, and one within-subjects factor that has three related groups and is repeatedly measured, i.e. three different brainstorming methods in this case. Since the statistical test perfectly reflects the design of this research, it was well-suited to choose for analysis. The primary purpose of using the two-way mixed design ANOVA is to understand if there is an interaction between the between-subjects and within-subjects factor in relation to the dependent variable (Cohen, 2008; Laerd Statistics, 2015a). To conduct the test, two average scores of non-redundant ideas, i.e. one average score for introverts and one for extraverts, were derived per group. These average scores represented the final data set used for statistical analysis in SPSS. Since the two-way mixed design ANOVA only reveals whether an interaction exists between the between-subjects factor and within-subjects factor on a dependent variable, the two-way mixed design ANOVA was consequently followed-up by independent-samples t-tests and paired-samples t-tests to test hypotheses H1-H4.

To understand if an interaction between personality type and brainstorming method that affects post-brainstorming satisfaction exists, the two-way mixed design ANOVA

was applied again. This involved the between-subjects factor of personality type, i.e. intro-verted or extraverted, and the within-subjects factor of brainstorming methods, including the three brainstorming methods applied. The hypotheses H5-H6 were further tested using paired-samples t-tests. This test is utilized to determine if there is a statistically significant difference between paired observations (Laerd Statistics, 2015b). To conduct the ANOVA and t-tests, the data from the questionnaire had to be coded (1 – very unsatisfied, 5 – very satisfied).

3.6 Validity and reliability

Experimental validity is defined as “the correctness or truthfulness of an interference that is made from the results of an experiment” (Christensen, 2008, p. 206). According to Sani and Todman (2008), three important aspects of validity apply to experiments, namely internal, external and construct validity.

Internal validity refers to “the extent to which causal conclusions can be drawn” (Gray, 2004). Since we cannot generally exclude the existence of other variables that influence our dependent variable, nuisance variables (NVs) need to be discussed and eliminated as far as possible (Sani & Todman, 2008). These variables are “undesired sources of variation in an experiment that affect the dependent variable” (Kirk, 2013). There are two ways of control, namely to eliminate the NV by keeping it constant throughout the experiment, or by turning it into a random variable (Sani & Todman, 2008). Even though there are no perfectly designed experiments, great diligence has been taken in creating a sound experimental design. Therefore, the random allocation of subjects to the groups has been assured, which is one controlling element for threats to validity (Gray, 2004).

External validity refers to “the extent to which it is possible to generalize from the data to a larger population or setting” (Gray, 2004). However, reducing the threat to internal validity and designing an experiment as representatively and realistically as possible, is contradictory (Sani & Todman, 2008). Therefore, external validity can only be improved to the degree that it does not hamper internal validity. First, regarding ecological validity, i.e. generalizing the findings to different settings (Sani & Todman, 2008), it can be stated that the experimental setting of a classroom for brainstorming sessions is somehow comparable to real-world settings. To illustrate, a meeting room at a company equals a classroom to a large extent. However, the presence of various brainstorming groups at a time is rather seldom. Second, referring to population validity, i.e. generalizing the findings to people differing from the sample (Sani & Todman, 2008), it needs to be noted that the results of students cannot fully be generalized to other populations. This is mainly due to differences in thinking and behavior compared to other groups such as workers.

“Construct validity is the extent to which a variable actually reflects the theoretical construct that we intend to measure” (Sani & Todman, 2008). The underlying condition is to operationally define all involved concepts before measuring them (Gray, 2004). In case of this research, the concepts of the IVs as well as the DVs were scrutinized and operationalized in chapter 2, leading to present construct validity.

Experimental reliability refers to “consistency, stability, or repeatability of the results of an experimental study” (Christensen, 2008). To conduct a reliable experiment, all components involved, i.e. number and identification of participants, as well as the dependent and independent variables, must be reliable. Regarding the number and identification of participants, a sufficient number of participants increases the reliability of the obtained results (Christensen, 2008). In case of this research, a total of $N = 87$, whereof $N = 62$ were subject for analysis, was regarded as sufficient to obtain reliable statistical results, since all statistical tests selected could be carried out while meeting the required assumptions. The subsequent partition into three sub groups based on personality type, relied on a reliable personality test (Cronbach’s alpha .08 to .89 for extra-version scale), namely IPIP-NEO-120 (Johnson, J. A., 2014).

4 Results

In the first instance, a two-way mixed design ANOVA was carried out to explore if there exists an interaction between the between-subjects and within-subjects factor in relation to the dependent variable, namely average ideas generated (DV-I). In the present case, personality type (IV-I) was the two-level between-subjects factor and brainstorming method (IV-II) the three-level within-subjects factor. Table 3 presents the means and standard deviations of average ideas generated (DV-I), sorted by personality type (IV-I) and brainstorming method (IV-II), respectively.

Table 3: Means and standard deviations of average ideas generated for traditional brainstorming, hybrid method 1, and hybrid method 2 according to personality type

	Traditional [G-condition]	Hybrid method 1 [IG-condition]	Hybrid method 2 [IGIG-condition]
Introverts			
M	3.81	4.13	5.94
SD	1.94	2.63	3.43
Extraverts			
M	6.77	6.87	8.29
SD	1.97	2.72	2.43

Figure 2 further graphically illustrates the derived results of the mean average ideas generated, sorted for personality type and brainstorming method.

Figure 2: Mean average ideas generated in traditional brainstorming, hybrid method 1, and hybrid method 2 according to personality type

Investigating the assumptions of the two-way mixed design ANOVA revealed that there were no outliers in the present data set, as assessed by inspection of a boxplot and by examination of studentized residuals for values greater than ± 3 . In addition, DV-I was normally distributed, as assessed by Shapiro-Wilk's test ($p > .05$) and by Normal Q-Q Plot. Besides, there was homogeneity of variances, as assessed by Levene's test of homogeneity of variance ($p > .05$) and homogeneity of covariances, as assessed by Box's test of equality of covariance matrices ($p = .063$). Mauchly's test of sphericity indicated that the assumption of sphericity was met for the two-way interaction $\chi^2(2) = .993$, $p = .609$. Running the test revealed that there was no statistically significant interaction between personality type (IV-I) and brainstorming method (IV-II) on average ideas generated (DV-I), $F(2, 60) = .201$, $p = .818$, partial $\eta^2 = .007$. Therefore, it was further tested for main effects. The main effect of brainstorming method revealed a statistically significant difference in average ideas generated within the three different brainstorming methods, $F(2, 60) = 8.537$, $p = .001$ ($p < .05$), partial $\eta^2 = .222$. This demonstrates that the average ideas generated significantly differed for the three brainstorming methods applied during the experiment. A pairwise comparison further disclosed that the mean difference is significant at the .05-level for (1) the traditional method (G-condition) compared to hybrid method 2 (IGIG-condition), as well as for (2) the hybrid method 1 (IG-condition) compared to hybrid method 2 (IGIG-condition). Likewise, the main effect of personality type showed that there was a statistically significant difference in average ideas generated between the two types $F(1, 30) = 14.023$, $p = .001$, partial $\eta^2 = .319$. This depicts an existence of significant differences between brainstorming performance according to personality type. The lack of statistically significant simple main effects, as laid out above, however, indicates that the differences in average ideas generated between the two personality types (IV-I) and three brainstorming methods (IV-II) cannot be traced back to the existence of an interplay between these two variables that jointly affect the DV-I. Still, the presence of main effects for both brainstorming method and personality type ascribes a general - though separate - effect of these two variables on average ideas generated (DV-I). Resulting therefrom, further post-hoc tests, namely independent-samples t-tests and paired-samples t-tests, were carried out to test hypothesis H1-H4.

Hypothesis 1: An independent samples t-test was run to determine whether there exists a significant difference in average ideas generated between introverts and extraverts when applying the traditional brainstorming method. Descriptive statistics indicated that extraverts (6.77 ± 1.97) generated more ideas on average compared to introverts (3.81 ± 1.94). Checking the independent samples t-test's underlying assumption revealed that there were no outliers in the data, as assessed by inspection of a boxplot. Average number of ideas generated for each level of personality, i.e. introvert and extravert, were normally distributed, as assessed by Shapiro-Wilk's test ($p > .05$). Besides, there was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .768$). Running the test indicated that there was a statistically significant difference in the mean average of ideas generated between extraverts and introverts, with introverts scoring lower than extraverts to a degree of -2.96 ideas (95% CI, -4.37 to - .55), $t(30) = 4.277$, $p < .0005$. Conclusively, H1 is accepted.

Hypothesis 2: To determine whether introverts generate significantly more ideas when applying a hybrid method compared to the traditional method, two separate t-tests were conducted.

First, comparing the traditional to the hybrid method 1, introverts generated more ideas on average while applying the hybrid method (4.13 ± 2.63) as opposed to the traditional brainstorming method (3.81 ± 1.94). A paired-samples t-test was used to determine whether there was a statistically significant mean difference in average ideas generated between the two methods. There were no outliers in the data, as assessed by inspection of a boxplot. The differences between the averages of ideas generated by introverts in the traditional and hybrid method 1 were normally distributed, as assessed by Shapiro-Wilk's test ($p = .554$). However, the observed increase is not statistically significant ($p > .05$).

Second, comparing the traditional to the hybrid method 2, introverts generated more ideas when applying the hybrid method 2 (5.94 ± 3.43) as opposed to the traditional brainstorming method (3.81 ± 1.94). There were no outliers in the data, as assessed by inspection of a boxplot. The differences between the traditional brainstorming method and hybrid method 2 were normally distributed, as assessed by Shapiro-Wilk's test ($p = .501$). The hybrid method 2 elicited an increase of 2.13 ideas generated (95% CI, 0.20 to 4.05) on average compared to the traditional method. This increase is statistically significant, $t(15) = 2.353$, $p = 0.033$ ($p < 0.05$).

Accordingly, H2 is rejected for the case of hybrid method 1, but accepted for the case of hybrid method 2, which caused a significant increase in average ideas generated by introverts compared to the traditional brainstorming method.

Hypothesis 3: To test whether introverts and extraverts contribute equal shares to the total amount of ideas generated when applying hybrid methods, it was first analyzed whether there still exists a significant difference between the types when applying hybrid method 1. Descriptive statistics indicated that introverts still contribute less ideas on average (4.13 ± 2.63) compared to extraverts (6.87 ± 2.72). The score of average ideas generated by introverts was 2.75 ideas (95% CI, -4.68 to -0.02) lower than of extraverts. An independent-samples t-test was run to determine if this difference is significant. There

were no outliers in the data, as assessed by inspection of a boxplot. Average number of ideas generated was normally distributed, as assessed by Shapiro-Wilk's test ($p > .05$). Besides, there was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .627$). The difference in mean score of average ideas generated between introverts and extraverts was proven to be significant, $t(30) = -2.908$, $p = .007$. This demonstrates that the gap of average ideas generated between the two personality types could not be overcome by hybrid method 1.

Second, it was scrutinized whether the same is true for hybrid method 2. Therefore, another independent-samples t-test was run. Descriptive statistics indicated that the mean score of average ideas generated by extraverts (8.293 ± 2.43) was higher than of introverts (5.938 ± 3.435). Hence, introverts' score was 2.36 (95% CI, -4.503 to -0.207) lower than of extraverts. There were no outliers in the data, as assessed by inspection of a boxplot. Average ideas generated was normally distributed, as assessed by Shapiro-Wilk's test ($p > .05$) and there was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .118$). Again, a statistically significant difference in the mean score of average ideas generated between introverts and extraverts was proven for hybrid method 2, $t(30) = -2.239$, $p = .033$. This result implies, that the method could overcome the gap of average ideas generated between introverts and extraverts either. Conclusively, H3 is rejected.

Hypothesis 4: To find whether introverts contribute significantly more ideas in hybrid method 2 compared to hybrid method 1, since more frequent changes are involved, a paired-samples t-test was conducted. Descriptive statistics already indicated that introverts generated more ideas applying the hybrid method 2 (5.94 ± 3.43) as opposed to hybrid method 1 (4.13 ± 2.63). The assessment of test assumptions depicted no outliers in the data, as checked by inspection of a boxplot. Further, the differences between the average ideas generated by introverts in hybrid method 1 compared to hybrid method 2, were normally distributed, as assessed by Shapiro-Wilk's test ($p = .612$). Result of the t-test indicated that the hybrid method 2 elicited a statistically significant increase in average ideas generated to hybrid method 1, $t(15) = 3.131$, $p = 0.007$. Therefore, H4 is accepted.

Hypothesis 5 & 6: To test the second part of the derived hypotheses, the results from the post-brainstorming satisfaction survey were analyzed. A total of $N = 62$, including 16 introverts and 46 extraverts, was considered for data analysis. First, the two-way mixed ANOVA was run to test whether there exists an interaction between personality type (IV-I) and brainstorming method (IV-II) that affects post-brainstorming satisfaction (DV-II). Results of descriptive statistics can be found in table 4.

Table 4: Means and standard deviations of post-brainstorming satisfaction for traditional group brainstorming, hybrid method 1, and hybrid method 2 according to personality type

	Traditional [G-condition]	Hybrid method 1 [IG-condition]	Hybrid method 2 [IGIG-condition]
Introverts			
M	3.86	3.86	3.94
SD	0.55	0.87	0.72
Extraverts			
M	4.12	4.10	4.25
SD	0.56	0.66	0.79

Figure 3 further illustrates the derived results by showing mean post-brainstorming satisfaction sorted for personality type and brainstorming method.

Figure 3: Mean post-brainstorming satisfaction after traditional group brainstorming, hybrid method 1, and hybrid method 2 according to personality type

An independent samples t-test was run to test H5, questioning whether introverts show a lower satisfaction level after traditional brainstorming compared to extraverts. Again, one outlier was detected that was more than 1.5 box-lengths from the edge of the box in a boxplot. Inspection of its value did not reveal it to be extreme and hence it was kept in the analysis. The score for average generated ideas was normally distributed in case of the needed data set, as assessed by Shapiro-Wilk's test ($p > .05$). Besides, there was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .471$). Descriptive statistics indicate that mean extravert satisfaction score (4.12 ± 0.56), after applying the traditional method, was higher than mean introvert satisfaction score (3.86 ± 0.55). However, this difference was not statistically significant, $t(59) = -1.592$, $p = .117$.

To test H6, a paired-samples t-test was used to determine whether there was a statistically significant difference between the post-brainstorming satisfaction level of

introverts after hybrid brainstorming compared to traditional brainstorming. First, satisfaction levels after the traditional and hybrid method 1 were compared. There were no outliers in the data, as assessed by inspection of a boxplot. The differences between the satisfaction scores of introverts applying the traditional brainstorming method and hybrid method 1 were normally distributed, as assessed by Shapiro-Wilk's test ($p = .221$). Descriptive statistics already revealed that introverted participants indicated an exact same satisfaction level after the traditional brainstorming round (3.86 ± 0.55) as opposed to the first hybrid brainstorming round (3.86 ± 0.87). Consequently, the hybrid method 1 did not elicit any increase in satisfaction level (95% CI, -0.386 to 0.386). There was no significant difference between the satisfaction levels ($p = 1.000$).

Second, the post-brainstorming satisfaction levels of introverts after the traditional and the hybrid method 2 were compared. The difference scores for the traditional method and hybrid method 2 were normally distributed, as assessed by Shapiro-Wilk's test ($p = .621$). According to descriptive statistics, introverted participants were more satisfied after hybrid method 2 (4.02 ± 0.67) as opposed to the traditional method (3.82 ± 0.54). Hence, the hybrid brainstorming method, elicited an increase of 0.200 (95% CI, -0.132 to 0.532) in post-brainstorming satisfaction compared to the traditional method. However, this increase was not significant, $t(14) = 1.293$, $p = .217$. Conclusively, both H5 and H6 are rejected. Finally, an overview of the results for all hypotheses can be found in table 5.

Table 5: Overview of hypotheses test results

	Hypotheses	Test results
H1	<i>In traditional interactive group brainstorming, introverted group members contribute significantly less to the total amount of ideas generated, compared to extraverted group members</i>	Accepted ($p < .0005$)
H2	<i>In hybrid brainstorming, introverted group members contribute significantly more to the total amount of ideas generated, compared to traditional interactive group brainstorming</i>	Rejected for hybrid method 1 ($p > .05$), Accepted for hybrid method 2 ($p < .05$)
H3	<i>In hybrid brainstorming, introverted and extraverted group members contribute equal shares to the total amount of ideas generated</i>	Rejected for hybrid method 1 ($p = .007$) ¹ , Rejected for hybrid method 2 ($p = .033$) ¹
H4	<i>In hybrid brainstorming, introverted group members contribute significantly more ideas if frequent changes between individual and group phases are included, compared to less frequent changes</i>	Accepted ($p = 0.007$)
H5	<i>Introverted group members show a lower satisfaction-level after traditional interactive group brainstorming compared to extraverted group members</i>	Rejected ($p = .117$)
H6	<i>Introverted group members show a higher satisfaction-level after hybrid brainstorming compared to traditional brainstorming</i>	Rejected for hybrid method 1 ($p = 1.000$), Rejected for hybrid method 2 ($p = .217$)

¹ H1: $\mu_{\text{introverts}} \neq \mu_{\text{extraverts}}$

5 Discussion

First, the results attested a general existence of differences in average ideas generated between introverts and extraverts. However, this cannot be traced back to an interplay between applied brainstorming method and personality type. Still, results indicate that both personality type and brainstorming method have an effect on the outcome of brainstorming. This fortifies earlier findings which have already accredited personality with an impact on brainstorming performance (Callaghan, 2009; Camacho & Paulus, 1995; Jung et al., 2012). What is more, previous research has also provided evidence that particularly differences in the introversion-extraversion dimension can play a significant role in brainstorming (Bradley & Hebert, 1997; Jung et al., 2012), which was likewise confirmed with this research. The findings of the present study hence support the “New Groupthink’s” claim that personality differences can be made accountable for variances in brainstorming productivity (Cain, 2013; Dossey, 2016). Besides, results also accredit a general difference in brainstorming performance of introverts between the traditional and hybrid methods. This provides a first indicator for the presence of a favorable effect of hybrid brainstorming on introvert’s contribution to brainstorming.

For hypothesis 1 (H1), it was predicted that in traditional interactive group brainstorming, introverted group members contribute significantly less to the total amount of ideas generated, compared to extraverted group members. This assumption was proved and therewith replicates previous research. Although only a few studies have broached this issue earlier, already Callaghan (2009) showed introverts to be less involved in brainstorming sessions. The present result again underlines the argument of the “New Groupthink” theory, stating that introverts fall behind extraverts in interactive group brainstorming (Cain, 2013).

Regarding hypothesis 2 (H2), the expectation was that in hybrid brainstorming introverted group members would contribute significantly more to the total amount of ideas generated, compared to traditional group brainstorming. This hypothesis was shown to be significant for hybrid method 2, however not for hybrid method 1. Still, introverts generated more ideas on average in both, hybrid method 1 (4.13 ± 2.63) and hybrid method 2 (5.94 ± 3.43), compared to the traditional method (3.81 ± 1.94). A general increase in ideas when applying hybrid brainstorming was attested earlier in literature, however regardless of personality type (Girotra et al., 2010; Jung et al., 2012; Korde, 2014; Korde & Paulus, 2017; Paulus et al., 1995). In the present research, based on the average ideas generated in the traditional method, introverts showed a relatively larger increase in mean ideas when applying hybrid method 1 (+8.40%) and hybrid method 2 (+55.91%) compared to extraverts (+1.48% in hybrid method 1 and +22.45% in hybrid method 2). However, the effect is not as large as in the study of Girotra, Terwiesch, and Ulrich (2010), who reported three times more ideas in a hybrid condition. Besides, hybrid method 2 elicited a significantly higher increase compared to hybrid method 1. This divergence in findings concerning the two hybrid methods can be traced back to more frequent changes between individual and group phases that are involved in hybrid method 2. This was predicted to be favored by introverts, since they oftentimes possess a shorter

attention span (Kasof, 1997). Conclusively, hybrid brainstorming methods have the power to enhance the contribution of introverts, whose performance can be maximized when frequent and fast changed between quiet and group phases are involved.

Hypothesis 3 (H3) forecasted that in hybrid brainstorming, introverted and extraverted group members contribute equal shares to the total amount of ideas generated. This prediction was statistically insignificant for both hybrid method 1 and hybrid method 2. Introverts still contributed significantly less ideas on average compared to extraverts, who generated the most ideas in each condition. The insignificant results mainly occur because not only introverts but both personality types experienced an increase in average ideas generated within the hybrid methods. Consequently, the performance gap could be reduced but not be closed. However, the difference in mean ideas generated between the two personality types narrowed when applying the hybrid methods. The difference between mean ideas generated by introverts and extraverts was hence decreasing from 2.96 (traditional method) to 2.74 (hybrid method 1) and finally 2.35 (hybrid method 2), respectively. On the whole, it can be concluded that even though introverts benefit slightly more from hybrid brainstorming compared to extraverts, and increase their overall amount of ideas, the method cannot overcome the performance gap between the two personality types.

For hypothesis 4 (H4), it was predicted that in hybrid brainstorming, introverted group members contribute significantly more ideas if frequent changes between individual and group phases are included. This hypothesis was accepted. Hence, introverts contributed significantly more ideas in hybrid condition 2 compared to hybrid condition 1. Neither has any study particularly investigated the effect of the number of changes between group and individual conditions, nor its impact on the performance of introverts. Therefore, this result adds original contributions to the respective body of research and cannot be directly compared to earlier findings. However, it is in line with inferences derived from prior studies in the field of brainstorming and personality (Korde & Paulus, 2017; Paulus, Dickson, Korde, Cohen-Meitar, & Carmeli, 2016; Paulus & Yang, 2000). In addition, the finding goes along with the general characterization of introverts. In this regard, Kasof (1997) found this type of personality to recharge energy through being quiet. Consequently, involving more frequent individual phases, such as in hybrid method 2, accommodates introverts. This likewise supports Cain (2013), who argues that introverts reenergize through solitude, which in turn functions as a catalyst to innovation.

With regards to post-brainstorming satisfaction of introverts, results indicated that post-brainstorming satisfaction cannot be directly traced back to personality type or brainstorming method. Since no other study has yet compared satisfaction levels of introverts and extraverts after hybrid brainstorming, this result cannot be compared directly to earlier publications.

Regarding hypothesis 5 (H5), it was expected that introverted group members show a lower satisfaction-level after traditional interactive group brainstorming compared to extraverted group members. This prediction had to be rejected. The satisfaction level of introverts was lower, however not significantly lower after traditional group brainstorming. This result is to some extent surprising when reviewing earlier literature.

In this regard, it was found that introverts oftentimes perceive meetings and group discussions, such as brainstorming, to be an energy drain (Culp & Smith, 2005). In case of the present research, irrespective of their inferior performance, introverts seem to enjoy traditional group brainstorming (satisfaction level: 3.86), although a little less than extraverts (satisfaction level: 4.12). Therefore, it can be concluded that irrespective of actual performance, traditional group brainstorming is much liked amongst introverts and slightly more amongst extraverts.

The hypothesis 6 (H6), which assumed that introverted group members show a higher satisfaction-level after hybrid brainstorming compared to traditional brainstorming, was likewise rejected. Since hybrid brainstorming comes along with individual reflection phases and hence time to think things through before discussing as a group, it was assumed that introverts prefer hybrid brainstorming over the traditional method (Callaghan, 2009). However, in contrast to expectations, no differences in introverts' satisfaction levels could be noted between the traditional and hybrid method 1. One reason for this discrepancy could be that introverts already reported quite high satisfaction levels after the traditional method and did not leave much room for higher scores. In this regard, they might have wanted to save credits for round 3. Another reason could be that introverts neither perceived any advantage over the traditional method nor felt more accommodated in hybrid method 1. Eventually, they generated ideas in the individual phase, but could not present them to the group within the group phase because extraverts took the floor. Since no second individual and group phase followed, introverts had no time to rethink about ways to enter the discussion. One may argue, that no learning effect could occur in hybrid method 1, since both phases were given only once. Regarding the difference of introverts' post-brainstorming satisfaction between the traditional and hybrid method 2, a slight – though not significant – increase could be observed. This increase can be traced back to the advantages that come along with the involvement of multiple changes between the two conditions, as discussed before. Conclusively, it can be stated that introverts feel more satisfied when applying hybrid brainstorming methods, while involving multiple changes between quiet and group phases satisfies them the most.

Finally, referring back to the research question, asking whether hybrid brainstorming can empower introverts to contribute an assimilable amount of ideas compared to extraverts, the following conclusion must be drawn: The method of hybrid brainstorming alone does not have enough power to close the performance gap between introverts and extraverts. In fact, extraverts still generate the most ideas in all brainstorming conditions. However, hybrid brainstorming helps to enhance both the contribution of introverts and their post-brainstorming satisfaction. Consequently, there is a tendency towards a narrowed contribution of introverts and extraverts in hybrid brainstorming, due to the enhanced performance of introverts caused by the change in method.

6 Conclusions, limitations and implications

6.1 Conclusions

To the extent that the results of the present experiment are generalizable, it can finally be concluded that the method of hybrid brainstorming has the power to enhance introvert's contribution to brainstorming and their post-brainstorming satisfaction, the latter however to a small extent. Therefore, applying this method can reduce the "New Groupthink's" effect on ideation. This entails that in hybrid brainstorming, introverts' performance and satisfaction is hampered less than in conditions that were shown to accommodate primarily extraverts, such as traditional group brainstorming. However, with reference to the research question, the method of hybrid brainstorming does not possess sufficient power to fully close the performance gap between introverts and extraverts. Extraverts still generate the most ideas in all brainstorming conditions and consistently show slightly higher satisfaction levels. Nevertheless, hybrid brainstorming helps to enhance the overall brainstorming performance of introverts to a larger extent than that of extraverts and therewith facilitates a more equal contribution of both personality types. However, in hybrid brainstorming, providing the right conditions was found to be crucial to achieving the desired effect. Therefore, multiple changes between individual and group discussion phases are required.

This research illustrated the "New Groupthink" theory's standpoint with regards to the widely-used collaborative ideation method of group brainstorming, still being the most commonly adopted approach for generating creative ideas (Korde & Paulus, 2017; Rietzschel et al., 2006). Since the method's application in its traditional form after Osborn (1957, reprinted 2013) was found to be to the detriment of introverts (Callaghan, 2009; Camacho & Paulus, 1995), one alternative method, namely hybrid brainstorming – which alters between individual and group brainstorming – was investigated within this research. Due to the fact that no research has yet investigated whether hybrid brainstorming helps to overcome the discrepancy between the contribution of introverts and extraverts in group brainstorming, this research has stepped into that gap. Consequently, the main aim of this study was to explore whether hybrid brainstorming empowers introverts to contribute an assimilable amount of ideas compared to extraverts.

Consequently, besides the overall conclusion as stated above, this research raises some relevant considerations regarding brainstorming. First, it can be stated that introverts tend to underperform in collaborative forms of ideation, which again underlines the existence of natural differences between introverts and extraverts that should not be disregarded. More specifically, this finding demonstrates that personality, although widely neglected in brainstorming literature, plays an important role in the search for the best brainstorming performance and that the empowerment of introverts constitutes a determining factor for success.

Furthermore, hybrid brainstorming was found to generally surpass traditional group brainstorming with regards to the quantity of ideas generated and post-brainstorming satisfaction levels. Hence, in contrast to traditional group brainstorming, this method possesses the ability of enhancing the overall brainstorming performance of introverts.

Besides, although to a smaller extent, extraverts also displayed higher satisfaction and performance levels when using hybrid brainstorming. This further demonstrates the method's general superiority over traditional group brainstorming. In particular, introverts were found to be most satisfied and to perform best when frequent changes between individual and group brainstorming were involved. This further emphasizes the importance of choosing the right method and designing the right brainstorming conditions to maximize overall performance. As a consequence, a need to rethink and adapt existing ideation methods to accommodate all personality types and finally obtain the best results arises.

Concerning satisfaction in brainstorming, it can be concluded that, irrespective of their lesser performance, introverts do not feel dissatisfied or unhappy after brainstorming. In fact, they seem to enjoy both the traditional and hybrid method, whereof the latter is slightly favored. This speaks for the existence of the positive effects this method can have on participants, which go beyond the pure quantity of ideas generated. Therefore, applying interactive group-, or hybrid brainstorming can satisfy participants. They generally feel productive and contributory – a factor that should not be neglected in both the brainstorming literature and the “New Groupthink” discussion.

The derived conclusions add original contributions to the respective body of research. First, they contribute new insights to the scarcely covered academic area concerning the personality's impact on brainstorming performance and underline its decisive role. Second, no previous research had found adequate solutions of overcoming the productivity barrier between introverts and extraverts in group brainstorming. Therefore, this study serves as a first step towards addressing this issue. What is more, it was the first of its kind to explore whether hybrid brainstorming has the power to close the performance gap between the two personality types. Third, unlike any other study, this research also compared satisfaction levels of introverts and extraverts in traditional group and hybrid brainstorming in addition to the widely-used measure of average ideas generated. This provided further insights into the methods' general degree of esteem.

6.2 Limitations

A number of limitations must be acknowledged with regards to the generalizability of this study. First, regarding the study's sample, it needs to be noticed that a non-random sampling method, namely convenience sampling, was applied for practical reasons. Although the sample size was regarded to be sufficient, including a larger sample would have facilitated a greater statistical power. Additionally, a commensurately higher number of brainstorming groups would have increased overall validity. Furthermore, an equal spread between introverted and extraverted participants per group would have been preferable, since an uneven distribution might have disadvantaged the contribution of the group's minority. This can mainly be attributed to potential group dynamics resulting from an uneven spread of personality types. Again, a larger sample size would have been needed to counteract this shortcoming. Besides, this study employed an experiment involving students, which is not equal to a natural group setting. Although this may be methodologically consistent with much of the research on brainstorming, this approach

presents some difficulty in generalizing the obtained results to real organizational settings.

Furthermore, it should be noted that the categorization of participants according to personality type was based on trust. This shortcoming is attributable to the fact that participants needed to independently report their test scores without being controlled. These scores consequently served as basis for their categorization. Since no other comparable and feasible test procedure was available to the researcher, this limitation was not restrictable.

To conclude, exclusively three brainstorming conditions were selected for investigation, whereas others were knowingly excluded due to the limited scope of this study. Accordingly, this study is limited to the specific conditions under investigation, namely one traditional and two hybrid conditions. Furthermore, the results exclusively refer to the employed time frame of eight minutes per brainstorming round, since no other time frames were tested. Hence, the obtained results cannot be generalized for the traditional group- or hybrid brainstorming method as such.

Lastly, referring to delimitations, this research exclusively employed quantitative measures without any qualitative elements. This is due to this study's particular focus on empowering introverts in brainstorming by increasing their numerical share to idea contribution. Likewise, the complementary satisfaction measures were solely of quantitative nature.

6.3 Implications and further research

This research intended to find ways to counteract the suppression of introverts' contribution to ideation caused by the rising trend towards boundless collaboration at the workplace. In particular, the collaborative ideation method of brainstorming was investigated to explore how to empower introverts and therewith lower the effect of the "New Groupthink". In general, the findings derived underline the importance in organizations to recognize differences between introverted and extraverted employees. For managers, this encompasses answering to employees' diverse and individual needs regarding personality, and to facilitate corresponding working conditions. It is hence recommended to find ways of accommodating both introverts and extraverts at work. In particular, organizational areas dealing with creativity and innovation should not regard collaborative ideation as the only true form, as it is however often the case. Especially in today's turbulent times, where creativity and innovation are key for organizations to defend their market position, it is of utmost importance to apply ideation methods in their most efficient forms. Accordingly, for teams who frequently apply traditional group brainstorming, a switch to hybrid methods is suggested, since findings have shown that this can lead to both an increase in overall results and the contribution of introverts. Besides, it is recommended that managers and team leaders make use of multiple ideation methods in order to accommodate and include the ideas of various personality types. In practice, including individual ideation phases in brainstorming may also take on different forms. To illustrate, a team could brainstorm about the same topic within several meetings and use the time in between to think individually before reconvening and continuing the

group discussion. Finally, for introverted employees who oftentimes feel overwhelmed by traditional group brainstorming, suggesting a hybrid approach to the group is also recommended.

Finally, the paper at hand provides a first step in approaching the underperformance and suppression of introverts in collaborative ideation methods. In particular, this research concentrated on the most widely applied ideation method of group brainstorming. Since there barely exist literature concerning the impact of personality differences on brainstorming, this academic area offers a large range of possibilities for further research. Especially hybrid brainstorming implies promising future research opportunities in the course of finding the most effective brainstorming method that balances the contribution of introverts and extraverts. Since creativity and innovation increasingly gain importance for organizations, investigating more ideation methods with regards to introverts' performances is recommended. Therefrom obtained findings could add valuable contributions to the search for methods that best balance the contributions of introverts and extraverts and yield most ideas. Since the conducted research found the specific hybrid brainstorming conditions to be crucial for the enhanced contribution of introverts, further research is necessary to explore which conditions are best-suited. This encompasses the investigation of the optimal amount of changes between group and individual ideation phases as well as the ideal time span of each phase. In addition, it is recommended to delve into a qualitative dimension, such as researching participants' reasons behind preferring one hybrid method over another. To conclude, conducting further studies in real settings, in order to obtain a higher level of generalizability of results, is recommended.

Abstract

The aim of the paper is to analyse how innovative financial tools can contribute to the development and sustainability of the territory and his local products.

This research is supported by a qualitative research of case study (Yin, 2014). Thus, the paper applies the CAOS model of micro-entrepreneurship by Paoloni (2011) with a few changes which make it possible to describe all variables that involve the company in a certain economic context. Using such model, we're able to share some factors and to classify different types of connections, identifying several kinds of existing relations.

Into economic context of Sardina, a little island in south west of Italy, where there are more than 60,000 agricultural enterprises, of which 60% shepherds, there is a constant difficulty in obtaining funding. This difficulty very often is related to the uncertainty of seasonal activity. Our work show how the use of innovative financial tools can encourage access to credit capital, even non-banking, of SME operating in the agrifood sector, and then how these innovative tools can promote the development and sustainability of the territory and his local products. This could be possible through the aggregation and cooperation of firms The paper also shows the active role of local authority "Regione Sardegna".

Following the case study, also allows a possible valuation of local products (Pecorino cheese) as, through a rotary pledge, they are the basis of the guarantees offered to the subscribers of the bond. Our work contributes to expansion of studies on the innovative financial tools for the promotion and development of the local agri-food heritage. This can be possible, on the one hand, through the growth of private local companies by the marketing of local products, and then, through the financial sustainability of the public authority that indirectly will see increased tax revenue deriving from the production of

local activities. The future research will be focused on the analysis of the specific economic results of the financial operation described here. Furthermore, will be focused on possible similar cases with the aim to development local product through innovative financial tools

The limit of our research are related to the short observation time since the finance instrument was issued, only in 2018. Furthermore, another limit for our research is the narrow territorial base of observation.

Keywords – Food, Innovative Finance, Sustainability, Value, Mini Bond

Paper type – Academic Research Paper

1 Introduction

During the crisis, in the bank-oriented countries such as Italy, a lot of SME has reached their economic activity for the lack of financial resources needed to the development the business. The paper discusses about the sustainability of SME business and the development of their local products that represented a real agri-food and agricultural heritage for the territory. To development this topic the main research question is:

RQ: how innovative financial tools can contribute to the development and sustainability of the territory and his local products?

Our research starts from the effects that the financial crisis has caused into SMEs dimension and focusing on observation of a single case study that, through active role of local authority “Regione Sardegna”, has enabled a lot of local entrepreneurs to conglomerates and take full advantages of the economic benefits arising from the use of “innovative” financial tool: mini-bond. It’s the case study of a shepherds cooperative company¹ established from 1966 in Oristano a little country of Sardinia island, in south-west from Italy. In July 2018, following a long period of financial crisis, the company issued “Pecorino Bond” by EUR 1.75 millions with the aim of development his product.

The paper concerns a lot of relevant factors: active role of local authority, the innovative financial tools chosen, methods of financial risk coverage and, last but not least, particular kind of guarantee reserved for private investors. All of this factor has the common aim of protection and development the local product “Pecorino Cheese”, know around the world as agri-food and cultural heritage.

In order to answer our RQ, we’ve used single case studies methodologies (Yin 2014) by applying the qualitative analysis model of C.A.O.S. (Paoloni, 2011). With this model is possible to describe all of qualitative variables on the “Pecorino Bond” case studies and also is possible show the relevant relationship (cardinal of first –second and third types) which enabled the success of financial operation.

This paper is structured as follow. In section 2, the relevant literature about evolution money market, the shift from a bank-oriented to a market-oriented enterprise’s system and the literature about the Italian SMEs is examined. Section 3 framework of case study

¹ The company name is Cooperativa Agricoltori Ovisini.

methodology and CAOS model used. Section 4 discusses and finding of “Pecorino Bond” case study is examined. Finally, in section 5 is described the outlines conclusion, limitations of our research and the future perspective of them.

2 Literature Review

The money market is regulated by financial intermediaries which means the issuance of a financial security. According to Pilbeam (2018) financial security is asset for one party and a liability for the other party. Spulber (1996) say that thinking about the role of intermediaries in an economy, it is analytically useful to recognize three types of agents: consumers, market-taking firms and market-making firms. The market-making firms, make a significant contribution in the global economy (Qi, 1998, and Diamond & Rajan 2001). Is possible to find two different types of financial securities in the market: debt assets and equity assets (Ennew et al. 2013). The distinction between debt and equity assets is of relevant importance because the holders of debt instruments commonly face relatively low risks compared to holders of equity.

Equity financing allows a company to acquire funds (often for investment) without incurring debt. On the other hand, issuing a bond does increase the debt burden of the bond issuer because contractual interest payments must be paid-unlike dividends, they cannot be reduced or suspended. The bond market is vital for economic activity because it is the market where interest rates are determined. Interest rates are important on a personal level, because they guide our decisions to save and to finance major purchases (such as houses, cars, and appliances, to give a few examples). From a macroeconomic standpoint, interest rates have an impact on consumer spending and on business investment.

Focusing on Italian scenario the Italian economic system the small and medium size enterprises (SMEs) and “micro-firm” represent 90% of the total Italian economic entities. According to some Italian scholars (Bertini, 1969, Aureli, Cesaroni, Demartini, 2004), definition of small, medium and large company results from the role the companies play in a society development process and not only from quantitative parameters as defined in the traditional business literature. So the national wealth of “made in Italy” is increased by this small entities and by their manufactured products. Over the last decades the issue about SMEs, and in particular, SMEs in going global, has gained the attention of scholars and business experts as a key factor to improve competitiveness and lead the “made in Italy” all over the word (Ricci et al., 2011). This is most important because to the company dimension, following a different availability of the intermediaries (in terms of volumes and interest rates) to grant financial resources on loan (Ferri et al., 2013). In literature is easy to find evidence how suggest that the companies most affected by the reduction in the supply of credit - especially after financial crises - are precisely those smaller in size and more dependent on the banking channel, featured of a greater information opacity and a smaller capitalization (Chodorow-Reich, 2014).

In Italy the global economic crisis of 2007-2008, triggered in the US had a global impact, and then the national sovereign debt crisis of 2011-2012, had the consequence of

stiffening the intermediaries in credit granting procedures (Bassanetti et al., 2009). Therefore in this economic context is important for the all enterprises but in particular for SME find new alternative channels of debt assets and equity assets (Caratelli & Fattobene, 2018). In recent years, among the channels of supply of alternative financial resources to the banking system, a "new" financial instrument, known as a mini-bond, has attracted particular interest. With this deadline, reference is made to debt securities (of any maturity) issued by companies with listed or unlisted shares, following a series of regulatory changes introduced in Italy like "Crescita"¹ and "Destinazione Italia"².

As reported in the Consob (2018) report, having placed mini-bonds on the Italian market 137 companies, of which 56% Pmi (compared with 58% in 2016); of the 137 units, the 10-50 million euro turnover class stood at 33% in 2017, while the companies that do not exceed 10 million turnover are 25%. Considering this results mini-bond instruments is a good debt asset for SME.

In this paper we would like to understand how this new financial instruments, particularly referring to debt asset called mini-bond can help the Italian agriculture sector and small agro-food companies.

One of fundamental part of the Italian economic system is the food industry and is an important sector in its manufacturing industry. The food industry has not been affected by the wider decline and loss of competitiveness in the Italian industry. Italian manufacturing industry is composed mostly of small and medium sized agricultural farms (Rossi et al., 2015).

Regarding the financial statements, the most important problem is the undercapitalization. It's typical of the entire Italian agro-food system. It is nonetheless especially alarming when these data are viewed in conjunction with the investments made by companies that are already heavily indebted. This is a weakness and a problem for small and medium agro-food companies and could undermine their competitiveness (Rossi et al., 2012)

At the same time agro-food system is significant in the economic system, just to understand the importance Rossi et al. (2014) show that Italy's products of designated origin continued to increase in number, to 210 registered PDO (protected designation of origin) and PGI (protected geographical indication) products (22.6% of the EU total). Most of Italy's PDO and PGI products are fruits, vegetables and cereals (nearly 40%), extra-virgin olive oil (19%), cheese (17.6%) and prepared meats (almost 16%). In this paper, we try to understand how is possible to transfer money between an institutional government company and a group of agriculture producer of a typical Italian cheese called "Pecorino" and at the same time maintain and increase the value of agro-food system products.

3 Methodology

In order to analyze our RQ we'll be used the method of Case Study within a descriptive single-case design. The case study methodology including both quantitative and qualitative data, helps explain both the process and outcome of a phenomenon through complete observation, reconstruction and analysis of the cases under investigation (Tellis, 1997).

Case study method allows to closely examine the data within a specific context. Case studies explore and investigate contemporary real-life phenomenon through detailed contextual analysis of a limited number of events or conditions, and their relationships (Yin, 2014).

We'll be used the CAOS model (Paoloni, 2011) with a few changes which make it possible to describe all topics that involve the company in a certain context. So far CAOS model is only used to relation capital valuation. The topics are personal characteristics of the entrepreneur (C), the environment in which the micro-enterprise operates (A), organizational and managerial aspects (O) and then the motivations for starting a new business or particular stage where the SME is observed (S).

Personal characteristics of the entrepreneur (C): defines distinctive factors of each entrepreneur affecting the role played by entrepreneur within its firm and capability to build networks and take advantages from them. Elements composing these dimensions are the following:

- anagraphic information of entrepreneur or company (name, surname, age, education, experiences);
- micro-enterprise information (denomination, legal form, dimension, location);
- motivation supporting the business;
- business vision;
- management form;
- entrepreneur role in the firm;
- decision making process activation.

The environment in which the micro-enterprise operates (A): explains the socio-economic-cultural context in which the enterprise is located. The environment can influence connections that a company creates interacting with subjects in this context. Thus, the environment also impacts on the relationships coming from the italian economic system.

Organizational and managerial aspects (O): are connected to entrepreneur's objectives, tasks and responsibilities within the organization; to understand how agrifood system is set into italian economic system and which are financial characteristics:

- roles assignment;
- responsibility identification;
- operative and management procedures definition to define how execute roles and business actions.

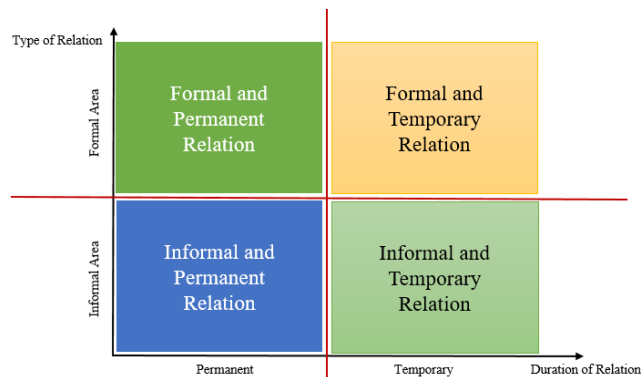

The motivations for starting a new business (S): It is the relevant phase in which the entrepreneur is focused on the following actions:

- study of the environment;
- write a business plan;
- find financial funds;
- choose legal form;
- build up the organizational structure;
- start the business

3.1 The model for analysing Case Study

The model we use to analyze the relations of SME in the single case study is found on the following Paoloni's matrix (Paoloni, 2011) based on four types of network relations. The matrix is composed by the intensity of the relation variable - permanent or temporary - and the type of relation variable - formal or informal.

The model identifies four network relations as shown in the figure 1.

Own Elaboration.

Figure 1 – Relations matrix

The relations are important to understand how the networks support the enterprise to development your business.

The process identified in the CAOS model (Paoloni, 2011) requires a careful analysis of the four elements. We will call the connections that link the point S with points C, O and A, cardinal links because they represent the cornerstone of all business relationships. Within these connections, there will be different kinds of relationships: formal, informal, temporary or permanent. The cardinal links are:

- first (S-C/C-S);
- second (S-O/O-S);
- and third (S-A/A-S).

4 The Case Study

The information data to describe the “Pecorino Bond” case study has provided to the authors from head legal of IFG Bank, banking institution responsible to operation

structure, and from manager of Pairstech Capital Management, PE fund responsible of placement of financial tools in the early stage.

4.1 Personal characteristics of the entrepreneur (C)

The company involved into “Pecorino Bond” is “Cooperativa Agricoltori Ovis” a cooperative company established from 1966 in Oristano a little country of Sardinia, island in south-west from Italy. Actually the company have 700 associates members, his mission is aggregate all the milk product by each individual shepherds and turn this into quality cheese. The leadership of the cooperative company is shared between shepherds. Each associates are expression of Sardinia’s history that contribute to the creation a cultural heritage. With same aim the company. has developed a property brand, since 2002 has ISO 9001 certification, and in 2008 has achieved IFS-FOOD quality standards. The performance data, pre cooperative-adjustment¹, and the balance sheet’s data for the period 2017 -2016 are:

Description	2017	2016
Revenues	30,42	27,18
EBITDA	5,45	1,67
EBIT	4,50	702,00
Firm Value	38,36	37,39
Working Capital	21,30	18,57
BV	10,13	5,82
Liabilities	28,23	31,57
BV+Liabilities	38,36	37,39

4.2 The environment in which the micro-enterprise operates (A)

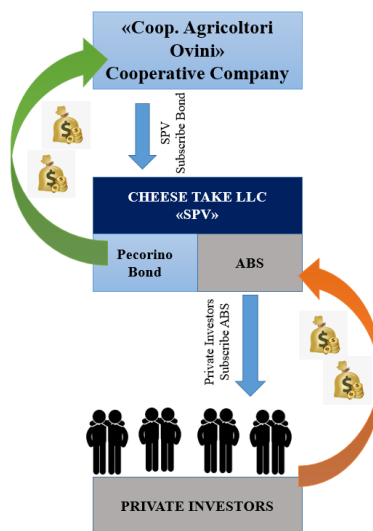

The environment where the company make her local product (Pecorino cheese) is Sardinia, a little island in south west of Italy. In this place, one of the most relevant economic activities is the dairy product that, over time, have become a really agri-food and cultural heritage know around the world as “Pecorino Cheese”.

The company establishments has equipped of high technologies for the milk transformation process. Their production capacity is over 180.000 milks liters by day and 22 million milks liters by year. The output is more diversify: from the only raw materials (milk) the company produce more than 25 kind of cheese.

4.3 Organizational and managerial aspects (O)

The figure 2 shows framework of financial operation:

¹ Cooperative-adjustment is a typical practice of agri-food labour cooperative company. This practice provides that at the time of the breeder’s milk contribution, he gets a down payment and, only when the production is finished the breeder can receive payment of the balance.

Own Elaboration

Figure2: Framework of Pecorino Bond

The company bond issuing has already just described into “C” section.

The SPV (Special Purpose Vehicle) is “CheeseTake LLC” company, established to SFIRS PLLCs, financial company owned to local authority “Regione Sardegna”. Cheese Take LLC has subscribed total of the “Pecorino Bond”. The financial resource needed for subscription, has been raised through the placement of ABS (Asset Backed Securities) instruments to private investors.

Through this “waterfall” framework the CheeseTake LLC, on the one hand, could subscribed the total of the bond for 1.75 million euro and then get from the company. repayment of principal with interest rate, on the other hand, could cover the bond risk-share instrument through the placement of ABS (Asset Backed Securities) instruments to private investors.

Moreover into Pecorino Bond operation has been planned a particular forms of guarantee about the financial tool.

A part of this are guaranteed by “Confidi Sardegna” PLLCs¹ and another part by a rotary pledge on Pecorino’s Cheese. Through this guarantee’s form, in the event of insolvency, the investors can be satisfied across the Pecorino. The percentage of cover is described in the next section “S” of CAOS model.

Finally, the entity that have implemented the legal framework is EFG Bank (Luxembourg), Italian head quarter.

¹ Confidi Sardegna PLLCs is the mutual guarantee funds established since 1974 by Confindustria Sardinia. Confidi Sardegna is also financial intermediaries supervised by Bank of Italy

4.4 The motivations for starting a new business (S)

In this section are described the relevant phase in which the “Cooperativa Agricoltori Ovini” company is focused on find financial funds. Our study starts with the observation of the crisis in the agri-food sector. In recent year, in Italy, the agriculture loans shall be regarded as equivalent of common firm lending with the major difference that the agriculture’s companies have a financial structure’s gap than a common merchant enterprise. Especially, the agriculture’s companies is failing to meet the request of real guarantee of Bank to credit access. In 2017 the agriculture and agroindustry loans amounted to EUR 332 million, of which EUR 160 million no performing loan (NPL).

For this reasons the local authority “Regione Sardegna” across her financial company SFIRS PLLCs, has actived a “protection” process of agrifood heritage through the minibond. In July 2018 SFIRS PLLCs, across her Special Purpose Vehicle (SPV) “CheeseTake LLC”, proceeded to subscribe total of minibond “Pecorino Bond” issuance by Cooperative Company. The loan period of Pecorino Bond is 24 month with redemption at maturity and yearly prefixed coupon payments to 3%.

At the same time CheeseTake LLC has issued ABS in the financial market, collateral to cover the bond risk-share instrument.

The local authority “Regione Sardegna” in order to raises for complete the financial operation has provided the ABS’s subscription a fund of eur 3 million. This financial resource can be used to a maximum of 20% per ABS.

Proportion of coverage of instrument are:

- 30% coverage by “Confidi”;
- 60% coverage by a rotary pledge on Pecorino’s Cheese;
- only 10% it’s without a coverage.

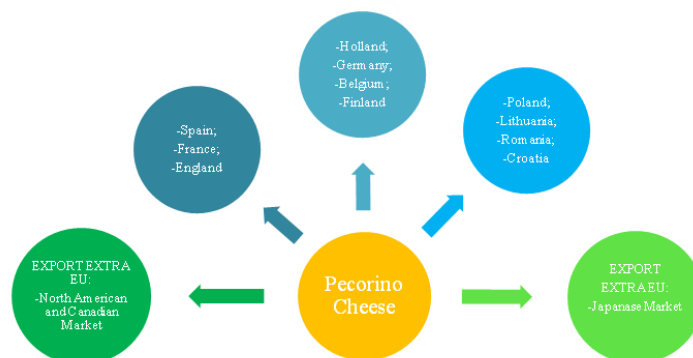

With this form of pledge, in the event of insolvency, the investors can be satisfied across the Pecorino. This coverage’s scheme causes that the Pecorino’s Cheese repossessed has an economic value at least 60% to face value of obligation outstanding. The pledge agreement provides for the appointment of Pecorino Cheese janitors. They’re chosen a member of “Cooperativa Agricoltori Ovini” and a member of Consortium of Pecorino Protection (Consorzio di tutela del pecorino).

The Consortium of Pecorino Protection (Consorzio di Tutela del Pecorino) and Agency Responsibility of Agriculture in Sardina (Italian acronym AGRIS) have been consulted by local authority “Regione Sardegna” in order to evaluation Pecorino Cheese for give an economic value in the pedge agreement.

The financial operation was concluded positively and it’s ongoing. Also ABS have been fully subscribed by private investors.

Financial operation “Pecorino Bond” is one of the first financial operation that a local authority - through a de-banked process – be try raises a private founds with the aim to safeguard development of local firms and their product, became a typical agrifood heritage.

Actually, the company has expanded her commercial network. The Pecorino is exported in many Europeans ed extra UE countries. The following figures (Figure3) show the destinations of Pecorino’s exportation:

Own Elaboration

Figure3: Destination of Pecorino Cheese Exportations

4.5 Analysis of Relationship

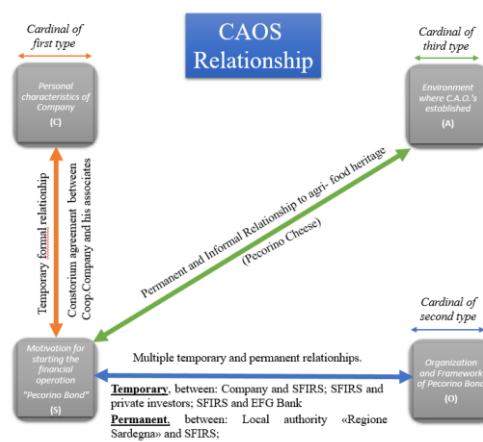

In order to the CAOS model the relationships that “The Pecorino Bond” has developments are:

- Cardinal links of first type (S-C): this phase is characterized by a formal and temporary relationship. The cooperative company has involved about 700 shepherds that, each for his contribution, are linked by a formal consortium agreement. All of shepherd will benefit from financial resource of Pecorino’s bond even if they must pay back the obligation at the end of 24 months;
- Cardinal links of second type (S-O): this phase is characterized by multiple formal relationship: few permanent and other temporary, but all linked to success of financial operation. The relationship formal temporary are:
 - Between Cooperative Company and SFIRS: across the SPV CheeseTake LLC the SFIRS has been underwrite all of Pecorino Bond. This relationship are limited for 24 months, as the maturity of the obligation.
 - Between SFIRS and private investors: those have subscribed ABS’s instrument issued by SPV CheeseTake LLC in order to guarantee her risk for the total underwrote of Pecorino Bond. Effectively this relationship could be permanent if the company will be insolvent in order to payback the debts. In this case, the relationship will last until the private investors will sell the Pecorino Cheese guaranteed seats by rotary pledge. But now we can’t refer on this.
 - Between SFIRS and EFG Bank: the credit institution has engaged to development legal framework of financial operation.

The formal permanent relationship are between local authority “Regione Sardegna”, company SFIRS and company Cheese Take LLC: for these there is a correlation equity’s share. The SPV CheeseTake LLC is owned by SFIRS and these is owned by local authority “Regione Sardegna”;

- Cardinal of Third Type (S-A): this phase is characterized by informal and permanent relationship. The link between the Pecorino Bond and the environment where the company is established it's just the agri-food heritage (Pecorino Cheese) which has always is part of Sardinia's territory. This proves it that that following financial crisis of shepherds the local authority "Regione Sardegna" is activated for build an operation that allow them financial resource for a fresh start: Pecorino Bond. Really the company and local authority "Regione Sardegna" are not related to any agreement but the intangible value that in the years the agri-food heritage (Pecorino Cheese) has built, it's been the value driver for preservation and development of local product and their production.

"Pecorino Bond" relations as shown in the figure 4.

Own Elaboration

Figure4: "Pecorino Bond" relations

5 Conclusions

Agro-food system is significant in the economic context, just to understand the importance Rossi et al. (2014) show that Italy's products of designated origin continued to increase in number, to 210 registered PDO (protected designation of origin) and PGI (protected geographical indication) products (22.6% of the EU total).

The small and medium size enterprises (SMEs) and "micro-firm" represent 90% of the total Italian economic entities. According to some Italian scholars (Bertini, 1969, Aureli, Cesaroni, Demartini, 2004), definition of small, medium and large company results from the role the companies play in a society development process and not only from quantitative parameters as defined. Our research investigates about how innovative financial tools can contribute to development and sustainability of the territories and his local product. In this way we examined, through a single case study (Yin 2014) and the CAOS model (Paoloni, 2011), a financial operation aimed to development a Sardinia's local products: "The Pecorino Bond". Through this case study it's possible to observe how this new financial instruments, particularly referring to debt asset called mini-bond

can help the Italian agriculture sector and small agro-food companies. Following the financial crisis period, the local authority “Regione Sardegna”, by her SPV “Cheese Take LLC”, has managed to cover financial resources for “Cooperativa Agricoltori Ovisini” cooperative company.

In July 2018 cooperative company has issued a minibond for 1.75 million, and only after the subscription, the “CheeseTake LLC” has issued ABS (Asset Backed Securities) instruments to private investors.

Through this “waterfall” framework the CheeseTake LLC, on the one hand, could subscribed the total of the bond for 1.75 million euro and then get from the company repayment of principal with interest rate, on the other hand, could cover the bond risk-share instrument through the placement of ABS (Asset Backed Securities) instruments to private investors.

Moreover into Pecorino Bond operation has been planned a particular forms of guarantee about the financial tool: a rotary pledge on Pecorino’s Cheese for 60% of minibond amount. This particular form of guarantee, in addition to ensuring the private investor, was designed with the aim to give an indirect economic value to Pecorino Cheese. In this way the Pecorino production, by the rotary pledge, has an economic value at least equal to 60% of the risk of insolvency of company.

The relationships between parties has illustrated in the CAOS model (Paoloni, 2011). It shows how the strongest relationship is that between the variables “S” and “A”: this phase is characterized by informal and permanent relationship. The link between the Pecorino Bond and the environment where company is established it’s just the agri-food heritage (Pecorino Cheese) which has always is part of Sardinia’s territory. This proves it that that following financial crisis of shepherds the local authority “Regione Sardegna” is activated for build an operation that allow them financial resource for a fresh start: Pecorino Bond. Really the Company and local authority “Regione Sardegna” are not related to any agreement but the intangible value that in the years the agri-food heritage (Pecorino Cheese) has built, it’s been the value driver for preservation and development of local product and their production. The other relationship, outlined in the body of the paper, between variable “S” and “C” and between “S” and “O” are characterized by formal and temporary relationship subsequent and consequent the informal and permanent relationship between the variables “S” and “A”: the territory (Company and local authority “Regione Sardegna”) and his local product (Pecorino Cheese).

The financial operation was concluded positively and to this day it’s ongoing. Also ABS have been fully subscribed by private investors.

In order to answer at our RQ, financial operation “Pecorino Bond” is one of the first financial operation that a local authority - through a de-banked process – be try raises a private funds with the aim to safeguard development of local firms and their product. Actually “Cooperativa Agricoltori Ovisini” has expanded her commercial network: Pecorino cheese is exported in many Europeans and extra EU countries.

The limitation of our research are related to the short observation time since the finance instrument was issued, only in 2018. Furthermore, another limit for our research is the narrow territorial base of observation.

The future research will be focused on the analysis of the specific economic results of the financial operation described here. Furthermore, will be focused on possible similar cases with the aim to development local product through innovative financial tools.

Abstract

The knowledge and the cultural heritage concerning traditional recipes based on local and ancient crop varieties are very diffused in small rural areas and in local communities, in particular in Italy. This kind of knowledge, if well recognised and documented, can contribute to the sustainable development of territories in which it developed through oral transmission of local people. The traditional knowledge concerning food and foodways, that can be interpreted in terms of intangible heritage asset of the territory, in this paper is studied using the logic of Knowledge Transfer (KT). In fact, a crucial step for the preservation of the knowledge for future generations is the involvement of local communities, in order to elicit and to track the information of which they are custodians. The final goal is to engage them in the management of food knowledge for the sustainable economic, social and environmental development of their territory; in other words to preserve the social capital for future generation. The objective of the paper is to conduct a survey, in a very specific territory, that is the “Bio-Distretto della Via Amerina e delle Forre”, in Central Italy, in order to gather

information concerning the actual awareness of local people and organizations concerning their food heritage and the values (cultural and economic) they attribute to it. The information retrieved will then be used as a basis for the preparation of a theoretical framework of valuation and management of food heritage through citizen engagement in other areas/organizations. The survey will have the structure of a questionnaire, used to elicit awareness, feelings and wishes about the food heritage and their desired management for the development of the territory, in order to achieve information about cultural and economic values of this heritage. In particular, for the latter type of values, a Contingent Valuation Method (CVM) will be used. The expected result in terms of Knowledge Management and Transfer will be the development of a tool that can be interpreted as a Participatory Rural Assessment (PRA) method. Indeed, the mix of surveys and public engagement techniques aimed at understanding the values and knowledge that local populations in Bio-Districts wish to sustain allows an informed and communitarian preservation of food intangible heritage.

Keywords – Food, Traditional Knowledge, Contingent Valuation Method, Bio-District, Survey.

Type of paper: Academic Research Paper

1 Theoretical Background

Cultural heritage does not end at monuments and collections of objects. It also includes traditions or living expressions inherited from our ancestors and passed on to our descendants, such as oral traditions, performing arts, social practices, rituals, festive events, knowledge and practices concerning nature and the universe or the knowledge and skills to produce traditional crafts. The importance of intangible cultural heritage is not the cultural manifestation itself, but rather the wealth of knowledge and skills that is transmitted through it from one generation to the next. The social and economic value of this transmission of knowledge is relevant for minority groups and for mainstream social groups within a State, and is as important for developing States as for developed ones.

Cultural heritage expressed as “food” is a complex moving target, manipulated by diverse people for diverse ends. It is both tangible and intangible, and falls under the UNESCO Convention on Intangible Cultural Heritage which states: “*The ‘intangible cultural heritage’ means the practices, representations, expressions, knowledge, skills—as well as the instruments, objects, artefacts and cultural spaces*” of social groups passed down through generations that contribute to identity, are grounded in place, and are ‘a mainspring of cultural diversity and a guarantee of sustainable development’” (Art. 2, point 2, p. 3). Cultural heritage in food includes both the material (landrace plants, tools, landscapes etc.) and the immaterial (traditional recipes, techniques, sensory awareness, philosophies of food and health etc.).

Food takes on great emotional weight when designated as “heritage” (Brulotte, Di Giovine, 2014). Prepared food is an expression of culture, while the folkloric study of foods is called *foodways* (including hunting, gathering, agriculture, aliment preparation

and consumption). Though cooking, sharing, and eating food with family and friends, or sometimes alone, are matters of physical survival as well as personal and community identity, foods are sometimes abstracted to carry other meanings. Food is more and more often seen as a particular experience that can give emotion and wonder when some dishes are tasted because they are considered real and true works of art, made by creative and sometimes inspired chefs. Gastronomic traditions and even the alimentary materials prepared and consumed are among the most pervasive and obvious constituents of cultural heritage. Perhaps more than any other element of human culture, cuisine and foodways provide indispensable insight into the history of humankind (Montanari, 2004).

Food becomes culture *when it is prepared* because, once the basic products of his diet have been acquired, man transforms them by means of fire and a carefully wrought technology that is expressed in the practices of the kitchen. Food is culture *when it is eaten* because man, while able to eat anything, or precisely for this reason, does not in fact eat everything but rather *chooses* his own food, according to criteria linked either to the economic and nutritional dimensions of the gesture or to the symbolic values with which food itself is invested. Through such pathways food takes shape as a decisive element of human identity (other than continuity, security, validation, economics and social control, comforting escape) and as one of the most effective means of expressing and communicating that identity (Montanari, 2004).

At the core of the study of food and foodways is the specific relationship between people and their food practices. Food carries many different meanings for people. Many foods represent religious and folkloric traditions, suggesting that they carry both overt and covert meaning for a group (Thursby, 2008). Recipes, which usually include instructions for ingredients, preparation, and the number of servings, range from those passed on by vernacular transmission, to thousands of written collections of ethnic and generic cookbooks. Beyond survival, the creative relationships established between people and food carry metaphoric and symbolic meanings.

The knowledge and the cultural heritage concerning traditional recipes based on local and ancient crop varieties are very diffused in small rural areas and in local communities, in particular in Italy. This kind of knowledge, that can be interpreted as Traditional Knowledge (TK), under the UN *Convention for Safeguarding of the Intangible Cultural Heritage* must be preserved for future generations (Labadi, 2013). Thus, it is important to identify and to develop some tools and techniques to obtain data for the valorisation and the promotion of food heritage in the light of TK (Inglis, 1993) and, in particular, Knowledge Transfer (KT). The interest of Scholars in Knowledge Transfer (KT) started at the beginning of the XXI century. In 2019, specific literature indexed by Scopus (www.scopus.com) on the topic accounts around 3,500 documents in the field of business, management and accounting studies with contributions by several countries. Thus, the knowledge creation and transfer intra and inter organizations is retrieved in numerous studies (Argote, Guo, 2016; Gil, Carrillo, 2016). The study of KT has been subject to some criticism by Scholars (Argote, Ingram, 2000) even if understanding the knowledge transfer is a relevant issue influencing organizational performance, business process and relationship with all stakeholders. KT is process of communications (Forsten-

Astikainen, 2010) and it is suitable for replication and adaptation (Williams, 2007) as well as for collective and individual transferring (Zhao and Anand, 2009). Additionally, knowledge transfer derives from the management of tacit and explicit knowledge (Nonaka, Takeuchi, 1995).

The study by Milagres and Burcharth (2019) analyse KT in inter-organizational partnership, proposing main factors influencing KT. They are following macro-environmental (e.g. industrial policy, macroeconomic policies, intellectual property regime), inter-organizational (e.g. cost-sharing and synergy-seeking motives), organizational (e.g. capabilities, intangible resources, behavioural aspects and internal processes) and individual levels (e.g. motivation, emotions, learning behaviour, resistance). Thus, Milagres and Burcharth (2019) argued “*factors impacting knowledge transfer gathers the most discussed topics in the literature, particularly those at the interorganizational and organizational (divided into the source and the recipient firm) levels of analysis*”.

The Knowledge Transfer Curve (KTC) by De Luca and Cano Rubio (2019) evaluate KT process following its speed instead of the content of the knowledge, identifying the relevance of KT for companies to compete in the market. However, knowledge is also shared through social practices (von Krogh, 2012) between two or more actors (Albino et al., 1998). Argote and Ingram (2000) stated that “*Knowledge transfer in organizations is the process through which one unit (e.g., group, department, or division) is affected by the experience of another.*”. Lastly, several authors investigated performance-based approach to measuring knowledge (Baum and Ingram, 1998; Darr, Argote, and Epple, 1995).

The knowledge concerning food and foodways, that is at the heart of the relationship between communities and their food habits, if well recognised and documented can contribute to the sustainable development of territories in which it developed through oral transmission of local people. In the process of Knowledge Transfer concerning foodways, a crucial step is the involvement of local communities, in order to elicit and to track the information of which they are custodians, their feelings as well as their attitudes and preferences towards the use of this intangible heritage. The final goal is to engage them in the management of food knowledge for the sustainable economic, social and environmental development of their territory; in other words to preserve the social capital for future generation. In the social sciences area, there is increasing interest in the concept of social capital; this concept could be defined as the norms and networks that enable people to act collectively. Some authors have investigated social capital could as a driver to economic development (Woolcock M. and Narayan D, 2000). Interdisciplinary work has suggested that social capital plays an important role in explaining the economic performance of contemporary societies (Whiteley P. F. 2000). There is a conventional macroeconomic approach of using indicators of social capital in formal growth models; as an example, some authors (Helliwell J. F., Putnam R. D, 1995) have also tried to build an indicator, the social capital index, and they have tested it in the Italian context. The index proposed is composed by 4 measures of civic community: a) newspaper readership, b) the availability of sports and cultural associations, c) turnout on referenda, d) incidence of

preference voting. Another approach in the empirical analysis is articulated in two stages carried out by means of a multivariate analysis and of a structural equations models analysis. However, there is a lack in this approach related to the effects of social capital on other aspects of development that can contribute in making growth more sustainable (Sabatini, 2000). In this study we want to try to fulfil this gap, investigating the relationship between communities and their food habits and the impact of the latter on the sustainable development of territories in which they developed.

2 Research Objective

The objective of the paper is to conduct a survey, in a very specific territory, that is the “*Bio-Distretto della Via Amerina e delle Forre*”, in Central Italy, in order to gather information concerning the actual awareness of local people and organizations concerning their food heritage and the values (cultural and economic) they attribute to it. The information retrieved will then be used as a basis for the preparation of a theoretical framework of valuation and management of food heritage through citizen engagement in other areas/organizations. The Bio-District seems particularly suitable for this kind of investigation, as it is a geographical area where farmers, citizens, tourist operators, associations and public authorities enter into an agreement for the sustainable management of local resources, based on organic production and consumption (short food chain, purchasing groups, organic canteens in public offices and schools) (Franco, Pancino, 2015). The local knowledge concerning food-ways and traditional techniques that smallholder farmers apply, indeed derive from the deep understanding of the context they interact with and are adapted to. As a matter of fact, all stakeholders of the Bio-District are a natural depositary of intangible heritage, potential sources of information and of subsequent management of their knowledge.

3 Methodology

To carry out this paper, a qualitative methodology (Eriksson, Kovalainen, 2015; Gummesson, 2000) will be applied. Particularly, an inductive approach, using the survey questionnaire method (Cooper et al., 2006; Hoque, 2018) will be used to collect data in order to derive a theoretical framework for assessing cultural and economic values of food heritage. The survey method allows for the collection of empirical information on the phenomenon analysed even if it originates some bias (de Villiers and Dumay, 2014).

The survey will be conducted in the Bio-District of “*Via Amerina e delle Forre*”, located in Lazio Region, in the Central Italy. Thus, we will use a structured questionnaire to elicit awareness, feelings and wishes about the food heritage and their desired management for the development of the territory. The objective is to gather information about cultural (historical, social and religious) and economic values of this heritage.

In particular, for the latter type of values, a Contingent Valuation Method (CVM) will be used (Ginsburgh, Thorsby, 2006). CVM is an approach designed to create the missing market for heritage considered as public goods by determining what people would be

willing to pay (WTP) for specified changes in the quantity or quality of such goods or what they would be willing to accept (WTA) in compensation for well-specified reductions/losses in the provision of these goods (Snowball, 2008). CVM circumvents the absence of markets for food heritage by presenting consumers with a choice situation in which they have the opportunity to buy or to sell the flow of services/benefits deriving from this kind of intangible heritage.

3.1 Sample selection and data collection

The sample derives from the Bio-District of “Via Amerina e delle Forre” (or Bio-District), located in Lazio Region, in the Central Italy. Thus, the sample of this research will be composed of companies and citizens belonging to the Bio-District. Additionally, email addresses will be collected in order to undertake the survey. Data will be collected using a survey questionnaire created through Google docs and directed to the Responsible of each selected company composing the BIO-District and to each citizen.

During July 2019, an email invitation to participate to the online questionnaire will be sent. In order to obtain a high rate of responses, a cover letter explaining the purpose of our paper will be sent.

The questionnaire will be divided into two main parts. The first part will contain questions concerning the cultural, historical and social perceptions of food and foodways. The second part will contain questions concerning the economic values, assessed through the CVM.

Additionally, the questionnaire will include both open-ended and closed-ended questions. The closed-ended questions will be structured in a five-point scale model ranging from “strongly disagree” to “strongly agree”.

The reliability of our questionnaire originates from pre-testing activities conducted by the authors. Additionally, the integrity of the proposed investigation is guaranteed by a joint work strategy among the authors. The results of the online questionnaire will be analysed and discussed among the authors to achieve implications on the topic analysed.

4 Expected Results and Conclusions

The expected result in terms of Knowledge Management and Transfer will be the development of a tool that can be interpreted as a Participatory Rural Assessment (PRA) method (Chambers, 1994). PRA not only aims at gathering knowledge about skills of local communities and their values, but it also aims directly at empowering citizens. Indeed, the mix of surveys and public engagement techniques aimed at understanding the values and knowledge that local populations in Bio-Districts wish to sustain allows an informed and communitarian preservation of food intangible heritage.

The main limitation of the paper is the restricted investigation area and the limited data collected. However, it can be a basis to develop a theoretical model for food-ways economic assessment.

Abstract

Over the last years, the worldwide agribusiness sector is facing challenges due to globalization, the increased customers' quality requirements in products and the development of new technologies. So, actors are looking for new business models able to guarantee competitive advantage in facing the global companies, to expand their operations, to improve the production processes as well as to develop new consumer market niches. A successful approach in order to support agri-businesses growth and competitiveness, helping them achieving higher performance is based on business network contracts. This organizational model enables networked agribusiness firms to operate on markets with the competitiveness of a medium-large firm without sacrificing their autonomy and flexibility. The paper investigates the phenomenon of Italian business networks contracts involving firms operating in the agricultural and agrifood sectors and which are localized in Southern Italy, as it results from the public database of RetImpresa, the dedicated Confindustria Agency for business networks in Italy.

By combining qualitative and quantitative analysis, the paper, on the one hand, analyzes how many business networks contracts have been formalized in Southern-Italy. On the other hand, the effects on firms' performance of business networks 'with legal subjectivity' (the so called 'reti soggetto', according to Law no.134/2012) are analyzed and compared to the 'contractual' business-networks ones.

The objective is to verify whether the network contract constitutes an effective organizational and production model that is functional to the needs of SMEs active in the various sectors of agribusiness industry or whether it is only considered a duplicate of other forms of collaboration.

Keywords – Business Network Contract, Small to Medium-Sized Networks, Agribusiness Sector, Agrifood Industry, Competitiveness

Paper type – Academic Research Paper

1 Introduction

The “business network contract” is a juridical-economic instrument designed and adopted in Italy in 2009 (the first out of all European Countries), to support and promote inter-firm cooperation processes and, so, to sustain the competitiveness of Italian firms (particularly of those smaller and less structured ones) on the domestic and international markets. It represents a model of strategic alliance between firms that, by signing the “network contract”, mutually agree to implement a common program: by co-operating in forms and fields fitting their own business activities; by sharing and exchanging information, know-how or industrial, commercial, technological services or facilities and/or mutually exercising one or more activities pertaining to the object of their respective businesses (Cafaggi, 2011). Over the time, the regulatory framework has been modified and amended (in 2010, 2012, 2014, 2016 up to the 2017 Italian Tax Revenue Agency's clarifications)¹ in order to enhance its attractiveness and encourage its dissemination.

Thereafter, the Decree Law No 179/2012 (on “Further urgent measures for Italy’s economic growth”), converted into Law No 221 of 17.12.2012, has allowed also the Italian agribusiness SMEs to conclude network contracts. The sector covers the whole food value-chain, from farm to fork: starting from the farmed produce all the way to the consumers’ plates, it includes ICT systems, equipment and machineries, transformation and packaging plants, logistics and food by-products and waste valorization. Most recently, the Decree-Law 24 June 2014, No.91 (article 1-bis, section 3), converted by Law 11 August 2014, No.116, introduced a dedicated discipline for network contracts stipulated, exclusively or mainly, between agricultural firms aimed at: expanding their individual and collective capacity to innovate; enhancing their competitiveness on the marketplace; promoting and supporting the processes of reorganization and modernization of the agricultural and agribusiness industry. The aim is to formalize

¹ The Italian “Business Network Contract” was established by the Law-Decree on 10 February 2009 No.5 (article 3, co. 4 ter), converted with some amendments in Law on 9 April 2009 No.33 (definition of the network contract). The Law was modified thereafter by: the Law-Decree No.78/2010 converted in Law No.122/2010 (allocation of tax benefits, administrative and financial services for companies belonging to the network); the Law No.221/2012 (creation of a mutual separate fund ascribable to the network and a common body within the network, which manages the execution of the contract in behalf of the partners); the Law No.134/2012 (conversion of Law-Decree No.83/2012; possibility for the network contract to acquire the legal subjectivity in presence of a common body and a patrimonial fund). The fiscal discipline of the Business Network contracts is regulated by the Tax Revenue Agency's Circular Letters No.20/E of 18th June 2013 (the juridical subjectivity of the business network determine a separate tax liability of the network) and No.75/E of 21th June 2017 (concerning the fiscal aspects related to the agricultural network contract in the light of the specific provisions governing the subject in the sector).

business aggregation through network contracts and/or consolidate the already existing partnerships to achieve a plurality of well-defined strategic goals on the basis of a joint network programme of activities¹, without the partner firms losing their juridical, economic and decision-making autonomy.

The entrepreneurs in the agricultural and agribusiness sector recognize to the networks a decisively important role in terms of solving critical problems, even serious, that characterize the sector (Censis-Confagricoltura 2012). In this respect, similarly to Europe, most firms operating in the sector belong to the SME category, very often they are family-owned (Istat, 6th General Agriculture Census, 2013), and they face with the difficulties of competing in an increasingly complex and supranational market. In a globalized market, the small size of firms reduces the competitiveness of Italian agribusiness industry (Eurostat, 2018a,b), especially in the functions in which the organizational dimension is decisive, such as innovation and internationalization (Ricciardi 2003, 2010). Other main obstacles that affect the development of SMEs are: limited managerial competences, generational turnover and lack of specialized professional skills; limited financial resources and unavailability of loans and credit from the banks (Bentivogli et al 2013), difficulties in exploiting technology. A further problem that the agricultural sector has to face is the balance between costs, which are always too high, and product prices, which are always too low to guarantee economic sustainability (ICE, 2018).

Cooperation and associationism are peculiar to the agricultural and agri-food sector, but still finds many obstacles to its full development. However, the environmental dynamics require: stable and constructive relationships (Powell et al. 1996; Dyer and Singh 1998; Ricciardi 2013), “equipped with effective knowledge sharing mechanisms; based on the participants’ sense making, extended in terms of ‘cross-sectorial’ and ‘cross-territorial’ dimensions (networks designed in order to exploit both global and local opportunities) and developed selecting carefully partners and their competences” (Massari et al. 2015:133).

Networks between firms are not therefore an option only to tackle the fragmentation of the agribusiness sector, but they seem to emerge as an alternative strategy to overcome the constraint of the small dimension of excellent agribusiness firms, often unable to compete in terms of innovation and internationalization (Ricciardi 2010; D’Arienzo, 2014 a,b).

Therefore, stable and well-governed networks could act as efficiency multipliers, generators of economies of scale and innovation (Ricciardi, 2003).

The reticular strategy (Williamson, 1996; Amstutz and Teubner, 2009; Cafaggi, 2008; Zazzaro, 2011; Anderson, 2013) could be a solution so as to successfully deal with the

¹ Among the most significant experiences emerge networks in which companies join together to conduct research in order to improve the quality of their products, find synergies and participate in shared financing projects. This is the case of the “CR 2050” network contract stipulated between sixteen Cremonese companies (of which 8 are agricultural and 8 industrial) to carry out research and experimentation programs in the field of crops capable of feeding biorefineries, which supply raw materials to companies that they operate in the chemical, biofuels, energy, cosmetics and pharmaceutical sectors. More specifically, the aim is to study methods of transforming agricultural production waste that enable the production of raw materials for chemical companies and biofuel producers.

critical shortcomings of agricultural and agri-food SMEs, particularly in the light of the strategic value of these industries for the Italian economy.

Together, the agricultural sector, the food and drink industry (processing and manufacturing), the distribution sector (wholesale and retail) are the driving forces of the food supply chain and the key pillars of Italian economy (Istat, 2018, 2019), accounting for approximately 13% of the national GDP (Ismea 2018) and for 11.2% of share of EU-28 total (Eurostat, 2018a) in 2017. Moreover, Italy reached its EU agri-food exports historic record (525 billion euros) and holds an 8% share (Ismea 2018), and recorded a particularly brilliant performance also in the export of machinery, both agricultural and processing, where it holds a world market share of 8.4% and 15.3% respectively (ICE 2018).

As a result, the Italian agri-food market plays a key role both nationally and internationally. Moreover, the Italian agribusiness, together with landscape, tradition, local culture and art, represents a great heritage of national identity. On the one hand, the great Italian territorial and climatic differences have been shaped in cultures, stories and traditions, exceptionally varied and unique. On the other hand, the great number of products bearing the prestigious PDO (Protected Designation of Origin), PGI (Protected Geographical Indication) and TSG (traditional Speciality Guaranteed) labels, which are exported all over the world, generate non-reproducible products and therefore a non-relocatable Made in Italy that no other country in the world has, thereby benefiting the territory's production system and economy. Some of the competitive advantages of the Italian food industry are:

- wide range of high quality products, high safety standards, and ability to combine tradition and constant process and product innovation. Producers, transformers, and all other players in the sector contribute to food safety, provide many high-quality products, and stand out in terms of technological innovation, sustainability, biodiversity and respect for tradition;
- close links with the territory and with the Italian cultural heritage. Farms and food industry firms improve the dynamism and social cohesion of the rural economy (contrasting phenomena such as the depopulation and desertification of rural areas), and their interest in the care of the environment fosters the production of local goods.

In this way, a virtuous circle is created: agriculture provides for the environmental protection (because the permanent link with the territory necessitates the preservation of ecosystems and biodiversity); the environment offers vast possibilities for tourism, since landscape, food and wine traditions, and local culture are a distinctive way of understanding the territory. This type of "circle" is one of the foundations of local development, because it respects and supports the territory.

That being so, the paper investigates, on the one hand, how many business networks contracts have been formalized by agribusiness firms operating in Southern Italy. On the other hand, the effects on firms' performance of "subjective business-networks" (with legal subjectivity) are analyzed and compared to the 'contractual' business-networks ones provided by Italian legislature. This choice is based on the consideration, supported by the

international literature (Williamson 1975; Storper and Harrison 1991; Oxley 1999; Fjeldstad et al. 2012; Ricciardi et al. 2014) that “subjective business networks” are more effectively governed and, therefore, work better by allowing partner firms to improve their economic performance and survive over time.

Therefore, the research aims to verify the following hypothesis: *the development of agribusiness network contracts in Southern Italy could give firms the possibility of increasing their critical mass without losing their autonomy, and so, increase the competitiveness of SMEs located in this area and, consequently, the competitiveness of Southern Italy, in line with the strategic objectives of the EU Regional Policy and Cohesion Policy.*

The remainder of the paper is structured as follows. After a brief review of the literature on business networks and the typicality of Italian regulation on the business-network contracts (section 2), the main features of business networks in the agricultural sector are described (section 3). Then, the methodology is described and findings are discussed (section 4). Finally, final remarks and suggestions for practical implications and future research are provided (section 5).

2 Business-network Contracts. Theoretical Foundations and Empirical

Aspects in Italy

Strategic business networks have been extensively studied in theoretical research and empirical work in the last thirty years, although with different approaches and under different perspectives. Many studies focused on the forms and characteristics of interorganizational relations (Todeva 2006), on inter-organizational trust (Zaheer et al 1998) which guarantees actions in the interest of collaboration and the motivations that lead companies to adopt cooperation strategies (Axelrod 1984; Child and Faulkner 1998) and their functioning, on competitive advantage and on the performance of companies (Alter and Hage 1993; Huxham and Vangen 2005); on the internal processes, the formal governance structure of the business networks (Brass et al 2004; Provan, Fish and Sydow 2007) and management practices network.

With most of Italy's economy made up of small-sized firms, specifically in the agribusiness sector (Wubben et al., 2013; Istat, 2018; Eurostat, 2018), networking strategies formalized in business contracts can help them to have easier access to global value chains and foreign markets (Accetturo et al. 2011; Giunta 2014; Agostino et al. 2015), and, by exploiting their complementarities (Castaldi et al. 2015), they may together reach the critical mass to do together what they cannot do alone (i.e. product and process innovations, development of network brands, implementation of shared certification procedures, or greater visibility on international markets), and then access benefits they wouldn't be able to obtain on their own.

This is a new production paradigm, with great potential for expansion and value creation. The network allows SMEs: a) to implement strategies and operate on markets with the competitiveness of a medium-sized firm without sacrificing their flexibility (Laperche and Liu 2013); b) to implement collective learning processes and reduce

uncertainty, benefiting from economies of scale (at the level of financial, human and technical resources, R&S, high quality) without the disadvantages of large size (Geretto and Zanin 2017); c) to achieve better economic performance (increased turnover and investments, reduction in costs and operational risk) and to improve creditworthiness compared to firms working stand alone, especially when the network organization is stable, planned and effectively governed (Tommaso 2009) and if the banks are able to evaluate the relational system (Ricciardi and Ingarozza 2018).

Then, SMEs grow; but in a virtual way, without exchanging holdings neither mergers and incorporation operations. This type of interaction among firms has gained attention at the European level, since several policies and actions in favor of micro and SMEs (see the Small business ACT for Europe, 2011) make reference to business networks, also by distinguishing them from the clusters. The essence of the network is that several SMEs carry out a common project exploiting their complementarity, without losing their classic attributes of flexibility and autonomy (Håkansson and Snehota, 1995).

In this respect, the firms belonging to networks have a wide negotiating autonomy in defining the subject of the network contract according to the strategic goals that participants want to achieve and fixing the kind of collaboration (i.e. horizontal or vertical networks) and the cooperation procedures. However, the Italian legislator has provided a *sui generis* model by regulating two different types of networks contracts: namely, “contractual-networks” and “subjective-networks”. Among these, partners can choose (and therefore adopt) the one best suited to the specific legal and economic circumstances. Networks operate on the market by making use of a “joint capital fund” (that is optional in the contractual networks) and by operating through a “joint body”, charged with managing, in the name and on behalf of the members, the execution of the contract, the single parties or the stages thereof. For the obligations entered into by the joint body in relation to the network program, third parties may exercise their rights exclusively over the joint fund.

The “contractual-business networks” (the pure business-network contract model) are networks based on contracts which, as such, do not acquire individual legal personality: the acts put in place by the network produce their effects directly in the juridical-subjective spheres of the participants in the network. The “subjective-contracts” are, instead, business-networks registered as such in the Italian Business Register held by the Chambers of Commerce, with a separate individual legal liability, networks representing separate new legal entities as regards the firms that are their members. As such, the subjective-network become an independent centre of rights and obligations towards third parties, and assumes a passive subjectivity for tax purposes (Revenue Agency Circular No. 20 / E of 18/06/2013), while the contracted network does not change the tax subjectivity of the contracting partners which therefore maintain total autonomy. The common body is no longer a proxy for the participants in the network but for the network itself.

Consequently, the business-network contracts and, particularly, the subjective networks emerge as a ‘typical contract’, and therefore distinct from other existing

contractual schemes, such as, for example, consortia and temporary associations of enterprises (ATI).

Moreover, it is a flexible tool, able to integrate and combine: business aggregation on shared programs; juridical autonomy of the firms, also for tax purposes; the benefits of the “market” with those of the “hierarchy” (Coase, 1937; Williamson, 1975; Sabel and Zeitlin, 2004). The small dimension, therefore, is no longer an intermediate stage compared to the large company but an independent phenomenon triggering alternative development paths to grow in size.

3. The Business-Network Contract in the Italian Agri-Business Sector

With the agricultural network contract agribusiness firms set up a stable organization aimed at exploiting their complementarities and, then, at improving production along the entire supply chain, through the implementation of quality standards, at reaching the necessary critical mass to achieve product and process innovations, at increasing their productivity significantly and developing high-range products in the typical Made in Italy productions (Compagnucci et al., 2016).

The conclusion of a business-network contract between agricultural firms, or between commercial and agricultural firms but having as their object “basic agricultural activities” (Tax Revenue Agency's Circular Letters No.75/E/2017)¹, can take the advantage of a special discipline (compared to the general one) aimed at fostering close collaboration between agricultural firms for joint exploitation of various potentials. Complying with requirements set out by Article 1-bis, Section 3 of Decree Law 91/2014 converted into law no. 116/2014, SMEs belonging to business networks which, individually or collectively, produce agricultural and agro-food products, are allowed to share land, equipment and machinery, tools, know-how (Ponte and Cheyns, 2013), but also to use joint hires of highly qualified human resources (with wages distributed among the partners who signed the contract) to achieve the purpose of the network contract, or to realize a common agricultural production that favors innovation and competitiveness in the agricultural market. Moreover, “the agricultural production resulting from the joint network's activities can be divided among the contracting parties in kind, by allocating to each of them, with originating status, the product's quota established by the network contract”. For example, if two farmers put an equal surface of land on the net and one of them grows wheat, while on the land of the other, maize is grown, at the end of cultivation each farmer owns half wheat and half corn as his own production. This means that the production obtained also in the land of other network operators, is as if it were obtained in its own land with all the positive effects foreseen by the fiscal legislation (Russo 2015).

¹ For example, the agricultural network cannot be configured if there are producers of grapes and one only makes the transformation into wine. This means that everyone must produce grapes together, including the owner of the winery and possibly the production of wine for all the firms cooperating within the network could be compensated by the greater workings in the vineyards by the producers without the cellar.

Therefore, thanks to a stable cooperation, working together on agricultural and processed agricultural products and distribute them among the individual firms sharing the factors of production, the costs of both equipment and workers (that a company alone could not afford) become economically accessible and can be reduced.

The advantages of business network agreements should provide the right drive for aggregations in agriculture and agri-food sector, overcoming the boundaries between the various sectors, in order to create a more modern and innovative system. The network contract makes all of this possible, as the lawmaker provided a broad frame that the members can modify and customize in autonomy, with their own intentions and according to their cooperation needs (Massari et al., 2015).

However, the Italian agricultural entrepreneurial tradition are firmly anchored in family logics. Small and medium agricultural entrepreneurs, given the family structure of their company, have little confidence in the possibility of establishing relations of reciprocal influence with other subjects (RetImpresa, 2013), and therefore, their strategic behavior tend to be tightly individualistic and autonomous (Ansoff 1987).

Numbers highlight the gradual affirmation of the business-network contract, as both a tool for programming and governing strategic collaboration between firms, and as important instrument of industrial policy successfully welcomed by Italian firms. At the end of 2018, the Italian system of business networks recorded 5,135 (Figure1): 85% are contractual-network (4,357), and 15% are subjective networks (778), for a total of 31,405 companies involved (+34.5% compared to 2017).

Source: Our processing of RetImpresa data (based on Infocamere data)

As for sectors (Figure2), based on the Ateco classification of economic activities, the sectors of origin of the networked firms are mainly related to agriculture (19%; 6,347 firms), manufacturing activities (16%; 5,557 firms), and trade (15.7%; 5,378 firms). In 2018, compared with the previous year, the agricultural firms involved in business-network contracts grew by 38% compared to + 34.5% of the overall national average.

Source: Our processing of RetImpresa data (based on Infocamere data)

As for agriculture, 79% of the networked firms in the sector favor the form of the network-contract. A similar trend also for firms that carry out activities related to manufacturing (80%).

The comparison of regional data (Figure3) also shows that agricultural firms belonging to networks have increased considerably in excess of the national average (+38%), especially in Umbria (+294%), Valle d'Aosta (+180%) and Campania (+113%) and more generally in the South and Islands (+63%). All this against a substantially stable picture of the number of farms registered in the Business Register (750,115 in 2018, equal to -0.24% compared to 2017).

	2017			2018			Var. % 2017-2018

Fig.3 - Agricultural firms in Networks by type of Network (2017-2018)

According to the last (2019) Centro Studi Confagricoltura Report, at the end of 2018, the business-networks mainly constituted of agricultural firms (i.e. the lead firm is

agricultural) are in 674, equal to 13.1% of the business networks in which agricultural firms participate.

Therefore, agricultural network contracts should be favored because aggregation, even in a light form, has now become a necessity to be competitive on international markets and to overcome the limits stemming from the small size of firms. In this respect, agricultural business networks have already received subsidies, tax credits and contributions and could still have some, both for the Italian legislator's favor with respect to collaborative strategic networks (in terms of both creation of new business networks and development of new activities by formalizing existing relationships) and for the EU-level regulatory and policy recommendations on encouraging and supporting the business networks development and enhance inter-firm collaboration at European level (European Commission 2011; Ecorys, 2014).

Agri-food business networks need to be developed, prioritarly in the South. In this area, it seems vital to project SMEs beyond their internal dimension, and weave deeper collaborations, aimed at increasing the quality and competitiveness of both the individual and the network in his together, at strengthening of the supply capacity, at the development of paths of internationalization, innovation and enhancement of the territory. Different types of collaboration and network types can to be tailored to the results/benefits sought (objectives).

4 Research methodology

This study carries out an evaluation of the effectiveness of the network contract for the agri-food firms by comparing the performance of a sample of firms before and after the formalization of the network contract. The analysis is carried out both on the firms of the contract networks and on the firms of the networks with legal subjectivity in order to verify if:

- a) participation in contract networks makes it possible to improve the performance of agri-food firms;
- b) participation in networks with legal subjectivity makes it possible to improve the performance of agri-food firms;
- c) the firms involved in networks with legal subjectivity, better planned and governed, improve their performance more than the firms involved in the contract network.

These research hypotheses are tested through a ratio analysis (Thanassoulis et al., 1996; Caves et al., 1982; Psillaki et al., 2010; Amado et al., 2017) on the firms located in Southern Italy that formally established a network contract, both as “contractual business-networks” (or network-contract) and “business networks with legal subjectivity” (or network-subject) in the years from 2010 to 2016, as it results from the public database of the Italian register of business network contracts (managed by the industrial association *Confindustria-Retimpresa*), dated March 3 2019.

Taking into account the rich and diversified literature about the relationship between participation in a business network and performance of the enterprise (Gulati 1995), some of accounting measures of performance are selected to estimate the ‘network effect’ on

the performance of enterprises belonging to networks (Franco 2011; Kawai 2012). Accounting performance measures were chosen for two reasons: firstly because economic and financial objectives are fundamental requirements for firms' survival (Cantele and Vernizzi, 2015); secondly, because they are the most useful and accessible tools for measuring firm performance (Beamish and Lupton, 2009; Baker, 1992, 2000; Budde, 2007; Cantele and Vernizzi, 2015).

Within the vast number of economic and financial measures, the main selected measures of performance at the enterprise level are the following (Table 1):

- profitability and growth measures (Hill et al 1992; Goerzen and Beamish 2005; Goerzen 2007): Return on Assets (ROA), Return on Equity (ROE), Return on Sales (ROS), Sales, Ebitda;
- productivity variable (Koka and Prescott 2008; Gronum et al 2012): value added created/employees;
- capital structure and liquidity: Financial debt/Equity ratio (Cantele and Vernizzi, 2015), liquidity ratio, Coverage of fixed assets.

Finally, a measure of debt sustainability (Ebitda/Gross Interest) has been considered.

Table 1 - Indicators/Measures of performance at firm level

Firm performance	Indicators	
Profitability and Growth	ROA	Ebit/Total Assets
	ROS	Ebit/Sales
	ROE	Net income/Equity
	Sales	
	Ebitda	Earnings before Interest, Taxes, Depreciation and Amortization
Productivity	Added value per employee	Value added/Employees
Capital structure and Liquidity	Liquidity ratio	(Total current assets - Inventories) / Payables due within 12 months
	Coverage of fixed assets	(Shareholders' funds + Payables due beyond 12 months) / Total fixed assets
	Financial debt/Equity	
Debt sustainability	Ebitda/Gross Interest	

Source: Own Elaboration

Using these variables the networking effect on companies' performance has been assessed by testing the different performance evolution demonstrated by firms that have joined a business-network contract before (one year preceding the signing of the contract) and after participating in the network (one year and two years after signing).

For each network we selected the year of drafting the network contract because we were interested in analyzing the evolution of performance indicators from the time (the year of the contract) in which the enterprises began to participate to business networks. A 2-years span after the network-contract drafting was considered a reasonable time to evaluate the effects of network participation on enterprises' performance. However, many companies included in the sample signed contracts in 2016 and, considering the availability of financial data (2009-2017, no financial data is available after 2017), for these companies it was possible to analyze only the performances achieved in the year 2017 and, therefore, only for one year following the signing of the contract. At the end, it was analyzed the evolution of performance indicators with two different lags: one year

(n+1) and two years (n+2) after the network-contract drafting compared with the one year before (n-1).

4.1 Sample

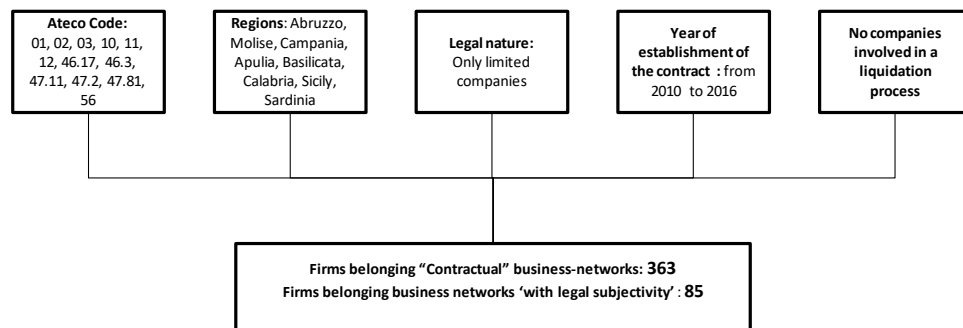

In order to test the research hypotheses formulated, starting from the total of 31,968 firms belonging to 4,503 networks-contract and 784 networks-subject, 363 firms involved in networks-contract and 85 firms involved in networks-subject of Southern Italy were selected.

The companies were selected by Ateco codes, Regions, legal nature (only limited companies) and year of establishment of the contract.

Economic-financial information has been obtained from the AIDA dataset in order to create a structured database comprising balance sheet figures of the above mentioned limited companies.

All the enterprises under a liquidation process at the time of data extraction (2019, from AIDA database) were not taken into account for a total of 12 firms (11 of the companies participating in the subject networks and 1 among the taken participants in contract networks). Finally, the quantitative analysis has been carried out on a sample of 448 enterprises, which includes 363 enterprises belonging to contractual networks and 85 enterprises belonging to networks with legal subjectivity.

The procedure used for the selection is shown in Figure4.

Figure 4 – Sample selection

4.2 Results

In order to examine whether a significant difference exists between the performance in the period before network contract and the performance after network contract the Wilcoxon signed rank tests, as proposed by Wilcoxon (1945), was used.

The reasoning behind the Wilcoxon Signed Rank test is relatively simple. In our study, the null hypothesis is that the median difference between the performance observed before and after network contract is equal to zero. If the null hypothesis is true, we expect the distribution of differences in performance to be approximately symmetrical around the null value; that is, whilst some firms may have improved their performance, others would

have deteriorated. Furthermore, we would not expect the firms that have improved (or deteriorated) their performance to appear systematically at higher (or lower) ranks. In this respect, the sum of the ranks should be approximately equal, without extreme values in one of the sums. If an extreme value is observed in one of the sums, it means that there is a high probability that the null hypothesis of no performance differences is rejected (Amado et al., 2017).

Tables 2 and 3 and Tables 4 and 5 highlight the results of the performance analysis for business networks ‘with legal subjectivity’ and for “Contractual” business-networks respectively. The first column includes the profitability, productivity, financial situation and debt sustainability variables. The second column includes the p-value of the used test (Wilcoxon Signed-Rank Test). The third column includes the number of firms in the two paired samples (network firms before and after signing the contract) whose variables were available for the test. The fourth and the fifth columns show the median values at the year n-1 and n+1 (or n+2). The sixth and seventh columns comprise the average values at the year n-1 and n+1 (or n+2). Finally, the last three columns show the number of enterprises for which there are better performances, worse or no difference compared to the year n-1.

The analysis of Tables 2 and 3 indicates that belonging to the network allows companies to obtain significantly better performance two years after the signing of the contract, while there are no significant differentials in performance after only one year. In particular, significant improvements concern:

- profitability and growth;
- productivity;
- debt sustainability.

With reference to profitability and growth:

- ROS on a median basis moves up to 2.79 (year n + 2) from 2.14 (year n-1) and the improvement concerns 18 companies out of 26;
- sales increases in 24 cases out of 31 (from 859 thousand euros to 1,514 thousand euros);
- the median value of Ebitda doubles from 53,000 to 106,000 and the improvement concerned 21 companies out of 31.

With reference to productivity, the added value per employee grows for 20 enterprises out of 28.

Finally, debt sustainability improves, since Ebitda/Gross interest ratio increases for 20 companies out of 30.

No material changes occur with reference to ROA, ROE, Liquidity ratio, Coverage of fixed assets, Financial debt/Equity.

Tables 4 and 5 show the results for the firms involved in “Contractual” business-networks. It is highlighted:

- an increase in sales both for the year n+1 (for 69% of the firms) and for the year n+2 (for 71% of the firms);
- an increase in Ebitda both for the year n+1 (for 56% of the firms) and for the year n+2 (for 58% of the firms);

- the fixed assets coverage index improve for 154/298 firms in the year n+1 and for 119/229 firms in the year n+2;
- the Ebitda / Gross Interest ratio indicates a greater sustainability of the debt after the signing of the contract both with reference to one year after and two years later: the enterprises for which debt sustainability improves are 55% (158/285) a year later and 60% (134/224) two years later.

As in the case of firms involved in business networks ‘with legal subjectivity’, no significant results are found with reference to the ROA, ROS, Liquidity ratio, Coverage of fixed assets, Financial debt/Equity. By the contrary, value added per employee increases for the firm belonging business networks ‘with legal subjectivity’, whilst no material change occurs in the case of firms involved in “Contractual” business-networks.

The analysis shows that the results found for the firms participating in “contractual” business-networks are in line with those of enterprises that participate in business networks ‘with legal subjectivity’. Moreover, in the case of the latter, the results are achieved after two years while there are no significant changes after only one year.

5. Conclusions

The Italian business network contract represents an innovative tool for competitive growth of SMEs, extremely flexible, able to adapt to the needs of companies of all sizes and sectors, integrating two concepts equally important, but among them apparently far: the collaboration of entrepreneurial shared programs and the guarantee of entrepreneurial autonomy.

This study has assessed the impact of participation in networks on firms' performances through the analysis of productivity and growth, profitability, capital structure, liquidity and debt sustainability.

Agri-food enterprises that participate in networks (both business networks 'with legal subjectivity' and "contractual" business-networks) have increased Sales and Ebitda, improved the capital structure (the balance between investments and sources of financing improves) and the debt sustainability (measured by the Ebitda/Gross interest ratio). This last indicator is however affected by endogenous factors of the companies, i.e. by monetary policies and fluctuations in interest rates.

This research is a preliminary study; thus, it has several limits that do not allow to generalize the obtained results. These latter, however, confirm, albeit in part, the research hypotheses, namely an improvement in performance linked to the participation in the networks even if not for all the selected indicators. Further empirical checks on a wider sample and observation period can improve the reliability of analysis.

Despite the aforesaid limits, this paper contributes to the literature by testing the impact of participation in business networks on agri-food firms' performance. The empirical tests indicate that the network contract can become one of the main instruments of industrial policy on priority areas of interest for the Italian economy, including the internationalization, the relaunch of the areas affected by crisis areas and the development of lagging areas of the country.

Abstract

Wine is one of the most traditional products with high symbolic value and for some countries in the world is a carrier of community knowledge, embodying immaterial and intangible assets. Furthermore it generates income, employment, economic and social value. Through a review of the various contributions of the research strands, this work aims to highlight what have been, over the years, the most discussed issues, the research areas most investigated and those that have aroused less interest, so that any gaps may emerge in the current academic scenario.

To comply the paper aim, a literature searches on Scopus has been conducted, using a set of selected keywords. This work uses a structured literature review (SLR) method proposed by Massaro et al. (2016) as was adapted by Paoloni and Demartini (2016). This paper contributes to extend the international literature through the construction of a comprehensive framework on the wine sector that, starting from the state of the art, highlights the contribution of intangible resources to the sector, as provides different input for future researches and analysis.

Keywords – Wine business, intangible assets, intangible heritage

Paper type – Academic Research Paper

1 Introduction

Wine is one of the most traditional products with high symbolic value for some countries in the world. It can be included into the "foodways" for the cultural, social and economic practices relating to the production and the consumption – as pervasive elements of each culture and means of expression of personal and common identity.

The last year 2017 will be remembered, worldwide, as one of the poorest years of the last twenty years in wine production, on the contrary, 2018, among the best and most abundant.

Data source OIV (International Organisation of Vine and Wine - www.oiv.int)

Fig. 1 Wine production trend (2018). The most country makers in the world.

These numbers referred to wine production, represent also the reason why “Wine” is a topic of research that involves a wide plethora of different interests.

Through a review of the various contributions of the research strands, this work aims to highlight what have been, over the years, the most discussed issues, the research areas most investigated and those that have aroused less interest, so that any gaps many emerge in the current scenario of field academic. In fact, the theme of the wine business lends itself to a multi-dimensional survey that we will discuss in this paper focusing on the topic of “Business, Management and Accounting” (BMA).

Above all in wine sector, it is more and more studied the highly context-specific and how a combination of tangible and intangible firms’ resources. That’s the reason why, according us, this linking is more interesting.

To comply the paper aim, a literature searches on Scopus has been conducted, using a set of selected keywords. Scopus has been used as it allows us to be confident on the quality of publications. Selected papers have been analyzed and classified them, in an attempt to identify main topics and results obtained thanks to research and analysis carried out so far.

This work uses a SLR method proposed by Massaro et al. (2016) as was adapted by Paoloni and Demartini (2016) limited to such part that are compatible with the different focus of this paper. Adopting it, we asked the following research questions:

RQ1: what is the focus of the wine literature?

RQ2: how is research on intangible heritage in wine sector developing in leading journals in the fields?

In answering our questions, this paper contributes to extend the international literature through the construction of a comprehensive framework on the wine sector by analysing the researches published over the period 2009-2019, which, starting from the analysis of the state of the art, intends on the one hand to highlight the contribution of intangible resources to the sector, on the other provide different input for future research and analysis. Our analysis shows the lack of interest from the scholars for the topic of intangible assets applied to the wine sector and offers interesting hints to launch new lines of research.

2 Research Methodology

This work uses a structured literature review (SLR) method proposed by Massaro et al. (2016) as was adapted by Paoloni and Demartini (2016). A SLR *“is a method for studying a corpus of scholarly literature, to develop insights, critical reflections, future research paths and research questions”* (Massaro et al. 2016:767). As Paoloni and Demartini point out (2016:2), a SLR uses a rigorous methodology through which it *“selects and evaluates contributions, analyses and synthesizes data, and finally it reports the research evidence with transparency, comprehensiveness and reproducibility”*. The literature that recognizes the usefulness of a rigorous SLR is extensive (Tranfield et al., 2003; Scandura and Williams, 2000; Littell et al., 2008) and the awareness of the usefulness of an SLR has increased in recent years and *“a research synthesis methods has changed rapidly to become more methodologically inclusive”* (Tsakalerou and Katsavounis, 2015:24).

According with the three first steps proposed by Massaro et al. (2016), we began our work by investigating the topics most frequently dealt with in the wine literature published from 2009 to present in the Scopus (search was made on March 2019). Our analysis aims to find article, title and key words of various documents such as articles, books, and book chapters.

More specifically, we adopt the framework developed by Paoloni and Demartini (2016:3) on based on Guthrie et al.'s (2012:71) previous work. To make the model more suited to our research topic, we have made some changes to the “A category” (article focus) by inserting the specific focuses of the prevailing literature in the field of “wine and intangible”, and we adapted the others to specific findings of our SLR. Furthermore, we followed several steps in order to no limit our area of investigation, and we described the process followed step by step (Broadbent and Guthrie, 2008). Finally, after reading titles and abstracts of the selected papers, we handed-pick some categories to identify the special focus of the papers and classify them in a way more useful to our work aims.

The classification system arising from Paoloni-Demartini (2016) framework is based on the identification of four categories of documents in which are included different and appropriate sub-classification of them. As underlined before, we adopted it whenever it is

possible and, in any case, we follow the Paoloni-Demartini (2016) approach to classify the detected and selected documents, introducing some integrations to develop a system more suitable to our RQs.

To establish literature review reliability and test its validity (Massaro et al., 2016:772), it was necessary an in dept reading of the selected papers, and it is disclosed us, on the one hand not every documents selected on the basis of the keywords were useful to the aim of our study and, on the other, some works excluded from the area of research (since classified by the data set in other subject areas, for example Decision Science) were instead fully relevant.

As Paoloni and Demartini point out (2016:2), “*the structured literature review is an iterative process in which the taxonomy of research themes and issues is developed and refined throughout the review and writing process*”. On base on this vein, in order to answer to RQ2, we extended the analytic framework to include each research area that revealed the key words “wine and intangible” irrespective of the research area.

3 The state of art in the field of “Wine and Intangible”

3.1 Selection of articles

According with the three first steps proposed by Massaro et al. (2016) we began our work by investigating the topics most frequently dealt with in the wine literature published from 2009 to present in the Scopus. Differentemente dal modello Paoloni-Demartini (2016), in una prima fase abbiamo preferito non selezionare alcun journal o specifiche parole chiave poiché il nostro obiettivo di ricerca era quello di individuare i temi maggiormente trattati in the field of wine (RQ1) e, in un secondo step, individuare la letteratura on intangible heritage in wine sector developing in the fields (RQ2).

At first, we found 28,119 documents results publish in 2009 to present of very heterogeneous content referred to term “wine”.

Fig. 1 - documents on wine by subject area 2009 (www.scopus.com)

Fig. 1 shows us that only 4% of them focus on the topics of our research area “BMA” (RQ1) with 1,819 articles.

Even in our specific field of study (BMA), a high level of heterogeneity remains in the topics covered (fig. 2). There is also a reduced number of contributions focused on the theme "intangible / intellectual capital" (RQ2) with only 5 works in the analyzed period (www.scopus.com). This result prompted us to extend our research to the other Subject areas.

Fig. 2 – documents on wine by subject area (focus on BMA)

As can be seen in Fig. 3, the number of articles published, which link “wine and intangible” without restricted subject area, increased over the last years, although the number is not so high (34 papers in ten years) and the topics are very heterogeneous (fig. 4).

Fig. 3 – number of article selected for keywords “wine and intangible”

Fig. 4 – subject area according to Scopus – our elaboration

The documents used for the SRL are shown in the fig. 5 and classified by year, relevance and scientific impact (number of citations).the tab. 5 indicates the papers used in the SRL.

Fig.5 – articles used in SRL

Year	Articles	Articles relevant	Articles not relevant	Cited by
2009	1	1	-	-
2010	1	1	-	21
2011	2	2	-	13
2012	2	1	1	3
2013	2	-	2	-
2014	3	2	1	10
2015	6	5	1	4
2016	6	3	3	21
2017	5	2	3	-
2018	5	3	2	-
2019	1	1	-	-
Total	34	21	13	72

3.2 Defining the analytic framework

As Paoloni and Demartini point out, the SLR “is an iterative process in which the taxonomy of research themes and issues is developed and refined throughout the review and writing process” (2016:2). To comply the paper aims, we adopt the framework developed by Paoloni and Demartini (2016:3) nevertheless, to make the model more suited to our research topic, it was necessary to made some changes at the categories proposed by them. The adjustments are the following.

The category “A” aims to seek the focus of the works in order to reveal the most significant aspects covered by the scholars or practitioners. Inside it, we inserted the specific items draw out of the prevailing literature in the field of “wine and intangible”.

The category “B” is used to classify articles. the research field was defined based on the reading of the abstracts of the selected papers. We decided not to use the classification system used by Scopus but to adopt more specific macro-areas that could more quickly connect each work to the field of intangible assets.

The category C aims the geographical area in which the research took place, regardless of the author's nationality. Furthermore, comparative researches are planned by comparing more nations.

The category D specifies which research methodology is adopted. In category “Other” are included those documents such as special issues, editorials, or proceedings, or other generic categories not framed in any of those provided.

The review process returned us the categories into the Tab. 3.

Tab. 3 – documents classification

Article focus	Research area
A1. Intangible Assets	B1. Management
A2. Internationalization strategy	B2. Economics
A3. Wine tourism	B3. Economic History
A4. Sustainable Development	B4. Linguistic
A5. Intangible and performance	B5. Medicine and Biological
A6. Cultural Heritage	B6. Other
A7. Health benefits	
A8. Consumer behaviour	
A9. Accounting	
A10. Other	
Geographical area	Research method
C1. Northern Europe	D1. Literature review
C2. Southern Europe	D2. Qualitative
C3. Asia	D3. Quantitative
C4. Comparative Study	D4. Mixed method
C5. Not specified	D5. Other

3.2.1 Article Focus

In the article focus category we have highlighted the specific theme of each article examined, in order to identify already existing research topics (RQ1) and, among these, identify those that could be better explored in the future. All papers (except the other category) deal with aspects directly or indirectly related to our RQ2.

A1 Intangible Assets: These studies focus on intangible resource endowment (reputation, family history and brand equity, local factors, other different capabilities as innovation) as a source of competitive advantage in the development of international strategies.

A2 Internationalization strategy: to identify what are the important practical implications for managers or owners who can improve their firm's export performance by assessing their internal resources (tangible or intangible) before considering which export

channel to choose. This is important to discover the vital opportunities to internationalization.

A3 Wine Tourism: these articles focused the element both tangible factors (as wine or typical food or other) and intangible factors (as history, wine family's brand, and other, regional value elements, or other) to develop the competitiveness.

A4 Sustainable Development: the increased trend for organic products and the concept of sustainable development, firms must invest in valuable and unique resources (tangible or intangible) to achieve long-term success and gain competitive advantages.

A5 Intangible and performance: this category concerns studies that investigate the effects on the financial performances of specific activities (as intangibles)

A6 Cultural Heritage: this category includes studies that analyze the contribution of traditional foods (such as wine) to the heritage of humanity.

A7 Health Benefits: it is included all studies on the health benefits of some foods in the Mediterranean diet, such as wine.

A8 Consumer Behaviour: this category includes studies that investigate consumer behavior on particular topics, for example on experiences of "creative" tourism or luxury choices and others factors

A9 Accounting: it includes one paper refers to financial report.

A10 Other: this category includes all documents on which it was impossible to group in the previous, for example they are conference proceedings or other where it is not possible identify them specifically.

3.2.2 Research Area

In this category we have identified six different research areas and focusing on the following areas:

B1 Management: management studies, organization, marketing.

B2 Economics: international policies.

B3 Economic History: historic studies.

B4 Linguistic: linguistic translations.

B5 Medicine and Biological.

B6 Other: studies which it is not specified the field of research or present only once and then have little relevance for statistical purpose.

3.2.3 Geographical Area

In this category we have identified mainly European countries, with some studies on Asian Continent.

C1. Northern Europe: France, Germany, Czech Republic.

C2 Southern Europe: Greece, Italy, Spain, Portugal.

C3 Asia: Georgia, China, Japan.

C4 Comparative Study: comparative research among countries.

C5 Other: it was not possible to identify the geographical area on which studies referring.

3.2.4 Research Method

In this category we specified the various types of research methods.

D1 Literature Review

D2 Qualitative Research

D3 Quantitative Research

D4 Research Mix (in case of mixed method of research)

D5 Other (other research methods or not identified methods).

3.3. Results

3.3.1. Article Focus

Fig. 4 – article focus

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
A1	1		1	1			1	1	1	1		7
A2						2	1	1	1	1	1	7
A3				1			2	1				4
A4							1			1		2
A5		1	1									2
A6								1				1
A7					2	1	1					4
A8								1	2	2		5
A9									1			1
A10								1				1
Total	1	1	2	2	2	3	6	6	5	5	1	34

After analyzing all studies published in the last 10 years, which deal the theme of wine & intangible, fig. 4 shows us how there is an extreme heterogeneity of the topics covered, in accordance with what appeared from the beginning.

3.3.2. Research Area

Fig. 5 – research area

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
Management	1		2	1			4	2	3	3		16
Economics		1				2	1	1	1	1	1	8
Economic History										1		1
Linguistic									1			1
Medicine& Biological					2	1	1	2				6
Other				1				1				2
Total	1	1	2	2	2	3	6	6	5	5	1	34

The Fig. 5 shows us that most of studies are in the Management area (47% of the total).

3.3.3. Geographical Area

Fig. 6 – geographical area

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
Northern Europe		1	1	1					1	2		6
Southern Europe	1		1			2	5	3	1			13
Asia								1		2		3
Comparative Study										1	1	2
Not specified				1	2	1	1	2	3			10
Total	1	1	2	2	2	3	6	6	5	5	1	34

The Fig. 6 reveals that 38% of the articles analyze case studies related to Southern Europe, while 29% of them do not specify any specific geographical area.

3.3.4. Research Method

Fig. 7 – research method

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
Literature Review												
Qualitative Research	1	1	1	2		2	4	4		5	1	21
Quantitative Research			1		2	1	1	1	3	1		10
Research Mix							1					1
Other								1	1			2
Total	1	1	2	2	2	3	6	6	4	6	1	34

The Fig. 7 shows that about 62% of studies use qualitative research methods, while only 29% use quantitative analysis. It emerge that there is not even study who adopt the literature review method.

3.3 Testing literature review validity

In the SLR, an important step is to test the validity of the literature review (Massaro et al., 2016). Therefore, we reviewed the 34 papers in the appendix to exclude those that are not relevant or not relevant to our area of research (Business Administration).

Fig. 8 shows that in the selected studies by Scopus, the 62% of them focus the theme of wine & intangible strictly related to our research topic. The remaining 38% are unrelated (e.g. health, cultural heritage and so on).

Fig. 8 – article focus per relevant papers

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
A1	1		1	1			1	1	1	1		7
A2						2	1	1	1	1	1	7
A3							2	1				3
A4							1			1		2
A5		1	1									2
Total	1	1	2	1		2	5	3	2	3	1	21

3.4 Measure article impact

According to Massaro et al. (2016) the focus point of the SLR is the identification of the impact of the articles surveyed.

In fig. 9 only the articles that had had at least one citation are reported, reclassified by number of citations, year of publication and research area. The restatement was made only for items useful for the purposes of RQ2 (see fig. 8).

Fig. 9 - Number of quotations per Research Area

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	Total
A1			8	3				6				17
A2						6+4	4	3				43
A3								12				12
A5		21	5									
Total		21	13	3		10	4	21				72

Generally, there is a low number of citations: just one study have more than 20 citations and another with 12. Then, the scientific impact of the document is not relevant.

4 Discussions

The SLR was very useful for defining the themes most dealt with in the literature on wine & intangible in the last decade and answer to RQ2. The documents closely related to the research topic (A1) are very interesting and, with an incidence of 20.5%, focus on intangible resource endowment. However they do not have a strong scientific impact because the most cited documents belong to the research area A2 to which 21% of the documents belong and an incidence of 20.5% on the total of the articles relevant to our research area.

The category A1, Intangible Assets, includes the studies focus on intangible resource endowment (reputation, family history and brand equity, local factors, other different capabilities as innovation) as a source of competitive advantage in the development of international strategies. The topics with the greatest scientific impact, measured in terms of the highest number of citations (Massaro et al., 2016; Schinel, 2011; Dumay, 2014) are focused on which of the intangible resources possessed by companies from *viticulture* sector can serve as a source of competitive advantage in the development of their international strategies as, for example, the family-owned or non family-owned character of the viticultural companies (Fuentes-Lombardo et al. 2011). Vidoli et al. (2016) estimate the efficiency of a representative sample of Italian wine producers following a spatial stochastic frontier framework that allows to evaluate the role of intangible local factors (first of all, local business climate and development of local learning) in influencing the economic performance of firms. Šperková, Hejmalová (2012) investigate the rivalry among existing competitors in the wine-making branch and show that individual companies use all their tangible and intangible means in order to extend their share and attract new clients.

The category A2, internationalization strategy, identifies what are the important practical implications for managers or owners who can improve their firm's export performance by assessing their internal resources (tangible or intangible) before considering which export channel to choose. The topics with the greatest scientific impact, as underlined before, is the analysis of the effects of the intangible resources, product quality, firm size, and international experience on the probabilities of some decisions about the export channel (Fernández-Olmos, Díez-Vial 2014). Furthermore in another work Fernández-Olmos, Díez-Vial (2015) demonstrate that firms improve their export performance when considering internal resources (humans included) and the export channel. Other scholars (Bertazzoli et al. 2014; Iannone 2015) identify and evaluate the competitive strategies of niche enterprises selling traditional protected designation of origin wine in domestic and international markets, for example seeking to successfully exploit the ability to manage intangible resources that have a strong emotional component differentiating the enterprise from similar ones. Pellicanò and De Luca (2016) demonstrate how a combination of tangible and intangible firms' resources in interaction with home-based external conditions plays a crucial role in the internationalization process.

The category A3, Wine Tourism, focuses on the element both tangible factors (as wine or typical food or other) and intangible factors (as history, wine family's brand, and other, regional value elements, or other) to develop the competitiveness. In this category, which includes about 9% of the contributions on the subject, we find the interesting work of Bregoli et al. (2016) one of the most quoted paper (17% of the total quotations). They analyze how wine and tourism operators understand the concept of a "wine route", to determine the impact that definition can have on wine production, tourism, food and hospitality.

The category A4, Sustainable Development, holds only about 6% of the contributions on the subject but none of them has received quotations so far. The topic treated are the increased trend for organic products and the concept of sustainable development, firms must invest in valuable and unique resources (tangible or intangible) to achieve long-term success and gain competitive advantages (Iannone 2015; Fanasch, 2018).

Finally the category A5, Intangible and performance, holds only about 6% of the contributions on the subject, as the latter, but includes the most cited papers (Amadiou, Viviani, 2010; 2011) that obtain the 30%, more or less, of quotations. The topics is addressed to investigate what extent intangible investments have a positive impact on wine companies' financial performance.

The in dept review of the documents covered in the other categories (from A6 to A10) revealed us that the topics are include documents not relevant for the paper aim. This result offers interesting insights for future insights of research.

5 Conclusion

This article contributes to the existing literature because it is the first work on the subject of wine and intangibles that carries out a systematic review of literature (Fig. 7)

offering interesting ideas to scholars so that their scientific contribution can contribute to the development of such an important sector for the economy of many countries and spread a greater awareness of the value created by the intangible assets in the wine sector.

The SLR on Wine (RQ1) and on Wine & Intangible (RQ2) shows that there is space to deepen all the topics related to the topic. Today there is an extreme variety of contents, but a reduced scientific impact of the current works, so much can be done by scholars to explore different interesting aspects and contribute to the existing literature.

Moreover, despite the vast literature on the wine business (1819 works published in the last 10 years), scholars have paid little attention to the theme of intangible assets. Our review of the literature underlines the topic analyzed as an emerging issue, which gives us the possibility of identifying new trends and future directions for both researchers and mainly studied actors: wine entrepreneurs.

Further steps in our research include a quantitative analysis through case studies, to highlight the link between intangible assets - territory and made in Italy, as one of the most important intangible assets, to create business value. Another line of research that we aim to analyze is the female contribution to the creation of intangible assets in the wine sector. In fact, not even a document on this interesting topic emerged from the SLR. This last aspect is an interesting topic of research if we consider the profound evolution in this sector: for centuries the wine sector was represented by men, but after the new contribution of women in agriculture and especially in entrepreneurship, women entrepreneurs are becoming an interesting new research topic.

Another important contribution of this paper is to have refined the classification criteria used by the Scopus algorithm, making them more detailed and allowing scholars to identify the most treated and the least discussed topics, on which it is therefore appropriate to offer a contribution.

The limitations of this paper are that they used only the Scopus database for SLR, which is certainly one of the most relevant sources of scientific literature, but it is not the only one. Our results could be improved by extending the analysis to data sets taken from other sources such as Google Scholar, SCImago Journal and Country Rank, Web, WOS-Web of Science.

Finally this study can be integrated by classifying the results by Journal distinguishing them by relevance and number of documents published on the "wine" topics.

Value Creation in the User-Centric Personal Information Ecosystem

Walter Castelnovo

Department of Human Sciences, Innovation and Territory
University of Insubria.
Via Oriani, 6 – 22100 Como (Italy)

Abstract

The emerging user-centric personal information ecosystem within the data-driven economy offers new opportunities and poses new challenges to organizations that base their business on the collection and use of personal information. In the user-centric ecosystem, the control over personal information is given back to the individuals who, as the information owners, can decide whether, under what conditions and in change for what to disclose their data to trusted counterparts. In this new scenario, organizations should revise their relationship with individuals to make them willing to disclose the information they need. Based on evidences from the economics and psychology of privacy literature, the paper argues that this could be done by involving individuals as coproducers in the value-generating processes that use personal information. Under this strategy, besides economic compensation and personalized services, organizations can leverage the ‘psychological’ benefits deriving from the coproduction experience as further incentives that can enhance the individuals’ willingness to disclose their personal information.

Keywords –Value creation, Coproduction, Personal information, Privacy, User-centric ecosystem.

Paper type – Academic Research Paper

1 Introduction

People using low cost and high processing capacity devices produce every day huge amounts of information that, by being generated by individuals, directly or indirectly pertains to them and should thus be considered as personal information (Kang, 1998). Acquisti, Taylor and Wagman (2016, p. 444) observe that “individuals’ traits and attributes (such as a person’s age, address, gender, income, preferences, and reservation prices — but also her clickthroughs, comments posted online, photos uploaded to social media, and so forth) are increasingly regarded as business assets that can be used to target services or offers, to provide relevant advertising, or to be traded with other parties”. This explains why personal information is increasingly being considered as a fundamental economic asset, the new ‘oil’ of the 21st century (WEF, 2011), an important currency in the new millennium to which also a relevant monetary value can be associated (Thaler &

Tucker, 2013). However, while a remarkable value resides in personal information, it often remains untapped and this raises the problem of how to unlock that value.

According to (WEF, 2013), the empowerment of individuals as the ‘owners’ of personal information represents a fundamental condition for unlocking its value. In the traditional organization-centric personal information ecosystem (O-CPIE), an asymmetry of power exists between organizations and individuals, due to an asymmetry in the amount of information about individuals held by organizations and the individuals’ lack of knowledge and ability to control how, by whom and in exchange for what information pertaining to them is used (Haynes & Nguyen, 2014; Solove, 2006; WEF, 2011). Giving back to people the control (if not ownership) over personal information means rebalancing the relationship among the various stakeholders influencing the personal information ecosystem.

The continuous technological evolution that makes personal information management tools available to individuals and the coming into force of new and more user-oriented personal information protection legislations (such as the EU General Data Protection Regulation) are creating the conditions for the emergence of a new user-centric personal information ecosystem (U-CPIE). In the U-CPIE, individuals are the ‘owners’ of the information they generate and should be allowed to decide whether to disclose their data to trusted counterparts to receive some benefits from them.

Organizations that collect and use personal information tend to adopt strategies based on economic compensation, free access to services or the delivery of better and more personalized services to obtain the individuals’ consent to the treatment of their information. While these strategies appear effective in many cases, their success depends on the exploitation of the information asymmetry between individuals and organizations. In fact, when individuals are requested to provide personal information in exchange for some form of material compensation, they may not be able to act as economically rational agents. On the one hand, individuals normally are not aware of the value their personal information can have for the organizations that use it and this makes it impossible for them to define a fair exchange value for their personal information. On the other hand, when they are made aware of the use that organizations will do of their personal information, individuals tend to over-estimate that value. For these reasons, compensation-based strategies that are effective in the O-CPIE could be less effective in the emerging U-CPIE. This rises the research question the paper intends to address, i.e. “What strategies, besides compensation, organizations can implement in the U-CPIE to make individuals more willing to share their personal information?”

The paper argues that to answer this question it is necessary to overcome a purely economic valuation of personal information and to consider other dimensions of value that appear to motivate the disclosure behaviours of individuals in contexts in which there is no material compensation, as in the case of online social networks. The individuals’ disclosure behaviour on social networks appears paradoxical since, despite their worries about privacy, they share a lot of personal information, including highly sensitive information (Awad & Krishnan, 2006; Norberg, Horne, & Horne, 2007).

Many studies have highlighted that the reasons that lead people to share their information on social networks are more related to the social and psychological dimensions of value than to self-interest. The paper argues that to unlock the value of personal information within the U-CPIE, organizations can leverage these non-economic dimensions of value by implementing an interaction strategy with the personal information owners (PIOs, henceforth) that: (i) considers them as information providers; (ii) involves them as coproducers in the value-producing processes that use personal information; and (iii) empowers them through an iterative, dynamic and dialogic interplay.

Methodologically, the paper is based on a conceptual research approach (Meredith, 1993) and refers to sources from different literature domains. On the one hand, sources from the economics and psychology of privacy are considered to explain the privacy paradox and its consequences. On the other hand, sources from the marketing literature are considered to identify strategies for involving the PIOs as coproducers in the value-producing processes that use personal information as a resource.

The paper is organized as follows. Section 2 introduces the concept of U-CPIE and considers some conditions that would allow to unlock the value of personal information within it. Section 3 discusses the privacy paradox to show how the individuals' disclosure behaviours can be explained with reference to the concept of psychological ownership. Section 4 argues for a valuation of personal information based on social and psychological factors that cannot be measured in monetary terms. Section 5 suggests considering coproduction as a strategy organizations can implement to redefine their relationship with individuals within the U-CPIE and discusses some implications that would follow. Finally, the last section draws some conclusions and suggests further research development paths

2 The User-Centric Personal Information Ecosystem

Defining personal information is not an easy matter since, due to the laws protecting the privacy of individuals, the scope of the definition constrains heavily the use of certain classes of information pertaining to individuals. In (WEF, 2011), a quite general definition of personal information is given as digital data 'created by' and 'about' people that strictly resembles the one given by Kang (1998) who defines personal information as data authored by an individual, describe an individual, or can be mapped to an individual. Definitions like these, that define personal information as personally identifiable information, pose several critical questions. On the one hand, as pointed out by Van Kleek, and O'Hara (2014), what does identifiable mean? Identifiable by whom? Using what methods? On the other hand, the technological evolution, the diffusion of data analytics tools and the emergence of powerful re-identification algorithms have made the identifiability concept obsolete in the definition of personal information since even anonymized data could have significant privacy consequences (Narayanan & Smatkov, 2010; Tene, 2011).

The definition of personal information based on the identifiability concept is strictly related to the idea of privacy as ‘the right to be let alone’, as defined by Warren and Brandeis in 1890 (Kang, 1998; Solove, 2006). Influential as it has been, this definition becomes more and more problematic in the highly interconnected world of today in which individuals are embedded in complex networks of relationships. An alternative view of privacy has been advocated by Westin (1967) who defines privacy as “the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others” (p. 7). Privacy can then be defined in terms of the control we have over information about ourselves or, more generally, in terms of the “control over transactions between person(s) and other(s), the ultimate aim of which is to enhance autonomy and/or to minimize vulnerability” (Margulis, 1977, p. 10). Based on this definition of privacy, an alternative view of personal information emerges as “the information over which a person has some interest or control, in order to negotiate their environment or order their lives” (Van Kleek & Ohara, 2014, p. 8).

Defining personal information as information over which the subject has control means giving individuals the responsibility over the management of their information and, hence, their privacy. As Whitley (2009, p. 158) points out, the “control over personal data is no longer something that is managed by organizations beneficently on behalf of individuals, instead individuals (about whom the data relates) have the opportunity to take an active role in the control and management of their personal data”. This entails a shift from the traditional O-CPIE model for personal information management to the U-CPIE.

In the U-CPIE, individuals considered as PIOs (although property rights can be hard to assign when considering personal information) can exert a higher control over their information and decide whether to disclose that information to trusted organizations in order to receive some benefits from them. However, allowing individuals to exert control is a condition which is necessary, but not sufficient, to unlock the value of personal information in the U-CPIE.

The World Economic Forum identified three conditions that need to be considered to unlock the value of personal information: deliver meaningful transparency, strengthen accountability and empower individuals. Deliver meaningful transparency means to make transparency practices more meaningful, actionable and relevant for individuals by simplifying the ways in which organizations communicate them how personal information is being used. Strengthen accountability means linking accountability to the impact of different data uses on individuals and distributing privacy risks equitably among all the stakeholders. Empower individuals means giving them a say in how their information is used, giving them the capacities to use it for their own purposes, and engaging them in understanding (and managing) the intended impact of information usage.

According to (WEF, 2014) meaningful transparency, strengthened accountability and empowered individuals are the conditions that enable trusted flows of information between the PIOs and organizations within the U-CPIE that amount to transactions in which a value is exchanged between them. Hence, to be effective, measures to foster

transparency, accountability and empowerment should be devised based on an appreciation of how PIOs value and use their personal information. To this end, the next section discusses the individual disclosure behaviours on social media to understand why individuals are willing to disclose personal information on them, despite their privacy concerns. Although the relationship among individuals on social media is radically different from the relationship between individuals and organizations, the disclosure behaviours on social media can give interesting insights on what elements organizations can leverage to enhance the PIOs' willingness to disclose their information in the U-CPIE.

3 Why people disclose their personal information: the privacy paradox

Although individuals express high levels of concerns about their privacy, they often disclose a lot of personal information, especially on social media, including sensitive information (Chang & Heo, 2014). Many authors have observed this incongruence between what individuals declare and how they behave and refer to it as the 'privacy paradox' (Awad & Krishnan, 2006; Norberg et al., 2007). Even when they have been made aware of the privacy risks, individuals often do not adopt privacy protecting measures and tools mainly because their costs are considered too high or because the benefits expected from information disclosure are perceived (or even rationally evaluated) as outweighing the risks for privacy.

Empirical researches show that when it comes to personal privacy, the individuals' decision-making processes are characterized by psychological biases, bounded rationality and incomplete information, which prevent them from acting as economically rational agents (Acquisti, 2004; Kokolakis, 2017; Norberg, Horne, & Horne, 2009). This weakens sensibly the argument that personal information disclosure is based on a risk-benefit trade-off evaluation and makes it interesting to consider why individuals disclose their personal information on social media, where there is no material compensation for information disclosure.

In a study of students' disclosure behaviour on Facebook, Chang and Heo (2014) found that the expected benefits seem to have effect on the willingness to disclose personal information only in case of 'basic information' (e.g., language(s) spoken, gender, college/university, current city of residence, a short personal description, hometown, and personal website/blog URL) and some 'sensitive' information (e.g., e-mail, profile picture, work experience, birthday, networks the participants join, and instant messenger screen name(s)). Instead, the disclosure of 'highly sensitive' information (for instance, mobile phone number, other phone number(s), religious views, political views, address, relationship status, family members, and interests in men or women) is not affected by how much users perceive benefits.

Chang and Heo's conclusion is in line with the findings of Lee Park and Kim (2013) that found that information disclosure on social media is related to self-clarification, social validation, relationship development, social control, and self-representation, with relationship development being the most frequently stated motivation for disclosure.

Similarly, Kokolakis (2017) observes that since social networking is a way of gaining social capital, individuals disclose personal information on social media to earn social capital.

The relationship between the individuals' behaviour on social networks, social capital, community building and collaborative identity construction has been widely explored within the literature (Ellison, Steinfield, & Lampe, 2007; Ellison, Vitak, Steinfield, Gray, & Lampe, 2011; Valenzuela, Park, & Kee, 2009) that highlights how the individuals' disclosure behaviour on social networks cannot be explained in terms of direct utilitarian benefits, such as those assumed to be at the basis of the rational risk/benefit privacy calculation. When they decide to disclose personal information, "individuals take risks in sharing parts of the 'self' with others, as the other parties can use the shared information in unexpected and/or undesirable ways" (Norberg et al., 2009, p. 502). Hence, a fundamental psychological dimension is at play in personal information disclosure on social media.

The psychological dimension of privacy has been highlighted in some recent studies that show how the sense of 'psychological ownership' represents an important driver, maybe the most important one, of personal information valuation over and above information sensitivity and privacy concerns (Cichy, Salge, & Kohli, 2014; Spiekermann & Korunovska, 2017). Psychological ownership (Jussila, Tarkiainen, Sarstedt, & Hair, 2015; Pierce, Kostova, & Dirks, 2003) concerns the individuals' perceptions of property toward tangible and intangible goods, irrespective of whether they also legally own those goods. Quite unsurprisingly, the development of a sense of psychological ownership has been found to influence negatively the individuals' willingness to disclose their data and to motivate people to retain their personal information (Cichy et al., 2014). If we assume that the willingness to disclose personal information relates to how individuals value it, then psychological ownership can be considered as one of the determinants of the value of personal information, as seen from the PIOs' perspective. In fact, the higher the sense of psychological ownership, the lesser is the willingness to disclose personal information, which means that the amount of money an individual will possibly accept for disclosing his information grows sensibly, and the higher is the individuals' willingness to pay to protect their data from being deleted or sold (Spiekermann & Korunovska, 2017). Moreover, quite interestingly, it has also been found that incentives appealing to the motives of psychological ownership are more effective than compensatory payments in attenuating the negative relationship between the PIOs' sense of psychological ownership and their willingness to disclose their information. Put it differently, the willingness to disclose personal information increases if individuals perceive this as a way to "express themselves, enhance their self-efficacy or contribute to their self-identity by supporting a greater good as a direct consequence of disclosing their personal data" (Cichy et al., 2014, p. 5).

As observed above, individuals are supposed to perform a risk-benefit evaluation to decide whether to disclose their personal information: they disclose their information because the benefits of doing outweigh the cost or risks.

The discussion in this section shows that the PIOs' disclosure behaviours can be influenced by the possible psychological benefits (related to the determinants of psychological ownership) that can derive from disclosure. This is what happens when personal information is shared on social media. However, they can also represent elements that, besides material compensations, organizations can leverage to implement an interaction strategy with PIOs that can enhance their willingness to disclose personal information in the U-CPIE.

4 PIOs as data providers: unlocking the value of personal information through coproduction

Firms collect and use personal information to create value through the execution of value-producing processes. Since these processes use personal information as a resource, the individuals that information pertains to should be considered as involved in them, playing a role like that played by customers who collaborate with firms to coproduce value. As observed in (Norberg et al., 2009, p. 499), "the input of information from consumers in economic terms can be conceived as a type of coproduction, since the consumer contributes this information, like a raw material, toward the production of other goods and services".

Customers' involvement as coproducers has been studied quite extensively within the marketing and service literature (Lusch & Vargo, 2006; Prahalad & Ramaswamy, 2004; Vargo & Lusch, 2004), also with respect to the psychological implications of coproduction (Bendapudi & Leone, 2003; Etgar, 2008). Fuchs, Prandelli and Schreier (2010) found that customers involved as coproducers experience higher levels of psychological ownership than customers who do not participate in the production and delivery processes. Moreover, Etgar (2008, p. 102) observes that the "very act of participation and performance of the relevant tasks can yield experiences that provide psychological benefits independently of the nature of the goods or services created in the process".

As observed in (Cichy et al., 2014), tailored incentive design that underpin psychological ownership can be highly effective in mitigating negative effects on the individuals' willingness to disclose personal information on social media. This suggests the possibility of exploiting the psychological benefits that can derive from coproduction as incentives that, together with material compensations, can influence the PIOs' disclosure decisions. From this point of view, it seems reasonable to expect that, within the U-CPIE, a strategy based on coproduction that helps establishing a positive relationship with the PIOs, could enhance their willingness to share with organizations a resource they need for their value-producing processes.

In the U-CPIE, coproduction is an almost unavoidable strategy for organizations that want to compete in the digital and data-driven economy. Once the control over personal information is given back to the PIOs, the potential economic value embedded in personal information will remain untapped if their owners do not consent to its use. Hence, the implementation of strategies for unlocking that value could represent a significant

element of competitive advantage in the data-driven economy. According to the World Economic Forum such strategies should satisfy three critical conditions: deliver meaningful transparency, strengthen accountability and empower individuals (WEF, 2013, 2014). Quite interestingly, a strategy based on coproduction satisfies these conditions.

In describing the conditions that could facilitate value cocreation experiences, Prahalad and Ramaswamy (2004) identify Dialogue, Access, Risk-benefits assessment, and Transparency (the so-called DART framework) as the basis for the interaction between consumers and firms. Dialogue implies interaction, deep engagement, and the firms' willingness to avoid opportunistic behaviours and to recognize an active role to the consumers. Access implies that consumers should be allowed direct access to the relevant information, which could require making available to them tools (mainly technological ones) enabling informed decision-making. Risk-benefit assessment is based on dialogue, access and transparency that allow consumers to acquire more information about potential risks of goods and services, which is the basis for sharing the risks and assume more responsibility for dealing with them. Finally, transparency implies reducing the information asymmetry, which is the basis for building trust between firms and consumers. What makes the reference to the DART framework relevant for the present discussion is the fact that the four dimensions it encompasses cover the three conditions for unlocking the value of personal information identified by the World Economic Forum.

When organizations avoid using (opportunistically) personal information in ways that are unimagined and unwanted by the PIOs, open dialogue, interactivity and transparency allow them, as coproducers, to get a clear understanding of how their personal information is collected and used. This allows overcoming many of the problems related to the most common practices of informed consent, which are mainly based on long, complex and generic documents, and strengthen meaningful transparency through information sharing. Access is the condition that enables the empowerment of PIOs and allows them to assume responsibility on the disclosure of personal information and to share with organizations the risks involved in the use of their information. Giving individuals direct access to the relevant information concerning the use of their personal information can be done by providing them with tools that allow tracking it, which is a fundamental aspect of the individuals' control over personal information. Pursuing transparency is a way to reduce the information asymmetry between individuals and the organizations that collect and use personal information. Through transparency, individuals can be made aware of not only how and by whom their personal information is used, but also of what value firms generate by using that information. By reducing information asymmetry, individuals can make more informed decisions on whether to disclose their personal information, and in exchange for what. This is the basis for strengthening accountability on both sides of the personal information value chain.

Based on the observations above, it can thus be concluded that the PIOs' involvement as coproducers in value-generating processes can represent a viable strategy organizations can implement to enhance their willingness to share personal information. Although many critical aspects need to be considered to give further support to this conclusion,

preliminary as it is, the discussion in this section nevertheless shows that coproduction can play a relevant role to enable value creation from personal information in the data-driven economy.

5. Conclusions, limitations and further research

Personal information represents a fundamental asset in the digital society to which a remarkable economic value can be associated. However, this value often remains untapped and this raises the problem of how to unlock it to generate further value in the data-driven economy. While it has been suggested that giving back to individuals the control over their personal information could ease the flow of information, it is not clear why and in exchange for what individuals would be willing to disclose their personal information to organizations that will use it to produce value.

Researches in the economics and psychology of privacy show that individuals do not value their personal information simply in economic terms. The peculiar relationship of personal information to the self makes the sense of psychological ownership a fundamental aspect of its value as seen from the PIOs point of view. Leveraging the determinants of psychological ownership can thus represent a possible strategy that, together with the more traditional compensation mechanisms, organizations can implement to free the flow of personal information within the U-CPIE.

The main contribution of the paper has been to show that this could be done by involving PIOs as coproducers in the organizations' value-producing processes that use personal information as a resource. However, this possibility has been discussed at a very preliminary level and without considering in depth how the coproduction concept has been developed within the management and the marketing literature, especially with respect to the conditions that can make individuals willing to coproduce. Hence, more research is needed to develop further and to test the hypothesis formulated in the paper also based on empirical data. Moreover, in the paper no distinction has been made among different types of personal information that can be associated to different types and levels of perceived risks. This represents a further limitation of the present study that needs to be overcome to identify the incentive mechanisms that can be most effective in the different cases.

However, preliminary as they are, the results of the discussion in this paper show how some well-known concepts from the management and marketing literature, conveniently reviewed, can help organizations to devise strategies for dealing with the new challenges posed by the emerging user-centric personal information ecosystem.

Networks for Regional Sustainability: a Case Study Approach

Stefanie Wesselmann

Department of Public Management
Osnabrück University of Applied Sciences
Caprivistr. 301, 49009 Osnabrück, Germany

Abstract

Climate change is the biggest social challenge facing the globalised world. The aim of this paper is to investigate the requirements for governance structures in regional sustainability programmes against climate change.

The study is an explorative case study. It is based on a literature review and expert interviews. It also involves the participatory observation of working groups meetings, and a design thinking workshop.

In spite of their enormous importance, little is known about the institutional conditions of the regional governance of climate change projects in Germany.

For this reason, the research project focuses on the important aspect of networking and governance structures. Consequently, the investigation will contribute to answering the question of which institutional framework conditions can raise the likelihood of climate change projects having a sustainable effect.

The outcomes of the application

This research has not only practical implications for the single case. The exploration of the critical factors of success also offers other regions important food for thought in shaping their governance structures. In particular, the design thinking process and the business network in the District of Steinfurt offer valuable points of reference.

Keywords - Regional sustainability, Governance, Climate change, Design thinking, Social ecosystems

1 Introduction

The negative effects of the unchecked consumption of resources was described as early as in the Club of Rome's 1972 report "The Limits to Growth". The prophecy described in the report matches the climate change crisis facing us today.

Since the 1980s, the issue of climate change has increasingly been the subject of public discourse. In order to combat climate change, the sustainable use of resources is called for.

In the Brundtland Commission report, the term "sustainability" is transferred to socio-economic processes. The following line of action is stated in this report: "*Sustainable development is development that meets the needs of the present without compromising the*

ability of future generations to meet their own needs. (World Commission on Environment and Development 1987, p. 41).

For this reason, many cities, as well as regions, have made climate change one of their key political objectives. There are numerous party programmes, master plans, voluntary commitments, smart city initiatives, etc.

Most of the programmes target the following measures (Bierwirth and Schüle 2012):

- Climate-friendly mobility
- Switching to regenerative energies
- Food and consumption
- Waste prevention
- Landscape conservation
- Reduction of energy consumption, e.g. in the residential sector.

In the area of conflict between ecological, technical, economic and social requirements, many cities and regions are struggling to strike a suitable balance between conflicting interests (Auffhammer 2018; Kabisch et al. 2017; Batisha and Thomas 2015). In so doing, many experts argue that the energy transition is more a social than a technical challenge (Wittmayer and Loorbach 2016).

With most people, awareness of activities that harm the environment and the realisation that changes in behaviour are essential do not usually increase the likelihood that they will actually change their behaviour. The same applies to consumers, representatives of business, and politicians, just to name a few of the biggest stakeholder groups (Thaler and Sunstein 2008; Kahneman 2012; Pettman and Zabel 2005; Bang et al. 2000).

The core question is therefore: how can cities and regions stimulate and perpetuate sustainable behaviour? Global sustainability problems require a multiscale approach that can zoom in and out from the macro- to the meso- to the microlevel, and vice versa (Loorbach and Shiroyama 2016).

To enable cooperation between these different levels, it is essential to develop network and governance structures (Cadman et al. 2015; Davidson and Lockwood 2008; Loorbach and Shiroyama 2016; Orenstein and Shach-Pinsley 2017; Schmitter 2010; Sol et al. 2018). It is much easier to implement climate change projects at the city level than at the regional level (Dierwechter 2017; Ehnert et al. 2018; Frantzeskaki et al. 2017; Gatrell et al. 2016).

The particular challenge facing regions is that they can only lay down guidelines to their municipalities to a very limited extent. This means that a region's municipalities will usually pursue climate action initiatives on a voluntary basis.

Collaborative and participative modes of governing are advocated to address sustainable development problems that cross geographical and political boundaries and whose solution requires the coordination and integration of the activities of disparate sectors and actors, as well as the participation of all those affected. (Davidson and Lockwood 2008).

Brand/Warsewa (Stablo and Ruppert-Winkel 2017) developed key success factors for regional governance processes. According to the authors, it is fundamentally important to

gain the support of the highest administrative level and of charismatic leading figures (Ruppert-Winkel 2018; Orenstein and Shach-Pinsley 2017). It has also proven beneficial to ensure that projects are linked to concrete municipal problems, and that solutions can be expected. To achieve this, it is helpful for appealing lead projects, possibly involving local celebrities, to be effectively communicated to the public.

Ideally, an administrative unit acts as an organisational hub, which provides a service-oriented platform for cooperation, ensuring efficient process management, including controlling (Stablo and Ruppert-Winkel 2017).

2 The case study

In a bid to explore the specific conditions for successful regional sustainability programmes, a local authority, which can be regarded as a regional alliance, was selected as the case study. The district of Steinfurt in North Rhine-Westphalia, a predominantly rural district in northwest Germany with a population of 434,000, has 24 towns/cities and municipalities¹.

The Agenda 21 process was launched in the district of Steinfurt in 1999. As early as ten years ago, the *Kreistag* (district council) decided unanimously to adopt the goal of becoming energy self-sufficient by the year 2050 in the context of a climate change project. As a result, the implementation of the concept enjoyed official political legitimacy and was established at the highest level.

As one out of nineteen local authorities, Steinfurt was chosen by the Federal Ministry for the Environment to prove whether it is possible to reduce greenhouse gas emissions by ninety-five percent by 2050 and to cut in half final energy consumption².

To achieve the institutional anchoring of this goal, the Agenda 21 Office was transformed into the Office for Climate Protection and Sustainability in 2013. It has since become a nationally respected player in climate (Stablo and Ruppert-Winkel 2017).

The tasks of the Office for Climate Protection and Sustainability include³:

- Climate protection and climate change
- Development of renewable energies and energy efficiency
- Reinforcement of regional added value, regional marketing
- Development of rural areas
- Promotion of citizen responsibility.

In the District of Steinfurt, the goal of becoming energy self-sufficient is operationalised as follows: by 2050, all the energy required in the district is to be produced carbon-free and consumed locally, whilst reducing energy consumption by half.

¹ District of Steinfurt https://www.kreis-steinfurt.de/kv_steinfurt/Kreisportrait/St%C3%A4dte%20&%20Gemeinden/, 10 January 2019

² District of Steinfurt, Office for Climate Protection and Sustainability, https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/%C3%84mter/Amt%20f%C3%BCr%20Klimaschutz%20und%20Nachhaltigkeit/, 10 January 2019.

³ District of Steinfurt, Office for Climate Protection and Sustainability, https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/%C3%84mter/Amt%20f%C3%BCr%20Klimaschutz%20und%20Nachhaltigkeit/, accessed on 3 April 2019

In this way, the money spent on heat, fuel and electricity should remain in the region and create a “regional added value”.

On the way to becoming a climate-neutral district, the innovative capacity of the regional economy is to be improved at the same time, reinforcing the structural change. The climate change mitigation targets serve the further purpose of creating a distinct profile for the district, aspiring to set an example for “ethically responsible social life”.

The 100% Climate Protection Master Plan¹ represents an important conceptual foundation. This master plan, drawn up in 2013, was the result of cooperative teamwork between the Office for Climate Protection and Sustainability, climate change stakeholders from local authorities and regional utility companies, experts from Münster University of Applied Sciences, and external climate experts.

The climate change policy objectives were elaborated upon in the master plan:

- Induce change by launching exemplary climate change projects that are visible and tangible to the local population, and turn the experience gained from model projects into application-oriented principles.
- Gradually improve networking and the targeted management of all climate change stakeholders and projects in the district, and organise structures to enable stakeholders to learn from each other.
- Strengthen the options for action and the initiative of civil society in the district by providing appropriate input, and enable companies, associations and citizens to achieve their own goals and implement their own projects relating to climate change and sustainability.

3 Governance structures in the District of Steinfurt

Seeking to achieve these climate change goals, structures and networks have evolved comprising bodies such as work groups, round tables, committees and associations. Most of the coordination is undertaken by the Office for Climate Protection and Sustainability.

Due to its lack of authority over regional networks, when it came to climate issues, the District of Steinfurt immediately recognised the importance of participation, and was quick to involve local authorities, citizens and companies in the region’s energy transition.

3.1 Community wind farms

A higher-than-average number of wind turbines have been installed in the District of Steinfurt over the last 20 years. Whereas in other regions, the development of wind farms met with strong resistance from citizens and residents, the District of Steinfurt attached importance to early grassroots participation. Public participation explicitly includes citizens’ investment in the turbines, enabling them to benefit financially from renewable energies.

¹ The 100% Climate Protection Master Plan, https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/%C3%84mter/Amt%20f%C3%BCr%20Klimaschutz%20und%20Nachhaltigkeit/energieland2050%20e.V./Service/Informationsmaterial/Masterplanbericht_Langfassung%20.pdf, accessed on 8 April 2019

After intensive networking, the Office set up a Wind Energy Service Station, specifically for the purpose of mediating in case of conflict.

3.2 Participation portal

Climate change projects run by the district and participating local authorities can be presented and discussed on a GIS-based participation portal. Online maps enable users to view where and when certain projects or events are being planned, and how they can get involved¹.

3.3 Company network

On the corporate side, an alliance of more than sixty companies from the region evolved, known as the company network². Thematically, the network focuses on developing renewable energies and on increasing energy efficiency, covering the areas of electricity, heat and mobility. In the process, the company network seeks to involve as many actors as possible along the various value chains.

3.4 The “energieland2050” association

In the context of network management, particular importance is placed on the energieland2050 association, founded by the District of Steinfurt in 2017.

This network consists of representatives from the political sector, industry, academia, municipal utilities, civil society and the 24 cities and municipalities belonging to the district. Considerable importance is attached to public participation³.

The “energieland2050” association is directed at three main target groups:

- Municipalities
- Companies
- Citizens/consumers.

The company network finances half of the association, which now has nine employees. This public-private partnership is another cornerstone of the district’s governance strategy.

All 24 local authorities belonging to the district are supported by the “energieland2050” association by undertaking activities such as:

- Preparing joint campaigns
- Collecting data and undertaking potentials studies
- Fundraising
- Linking and qualifying municipal climate officers.

The district’s service-oriented networking activities also enable smaller local authorities to undertake local climate change projects, increasing the measures’ leverage.

¹ Participation portal of energieland2050, <https://energieland2050-dialog.de/>, accessed on 3 April 2019

² District of Steinfurt Company Network, https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/Ämter/Amt%20für%20Klimaschutz%20und%20Nachhaltigkeit/energieland2050%20e.V./Für%20Unternehmen/Unternehmernetzwerk/, accessed on 3 April 2019

³ <https://energieland2050-dialog.de/>, accessed 10 January 2019

A qualified advisory service is being established for companies and citizens under the name “energieland2050 consultants”. Freelance energy consultants who meet predefined quality criteria are permitted to use the trademarked name “energieland2050 Consultant”. The aim of introducing the “energieland2050” consulting brand is for the district to boost the role and profile of the region’s diverse consulting expertise for the region¹. Besides developing networks and implementing specific climate change projects, considerable importance is attached to public relations.

In order to motivate a region’s stakeholders to participate in governance processes, their interests and expectations of benefit need to be analysed in detail. Team spirit and coherent action can also be built by recognisable and identity-shaping communication that exerts an internal and an external effect. This is usually achieved with the use of an umbrella brand. The lack of official authority means that people must be motivated by symbolically communicating a common vision, and projects seeking to realise this vision.

There is a consensus that the better network partners’ needs have been analysed, the more likely it is that their behaviour can be influenced. In this context, the design thinking method offers new potential insights. Inspired by lifestyle research, this method focuses on developing representatives of certain target groups, referred to as personae, in an attempt to explore and extrapolate their behaviour.

3.5 Design thinking

As the term “design” suggests, design thinking was originally an innovation method for designing technical devices and user interfaces. However, large software companies such as Google, Apple and SAP are increasingly establishing design thinking as a method for systematically approaching complex problems from all walks of life. As such, the method takes the content and scope of the classic term “design” much further (Grots and Creuznacher 2016; Reinecke 2016; Plattner et al. 2018).

3.6 Principles

Unlike with technology-based methods of innovation, attention is centred on the user in this case (human-centred approach). The user’s needs and behaviour are the starting point and point of reference for the entire process (Schallmo 2017).

Another important characteristic is work in multidisciplinary teams. Unlike with many methods that foster creativity, which often occur within an unstructured process, design thinking pursues clearly defined process levels, sometimes involving strict time management. One important characteristic of the method is its use of iterative loops, i.e. the multiple repetition of stages to achieve a solution step by step (Plattner et al. 2011).

The work process involves several methods commonly used in innovation and creativity management, with the difference being that emphasis is placed on visualisation techniques (Poguntke 2016).

¹ energieland2050 consultants, https://www.kreis-steinfurt.de/kv_steinfurt/Kreisverwaltung/Ämter/Amt%20für%20Klimaschutz%20und%20Nachhaltigkeit/energieland2050%20e.V./Themen%20und%20Projekte/energieland2050%20Berater/, accessed on 3 April 2019

3.7 Process stages

The number of stages varies depending on the model; the six-stage process model based on Hasso Plattner Institute's School of Design Thinking is in widespread use.

Figure 1. The design thinking stage model, Hasso Plattner Institute

At the first stage (“Verstehen”: “Understand”), the phenomenon to be addressed is described in detail. This description defines the framework for formulating a common understanding of the issue at hand. Another important goal at this stage is team building (Plattner et al. 2011).

At the second stage (“Beobachten”: “Observe”), teams view the matter under consideration from the perspective of the relevant user or person concerned. This stage involves “creating” what is referred to as a persona, who acts as a kind of representative for a certain target group. It is important to describe each persona in as much detail as possible: name, age, family situation, level of education, profession, interests, values and hobbies. Less tangible emotional aspects such as the persona’s dreams, unmet needs and problems are also described and visualised.

This approach enables players to “delve” emotionally into the individual’s lifeworld, seeing things from his or her perspective. The insights gained enable products and services to be created in such a way that best meets customers’ needs.

At the third stage (“Sichtweise definieren”: Define point of view”), the insights gained are gathered, structured and condensed to form a specific issue.

The fourth stage (“Ideen finden”: “Ideate”) involves the actual creative process. Participants switch from the “problem domain to the solution domain”, using various creativity techniques to generate as many ideas as possible.

The aim of subsequent prototyping (“Prototyp”: “Prototype”) is to visualise and materialise the idea, with the purpose of making it clearer and emotionally more comprehensible. Prototyping can be performed in very different ways: using drawings, Lego objects, card models or role play, to name a few.

At the last stage (“Test”), the prototype is tested to see whether it suits the relevant customer/user; it can then be adapted as required.

Principles of this method have already been used in urban planning for some time under the term “urban design thinking”, which involves the user-centred design of areas and districts (cf. for example (Dovey 2016; van Eijck et al. 2017). The City of Mannheim,

for instance, uses urban design thinking in its “Migrants4Cities” project to stimulate urban innovation by highly qualified migrants in a bid to achieve sustainable urban development.

3.8 Design thinking in the District of Steinfurt

As many studies have shown (cf. as representatives for many others: (Deffner et al. 2012; Ernst et al. 2016; Bang et al. 2000; Institut für Sozial-Ökologische Forschung 2010; Pettman and Zabel 2005), stakeholders from the Office for Climate Protection and Sustainability also assumed that the issue of climate change is too abstract for many people, bearing little relation to their personal daily lives.

For this reason, differentiated target group analyses are an essential prerequisite to identifying who is receptive to certain offers and solutions, and which problems they face. The Office for Climate Protection and Sustainability therefore decided to implement a design thinking process in 2015.

The situation analysis at the start of the process revealed that “energieland2050” was indeed known to experts as a vision of the future, but not to individuals in the region, apart from the closest network partners. Most were unaware of the added value that may be generated by participating in the project.

To gain a better understanding of the target groups, six design thinking workshops were held with different target groups¹.

The following six personae were selected and addressed:

- Climate officer / municipality
- Entrepreneur / energy industry
- Entrepreneur / craft industry
- Citizen / young person
- Citizen / woman with children
- Citizen / senior citizen 60+

One persona is presented as an example below. The persona Josef Heubaum was created in one design thinking workshop to represent the target group of craft industry entrepreneurs.

¹ The author participated in two of these workshops as an observer.

Characteristics:

Josef Heubaum is a 55-year-old craft entrepreneur. He is married, with three children. The master carpenter runs his own business and has 15 employees.

The following values are important to him in life:

- Tradition
- Thrift
- Home region
- Family
- Quality.

His work-related problems include:

- A latent fear of losing his livelihood, despite having full order books
- Fear of big competitors (IKEA, Finke etc.)
- Uncertainty caused by continuous change processes.

In his company, Josef Heubaum places great importance on quality. All the same, he is not a committed environmental activist.

The following goal was formulated: to persuade him to seek support from an energieland2050 Consultant in making his company more environmentally friendly.

This could include the following measures:

- Having a photovoltaic system installed on the roof
- Purchasing vehicles with emissions in mind
- Purchasing/supplying regionally.

The following communication goal was formulated: to persuade him to be an “energieland2050 ambassador” so that he would share his experience within his networks and spread his knowledge.

In order to achieve these goals, the participants first looked at what had so far prevented him from participating in the “energieland2050” network.

The following reasons were elaborated during the workshops:

- A lack of time (it is not his core business)
- No legal obligation to behave green
- A lack of personnel
- A general feeling of scepticism towards the public sector (Office for Climate Protection and Sustainability)
- A lack of cost pressure
- The previous appeal was not direct enough
- A lack of information.

Building on this analysis, the workshop participants thought about the ideas and messages that could be used to reach the persona Josef Heubaum:

- “As a craftsman, you are part of the energy transition, and can earn money from it.”
- “From the region for the region.”
- “So that your grandchildren can have a good life here, too.”
- “Give something back to your home region”

It was also considered important to establish access to the networks and multipliers of the target group. If the associations and institutions to which Josef Heubaum belongs were involved in the project, this could increase his trust and confidence in the project. The company network would be the ideal connecting factor.

Similar analyses were conducted along the stages of the design thinking process for the other five personae, and ideas were developed. These ideas formed the basis for fleshing out concrete measures and developing an umbrella brand concept.

4 Conclusion

The success factors for regional governance projects mentioned at the beginning of the paper are applicable in essential respects to the District of Steinfurt. The early resolution by the *Kreistag* (2010) gave the work of the Office for Climate Protection and Sustainability political legitimacy, and established it at the highest level.

The Office for Climate Protection and Sustainability acts as a coordinating office that helps network partners to achieve their own goals and reach their target groups, increasing the measures' leverage. In addition, impetus is continuously provided to support the partners' self-organisation and to transform loose networks into permanent entities, as was the case with the launch of the "energieland2050" association as a public private partnership.

According to the initiators¹ and the participants², the design thinking method was classed as appropriate for developing target group-oriented activities and an umbrella term concept.

Many of the projects build on local projects, and are designed to be participatory from the very beginning. As a result, they theoretically encourage the involvement of a wide range of actors. However, citizens are still largely unaware of the "energieland2050" brand. One reason for this is the difficulty in communicating measures to a predominantly rural administrative district³.

Communication about the umbrella brand declined substantially after the funding ended, meaning that there was no longer sufficient accompanying communication about the initiative. This is particularly due to the fact that the local authorities make no or little use of the umbrella brand in their communication activities.

An important research issue for the future is to determine whether the structures that have now been created (energieland2050, company network, etc.) suffice in order to ensure the work of the climate projects in the long term, or whether the Office for Climate Protection and Sustainability will need to continue providing support.

The actual question of whether local citizens' behaviour has changed due to the activities outlined would have to be evaluated in the context of an extensive empirical analysis, which has yet to be undertaken.

Abstract

Knowledge is a strategic tool for public administration. Therefore, knowledge management would affect organizational effectiveness. In the context of the new approaches of public management, especially considering the public value management point of view, knowledge transfer with stakeholders should be the norm. The present study identified a gap in the academic literature in relation to stakeholder management practices and how do public bodies involve their stakeholders in the decision-making processes. The paper proposes several lines of mapping the interactions between public administration and its stakeholders by considering the value attributed to stakeholders, the awareness of their needs and desires, as well as the degree of involvement into the decision-making processes.

Keywords – knowledge management, knowledge transfer, stakeholder management, stakeholder mapping, public administration

Paper type – Academic Research Paper

1 Introduction

Knowledge management in public administration has been the aim of increasingly more academic papers in the past decades (see for instance some of the recent literature reviews undergone by Biswas, Khan and Biswas, 2017; Massaro, Dumay and Garlatti, 2015; McEvoy, Ragab and Arisha, 2017; Laihonon and Mäntylä, 2018). A relatively large

amount of the literature in the field is dedicated to knowledge transfer (Amayah, 2013; Chen and Hsieh, 2015; Pee and Kankanhalli, 2016; Sandhu, Jain and Ahmad, 2011; Tangaraja et al., 2015). Knowledge transfer, both inside and outside a public organization, is stimulated by the new approaches in public management, which make these organizations not only more transparent and accountable, but also more connected to its stakeholders and eager to cooperate for the benefit of the communities it serves.

Public organizations adopt a multi-actor perspective (Osborne, 2010), leading to setting up dynamic networks aiming a wide common welfare. When we consider smart cities, the relevance of knowledge and the need of knowledge sharing – both ways from and towards public organizations – is even more evident (Pinzaru, Zbucnea and Vitelar, 2018). In the context of knowledge management and new public management approaches, stakeholders are increasingly more relevant (Bingham, Nabatchi and O'Leary, 2005; Riege and Lindsay, 2006). By involving stakeholders, the new public management strategies lead to co-creation, more effective programs and better impact in the communities (see for instance Black and Gallan, 2015; Bovaird and Loeffler, 2012; Bryson, Sancino, Benington and Sørensen, 2017; Osborne, Radnor and Strokosch, 2016). Another relevant aspect is the facilitation of knowledge transfer from stakeholders to public administration. Having this in mind, the literature in knowledge management focuses in a significant degree on stakeholder management (see, for instance, Bourgon, 2007; Butler et al., 2008; Richards and Duxbury, 2014; Riege and Lindsay, 2006).

Investigating the literature in the field of public management, one observes, that even the importance of its stakeholders is recognized, the studies focusing primarily on stakeholder management are lacking. Therefore, the present study aims to contribute to covering part of the gap by understanding how does public administration involve stakeholders in its decision-making processes. By scrutinizing the literature, we develop hypothesis to be tested in subsequent research.

2 Understanding the role of public administration within society

Today, managing complexity does not rely any more exclusively on virtues of public management but requires that all stakeholders are able to promote exchange, collaboration and cooperation building social, knowledge-oriented and public value-driven networks within social ecosystems. Public organizations should follow the public value view to shape strategy and action within ecosystems by engaging stakeholders and involving civil society as a proactive actor in constructing governance within public-private networks for shared and common partnerships. Creating and maintaining public value relies on sustaining a networked governance that supports multilateral cooperation to cope with changing contexts (Hartley, 2005).

Public value is created in relationships in which the public is involved to act for and benefit of value creation (Meynardt, 2009). Increasingly, value creation is emerging within service networks because customer participation supports mutual relationship with a provider as a condition to unlock the potential of value co-creation (Black and Gallan, 2015). Public administration should adopt a public value management view to value

creation process within society (Stoker, 2006) meeting public needs and promoting the public interest as the result of a dialogue, developing policies as an issue of collaborative processes that contribute to designing trust-based relationships and planning successful action in long-terms (Denhardt and Denhardt, 2000).

Creating public value relies on reinforcing networks of social ties where public administration interacts with stakeholders within community in order to facilitate public wealth (Borgonovi, 2001) and contribute to services delivery by sustaining the relationships with multiple inter-dependent actors, inform the policy making systems promoting multiple processes (Osborne, 2006). In public service delivery, strengthening cooperation and partnerships facilitates trust and conflict reduction in relational exchange, helps reveal both transformational approach to service improvement and distinctive competencies (Entwistle and Martin, 2005). Public administration should face uncertainty by engaging with external stakeholders looking at an ecosystem perspective in order to better support public governance (Dumay, Guthrie and Farneti, 2010; Osborne, 2006).

In following a public value management view, public administration should consider the relationships as dominant focus because «government activity is interconnected and interdependent and, as such, may require more collaborative effort in the pursuit of public value» (O'Flynn, 2007, p. 361). Value creation relies on following a multi-actor perspective that implies to interpret differences among actors, levels, spheres and logics and to consider how to develop capacity and agreement about co-producing public value by obtaining authorization and legitimation (Bryson, Benington, Sancino and Sørensen, 2017). Public administration should strengthen collaboration with citizens as partners as related to «active, bidirectional act of participation, involvement, and unification of forces between two (or more) parties» (Vigoda, 2002, p. 527). Public administration should serve the public interest engaging stakeholders in sustaining information and knowledge sharing to develop successful cooperation enhancing responsiveness within society (Bryer, 2006). Sustaining governance helps dialogue between stakeholders and public organizations as key source to construct transparent processes that enable effective two-way knowledge transfer and lead to sustainable policy solutions (Riege and Lindsay, 2006).

H1: The more public administration values its stakeholders, the more their input is incorporated in its policies and actions.

3 Stakeholder management within public administration

3.1 The relevance of stakeholder management in public organizations

Public administration is operating for the benefit of the wider public, its stakeholders. Therefore, the success of the implemented strategies and projects should be evaluated by these stakeholders. Nevertheless, this process is not simple considering the variety of stakeholders, and their various relationships with the public body. For better management, stakeholders should be understood. They should be analyzed and mapped.

The stakeholders' theory is still evolving, with different aspects to be developed: despite attempts in proposing stakeholder homogeneity and independence models (Fassin, 2008, 2009), there is no robust stakeholder theory model to be generally recognized (Wagner Mainardes, Alves and Raposo, 2011). Moreover, there is a body of work to be done on practical aspects of the stakeholders mapping approaches, from the inherent conflicts (and how to deal with them), to the direct relationship between the stakeholders' management and the organizational efficiency (Wagner Mainardes, Alves and Raposo, 2011).

Identifying, mapping and managing stakeholders of the public administration are activities discussed mainly from the perspective of efficiency (Bryson, 2004; Meynhardt, 2009), of large scale programs involving different institutions (Heikkila and Gerlak, 2005), of the change management strategies and techniques (Rainey and Fernandez, 2006) and of the knowledge management paradigm (Riege and Lindsay, 2006). Stakeholder management is understood as a part of the strategic management in the case of the public organizations that develop performance management strategies (Isaac Mwitta, 2000; Verbeteen, 2008), and evidence from practice highlights the complexity of stakeholders' understanding and mapping (McAdam, Hazlett and Casey 2005; Bovaird, 2005; Williams & Lewis, 2008).

As for the practice, the human resources paradigm provides managers from the public institutions with four major dimensions to understand and map stakeholders: the functional role (the position of the individual stakeholder), his/her interests, the means of action at its disposal and the justifying principle (Ferrary, 2005). The most recent discussions on the topic are developed from the perspective of collaborative projects (Bryson et al., 2013), pointing out the need to design flexible inclusive processes in which stakeholders can be involved, as well as the need of a flexible power dynamics' management (Bryson et al., 2013). Even if there is an academic trend to model the usage of technology, more specifically of the digital one in all aspects of management - the one of the public administration included -, it should be seen more like a tool to efficiently manage specific activities such as communicating with stakeholders and boosting their engagement (Bryson et al., 2013).

H2: The more public administration is aware of its stakeholders, the more efficient it is.

3.2 Involving stakeholders in the decision-making processes of public administration

Knowledge transfer is a relevant subject for knowledge management in public administration, which determined a relatively high segment of the studies in the field - around 15% - being dedicated to it (McEvoy, Ragab, and Arisha, 2017). These studies present a complex image of knowledge sharing within and outside the public administration, considering both internal and external factors, both human and organizational ones (Pinzaru, Zbucnea and Vitelar, 2018, p.701).

A prerequisite for involving stakeholders in the decision-making processes would be to encourage knowledge transfer and cooperation across the boundaries of the public body (Wiig, 2002). Designing an "Intelligent Organizational Behavior" also facilitates it.

This leads to implementing an active KM strategy, encompassing the development of a learning organization, knowledge acquisition and packaging, organization architecture and process redesign (Wiig, 2002). Therefore, knowledge transfer is not a simple state of mind; it involves a certain strategical organizational framework. It also needs organizational capabilities and infrastructure.

Knowledge transfer in public organizations is also influenced by their senior managers (Currie, Waring and Finn, 2008; Dawes, Cresswell and Pardo, 2009; Handzic, 2011; Pee and Kankanhalli, 2016). The impact of senior management could be either formalized in a shared vision, processes and actions, or could be less formal, based on example and encouragement of knowledge transfer.

H3a: Strong leadership support for knowledge transfer enhances the reception and use of stakeholders' inputs in the decision-making processes of public administration.

Knowledge Management is strongly influenced in public organizations by the organizational culture (Riege and Lindsay, 2006). Therefore, best practices of involving stakeholders into the decision-making processes should be associated with a knowledge management – connected organizational culture. A mediating factor seems to be the accountability and transparency culture (Riege and Lindsay, 2006, p.26). The need to involve stakeholders into the decision-making processes is acknowledged (Rod, 2006; Rybakovas, 2007). Nevertheless, it is not necessary the norm.

We also stress that the transfer of knowledge between public bodies and their stakeholders is a two-ways process and tacit knowledge is at the core of this process (Riege and Lindsay, 2006, pp.27-28).

H3b: Organizations with stronger awareness of their stakeholders involve them more in the decision-making processes.

4 Conclusions

There is a limited body of literature helping public administration better involve stakeholders in the decision-making processes (Riege and Lindsay, 2006, p.37), although this is a trendy recommendation in the public administration management theory. In the same time, public managers should also be cautious and consider the limits and risks associated to involving citizens and other stakeholders into the decision-making processes (Irvin and Stansbury, 2004).

Involving stakeholders in public administration strategies and projects leads to co-creation and increased public value, possibly to social innovation. Also, the effectiveness of the activity of a public body would increase by stakeholders' involvement and by considering their voice in the decision-making process. In this way, the needs and desires of the public would be, theoretically, better addressed and the beneficiaries would be more satisfied. In practice, the processes of stakeholder management and involvement are not so smooth.

Knowledge transfer between public administration and its stakeholders depends on many different factors. Previous studies suggest that the stronger the awareness of their

stakeholders, the more public administration takes them as points of reference, considers them as partners and involves them into the decision-making processes. This process is in a wide degree influenced by the attitude of the senior leadership.

Abstract

Knowledge ecosystems offer an important perspective in studying knowledge management, innovation and value creation across large and holistic communities. Health communities could be defined as such because of their complexity, representation of multiple stakeholder groups, varieties of knowledge, and also individuals, where the ultimate goal is health, as a consequence of patient value creation. The community approach serves the main goal of patient value creation, as it responds to the need for a systematic approach in encouraging patients to play a more active role in health. It is important to integrate patient engagement strategies into all efforts to improve the effectiveness and efficiency of care. Patient value creation includes much more than the clinical communication, and the knowledge domains extend far beyond clinical knowledge. We need to answer, how ecosystems create and deliver value in sustained way (Levit et al., 2013). Based on this problem formulation, with this paper we aim at answering the following research questions: how to manage holistic knowledge across health knowledge ecosystems? what are the main barriers for knowledge sharing and integration for patient value creation? In order to answer these questions, we apply knowledge creating community approach (Paavola, et al 2004), where various stakeholders create and share knowledge of clinical, and social domain, that all together contribute to patient value creation. In order to understand the complex nature of knowledge flows in the health ecosystem, (collection, mapping of knowledge flows, and identification of preconditions for knowledge exchanges and co-creation) we have applied phenomenological approach. We have applied case study method with the research base at Lithuanian Health Science University Hospital, Department of Obstetrics and Gynecology and associated communities. The research on knowledge creating communities in health from the patient perspective has indicated important tendencies, and knowledge management implications in the field. Qualitative empirical study has revealed a specific knowledge development pattern from the patient perspective - knowledge socialisation and development starts within very close and trusted community members. Trust, validity, reliability and responsibility of knowledge has

emerged as a full mediators for knowledge absorption. Thus, health communities and knowledge ecosystems need safe places for “unverified” knowledge in order to ensure that the important trends and unresolved questions are not missed.

Paper type – Academic Research Paper

1 Introduction

Knowledge ecosystems offer an important perspective in studying knowledge management, innovation and value creation across large and holistic communities. Health communities could be defined as such because of their complexity, representation of multiple stakeholder groups, varieties of knowledge, and also individuals, where the ultimate goal is health, as a consequence of patient value creation. Knowledge ecosystems are defined as a unique set of actors and interactions and thereby evolves in its own manner (Valkokari, 2015). They also represent environments that trigger intellectual interactions and innovative productions (Bahrami & Evans, 2005). Knowledge ecosystems can be seen as “organizations comprising diverse actors bound together by a joint search for valuable knowledge while having independent agency also beyond the knowledge ecosystem” (Järvi et al., 2018). Knowledge ecosystems focus on the generation of new knowledge, where research institutes and innovators, such as technology entrepreneurs, play a central role in business and innovation ecosystems (Valkokari, 2015). As we address knowledge ecosystems in health domain, we see few gaps within the existing literature. First, health knowledge ecosystems extend far beyond business and innovation community domains, as it also involves stakeholders from various society groups, and institutions. Second, knowledge circulated across the ecosystem is of various nature, novelty, and follows different validation procedures (academic validation, industrial validation, community validation and so on). Third, knowledge interactions, exchanges and new knowledge creation across actors are multilevel and complex. Last, but not least, the integration of various knowledge in patient value creation carry collective, but also individual character, and thus its integration for health decision making is always embedded in situations and contexts of knowledge application.

Still, the majority of knowledge management efforts in health care are focused on the use of information and communication technologies (Nicolini et al., 2008). Despite the recognition of healthcare as a knowledge driven process, and the importance of knowledge management tools in health sector (Bordoloi & Islam, 2012), it often applies static context and does not support knowledge development and sharing between the actors. Knowledge ecosystems approach thus offers much broader perspective on health knowledge management, especially in relation to patient value creation within health

communities. Communities can vary in format (virtual vs face to face) (Kothari et al., 2011), or have different underlying structures, such as domain (knowledge and expertise held by members); community (relationships and sense of belonging among members); practice (the common set of frameworks, ideas, and tools members share in their work context) (Chua, 2006), and thus knowledge management provides positive results in terms of building connection between people and organizations, and also creation, dissemination, collaboration, innovation and acquisition of knowledge for value creation. Flexible structures within communities urge people to create new ideas and share their tacit knowledge (Akram et al., 2011). Therefore, the community approach serves the main goal of patient value creation, as it responds to the need for a systematic approach in encouraging patients to play a more active role in health. It is important to integrate patient engagement strategies into all efforts to improve the effectiveness and efficiency of care. Innovative delivery systems are including patients as part of the solution, recognizing that high-quality care should help patients gain the skills, confidence, and knowledge they need to manage their health (Hibbard & Greene, 2013). In practical terms, it means effective patient-clinician communication and shared decision making as the key components of patient-centered care. These components require that informed, activated, and participatory patients and family members interact with a patient-centered care team that has effective communication skills and is supported by an accessible, well-organized, and responsive health care system (Epstein & Street, 2007). However, patient value creation includes much more than the clinical communication, and the knowledge domains extend far beyond clinical knowledge. The specific contingencies of the environment and knowledge flows needs to be studied in order to understand how and when they affect patient value creation. More importantly, we need to answer, how ecosystems create and deliver value in sustained way (Levit et al., 2013).

Based on this problem formulation, with this paper we aim at answering the following research questions: how to manage holistic knowledge across health knowledge ecosystems? What are the main barriers for knowledge sharing and integration or patient value creation? In order to answer these questions, we apply knowledge creating community approach (Paavola et al, 2004), where various stakeholders create and share knowledge of clinical, and social domain, that all together contribute to patient value creation.

In the first part of the paper, we discuss the various types of knowledge, shared across health knowledge ecosystems, look at the mechanisms of knowledge integration, and also discuss the barriers and facilitators of knowledge creation from the literature perspective, which is later tested via qualitative study.

2 Knowledge shared across health knowledge ecosystems - barriers and facilitators of knowledge creation

From the knowledge management theory perspective we know, that the standard knowledge management processes encompass multiply activities, such as knowledge search, recognition, transfer, sharing, absorption, and knowledge creation. These activities

are always embedded in the knowledge context, such as knowledge artefacts, specific languages involved, institutional and cultural norms, defining formal and embedded knowledge sharing standards, the distinction between tacit and explicit knowledge, and also, knowledge environments (Nonaka, 1998). Abide (2008) highlighted the types of knowledge relevant to the functioning of the health ecosystem, such as patient, practice, medical, resource, process, organizational, relationship and metric knowledge, which creates an overall system. The study also discussed knowledge management modules such as management of explicit and tacit knowledge, clinical experiences and culture of errors, collaborative problem solving, practice of medical practices and protocols, educational resources for doctors and patients, social knowledge, communities of practice, expertise and interests, and data enriched by observations and medical records analytics. Osterlund (2007) has outlined areas of cooperation for the exchange of knowledge between different healthcare communities. These and other works created the basics for the research on health communities, knowledge creation and development through the knowledge exchange and learning environments in both the virtual and real world.

At the moment health communities are increasingly pursuing data. Informatics and managers are trying to create data storages and management strategies to balance costs and accessibility for this amount of the data (Jiang et al, 2016) . However, usually this kind of storages means, that only clinical data is recorded and could be re-used for solving future health issues. Of course databases can represent abstracts of the commonly used data in a structured format and help to optimize common use cases. According to Rosenbloom et al. these efforts have largely focused on supporting data models that can facilitate exchange for clinical use and research. Results of these efforts and early research evaluating the use of these novel models are beginning to appear in the biomedical literature. But integration community based knowledge and learning sources still stands outside of conventional medical investigation domain. Creating supportive, caring environments for patients is a basic principle of holistic healthcare practice and an increasingly important aspect of today's health care delivery system. Building on patient-centered comparative effectiveness research would allow populations in the world to share their data not only for research, but to use it for the daily health issues. Creating such a knowledge sharing model would provide evidence for patients and their families to make informed medical decisions, and to engage patients and families directly (PCORI, 2017). Community empowerment and integration of various sources of knowledge in health innovation and co-creation processes becomes critically important for the future success of health systems worldwide (Petraite et al., 2018).

It is already known that a patient-controlled health-record infrastructure can support the development of highly desirable health system qualities. Firstly, to allow a patient to effectively become a health information exchange of one. As members of health decisions team, patients could obtain and share their data with their medical professionals or other members (Mandl & Kohane, 2016). But important challenges in achieving common goal of using data to develop knowledge that helps promote health related to efficacy, accuracy, utility, safety, privacy, and security can be met. When models for health

information technology will open up the point of care for innovation and connect patients at home to their healthcare data, using additional information about health issues could meet unexpected results, so that's why is important to explore presumptive difficulties or barriers before feasible actions (Mandl, Mandel & Kohane, 2015). Firstly, technical challenges can meet issues as a longitudinal clinical data or having information on care provided outside their health system (Fleurence et al, 2014; Hersh et al, 2013). If every member of a team, can be informational source, it is important to make a decision, how this information turns into based knowledge for others. Problems could be associated with the design of appropriate clinical studies, informing prospective participants, and obtaining permissions in a manner that protects human rights (Trinidad et al, 2011). Clinicians are more likely to adopt and use measures that enhance the clinician's ability to deliver high-quality care, they often see disease-specific measures, as more relevant than general measures of overall functional status (McGlynn et al, 2014).

Attention to security and privacy is critical to develop and sustain patient trust and encourage participation (Daugherty, Wahbe & Fleurence, 2014). As example, informatics community can be an important partner to patients, clinicians, administrators, and researchers in health services, but first comes patient safety and privacy – security issues must be ensured. Challenges can be met when dealing how to successfully supporting patients through a variety of governance structures and setting policies, patients' willingness to provide this information depends on their belief that the data will be used in practice (McGlynn et al, 2014). Of course, also it's important to synergize efforts to avoid duplication and waste of resources (Ohno-Machado, 2014) and to harmonize data through efficient cross-networking (Ogunyemi et al, 2013). Also

Organizational challenges can be faced associated with the rapid development of a national resource, populations served, health systems included and many other characteristics. Such a models success and long-term sustainability will also depend on communicating with health system leaders and providing them with evidence of the benefits of conducting high-quality, efficient research as part of the routine delivery of care (Daugherty, Wahbe & Fleurence, 2014).

After all it still one of the major challenges is lack access to high quality health system data for development and validation (Taylor and Mandl, 2015) and patient involvement as an equal member.

Patient value creation – defines the framework for performance improvement in health care. Strict measurement and improvement of value is the way to drive progress. Yet value in health care remains still misunderstood (Porter, 2010). In the service management discourse the patient is seen as a customer, who actively makes choices, seeks information and creates values (Nordgren, 2009). Generally, value creation involves a process that increases a customer's well-being, in that the customer becomes 'better off' in some approach (Grönroos and Voima, 2013). In a well-functioning health care system, value should always be defined around the patient and should determine the rewards for all other actors in the system. In health care system value is measured by the outcomes achieved, not the volume of services delivered (Porter, 2010). This is important if we consider that patient engagement can occur at varying levels (micro-, meso-, and macro-)

(Hardyman et al, 2015). This is of importance to health care given the multiplicity of providers that can be involved in a single health care encounter.

Value co-creation already defined as “benefit realized from integration of resources through activities and interactions with collaborators in the customer’s service network” (McColl-Kennedy et al, 2012). Every stakeholder value propositions are also viewed as having a key role in co-creation of value ‘between stakeholders’. These propositions, being central in aligning value, may then be reflected within organizations services (Fyrberg Yngfalk 2013; Frow & Payne 2011; Osborne, Radnor & Nasi 2013). Patients are seen as wishing to be part of their value creating. But this has particular relevance in health care, where there is potential to cause harm. This has implications given that the responsibilities and tasks of health care professionals are regulated and institutionalized, which cannot necessarily be delegated to patients (Nordgren, 2008). That means that could be one of the possible barriers when creating well-performed health ecosystem. It should be noted that not all patients will have the same motivations when engaging in value co-creation. Some individuals may see greater value in engaging in certain activities than others (Shau et al, 2009). Well-defined, organised and practically checked co-creation through patient engagement could create highest value when creating health.

As we can see in any field, improvement of the system depends on having a shared goal that unites the interests and activities of all stakeholders. In health care, however, stakeholders have many, often conflicting goals, including access to services, profitability, high quality, cost containment, safety, convenience, patient-centeredness, and satisfaction. When there is lack of clarity about goals, it is leading to slow progress in performance improvement. Achieving high value for patients must become the goal of health care delivery - if value improves, patients, payers, providers, and suppliers can all benefit while the economic sustainability of the health care system increases (Porter, 2010).

Public health improvement is an ultimate goal to everyone as health care user or provider. Already identified, or some new barriers can reduce co-creation process or harm even created values. Areas for further analysis and empirical to patient engagement and value co-creation in health care also must be identified in the future. Creation of health knowledge ecosystem is a complicated process, however, after anticipating and evaluating potential barriers, removing them and using facilitators - maximum results can be achieved.

3 Materials and methods

In order to understand the complex nature of knowledge flows in the health ecosystem, (collection, mapping of knowledge flows, and identification of preconditions for knowledge exchanges and co-creation) we have applied phenomenological approach. Phenomenological approach (Creswell, 2007) is widely applied while investigating commonalities in different experiences of individuals, when they face the phenomenon. According to Wilson (2002), entire approach allows us to get closer to the experiences of the participants of the research object, and also to reveal the essence of the object and its

structure through the framework of the experience of the participants (Wilson, 2002). We have applied case study method with the research base at Lithuanian Health Science University Hospital, Department of Obstetrics and Gynecology and associated communities.

The qualitative research method chosen allows us to have an in depth view on opportunities and barriers associated with the new approach to the health knowledge management within communities. The analysis of health community knowledge flows is based on the patient centric approach, and draws on qualitative, semi-structured interviews with 10 pregnant women from Kaunas Clinics of Lithuanian Health Science University. Interviews were semi-structured and typically lasted half to one hour, and were conducted in September 2018. Interviews were recorded, transcribed, and coded and analysed inductively to trace themes arising from the data. Participants were recruited through pregnancy and prenatal courses support groups and social media through snowball sampling. The research questions examined the health topics and knowledge sources that are addressed on social networking sites related to pregnancy, and other sources.

4 Results

Qualitative empirical study has revealed a specific knowledge development pattern from the patient perspective - knowledge socialisation and development starts within very close and trusted community members, such as doctors, providing immediate care *“If something is not clear to me, I usually go to the doctor to check and consult additionally”, „But there may be some situations, when I am not sure, if my situation is so serious that I need to go to a hospital. I just want to ask some professional’s opinion“, “I usually refer to my acquaintance obstetrician and she can give me an advice if some feelings or processes happen are normal for me, or I should contact the doctor. Recently, I felt pains, and she advised me to go to the hospital. So I did.”* or friends and families: *„I have a friend who is knowledgeable in questions of healthcare, so I ask her. Because I do not want to disturb a doctor each time.”; “Usually I refer to my acquaintance who is obstetrician and she gives me advices if some feelings or processes happening are normal for me, or I should contact the doctor”*. In addition, hospital facilitated communities of practice also are considered as a trustworthy source of knowledge and learning, where important elements of knowledge are being created. Still, the novelty, timeliness and scientific validation of knowledge being shared is critically important for successful combination and externalisation activities *“I think, doctors who are older, than retirement age, must leave, it is time to have a rest. Because they do not feel any need to be interested in the newest knowledge, scientific research, findings, but rely exclusively on their experience, comparing to younger doctors have fresh knowledge gained recently in the universities. I think, it is good that they know a lot, but being categoric decreases my trust. That is why I value opinions of different doctors“, “I am looking for sources where doctor’s name is written, and authorship is provided. Those must be journal articles, based on scientific research. Or written by trustworthy doctors or medical specialists.”*

Therefore, web based communities of much wider scope and coverage are not participating in valuable knowledge creation that later would be combined and internationalise exactly because of the lack of validation and trust *“I will never take a medicine, because it is written online. I don’t want to risk. I always listen to the opinion of professional”*. Still, these types of communities can be an important source of problems identification that still need valid solutions, *“Looking for an information in the internet, forums reading stories of other women, helps me to decide if smth may be really serious. But I never rely on a single source of information. But, reading the internet information, you can evaluate, understand, if that is a signal when you must seek for a medical help, or it is not so scary as it seems at a first sight”* and yet are not addressed by the professional health care system stakeholders and validated community *“Because different women have different experiences. Everything is individual and may not fit to my situation. I don’t like those forums, because they may provide you with subjective, misleading information.”*

Third, trust, validity, reliability, and responsibility of knowledge has emerged as a full mediators for knowledge absorption. Lack of responsibility, and also the professional knowledge validation might have negative impacts on the overall condition and wellbeing of the patient, primarily because of causing stress and also being emotionally harmful - *“So I am trying not to go to the Internet to avoid stressing situations”*; *“You know, I was afraid to search it [information]. Because, I know I will read a lot of info, paraphrase it in my thoughts, compose it differently: “It is so bad... what if it is bad?”*, *“If you will read about medical issues from the Internet, it might seem to you that you are going to die. It is nonsense to read about unborn child’s organs development, being pregnant. I have tried, but my husband forbids me to do that.”* The issue of reliability and responsibility might prevent new knowledge to be accepted at the ecosystem even though it could provide important ideas and novelties, and help identify problems. Thus, health communities and knowledge ecosystems need safe places for “unverified” knowledge in order to ensure that the important trends and unresolved questions are not missed. Still, the internet based sources, including communities, serve as a first though not trusted knowledge source that shapes behaviors of patients, and at the certain level influences next steps of actions. *“Sometimes it [e-sources] helps, but I still contact the professionals, because I don’t want to risk my baby’s health”*; *“ I still trust doctors more. Anyway, they know more, than friends and mamas [pregnant women], so I am more inclined to follow the doctor’s advices. They are graduated specialists, experienced”*. The need of individually adjusted knowledge is also very high, and yet not satisfied by the internet communities. Thus, a need for trusted, explicit, and reliable knowledge on the web is fundamental in order to facilitate community knowledge creation for patient value creation.

5 Discussion

The research on knowledge creating communities in health from the patient perspective has indicated important tendencies, and knowledge management implications in the field.

Conceptually designed model of health knowledge ecosystem, that encompasses wide range of stakeholders suggests the application of organisational knowledge management practices, and is based on the ontology of knowledge creation between individuals, groups, and organisations. In order to address the complex phenomena of knowledge development, sharing, transfer and absorption between health communities, we have developed a systematic model for knowledge integration that includes various stakeholders (see Figure 1).

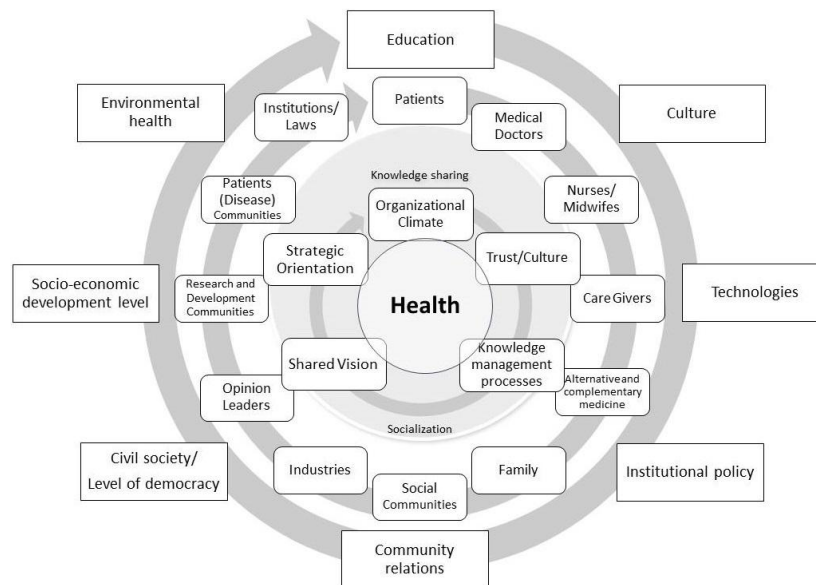

Figure 1 Knowledge Management Model for Communities Creating Health: a Systemic Perspective

Healthcare, based on value creation for public health issues, focuses on patient-centered approach. The traditional attitude that the patient is in the middle of the system as a client getting services no longer is meaningful. It is limited in its ability to improve value from the patient perspective. According to Kamal (2018) “shared decision making is a collaborative decision-making approach that can be broadly defined as a process by which a patient and a physician collaborate to mutually reach a health care decision that is best aligned with patient preferences”. By changing the paradigm from disease treatment in to saving and staying healthy, patients are interested in their own health, thus becoming a participant in improving health. Collaborative decision-making is becoming a key focus for achieving a sustainable health system and a decent service. Such services compatible with patients preferences, improves not only emotional but also economic indicators – the faster health indicators are achieved, the less expensive treatments are used. The culture of health gives opportunities to take care own health, to share valid and trustworthy informational and also take part in community healthcare improvement. Such co-creation of knowledge allows to manage personalized information, not only clinical data. And this is how patient can bring the value not only in own health decisions, but also into community, where trustworthy, explicit, and reliable knowledge is fundamental need in

order to facilitate community knowledge creation and level of a community health. Defining, measuring, and implementing creation value-based health care at the patient level, with consideration for patient preferences and engagements, is a more improving health care approach.

6 Conclusions

Value creation is already well defined approach, but health sector is always more specific and sensitive, when it requires any changes. Every possible change can equally improve or harm both, systematically or individually. Knowledge management tools in health sector it often applies static context and does not support knowledge development, but patient value creation includes much more than just recording clinical data. Knowledge co-creation across large and holistic communities involves stakeholders from various groups and environments. Health communities could be defined as such because of their complexity, representation of multiple stakeholder groups, varieties of knowledge, and also individuals, where the ultimate goal is health, as a consequence of patient value creation. To understand how and when they affect patient value creation, firstly components of knowledge flows must be indicated. It is still remains a question how ecosystems create and deliver value in sustained way. However, first steps are made to indicate what could affect an integration of successful knowledge co-creation, when a patient is acting like an equal member of health care team. Considered that patient acting as a value creator, as an informed, active, responsible participant and could occur at varying levels. That is how single health care encounter may affect positively all the holistic community. Though, integration of different actors or knowledge for health decision making is always embedded contexts of knowledge application. In this article main barriers defined why integration community based knowledge and learning sources still stands outside of conventional medical investigation domain.

Firstly, amount of clinical data, and also, just the clinical data is recorded and could be re-used in future healthcare decisions. This includes also management strategies to balance cost, but knowledge sharing model would provide evidence for patients to make informed medical decisions. From this approach also we need to add that organizational challenges can be faced associated with. Long-term success depends on health system leaders and their attitudes to efficient research as part of the routine delivery of care.

Secondly, allowing a patient to become a part of health information exchange may meet one more challenge – quality of information and also patient safety. Patients could obtain and share their data with their medical professionals or other members, but also they can use their possibilities to change, hide or add information, that does not respond to reality. Also there comes and patient safety of personal data issues – how many other persons can see or use it for other unrelated purposes. Also this includes and technical challenges with issues as a longitudinal clinical data or having information on care provided outside their health system. Attention to security and privacy is critical to develop and sustain patient trust and encourage participation in such as knowledge co-creation model.

The issue of trust, validity, reliability, and might prevent new knowledge to be accepted at the ecosystem even though it could provide important ideas and novelties. The application of health centric patient-value approach in designing knowledge management systems may help identify and solve problems faster. Thus, health communities and knowledge ecosystems need safe knowledge sharing and learning environments for “unverified” knowledge in order to ensure that the important trends and unresolved questions are not missed.

Abstract

*Corruption and misconducts, “the abuse of entrusted power for private gain” (Pope, 2008), are pervasive virus that negatively affects the public lives of many Countries. Given that the 9% of the worldwide GDP on average is represented by health expenditure, healthcare is particularly vulnerable to corruption (Petkov and Cohen, 2016; EU, 2017). Due to the large number of services delivered, Public Hospitals and Local Health Authorities undergo a high risk of misconducts, which could bring not only to a waste of public resources, but also to undermine access to the services, impoverishing their quality and the possibility for sustainable development of countries (Braithwaite, 2013; Neu et al., 2013). Corrupt practices and fraud affect up to 25% of expenditure on medical and non-medical goods (Sorenson and Kanavos, 2011); these increase inequality and determine substantial well-being and value losses (Porter, 2010). Corruption can be expressed by the Klitgaard's equation (1998): **Monopoly** plus **Discretion** minus **Accountability**. Hence, to limit corruption phenomena an efficient way seems to be increase accountability and transparency by strengthening of internal controls (Christensen and Skærbæk 2007; Fadda et al, 2017).*

Accordingly, e-Procurement in the public domain can be seen as a tool to support the delivery of public purchasing process, improving efficiency and transparency of transactions (Carayannis and Popescu, 2005; Croom and Brandon-Jones, 2005); Budgeting control system is a powerful tool to align strategies and plans with operational decisions (Garrison et al, 2010), suitable for simultaneous controls in daily management and purchasing decisions (Provenzali, 1991).

Therefore, the goal of this work is to understand if it is possible to integrate the simultaneous budgeting-based control system with the e-Procurement procedures (through an ERP software), and how this integration could potentially limit misconducts in healthcare purchases.

After a theoretical background about themes of Corruption, e-Procurement and Budget, a single pilot qualitative case study (Yin, 2014) has been conducted. In particular, we developed a qualitative inquiry (Patton, 2002) based on face to face interviews (Said et. al, 2017) with two high-qualified SAP® developer-providers.

This contribution attempts to clarify how internal controls impact on the “responsibility chain” (roles, responsibility, transparency degrees of discretion) of procurement process in public healthcare, by increasing level of accountability.

This paper fosters debate about relationship between corruption and level of internal control system of Healthcare Organization. This would have considerable consequence also for practitioners involved in ERP software development.

Keywords – Budget, e-Procurement, Corruption, Internal Control, Healthcare.

Paper type – Academic Research Paper

1 Introduction

Corruption and misconducts are a pervasive virus that negatively affects the public lives of many countries around the world. Corruption, in particular, could be considered as “the greatest obstacle to economic and social development” (Braithwaite 2013, Neu et al 2013).

Many definitions of this phenomenon have been provided over time (Bardhan 1997, Liu 2016). Although a unique definition of corruption has not been provided yet, on the other hand one of the most commonly shared definition is the “the abuse of entrusted power for private gain” Pope (2008).

Given that the 9% of Gross Domestic Product on average for Organization for Economic Co-operation and Development Countries is represented by health expenditure, there is a shared agreement that Health facilities are particularly vulnerable to corruption, especially regarding procurement procedures (Petkov and Cohen, 2016; EU, 2017).

Health organization are currently facing a growing demand for health services. This phenomenon is affected by the health status of the community, progress in medical technologies, costs and patients’ preferences (WHO, 2014). Accordingly, purchases of drugs, medical devices, machineries and common consumables represent those operative inputs that can potentially improve population health, access to care and quality of life by providing an effective healthcare service. However, due to the large number of services delivered and the amount of financial resources managed, Public Hospitals and Local

Health Authorities undergo a high risk of conducting misleading behaviours, which could undermine access to the services and their quality. Misleading behaviours triggered events are represented by the possibility to alter a fair economic price, clinical efficacy, maintenance needs, usage of technologies for pursuing private gains. Therefore, damages generated by corruption lead not only to a waste of public resources but also undermine the possibility for sustainable development of countries, increase inequality and determine substantial well-being losses. With regard to procurement process, opportunistic behaviours are strongly encouraged by unstoppable interactions between public and private sectors, which involve various stakeholders with different perspectives concerning the value added by health technologies (Drummond et al., 2013). Corrupt practices and fraud affect up to 25% of expenditure on medical and non-medical goods (Sorenson and Kanavos, 2011). Implications of corruption in the procurement of health technology are mainly represented by the acquisition of low quality and ineffective products, which are not aligned with health needs (Petkov and Cohen, 2016).

The owners of public hospitals, indeed, are citizens who cannot nominate or oversight managers directly. Hence, the separation between formulation of policy and administrative action has been considered the way to improve the efficiency and effectiveness of Public Administration, to contain opportunistic behaviours and, thus a pre-requisite for a sustainable development (Barberis, 1998; Osborne, 2006).

Structure, culture and tradition design the essence of how public administrations work: the legal setting largely determines what can be done or not and which solutions pursue or not. Governance mechanisms have a great role in determining internal control systems and their reliability and, at last, how much it easy for the corruption finds its pathway into organizations (Zahra et al., 1995). In other terms, the triangle: 1) public administration, 2) internal control systems and 3) corporate governance mechanisms represent the spectrum where the corruption could take its dangerous role (Di Pietra and Melis, 2015).

Corruption can be expressed with the following equation: monopoly plus discretion minus accountability (Klitgaard 1998). Monopoly and discretion (by bringing low transparency) are positively related with the level of corruption within a Country, while accountability negatively. Although this equation is generally valid, it seems particularly suitable for the healthcare context; this field has the following peculiarities, which makes it vulnerable to corruption:

- High discretion of clinical decision;
- High information asymmetry between clinicians and patients;
- Monopolistic power of public health providers in many specialized healthcare services.

Consequently, the aim of the public organization reforms has been to underpin performance management and increase the transparency and accountability of health organizations in order to increase as well responsibility of managers and decision-makers. Accordingly, the introduction of e-procurement goes in this direction by promoting fair competition and low “cost-effective” prices (Cohen et al, 2002).

Ex-ante better design of governance mechanisms, internal system controls and performance management tools as a whole, is felt even more in the public sector: this is essential for preventing opportunistic behaviours and avoiding information losses (Christensen and Skærbæk, 2007)

Hence, to limit corruption phenomena an efficient way seems to be the strengthening of internal controls (Fadda et al, 2017, Palozzi et al, 2018). Accordingly, the budgeting control system would be a powerful tool to align strategies and plans with operational decisions. Budget is suitable not only for planning activities, but also for simultaneous controls in daily management and purchasing decision. (Provenzali, 1991).

Starting from these preconditions the aim of this work is to answer to the following research questions:

“Within the Healthcare Public Providers context, could Budgeting Control System be integrated with the e-Procurement process in order to verify consistency between plans and purchases? And, could this integration be effective in limiting potential decision-makers misconducts in health procurement?”

In other words, this contribution attempts to understand which features of Budgeting Control System increase awareness and accountability in the e-procurement process.

Based on an Enterprise Resource Planning (ERP) software, the integration between Budget and eProcurement allows intervening on all the variables of the corruption equation: Budget increases public hospitals' responsibility and transparency in financial resource employment (Kassel, 2008; Barret, 2014), e-Procurement promotes traceability of purchasing process.

Thus, this contribution attempts to clarify if it is possible to practically formalize the “responsibility chain” in the procurement process within the electronic market. Responsibility chain expresses relationships between roles, responsibility, accountability, degrees of transparency of decision-making process which bring to approve (or not) a health furniture, without opportunistic pressures and in coherence with the value-based healthcare principles (Porter, 2010).

To achieve its purpose, this paper follows the following outline: after this brief introduction, the second section reports a background addressed to the issues of corruption, e-procurement and Budgeting. The third section explains how the interview-based qualitative pilot case study (Patton, 2002; Yin, 2014) intercepts opinions of two SAP® developers/providers in order to understand the real feasibility of an ERP integration between Budget and e-Procurement. The fourth presents findings of the inquiry. The last section discusses results obtained and provides some consideration about the potential impact of such control tool on misconducts, in relation of the procurement phase within Healthcare Organization context.

2 Background

As recognized, corruption negatively affects public lives of many countries around the world, whose damages lead both to waste public resources and to undermine the

possibility for a steady and fair growth of countries, increasing inequality and determining huge well-being losses

Referring the issue to the health sector implies an investigation about how much misconducts affect the creation of public value and, thus, wealth of people. However, healthcare professionals do not always understand what is the corruption range and how it impacts on their daily operations; conversely, anti-corruption specialists often are not able to really understand the complexity of the healthcare system (Petkov and Cohen, 2016); the result is a continuous providing of anti-corruption rules and structured procedures, often disconnected from the clinical practice needs.

Potential structural malfunctions could be observed at the NHS-hospital or Region-hospital level (Beerli and Navot, 2012), where healthcare providing is strongly influenced by scientific and technological advancement, which affects expenditure of both current supplies and strategical assets. Hence, the procurement process seems to be particularly vulnerable to opportunistic behaviours of decision-makers, which could result in corruptive conducts aimed at private gains.

European Union (2017) defined six typologies of corruption in healthcare:

1. bribery in medical service delivery;
2. procurement corruption;
3. improper marketing relations;
4. misuse of (high) level positions;
5. undue reimbursement claims;
6. fraud and embezzlement of medicine and medical devices.

All these distorted practices could lead both to waste resources and to decrease the access to healthcare services and treatments.

Referring with the procurement process, corruption appears into the possibility to alter fair economic purchases within manipulated negotiations; this, potentially, means: higher price supplies, overestimation of supply volumes, falsification of maintenance needs, not appropriateness health technologies employment, etc.

In this scenario, the higher the ineffective managerial structures and control mechanisms, the higher the possibility of observing corruption (European Union, 2017).

Accordingly, since the introduction of New Public Management (Hood, 1991; Dunleavy and Hood, 1994; Barberis, 1998), and its evolution to the paradigm of Public Governance (Osborne, 2006; Bovaird et al., 2009), the separation between Policy and Administration has been considered the way to contain opportunistic behaviours within Public Administrations in order to improve their efficiency and effectiveness. In this direction, many jurisdictions' reforms have attempted to contain misconducts through the improvement of rules aimed at regulating corporate governance mechanisms and internal control tools (Cooper et al, 2013). Within these reforms, we can find the introduction of new procurement process for Public Organization built on centralized and electronic (e-) markets.

With the term e-business we consider information exchange, commercial transactions and knowledge sharing between organizations (Croom, 2005) by using an information

technology interface completely integrated with the organization's processes (Graham and Hardaker, 2000), in coherence with the broader organizational strategy.

In particular, e-procurement is the mirroring of procurement activities on the internet (Croom and Johnston, 2003), which deals both with all the "technology solutions" that facilitates procuring goods and services (Presutti, 2003) and with the automation of the procurement process (Vaidyanathan and Devaraj, 2008); it also includes the activities of purchase request, authorization, ordering, delivery and payment supplier (Chaffey, 2007). E-procurement can be defined as the use of information technologies to facilitate B2B purchase transactions (Wu et al., 2003), which enables firms to more efficiently and accurately capture and aggregate the value of "how much" they are spending.

E-procurement in the public domain can be seen as a tool to support the delivery of public procurement policy, improving efficiency and transparency of transactions (Carayannis and Popescu, 2005; Croom and Brandon-Jones, 2005).

Benefits can have a twofold nature (Garrido, 2008; Dai and Kauffman 2004):

- financial (quantitatively and monetary measurable);
- organizational (qualitatively measured)

Starting from the financial benefits, e-procurement allows increased efficiency in the organizational structure, especially in the reduction of purchasing department size, levels and number of functional areas involved in the purchasing process. It implies gains in the administrative process and procurement costs.

Moreover, e-Procurement prevents single users or buyers from purchasing outside the negotiated contracts and from different sources. Maverick buying is considered a relevant cause of internal inefficiency and increase in the total cost of ownership of the purchased goods and services. Accordingly, Barratt and Rosdahl (2002) claimed that it improves transparency of prices and in the relations with suppliers (contractual conditions, time and terms of each order, order tracking and tracing), that brings to higher accountability of operation-purchasing processes (Puschmann and Alt, 2005, Currie, 2000).

In particular, referring with the transparency in public sector, positive impacts of e-procurement can be summarized as follows:

- better control and maverick-buying reduction (Croom and Johnston, 2003);
- attracting more new suppliers to do business with government (Rotchanakitumnuai, 2013)
- reducing corruption between purchasing officers and suppliers (Panayiotou et al., 2004)
- preventing from information asymmetry (Croom and Brandon-Jones, 2007)
- traceability of information and all the daily operations (Belisari et al, 2019)
- reinforcing user compliance (Belisari et al, 2019)
- reducing opportunities for corruption in public procurement process (Neupane et al, 2014)

Following Figure 1 illustrate the process flow of public procurement:

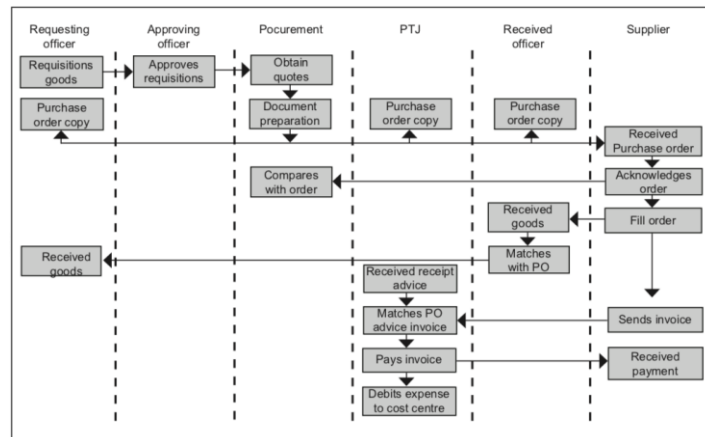

Figure 1: The procurement process for the public Procurement. Source: Said et al 2017.

Within this process three are the stages identified as highly vulnerable to corruption: 1) the need of assessment; 2) during the selection of supplier; 3) monitoring of services. (Said et al, 2017).

In Italian context, according with Raffa and Esposito (2006) the procurement code over regulates the use of the public procurement procedures, so that the purchasing process is often paralyzed. Moreover, the Italian government concentrated in the hands of a state-led agency (CONSIP) the power of negotiating big contracts aimed at buying standard goods. With exception of special equipment, the most of purchasing of details of such auction contracts and the availability of goods, firms operating in the public sector have to surf CONSIP's electronic catalogues. In healthcare field, the process starts with defining both the items and the rules that would be followed during the bidding. Usually, the price is the key determinant for awarding the contract. Figure 2 describes the auction process in the Italian public health care system. The auction may take advantage of multiple criteria of assessment (Bichler, 2000)

Figure 2: e-Reverse Auctioning Process. Source: Raffa, L., & Esposito, G. (2006).

Said et al (2017) have analyzed the process of public purchasing through the e-Procurement; the activities are listed in the following Table 1.

Table 1: The activities of e-Procurement

N	Activity
1	User requests to purchase goods or services.
2	Procurement officer checks the availability of funds in the financial system
3	Procurement officer chooses potential suppliers based on the selected registered code in the system
4	Successful supplier would be chosen based on the goods services provided in addition to the exact specifications requested by the users.
5	Once the supplier is selected, the procurement officer would send the proposal to the authorized personnel for approval.
6	Procurement officer generate the purchase requisition through the system and sent it to the successful supplier
7	At the time of delivery of good, supplier include invoice and delivery notes.
8	The store keeper verifies the supply received and generates a receipt note in the system
9	The payment process would proceed, after all reconciliation process with the order were completed.

Source: Authors' elaboration inspired by Said et al (2017)

Across this e-procurement process (in particular for activities from 1 to 6), it would be possible to compare what is the amount of financial resource licensed by the Healthcare Organization Budget with the actual purchases for the different kind of goods and services.

Budget is a quantitative plan for acquiring and using resources over a specified time (Garrison et al, 2010). It is used for two distinct purposes:

- *Planning*, that is “how developing goals” and preparing various budgets to achieve those goals.
- *Control*, that regards the action taken by management to increase the integration of all parts of the organization in working together in order to achieve the goals fixed at previous stage.

Budget is strictly connected to Responsibility Accounting, whose basic idea is that a manager should be held responsible for those items that he/her can effectively control to a significant extent. This implicates a personalization of accounting information and assignments to individuals, who will be responsible for revenues, costs and performance of the operational Unit they govern.

In particular, for an organization as a whole, the master budget consists of a number of separate, but interdependent, budgets that formally lay out the company's sales, production and financial goals. Among these budgets, the production one (composed by direct materials, labour, and service budgets) details the resource that must be purchased to fulfill the expected production as contrasted to expected sales. In the context of a healthcare organization is production budget where the use of consumable components (e.g. prothesis, medical device, drugs, etc.) or new capital equipment employment are authorized.

However, a static planning budget is inappropriate for evaluating how well resource consumption is controlled. If the actual level of expense differs from what was planned, this should be kept into account in terms of impact on costs: if this difference is negative, the spending variance (difference between how much a cost should have been and its

actual amount) should be immediately highlighted and labeled as unfavorable (or vice versa).

Budget, as said, should be suitable for simultaneous controls of daily management activities (Provenzali, 1991). By verifying the consistency between actual and planned costs, it could give indication about the cost-effectiveness of resource employed, identifying also the responsible of the purchasing of those resources used. In this perspective, in accordance with Casati (2000) budget becomes a comprehensive tool able to:

1. map goals,
2. count resources for their achievement,
3. to set control parameters able to trigger, in case, corrective actions.

Moreover, in a Healthcare Organization budget is a “bridge” between business administration and clinical management aimed to formalize strategic plans into practical actions, which brings to “more efficient use of hospital resources” (Barr, 2005).

In this perspective, Budget has stopping to be a tool aimed at the mere authorization of expenses on the base of a check of funds availability. It should evolve into a formal validation of the appropriateness of the resource employed, able to connect the responsibility of who promotes the purchase with the results obtained.

Accordingly, by increasing the level of ERP-based internal controls, budget could surely contribute to fight misconduct within procurement within Healthcare Institution (Fadda et al., 2017)

2.1 Research Problem

In the context of Healthcare Organizations, what happen if the amount of the actual cost of a specific supply is considerably higher than how much it should have been, as licensed in the planning budget? Who has been held responsible? Which are the potential corrective actions?

The attempt to answer these questions is the very engine of this work: understand if it is possible to integrate the simultaneous budgeting-based control system with the e-Procurement procedures (within the electronic market) through the use of an ERP software.

Our expectation is to understand if the presence of procedural mechanisms of control are able to monitor the responsibility chain of procurement process in case of significative variance among planned and actual purchases.

Variance can be:

- i) quantitative, if the purchase differs in term of financial resources or in terms of quantity of goods (or services)
- ii) qualitative, if the purchase differs in term of composition of expenditure.

Potentially, this check should hold responsible those who promote the purchase, increasing accountability and thus limiting their misconduct or opportunistic behaviours.

3 Method

To get this goal, we ran single pilot case study (an “empirical inquiry that investigates a contemporary phenomenon within its real-life context”, Yin 2014), with the purpose to intercept some insights from information-rich key informants.

In particular, we developed a qualitative inquiry (Patton 2002) based on face to face interviews (Said et. al, 2017) with two SAP® developer-providers. The interviewees hold the following apical job-position within their organization:

1. The Chief Executive Officer at Technis Blu Company (SAP® Partner)
2. The IVE Services Industries Director at SAP® Italy

The framework for the analysis includes the following main topics:

- A. Acceptance of Budget as a Managerial Control Tool
- B. Functional Interaction between budget and procurement
- C. Employment of an ERP software as support of procurement
- D. Accountability
- E. Transparency
- F. Abuse of discretion
- G. Functional Integration between an ERP software and Public Electronic Market

On the base of their professional experience (Scapens, 2004) we asked participants to talk about such open topics. Interviews, in Italian language and integrally recoded, were transcribed and coded them for each of the seven topics. We used sentences to analyse the data on the basis of such portions of text. Once the coding process was carried out, we sorted and analysed all the portions of text coded. Then, we analyzed data by generating a large quantity of codes by assigning labels to sections of text that have some distinct meaning in order to categorizes, organize and interpret them.

4 Results

In relation to our interviews, we derived around 80 raw concepts, included in approximately 30 pages. Based on interviewees’ experience on SAP® development, this selection process was finalized to build and refine categories into more specific concepts, clustered per topic. Interviewees’ opinions are included in the following Table 2. After each statement, a code is shown in order to distinguish the interviewee who agrees with the assertion: K1, K2 (where K1 represents the Key Informant 1 and so on).

Table 2: Findings form interviews

A. Acceptance of Budget as a Managerial Control Tool <ul style="list-style-type: none">• Internal control is the keystone to fight misleading and opportunistic behaviours. (K1, K2)• Always more frequently, in the field of Managerial Control in Healthcare is used to use the Budget as an operating control, and not only as a planning support. (K1, K2)• Budget have to be considered a tool for: i) ex ante, ii) simultaneous, iii) ex post controls, provided by different forms and features. (K1)
B. Functional Interaction between budget and procurement <ul style="list-style-type: none">• In the Healthcare context, the budgeting process is commodity-related; this means that its connection with procurement procedures has to be tailored with the kind of goods or services purchased (K1); for instance:

<ul style="list-style-type: none"> ○ in case of drugs purchasing, budget has the role of monitoring the transactions; but, due to clinical safety reasons, it could never stop the supply; ○ in case of medical devices purchasing, budget has the role to verify the fund availability; moreover, for special equipment which need staff training, budget tool has to be integrated with the SAP® “project management” tool. • During the procurement process, an ERP software provides a simultaneous control of the consistency between funds earmarked for a specific supply and funds actually employed. (K2) • Higher risks of misconducts are during the sourcing phase of suppliers, goods and service; during the procurement procedure, these risks are reduced. However, if an anomaly was observed, it is possible to locate who has held the responsibility; this both discourages misleading behaviour and potentially triggers penalty mechanisms. (K2)
<p>C. Employment of an ERP software as support of procurement</p> <ul style="list-style-type: none"> • An ERP software would allow users to standardize procurement procedures; however, due to the necessity of healthcare field, often it is not suitable to define replicable procedures valid for different kinds of purchase. (K1) • An ERP software would reduce the common risks of anomalies in procurement process (K1): <ul style="list-style-type: none"> ○ Invoicing is automatically connected with the order; ○ The choice of supplier could be integrated with the electronic market in case of common goods searching (otherwise, in case of customized supplies, this choice cannot be automated). • In the case of SAP®, it supports the purchasing process through two tools: Material Management as support for accounting and Ariba as support for the cash outflows cycle. (K1). • Through these tools SAP® encourages budget-based controls both for (K2): <ul style="list-style-type: none"> ○ Funds availability; ○ Appropriateness of purchases as compared with those planned. • Budget, within ERP System, is still employed as a control tool in healthcare organizations. (K1, K2)
<p>D. Accountability</p> <ul style="list-style-type: none"> • During procurement transactions, it should be always identified the responsible of Cost Center who promote the purchase. (K2) • The responsible of procurement should have a mere technical role aimed at the issuing of purchasing order; actually, he/her holds the responsibility (and the power) of the whole procurement process (K2) • In a Healthcare Organization, the procurement process should involve different individuals with very heterogeneous competences: clinicians, responsible of procurement, Ethic Committee, Scientific Committee, HTA units. (K1) • Supervision of appropriateness of purchases should be due to Ethic and Scientific Committees; while, the Head of a Cost Center should have the responsibility of the Budget of his/her department. (K1) • For example, SAP® is based on rules and responsibilities; by a personal logon (user and password) is always possible to verify “who were” that “does something”. (K1) • The only solution to risks of misleading behaviour is the fragmentation of purchasing process in different activities, whose responsibility is held by different independent subject, interconnected among each other (K2).
<p>E. Transparency</p> <ul style="list-style-type: none"> • Transparency derives from the possibility to historicise information. (K1, K2) • For example: <ul style="list-style-type: none"> ○ SAP® improves traceability of transactions by a drilldown approach applied to the procurement process. (K1) ○ SAP® verifies the whole purchasing chain: by the login (user and password), it traces “who” is interested the advancement of an order. (K1) • Transparency is scaring. Higher is the transparency of a process, more evident will be its inefficiencies (attributable to a specific responsible). (K2)
<p>F. Abuse of discretion</p> <ul style="list-style-type: none"> • An ERP system can never judge clinical discretion and choices. (K1) • The budgeting controls could limit the abuse of discretion (maverick behaviour) in purchasing process. (K1, K2) • Multiple authorization workflows decrease risks of abuse of discretion. (K1, K2) • Rigid approval procedures for specific purchases (previously defined) contain abuse of discretion. (K1, K2)
<p>G. Functional Integration between an ERP software and Public Electronic Market</p> <ul style="list-style-type: none"> • From a technical point of view, an ERP software (such as SAP®), can be easily integrated with the Public Electronic Market. This can be particularly suitable to reduce misconducts in supplier choice.

(K1, K2)

- The integration would make possible to automatically identify within the Electronic Market those suppliers who own the features to satisfy the demand of those goods and services looked for. (K1, K2)

5 Discussion and Conclusion

“Within the Healthcare Public Providers context, could Budgeting Control System be integrated with the e-Procurement process in order to verify consistency between plans and purchases? And, could this integration be effective in limiting potential decision-makers misconducts in health procurement?”

As answer to the research questions, this study could affirm that a functional integration, through an ERP software, between Planning Budget and e-Procurement is possible and easily achievable from a technical point of view. In particular, the Budgeting system is still considered as a managerial tool for simultaneous control of operational activities provided by healthcare organizations. Its integration within e-Procurement logics, moreover, allows a continual check of resource employment from the responsible of the Cost Center within the organization.

With the exclusion of drugs, whose procurement can never be stopped due to obvious clinical reasons, integration between Budget and e-Procurement becomes a tool that potentially allows to verify the operational appropriateness of purchases, by overcoming the mere checking of the fair employment of financial funds. In some cases, this involves authorizing information materials coming from Ethic Committee, HTA Unit or Scientific Direction of Organization.

Even if managerial control tools cannot deal with decision of the clinical practice, they allow to map those who hold the responsibility of any phase of purchasing process, by locating also those officials who have authorized purchases that significantly differs from what budgeted.

In this sense, integration between Budget and e-Procurement magnifies the control possibilities that are owned, separately, by each of the tools. Hence, this integration strategy verifies the contingency between planned and actual purchases; this extends the “responsibility chain” from operational needs planning to the actual delivery of goods or services purchased. Accordingly, the choice of a supplier becomes the outcome of an objective process, which is parametrized on operational necessities and not on subjective propensities of Procurement Officers. This potential change involves the Principal-Agent Theory (Eisenhardt, 1989; Jensen and Mecklinig, 1976; Whipple and Roh, 2010) in term of relation between buyer and supplier.

Moreover, according to Kramer (2012), the improper selection of suppliers by approving higher price, accepting low quality goods and engaging unnecessary service or consultations probably has driven by corruption in public procurement (Said et al, 2017).

Thus, segmentation of procurement process in many sub-phases makes possible to isolate who hold responsibility of each sub-phase and his/her relationship with the supplier, since the planning of supply. In addition, the possibility to historicize

information increase the traceability of transaction and, then, the transparency of the entire procurement process.

Give the above, the continual control of financial resource employment has a positive impact on Accountability of purchasing process in healthcare. Sure enough, the integration between Budget and e-Procurement:

- individuates those who hold responsibility of each stage of procurement process;
- decreases subjectivism in supplier choice;
- triggers a justification mechanism (also clinical, if necessary) when actual expenses were too much different from those applied (both per amount and per operational composition).

These three endpoints should have the results to decrease misconducts and maverick behaviours, with the endpoint to prevent corruption activities during the procurement process (Said et al, 2017).

As simultaneous control tool for the operational management, the study demonstrates how Budgeting System increases the makings of e-Procurement to fight potential corruptive behaviour from public Officers, by triggering authorization mechanisms, which make more transparent the purchasing, process.

In particular, this study has referred with the combination of the following three elements:

- A. Managerial ERP software based on a rules and responsibilities for users;
- B. Variance analysis potentialities of Budgeting system;
- C. Fairness of a “step-by-step” on-line purchasing pathway, structured a priori, and form a Third Part.

This way, according with Christensen and Skærbæk (2007), it is possible to create conditions to decrease the abuse of discretion in procurement process, which would become more transparent, with the result of Accountability increasing.

However, the introduction of a high structured procurement process could be affected by resistance to change by those employees (both clinical and administrative) involved.

In this regard, a statement belonging to the Key Informant 2 has been extremely meaningful; K2 argued that:

“The increasing of Transparency could upset the whole Organization”.

With this sentence the interviewed has intended to underline two main aspect related to the improvement of internal managerial control system within healthcare organizations:

1. Increasing Accountability is scaring; it highlights internal inefficiencies (both aware and unintentional) and individuates the responsible of inappropriateness employment of resource.
2. No one wants to hold too much responsibilities in his/her job (often without additional benefits which justify these duties). Thus, employees ask for rigid procedures (in order to discharge part of own responsibility on the procedure itself); this behaviour brings to drastically slow down decision-making and operative processes.

Probably this is the reason why, as stated by the K1, just few Public Hospital and Local Health Authorities in Italy have decided to use a comprehensive internal ERP, such

as SAP[®], for managing and monitoring all the processes of healthcare delivery and those resources their related.

For sure, results of our enquiry confirm that, all the organizational level, the only “mechanical” method to reduce misconducts during procurement process is to intervene on the “responsibility chain”, by strengthening it. As stated by Fadda et al (2017), by increasing the level of integrated internal control system is possible to increase the organization Accountability. According to the Klitgaard’s equation (1998), corruption decreases.

Clearly, this study and its findings are not free from limitations; firstly, the sample of interviewees is too small. Although the key informants are two high skilled managers that operate in the field of ERP implementation within MCs since 90s, their points of view should be partial and limited to their own experiences and to their involvement with SAP[®] supply. Hence, extending the sample to other key informants with different background would be advisable.

Secondly, the literature background about interrelationships among the huge topics of corruption, e-Procurement and Budget deserves to be better explored and clarified, in order to classify which levers of controls positively impact on misconducts.

Both these two major limitations lay the foundation for further detailed enquiries whose aim, as that one presented in this paper, is fostering debate about relationship between misconducts and level of internal control systems (Di Pietra and Melis, 2015), in the context of Healthcare Organizations.

By the way, in the lens of healthcare sustainability, the present work surely highlights the necessity to look for technical ERP solutions able to support “managerial-rational” approaches in clinical practice, which continually involve decision-makers, form the planning process to the procurement procedures.

Abstract

Public organisations should contribute to value creation moving towards sustainability as a vision for strategy and action, redesigning trust-based relationships with stakeholders and sustaining governance networks within ecosystems. As organisations seeking sustainability, public organisations should evolve as communities developing strategic, managerial and technological sources to enable and facilitate public value creation within society. Public organisations should achieve sustainability and develop the community adopting a logic service view as strategic choice, strengthening transformational and ethical features of public managers as leaders, and developing the potential of information technology by driving the transition from using technology in government to developing digital, smart, lean and open platforms for value creation, innovation and networking as sources that enable public organisations as sustainable communities.

Keywords – public organisations, sustainability, value creation, community.

Paper type – Academic Research Paper

1 Introduction

Today, public organisations should rethink how to approach the sustainability as a vision for change to drive public decision-making, management and governance (Goodsell, 2006; Fiorino, 2010), to rediscover the community as a source that enables networks to develop and contribute to public value creation, promoting social interaction between public and private spheres. Public organisations should serve the public interest as the result of dialogue with citizens (Denhardt and Denhardt, 2000), promoting collaborative processes that involve private, public and no profit organisations in order to achieve policy objectives within a community (Bourgon, 2007). Creating public value relies on sustaining networked governance and multilateral cooperation to cope with changing contexts. Public organisations evolve as communities following the public value and service logic views to shape strategy using technology and strengthening public managers as leaders that engage stakeholders involving civil society in constructing governance networks and shared partnerships (Hartley, 2005).

It is time to rethink the role of public organisation that contribute to facilitating value creation promoting multilateral relationships between public and private actors within society. Public organisations should develop as a community and intermediary network between public sphere and private sphere, enhancing enhances shared values within ecosystems. Public organisations should act as enablers of social and public value creation. Technologies open up to digital and smart ecosystems. Public managers as agents of change should exercise leadership in interacting within organisations and with external stakeholders. Following a service logic view for value creation, public organisations should develop managerial and technological sources to enhance processes that enable civil society and stakeholders to engage in public-private partnerships and drive public, digital and open ecosystems that support dialogue, knowledge and information sharing, social exchanges, interaction and citizen-centred services effectiveness (Osborne, 2018; Dumay, Guthrie and Farneti, 2010; Stoker, 2006; O'Flynn, 2007; Moore, 1995).

The aim of this study is to elucidate how public organisations evolve as communities and contribute to facilitating value creation identifying a pathway towards sustainability developing strategic, managerial and technological capabilities within ecosystems. As organisations that achieve sustainability through public value co-creation, public organisations should adopt a service logic view enabling the service users to actively contribute to value creation (Osborne, 2018). Information and communication technologies (ICTs) help public organisations to work through networks that involve private and public actors, developing knowledge and capabilities in the pursuit of public goals (Janowski, Pardo and Davies, 2012). ICTs help strengthen collaboration and support the exchange between governments and civil society for service innovation, governance, administration effectiveness and support to institutional reform (Lips, 2012). ICTs are driving public organisations as digital and smart communities to support public value creation within open ecosystems (Larsson and Grönlund, 2014; Granier and Kudo, 2016). Creating public value relies on accountable public managers that helps construct

community shared values, interacting with citizens and proactively to support networks (Bryson, Crosby and Bloomberg, 2014).

The paper is structured in six sections. Following the introduction and methodological section, in the third paragraph, the theoretical background relies on rediscovering sustainability within public organisations as a source for strategy and action, as a vision for change and innovation. Public organisations as communities should follow a logic service view as a service strategy oriented to sustainability within ecosystems. In the fourth paragraph, it is explained how public organisations evolve as communities within ecosystems managing strategic, managerial and technologic capabilities. In particular, public organisations are moving from being organisations to becoming communities adopting a service logic view to value co-creation processes, strengthening the role of public managers as ethical and transformational leaders and agents of change within and between organisation and society, and promoting digital and smart platforms and open ecosystems. In the fifth paragraph, the discussion is presented. Finally, conclusions are set out.

2 Methodological section

The study is theoretical and relies on a literature review relating to public organisations that proceed towards sustainability developing strategic, managerial and technological sources that drive public organisations to evolve as a community that contributes to value creation and encourages efforts and cooperation for public wealth. The selected contributions are interpreted in a narrative synthesis in order to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

3 Towards public organisations as communities oriented to sustainability within ecosystems

After the promises of New public management about efficiency and effectiveness, public organisations should serve the public interest adopting a public value management view as a vision (Stoker, 2006; O'Flynn, 2007), moving towards an ecosystem and community perspective where public administration, business, no profit organisations, civil society, individuals and groups contribute to sustaining knowledge and public value creation within society (Osborne, 2010). Public organisations should rethink how to adopt a sustainability-oriented approach because «they are embedded in society, producing not only benefits (and obligations) for individuals but also providing public goods and services, establishing collective efficiency, and creating collective rules and purposes» (Hartley, 2005, p. 34). Public administration should develop bottom-up policies involving the civil society to provide and input and contribute, encouraging civic engagement and collaborative citizen-centred public management as means to provide benefits for the community (Cooper, Bryer and Meek, 2006). Public organisations should achieve

sustainability as a vision for managing *res publica* within communities and creating value within ecosystems (Fiorino, 2010; Goodsell, 2006; Dumay, Guthrie and Farneti, 2010), redesigning trust-based relationships with stakeholders, citizens and where the public is involved (Meynardt, 2009). Public organisations should serve the public interest as result of dialogue with citizens (Denhardt and Denhardt, 2000) and consider the role of civil society and governance networks following a public value management view (Stoker, 2006), involving the stakeholders to take part in public policy, decision-making and work government (Bingham, Nabatchi and O’Leary, 2005), and promoting social and urban development by interacting with stakeholders within ecosystems (Zbucnea and Romanelli, 2018). Public organisations should contribute to expressing the values of a community facilitating public discussion, integration and citizen participation for services design and delivery, to achieve policy objectives (Bourgon, 2007). Sustaining networked coproduction of public services by virtual communities helps support a community approach to public service support (Meijer, 2011). Users and community contribute to services co-production «where all the parties make substantial resource contributions» (Bovaird, 2007, p. 847). Public organisations should identify a pathway for sustainability looking at an ecosystem perspective (Dumay, Guthrie and Farneti, 2010) interacting with their stakeholders, sustaining multiple relationships with interdependent actors and promoting co-construction and co-innovation where the locus of co-production is the service system (Osborne, 2006; Osborne, Radnor and Strokosch, 2016). Following a service logic view to public value creation (Osborne, 2018), public organisations should identify a strategic pathway for sustainability that relies on public managers acting to realize rights and responsibilities, meeting citizen preferences and interacting with community (Stoker, 2006; O’Flynn, 2007; Moore, 1995). The advent of interactive and digital technology helps public organisations to adopt and strengthen a community/citizen and smart approach in order to support public-private partnerships, involving citizens in policy-making for sustaining public values, equity and development (Larsson and Grönlund, 2014; Dunleavy, Margetts, Bastow and Tinkler, 2005).

4 How public organisations evolve as sustainable communities

Public organisations should contribute to public value creation promoting dialogue, cooperation and social exchange within ecosystems. In becoming sustainable communities, public organisations should proceed towards sustainability as a source for strategy, action and change (Fiorino, 2010), managing strategic, managerial and technological capabilities. As sustainable organisations, public organisations should develop knowledge sources to achieve social and policy issues (Leon, 2013) building inter-organisational relationships within ecosystems (Osborne, 2010, Hartley, 2005). Public organisations should adopt a service logic view in order to facilitate value co-creation by the service users, rediscovering the public manager as a leader and agent of change, and using technology to drive public organisations as digital platforms and ecosystems (Osborne, 2018; Bryson, Crosby and Bloomberg, 2014; Harrison, Pardo and Cook, 2012).

4.1 Rethinking service logic-oriented public organisations

Public organisations should rediscover a service logic view by interacting with citizens as services users and co-producers of value, developing collaboration with stakeholders. Public organisations should facilitate value creation processes, enabling the service users to contribute to production, design, innovation and value of public services (Osborne, 2018). Citizens, clients and governmental organisations should be active co-producers of public value (Moore, 1995). «PSOs do not create value for citizens – they can only make a public service offering. It is how the citizen uses this offering and how it interacts with his/her own life experiences that creates value» (Osborne, 2018, p. 228) whilst «co-production assumes a process where the PSO is dominant and where the logic is linear and based upon product-dominant conceptions of production» (Osborne, 2018, p. 225). Value creation relies on public organisations sustaining multiple relationships promoting co-construction and co-innovation where the locus of co-production is the service system (Osborne, 2006; Osborne, Radnor and Strokosch, 2016). Public organisations should rethink a pathway for public value co-creation that «assumes an interactive and dynamic relationship where value is created at the nexus of interaction» (Osborne, 2018, p. 225).

Public organisations should consider the public service delivery as a relational and process-based phenomenon supported by digital technologies that help public organisations to ensure services efficiency, quality and sustainability adopting an end user-driven (Osborne, Zoe, Radnor, Kinder and Vidal, 2015). Public organisations should enable the users to create value because «it is the citizen and/or service user who creates the performance and value of a public service, with the PSO acting as a facilitator of this process» (Osborne, 2018, p. 229). As organisations achieving sustainability coherently with a service logic view, public organisations should promote collaborative, long terms and trust-based relationships enabling the citizens and/or service users as the actors with their needs, personal abilities and experiences that actively drive value creation (Osborne, 2018).

Proposition 1: Public organisations as communities should adopt a service logic view in designing services and processes in order to facilitate value co-creation where the service users contribute to creating the performance of value.

4.2 Rediscovering public managers as leaders between organisation and society

While managers utilise and control human resources, leaders should motivate people, inspire, develop and innovate (Bennis, 1989). Managers should strategically develop human resources in order to achieve organisational objectives and act as leaders that exert influence on public service motivation of employees in order to support them to contribute to public service value (Park and Rainey, 2008). Successful changes rely on rediscovering public managers as leaders that implement programs, support the employees that feel to contribute to public services, interact with citizens and exercise multiple accountability within society. Public managers should attend to community

values helping networks, enhancing effectiveness and accountability within society (Bryson, Crosby and Bloomberg, 2014).

Public managers should also exercise an ethical guide in order to support employee commitment and job satisfaction, and to improve the absenteeism reduction. Public managers as ethical leaders help face and solve ethical questions that exert positive influence on employees' behaviours and attitudes at work (Hassan, Wright and Yukl, 2014). Administrative leadership relies on public management capabilities playing a key role in driving the organisations to achieving the objectives (Van Wart, 2013). Thereby, political instability can exert influence on strategic reform strategies and on the stability of the roles of public managers that feel less identified within organisational goals and less motivated to lead the employees (Dutton, Dukerich and Harquail, 1994). Political instability and uncertainty contribute to decreasing the motivation to lead for public management and exerting high level of dissatisfaction at work denying to public managers the need to lead followers (Weick and Sutcliffe, 2011; Chan and Drasgow, 2001). Public management should exercise leadership and plan strategic activities that contribute to driving processes of change, leveraging on the personal characteristics of the individuals. In particular, public managers should behave as transformational leaders driving the employees to better work and believe in public service in a context of change, paying attention to people, identity and relationships in order to motivate the employees in performing the task within organisations (Van der Voet, 2014; Karp and Helgø, 2008). Transformational leadership helps support public service motivation and enhance the commitments to public mission, fostering job satisfaction, work performance and quality (Moynihan, Pandey and Wright, 2009; Park and Rainey, 2008).

Proposition 2: Public organisations should ensure stability and reduce uncertainty in order to drive public managers as agents of change, train and develop transformational and ethical leaders that support public service motivation of employees that feel to contribute to public services systems.

4.3 Developing technology within public organisations living within ecosystems

Public organisations should drive digital evolution that helps redefine relationships with government stakeholders building communities within society. ICTs help support the building of networks and enhance the relationships between public organisations and civil society facilitating knowledge sharing, social exchange and partnerships to achieve public value issues, to promote openness, leadership, integrated service delivery and management within ecosystems (Janowski, Pardo and Davies, 2012; Lips, 2012). Public organisations are embracing ICTs to connect with networks, to drive change in democratic processes, and to create new governance structures that enable change, enhance government effectiveness, support public sector reform, and strengthen citizen engagement and relationships between civil society and government agencies (Bannister and Connolly, 2012). Digital government relies on creating a digital ecosystem for public value creation by strengthening cooperation, ensuring openness, inclusiveness, engagement and participation in policy-making and service design, opening to a data-driven culture and strategy in order to better serve citizens and business that access to

social and informative exchange (Oecd, 2014). Technology enables the relationships between citizens and public organisations towards a community/citizen centred approach as oriented to a public service design (Dunleavy, Margetts, Bastow and Tinkler, 2005; Meijer, 2011). Technology helps empower the citizen as responsible partner in delivering public services (Linders, 2012). The future of public services delivery and design relies on building digital platforms and spaces that contribute to services co-production and value co-creation (Fishenden and Thompson, 2013) leading to open, public and networked ecosystems that help promote innovation and transparency, support citizen engagement, knowledge and information sharing (Harrison, Pardo and Cook, 2012). ICTs enable public organisations to proceed towards sustainability moving from transformation to contextualisation by promoting policy driven e-governance platforms (Janowski, 2015). ICTs contribute to enhancing social and knowledge-based interaction between public and private sphere as a source for value creation and services co-production. Digital technologies are leading sustainable public organisations to encourage private-public collaborations, to evolve as smart communities that rely on proactive citizen participation, and help drive smart culture in government, empowering citizens as co-designers and co-producers of public services and leading to innovation and knowledge development (Larsson and Grönlund, 2014; Gil-Garcia, Zhang and Puron-Cid, 2016).

Proposition 3: Public organisations as communities should develop the potential of technology in order to advance digital, smart and open communities as spaces and platforms that help encourage partnerships and collaboration among private and public actors within ecosystems.

5 Discussion

In coping with an increasing complexity and uncertainty, public organisations should contribute to facilitating value (co-)creation processes, proceeding towards sustainability as a vision for action and change in order to drive the wealth of communities and advance the progress of society. As sustainability-oriented institutions, public organisations should develop and integrate strategic, managerial and technological capabilities in order to evolve as communities that play a key role for services co-production and value (co-)creation within ecosystems, defining policy choices and interacting with civil society to propose better policy solutions and services design. Public service organisations should promote collaboration encouraging inter-organisational and long-terms relationships, where multiple inter-dependent actors and processes contribute to public services delivery and help policy making. As shown in figure 1, the main contribution of this study is to identify some pathways that enable public sector and services organisations as value creation-oriented and sustainable communities within ecosystems.

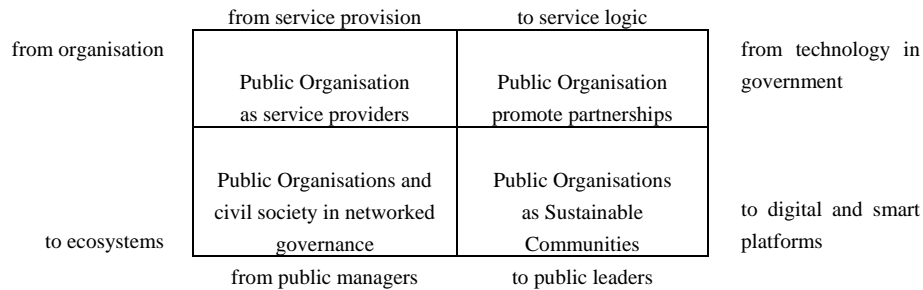

Figure 1 – Towards public organisations as sustainable communities

As services providers, public organisations contribute to service provision following an organisational view in order to serve the public interest, strengthening the role of public manager and driving e-government processes. As organisations embedded within social and economic ecosystems that merely contribute to service provision, public organisations should use the potential of digital and smart government and platforms in order to involve civil society within networked governance where public managers attend to value community and interact with citizens to build shared partnerships.

As institutions oriented to public value and service logic view, public managers behave as agents of change exercising administrative, transformational and ethical leadership to drive public organisations to promote cooperation, dialogue and partnerships by using and developing technology. Public organisations become sustainable communities following a service logic view to public service delivery and design, strengthening public managers as effective and ethical leaders within and between organisation and society, and developing smart and lean platforms and communities within ecosystems. Thereby, public managers should play a key role to drive change and support innovation process in order to feel themselves more identified within organisational goals, being motivated to lead employees in their work and commitment. Public organisations as communities should consider the sustainability as a source that helps value creation processes and enables the wealth of people and business ensuring social, financial, economic and democratic performances.

6 Conclusion

In this study, there are theoretical, managerial and organisational key implications. Public organisations as communities promote value co-creation sustaining the dialogue and supporting cooperation among private and public actors as the result of multilateral relationships, social exchanges and shared values. Public organisations as communities tend to follow a service logic view as strategic approach to public service systems, sustaining the potential of technology to drive smart, lean and open communities within

ecosystems, and empowering public managers as accountable, ethical and transformational leaders in front of the society.

Public organisations should select a sustainability and community-oriented pathway adopting a logic service view as strategic choice (proposition 1), strengthening transformational and ethical features of public managers as leaders (proposition 2), and developing the potential of information technology in order to drive the transition from use of technology in government to drive digital, smart, lean and open ecosystems for value creation, innovation and networking (proposition 3) as sources that drive public organisations as sustainable communities.

In this study, there are some limitations. This study identifies some theoretical propositions and provides a framework of analysis in order to drive public organisations as sustainable communities. Thereby, any empirical research and case studies are provided in the analysis because public organisations are still in infancy in dealing with sustainability as a source for change and innovation in governance and services design within ecosystems.

Further research perspectives and investigations will consider how the hypothesized propositions can be applied within local autonomies and be translated in managerial and leadership programs, human resources policies and practices, technological advancements and digital platforms that contribute to enhancing the community development within public organisations that interact with civil society in order to develop knowledge sources, organisational frameworks, strategies, value-oriented processes, and shared culture within social and economic ecosystems.

Towards Sustainable Communities within Urban Ecosystems

Mauro Romanelli

Department of Business and Economics
University of Naples Parthenope
Via G. Parisi, 13 Napoli 80132, Italy

Abstract

Cities of tomorrow should evolve as sustainable communities that promote social and economic growth and development, and contribute to creating public value within urban services ecosystems. The aim of the study is to elucidate how cities can identify some pathways to develop the city as sustainable urban community. Cities as sustainable and smart communities should promote continuous innovation within knowledge-based, technological-enabled and learning-oriented society. Cities should select a pathway for sustainability promoting smartness as strategic and cultural vision that helps design and production of citizen-centred services, driving urban organisational networks and cooperation to develop knowledge management and innovation systems. As sustainable communities, cities should select a sustainability-oriented pathway to develop the community, enabling all the stakeholders to actively play a key role to support innovation and urban value creation. Cities should use technology in order to design a human-centered and community-oriented urban strategy for growth and development engaging urban stakeholders in innovation processes and systems, investing in urban intelligence as engines of sustainable development.

Keywords – sustainable cities, smart cities, smart communities, urban ecosystems, innovation.

Paper type – Academic Research Paper

1 Introduction

Rethinking cities of tomorrow relies on rediscovering sustainable and urban communities that promote social and economic growth. Cities contribute to engendering social and public value within urban ecosystems (European Commission, 2017). As engines and drivers of social and economic change, cities should become communities that develop and implement continuous innovation to drive sustainable competitiveness of urban service ecosystems and to improve the quality of life (Begg, 1999; Gómez-Baggethun and Barton, 2013). As ecosystems that create value and develop open innovation, adopting a knowledge-based approach to local urban growth (Newman and Jennings, 2008; Evans, Joas, Thundback and Theobald, 2005; Paskaleva, 2011; Knight, 1995), sustainable cities support strong growth as inclusive, smart and urban communities

that promote environmentally responsible behaviours (Deakin *et al.*, 2012). The future and sustainability of cities relies on urban communities that acquire intellectual capital fostering knowledge-based processes and infrastructures developing sources for innovation (Eger, 2005; Deakin, 2014). As smart and sustainable communities, cities should identify the smart approach as a vision that enables the city as a knowledge-based and technology-enabled engine that is able to design and implement urban development and sustainability of urban ecosystems (Lindskog, 2004; Gómez-Baggethun and Barton, 2013; Leydesdorff and Deakin, 2011).

The aim of the study is to elucidate how cities identify a pathway to evolve as sustainable and urban communities. Cities should select a pathway for sustainability promoting smartness as a human-centred vision to ensure citizen-centred services and drive urban organisational networks and cooperation in order to develop knowledge management and innovation systems and sources. Within knowledge-based, technological-enabled and learning-oriented society, cities should develop as sustainable and smart communities that promote continuous innovation within services ecosystems.

The paper is structured in six sections. Following the introduction and methodological section, in the third section, cities should be considered as sustainable and smart communities that evolve by developing technology-enabled innovation, knowledge sources and constructing the community as an organisational framework for innovation in order to drive growth in urban landscape. In the fourth section, it is elucidated how to drive cities as sustainable and smart communities that proceed towards sustainability, become smart cities and use technology in order to promote innovation. In the fifth section, a framework of analysis is presented in order to elucidate how cities can identify some pathways that are oriented to lead cities to becoming sustainable and urban communities. Finally, conclusions are outlined.

2 Methodological section

The study is theoretical and relies on a review of the literature that is related to understanding the concepts of sustainable city, smart city and smart community as drivers that enable urban stakeholders to design services and develop innovation driving the cities to proceed and evolve as sustainable and urban communities. Smartness, sustainability and community are the key words and values that help cities to rethink strategy and action about future urban development. The selected contributions are interpreted in a narrative synthesis in order to elucidate new perspectives and advance theoretical frameworks on emerging issues (Denyer and Tranfield, 2006; Dixon-Woods, Agarwall, Young, Jones and Sutton, 2004).

3 Cities as sustainable and smart communities

There are many definitions about what a city is. Cities as organisations rely on citizens as human resources and contribute to exercising social, economic, productive and cultural functions and performing task in order to create social and public value within

ecosystems. «Cities are complex entities and play multiple and complex economic and social roles» (Marceau, 2008, p. 126). According to Clark (2004) «cities are economic and social systems in space. They are a product of deep-seated and persistent processes which enable and encourage people to amass in large numbers in small areas» (p. 3). Cities should evolve as smart-driven and sustainability-oriented communities in order to build urban future development. As smart communities, cities should adopt a smart vision, select both knowledge-based and innovation-oriented strategies in order to achieve sustainability as a source that helps to design and implement urban development, social and economic growth within urban ecosystems (Eger, 2005; Gómez-Baggethun and Barton, 2013; Knight, 1995; Leydesdorff and Deakin, 2011; Lindskog, 2004; Zygiaris, 2013). Sustaining smart growth relies on revitalizing economic growth in urban areas by developing smart cities and communities that contribute to promoting innovation processes (European Commission, 2012). Cities as communities are made of people: their lives and beliefs influence their actions and thoughts driving history, values and beliefs of their cities (Carrillo, 2004). Developing cities as sustainable communities relies on strengthening social capital (Bridger and Luloff, 2001), making the cities as socially inclusive communities (Deakin *et al.*, 2012) and empowering citizens to actively play a key role in urban value creation in order to contribute to achieving urban sustainability (Haapio, 2012). Cities of tomorrow should sustain the competitiveness of urban ecosystems, enabling people, organizations and business to work and live in knowledge-based and global society (Begg, 1999). Cities as learning and knowledge-oriented systems support creative and morphogenetic processes over time (Camagni, 1996). Sustaining smart city and community development by information technology helps to empower individuals and groups to use skills and information for promoting change within communities and sharing data, information and knowledge for problem solving (Stratigeia, 2012; Chourabi *et al.*, 2012).

As sustainable and knowledge-based organizations, cities as communities should drive value creation in short, medium and long time dealing with knowledge and selecting a knowledge-based strategy in order to develop urban social and economic growth, and achieve social and environmental issues (Knight, 1995; Leon, 2013; Leon, 2018), using technology as a catalyst to transform the economy of an urban community by knowledge sources in order to drive sustainable growth (Eger, 2005; Eger, 2009). Cities should adopt a sustainability-oriented horizon in order to survive as successful urban communities because «cities live and die» (Schnore, 1971, p. 34). Cities as sustainable ecosystems and engines of economic and social growth are social incubators of change and innovation within urban communities (Newman and Jennings, 2008; Evans, Joas, Thundback and Theobald, 2005). Cities should design sustainable urban forms in order to rediscover the city as a community by shaping the urban ecosystem as open space and community-oriented environment (Jabareen, 2006). Sustainable urban development relies on promoting change urban management for urban growth (Mieg, 2012). Cities as smart communities proceed in a significant and positive way becoming spaces, places and platforms that enable to rediscover the opportunities offered by strategic collaboration, dialogue and cooperation between all the stakeholders or *helices* of urban environment

(government, industry, university and civil society) (Lindskog, 2004; Eger, 2005). Sustainable urban development relies on making the city as a system of innovation in order to solve the problems of sustainable development (Johnson, 2008). Cities as communities contribute to developing social and business networks that involve private and public actors to share skills, values and knowledge sources to drive social and urban development (Zbucheá and Romanelli, 2018). Smarter cities should develop innovation to promote governance and community development (Allwinckle and Cruickshank, 2011) sustaining collaborative organizational forms that benefit the urban services, business and social ecosystems (Deakin, 2014; Gómez-Baggethun and Barton, 2013; Lombardi, Giordano, Farouh and Yousef, 2011; Leydesdorff and Deakin, 2011).

4 How to drive cities to become sustainable communities

As evolving and social organisms, cities should design and aliment dynamic processes that involve all the urban stakeholders to develop and manage knowledge, assume values and ideals, select actions that contribute to making the city as a sustainable community. Cities should follow a smart approach as a vision to service innovation by technology. Cities should identify a pathway for sustainability as a vision that supports urban growth and learning in long-terms. They should evolve as a communities and engines of social and economic innovation that involve all the urban stakeholders. Sustainable cities as smart urban communities contribute to creating social, economic, cultural and public value, developing knowledge sources to achieve social and policy issues and to build innovation-oriented and knowledge-driven inter-organisational relationships (Knight, 1995; Paskaelva, 2011; Leon, 2013).

4.1 Towards sustainable cities

Cities of tomorrow should design and implement an inclusive, open and cohesive city developing creativity, diversity and social innovation (European Union, 2011). Sustainable cities «have strong economic growth, are socially inclusive in their growth, and are environmentally responsible» (Deakin *at al.*, 2012, p. 8). Building urban sustainability relies on strengthening the community, empowering citizens to play a key role in constructing development and values of the city, and promoting the construction of social capital as a source for achieving sustainability within social ecosystems (Carrillo, 2004; Bridger and Luloff, 2001; Haapio, 2012). Sustainable cities are socially inclusive and responsible in promoting urban growth (Deakin *at al.*, 2012, p. 8). Cities contribute to creating communities and learning systems that sustain creative processes over time (Camagni, 1996; Schnore, 1971). As places where most part of humanity is living (Newman and Jennings, 2008), cities are engines of economic and cultural growth in urban areas. Sustainable cities contribute to promoting social interaction and stimulating creativity by improving the wealth of people within community (Camagni, 1996).

Cities as meeting places and spaces contribute to sustaining learning and education. Cities are services providers and social incubators for driving change and innovation (Evans, Joas, Thundback and Theobald, 2005). Sustainable cities tend to improve

community-oriented and people-centered services (renewable energy, efficiency in use of water and electricity, green areas, fast public transportation and waste recycling systems) and contribute to building community by encouraging urban governance (planning and decentralization, civil and political rights), promoting social and economic development (education, green energy access, employment, green productive growth) and strengthening environmental management as drivers that help ensure better quality of life (UN, 2013). Cities help people, customers, enterprises and governments to support sustainable development (Satterthwaite, 1997) leading citizens to take everyday decisions (Haughton, 1997), driving change by achieving long-term horizons and successful issues (Czarniawska, 2002). Thereby, technology helps cities that aim at becoming sustainable. Cities select a pathway for sustainability using information and communication technologies (ICTs) to develop e-services through innovation and sustainable use of resources (Cocchia, 2014). ICTs contribute to sustaining smart strategy, improving services and quality of life towards sustainability (D'Auria, Tregua and Vallejo-Martos, 2018).

Cities as sustainable communities develop a framework to monitor system performance, help policy-making and facilitate feedback for individuals and business to build an intelligent urban system (Innes and Booher, 2000). Building sustainable urban development relies on improving the quality of life for people in a city in terms of ecological, cultural, political, institutional, social and economic elements without a burden can occur on the future generations. A sustainable city should be able to reform the way by which the city can interact with global economy and environment (Haughton, 1997). Sustainable cities contribute to promoting sustainable urban development improving and extending the wealth of people within a community (Trindade, Hinning, da Costa, Marques, Bastos and Yigitcanlar, 2017). Sustainable cities pay attention to social changes and equity to support development dealing with resilience, managing decision-making processes Sustainable cities offer new approaches to services relying on human side of change looking at the future and achieving goals in a community-based view following long-time horizon (D'Auria, Tregua and Vallejo-Martos, 2018).

4.2 Cities develop a smart approach to drive urban growth

Cities become smart by investing in human and social capital and developing new communication (transports and technologies) infrastructures, promoting sustainable economic growth and participatory governance to ensure high quality of life (Caragliu, Del Bo and Nijkamp, 2011). Cities should select a smart approach and vision for driving growth, service and community development within urban ecosystems (Zygiaris, 2013; Stratigeia, 2012). Cities should promote smartness as a vision that enables the city as a smart community that is oriented to change (Deakin, 2011) in order to modernize urban services and infrastructures employing ICTs in order to rethink the city design and planning. According to Giffinger *et al.* (2007) smart cities use technology to develop smart industries and smart economies, promoting smart mobility, sustaining smart government, relying on smart people and enhancing smart living and smart environment. Technology helps cities to design a path for sustainability relying on adopting and

following a smart approach for development. «Increasingly cities are seeking to become ‘smarter’ in how they are managed and developed in order to become more sustainable» (Deakin *et al.*, 2012, p. 8). Promoting smartness makes cities as urban communities that embrace a change orientation for driving urban development (Deakin, 2011). Cities should promote smartness as both a human-centred vision to urban development and a source that enables the involvement of local stakeholders in planning, defining and driving the sources for urban transformation of the city (Lara, Da Costa, Furlan and Yigitcanlar, 2016). Cities should adopt a smart orientation to improve urban services and enhance urban values, cohesion and innovation because smart city comprise: land, technology, citizens and government. Technology helps businesses, public bodies and citizens to develop and improve services infrastructures to drive the urban development in geographical areas (Dameri, 2013). Smart cities as communities achieve long-term issues using information technology in order to promote and extend high quality of life in urban environments strengthening the connections between productivity, economic growth and human capital, enhancing service systems and capabilities in an urban network and ecosystem (Albino, Berardi and Dangelico, 2015; Shapiro, 2006). Cities should adopt a smart strategy for continuous and sustainable urban development over time in order «for improving the operational and managerial efficiency and the quality of life by building on advances in ICTs and infrastructures» (Nam and Pardo, 2011, p. 186). Smarter cities should develop innovation for application as social, cultural environmental platforms rediscovering governance and community (Allwinkle and Cruickshank, 2011).

4.3 Promoting smart communities for innovation

Chourabi *et al.* (2012) refer to smart communities as cities that interact with citizens ICTs sharing data, information and knowledge for problem solving. Smart communities help all the members of a community (local government, business, education, healthcare institutions and the public) to learn to work together rediscovering the potential of information technology to transform the community in a positive way (Lindskog, 2004). According to Concilio, Cullen and Tosoni (2019) urban innovation relies on organizational and partnerships structures, citizen empowerment, knowledge creation and exploitation, networks of knowledge and innovation, adaptability to change and resilience. Smart communities enable citizen participation in services co-production (Granier and Kudo, 2016). «The process of reinvention and renewal of an entire community involves all its citizens and its institutions. Government, industry, academy and the citizenry each must assume responsibility for the future of the region and must share in the governing process to prepare the community for the challenges of the global digital age» (Eger, 2005, p. 34). Cities should be *loci* of innovation and innovative milieus (Shearmur, 2012). «It is in cities that, for example, innovative partnerships between government, business and communities may be easiest to arrange since the organisations concerned are smaller than at national levels and in principle at least more permeable than higher levels of government, leading to faster problem-solving and greater room for policy experimentation» (Marceau, 2008, p. 138). Cities should rethink how to promote urban growth, innovation and development by embracing a triple helix

model and rediscovering the active role of civil society as critical stakeholder that contributes to innovation processes and systems driving cooperation that involves industries, government, university and citizens (Lombardi, Giordano, Farouh and Yousef, 2011; Leydesdorff and Deakin, 2011). Cities should drive economic growth and become the main actors that stimulate open innovation, encouraging multi-level private-public partnership and cooperation to co-create, co-design and co-implement innovative solutions and action, promoting innovation as a means for public governance and stakeholder involvement (European Commission, 2017). Cities investing in innovation, technology and knowledge sources become knowledge-oriented cities that drive urban development and support learning environment (Kominos, 2013). As «laboratories of knowledge development and knowledge and application» (Kunzmann, 2014, p. 18), cities should contribute to sustaining an open innovation approach linking technology, people and territory in order to develop knowledge sources and policies to reinforce the cohesion of urban communities (Paskaleva, 2011). Cities as smart communities should acquire intellectual capital attracting and retaining skilled and talent people sustaining innovation systems by reinforcing knowledge and intellectual infrastructures (Leydesdorff and Deakin, 2011; Knight, 1995), involving public and private actors in order to drive social and urban development (Zbucheá and Romanelli, 2018).

5 Discussion

Rethinking a pathway for driving cities as sustainable urban communities relies on reconsidering the strategic role of cities within knowledge-based, learning-oriented and urbanized societies. Cities as smart communities contribute to improving the quality of life and competitiveness in urban, local and global environments. Increasingly, cities become incubators and spaces that enhance social and economic sustainability and innovation.

As shown in figure 1, the main contribution of this study is to identify a framework of analysis to understand how cities tend to identify some trajectories of sustainable development within urban ecosystems ecosystems. The analysed framework is presented in order to elucidate how cities identify a pathway to drive urban communities to proceed towards sustainability as a source for action and vision for change within urban ecosystems.

Figure 1 – Driving cities towards sustainable urban communities

Cities as communities design the future promoting sustainability and developing smartness as a strategic orientation that relies on technology-enabled services, managing knowledge for driving urban development and constructing organisational frameworks for innovation design that is oriented to collaboration and relies on enhancing innovation and social networks within urban ecosystems. Cities should develop innovation as a source that helps urban communities to drive social and economic growth and promote development by involving all the stakeholders of urban ecosystem, mobilizing organisational and managerial competences that enhance public value creation. As future-oriented communities oriented, cities should consider the sustainability as a condition that guides urban communities to assume behaviours and plan initiatives in urban planning in order to develop innovation-driven and community-oriented pathways. Smart and sustainable cities contribute to building the community as a value and source for development. Technology-enabled and services-oriented urban communities acquire human capital and develop knowledge sources helping organisational and individual learning in order to enable value creation within urban service and innovation ecosystems. As sustainable communities, cities should promote smart growth to develop the urban community and support a sustainability-oriented pathway moving from ensuring services to involving all the stakeholders to play a proactive role in the urban value co-creation process, rediscovering knowledge sources and promoting innovation in order to construct better policies for urban governance and entrepreneurship.

6 Conclusion

Cities of tomorrow should evolve as communities living in urban service and innovation ecosystems. Technology is a necessary but not sufficient source to enable cities to acquire, use and manage knowledge for breeding innovation and sustaining urban learning within ecosystems. Cities should use technology in order to plan a human-centered and community-oriented urban design for growth and development engaging with urban stakeholders and investing in human resources and urban intelligence as engines of sustainable, social and economic development. There are managerial, organizational and social implications. Cities should develop technological and knowledge sources to enable innovation processes that help drive sustainable growth in urban ecosystems. The study is conceptual and provides only a theoretical framework of analysis. It does not provide any empirical analysis. Future research perspectives imply to consider how cities use information technology to develop innovation in services, knowledge creation and governance as drivers of value creation within Italian local autonomies.

Abstract

Exploitation and exploration are strongly complementary and both essential for successful innovation, organizational learning, and even organizational survival, although the simultaneous pursuit of both appears to be very difficult. In the literature, several studies focus on the issue of balancing exploration and exploitation at the firm level, while poor attention has been paid to firms' systems at the territorial level, such as geographical clusters. Based on this premise, the present paper tries to cover this gap by evaluating the effects of the exploration and exploitation on the economic and innovation performances of local systems of firms. An econometric analysis on the 103 Italian Provinces over the period 1999-2015 was performed. Main results show that Italian firms operating in the same province perform on average more exploration in unrelated technological domains than in the case of the same technological area. This behavior is not beneficial in terms of economic performance in the short run, but is conducive of innovation and employment. In the same technological domain, the exploitation of existing knowledge is prevailing among local systems of firms and affects negatively the employment. Finally, the paper aims to contribute theoretically and methodologically, to the scientific debate about the application of exploration-exploitation framework beyond the boundaries of single firms. In particular, results could support i) policy-makers in defining proper and customized initiatives and measures able to boost local economic and innovation growth; ii) academics and scholars in developing comparative studies

among diverse geographical contexts, benchmarking analysis and best practices identification at provincial, regional and national level.

Paper type – Academic Research Paper

1 Introduction

Since the publication of March's (1991) pioneering article, the terms "exploration" and "exploitation" have increasingly come to dominate studies in the fields of innovation strategy, technology management, organizational learning and adaptation, and economic growth (e.g., Aghion and Howitt, 1992; Allen and McGlade, 1986; Benner and Tushman, 2003; Burgelman, 2002; Holmqvist, 2004; Katila and Ahuja, 2002; Levinthal and March, 1993; McGrath, 2001; Tushman and O'Reilly, 1996).

Exploration refers to learning gained through processes of concerted variation and planned experimentation (Baum et al., 2000). According to Benner and Tushman (2002) exploratory innovation involves a shift to a different technological trajectory. Along the same line, He and Wong (2004) defined exploratory innovation as technological innovation aimed at entering new product-market domains.

According to He and Wong (2004) exploitation strategies trigger learning processes aimed at improving the product-market domains. Therefore, exploitation refers to learning gained via local search, experiential refinement, and selection and reuse of existing routines domains (Baum et al., 2000). As a result, exploitative innovations involve improvements in existing components and build on the existing technological trajectory (Benner and Tushman, 2002).

Following March (1991), exploitation and exploration strategies are strongly complementary and both essential for successful organizational adaptation, technological innovation, organizational learning, and even organizational survival. However, although both exploration and exploitation are essential for assuring organizations' competitive advantages in the short and long-term, the simultaneous pursuit of both appears very difficult. First, they compete for scarce organizational resources, since more resources devoted to exploitation imply fewer resources left over for exploration, and vice versa. Second, both types of actions are iteratively self-reinforcing, as exploration often leads to more exploration, and exploitation to more exploitation (Cao et al., 2009). Finally, the mindsets and organizational routines needed for exploration are radically different from those needed for exploitation (Gupta et al., 2006).

Most of researches on the topic have highlighted the need for organizations to pursue strategies to balance exploration and exploitation, in order to achieve high performances in terms of learning, innovation and economic growth (Cao et al., 2009; He and Wong, 2004; Venkatraman et al., 2007). The dilemma between exploration and exploitation was therefore the object of particular attention in the field of organizational ambidexterity

(e.g. Junny et al., 2013). This rich line of studies has produced numerous researches at the level of the single company (e.g.:Raisch and Birkinshaw, 2009), dyadic collaborations (e.g., Lavie and Rosenkopf, 2006), strategic alliances (e.g: Lin et al., 2007). Little attention has been paid by the literature to the issue of balancing exploration and exploitation in the context of geographical firms' clusters. There is also a growing interest on the topic of how to reach the ambidexterity at the level of clusters or innovation networks (Bocquet and Mothe, 2015; Ferrary, 2011; Kauppila, 2007; Wolf et al., 2017), but the geographical dimension of the problem and the performances' implications at the territorial level are under-investigated (Wang et al., 2015). Thereby, this paper tries to cover this gap by evaluating the effects of the exploitation and exploration strategies on the economic and innovative performance of a local system of firms.

We believe our interest on the effects of the two strategies on a system of firms rather than on a single organization significantly contributes to the existing and growing literature (Ferrary, 2011, Kauppila, 2007). In fact, analyzing which of the two strategies is more conducive for the territorial development and growth, allows us to answer to an open question characterizing the studies in the field of economic growth and regional development, namely the relevance of heterogeneity in firms' competencies and capabilities for the competitive advantage of the local systems of firms (Boschma, 2005; Schampet al., 2004). Exploration strategies have been found to have a higher effect on the level of knowledge heterogeneity, because those strategies span on a wider range of technological knowledge. On the contrary, exploitation strategies involve an intensive search along an existing knowledge dimension, producing a lower diversity in the knowledge system (Quintana-Garcia and Benavides-Velasco, 2008). A fully understanding of the benefits and costs going along with the adoption of these distinct strategies at a territorial level still lacks, hence calling for further investigations.

To reach this aim, an empirical research has been conducted on the 103 Italian Provinces, by measuring for each Province both economic and innovative performance and indexes that capture the exploitation and exploration strategies. An econometric analysis on the 103 Italian Provinces over the period 1999-2015, controlling for an extensive set of control variables, is applied.

The remainder of the paper is organized as follows. Section 2 briefly introduces the exploration-exploitation framework and its relevance at the local level. Section 3 presents the research methodology, describing data, variables, and estimation method. Then, Section 4 reports the empirical results, while Section 5 concludes.

2 Background

The seminal paper of March of 1991 gave rise to a wide debate in various research fields (organizational learning, technological innovation, innovation strategy, etc.) on the need for organizations to search a trade-off between exploration and exploitation. Most of the studies on the subject have highlighted that exploration and exploitation are two distinct and complementary learning and innovation activities, both required to sustain survival, learning and innovation (Benner and Tushman, 2002). At the same time,

exploration and exploitation compete for scarce resources (Garcia et al., 2003) and refer to diverse time horizons in producing returns (March, 1991). March claims (1991, p. 73): “compared to returns from exploitation, returns from exploration are systematically less certain, more remote in time and organizationally more distant from the locus of action and adaptation”. Consequently, organizations naturally tend to focus on the refinement of existing knowledge and competences to gain efficiency and high returns in the short time, with the risk to experiment a competence trap and loose flexibility toward turbulent and changing environments (He and Wong, 2004). On the other side, pursuing exclusively exploration is associated with less efficiency in the short run and more uncertain returns (O’Reilly and Tushman, 2013).

Literature widely supports the idea that pursuing both exploration and exploitation, namely the ambidexterity strategy, is a key to successfully coping with the trade-off issue between exploration and exploitation at the single firm (Raisch et al., 2009) and strategic alliances’ levels (Lin et al., 2007). Numerous empirical studies (for an extensive review refer to Junny et al., 2013) have been conducted to test “the ambidexterity hypothesis” (He and Wong, 2004). Most of them find a positive relationship between the ability of an organization to follow an ambidexterity strategy and the performances implications, particularly when the domain of technological innovation is analyzed. These empirical studies mainly refer to established firms (e.g: Cao et al., 2009; Lubatkin et al., 2006) or to collaborations in strategic alliances between small and large firms (e.g: Lin et al., 2007). The applications of the exploration-exploitation framework to study innovation and growth of local systems of firms are very poor. There is a growing interest on this topic as demonstrated by the study of clusters’ ambidexterity. As stated by Wolf et al. (2017) “A cluster is ambidextrous if it manages to balance innovative activities that exploit existing competencies and is open to novel technological approaches by means of exploration”. According to Bocquet and Mothe (2015), a cluster can be ambidextrous if the firms inside the cluster are singularly ambidextrous, or if a portion of firms in the clusters perform exploration, while the remaining part is devoted to exploitation. Performances implications in terms of growth and innovation implications at the territorial level are taken for granted and not empirically investigated in these studies, that are mostly oriented to identify antecedents of ambidexterity, particularly by examining the role of governance structures or managerial orientation in this specific context. The present paper tries to explore more in depth whether and how exploration, exploitation and eventually both are pursued by a local system of firms placed in the same local area and tries to investigate performances implications at the level of Italian provinces.

3 Research Methodology

3.1 Data Sample

The dataset is represented by the 103 Italian Provinces. The idea to focus on provinces (NUTS3 classification) depends on the fact that little attention has been paid to the analysis of exploration and exploitation at such geographical level. From a

methodological point of view, this level of analysis lets to collect more detailed data and taking into account different industrial specializations inside a regional setting. From a policy perspective, this methodological choice appears to be relevant as results could support policy-makers in defining proper and effective economic and innovation measures at provincial rather than regional or national scale. The focus on Italy is justified by the traditional presence of diverse industrial geographical clusters and productive vocations within a same region/province, making interesting and relevant to investigate exploration and exploitation in this context. Indeed, to build our dataset we used different statistical sources: the Italian Office of National Statistics (ISTAT) databases; the European Patent Office (EPO) database; the Ministry of University and Research (MIUR) database, and the UNIONCAMERE database. Particularly, data on GDP, employment, population, and R&D investment come from ISTAT databases, data on university are extracted by the MIUR database, data on firms in two-digit and three-digit NACE codes come from the UNIONCAMERE database, and finally data on patents are provided by the EPO database. Data have been collected for each Province and refer to the period 1999-2015

3.2 Variables

3.2.1 Dependent variables

As the phenomenon under investigation is the development and growth of local areas, we used as dependent variable the number of patents developed in each province, as an indicator of the innovative performance (e.g. Jaffe and Trajtenberg, 2005; Acs et al., 2002), and the GDP, the employment rate (Employment-to-population ratio), and the unemployment rate as indicators of the economic performance.

They have been measured by:

$$Patent_p = \text{Number of patents registered in the province} \quad (1)$$

$$GDP_p = \left(\frac{GDP_{region}}{N.employees_{region}} \right) \times N.employees_{province} \quad (2)$$

$$Employment_rate = \frac{Employees}{population} \times 100 \quad (3)$$

$$Unemployment_rate = \frac{Unemployed_workers}{total_labour_force} \times 100 \quad (4)$$

These variables have been measured in a time period of seventeen years (1999-2015). Finally, in order to exclude endogeneity problems, the dependent variables are lagged of three years respect to the independent variable.

3.2.2 Independent variables

To capture the characteristics of the strategies carried out within the provinces, in terms of exploitation and exploration, the degree of a province's industrial heterogeneity has been measured by using the inverse Gini coefficient (Greunz, 2004; Paci and Usai, 1999; van der Panne and van Beers, 2006). The index aims at capturing the level of concentration of firms in a specific industrial sector and it has been measured over a period of seventeen years.

Specifically, focusing on the manufacturing sector, we use two different measures: 1) the inverse Gini coefficient of the distribution of firms by sector (two-digit level) in each province ($\text{invGini}_{\text{unrelated-sector}}$); 2) the inverse Gini coefficient of the distribution of firms within each two-digit sector in each province ($\text{invGini}_{\text{related-sector}}$). The $\text{invGini}_{\text{unrelated-sector}}$ measures the heterogeneity across unrelated manufacturing sectors, as those characterized by a greater technological diversity. Instead, $\text{invGini}_{\text{related-sector}}$ measures the heterogeneity across related manufacturing sectors, namely those characterized by a greater technological similarity. Following Frenken et al. (2007), we assume that the related manufacturing sectors are those that share the same 2-digit NACE code.

The Gini index is defined as follows:

$$\text{invGini} = 1 - \left(\frac{\sum_{i=1}^{n-1} (Q_i - P_i)}{\sum_{i=1}^{n-1} P_i} \right) \quad (5)$$

Where:

- i indexes the manufacturing sector ($i = 1 \dots n-1$), classified into the two-digit NACE code for the $\text{invGini}_{\text{unrelated-sector}}$ and into the three-digit codes that share the same 2-digit class for the $\text{invGini}_{\text{related-sector}}$;
- $Q_i = \frac{\sum_{j=1}^i F_j}{CF}$
- $\sum_{j=1}^i F_j$ is the cumulative sum of firms in each manufacturing sector, classified into 2-digit NACE code/ 3-digit code, when the sector is ordered in increasing order;
- CF is the total number of firms.
- $P_i = \frac{i}{n}$

The inverse Gini coefficient ranges from a minimum value of zero to a maximum of one. Values of the index close to zero indicate that the industrial system in the province is specialized into a very few sectors, while values of the inverse Gini coefficient close to one indicate that the province industry specialization is spread across the different manufacturing sectors. Therefore, we assume that values of $\text{invGini}_{\text{unrelated-sector}}$ close to

one reflect exploration strategies towards industries that are characterized by a greater technological diversity, while values of $\text{invGini}_{\text{related-sector}}$ close to one reveal exploration strategies towards industries technologically related. Values of the inverse Gini coefficient close to zero indicate exploitation strategies within the province.

3.2.3 Control variables

The analysis includes several control variables. First, in order to take into account the general economic conditions of the provinces, we use a polytomic variable for provinces localized in the Northern Italy, generally considered as a more advanced and developed area (Mariotti et al., 2008). Four other controls have been included that may affect the province innovative performance. Specifically, the first variable refers to the presence of universities within the province area, which are considered as sources of new knowledge (Benneworth and Hospers, 2007; Cooke and Piccaluga, 2004). The second variable measures the R&D expenditure in the area. The index is defined as follows:

$$R \& D_p = \left(\frac{R \& D_r}{F_r} \right) \times F_p$$

Where:

- $R \& D_p$ is the amount of R&D investments in region r where the province p is located.
- F_r is the total number of firms in region r .
- F_p is the total number of firms in province p .

R&D expenditure has been frequently used as a proxy for the local capability to generate new knowledge and innovation (Cohen and Klepper, 1991; 1992; Frenken, 2007).

Thirdly, we control also for the scale of local economic activity, measured by the total number of firms located in each province as a determinant of some type of cross-fertilization and economic advantages, usually called urbanization externalities (e.g. Lorenzen and Frederiksen, 2008). In other words, the number of firms in each province aims to measure the entrepreneurial system considered as a factor influencing the local economic growth (e.g. Bertinelli and Black, 2004; Hendersen, 1997; Lorenzen and Frederiksen, 2008). Indeed, the scale and/or the diversity of local economic activity outside the own industry, by involving an exchange of complementary knowledge between economic actors operating in diverse fields (Isard, 1956; Jacobs, 1969), could enable innovation and economic growth. As highlighted by Jacobs (1969), relevant sources of knowledge are often not necessarily found within, but rather outer the own industrial environment. Thereby, a more diversified industrial structure may provide

access to different and complementary technological knowledge and therefore boost innovative activities (Beaudry and Schiffauerova, 2009).

Finally, we control for the technological level of the local industry in each considered province (Head et al., 1995), by using a polytomic codified variable.

4. Results and discussions

4.1 Descriptive statistics

In order to estimate the relationship between the economic and innovative performance and exploitation and exploration strategies carried out within the province, proxied by the variables presented in Section 3, we apply a linear estimator. The reason for choosing such estimator is because a linear regression well-adapt to our model.

The descriptive statistics together with correlation matrix are shown in Table 1 and Table 2, respectively.

Table 1. Descriptive statistics

	Mean	St. Dev.	Min	Max	Obs
Patent (n.)	36,08	2,95	0	714,78	515
GDP _p (€)	23,06	0,034	21,18	25,67	515
Empl_rate	49,94	0,57	23,57	72,36	515
Unempl_rate	9,23	0,23	1,85	31,46	515
invG _{unrelated-sector}	0,42	0,004	0,15	0,73	515
invG _{related-sector}	0,34	0,002	0,11	0,48	515
R&D _p (€)	15,61	0,15	9,06	21,30	515
N _{university} (n.)	0,80	0,07	0	15	515
N _{firms} (n.)	35086,77	1800,12	2122	338010	515

Focusing on the results shown in Table 1, it is possible to note that Italian provinces, over the time, have not strongly invested in R&D activities; this result is confirmed by the average number of EPO patents at provincial level. The values of the two inverse Gini indexes show that Italian firms follow mainly exploitation strategies within the provinces as their values are more close to 0 than 1. Put differently, the industrial system is specialized into a very few sectors within each province. Moreover, being invGini_{unrelated-sector} slightly higher than invGini_{related-sector}, and its maximum value equal to 0,73 (Table 1), it is possible to conclude that some provinces realize exploration strategies towards industries that are characterized by a greater technological diversity.

Focusing on the analysis of the Maximum and Minimum values at provincial level we can claim that the best performing provinces are mainly located in the Northern Italy. In particular, Milan is the best performing province in terms of number of patents, GDP, activities, and number of firms, while the best Italian province in terms of employment rate is Parma. The lowest unemployment rate is up to Reggio Emilia. Roma is the best

province in terms of number of universities and investments in R&D activities. On the contrary, in the Southern Italy it is possible to find the worst provinces in terms of GDP (Isernia), employment rate (Vibo Valentia), unemployment rate (Crotone), and number of firms (Isernia). It is important to underline that such results are not shown in this paper, but they are available upon request.

Table 2 shows the correlation coefficients among variables. The correlation matrix shows that the variables are not significantly correlated: Pearson correlation coefficients are almost all lower than 0.5 at a p-value less than 0.05.

Furthermore, to understand whether multicollinearity exists between independent variables, the variance inflation factor (VIF) test has been performed. Accordingly, as a rule of thumb, a multicollinearity problem does not threaten the validity of models if VIF scores are less than 10. All independent variables got the value of VIF lower than 4 in this test. Therefore, multicollinearity does not bias the regression results. This result is confirmed also by R^2 very large in both regression analyses performed.

In the following sections, the results of the linear estimation are presented and discussed.

Table 2. Correlation matrix

Model Estimation

The results of linear estimation of effects of exploitation/exploration strategies on the economic and innovative performance for Italian provinces over the period 1999-2015 are reported in the Table 3 and Table 4.

In particular, Table 3 reports the effects of the exploration strategies across technologically unrelated industries on the economic and innovative performance of the Italian provinces. Table 4 reports the effects of the exploration strategies across technologically related industries on the economic and innovative performance of the Italian provinces.

Table 3. Linear estimation of the effect of exploration strategies across technologically unrelated industries on the economic and innovative performance (1999- 2015).

	GDP _p	Patent	Employ_ rate	Unemploy_ Rate
invGini _{unrelated}	-0,780* (0,462)	36,954 (47,890)	24,651*** (5,705)	-17,310*** (3,503)
R&D	0,138*** (0,015)	-2,625* (1,514)	2,133*** (0,180)	-0,430*** (0,111)
N _{firms}	0,000*** (0,000)	0,001*** (0,000)	0,000*** (0,000)	0,000*** (0,000)
N _{university}	0,021 (0,016)	-4,894** (1,630)	0,539** (0,194)	-0,193 (0,119)
Geo_area	-0,128*** (0,024)	-18,716*** (2,489)	-7,057*** (0,297)	4,138*** (0,182)
Tech_Industry	0,052 (0,043)	-15,720*** (4,423)	-0,010 (0,527)	-0,511 (0,323)

Numbers in parentheses are the standard errors

Asterisks denote the significance of the coefficient estimates: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Results show a positive and significant relation between the invGini_{unrelated} index and the Employment rate and, coherently, a negative and significant relation between the invGini_{unrelated} index and the Unemployment rate. Moreover, a negative and significant relationship exists between invGini_{unrelated} index and the GDP, that is a measure of the provincial economic performance. The existence of a negative and significant relation between invGini_{unrelated} index and the GDP is consistent with the literature, as investments in exploration strategies imply high costs for the systems performing them and more uncertain income, at least in the short period. Put differently, this means that there is a lost of efficiency in the short run with respect to the cases in which firms of the local system focus on the same technological domain.

As for the effect on the innovative performance of the province, measured by patents, we find a positive coefficient, in line with our expectation that exploration strategies may increase the likelihood that some innovative activity occurs, although not significant.

Table 4. Linear estimation of the effect of exploration strategies across technologically related industries on the economic and innovative performance (1999- 2015).

	GDP	Patent	Employ_ rate	Unemploy_ Rate
invGini _{related}	6,653*** (0,477)	132,301*** (49,421)	-46,195*** (5,887)	12,143*** (3,615)
R&D	0,138*** (0,015)	-2,625* (1,514)	2,133*** (0,180)	-0,430*** (0,111)
N _{firms}	0,000*** (0,000)	0,001*** (0,000)	0,000*** (0,000)	0,000*** (0,000)
N _{university}	0,021 (0,016)	-4,894*** (1,630)	0,539*** (0,194)	-0,193 (0,119)
Geo_area	-0,128*** (0,024)	-18,716*** (2,489)	-7,057*** (0,297)	4,138*** (0,182)
Tech_Industry	0,052 (0,043)	-15,720*** (4,423)	-0,010 (0,527)	-0,511 (0,323)

Numbers in parentheses are the standard errors

Asterisks denote the significance of the coefficient estimates: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Results reported in table 4 show a positive and significant relationship between the $invGini_{related}$ index and the GDP and the number of patent applications (a typical measure of the innovation outputs). Such a result suggests that exploration strategies across technologically related industries increase both the economic and innovative performance of the province.

On the contrary, we have a negative and significant relationship between exploration strategies across technologically similar industries and the Employment rate and, coherently, a positive and significant relation between the $invGini_{related}$ index and the Unemployment rate.

In general and taking into account data reported in Table 1, it is possible to claim that firms located in Italian provinces try to balance exploration-exploitation strategies (with a small preference for exploitation) when considering unrelated technological domains. This result is in line with the literature about the ambidexterity that underline the need for organization to pursue simultaneously both the strategies, although it is a very complicated task (Cao et al., 2009; Gupta et al., 2006; March, 1991).

On the contrary, Italian firms opt mainly for exploitation strategies when organizations share common technological expertise.

Finally, exploration strategies across diverse technological domains have a positive and significant impact on the innovation performances and on the employment in a local area, while the economic performance in the short run is negatively affected. On the contrary, exploration strategies in similar industries affect positively and significantly the GDP and the number of patent applications, whereas impacting negatively on the level of employment.

5 Conclusions

The paper aims to better analyze the impact of exploration and exploitation strategies on the local economic and innovation development. In other words, although a wide stream of literature focuses on the analysis of the balance of exploration-exploitation strategies at the firm level (e. g.: Cao et al., 2009; He and Wong, 2004; Lubatkin et al., 2006) and some contributions exist with respect to networks or clusters (e.g. Bocquet and Mothe, 2015; Ferrary, 2011), little attention has been paid by the literature to this issue in geographical contexts, such as the provincial level (Wolf et al., 2017).

According to this, the paper tries to address this issue by evaluating the effects of the exploitation and exploration strategies on the economic and innovation performances of local systems of firms in Italy.

Based on this premise, an econometric analysis on the 103 Italian Provinces over the period 1999-2015 has been performed.

Results show that Italian firms operating in the same province try to balance exploration-exploitation strategies with respect to unrelated technological domains (mean value of $invGini_{unrelated} = 0,42$), while they opt mostly for exploitation in related technological areas (mean value of $invGini_{related} = 0,36$).

Results also show that the impact of increasing exploration in a province, on the economic and innovation performances, depends on the way the exploration activities are performed. When exploration is devoted to cover differently technological domains, there are good results for the rate of employment and for innovation, but reduced economic performances. On the other side, when exploration is focused on similar technologies domains in a same technological area, then there is a benefit in terms of GDP, but not in terms of employment rate.

Thereby, we believe that our paper could contribute, theoretically and methodologically, to the scientific debate about the implications of pursuing ambidexterity strategies in geographical contexts. Specifically, the analysis of the impact of these two strategies on territorial development and growth, could support policy-makers in defining proper and customized initiatives and measures able to boost local economic and innovation growth.

Finally, this paper has also implications for academics and scholars. Specifically, we propose an interpretative and econometric model to analyze the impact of exploration-exploitation strategies in different geographic contexts both at European and International level. Such analyses could represent a crucial preparatory step to support comparisons among diverse contexts, benchmark analysis and identification of best practices at provincial, regional and national level.

Migration and Diversity Potentials for Organisations

Petia Genkova

Osnabrueck University of Applied Sciences
Osnabrück, Germany

Abstract

A successful integration of migrants in the labour market and in organisations is getting more important based on demographic changes. The central aim of the investigation is to deal with problem fields of the Human Resource Management, which arise by demographic changes regarding migration. Therefore, an explorative qualitative study with human resource managers and diversity representatives of the large DAX companies was conducted. The views of leaders and employees with and without an immigration background regarding diversity potentials in organisation are compared in this study. The results indicate that diversity is important for organisations. Employees have recognised the importance of diversity. Managers have not recognised the seriousness and urgency of cultural diversity and diversity actions. Human resource managers are not able to assess the additional stress of migrants correctly and to consider them in their day-to-day management and diversity actions.

Keywords: migration, diversity potentials, intercultural competence, human resource management

1 Introduction

The issue of diversity has high priority in Germany but also in other European countries. The process of globalisation as well as the European Integration increases the need for action of societies and organisations to adapt their structures and processes to demographic changes and diversity. Since the 19th century, the life expectation of people has doubled in Germany. (German Federal Statistical Office, 2015).

To ensure the employees' and leader's performance, organisations have to select suitable employees, who bring required diversity-competences like intercultural competence, social and digital competences, to address effectively the challenges of the 21st century. The interaction of people from different cultures is no longer an exception, but every day present (Fantini, 2009). People from different cultures are often discriminated in practice, although they are important potentials for organisations. Thus, organisations have to promote proactively, especially ageing employees, women and persons with an immigration background (Fuchs & Dörfler, 2005).

A successful Diversity Management is seen as indispensable for organisations in the long term. The strong interest of society and economy regarding Diversity Management

can be explained by the fact that the society has changed due to demographic processes and strong migration flows in the last two years, 2016 and 2017, in Europe. The result is a greater heterogeneity in societies and organisations.

More than 2.600 companies and institutions are signatories of the Diversity charter of German companies. However, by considering the national cross section of organisations in Germany, it is shown that around two thirds of the companies are not active regarding diversity and did not implement diversity management (KFW Research, 2017). Diversity has to be organised and consciously integrated in the respective organisation, when it should be used as a chance (e. g. Thomas, 2003; Franken, 2015). Migration delays the process of ageing society, but cannot solve it permanently (German Federal Statistical Office, 2016). So this article focuses on a more successful integration of diverse employees.

2 Diversity Management

Diversity Management describes the personnel diversity in organisations (Becker, 2006) and the commonalities and differences of individuals (Krell, 2003). It indicates both the obvious and barely perceived and salient characters like age, religion, sexual orientation, cultural values as well as barely obviously changing characters like language and competence (Miliken & Martin, 1996) and the values of equal opportunity and fairness.

Diversity Management aims to create diversity in organisations and to change the values, attitudes and behaviours of organisation and working groups (Ashikali & Groeneveld, 2015). The prerequisite for an organisation for the success of diversity is the appreciation of employees and their different individuality (Vedder, 2011). Persons should be treated equally, except of their cultural individual characteristics and should use their skills free from norms and stereotypes (Vedder, 2011).

Diversity of employees can have different effects in an organisation. It depends especially on the fact how diversity is respected. If the variety refers to status, negative effects for the organisation's performance are shown. If employees bring experiences, e. g. based on their different cultural background, it can have positive effects. An active promotion of this kind of diversity can contribute to an improvement of organisational results (Garib, 2013).

Diversity can be enriching for organisations and individuals, when they do a perspective change (Page, 2007). Studies pointed out that individuals with a pro-diversity belief describe multicultural groups as good, precisely by the fact of the group's diversity. People with a pro-diversity belief identify themselves stronger with the group (Van Dick et al., 2008). This accords to the social identity. Wolf and Van Dick (2008) illustrated in their study that people, who see migrants as an enrichment, have more contacts to them and express less racism than those, who do not see migrants as enrichment for the society. Stegman (2011) pointed out in his Meta-Analysis that pro-diversity beliefs as well as a positive diversity culture result in beneficial results for groups and individuals and increase job performance.

Different reasons exist about the organisation's reason and normative convictions of integrating diversity in their company strategy and culture (Ely & Thomas, 2001; Van der Zee & Otten, 2014). The first approach is the discrimination-and-fairness approach. The equal opportunity of everyone is of central importance. Quotes like anti-discrimination laws can be mentioned as examples. The second approach is the access-and-legitimacy-perspective. This approach understands diversity in the organisation as an access to new markets and is seen as an added value by the organisations (Van der Zee & Otten, 2014). The third approach is the integration-and-learning-perspective. Diversity is seen as a resource for learning, changing and renewal. Managers appreciate diversity on every level and encourage the exchange of different opinions. All three diversity's approaches are successful to motivate managers to diversify their staff. But only the integration-and-learning approach leads to reach sustainable advantages (Van der Zee & Otten, 2014).

Leaders take an important role in diversity management. They have an influence on the satisfaction, health and performance of employees (Franken, 2015). Managers take over different roles in their function as a leader and are between role model function and performance pressure (Franken, 2015). Especially, managers take over a central role by initiating diversity management (Wildermuth & Gray, 2005). Top managers take over the role of developing the diversity strategy. Leaders of the middle management implement the strategy. Therefore, the middle management plays a key role and demonstrates variety. They carry responsibility for a successful implementation of diversity management and are supporter of diversity competences (Thomas, 1990). The task of the leaders is to convince employees of the issue of variety (Dreas & Rastetter, 2016).

All studies have one in common. When organisations do not implement diversity actions in their company, the effects are negative and impair the working conditions for heterogeneous and homogeneous organisations.

It is shown that diversity is a competitive advantage, but at the same time, it can be a source of conflicts and counterproductive behaviour. A diversity fair personnel selection is important for organisations because it gives organisations flexibility and adaptation (Kersting & Ott, 2016).

3 Age and Migration as Diversity Categories

The employment of persons with an immigration background and ageing persons can have advantages for organisations, but can also lead to difficulties. Employees are confronted with different challenges by the international cooperation, which can lead to stress (Holmes & Rahe, 1967).

Thereby, immigration background is defined according to the typical definition of the German society: a person with migrant background has at least one parent without a German background that immigrated to Germany after. But in 2015 alone, around 4.7 million people have immigrated in the EU-states, whereby around 2.4 million people were from third countries. The highest level of immigration is recorded by Germany, followed by the United Kingdom, France, Spain and Italy. The consideration of the migrant population shows that around 35.1 million people, who were born outside of

Europe live in the EU. 19.3 million people, who were born in another EU-state, live in the EU (Eurostat, 2017). Romanians, Poles, Italians, Portuguese as well as Englishman belong to the five biggest groups of EU-citizens, who have lived before in other EU-state (Eurostat, 2017).

The research regarding migration has developed between the 1950 years and the 21st century. Following approaches were thereby considered: intercultural learning, stress approach, social identity as well as acculturation. All approaches were considered stronger in the research based on economic changes. Regarding diversity, the stress approach is predominantly in the research. The reason is that short-term and long-term interactions are characterised by stress.

In the context of migration, the perception of stress as well as the physical and psychological health was considered in the past (Eggerth & Flynn, 2013). The extent of the experienced burden is high, when the coping behaviour is ineffective or the number of appearing stressors is high (Eggerth & Flynn, 2013). Experienced discrimination, profound stress events as well as social isolation, e. g. by colleagues, can have an impact on the well-being of persons with an immigration background (Bozorgmehr & Razum, 2015). Discrimination cannot be made only by individuals but also by organisational processes and structures which makes it difficult for migrants to get access to the labour market and to work in their key qualification. This is called structural discrimination. Only a structural integration can support persons with an immigration background to work in their key qualification.

From the sociology perspective, the structural integration in the labour market is an important prerequisite to develop a national sense of belonging for persons with an immigration background.

In most of the organisations, a structural discrimination is found. This means that the labour market chances of persons with an immigration background are smaller compared to persons without an immigration background. The foreign graduation of persons with an immigration background is often not recognised and, therefore, they cannot work in their primarily qualification and work below their qualifications (Badura et al., 2010). Studies have shown that there is a negative relation between the education and the psychological integration. This phenomenon describes that higher educated migrants abandon from the host society (De Vroom & Verkuyten, 2015).

The so called glass ceiling effect is a phenomenon regarding gender and discrimination. The effect describes an invisible barrier that hinders a given ethical group from rising beyond the highest level in a hierarchy. Relating to big organisations, particular, it means the opportunities for qualified women to get into the top-management, which are much smaller than for men. This effect is stronger for persons with an immigration background. The frustration and the disappointed career expectation lead to a critical consideration of the host society.

The stress level increases through at the daily cooperation between people with and without an immigration background. The interpretation of unclear cultural patterns and the questioning of the organisational processes and structure cause many conflict situations.

Not only persons with an immigration background can feel stress, but also persons without an immigration background because habitual and firmly social established perspectives change. Persons with and without an immigration background have to adjust to new working methods and views (Asbrock et al., 2012).

This means for employees and managers to acquire intercultural competences to be able to work in multicultural teams and to fulfil the working challenges of the 21st century effectively.

In the research and in practice, it is always tried to determine whether direct positive effects of diversity management exist regarding the economic success. The results of the investigation are heterogeneous and depend strongly on the cultural specific relations (e. g. Genkova & Ringeisen, 2017).

The question about the advantages of diversity management for employees and companies is getting more and more important. The effects of diversity actions are often questioned in practice and fast quantifiable successes are expected. The research results determine that diversity sensitive attitudes are predictors for success. The change of attitudes of employees is carried out by top-down actions. This is examined by the research and practice. Thus, the role of the manager is mostly important for the implementation and acceptance of diversity actions (Dreas & Rastetter, 2016). This also applies for younger and ageing employees with and without an immigration background.

Finkelstein et al. (1995) has shown in a meta-analysis that younger persons evaluate the development potential of ageing employees less, compared to younger employees. The meta-analysis examined the work-related assessments of younger and ageing employees. At the same time, younger employees evaluated ageing employees as reliable. The Human Resource Management assesses inter alia ageing person, if they fit to the advertised position in the organisation. The appraisal of aptitude depends strongly on the attitude of human resource managers whether the position covers the role expectations about ageing persons (Diekman & Hirnisey, 2007). Bell et al. (2011) have shown in their meta-analysis that the diverse age base has no effects on the team performance. The advantages of a team with ageing members are that ageing employees have experiences and routine in cooperation with e. g. long-term customers. Furthermore, they can share their expertise with younger employees (Wei & Lau, 2012).

The role of top-down actions and leaders is seen as empirical verified regarding the implementation of diversity. The research questions of the study are as follows: Which context variables are seen as important?; Which stumbling blocks exist in the implementation?; Do managers and human resource managers see the problem fields? So this article focuses on the implementation of Diversity Management. It gives hints for a more successful integration of cultural diverse employees.

4 Methodology and Data

This study deals especially with the key issue of the Human Resource Management's challenges regarding the diversity. Persons with an immigration background as well as ageing people are important potentials for organisations. For this purpose, explorative

qualitative interviews were conducted. The aim was to analyse which role have managers regarding diversity and which competences are important to ensure equal opportunities in the personnel selection and to be diversity competent.

Therefore, 63 telephone interviews with managers (N = 17) and human resource managers (N = 13) as well as employees with (N = 18) and without an immigration background (N = 15) from different organisations were asked about the issue of equal opportunities, especially equal opportunities of persons with an immigration background and elderly employees. To answer the central questions of the study, following hypotheses were generated:

Explorative hypothesis: Managers and employees assess the need of diversity actions as equivalent.

Quantitative hypotheses: Hypothesis 1: Managers and employees differentiate regarding the expression of the stress level of employees with and without an immigration background.

Hypothesis 2: Managers and employees differentiate regarding the forms of the subjective assessment of the social competence.

There are rarely praxis-relevant and scientific results of diversity, especially cultural diversity and age diversity regarding managers and human resource managers. A qualitative interview was chosen as a survey method because it enables, compared to a quantitative questionnaire, to present the relationships and backgrounds of the topic diversity and the challenges of the Human Resource Management from the view of managers and human resource managers. Furthermore, conclusions for diversity potentials and stumbling blocks regarding the equal opportunities of persons with an immigration background and ageing people can be drawn. The interviews were conducted with a structured interview guideline.

Through qualitative interviews, non-concerned aspects can be figured out and, in turn, conclusions can be generated. In this case, which competences are important for diversity and to what extent diversity actions are necessary (Mayer, 2013). The questions of the interview guideline include the view of managers and human resource managers regarding the importance of diversity in organisations as well as the assessment of the subjective evaluation of lacking skills, e. g. intercultural competences. Therefore, it is examined to what extent stress has an impact on employees with and without an immigration background. The standardised interview is based on an interview guideline, which is designed deductive, theory-based (Mayer, 2013). The use of an interview guideline increases the structure of the questions as well as the comparability of data (Mayer, 2013).

In total, the interview guideline is based on open and closed questions, e. g. "How stressed are employees with an immigration background in your company at the moment, in your opinion?" The closed questions were answered on a 5-Point Likert Scale, e. g. 1= not at all stressed until 5 = very stressed. The combination of open and closed questions enables on the one hand to experience the individual views of managers and on the other hand to compare the interviews among each other.

The interview guideline includes different parts. One part deals with the questions regarding the issue of diversity as well as company-related questions like equal opportunities of employees with an immigration background in organisations. Another part deals with the aspects of social competence and the impact of cultural stereotypes and prejudices regarding the personnel selection. Further questions deal with the issue of leadership and stress. The aim is to experience whether employees with an immigration background have different stressors than employees without an immigration background. In the last part of the interviews, the respondents are asked about the issue of competence, inter alia which competences have the biggest impact on the equal opportunities in the personnel selection.

The interviews were analysed by the quantitative content analyses by Mayring (2015). The aim of the quantitative content analysis is to analyse the material of a communication (Mayring, 2015). The interviews were analysed by the frequency analysis with the aim to count the elements of the material and compare their frequency with other elements (Mayring, 2015). The transcribed, anonymised interviews were analysed with Excel.

The sample consists of 17 managers and 13 human resource managers. 17 of them are male and 13 female as well as 15 employees without an immigration background and 18 employees with an immigration background. 20 are female and 13 male. The age average of the managers and human resource managers is $M = 40.83$ years ($N = 29$; $SD = 9.30$). The age average of the employees with and without an immigration background is $M = 35.48$ years ($N = 33$; $SD = 9.99$).

5 Results

In the following, the results of the study will be presented. Explorative hypothesis: Managers and employees assess the need of diversity actions as equivalent. The results show that managers and employees assessed highly the diversity quotas, e. g. quota of women and migrants. These quotas are not usually legally consolidated by the view of managers and there is a lack of official guidelines. Managers claimed in the interviews that such quotas exist and are implemented as internal orientations in organisations. Further actions are a diversity department, equal opportunities officer, diversity representative, who apply actively the implementation of equal opportunities and diversity sensitization.

Most of diversity actions deal with the diversity aspects gender in Germany. Managers listed up different trainings, language courses and exchange programs, culture trainings which contribute to the implementation of diversity.

Human resource manager listed up trainings, joining the Diversity Charter of Germany Companies and the cooperation with the Federal Employment Agency. According to the statements of recruiters "individual intercultural competence trainings are offered for employees who would like to deal with intercultural competences and to analyse their own intercultural competence." The trainings include e. g. issues like "How to recruit internationally?", which aims at the intercultural difference at the recruiting." Further issues are "anti-prejudice [...] or emotional competences."

In contrast, employees with and without an immigration background mentioned that hardly or no diversity actions are implemented in the interviewed companies at all. This shows that employees with an immigration background assess the implementation of diversity actions as insufficient and are unsatisfied with that. Most of the diversity actions deal with the communication of diversity in companies like On- and Offline platforms, diversity departments and diversity committees. Both groups mentioned that trainings are offered in the organisations.

Most of the interviewed employees work in organisations that belong to the Diversity Charta of German companies and have implemented diversity in their company strategy. Employees figured out that the own professional development and the equal treatment at the personnel selection and development are important. Employees mentioned the following aspects as solutions: “Anonymous applications will not asserted. [...] Those, who have employee responsibilities and make personnel selections should do diversity competence training. They have to reflect themselves, if they are poised to hire someone, who is different than them. [...] I think that is actually the question and has to be answered by the human resource managers: Am I ready to hire somebody, who is different than I?” Following the statements of employees, also a form of benefit analysis can be helpful “[...] which hide the background of people as good as possible. So therefore, only the professional skills, social competence and media competences are measured without being influenced by the appearance of the person, e. g. gender etc.”

Both interviewed groups agree that openness, cultural interests are very important regarding the relevant competences. Social competences like tolerance and self-reflection are also important, followed by the intercultural competence and the cultural knowledge and awareness. At this point, a tendency is verified like in the previous results: the employees with and without an immigration background list up more competences and differentiate stronger regarding the promotion of intercultural competence.

Managers assess the tendency for the promotion of relevant competences for the future. They do not see the importance of the promotion of theses competences for the present. Therefore, managers do an external attribution. Interesting is, that managers mention risk tolerance as a relevant competence for diversity and associate them with risks. Furthermore, they mention emotional stability, intercultural flexibility, social identity, intercultural anti-prejudice as well as sensitisation for cultural differences. Employees mention instead empathy and openness, social competence, self-reflection, cultural knowledge and tolerance.

The research indicates that perspective change and experience exchange are stronger predictors for intercultural decision-making (e. g. Genkova & Ringeisen, 2017). The perspective change is a stronger predictor than empathy. Risk tolerance is not a relevant competence for diversity and the increasing of intercultural competence. This indicates that managers perceive diversity as a threat and assess the stress level for them as high because they are multipliers for diversity (see Table 1).

Table 1: Importance of Diversity

Managers/ Human Resource Managers	Employees with and without an immigration background
Seriousness and urgency of diversity is not clearly recognized	Seriousness and urgency of diversity is not clearly recognized by employees without an immigration background
Incorrect assessment of the stress of migrants	Good assessment of the stress level of migrants by employees without an immigration background
No consideration of the stress level of migrants in the day-to-day management	Risk of problematization of diversity

This shows that managers and employees consider the relevance of diversity measure as important. But it became obvious in the interviews that employees deal more with the issue of diversity than managers, based on the number of mentions and differentiation. Reasons for that can be that employees are more confronted with diversity and have more contact with it by colleagues and customers.

The citations indicate that there is a difference between self- and outside perception of managers and employees. Both groups attribute deficits and the need for diversity actions stronger to the other group. The research and practice shows that diversity processes proceeds top-down (Dreas & Raststetter, 2016). A further result of the present research and Best Practices is that top-down processes are only successful, when the expression of diversity sensitive competences is high (Dreas & Raststetter, 2016).

Hypothesis 1: Managers and employees differentiate regarding the expression of the stress level of employees with an immigration background.

The results of the hypothesis demonstrate that the assessment of the stress level of employees with an immigration background is the same of managers and employees ($T = .035$; $df\ 1; 49$; $p = .972$).

These results are supported by the qualitative analysis. The qualitative analysis showed that especially prejudices and the impatience of others based on eventually language problems as well as different work attitudes based on intercultural differences are stressing for employees with an immigration background. This is supported by statements of employees with an immigration background: "People with an immigration background have the feeling: I have to give more than 120 % than my German colleagues. This is one reason why migrants feel more stressed."

Hypothesis 2: Managers and employees differentiate regarding the forms of the subjective assessment of the social competence.

The results confirm that there is no significant difference between managers and employees regarding the subjective assessment of social competence ($T = -.489$; $df\ 2; 59$; $p = .628$). This can be an indication that both groups feel prepared for the challenges of diversity management. These results indicate that the need of increasing the competences is attributed to others. This is confirmed by the previous research.

6 Discussion and Conclusions

The results indicate significantly that the relevance of diversity is recognised by employees and managers. But it is determined that this tendency is stronger for

employees than for managers. Managers have often spoken about the importance of diversity measures for the organisation performance, justice and fairness for employees in the interviews. The managers have defined these aspects as important for the future and see no actual need. This means that managers deny the actual need of action and do not recognise or diagnose the stress level of employees with and without an immigration background enough, based on the diversity change. Managers have recognised the seriousness and urgency of diversity. But regarding cultural diversity and equal opportunities of persons with an immigration background, they do not see the urgency. Human resource managers are not able to assess the additional stress of migrants correctly and to consider them in their day-to-day management. The employees have recognised the importance of diversity. Regarding the equal opportunities of persons with an immigration background, employees without an immigration background do not see the importance in personnel actions, in contrast to employees with an immigration background.

Employees without an immigration background assess the stress level of employees with an immigration background well. In the interviews, employees have already spoken about the risk of problematization of diversity. The interviews have shown that in the western part of Germany, e. g. in the Ruhr area in Germany, such a concept would be superfluous because there is a high proportion of migrants and it is normal to work with different cultures together. An important diversity competence part is the intercultural and social competence. Empathy, tolerance and communicative competences, openness, self-reflection and emotional competences as well as cultural knowledge and awareness were also mentioned. Both groups have indicated the need to promote the competence by trainings and experiences abroad. This sounds partly contradictory to the results that both groups do not have significant differences regarding the subjective assessed social competence. The self-assessment is very high in addition, although the qualitative questionnaire classifies it as high.

In this study it can be positively highlighted that the sample of 63 managers and employees with and without an immigration background in total has a relative high diversification. Furthermore, the diversity aspects age and culture could be considered by different perspectives, by involved persons and managers, who develop diversity strategies for their companies and employees.

The interview guideline covers many issues of diversity management. The combination of closed and open questions increases the comparability of the interviews, compared to interviews with only open questions. But the results of structured interviews are less comparable, inter alia due to the open questions, whereby the analysis is more difficult. The results would have been more comparable, if a standardised, quantitative questionnaire was used and a higher sample could be asked. But the results would not have been so diverse like with the selected interviews. The topic diversity, especially equal opportunities of persons with an immigration background is hardly investigated. The qualitative investigation was used for generating hypotheses and delivers approaches that have to be examined in detail in the future.

There are some limitations of the study. The interview guideline deals partly superficial with some topics of diversity and does not question some parts in detail, e. g. which diversity actions are the most effective ones for elderly employees. However, other companies can differentiate from the sample due to other characteristics, e. g. size, structure, implementation of a diversity department. The interview guideline should be extended on the basis of the results of the study. Furthermore, it is necessary to investigate the category systems regarding their quality criteria.

The interviews pointed out that regional difference exist in Germany regarding the importance of diversity actions. Furthermore, the interviewed persons have answered the questions of the interviews differently in detail. Therefore, the results have to be considered critically. The interviews of the study were used for generating hypotheses for a quantitative questionnaire. Therefore, additional aspects regarding equal opportunities of persons with an immigration background could be measured. These aspects could not be asked in detail in conventional quantitative surveys. It was able to take a stronger focus regarding the urgency of diversity.

But there are some limitations regarding the sample: The results of the interviews give only approaches regarding the equal opportunities of persons with an immigration background and ageing people. To get a representative sample, a more comprehensive sample should be made with managers from different working fields, locations in Germany and other small, medium-sized and large organisations. The study could confirm that differences between employees with and without an immigration background exist regarding the importance of diversity concepts in personnel actions.

It has to be considered, whether the answers were given due to social desirability or deliberate misrepresentation because the survey method was an interview. A deliberate misinterpretation can be excluded because the respondents participated voluntarily and had not to expect any sanctions or other effects by specific statements. Social desirability could be minimised by the anonymisation of the data but it could still occur due to the social interaction during the interviews. This could lead to a distortion of the results because e. g. the individual responsibility or the skills of the own person were presented more positive.

To summarise: Diversity principles have to be more integrated in the company guidelines and manager guidelines. Apparently, leaders should be more sensitized, so that they are able to diagnose the present need of diversity correctly and are willing to implement the actions now and not in the future.

Abstract

Innovations in Internet Technologies have radically changed the business in Travel industry. A variety of internet technologies, mobile and non (websites, portal, apps), enabled customers to plan and book complete travel solutions at the best available rates. Among the Internet Distribution Systems (IDS), that are web tools to support users from information collection to booking travel products, Dynamic Packaging (DP) is emerging as a key approach. DP, besides providing automated online travel packages, has a conceptual model of a great importance to reflect on the strategic issue of Travel industry: integration. How it emerges from our conceptual analysis of DP models (DPMs), effectiveness of DP depends from travel inter-system and intra-system integration. The first, affects DPM's capacity of create coherent travel packages, while the latter affects the capacity of providing efficiency in travel. This latter dimension of integration is deepened in this paper presenting a case study. Namely the case study demonstrate how DP conceptual model is effective to integrate independent, private Bus transportation services/providers, operating at the national scale. The relative technology platform is able to provide integrated, multicarrier travel tickets. By leveraging on DPM, then, improvements on the bus transportation services can be achieved, and impacts on the travellers marketing behaviours are expected, such as increasing the bus transport against the private car.

Keywords – Dynamic Packaging, Travel Industry, Business Model, Integrated Bus transport.

Paper type – Academic Research Paper

1 Introduction

A major innovation, occurred in last decades in travel industry, has been the pervasive penetration of internet. Internet took the central role, making the online distribution of hotel rooms, airline tickets, and other travel products, the most successful products sold

on the internet (Runfola, Rosati, and Guercini 2013). More in general, thanks to Internet and the related online technologies supported by both hardware and software innovations, a wide number of 'information-based' products, as travel ones, are almost exclusively sought and reserved online (Akoumianakis et al. 2011).

The process of planning and purchasing the travel has also changed considerably. Consumers approach the issue autonomously, the role of traditional travel agencies has been replaced by online 'agencies', the trip structure is broader and/or specialized due to higher customers' interests and needs.

In order to take advantage of the business opportunities offered by the Internet, and to pander the changes that have characterized the evolution of travel demand, a considerable number of online brokerage services, so-called "cybermediaries", have appeared in the business of travel (Cardoso and Lange 2007). Together with them, information systems and technology specialized in online intermediation have also been developed to facilitate the search and purchase of travel "elements" (travel products). All this internet-based tools designed to support the online sell/purchase of products are part of the large family of Internet Distribution Systems (Cardoso and Lange 2007; Järvelä et al. 1999; Runfola et al. 2013). It is interesting to underline the twofold key of investigation that the IDSs have determined in the literature, one Information Science-based, the other Business Management-based. With reference to the latter, the line of analysis of the Business Models incorporated by the IDS is relevant (Akoumianakis et al. 2011; Cardoso and Lange 2007; Henne 2014; Runfola et al. 2013).

Among the IDS, a relevant role is being acquired by the web systems able to offer integrated travel packages, called Dynamic Packages (Al-Dmour, Fouzia, and Sarayreh 2016; Cardoso 2006; Cardoso and Lange 2007; Järvelä et al. 1999; Runfola et al. 2013). They are information systems able to search, select, aggregate two or more travel products distributed online, and to configure a travel solution, that is travel configuration ad hoc for the customer requirement. DP enables users to automated search and booking of many travel products, from different providers, harmonized in one integrated travel ticket. There are two key elements of DPs that are catalysing the customers' attention: dynamic updating of prices and discounts (which follow the dynamic pricing policies of providers), the stipulation of a single transaction for the entire package with a single payment, and the accumulation of the discounts of the single travel products.

DP has, besides the business model, a significant conceptual model since it provides insights to reflect on the strategic issue of Travel industry: integration. How emerge from the original conceptual analysis of DPM hereinafter, operational performance of DPM depends by integration of travel products (TP) selected from the same travel system, and by the integration of TPs selected from different travel systems. We call this integration capacity of the DPM as travel "inter-system" and "intra-system" integration. The first one affects DPM's capacity of create coherent travel packages, the second one affects the capacity of providing efficiency in travel. This latter dimension of integration, that regards the single travel systems (transport, accommodation, subsistence, touristic offer), is deepened in this paper presenting a case study. Namely the case study demonstrate how DP conceptual model is effective to integrate autonomous, public Bus transportation

services/providers, at a national scale, and integrates bus travel products allowing integrated packaged tickets.

The Paper is structured as follows. Section 2 presents a brief review of developments and innovations in the Travel Industry. Section 3 analyses the DPM in its conceptual and business aspects. Section 4 presents a case study regarding a DP solution that intercept the business opportunities and challenges in the Integrated Bus Transportation market. The section 5 ends the paper addressing conclusions, implications, and limitations of this research.

2. Evolution and Innovations in Travel Industry

The internet technologies have radically changed the traditional processes of searching and booking travels operated by customers, as well as the distribution processes set up by providers of travel services. Internet and its related tools is a powerful distribution channel for many products, especially for *information-based* products as the travel ones are (Akoumianakis et al. 2011). If, on one hand, there are many advantages of online searching and booking of travel, like the saving of costs otherwise charged by agencies as commission, on the other hand it can be time consuming, since the booking of travel products over the internet needs additional time for non-specialized operators, and additional knowledge, expertise, experience, to achieve satisfying package configurations as the travel agency does (Cardoso and Lange 2007). In fact, many studies report about the problems and difficulties arising during the online travel organization and purchasing: from the need of phone calls to the provider for the reservation, to clearer or detailed information than those available on the internet, to the knowledge gap in understanding configuration principles and contractual rules (Cardoso and Lange 2007; Öörni 2003).

Because of this, some are sceptical about the efficiency of electronic markets, especially with regard to travel. Some scholars argued that at best as efficient, the electronic market of travel products is as efficient as their conventional counterparts (traditional travel agencies), mainly addressing this to poor availability of product information and a lack of systems integration (Öörni 2003).

Due to the advent of online distribution of travel products, however, the traditional Travel Agency services faced important changes in their Business models. Results of this changes are mainly consisting in reduced commission revenues, if not “commission free” (as already done by Airlines), opening to the e-providers of travel products.

In response to the mentioned problems the travel product providers improved their online distribution channel, including reservation system (hotel website, travel provider website or app, etc.), and third party providers, broadly defined as Internet Distribution Systems, or Online Travel Agencies (Runfola et al. 2013) entered and raised in the travel market. Online travel agencies gained consumer and provider preferences because of their competitive pricing, of the easy comparing of the prices, of the ability to market highly perishable products like hotel rooms (Runfola et al. 2013), or carrier’s seat. A particular IDS, or OTA, is represented today by DPM.

The Dynamic Packaging is emerging as an innovative approach able to support an innovative business model in Travel and Transportation market. DP is an online automated configuration and assembling of single, individual, autonomous travel products available on the internet, in the providers' webpages. The travel products are selected by the user to make selection, combination and reservation. Regardless to the origin of the inventory of travel products, the package that is created is treated as one operation, and implies just one payment by the customer (Cardoso and Lange 2007).

3 Dynamic Packaging. Concepts and Business Models

We define a *Travel Product* (TP) as any travel good or service, distributed online, that once combined with at least another TP, allow the creation of a *travel solution*. For instance, an hotel room, an airline travel, a bus travel, a car rental, a local tours, are usual TPs that are aggregated in order to have a feasible and satisfying travel solution. Type and amount of travel products to include in one travel solution depend on customers' wants and needs, such as purpose of the travel (business, leisure), interests, duration, and by travel constraints, like budget, Origin/Destination, available transportation systems. Any combination of travel products aimed at providing a travel solution for the customer's requirements, is a **travel configuration**. The process of combination of TPs is the so-called travel packaging.

DPs are online web solutions/technologies able to package, dynamically, travel products, to form dynamic travel configurations. They automate the process and elaborate providers' website data. Users of this DPM are both travel agencies (B2B) and travel customers (B2C).

More in detail DPMs are fully automated packaging online applications, which use of up-to-date travel product information. They apply a single price for the entire package, provide of guidance and support in the selection of travel products and packaging, by leveraging on products already selected by the customer in the past (Cardoso and Lange 2007). DP automates the process of configuration and assembling, through the internet, of packaged travel products for individual customers (Cardoso 2006). DP is performed by software platforms which dynamically retrieve, analyse, select, combine, on line available information of TPs, and return travel packages ready to be booked. It is important to stress that the results of DP are dynamic, this implies that they change continually over time, and that the payment is unique for all the TPs included in the package. The package is handled seamlessly as one transaction, hiding the pricing of individual components, within a one-to-one commercial relation between the DP provider and the travel customer (Cardoso and Lange 2007).

Due to the high level of autonomy and heterogeneity of TP's data - they belong to travel providers, are sourced by the DPM from online providers' internet channel - DPMs cannot be successfully developed by considering only syntactic and structural integration of data. A core problem of DP systems is then integration and interoperability with travel (or tourism) information systems (Cardoso 2006). The package that is created must be

seamless, require one single transaction, just one payment from the consumer, and then the hiding of the single products' prices.

Conceptually the travel package is obtained by grouping together TPs from one or more travel systems, and by grouping together two or more locations. We reduce the travel systems to: transportation, accommodation, subsistence, touristic offer.

According to the customers' requirements, DPs adopt two “pure” (or theoretical) grouping approaches to package any travel solution. Namely it employs: a “intra-system” packaging (that is the grouping of two or more TPs of the same travel system, like transportation services), an “inter-system” packaging (that is the combination of two or more TPs, from as many travel systems). Any customers' travel requirement can be seen as the combination of intra-system and/or intersystem packaging of TPs.

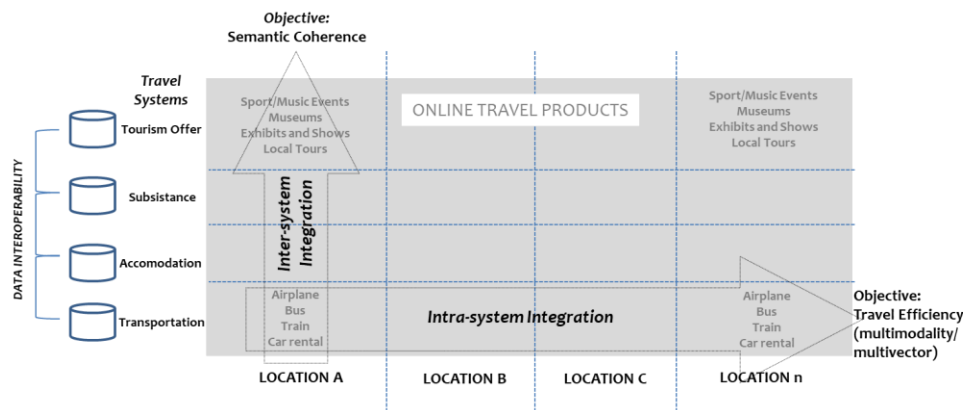

Fig. 1 – A conceptual model of DP.

2 Archetypes of DP applications can be identified: hard-coded, web services. By the mean of interfaces, the first type allows the interoperability of decentralized, autonomous, heterogeneous travel information systems. This kind of applications are limited in terms of dynamism because the diversity of the scopes, technologies and information structures makes the interoperability of information systems complex and stiff.

Web services, instead, duly combined with semantic tools, allow for a dynamic and flexible design of a travel package (Cardoso and Lange 2007).

On the basis of the DP conceptual model, any travel can be seen as a simple transportation from the location A to the location N, whose packaging would provide the best transportation solution (according to some performance: time, cost, accessibility, availability, etc.). Nonetheless the travel can pack a travel to just one location, involving products from all the other travel systems. Packaging is then reducible to a set of O&D, and to a set of diversified travel systems involved in the travel configuration.

In order to best perform this two dynamic packaging needs, recent advances in Semantics and Data systems interoperability can support an improvement of performances.

How emerges from the proposed conceptual analysis of DP model above, operational performance of DPM depends by the integration of TPs selected from the same travel system, and by the integration of TPs selected from different travel systems. We then argue to distinguish this integration capacity of the DPM in travel “inter-system” and “intra-system” integration. The first one affects DPM’s capacity of create coherent travel packages; this has impact mainly on the travel customers’ emotional satisfaction. The second one affects the efficiency of the travel; this impacts the physical satisfaction during the deployment of the travel. This latter dimension of integration, that regards the single travel systems (transport, accommodation, subsistence, touristic offer), is deepened in this paper presenting a case study.

Besides the conceptual model of DPs, it is important to review and understand the business model by which a DP solution provides service.

The Business Model is the basic mechanism by which a company, fulfilling customers’ demand of products or services, gain revenue, profits, competitiveness. It is the ‘how’ a firm delivers value to customers and converts payments into profits (Teece 2010). More practically it is a conceptual tool containing the most important objects, their relations with the objective, and the logic of a business. The business model describes the logic according to which an organization creates, distributes and captures value (Osterwalder and Pigneur 2010)

Three main aspects emerge from the extant literature with regard to BM: the type of services delivered, the degree of innovation in adopting new technologies and the revenue model (Järvelä et al. 1999). Following this characterization as mean of classification, four Business models can be identified for online TPs providers: *E-Booking Services*, *E-Travel Agent*, *E-marketplaces*, *Meta Booking Engines* (Järvelä et al. 1999).

E-Booking Services are online intermediaries operating through a ‘booking engine’, which allow customers to make reservations guaranteed by credit card. No payment is allowed online, instead the payment is due once received the service (i.e. check-out at the hotel). The revenue model is commission based. This services can be *multichannel* (combination of on and off-line transactions, i.e. Tui.com, Alpitourworld.com) or *pure player* (exclusively online, like Booking.com, Hrs.com, Laterooms.com) (Järvelä et al. 1999; Runfola et al. 2013)

E-Travel Agents are actually *E-Booking Services*, *multichannel* or *pure player*, having an e-commerce platform integrated to the booking engine. This model enable customers to finalise the transaction by charging a credit card. The revenue model is both commission-based or merchant (application of a *Mark-up*).

E-Marketplace is the Business model that characterizes the leading IDSs. This model pertains to those online operators which offer a wide range of TPs, by various providers, in most of the cases with a DP system, thereby selling travel package solutions. Also within this one, we find *multichannel* (e.g. Octopustravel.com) or *pure players* (e.g. Expedia.com, Lastminute.com).

Meta Booking Engines are websites that support the buying process with functionalities such as price comparison and review systems. User-generated content are of great importance for the full functionality of this model, thus tourism blog or websites

like tripadvisor.com and travepod.com are generally included (Runfola et al. 2013), as well as price charts showing a product's full price history, able to support customer in forecasting future prices.

It is interesting to stress that the *revenue model* has mainly shaped alternative classifications of business models, with regard to the merchant players (Jerath, Netessine, and Veeraraghavan 2010; Runfola et al. 2013). On the basis of the revenue model adopted four basic types can be identified (Jerath et al. 2010): *transparent sales*, *last minute/inventory control sales*, *opaque selling*, *flash/collective buying selling*. In the first one the regular price is displayed up-front (i.e. Expedia), and the customer can make comparisons with other retailers, or with the nominal price of the travel product provider itself. In the second, last minute pricing, the retailer sales a distressed inventory, late in the product's sales life cycle, before its expiration, at a significantly discounted price (i.e. Lastminute.com) (Runfola et al. 2013). The *inventory control sales*, in contrast to last minute, aims to reduce distressed inventory by offering a limited number of low-priced allocations far in advance of check-in, and reserving the lasting allocation for the late arrivals at a higher rate (Jiang 2007).

In order to prevent the distressed inventory (which arises both in the last minute model, due to the tendency of customer of postpone the purchase in order to get a further discount, and in the *inventory control sales* because of the possibility to not allocate the final over-rated allocations), retailers have adopted different solutions aimed at reducing the consumers inclination to price comparison and implementation of purchasing strategies and behaviours, often resulting in unsold inventory.

Opaque selling is the model in which the consumer before the purchase from the intermediary, doesn't know some of the product's attributes (i.e. the ultimate provider, the exact starting date of the service) (Jerath et al. 2010). The hidden attributes will be revealed only after the purchase (e.g. Hotwire.com, Priceline.com, Cheaptickets.com). Many advantages are addressed by the literature to this recent model, over the prevent of consumers' strategic behaviours and distressed inventory (Runfola et al. 2013). However, this formula is not free of any disadvantage or risk.

The raising of this *opaque selling* is encouraged by the so-called *private sales* or *flash sales* or *collective buying selling*. This model relies on virtual communities, which are emerging as important marketing channels for a variety of industries (Kim, Yang, and Kim 2009), and address to their members the offer of significant benefits. The main characteristic of this model is that the discounted *opaque* prices are visible and can be purchased for a very limited period of time only by members that have previously registered with the service (Runfola et al. 2013). This registration and related identification of the potential consumer is even more supported by the use of social media profiling (e.g. Facebook.com, Twitter.com), thus contributing to the wider phenomenon of 'social commerce'.

Differently from Järvelä et al., (Cardoso and Lange 2007) reduced the Business Models of DPs to the *agency model* and the *merchant model*. In the agency model the customer book a travel package, or just a product, using a travel agent. The consumer pays directly the travel product, and correspond a fee to the Agency, determined as a

percentage on the base price. This model is extinguishing according to recent data and trends, which are confirming that this model is no more appealing for companies, in contrast to simple flat booking reward, or commission-free.

About the merchant model it consists of a wholesale arrangement, with net rates and product/inventory availability with cut-off dates. Within this model a travel agency buys a set amount of the inventory, at a wholesaler price, then resell it to a consumer at a higher price, but anyway usually lower than the nominal price. This model particularly apply to hotel rooms.

According to the agency model the online travel agency passes the customers' reservations to the travel supplier, getting a commission. Under the merchant model the online travel agency books in advance a set amount of the inventory (or inventories, if the case of travel packages: hotel rooms, airline seats, event tickets, etc.) from the supplier, then proposes to the market its travel products/packages.

In this second case, the exposition to risk is higher but a higher financial performance is expected. Very important are in this case the capacity of interoperate with travel systems, in order to find and book convenient travel products (i.e. leveraging on suppliers' revenue management) and simultaneously to control risk by defining an optimal trade-off between variety of travel products, and set amount of booked products.

4. Dynamic Packaging of Bus Transportation travels. A Case study

4.1 The Case Study. Brief overview

This section presents and analyses the case of an innovative technological platform developed by an Italian company, ECHOPRESS an academic spin-off of the University of Calabria, based in Rende (Italy), specialized in web and mobile based solutions in the field of ICT services to transport and mobility companies.

The platform is under development, but represents a significant case of intra-system Dynamic Packaging. According to a case study methodology (Baxter and Jack 2008; Eisenhardt 1989; Yin 2003) then it is a *polar type* capable of explanatory power and theoretical significance (Mills, Durepos, and Wiebe 2010).

The technology platform aims to dynamically integrate TPs (bus transport services, per legs and networks), offered by participating transport companies, while providing on the demand side an aggregator of public transport products at national scale, in multimodality (Bus and Train), and multicarrier, with a single payment of the booked travel package.

The company currently already offers booking systems, e-ticketing, self-ticketing, helpdesk, for projects aimed at online booking and customer care. In particular, the company offers a software solution called SMARTBUS that offers fleet management, e-ticketing and remote controlling services to companies operating in the road transport sector.

4.2 The Context. Market and Regulatory opportunities

Italy is one of the European countries with the highest density of internal traffic that is distributed unevenly throughout its transport network which includes 278 ports, a railway network of 16,752 km, a road network (state roads, regional roads, provincial, municipal) of approximately 255,980, a highway network of 6,751 km (of which 5,724.4 km a toll) and 45 Enac certified airports (TTS Italia 2016). Due to morphology and demographic distribution, the main transportation system is the private car and the Bus.

The regulatory and strategic framework at the Italian level pushes and supports the interoperable electronic ticketing systems in the national territory. The relative Decree came into force on January 25, 2017 (Ministry of Infrastructure and Transport, Ministerial Decree No. 255 of 10/27/2016). The decree also highlights the importance of data standardization according to the Big Data paradigm, as the art. 7 (Monitoring) of the aforementioned regulation decrees that the data acquired through electronic ticketing systems, constitute a priority source for the population of the database of the National Observatory on local public transport policies.

4.3 The Business model

The business idea behind the DP platform is to make the public *Bus and Train* transport (local public transport services, national and international lines, tourism services) competitive. The extant offer of such services in Italy's market is very fragmented as far as buses are concerned, with many small and medium operators sharing the market for routes, according to the logic of optimizing revenues rather than customer service. In fact, the customer must research, plan, combine, and pay for the transport service by leg, one separately from the other, and not by Origin/Destination. Moreover, this fragmented transport system, reflects into long travel times, and relatively expensive rates. This is true both for multimodal transports and bus multicarrier.

The problem exacerbates in Italy, because of the short-medium transport routes: the potentially more competitive transport systems are the combinations bus-train, but the aforementioned market situation pushes the demand toward the private cars, generating further detriment of the public service.

This mechanism gradually weakens the bus transport system itself, whose operators periodically revise and optimize the services (routes, carriers, origin/destinations, fleet management, etc.) according to a cost recovery, which results in a further market detriment against the car.

4.4 The intra-system DP.

The platform is an innovative DP solution, which aims to aggregate the offer of transport and to innovate in the DP logic the process of purchasing a transport service (multimodal bus-train, or multi-carrier), by consumers or agencies of travel. On the supply side, some innovative tools for accessing and analysing historical data about the whole system of routes will be available, in order to improve the quality level of the offer.

Despite the growing demand for collective mobility services, there are still very few examples of technological platforms able to act as aggregators of information and services to support mobility and public transport services, with particular reference to multimodal transport (iron-rubber) and multi-vector.

On the demand side, the platform tends to offer the passenger support and assistance along all stages of the "life cycle" of customers' journey. Currently in the Italian panorama there is no single system able to aggregate all the information to plan trips within the national territory, using a combination of multimodal collective transports that also allows to purchase integrated travel solutions.

The platform is then an aggregator of data and information (stops, routes, polymetrics, schedules, fares, etc.) of local and national road and rail public transport, allowing the various participating operators to improve passenger handling processes with a triple purpose:

- provide potential customers with useful information to plan their trip regardless of the carrier and the means used, in order to provide flexible and seamless travel solutions;
- provide transport companies with a multimodal and shared web-based platform;
- create data exchange services (API, WIDGETS, WEB SERVICES) that allow operators in other sectors, such as tourism, to easily integrate the information and travel solutions produced by the platform.

The business principle on which the initiative is based is that of multi-side platforms. The platform is not limited to managing the DP, but wants to process and exploit the large amount of data to return strategic services to transport companies, such as dynamic pricing management, control and monitoring of company performance, CRM (to manage the customer relations).

The platform, thanks to the integration with geolocation technologies, is able to process and return to the traveller a quantity of dynamic data generated in real time (eg position and accumulated delay of vehicles, sales data, loading rates).

The analysis of static data, historical series and dynamic data will also offer the possibility of introducing dynamic pricing services. A Yield Management module will also be introduced, besides the implementation of social rewarding policies (reward for users' social activities), Social Customer Relationship Management (Social CRM) aimed at managing company-traveller relationships.

5 Conclusions

How emerged from the proposed conceptual analysis of DPMs, DPM's integration performance is a key element. It is determined by the integration of TPs selected from the same travel system, and by the integration of TPs selected from different travel systems. We supported the idea of distinguish this integration capacity of the DP in travel "inter-system" and "intra-system". The first, which affects DP's capacity of create coherent travel packages, has impact mainly on the travel customers' emotional satisfaction. The

second one, which in turn affects the efficiency of the travel, impacts the physical satisfaction during the deployment of the travel.

According then to the aim or nature of the travel (i.e. short business travel, long holiday travel) the DPMs can specialize to have high market performances, and customer satisfaction. They can be vertical integrator, or horizontal integrators, according to their travel specialization. This somehow suggest a market specialization of DPs, and address the identification of the main operational challenges of the two kinds of DP.

The case we analysed, emerges as a horizontal integrator, and represents a sample on the second kind of DPs, horizontal integrators.

Future developments of the research here tracked will involve the operational analysis of the sampled case, along with the analysis of a case study falling into the vertical DP integrators.

Abstract

This paper sheds light on the disclosure of knowledge transfer (KT) and how disclosure impacts and is impacted by the stakeholders of a public university and its anchored legitimacy.

This is a qualitative case study that focuses on an Italian university. A mixed-method approach is adopted, triangulated from different sources. The methodologies used are drawn from active research and, in particular, our study relies on an interventionist approach.

KT disclosure is found to be more efficacious than KT reports in anchoring the legitimacy of an institution in its territory. This shows that the nature of the knowledge influences the transfer process. Disclosure must be smoothly adapted to formal or informal KT.

Research limitations/implications – In a single case study, our paper provides evidence for the implications of KT disclosure.

This study shows the potentiality of disclosure for KT in terms of unlocking and offering new opportunities for relations between universities and territories.

In an environment with few studies on the peculiar situation of a generalist university, the paper provides new insight into the importance of KT disclosure for strengthening links with the local community and enhancing legitimacy. This is essential for an anchored institution, and a novel concept of anchored legitimacy is presented.

Keywords – knowledge transfer, anchored legitimacy, generalist public university, anchor institution

Paper type – Academic Research Paper

1 Introduction

Universities, in performing their role as knowledge generators, must guide their programs according to societal value (Cesaroni and Piccaluga 2016). This implies that universities should become public leaders, galvanizing the interest of salient stakeholders, crafting strategies aimed at precise societal objectives (Mazzucato 2017). Brokering relationships of trust is a prerequisite for achieving any societal goal, as it is grounded on collective efforts, symbiotic partnerships and citizen engagement (Mazzucato 2018). In the past, public universities, were often small, elite institutions— known as “ivory towers.” Only recently have they become interested in discoursing with stakeholders (Geuna and Muscio, 2009). At the current time, they are digesting how essential trust is in confirming their social contract with stakeholders, and they are working on that trust by enhancing their commitment to disclose information.

Institutions periodically account for their activities in reports, and stakeholders are interested in the disclosure of crystal clear information, due to their idiosyncrasy, secrets, and obscure nature (Dumay 2016). For public universities, the emphasis is put on overreporting, because of the corporatization of public sector functions and the desired measurement of the performance of intellectual capital (IC) (Demartini and Paoloni 2013; Martin-Sardesai et al. 2017; Secundo et al. 2010). While the results achieved in the field of IC confirm the importance of disclosing precious information and its impact in financial terms (Guthrie et al., 2012; Dumay and Garanina, 2013), a generalist public university, as in case study presented here, may use disclosure to raise external funds, to build relationships of trust, and coordinate efforts towards enacting a precise direction for achieving societal relevance towards problem such as health, nutrition, quality of education, wellbeing (Laredo 2007; Philpott et al. 2011; Rolfo and Finardi 2014). The literature on IC in public sector has numerous case studies, little work has been done on the role of IC disclosure, reporting and media in universities (Dumay et al., 2015b).

Knowledge transfer (KT), a use of IC, is the motion of the results of research at a university from within it to a party or parties outside it, through formal or informal mechanisms, through harder or softer activities, whether commercially or not. In generalist public universities, KT depends on the academic knowledge created, as universities represent a unique context for knowledge management (Massaro et al., 2015). KT is part of the so-called third mission, and it is coming to be considered a strategic pillar for public universities (Parker 2013). Beyond teaching and research, third mission suggests universities to become “entrepreneurial” paying greater attention to aspects related to knowledge generation, implementation and exploitation (Elia et al., 2017).

Although legitimacy theory has already examined pragmatic, moral, and cognitive legitimacy in a variety of contexts (Bebbington et al., 2008; O’Dwyer et al., 2011; Dumay et al., 2015a), the nature of the relationships between public universities and their stakeholders requires an evolution of the theory toward anchored legitimacy, as public universities are effectively anchored institutions (Howard 2011). Their anchored legitimacy requires universities to bet on the risks and rewards from KT, disclosing salient information related to KT (Cesaroni and Piccaluga 2016; Etzkowitz and

Leydesdorff 1997). We understand anchored legitimacy as the legitimacy of an institution that is bounded within a territory, whose social contract it is not possible to break, and that cannot fail or leave its territory. A public university shapes a city and vice-versa (Garcia 2007). This new concept will be examined in the light of existing legitimacy theory; however, here, the first driver of the evolution of the public university, namely, the disclosure of salient information. This paper investigates how KT disclosure is implemented at a public university and how the disclosure impacts and is impacted by the stakeholders of the university, undermining that anchored legitimacy.

The paper proceeds as follows. Section 2 reviews prior studies on KT for universities and lays out KT in the light of anchored legitimacy. Section 3 briefly contextualizes the case and its materiality. The methodological section shows the triangulation and analysis of the data. The findings will be presented in section 4 and will be interpreted using legitimacy theory. Finally, the discussion, conclusions, and the limitations and prospects of this study, close the paper.

2 Literature review

The social contract between public universities and its stakeholders is grounded on the production, diffusion, and transfer of the high-quality knowledge needed to sustain the development of society and the upbringing of future generations. The disclosure of KT outcomes is becoming essential for public universities, beyond a simple reporting and accounting for those outputs.

The institutionalization of the third mission caused administrators of public universities to elevate KT to a strategic role, because it is grounded on a knowledge exchange between the university and community, including training and development (Gibbons et al., 1994; Gibb et al., 2013; Miller et al., 2016). With the lens of legitimacy theory, it is possible to see how universities pragmatically report to internal and external stakeholders and allow an evaluation of their performance and activities by them (Ntim et al., 2017). Morally, they started to voluntarily disclose various information on their mission, processes of value creation, and overall sustainability (Alonso-Almeida et al., 2014; Ceulemans et al., 2015b). This disclosure was done with the purpose of informing and educating their publics (Bebbington et al., 2008) and allow the administrative practices of public universities to come to light Lindblom (1994).

Sustainability, social and environmental, and IC reports are attempts to report information, but for various reasons they rarely focus on KT (Sangiorgi and Siboni 2017; Siboni et al. 2013). Little is known about KT disclosure, despite the attempt of measure KT keeping track of the number of patents issued, number of academic start-ups, and innumerable other items that are easier to account for. The focus on KT requires going beyond numbers and identifying the relationship between the generator and the receiver of knowledge. However, the question remains: what are the generators and receivers of knowledge, and what is the content of the transfer?

The literature identifies two forms of KT in universities: formal and informal KT, which coexist (C Grimpe and Hussinger 2013; Christoph Grimpe and Fier 2010). Hard

activities of KT are defined as those having tangible outputs and that are entrepreneurial in nature, such as spin-offs, patenting, and licensing. Softer activities remain important, however, and these are part of the traditional culture of academia, such as academic publishing, the production of qualified graduates or winning grants. The literature privileges the narration of the hard initiatives, as they are more easily measured and reported by numbers (Ratinho and Henriques 2010), while less attention is given to softer outputs (Abramo et al. 2009, 2011) in spite of the fact that they have a significant impact on economies (Cohen et al., 2002).

KT can also be categorized according to its formalism. The formal mechanisms of KT often embody or directly lead to legal instruments, such as patents or royalty agreements (Geuna and Muscio, 2009; Calcagnini and Favaretto, 2016), while KT's informal activities are the non-contractual interactions of the involved subjects (Agrawal 2001). Again, formal activities that take on legal forms can be easily identified and measured, as in the case of commercial and non-commercial KT (Landry et al. 2010), but informal knowledge exchanges are more difficult to track (Olmos-Peñuela et al., 2014b).

A public university following the Humboldtian definition creates academic knowledge in the forms of capital goods and final goods. The hard sciences typically produce capital goods, with their larger chances of appropriation and wider scope of application; the second case is more typical of the social sciences and humanities, the products of which have a more limited scope of appropriation and application but can directly affect the utility of stakeholders (Ankrah and AL-Tabbaa 2015).
